Abstract

We theorize children's emotional relationships with *place* in terms of love, care, and solidarity, drawing upon Lynch (2007). However, rather than restricting emotional relationships to human-human interactions, we extend the relational and emotional *other* to the more-than-human world and to *place* itself. Can children situate themselves as interdependent beings with other living and non-living entities in *place*? Can they come to understand that they are not separated from "nature" but are part of "nature," emotionally interconnected with the living systems of Earth?

To investigate children's emotional relationships with *place* and the more-than-human world, we analyzed their representations of "nature" and themselves following an excursion to Karawatha Forest in South-East Queensland, Australia. The children were 11–12 year-old (in Year 6 or 7) and attended four different primary schools in the Brisbane area. The excursion was based on a place-responsive pedagogy that followed the story of Bernice Volz, whose civic action in the 1990s was crucial for establishing Karawatha Forest and lagoons. Ron Tooth and other staff at Pullenvale Environmental Education Centre (PEEC) designed a *storythread* educational program for Karawatha that situates Bernice's story as pivotal in mediating children's experiences. Their connection to *place* is also mediated throughout the excursion by *dadirri*, an Aboriginal practice of attentiveness to, and feeling in *place*. Following the excursion, children shifted toward an understanding of "nature" as agentic, knowledgeable, emotional, and not as separate but as bonded to them. They envisaged relationships of love, care, and solidarity with "nature" in the present and future, and for some the excursion marked a significant change in identity. The implications of this place-responsive pedagogy are considered in the context of neoliberal times and accountability pressures for teachers.

Introduction

In this chapter we consider how upper primary school children from three schools and a range of social and cultural backgrounds emotionally connect to *place* as they participate in a place-responsive excursion to the Karawatha Forest reserve in South-East Queensland, Australia. Throughout the Chapter we use "nature" to communicate our rejection of binaries between natural and human spheres or between nature and human culture. We use "nature" as a shorthand way of indicating the historically and culturally contested meaning of the "more-than-human" world. In the extract below, Bill Neidjie (Neidjie, Davis & Fox, 1985, p.51) positions "feeling" as central to our relationship with place. He writes from an Indigenous perspective on country but it resonates strongly with the approach explored in this chapter.

I feel it with my body,
with my blood.
Feeling all these trees,
all this country.
When this wind blow you can feel it.
Same for country....
You feel it.
You can look,
but feeling....
that make you.

This decentered sensibility about dialoguing with "nature" and feeling with "nature" is also reflected in our analysis of children's accounts of their excursion to Karawatha (see also, Tooth & Renshaw, 2018). Like Bill Neidjie, we want children to relate to the more-than-human world in loving, caring, and respectful ways, seeing themselves in solidarity with the living systems of the Earth rather than as separate entities. The children's excursion to Karawatha has been designed as a *storythread* based on the actual story of Bernice Volz and her team of local activists who advocated in the 1990s for setting aside 1000 ha of remnant forest and lagoons that became the Karawatha Forest reserve (see Tooth & Renshaw, 2018). Children experience Karawatha's diverse ecological zones and lagoons following in Bernice's footsteps. They are emotionally drawn into the place as they interact with the birds, insects, frogs, trees, rocks, sand, and crystals of Karawatha. The *storythread* pedagogy (Tooth & Renshaw, 2009; Tooth, Wager & Proellocks, 1988) is designed to engage children's senses and emotions in a place-responsive manner, rather than treating Karawatha as a convenient site to conduct inquiries on "nature." Later in the Chapter, we categorize the different types of representations of "nature" that emerged from children during the excursion. As their comments and reflections were collated, we realized that the children had moved beyond a view of "nature" as inert and separate, to a view of "nature" as relational, active, and emotional. Rather than separating themselves apart as "human" set against "nature," they began to represent themselves as related to "nature," equal with "nature," and sharing emotions, thoughts, and destinies with "nature." These insights and sensibilities arise from children through participating in the place-responsive excursion to Karawatha. We turn now to describe our approach to place-responsive pedagogy and to the importance of emotionality within our approach.

Place-Responsive Pedagogy and Emotionality

Place-responsive pedagogy is at the center of our approach to environmental education as outlined in Renshaw and Tooth (2018). Other scholars have influenced our understanding of place-responsive pedagogy, including Greenwood (2014) who foregrounded the importance of the cultural and material entanglements of place and the shared responsibility of people to care for local places in a globalizing world. Mannion et al. (2013) highlighted for us *place-responsive*

pedagogy rather than *place-based* pedagogy and the crucial role of teachers in enabling students to be responsive to the cultural and material affordances of place. But it was the notion of place as theorized by Margaret Somerville (2010) that primarily influenced our understanding of place-responsive pedagogy. Somerville draws upon insights from Gruenewald's (2003) critical place-based pedagogy and the epistemologies and ontologies of Indigenous Australians (Cohen & Somerville, 1990) to propose that place involves processes of embodiment, storying, and contestation in the contact zone between cultural groups and their different forms of knowing and being. Here we expand these three features of place to include emotionality as a key feature of place-responsiveness. We also seek to expand the boundaries of emotionality by considering it as a distributed feature of place rather than as centered in the human person – the place itself, we suggest, is imbued with emotions that are felt and shared by the participants whether they are human or more-than-human actors. Our approach is consistent with the posthuman epistemologies and flattened relational ontologies that inform the chapters in this volume (see also Barad, 2007; Taylor & Pacini-Ketchabaw, 2015; Taylor, Pacini-Ketchabaw & Blaise, 2012). Writing this Chapter has provided us with the opportunity to revisit our approach to place-responsive pedagogy (Renshaw & Tooth, 2018) and to consider how a post-human epistemology, ontology, and a distributed notion of emotionality might further enrich the design of pedagogies that make a difference in children's lives.

Embodiment (Somerville, 2010) suggests that we learn through the relational activity of the body-in-place – through engaging with the materiality of the place with our senses and actions. Pedagogies based on embodiment turn our attention outward to a dialogue with the situated materiality and emotional tonality of place itself. Embodiment is not a detached and objectifying cognitive form of knowing but an emotional and sensorial whole-body form of knowing in place. Rather than thinking of place as an entity to be studied and objectified, embodiment suggests that we relate to place in a highly visceral manner that involves responsiveness from our heads, hearts, and all our sensory systems.

In addition to embodiment, along with Somerville (2010), we theorize place in terms of stories. Massey (2005) defined place itself as a set of overlapping and unfinished stories and through this definition she highlights the inherent emotionality of place. Stories draw us into relationships with characters in place (both human and more-than-human characters) and engage us emotionally with these characters. Storying has been a pedagogical design principle used by Tooth for over three decades (Tooth et al., 1988; Tooth & Renshaw, 2009). He devised the pedagogy of *storythread* to engage students actively and emotionally as they role-played real and fictional characters within a narrative constructed specifically for different places. For example, Bernice Volz's story of environmental advocacy is central to the existence of Karawatha, so children shadow Bernice's journey as they explore the forest and reflect on what it means to be an environmental advocate. Learning through *storythread* transforms the way students can experience a place. As Tooth noted (Tooth, 2018, p. 47), story laid over the landscape imbues the features of place with emotional significance for the students and opens

up imaginative ways for them to make sense of the more-than human world. The professional experience of Tooth and colleagues over many years has demonstrated that students become emotionally involved when living through the events and dilemmas of a *storythread*. While the story is devised and the performance is staged, the emotions are real. Students routinely express strong emotions of love, excitement, caring, or relief as they participate in the unfolding *storythread*. Below we elaborate further the story of Bernice Volz and her relationship with Karawatha that continues to the present day as she grapples with ongoing threats to the place she loves. Bernice's locally situated story, of course, is not unique but one of a myriad other unfolding stories of fragility and love and contest that are occurring simultaneously across the Earth. The local-global significance of storying is important to acknowledge – children are being drawn into local stories, but these are relevant across the world as people everywhere struggle to address adequately local threats to the living systems of the Earth.

Somerville theorizes place, finally, as a cultural contact zone of difference. Place is inevitably the site of contested stories (Massey, 2005) that arise from different agendas, epistemologies, and ontologies that participants bring with them. Contest, negotiation, and conflict are inevitably highly emotional as different interests struggle to be reconciled. In Australia, Indigenous custodianship of place draws students and teachers into stories of historical dispossession and cultural marginalization, as shown by Sue Gibson and Mark Cridland (2018) in their study of an Indigenous educational program conducted at the Barambah Environmental Education Centre in Queensland, Australia. They found that students were moved to reflect on their own cultural assumptions and to shift their perspectives and values as they learned how Indigenous people were able to live productively in the forest at Barambah (Gibson & Cridland, pp. 107–112). The contest between Indigenous notions of place as country, and Minority western notions of place as natural resource, is not brought from outside into Barambah. The contest about country or resource and the emotionally charged historical events of Indigenous dispossession are part of the place itself. This is reflected in the story told by Mark Cridland (Gibson & Cridland, 2018, p. 102) about his sensing the presence of Indigenous people past and present as he walked the tracks of Barambah. It is quite moving for anyone to acknowledge that they are walking where others have walked for millennia or to realize that the trees growing so prominently on the bluff were growing there prior to European colonial occupation. What if they were harvested for timber? These contested considerations are part of the place and will emotionally engage students and teachers as they enter the place and learn about its history.

Emotionality: Love, Care, and Solidarity

In conceptualizing emotionality we adopt and extend the framework of love, care, and solidarity that was initially proposed by Kathleen Lynch (2007) to theorize human labor and especially the work of women. Lynch had critiqued Nancy Fraser's

(1997, 2008) well-known model of social justice (material redistribution, cultural recognition, and political participation) by highlighting that it focussed on public objectified spaces and neglected the interdependent local places that bound people into emotional relationships with others through attachments of love, care, and solidarity. Lynch (2007; Cantillon & Lynch, 2017) developed her critique in the realm of humanity, privileging human-human relationships rather than placing such relationships in the context of the more-than-human world. Her notion of humans as "relational beings within a matrix of social and emotional relations that give meaning and purpose to life" (Lynch & Baker, 2009, p. 227) is a vision that we endorse. However, we would extend the "relational other" to the more-than-human world (Renshaw, 2017). Indeed, Lynch (2017) has begun recently to acknowledge that love, care, and solidarity should encompass the way we ethically relate to each other as well as how we relate to all living creatures and the environment. We extend Lynch's recent thinking about ethical and emotional relationships with living creatures and environment by considering how *place* can be the object of love, care, and solidarity and indeed reciprocate such emotions.

There are key places in our lives that we *love* due to shared (partial) history, intimacy, and familiarity. Such places provide us with a sense of belonging. For example, Linda Venn (Venn & Lazaredes, 2018, pp. 122–123) recounts her relationship with the Paluma Cloud Rainforest in North Queensland, Australia, as one of love – it is the place where she swam with her grandmother, where she played with friends, met her lifelong partner, and where she taught for many years as an environmental educator. Her embodiment of Paluma is emotional and long-lasting, and the Paluma Cloud Forest continues to nurture her wellbeing imaginatively and physically. Noelene Rowntree (Rowntree & Gambino, 2018, p. 74) reports a similar emotional relationship with the Bunyaville Conservation Park where she played and sought solace as a child and where as an adult she shared time with her daughter and eventually became an environmental educator. The intimate knowledge and love that these educators have for such places enables them to tell stories-in-place that routinely beguile and enthral students who come on excursions. In addition to *love*, Lynch (2007) describes relationships of *care* based on an ethic of real concern and mutual responsibility. Caring for a local creek, or a stand of trees, or a community garden entails visiting and being aware of what's happening to that place and concerned to ensure that its well-being is maintained. In turn the place reciprocates by providing the carer with aesthetic pleasure, fresh air, and water as well as food (perhaps). Beyond the more immediate circles of love and care, Lynch (2007) envisages relationships of solidarity which we see as entailing "standing with" and "speaking-up" for places whose integrity is threatened in various ways. Relationships of solidarity are expressed by advocating for places based on ones interconnected relationship with the living systems of the Earth. So we theorize emotionality in this Chapter as a set of relationships in and with place, rather than as an internal personal set of feelings. We further illustrate this relational approach to emotionality by considering a recent incident involving *love*, where the ecosystems at Karawatha were threatened.

Loving Karawatha: "Does This (a Piece of Bitumen) Belong Here?" (Year 6 Girl, Aged 11)

Karawatha is a place set aside, a remnant of different types of forests and freshwater lagoons. Its unique geological features (including porous sandstone ridges) have protected the lagoons from the polluted runoff from nearby motorways and roads, so it is one of the last remaining habitats for a large number of frog species. Its trees provide a food source for endangered glossy black parrots and koalas. But it is not closed to the public. Local residents walk their dogs (by regulation they should be on a leash) and generally explore the whole forest via firebreaks and pathways. Fires have been deliberately started at times and caused considerable damage to the forest. Nonetheless, it remains beautiful and is being promoted as a tourist destination due to its biodiversity and proximity to both the Gold Coast and Brisbane in Queensland Australia. Recently a new Discovery Centre was opened to showcase the unique flora and fauna of Karawatha, and new tracks were constructed to enable access for the increasing number of visitors. Just after the tracks were laid in 2017, Bernice Volz and Ron Tooth visited the new Discovery Centre and later walked up the hill to observe the new tracks. In horror they looked down the hill at newly laid bitumen tracks winding into the forest. The pollutants released from the bitumen would eventually render the lagoons toxic to the endangered frogs that flourish there. The sandstone ridges, that had for millennia filtered the water flowing into the lagoons, were rendered powerless because a contractor had driven over the ridge and spread bitumen throughout the protected side. Bernice loved Karawatha. It was her experience decades earlier of exploring the lagoons that generated her love for the place, and now in one act of unintentional vandalism, the place was threatened. Ron recalls his dismay that council officers he knew and respected could have authorized the bitumen tracks. He and Bernice urgently contacted the council and requested a meeting to try to remedy the situation. It turned out that the officers were stretched for time and resources and had been unaware that bitumen had been laid. They organized for the bitumen tracks to be removed and the track remade with locally sourced sand. About a month later on an excursion to Karawatha, a Year 6 girl found a small piece of the bitumen lying hidden in bushes near the track and asked, "*Does this belong here?*" The bitumen is presented by the surrounding sand and vegetation as not belonging. The materiality of the place itself is rejecting the bitumen by making it so obviously alien in its black shiny stickiness in contrast to the light-colored and dry textured sand.

This recent story about bitumen in Karawatha illustrates how human activity can unwittingly harm places that are loved. In this case, love for Karawatha prevailed. How might we interpret these events from a posthuman and distributed sense of emotionality? The lagoons and frogs could be regarded as active agents in these events through their emotional relationship with Bernice. Over many years they enthralled and nurtured Bernice's love for them. In turn, Bernice's story enthralled Ron Tooth who could envisage a powerful *storythread* about environmental advocacy based on Bernice's emotional connection to Karawatha. It was this distributed love between the place, the frogs, and Bernice (captured in the *storythread* designed by Ron Tooth) that was crucial in convincing the council officers to quickly remove the bitumen. They were very aware that Karawatha was visited by thousands of

students who shared Bernice's love for the place. They also valued Karawatha and were keen to rectify the error of laying bitumen when it was brought to their notice. Their relationship with Karawatha is based on *solidarity*, but their limited resources to micromanage projects, and the competing demands on their time, made solidarity a tenuous way of ensuring that Karawatha would be sustained over time. It was the *love* of Bernice shared with many thousands of children through the *storythread* pedagogy that was crucial in the positive outcome in this instance. Nonetheless the fragility of the place remains palpable, and it calls out for ongoing love, care, and solidarity if it is to be sustained.

It was brought to our attention (Personal communication with Bob Stevenson, 27th November 2017) that one consequence of removing the bitumen and replacing it with sand is that people in regular wheelchairs will be largely excluded from most parts of the forest. The challenge remains of ensuring access for people with disabilities to forest reserves such as Karawatha while maintaining the integrity of the systems that support the diversity of life in the forest. Russell and Fawcett (2013, p. 371) asked the question, "Who is missing even at the margins?" They highlighted the scant research on inclusive practices in environment education and the importance of exposing "ablest" assumptions in how excursions are planned and conducted. Children with disabilities do participate in the Karawatha excursion in adapted wheelchairs provided by the children's family or the school. Children with severe disabilities can be transported by four-wheel drive vehicles to key places in Karawatha such as one section of the lagoons that feature a boardwalk – it was built to ensure that people could access these lagoons without damaging them. So, Karawatha as a place, as a story, provides a poignant example of contested interests between the more-than-human world and the interests of all people. In this case practical solutions have been designed to reconcile these interests, but the site remains fragile, so tensions will remain about access and suitable infrastructure. We consider now the actual place-responsive pedagogy that mediates children's relationships to Karawatha.

Pedagogical Tools That Mediate Children's Emotionality in Place

Prior to their visit to Karawatha, students listen to and discuss extracts from interviews with Bernice about her life as an advocate for Karawatha. They learn about the microclimates of Karawatha and practice attentiveness by silent listening, observing, and reflecting (outdoors) on the features of their school grounds. On the excursion day, students traverse Karawatha imagining themselves walking in Bernice's shoes as well as in the footsteps of the Indigenous custodians of the land. The teachers from Pullenvale Environmental Education Centre (PEEC), who work with Ron Tooth, shape the experiences by deploying micro-pedagogical tools that engage students imaginatively and emotionally with the place.

Dadirri is central to the place-responsive pedagogy at Karawatha. It is an Indigenous practice identified by Miriam-Rose Ungunmerr-Baumann of the Ngangikurungkurr people in the Northern Territory (Ungunmerr-Baumann, 1988, 2002). She describes it as an inner deep listening and quiet still awareness. She offers

dadirri as a practice for everyone (not just Aboriginal people), so on this basis Ron Tooth and his PEEC colleagues created a series of *dadirri* experiences throughout the Karawatha excursion to facilitate children's personal and emotional connections to place. These *dadirri* moments are described below.

White Crystal Dadirri

The journey into Karawatha begins with a protocol of respect and acknowledgment of Aboriginal people that is conducted in silence. The protocol involves students scooping up white crystals from the track at the entrance and allowing the crystals to pour slowly back to the track. Aboriginal people have walked on these crystals for millennia, so by pouring the crystals through their hands and listening to the crunch of the crystals under their feet, the students are given the opportunity to show respect for Karawatha as an Aboriginal place and to make their own sensory and tactile connections to the place. They walk in a single line listening to the sound of the crystals under their feet and observing the forest where the sandstone ridge falls away on each side of the track. They continue to walk the white crystal track in silence until a giant tree comes into view, where their voices return and a different form of *dadirri* is introduced, namely, animal *dadirri*.

Animal Dadirri

The track along the sandstone ridge opens to an area of flat sandstone surrounded by boulders that are partly buried and strewn haphazardly along the ridge. Birds watch from trees as students approach. Goannas, lizards, insects, and beetles can be observed scampering between the rocks to hide in clumps of grass or in leaf litter. *Animal dadirri* invites children to adopt a certain kind of attentiveness to the animals they see – to sense the forest as if they were one of these creatures. To further facilitate this shift in perspective, students are provided with digital cameras that magnify fine details and help them imagine what an ant, lizard, snake, beetle, bird, marsupial mouse, frog, etc. might see. Children are inventive in placing the cameras down in the grass or under logs, or close to leaves or along the trunks of a tree, often facing the sky to simulate an animal's line of sight. Students crawl through grass, slither under rocks and trees, and squeeze their bodies into gaps as they simulate a particular animal's perspective on the world. This is a very tactile and embodied form of *dadirri* that simultaneously allows children to sense emotionally what it might be like to be that animal.

Rock Dadirri

The sandstone ridge provides a vantage point to see the structure of Karawatha's catchment and understand how the water flows downhill through the sandstone to form the system of lagoons that is hidden among the dense bushland in the distance.

Rock *dadirri* (in contrast to animal *dadirri* where children are active and physically inventive) requires students to become totally still as if they've become part of the rock itself. Their hands are in contact with the solidness, grainy texture, and coolness of the sandstone. Being rock they can imagine eons of time and the generations of Aboriginal people who also observed Karawatha from here. By sitting still and quiet, forest creatures and birds often come very close to the children, treating them as if they are actual rock. Children sit frozen in these encounters and soak up the experience as it unfolds. *Rock dadirri* is designed to help children understand the unique features of sandstone as porous material, so this *dadirri* experience is concluded by the group gathering to observe water being poured on to the rocky surface and vanishing almost immediately into the porous sandstone. From this surprising experience of seeing water vanish into apparently hard rock, children can more easily imagine how water is collected and filtered along the sandstone ridge before forming the system of lagoons below.

The emotions that are engendered throughout the excursion to Karawatha by practicing various forms of *dadirri* culminate in the afternoon when students compose a letter to Bernice about their experiences and finally speak to her via mobile phone. The conversation is always emotional as students hear the voice of Bernice and want to tell her about their experiences. They have followed in her footsteps and experienced the place partly through her eyes, and they know Bernice's story of advocacy that was instrumental in the establishment of Karawatha as a forest reserve. It is not surprising, therefore, that during this phone conversation they express a love for Karawatha and a commitment to caring for it in the future. The students continue to talk about their visit to Karawatha after the excursion; they write responses to Bernice and reflect on what it means to live, like Bernice, as environmental advocates in their own school and community.

Categorizing Children's Representations of and Relationship to "Nature"

The literacy-related activities of writing, drawing, and conversing, which are part of the Karawatha excursion, provide a window into understanding how children represent "nature" and how they relate to "nature." Our assumption is that children begin as cautious observers of "nature" and see themselves as separate from "nature." This is expressed clearly by one child in a letter to Bernice after the Karawatha excursion. She writes about her initial phobias,

> I used to hate dirt and mud but after what I have learnt today, it turns out that mud wasn't that bad and now I love it. I naturally had a phobia of bugs but now I'm fascinated by them. Thank you for what you have done.

Rowntree and Gambino (2018, p. 75) likewise recorded a group of youngsters arriving at Bunyaville Environmental Education Centre for an excursion where they expressed fears about wild and unknown creatures in the forest. Venn and Lazaredes (2018, p. 124) found at Paluma Cloud Rainforest that many children initially expressed

apprehension about being alone in the forest and were fearful of perceived dangers like spiders and snakes. Pattison also (2018, p. 142) reported that many students are apprehensive and fearful as they explore the intertidal zone at Nudgee Beach (near Brisbane, Australia). After the Karawatha excursion, we were looking for different responses from the children – responses that suggested an interconnected and relational understanding of "nature." Below we categorize responses that were collected in 2013 from the letters that 108 children (50 girls and 58 boys) composed to Bernice Volz at the end of the excursion. The children were from upper primary school, predominately in Year 7 (about 12 years old) with a few from Year 6 (about 11 years old). They came from four different State Schools and participated in the excursion on separate occasions. The task of writing the letter was described to the children as an opportunity to tell Bernice what had happened to them on the excursion and how they felt about what she and her friends had done to preserve Karawatha. The letters varied in length from a single sentence to a number of paragraphs.

In our initial examination of the text of the letters, we noted the many positive and heartfelt responses from students, as would be expected at the conclusion of their journey through Karawatha following in the footsteps of Bernice. The text below from one 12-year-old girl is typical of numerous similar responses.

> I feel really peaceful, calm and somehow fun in a relaxing way at Karawatha Forest. I actually have never been to a real forest that actually has beautiful butterflies, gorgeous rocks, natural lagoons, rare trees and rare animal species it feels so special.

Her vivid description positions her as calm and "at home" in the forest, in contrast to the fearful children referenced above, but she remains an observer of the "gorgeous" features of the forest. These types of responses from children do not convey a major change in their relationship with "nature," or a new sense of "nature" as agentic, or as intimately interconnected with their own identity and destiny. However, there were many responses from the children that did indicate such changes, and we turn now to consider these.

The first category concerned changes in the children's sense of bonding with "nature" and becoming part of "nature" ("*I feel as if I'm a part of the environment*"). The second category concerned a changed view of "nature" itself where agency and knowledge are represented as simultaneously part of the human *and* the more-than-human world ("*Nature talks to me and it has so many stories to tell*"). The third category concerned changes in children's sense of solidarity with "nature" that motivated them to speak-up for "nature" ("*I learnt that a group of people can save a whole forest it is truly stunning*"). Across these categories an emotionally attuned sensibility to the more-than-human world is evident.

Students' Sense of Bonding with "Nature"

In the following account, a child represents the forest as sharing stories with her. She has entered a conversation with "nature" that is trying to show her the importance of

the Karawatha story. Her response to the grass whistling and the birds singing suggests learning far beyond the purely cognitive. It's a visceral response from the "body-in-nature," rather than a detached appreciation of "nature."

> I really feel the nature coming into me and trying to show me why you had saved Karawatha. The zones and the beautiful tracks have been so inspiring today. I could hear the grass whistling and the birds sing.

The visceral responsiveness of the "body-in-nature" is expressed also by the child below. The student opens her eyes to see the clear sky and dark leaves; her breathing is almost audible, in and out, as she listens to the sounds of the forest. Her words convey embodiment and a clear connection to "nature." She is being changed through her experience in place, and she seems enthralled by it ("an amazing delight").

> As I leaned back on a vine-covered log feeling the banksia flowers brush against my fingertips, then, I close my eyes, relax, and let my imagination take over. When I open my eyes, I look up at the clear sky and dark tree leaves, breathing in and out deeply whilst listening to the variety of bird noises was an amazing delight.

In this next account, the child explicitly reports "feeling part of the environment" as Karawatha Forest has "grown on me." It is the materiality of the place – the lagoons, plants, birds, frogs, and plants, and the richness of her sensory experiences – that is associated with her sense of bonding with the environment.

> I feel that Karawatha forest has grown on me and I feel as if I'm a part of the environment. The lagoons are SO cool. The sounds of the birds and frogs. The plants are in various different sizes and shapes and all the smells.

In the short comment below, this child conveys that they have learned "to bond" with the forest in such a deep way that they know what it needs; it needs to be saved. Embodiment has led to advocacy and the desire to speak for the forest. This is something we have often seen in our environmental programs where students feel compelled to act because they have come to love and care about a place just as Bernice did. We explore such solidarity with "nature" further below.

> I've learnt how to bond into the environment and can tell what the forest needs, it needs saving.

Students View "Nature" as Having Agency and Knowledge

In the text below, animals are given agency: frogs sing as a choir, and fish (tadpoles) love the lagoon as they jump and splash. These are no longer imaginary storybook animals but the living creatures of the forest that the child has seen.

> There is so much wildlife everywhere, I just love listening to the birds . . . sing and the frogs singing as a choir. As we approach the lagoon, I hear all the frogs stop but one, I think it was a warning call or something. I could tell that the fish (tadpoles) loved the lagoon because they were jumping and splashing and they owe it all to you.

In the extract below, the forest is given an agentic "presence" that it shares with Bernice and the child. It doesn't give up even in the face of natural disasters. Human and more-than-human interests are equated here in this representation of the forest. The forest didn't give up, Bernice didn't give up, and the child won't give up. The agency of these three characters (forest, self, and Bernice) has a moral dimension which reflects the pedagogical intent of the Karawatha narrative to move children to understand and practice advocacy for the places that matter in their lives.

> I loved the calmness and spirited feeling in the forest. The best feeling was to watch this amazing divine forest. No matter how much disasters there has been this forest doesn't give up. I have learnt to never give up of what I love and no matter how much people doubt you, you never give up.

This sense of equivalence is captured also below in the child's comment, "we're not the only livings things that live on earth." The surprise and pleasure of this student in realizing that other creatures are "living" in the same way that she is "living" is expressed with vitality and vividness and echoes Bill Neidjie's insight, "you can look, but feeling. . .. that make you" (Neidjie Davis & Foz, 1985, p.51) It's a place where trees glow, the air is fresh, and the world is full of surprise. Everything is animated and full of life. This is not a detached description of space but an emotional response to place. It resonates with the ontological and epistemology stance conveyed in Bill Neidjie's poem that we relate to "nature" through kinship and friendship.

> I think the most important discovery I made today was we're not the only living things that live on the earth. The fresh air surprised me and the trees when I looked up at them against the light sky, looked like they were glowing. I have never had this much experience with nature before.

The pedagogical tool of *dadirri* that mediates children's experience of Karawatha is regarded by some children as central in facilitating their appreciation of "nature" as agentic and knowledgeable. Below a child writes in a decentered way that positions her both inside and outside the experience: "inside," she feels the emotional sensorial connection with the life around her; and "outside," she looks and, in looking, becomes acutely aware of the "lives" of insects, ants, trees, and birds but especially their activity and their agency. Insects are "working" and birds are "chirping," and she knows this because of *dadirri*.

> There were lots of wildlife around and when I did dadirri it helped me sense all my surroundings. There were a lot of little insects and ants working on the trees and birds chirping at the back.

A second child takes this idea further when he recounts that *dadirri* "really works" because animals "don't think you're a threat" and you can come in close, or, as his statement implies, the animals "think" and in "thinking" have their own agency.

> I learnt about dadirri and that it really works. Birds don't think you're a threat and it's a good way to see all the wildlife.

How birds think or feel is not what matters here but rather how this boy's thinking has changed and how he has now entered into a more relational way of explaining "nature." The inference here is that the birds are agentic in deciding whether you are a threat or not and that you will be rewarded if you use *dadirri* because this enables you to "see all the wildlife." Agency is taken to a more emotional level in the next account where a student imagines "nature" talking to them and telling stories, which creates a partnership and conversation that is "deep and meaningful."

> You have helped me learn that nature is more than a flower attached to a branch or a bird in the sky, it is deep and meaningful. It talks to me and it has so many stories to tell.

Students Express Love, Care, and Solidarity with "Nature"

As Somerville (2010) and Massey (2005) proposed, contest is a part of *place* as competing agendas, epistemologies, and ontologies come into contact and struggle to be reconciled. In the following responses from students, we see how they engaged with contestation as part of an experience of love, care, and solidarity with "nature." They encountered contestation through the story of Bernice who lobbied politicians to purchase private properties in order to establish Karawatha but also in their own embodied experiences of Karawatha. In the following account, this student expresses her new found solidarity with nature, and combined with her new knowledge about herself, she repositions herself as an advocate and recognizes that she can do "little things" to help protect the environment.

> I have learnt a lot about myself during my time at Karawatha. I now know that everything I do has an impact on the environment and by doing even just little things, I can help protect it.

In the extract below, another child now wants to care for "nature" because she has been inspired by Bernice. She expresses a strong desire to do "something for nature" because she has seen how Bernice saved the frogs, trees, and bugs from being lost. It's that she "saved them from harm" and "saved lives" that has caught her imagination. It's not "the ecological facts" of Karawatha alone but the love of Bernice for Karawatha that's carried by these words that inspires her to "make memories" and to "do something."

> Being able to be in a place that could have been built into a shopping centre is awesome. Rare frogs trees and bugs live there and you saved them from harm. You saved lives. You

> saved Karawatha. You let us make memories. I feel like I can do something for nature. You inspired me.

In the short account below, a child states that he would "love" to return to Karawatha to tell his parents the "story of how Bernice saved it." This is a simple statement of intent, but his choice of words: "love," "beautiful," and "saved," indicates an undercurrent of emotionality and his desire to share and communicate the "story." This story links his personal relationship of love within "my family" to his sense of solidarity and caring about Karawatha as beautiful and now "saved" through the actions of Bernice. Here we can glimpse how the *storythread* pedagogy provided him with a way to weave together a personal story from the whole emotional experience.

> I would love to come back here again and show my family how beautiful it is and tell them your story on how you saved it.

In the account below, a girl is unambiguous about never wanting to be an advocate for the environment, and yet the experience of the Karawatha story changed all this. She now thinks about how trees "dance in the wind" and loves that the birds and animals are "so free." The aesthetics of *place* has captured her feelings and made her "think" about not dropping litter, yet "think" here conveys more than "detached cognitive thought"; it conveys emotionality in and for *place*, which is facilitating her change of habits and care for the environment beyond Karawatha.

> I never did want to be an environmental advocate, but since I walked through Karawatha it's changed me. I now think more about trees and how they dance in the wind. Birds and other animals how they're so free. I also think more about not dropping litter.

Finally, in the following account, a child explains how *dadirri* allowed her to see the detail of animals actively crawling and gliding and the solidarity she felt with them which she described as so "wonderful listening." You can feel the emotion and wonder in her words for these creatures and how it gives energy and vitality to the idea that "a group of people can save a whole forest." This is something she hadn't thought was possible before she visited Karawatha and heard the story of Bernice and her committed group.

> When we did dadirri it was wonderful listening to all the different bird calls and watching little insects crawl around and the amazing birds swiftly gliding through the trees. I learnt that a group of people can save a whole forest it is truly stunning.

There is an entangled form to the representations of "nature" and "self" in some of the letters to Bernice. The changes children reported in their relationship to "nature" are entangled also with a strong sense of personal change. To examine these entangled changes, we introduce the concept of *perezhivanie* (Vygotsky, 1934) defined as emotional or lived experience in a specific context (see Ramos & Renshaw, 2017) and analyze extracts from children that exemplify this phenomenon.

Perezhivanie: Identities Emerging from Emotional Experience in Place

For some children the whole experience of the excursion is associated with emotionally charged reflections on their past, present, and future and a changing sense of identity. In the following account, a student makes the remarkable claim that she has found herself ("I have found me"). A nascent ecological identity is emerging, and one senses that this child is as surprised as anyone that this is occurring.

> I have found my inner-self, I have found me. The way the birds talk to me . . . words cannot describe the sensation.

In a similar way, the child below sees herself as a "new girl" and a "new person" and notes that this is the "first day" in her transformation.

> It is very hard to say or describe what I feel like. I am a new girl and a new person. . . .. I will always remember this as . . . my first day doing my new favourite hobby, being with nature.

What is remarkable in the extract below is the way the child's reflections center more generally on her life in the past and her emerging sense of identity. She remembers how hard her life has been but also the gifts that life has given her. Her thoughts about the excursion to Karawatha, her emotions, her past life, and her identity are entangled – woven together dynamically in a complex experience in *place*. In the moment of writing to Bernice, situated near the lagoons in Karawatha Forest, her reflections encompass her identity in the past, present, and future within a heightened emotional state. Such significant moments are not uncommon when children participate in place-responsive experiences based on *storythread* pedagogy.

> I now know why you wanted to save this amazing place . . . I found inside this sacred place that all my worries disappeared with the sights and sounds of the city. When we sat still everything that I saw as ordinary I found something so amazing "the extra-in-the–ordinary." Something inside me made me want to stay there forever. Watching the insects and colourful birds swoop and glide through the clean air. I've had a hard life but not as hard as others so in that moment I was reminded of the beautiful things and people that life has given me. [Emphasis added by authors] I want to say thank you from the bottom of my newly environmental heart. Thank you for saving this gorgeous place. Thank you for making that moment possible. Thank you for all the hard work and love you put into protecting this forest. Also, I loved talking to you on 6.6.13. You are the most inspirational lady ever. Yours truly, (Year 6 student)

We have written about this emotional place-entangled phenomenon recently (see Tooth & Renshaw, 2018; Ramos & Renshaw, 2017; Renshaw & Tooth, 2016) deploying the Vygotskian notion of *perezhivanie* (Vygotsky, 1934). *Perezhivanie* is a concrete emotional experience in *place* that is accompanied by a sense that significant change is happening to oneself and reflective awareness of the

process. It has been used by Fleer and Hammer (2013) to investigate early childhood dramatic play and by Fernholt (2015) to research *storyworlds* creatively imagined by young children with adult assistance to explore important events and emotions in children's lives. The events in the *storyworld* are recalled and discussed by children and adults as they revisit the episodes, acting "as if" they are floating above the scene, recalling and evaluating the emotional experiences within and beyond the stories (Tooth & Renshaw, 2018, p. 39). The Karawatha excursion is similar to *storyworld* and dramatic play – it too involves students participating in storying and reflecting on the significance of the story for their lives. In the extract above from the girl's letter to Bernice, we can see: (i) the elements of the story, (ii) the embodied nature of her experiences, and (iii) her awareness of the contest about Karawatha. These elements coalesce in her "newly environmental heart" which points to her future as an environmental advocate. We noted recently (Tooth & Renshaw, 2018, p. 40) that "this is the student's *perezhivanie*, her emotionally lived experience," arising from the story of Bernice, and stories inscribed in the place, and personal moments that were distinct for her as she walked through the forest. Not every student will experience *perezhivanie* on such occasions, but for some the elements of the experience combine to make Karawatha a significant event in their lives as they reflect on their identities and their futures.

Conclusion

In this Chapter we theorized children's emotional relationships with *place* in terms of love, care, and solidarity and presented evidence that children can situate themselves as emotionally entwined with other living and non-living aspects of *place*. They can come to understand that they are not separated from "nature" but are emotionally interconnected with the living systems of Earth. Crucial to the development of these sensibilities was the place-responsive pedagogy at Karawatha that engaged children in reflective experiences as they journeyed in the footsteps of Bernice Volz through the forest and to the lagoons. The children's learning was mediated by Bernice's story of advocacy, her love for Karawatha, and the *dadirri* episodes that heightened children's attentiveness to the more-than-human features of the forest. This is the beginning of change – children have entered a portal into a transformed understanding of their relationship with "nature," but such emotional experiences in place need to be supplemented by other experiences and reflections. What if the context of learning is not the "sacred," "gorgeous" forest "saved" by Bernice and the "amazing" animals including endangered frogs, parrots, and koalas. How might an interconnected sense of "nature" be engendered and emerge in their own backyards far from the magic of a place like Karawatha? This is a pedagogical challenge Ron Tooth and his Pullenvale colleagues have considered for the past 10 years. So we conclude the chapter by examining the possibilities for place-responsive pedagogy in everyday school contexts.

Teacher Knowledge, Love, Care, and Solidarity with Place

Teachers are crucial, especially their knowledge and emotional responsiveness to place. Reviewing the diverse place-responsive pedagogies included in the volume by Renshaw and Tooth (2018), Stevenson and Smith (2018) highlighted the crucial role of teacher knowledge about and dispositions to the more-than-human world. Indeed, each contributor to that volume provided a moving account of their intimate knowledge and emotional connection to the places where they taught as environmental educators. They did not have to pretend to love the place. They also did not need to simulate understanding or knowledge of the place – their deep knowledge of the ecology and history of the place enabled them to support confidently children's own discoveries as they experienced the features of the place firsthand. But teachers working in conventional school settings do not always have an understanding of "nature" as relational and emotional or an understanding of themselves as interconnected with the living systems of the Earth. Ron Tooth and his colleagues at Pullenvale have observed that many teachers who accompany their students on excursion to Karawatha have their own epiphanies regarding "nature." Along with their students, they begin to see "nature" as relational and emotional, and many express the desire to implement a place-responsive pedagogy in their own contexts. This is the first step in adopting a place-responsive pedagogy – developing at least an inkling of the ontological and epistemological stance to "nature" expressed simply by Bill Neidjie (Neidjie Davis & Fox, 1985, p. 51) as, "I feel it with my body, with my blood. Feeling all these trees, all this country."

In further elaborating and adopting a place-responsive pedagogy in conventional school contexts, teachers could consider the general principles arising from Somerville's notions of embodiment, storying, and contestation. Each place has material features that can be experienced and explored through the senses and through activities that enable connections to become visceral and firsthand knowledge, rather than abstracted knowledge gained from a distance. Each place can also be represented as a set of stories constructed through the activities and lives of participants from past generations, including Indigenous stories of country that are relevant locally. Learning about the history of place imbues it with cultural significance that enriches the experiences of children in that place. But stories and histories also reveal contestation and conflicts between different interests, and these need to be included in a place-responsive approach.

Place-Responsive Professional Learning for Teachers

In partnering with a number of schools during the last 10 years to explore place-responsive pedagogy (see Tooth & Renshaw, 2018), Ron Tooth and his colleagues have seen many teachers reimagine themselves and their work as inherently related to place. Each partner school came to recognize that students can connect to "nature" in their own school grounds and that pursuing entwined relationships between people and place can constitute the core of a worthwhile education. The partnership

stories are about teachers finding themselves "in place" and recognizing the truth of what a child articulated at the end of a *storythread* excursion, "today I was the most myself that I have ever been." The teachers at the partner schools gradually recognized the worth and beauty of their local places where even a blade of grass, a garden, a single tree, or a piece of remnant bush on the boundary could become a focus for learning with "nature."

Reflecting on the legacy in each of these schools in the context of contemporary educational policy, we have drawn two conclusions about introducing place-responsive pedagogy. The first relates to the pivotal role of the school leader (Porritt, Hopkins, Birney & Reed, 2009). There are always difficulties associated with introducing innovation into a school, not the least being the competing policy pressures on the principal and teachers. In each of the partner schools, the principal's positive mind-set and enthusiastic support for a place-responsive pedagogy was critical. Working with place-responsiveness was, at times, a courageous choice because it exposed them to risks associated with current neoliberal educational policy and the reductive demands of a competitive and performance-oriented system of education.

The second conclusion relates to the necessity to convince teachers that place-responsive pedagogy was something worthwhile and that it would benefit their students. Teachers are typically pragmatic and if they cannot quickly see that a pedagogy is feasible in their specific context, they will soon lose interest. What allowed the teachers at the partner schools to persevere and move forward with confidence, apart from the drive of their principals, was the positive changes they saw in themselves and in their students as connections to place were explored. As this happened many teachers reported that something "quite amazing" was happening to them and to their students, especially with the reluctant learners.

One interpretation of such amazing change for teachers and students is to consider the emergence and growth of their ecological identity (Thomashow, 1995). It is what enabled teachers to see the importance of emotion and emotionality in their work and to recognize that this is what was drawing disengaged students back into learning. Their effect on disengaged students is what finally convinced teachers of the efficacy of using emotionally engaging stories, like that of Bernice Volz and Bill Neidjie, and then linking these to direct experience in ordinary places as a way of creating an understanding of "nature" as relational and of "humans" as intricately interconnected with and part of "nature."

Abstract

In this Chapter, we explore some of the work of an arts and wellbeing charity in the UK called Cambridge Curiosity and Imagination (CCI), a group of artists, educators, parents, and researchers with an interest in how the arts can transform lives. CCI projects aim to open up spaces for creativity, actively engaging with people of all ages and backgrounds. Much of their work involves connecting children to the outdoors. We describe and discuss how the artist pedagogues working with CCI perceive and articulate the positionality of the children they work with in relation to non-human nature and the significance of the imagination in this regard. We then reflect on what this positionality means for posthuman perspectives on the stewardship approach, arguing that humans being both *a part of* and *apart from* nature have important consequences for our capacity to steward the Earth. These artists and children work together in spaces with meaning for children; as such, their work fits with the theoretical framework of pedagogies of place. We explore how the artists conceive of "place" in their work with children and how this influences the way they situate children in relation to both human and non-human nature, highlighting the data on the role of imagination in this relation. The Chapter emerges from ongoing exploratory case study research involving thematic analysis of data from a focus group discussion and individual interviews with the artist pedagogues, as well as archival material from the charity. In our discussion of the findings of our study, we reflect on the usefulness of the notion of childhoodnature in this context, showing how this charity's work can contribute to its conceptualization and what it can contribute to current debates around the validity and usefulness of the stewardship approach.

Place-responsive pedagogy · Artists · Stewardship · Imagining

Introduction

The notion of childhoodnature, while new, can be traced back to the dialectics of nature and childhood from Romantic eras where childhood is affiliated to nature both positively (from Rousseau as a state of "natural" innocence that society jeopardizes) and negatively from pre-Romantic eras, where childhood is seen as pre-socialized wildness that may itself be brutal, like nature, or carry original sin and needs to be trained and civilized through education. These early associations between childhood and nature via shared innocence have been identified by Taylor (2013) and have also been written about from eco-critical perspectives (Whitley, 2013). They hint at the current developments in the field of Environmental and Sustainability Education (ESE) research and in children's geographies', leading a trend toward the entanglement of posthumanism (Clarke & Mcphie, 2016; Gannon, 2015; Malone, 2015;

Rautio, 2013). What this posthumanist direction entails is a move away from the idea of humans and nature being separate. Posthumanism encourages a rejection of an anthropocentric view of nature where humans can in fact be disconnected from it as Louv (2005) and many others propose and toward an understanding that nature and humans are one and the same (Malone, 2015).

To try to understand this idea of humans being both a part of and apart from nature, we suggest a metaphorical representation of nature as a whole as an orange, made up of different segments each a part of nature but also with a form and shape in their own right, as the segments of an orange have. So we might conceive of nature as being constituted by segments that represent trees, humans, chickens, rocks, bacteria, and so on. This means that when we talk about nonhuman nature, what we mean is what remains of the orange when you take the human segment out. It also means that although you can extract humans from nature, humans still have the same qualities as the whole of nature has (like a segment of an orange still has the same texture and taste as the whole orange or any other segment of it).

A point of significance here is the way in which such an approach challenges the notion that humans can be or are stewards of the earth (stewardship: Taylor, 2017). If humans are in fact nature, as beech trees and lions are, then human exceptionalism and human stewardship of the earth become much more difficult concepts. We will return to human stewardship in our conclusion but to begin with we want to show how our investigation of an arts charity (Cambridge Curiosity and Imagination, CCI) working on pedagogy arising at the intersection of creativity, nature, and childhood provides evidence in support of the developing childhoodnature concept.

In this regard, we conceive of the childhoodnature concept as a means toward demonstrating the way that the qualities of nature are to be found in equal measure in both children and in non-human nature, such as the wind or trees. At the same time, this conflating of childhood and nature does not need to deny the uniqueness of human childhood, but rather it demonstrates that the uniqueness of human childhood is equaled by the uniqueness of the younger phases of the wildlife of other living organisms (such as being a lamb or being a bear cub might do).

To achieve our goal of showing how our investigation of CCI's work provides evidence in support of this concept, in the next section, we will outline the structure and features of the charity, and the role of the artists within it, as well as introduce their work in terms of the pedagogies of place theoretical framework. Although the research methods are described later, it is worth noting that this initial description draws on the charity's website, as well as on statements made by artists in interviews about their work. (The artists we interviewed have agreed to be named in this study: we talked to Caroline, Deb, Debbie, Elena, Helen, Sally, and Susanne.)

The Pedagogical Context: Cambridge Curiosity and Imagination (CCI)

CCI is an arts and well-being charity helping to shape cohesive and collaborative communities in Cambridgeshire (a region in the East of England) and beyond. It began as an artist-led collective in 2002, drawn together by artist Nathan to deliver

groundbreaking creative projects, initially in learning environments. Many of the original group of artists, educators, parents, and researchers have been actively engaging communities in the region ever since. The organization became a charity in 2007. While CCI most frequently works with school and community partners, they have been able to develop wider applications for their approach and now run programs in health and social care settings. Common to all their work is a focus on developing a sense of agency and voice for everyone through engagement with the arts.

Children are at the heart of the charity's work. As one artist, Caroline, says: "Children lead and the way we work, [we] give them the chance to be themselves and to be creative." CCI explores how their ideas and questions can lead the way in creative explorations with artists traveling alongside to support the process. A core group of ten artists works with CCI regularly, with others supporting particular elements, as appropriate. It is important to note each artist in CCI has their own individual practice; however, for the purposes of this research, we focus on the work they do together and the shared philosophy that underpins their approach to CCI projects. Such projects are planned to ask questions about the world, often taking place in communities with specific challenges. CCI's work is managed by a director and a small team of dedicated and creative colleagues, who work very closely with the artists and those involved with the projects, to shape how projects evolve. There are also a number of people who act as "critical friends" and patrons for CCI. One such patron is Robert Macfarlane who describes a CCI project: Ways into Hinchingbrooke Country Park, in his seminal book, *Landmarks* (Macfarlane, 2015).

It is important to note that this undergirding philosophy of giving children the space to lead is like inviting them to be artists and so members of CCI for the time that they are engaged in a project. As Susanne says: "I am working with the children who live around [a site of a new housing development] and trying to take something of the contemporary artist processes to them… I've made… we've made all the children around that area into Artscapers, so they get a badge, they belong to this big Artists in Residence group" (see "Composition 4: the Childhoodnature Imaginary" by Artists and Children from CCI book for more details about this project).

The mode of working varies quite significantly depending on the project. Each project usually involves artists working in pairs, but how the project begins, unfolds, and ends is determined by the participating children, the requirements of the funders, the school (or other institution), the specific artists' preferred working styles, and the place where the work is done. The work can happen during the school day where a year group or class might be "off timetable" for the day, or it can happen in the school grounds at the weekend; alternatively, a combination of different approaches can be adopted.

One example of an ongoing project involving artists that we interviewed is called Fantastical Cambridgeshire. A key partner for this project is Cambridgeshire County Council who provided additional funding for it, alongside the grant from Arts Council England. In this project, artists and children are creating a series of fantastical maps of the surrounds of primary schools in a town in Cambridgeshire through a process of what is described as *creative adventuring*. They do this by working

together in a variety of ways on processes that could include drawing maps in one minute (called One Minute Maps), making collages with old maps, a playful way of exploring called "found mapping," among other activities. While the artists present ideas by bringing in particular provocations in the form of materials or suggestions for ways to go, the children are invited to lead their own explorations and identify spaces they would like to spend time in – an orchard, the path by the river, and a churchyard have all been investigated in recent projects. In one example, children are provided with chalk and a playground area and asked to draw "home." In another example, they are taken to a cube space about 10 m by 10 m by 2 m on the school playground that has been cordoned off with string. The idea is that they will create a 3D map using found materials from the school grounds and any of the materials like brightly colored tape, string, wool, newspaper, and so forth that the artists have gathered. This is filmed by a drone; the person who is doing the filming has heard about the work and offered to come in and do this. These sorts of emergent methods from an open-ended beginning are a common feature of the way the projects are run. As artist pedagogue Helen, says: "I will take the risk each time that something will emerge [. . .] and it always does emerge, you know, and it's always a bit risky [. . .] but more often than not you will find someone or something that interests you and that will lead the project and then they'll open the door to other ways of thinking about a place."

Documentation is an important element of the charity's work. Everything is carefully documented and shared on the CCI website and ultimately in this case described above, reimagined by another artist – illustrator Elena Arévalo Melville – who creates unique fantastical maps of these localities. The maps created to date can be viewed on the CCI website (the companion chapter in the book accompanying this publication contains examples of the work of the young artists who collaborated with CCI).

The Fantastical Cambridgeshire project is particularly in tune with what has been described as *place-responsive pedagogy* by Mannion, Fenwick, and Lynch (2013). Set within the field of environmental education, place-responsive pedagogy seeks to encapsulate the way in which educators create assemblages of people, places, and purposeful activities to create effective learning experiences about environmental issues. Place-responsive pedagogy emerges from the vibrant and active field of place-based education (Gruenewald, 2003; Mackenzie & Bieler, 2016) that has long been popular in the field of environmental education. In privileging the local or in being lococentric, it has been described as "paying close attention to the place where you live" because this is "the best way to learn how to perceive the biosphere" (Thomashow, 2002, p. 5). It is not without its critics (see, e.g., Garrard, 2010; Heise, 2008), but this ethic of proximity has been accredited with the potential to instill a love of place and an ethic of care for nature by numerous writers and researchers (e.g., Gruenewald, 2003; Fettes & Judson, 2010). What is different about the place-responsive pedagogy practiced by CCI artists is that their purpose is not to inculcate an ethic of care for the environment, or indeed to address issues of sustainability, but to enable creativity through playful engagements with nature (broadly conceived). So as pedagogues they work with and alongside children,

emplaced with them in the places that are familiar to the children; observing, suggesting, guiding, and enabling them to follow their curiosity and in creative and imaginative ways, to play with the ordinary until it becomes extraordinary and fantastical. As Sally explains: "I aim and intend always to work alongside children, alongside the teachers, alongside any of the participants that I happen to be working with, whether they're elderly folk or teenagers in a museum."

At this juncture, we explain our utilization of the term "emplaced." Drawing on the work of Michael Bonnett (2012) who uses emplacement to elucidate the way that environmental concern and human sense of place questions contemporary moral sensibilities, we employ emplacement to represent the way in which human action and being is always linked to a particular place or is lococentric. In line with MacKenzie and Bieler (2016) and others (Clarke & McPhie, 2016; Gannon, 2016; Malone, 2015), we understand place in the posthuman sense, as a fluid entanglement of nonlinear time, geographic location, human relationships, and memories of prior experiences, current individual experiences, and the interplay between these. As such, the practice of the artist pedagogues and the young artists they work with emerges from this entanglement of dimensions. As our data will show, this is very much in line with the way these artist pedagogues themselves conceptualize place.

Returning to the exemplification of CCI's work through describing some of their activities that we undertake in this introduction to our study, another example of a CCI project also described in the companion book is Artscapers in North West Cambridge, commissioned by the University of Cambridge as part of their public art program. As Susanne describes it:

> They've commissioned contemporary artists, quite well-known contemporary artists, to work on that site and I'm looking at the processes and the way that the contemporary artists work. I am working with the children who live around the site and trying to take something of the contemporary artist processes to them. . . I've made. . .we've made all the children around that area into Artscapers, so they get a badge, they belong to this big 'Artists in Residence' group. That project includes sustainability and place and space and the outdoors [. . . and it is. . .] to do with communities and the future and how people might live together. (See companion chapter)

One question asked by the Artscaper's project is: "how can children help others to think creatively about planning and implementing changes in a city?". This approach is similar to the one used in the project reported on by Malone (2013) on participatory city design, and the question itself demonstrates the way in which the organization as a whole approaches children, an approach which fits well with participatory theory. Participatory theory is in part a response to the UNICEF Convention on the Rights of the Child and encapsulates the ethics of treating children as humans with their own rights, opinions, and power (Hart, 1992). Environmental education (EE) has worked extensively with this theory (see, e.g., Reid, Jensen, Nikel, & Simovska, 2008), particularly as means of doing research where children are given ownership of their data and are treated as co-researchers with the right to choose to be involved and to withdraw and the right to a voice regarding how data are interpreted. In some cases, children determine the direction of the research, asking the questions and

deciding on the research design (e.g., Alderson, 2001; Barratt Hacking, Scott, & Barratt, 2007; Christensen & James, 2000). It will become evident through this Chapter that the way this group of CCI artists works with children is strongly aligned with a participatory approach to pedagogy.

Place-Responsive, Participatory Pedagogy

What our research uncovers is a place-responsive, participatory pedagogy that emerges at the confluence of children, artists, nature, and place that has implications for the childhoodnature concept and thus for how we see our role regarding the sustainability of the planet. We will explore how this happens in the next section by outlining the ways in which these artists conceptualize the interplay between children and nature and how this influences their pedagogy and the pedagogical philosophy of CCI.

Childhoodnature Through the Lens of CCI

In this research, we wanted to explore what emerges from this confluence of an artist collective, nature, place, and children in the context of the charity: CCI. We have identified a number of significant strands through the research, one of which strongly appropriates the characteristics of the childhoodnature concept: this is that these artists think about children and nature in tandem: nature and childhood have shared qualities, such as being open and being disruptive, and the way they are talked of in the same context at the same time is suggestive of them being philosophically connected in the ontological approach that these artists demonstrate in this research. While individual artists have their own particular take and very unique approaches to the projects they do with CCI, collectively they define nature broadly, and they can find it anywhere. Nature might be an object (a stone or a shell) or an action (like breathing) or a process (a nail rusting), and it can be both wild and present in tame spaces. Nature is a disruptive force that leads to creative and critical thinking about familiar spaces. In the same way, the artists share a philosophy of children inhering in nature. Children can move between worlds, disrupting time and routine by allowing themselves to be led by a falling leaf or following a path in a woven structure or a wood that has no particular destination or being drawn into a puddle while moving between teaching activities. This impression was further articulated by the way the relationships between children and nature were depicted in their drawings; children were positioned throughout the sketches, in all of the different elements they drew. The data we gathered is, therefore, suggestive of a proximity in the way these concepts of nature and childhood are understood in this context that has a profound impact on how these artist pedagogues work. Their understandings of these terms intersect at a number of points (e.g., in seeing both children and nature as disruptive forces, or as fluid, embodying dialectical relations equally). While the pedagogy CCI artists practice is largely child-centered and child-led, their shared

philosophy on nature and childhood guides their practice in this context and illustrates the notion of a childhoodnature assemblage that underpins this publication. This Chapter will focus on the data emerging from our research that exemplifies this strand of our findings.

Research Methods

Our ongoing exploratory case study (Yin, 1993) of CCI aims to produce thickly described data of an ethnographic nature within a constructivist, interpretivist framework (Whitehead, 2004). The data collection for this aspect of the project comprised a "talk and draw" focus group interview with seven CCI artists. This was followed by individual interviews with the same artists. The directors of CCI were provided with a questionnaire that was designed after the artist interviews to elaborate on the data generated during the interviews. An impromptu interview with one director was also carried out to elaborate on some of the interview and questionnaire data. Our data is also backed up by archival research on CCI's detailed and active, constantly updated website.

"Talk and Draw": Working with New Methods

One innovation in these methods was the way in which we set up the focus group, here called a "talk and draw" focus group. We asked the artists to bring in their favorite implement for drawing or painting, and we provided them with a large sheet of paper stretched across the whole table to doodle on as we talked. This created a very useful focal point and provided further data for us about how these artists thought about childhood, nature, and place and the interplay between them.

These focus groups and interviews were audio recorded and transcribed. The transcriptions were sent to the artists for verification, and they made some suggestions and amendments, which were incorporated. The amended transcriptions were submitted to thematic analysis using NVIVO and a process of coding to back up our impressions from the interviews. The interviews were carried out by two of the authors and another colleague; the findings have been discussed on a number of occasions between the four authors and another colleague to check for validity and to increase the reliability of our conclusions. These conversations have also enabled us to draw on the interdisciplinarity of our research team and advisors (including educationalists with backgrounds in geography, natural science, and English literature), bringing our divergent experience to bear on the data and enriching our ability to interpret the data from various perspectives and epistemological framings.

Our extended conversations with the artists as a group focused on these three elements: nature, children, and place. This generated a revealing discussion, which demonstrated very strong intra-play between these artists as individuals and interplay in their own conceptualizations of these terms. It was clear that the pedagogy that emerges at the confluence of these three concepts was strongly influenced by

their entangled notions of them and their interactions with each other through their identities as CCI artists. In other words, the pedagogy they practice is shaped by the fact that they each individually view place, nature, and childhood in broad ways, as open concepts with no fixed definitions or rigid boundaries whose conceptualization is determined in situ, with fluidity in the context where it is being worked on. A child can only be understood to be fearless or a risk taker when that child is demonstrating those qualities in action. Nature seems tame when in a library garden, but in that same place, it is a source of disruption when it drops a leaf onto a child's book as she draws. The pedagogy is also shaped by the interactions between the artists themselves who often work together in a classroom on projects in schools or in communities. Their mutual understandings and long-term relationships influence the directions that they choose to follow, led by the children.

With that in mind, the focus of the remainder of this Chapter will be an exploration of how these emplaced artist pedagogues with orientation toward nature position children in relation to nature and what the impact of this might be for the way they design pedagogical interventions. Through this, we will develop the theme of childhoodnature in relation to the stewardship approach and the pedagogy of CCI. In the discussion section, we will use vignettes from the artists' experiences of working with children in place to illustrate the different themes arising from the data relating to children's positionality.

Findings and Discussion

Nature and Children in Tandem

In this section, we include extracts from our data, arranged (approximately) chronologically as the conversation unfolded in the discussion. We also include an illustration from each of the artists from the "talk and draw" activity. We have not analyzed these drawings in depth for this Chapter, but rather we have included them when they elaborate the point that the artists make verbally. This was the spirit in which the drawings were created during the focus group, and so it is appropriate to use them in that way here, although we acknowledge their richness as independent data that merit further analysis.

The first observation about our data that is noteworthy is that the vast majority of the statements made by these artists in their discussions of the meaning of nature made reference to children too. This means that their way of talking about nature was proximal to their way of articulating their thoughts on children. Similarly, when asked to show where in their illustrations of the discussions about nature and place they would put children, responses were illuminating. Elena says: "They are everywhere. I don't know how else to say that." Debbie agrees that they are ". . .in there, just everywhere." And Sally says: "Yeah, I completely agree with Elena, almost everywhere, coursing through the whole thing." These assertions are accompanied by gesturing toward their drawings. Susanne's way of incorporating children in playful

Fig. 1 In the mouth of the wolf by Deb Wilenski with the child drawn inside the wolf's mouth which represents fearlessness and daring within nature

ways in different positions all around her picture is particularly indicative of this perspective (see Fig. 3).

Deb says "I put [the child] right in here in his [the wolf's] mouth (see Fig. 1). There's an Italian phrase, I can't remember exactly, 'In bocca al lupo,' or something like that, it means in the mouth of the wolf, and is used to say good luck, but it's about getting right into the mouth of the wolf and being fearless and being daring. So that's what I most enjoy about [children] anyway."

Sally then elaborates: "this [illustration] has been made in a different kind of stream of consciousness, but definitely I would have a child hiding inside the shell, you know, there'd be like a big shell and they'd be hiding, they'd have a sense of a secret hideout. . .you know, a retreat. And then juxtaposed with that the same child might be balancing with one foot on this high wire, [..] taking a risk [. . .] really fearlessly, in the sense of what Deb is talking about." This can be seen in her illustration in Fig. 2.

What these quotes show is at once a commitment to the immanence of children in these artists' work, the thereness of them. It shows that they can visualize the child in any space in which they are working or thinking. The extracts also emphasize an awareness that children are different, that one child might be both fearless and fearful and that childhood comprises these dialectical relationships in extremes. What is more, both extracts demonstrate how this work between child and artist encourages risk taking and creative thinking, in line with other chapters in this section of this book.

This proximal thinking about children and nature across artists' explanations of their perceptions of nature begins to suggest the validity of the childhoodnature concept. It is worth noting that when we asked these questions, the interviewees knew that we would be exploring all three concepts (nature, place, and children) together so it might have been that this juxtaposition in our method sets up the connection. However, while the conversation about nature immediately led the artists to reflect on children, questions about nature did not lead to reflections

Fig. 2 The fearful and fearless child by Sally Todd

about place. We had to ask a separate question to get at their perceptions of that concept.

Nature Is. . .

We will now explore the way that these artists think about nature, but first we want to highlight that there is a differentiation made here between place and nature. While nature is seen as open and fluid, place is as Debbie says: "*the most fluid of all*." We will come back to this point later in our discussion of place-responsive pedagogy.

. . . A Natural Object or an Action

When asked to think of an object that represents nature, Sally suggested a shell. "I've done a tree," says Susanne (with children everywhere: see Fig. 3). Helen, however, resists the trope of representing nature with an object as too limiting; instead she prefers the way children think: "I think it's that freedom. They're not preoccupied about what they think other people think it should be." In a similar way, Caroline uses the verb "breathe."

The notion of nature as "freedom" is significant for the childhoodnature concept because freedom is a human expression, although this does not preclude the possibility that other animals also value the sense of being free. In characterizing nature in terms of something which is undoubtedly human, Helen's thinking indicates the dissolution of the nature/human binary. Caroline's identification of an action that is shared by all living organisms and is reliant on a nonliving element (oxygen) does the same thing. It brings humans into line with other elements of non-human nature. Characterizing nature as breathing dissolves the borders between humans and non-human organisms and demonstrates the interconnected of life with its environs

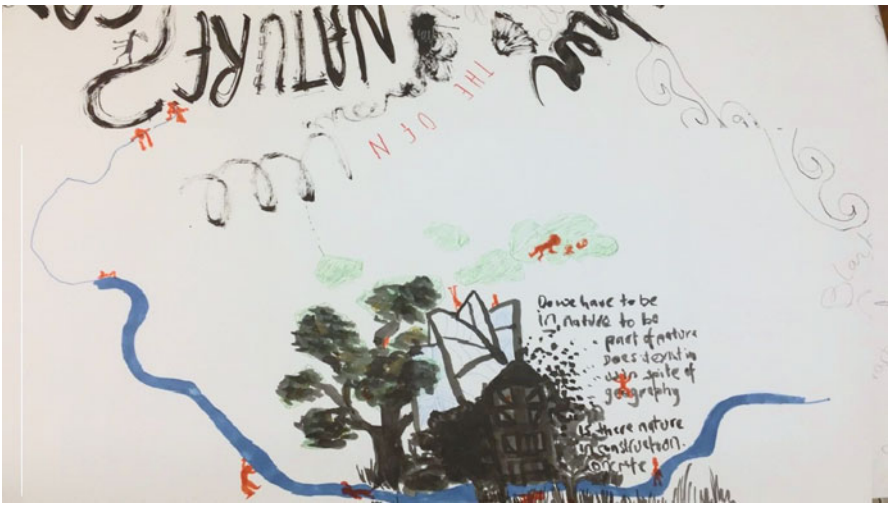

Fig. 3 Children present everywhere and from every perspective in nature. By Susanne Jasilek

through replicated activity (breathing) and sharing resources (oxygen and carbon dioxide).

. . . Also Human-Made

In our focus group, we had been talking about the fact that the objects chosen were natural and we were thinking about what that might mean, whether that meant that there are boundaries on this concept. Susanne says: "I can't see the beginning or end of nature, really. So for me I don't know how to put a boundary on it." She goes on to describe some of her work on the Artscapers project. She takes children on a walk with a small collection bag and asks them to imagine that this is the first time they have encountered nature, what things would they collect? "They weren't all natural things, they had some bricks and things. [. . .] I suppose it is whatever is on a site, the objects on some site become part of nature really, man-made (sic) things too." Again this quote shows how these artists incorporate their experience with children into the way they conceptualize nature. But the comment elicits similar anecdotes from the other artists about their work and how found objects on sites are nature, whether they are man-made or not. Sally says: "that reminds me of the rubbish dump we worked on [. . .] it became a wild nature reserve [. . .] and the rubbish was still bubbling up to the surface [. . .] a really encrusted, like burnt out bit of metal that a young child picked up, and it is in the same quality as picking up a leaf, and she said: 'look, a burnt witches house!' They did not make the distinction between nature and. . .." Here again we see that not only does Sally understand nature to be present in the metal rusting, but she comments on the fact that the children think

the same and more. For her, what is remarkable is that the children will not distinguish between leaf nature or rusty-metal nature, letting either inspire "wild imaginings."

At this point in the conversation, Deb interjects with her experience of carefully choosing sites with the CCI director which will work for the children and not going for sites that are "too manicured" or as Sally puts it: "too landscaped" but rather "have qualities of being slightly unkempt, definitely wild." "So that sense of coming into a wild world that is also there to be made something of by the children." This site-choosing process is clearly very important to the pedagogy of this organization and their sense of grounding their work with children in a place. It speaks to the notion of place-responsive pedagogy mentioned earlier. In the focus group discussion, it leads to some disputation of place-responsiveness by CCI artists which we will return to later in our discussion.

. . . Without End or Beginning

Moving beyond the artists' articulations about sites and material objects as a way of understanding their thinking about nature, Elena expresses the difficulty of "defining where nature ends and what is non-nature anyway?"

. . . Disruptive

"It's such a broad title, nature, it could just go in every direction," says Sally. And yet there are some boundaries here in our data. There is a propensity toward natural objects and wilder spaces and their disruptive, arrhythmic, unplanned potential. Nature is about fluidity and openness, but it is also about the world out there; we are a part of that, but the (very human) systematization of activity and the allocation of time are not. Nature is what provides opportunities that disrupt the ordered, routinized daily living. This aspect of CCI pedagogy has the potential to encourage creative thinking and resilience through its encouragement of taking a different perspective on daily encounters with time and space. It also contradicts somewhat the idea that humans are entirely a part of nature. In identifying how adults aim to control disruptive elements in both children and nature, we are challenged to think about whether adulthood and childhood are equally constitutive of nature, as the childhoodnature concept would suggest.

To illustrate this point, here is what Sally had to say: "I am now thinking about the library garden, which was a very cultivated space, but still because being outside, so it's like an active space, a leaf might drop on a child's paper while they're drawing, which wouldn't happen in the classroom, or the wind. . . There's something about that, okay, it's not an unkempt space, it was a very constructed space, the library garden, and yet it still lent itself to the wild imaginings of young children." As Helen says: "nature provides opportunities that disrupt and challenge that [sense of the constructed, the domesticated]."

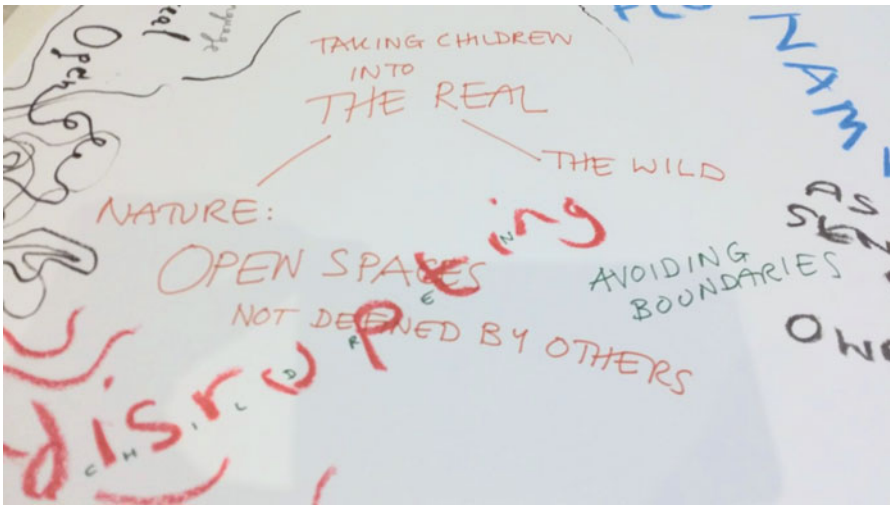

Fig. 4 Helen Stratford illustrates nature and children as disruptive, open, and real

Continuing this trend toward disruption (a word which Helen has used in her stream of consciousness doodling, see Fig. 4), Helen says:

> "I think it's about finding those open spaces and perhaps that's what nature is, within a CCI sort of context it's open spaces where children can be inspired and they're not defined by other people." Sally elaborates: "I wonder if there's something about the sense of an open space, whether it's the playground or whether it's beyond or whether it's inside in this interior world of our mind, it's kind of like the studio space, like Reggio Emilia sets up, how do we find ways of offering that for children? I'm just thinking about a few days ago [. . .] I was going to [School Z], and one of the children drew one of the playground areas because they were showing me around their playground and they drew the blank space, they called it the blank space, and it was this in a way constructed outdoor landscaped space for play, but the drawing was described as the blank space and I thought that was so beautiful. And someone else said 'The not really. . .the nothing really there circle, there's nothing really there', and then I thought 'Wow, that's amazing,' and then another child filled it immediately with a knight and a dragon."

This quote identifies the Reggio Emilia influence in these artists' work. Reggio Emilia is an approach to early childhood pedagogy that developed in the region of Italy called Reggio Emilia and was championed by Loris Malaguzzi (Miller & Pound, 2011). All of the CCI artists we spoke to had been exposed to this approach, either directly or indirectly, and it is important to be aware of this as it colors much of what they do. The notion of an emergent curriculum that Deb talks about is a particularly cogent example of the way that these artists' work appropriates the Reggio style.

. . . Your Imaginings

Returning to the way in which these excerpts exemplify nature, what they show is a conceptualization that is not completely all encompassing but is also not limited to things that are not human-made; rather it is about a sense of being uncontrollable, somewhat intractable, and unpredictable. It is also about the imagined, as Deb says: ". . .if nature is what's on the ground and it's the things that are growing right in front of you in the natural world, how much of what we see when we look at [nature] is determined by what we imagine about it as well and what we've read, stories that are there in my head, or built, or illustrations or whatever." Here we see that these artists are not only talking about nature as being something that opens out the imagination but that nature is also that which we, as humans, bring to it from our previous experiences. Nature is also our imaginings and this is depicted in Fig. 5 by Debbie.

Place Is. . .

While nature has some boundaries for this group of artistic women, place has very few (Fig. 6). This does not mean that place is unimportant; on the contrary, it is central to the way these artists work. Their pedagogy emerges out of their sense of emplacement and responsiveness to the way a place presents itself, both in and of itself but also how children react to it; from the very careful selection of a place described by Deb earlier to the fact that sometimes place is the reason for engaging the artists. Debbie (an artist working primarily with willow) describes a project where the local fire brigade asked them to come and work with the community that used a particular outdoor space where

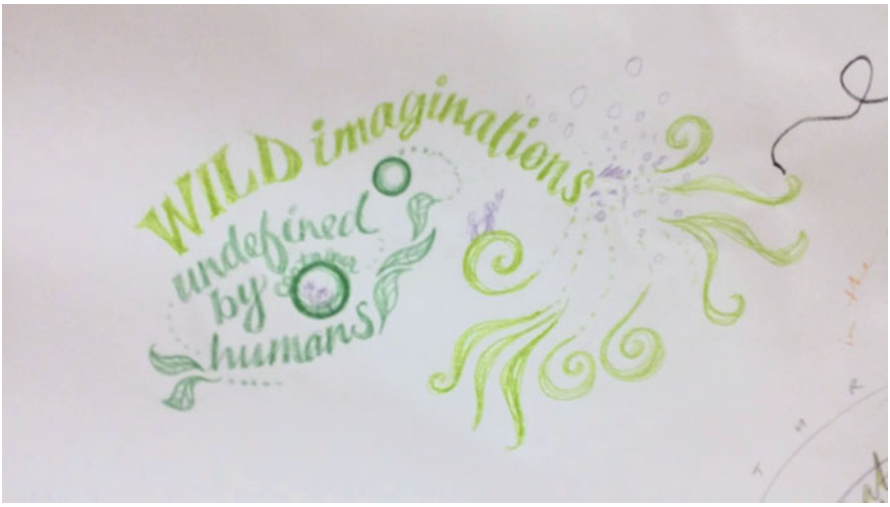

Fig. 5 Nature is wild imagining by Debbie Hall

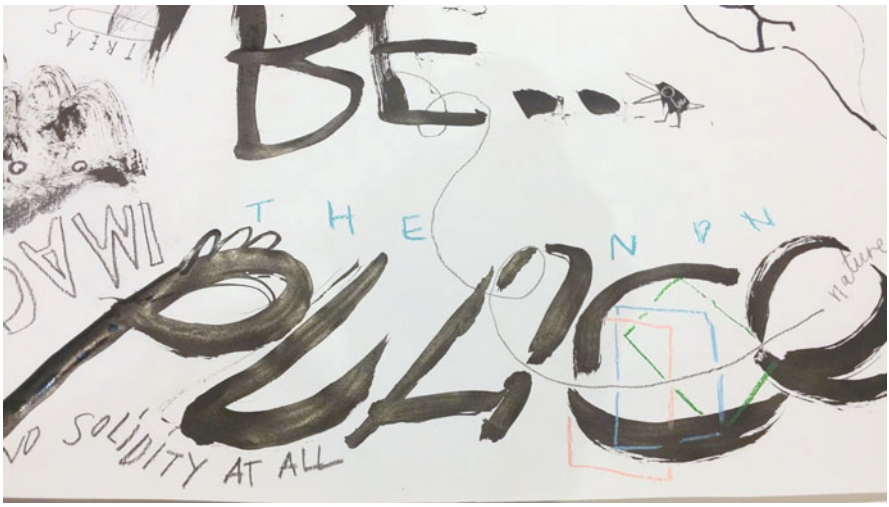

Fig. 6 Place has no solidity at all by Elena Arevalo Melville

there were repeated cases of arson and destructive behavior: "a huge adventure playground [. . .] which, though in a large green space, was in an urban, [somewhat neglected] environment, and part of the project was to actually see if we're sort of re-naturing it a bit with the willow and giving them a bit of ownership of the playground by creating their own stuff there, did that make a difference to how they treated it?"

. . .Owned and Created

This quote brings out ownership and place-making as significant elements of CCI practice. Both of these ideas are harmonious with participatory theories of learning identified earlier. Making place is an important aspect of the work of Keith Basso (1996) who discusses its role in constructing history using the imagination, through localized narratives repeated through the generations. He describes place-making as a "universal tool of the historical imagination" (p. 5). Place-making as it arises here is highly reminiscent of how Fettes and Judson (2010) outline imaginative place-making. They suggest that conscious efforts by pedagogues to involve the imagination in place-making has the potential to increase significantly the strength of attachment to place, which, they argue, can increase environmental concern and positively impact on environmental behavior. These CCI artist pedagogues value imagination very highly and identify the power that children have to engage it effortlessly, and they actively encourage this through their work with children. In this regard, Caroline says: "[. . .] children define place, they have a 'power' – in inverted commas – to actually create a place. From my experience of working with children in nature I always was amazed to see how they could enter nature, enter any space and just make it their own and create place in that way."

Deb and Elena add to these articulations about place-making in the following exchange, which both emphasizes the role of the imagination but also identifies how selective a process place-making is:

> Deb: "[These] narrative ways of making a place your own, or defining a place or saying what does a place mean to them, and especially with the maps that's what I've really enjoyed, that Elena has been able to pick up these different languages of landmarks, maps that represent routes that are actually there but also things which come and go depending on what scale you're looking or what stories you've made in the classroom, that kind of thing."
> Elena: "Yes, because there are many layers to place. So a place exists in a physical sense and then in a cultural sense and each person brings to it also their imagination. The maps that I created are just really mediocre snapshots of the projects, because there's so much that has to be left out to be readable. [But} we are always selective on how we see space and place. And of course children are selective as well and they also bring their culture and their imagination and so putting all that together in a single image is always incomplete."

. . . Also Imaginary

This excerpt brings to mind Ardoin's (2006) research whose work on drawing together place research from different disciplines identifies four dimensions in defining place: the sociocultural, the biophysical, the political economic, and the psychological. While Ardoin's definition of the dimensions of place is useful and encompassing, and her way of modeling these dimensions to show how they overlap is highly significant, there is something about it that deconstructs the concept too much for the context described here. Our experience of working with these artists exemplifies a tendency toward entanglement that does not lend itself to deconstruction, rather it emphasizes the need to keep all of these dimensions in play at once in a dialectical, relational manner. Moreover, while the sociocultural dimension of Ardoin's model attempts to capture the role of the imaginary, it is somewhat inadequate as it does not capture the active process by which nature captures the imagination, simultaneously reforming both nature and the imagination. In fact, our data suggest a further dimension to Ardoin's model, which would be called the imaginary. This is something that Fettes and Judson (2010) also write about, although they talk about imagination more broadly and include emotional engagement, active cognition, and a sense of possibility in exploring imagination as a dimension of place.

. . .Time

Another element of place that is significant for these artists is time. As Elena puts it: "place is just completely connected to time and to perspective. I mean you can never go back anywhere, because every time you go back somewhere you've experienced it already, it's loaded with memories, so in a way it's not a constant, so every place is rediscovered in a way, even if you've been to it many times." Besides identifying time interwoven into the conceptualization of place, this quote speaks to the notion

Fig. 7 Caroline Wendling incorporates time and space in her image of place

of entanglement in place as it is described by authors such as Malone (2015) and Clarke and McPhie (2016). For instance, Clarke and MacPhie's work developing Deleuze and Gautarri's posthumanist perspective on place elucidates place as continuously being recreated through novel and changing relational constituents. These artists are articulating that idea here (Fig. 7).

About the significance of time in creating a place Sally says: "I think it's a kind of critical sense of interrupting the rhythm that maybe is happening in a lot of educational settings. So that's something that we try to bring in, [. . .] that sense of offering a different rhythm, so to really inhabit somewhere, to then build on that relationship or engagement with inhabiting, embodying a space" and Helen says: "I do it with fluid space as well. Finding an open space is often through opening out time, I think even in those very defined structures of the school where time is controlled down to the last minute, I think saying 'Well actually you can spend as long as you need'" and Sally adds: "Even if you've got an hour, it's how can you bend time." Helen explains: "[. . .] through detail, really detailed looking at something as well, saying 'I'll give you these tools or this possibility and you can just take your time to really look in detail at a space that you might think you know.'"

Throughout these discussions, what keeps emerging is the notion of disrupting and defamiliarizing, and these quotes show how time, as an element of place, is used as a pedagogical tool to disrupt daily rhythms and create new places, owned by the children in a way that cannot be constructed by adult interventions. In encouraging children to play with time in this way, these artists are giving opportunities for the children to be creative and to harness their capacity for playful engagement with familiar spaces and objects.

These musings on time in our discussion elicit the following reflections from Susanne:

> [. . .] place has no solidity at all, [. . .] I used to go in like a classroom and then I would say 'Oh, I want you to find the tiniest details and go and draw them', and straightaway your room is totally transformed. [. . .] the place just expands and you don't even have to move virtually out of a classroom, and you can do that outside as well, so the whole concept of place is totally un-rigid and fluid, [. . .] and it's just like a sort of. . .it's not even a jelly, it's like a sort of magical air or something, in some ways. It's us, it's our minds, the children's minds, they do that, they expand it, they change its shape, they change the smell, they change everything about it just by being with the right prompts or encouragements. You don't have to say very much, they'll just get a sentence and they're off.

This quote exemplifies the role that these artists give to the children's imaginations in determining place. It also demonstrates the kind of place-responsive pedagogy that they both use but also create. So they employ responsiveness to a place by using its affordances such as found items (the rusted metal or the leaf) and a nearby beach as inspiration but also by encouraging children to respond to their own familiar spaces, by "the sense of how you are in our space in a different way, even in your regular space. [. . .] Just a tiny little thing like [. . .] lying down, it's incredible, it's quite powerful" or by "drawing the tiniest details' that make a place expand."

Debbie talks about how she uses willow in a very practical way to make children slow down and to bend time. Again here we see how these artists' pedagogical practices emerge at the intersections of their understandings of place and childhood.

> [. . .] if the school says we want living willow but we want a tunnel [. . .] I will usually try and persuade them that they'd really like a dome. Not only is it stronger. . .but with tunnels, when [children] see it, they just run straight through it. It doesn't really offer anything other than that, but a dome provides somewhere they can sit, they can chat, they can. . .I think really they take more time in looking what it is, because they sit down and really be in it and kind of like spot ladybirds on the leaves, and they use their imagination – then it can be whatever they want it to be.

Pedagogy Is About Holding Open Spaces for Exploration

Deb talks about herself and her colleagues as pedagogues: "We're making space, we're holding a space open, but that is quite an active way of standing back, it's not just passively following where the children go." Here the notion of place-making outlined by Fettes and Judson (2010) is once again pertinent.

So these active approaches of prompting and encouraging children are born out of a sense that, when given space children, as Helen says: "[have] that freedom. They're not preoccupied about what they think other people think it should be" and Sally says: "[. . .] children seem to fluidly get back or get into that state very, very quickly, very readily, so the naming of things is more fluid for them maybe." Caroline says: "They have still a power to dream and imagine and they do that extremely well."

Here we see that these artists conceive of childhood as a state where preconceived notions of what things are, matter less. Childhood is characterized by slippage into realms of fantasy and imaginary, and the fantastical and the actual are not nearly so clearly delineated. Alongside this, they see that nature offers means of encouraging that slippage, a means of defamiliarizing a place and disrupting every accounted for minute.

Sally says: "that's a kind of trope that we have to learn to do all the time as adults; to reintroduce the sense of de-familiarising familiar, and it's something I think as artists we all are very practised at doing, but it's still a challenge isn't it? Then children seem to fluidly get back or get into that state very, very quickly, very readily." It is clear that, for Sally, art is about defamiliarization and her perception is that children are very good at doing that (Fig. 2).

In some sense, we might then think about the kind of pedagogy here as one of place-making through artistic practice. These artist pedagogues provide space for children's artistic practices in the form of place-making, inspired by nature. They open up the sense of possibility (as identified by Fettes & Judson, 2010) that is inherent in nature for children who, as these artist pedagogues well know, will gleefully and playfully make real. Of course, this work has a feedback effect on the art that these women create with some of them seeing their pedagogy as integral to their art and others taking a different view on this. However, this is something which we will explore in a different publication.

To some extent our data exemplify the way that a child-led, child-centered pedagogy of the kind practiced by individual CCI artists that emerges from the tandem or proximal manner of thinking about children and nature (a childhoodnature epistemology) elicits opportunities for problem-solving, creative thinking, and adaptability, in line with the focus of this section of this Handbook. While our data do not directly exemplify critical thinking and resilience, it is possible to extrapolate that improved problem-solving and greater adaptability are likely to increase a child's resilience and capacity for critical thought. These attributes are important capacities in times of accelerating change and have been shown to be significant outcomes of place-responsive pedagogical approaches. This research is particularly useful for showing how tandem thinking about children and nature can draw out and emphasize the role of imagination in place-making. We think the work of CCI has the potential to extrapolate this strand of the childhoodnature assemblage, and Fettes and Judson's (2010) imaginative place-making supplies a useful theoretical touchstone which might be considered in this context. Our findings suggest that their work has the potential to contribute to the notion of a childhoodnature assemblage where it intersects with pedagogies of place.

However, what we think is particularly valuable arising from this research with CCI is the role of the philosophical approach that these artists take to conceptualizing nature and childhood. To return to the metaphor of the orange, the fluid, adaptable, open conceptualization, and appreciation of these two connected but sometimes separate subjects, held proximally, underpins the creative, playful encounters between child-in-place, artist, and opportunity that results in the highly imaginative artistic creations seen on the CCI website and in the companion Chapter. In this

sense, the shared philosophy of this group of CCI artists issues an emplaced pedagogy which corresponds to notions of childhoodnature.

To Disrupt and Familiarize: Some Concluding Comments

We will now conclude by reflecting on what this philosophical approach means for the dialectic of humans as a part of or apart from nature and discussing the usefulness of the childhoodnature concept in the context of CCI as a means of addressing some of these dialectical issues. In this endeavor, we bring Michael Bonnett's (2012) work on the importance of localized emplacement back into consideration. Bonnett reflects on the value of using our very local, embodied relations with particular places as a means for modifying our moral outlook. He discusses the dialectical nature of our relations with place as one of both ecstasis (being able to see our place from a removed position or "apart from") and mutual anticipation (where human and surroundings are constantly mutually responsive to each other or "a part of"), and he concludes that, at the very local level, this has potential positive consequences for improving how we treat our environment. Here we will use a similar notion of a dialectic but at a level of our understanding of our place in nature on the grander, planetary scale.

> Caroline: "I feel that us as civilised humans have made a separation between us and nature, and the way we look at nature and the way we behaved in the past with nature, comparing it, trying to clean it up, trying to make it less scary for us, more accessible. And then at the same time now of course we are desperately trying to preserve what we consider as being nature, but my question is, is it still nature? Is that really nature? All those little pockets or places that we can go on a stroll, on a walk, and they are all perfectly tidy and looked after. But what is nice, and this is where this thing was interesting for me, is that the idea of children, it's that children have still the power – and this is an important word for me, power – and I put that close to nature. They have still a power to dream and imagine and they do that extremely well. So you can take children just outside their classroom and well, in a little puddle, if they see the sky being reflected or anything it will be a very special moment for them. So I'm just sort of trying to think about nature as something we can all be into it at some stage, and be part of it, and physically part of it, and we don't have to think about it as being something else outside of us."

Caroline's response to a question about the meaning of nature pinpoints the struggle between identifying ourselves as apart from or a part of nature but also points to how this artist pedagogue experiences that children are not troubled by this dialectic. Neither are children so concerned to separate what is real and what is imagined; as Sally says, the slippage happens easily into imaginary realms. This power of children to dream and imagine and be inspired by nature identified by these artist pedagogues in whatever form it presents itself brings to mind the work of Gannon (2016) and Taylor (2017). Taylor makes a strong and compelling case for moving away from human stewardship strategies because of the way that they influence our thinking about our relationship to the world. It is very difficult to imagine ourselves as a part of nature as many authors now argue we should (Clarke

& Mcphie, 2016; Fettes & Judson, 2010; Haraway, 2008, 2015; Malone, 2015) if we are somehow seeing ourselves as responsible for saving the planet. In being responsible, we are at once also exceptional and individualistic. In fact, the logical argument would be that we cannot see ourselves as "saviors of the world" at all if we are to understand ourselves as relational, entangled becomings-with, as Taylor (2017) explains with the work of Haraway. However, what our data from artist pedagogues suggest is that we are at once exceptional *and* integral that the nature/culture binary is both a useful heuristic and a troubling dialectic. In the language of "common world pedagogies" used by researchers from the Common Worlds Research Collective, the existentialist state of beings-as-becomings-with does not need to exclude exclusion or ecstasis. In fact, thinking of ourselves both apart from and a part of nature, able to operate in both and move between these seemingly opposed positions may hold the key to Haraway's (2015) call to "make kin." Perhaps in knowing ourselves and others as exceptions, we are better able to make kin with others. So rather than avoiding othering, we can use our undeniable tendency toward othering (Bonnett, 2012) as an heuristic for enabling interspecies understanding and familiarization to make kin or "family-rise."

Perhaps children, nature, and artists (as disruptive influences) have to fall outside of these definitions so that we can learn from them to achieve this process of kin-making? In so saying, the conceptualization of nature and childhood as childhoodnature is both useful in its integrative potential and in how it highlights the historical tradition of human exclusion and our undeniable tendency toward othering. In thinking consciously about our tendency toward thinking about humans as superior, we are encouraged to diminish it, but we are also able to build on our unique potential to positively influence the sustainability of life on Earth. What is more, if we can think of ourselves as having unique potential, we can also think of other species as having those same qualities, at once the same orange but also, as separate segments of the whole orange, uniquely able to affect the flavor of the orange. If we think of each organism as having distinctive qualities that have significant influence on the whole orange, but also that distinctive existence is entirely dependent on their being a part of the whole, owing their existence to being a part of the whole fruit growing on the tree, we can begin to move toward an equitable way of life and eco-justice for all.

What these emplaced pedagogues do at once draws on children as individuals and separate from nature but also on their power to slip between this world of ecstasis, to use Bonnett's term, and the world of integration with nature. The pedagogy that emerges from their emplacement with children in nature is one that both disrupts and familiarizes a that both makes real and imaginary. It is a pedagogy that disturbs rhythms and distorts time by paying careful and close attention to children's curiosities and interests as expressed in places. It is a pedagogy that manages to at once be led by children but also to lead children through exciting and challenging places. In so doing, this pedagogy is one that may enable a journey toward eco-centrism without ever articulating it; simply by being equitable in its approach, this artistic pedagogical practice puts children on this path about which more research from the child's point of view is warranted.

Acknowledgments This chapter emerges from a focus group discussion with Elena Arevalo Melville, Debbie Hall, Susanne Jasilek, Helen Stratford, Sally Todd, Caroline Wendling and Deb Wilenski. This group of artistic women shared their experiences of working with children at the intersection of nature and creativity with us, and so much of the text has been "written" by them. We are inspired by your work and grateful to you for sharing it with us. We would also like to thank David Whitley for his support and advice in undertaking this research.

Abstract

Natural environments play a key role in childhood development, promoting mental, physical, and social competencies. However, children's presence and movement in open spaces, especially in urban areas, are becoming increasingly limited. This results in decreased opportunities to experience elements within a natural environment. One solution for this situation is to create safe natural environments within the neighborhood which allows children to have daily contact with natural environments and integrating it into their learning. We introduce the concept of nature experience areas, which consists of natural elements such as trees, shrubs, sticks, and few artificial playground elements. Nature experience areas provide open spaces for children to play freely with little or no assistance by adults. It is argued that children can playfully use their body and senses, thus providing a context for hands-on learning. The potential of natural environments for children's play and the effects of nature experience areas on children will be outlined in a brief review. Then the approach and findings from two studies are given: the first involved a quasi-experimental design including structured observations, while the second included in-depth interviews with children. Results show that activities on a conventional playground consist of primarily repetitive movements, compared to nature experience areas where a higher variety of play behavior appears. Favorite places of children within the nature experience area are characterized by a high degree of complexity and provide opportunities to climb and explore the area. The potential of natural experience areas for nature contact and free play is discussed.

Introduction - The Meaning of Natural Environments in Childhood Development

Children experience their direct physical surroundings in a multisensory way. In this Chapter, we address the meaning of natural environments in the context of childhood development. Natural environments are defined as areas without or little built infrastructure. At first we will provide an overview of literature about the interaction between children and the natural environment. Then we introduce results of two empirical studies focusing on natural experience areas for children.

Recent Trends of Child Interaction with Natural Environments

Childhood conditions have been changing dramatically in the last few years. This affects children growing up in urban areas as well as children growing up in rural areas (Blinkert, 2016). A so-called modern childhood in industrialized countries can be characterized by the following trends.

1. Childhood is increasingly organized. Children are more involved in education and care institutions than they have been in former times, thus having less leisure time available (Bamler, Werner, & Wustmann, 2010). They spend most of their spare time apart from school in institutions or at organized spare time activities. At the same time, a tendency toward all-day schooling increases which leads into the same direction (Raith, 2015). Due to these developments, the opportunities for children to play freely and without supervision decrease substantially.
2. Furthermore, children are more and more influenced by increased media consumption. Often, spare time is spent using digital media such as television, computer, and smartphones (see ► Chap. 40, "The Child-Nature Relationship in Television for Children" by Pettersson). A lot of children have access to the internet at all times (Blinkert, 2016). However, at the same time, children miss physical activity and social interaction with peers.
3. The radius for autonomous actions of children has decreased drastically in the last decades (Blinkert, 2016). Besides the aspects given above, another reason is increased traffic. Traffic density can cause serious accidents, feeding the increased worry of parents for their children's safety.

Due to these developments, some authors are suggesting that children are developing a nature deficit disorder which can have drastic consequences for society nowadays. Louv (2011) argues that children who are not able to experience natural environments – in contrast to built environments – lack a connection to nature and develop a nature deficit disorder, characterized by physical and psychological deficits. This development is rather critical since children need a diverse environment including various affordances or a holistic development. These are especially present in natural environments (Louv, 2011) since natural environments enable continuity and change at the same time. Continuity and change arouse by seasons and weather, meeting the need of children for reliability, safety, orientation, and at the same time curiosity, imagination, and adventure (Gebhard, 2014). Simultaneously, limitations and resistance in natural environments support the development of one's personality and help to become aware of one's own strengths and weaknesses (Renz-Polster & Hüther, 2013). Facing these tendencies of a modern childhood, we should take a closer look at the effects of natural environments on childhood development.

Significance of Natural Environments for Child Development

Numerous studies are stressing the importance of gaining experiences in natural environments – in contrast to built environments – during childhood. Especially in a time with increasing diagnoses such as attention deficit disorders, attention deficit hyperactive disorder, obesity, and cognitive problems, natural environments play an assuasive role (Mustapa, Maliki, & Hamzah, 2015). The exposure to natural environments has a restorative effect (Hartig, Mitchell, de Vries, & Frumkin, 2014), e.g., children with attention deficits are able to concentrate significantly better after being exposed to natural environments than after being exposed to urban environments (Taylor & Kuo, 2009). However, the effect of natural environments is much more general. Restorative effects of natural environments have been shown on different levels (Hartig et al., 2014). Children who are highly exposed to natural environments show significant differences on a physical, mental, and social health level compared to children with less exposure to natural environments (see ▶ Chap. 50, "Everyday, Local, Nearby, Healthy Childhoodnature Settings as Sites for Promoting Children's Health and Well-Being" by Green, Dyment, and Dooris).

Physical Effects of Natural Environments

Children get less sick and develop better motor skills in a forest kindergarten compared to a conventional kindergarten (Grahn, Mårtensson, Lindblad, Nilsson, & Ekman, 1997). Additionally, children are more resistant to illness. They develop better motor skills and present a healthy body weight (Jung, Molitor, & Schilling, 2012), and children's motion intensity is higher in natural environments than in built environments (Wheeler, Cooper, Page, & Jago, 2010). Also, children develop more diverse motion patterns (Fjørtoft, Kristoffersen, & Sageie, 2009).

Mental Effects of Natural Environments

Executive functioning skills, which are obtained by measuring the attention span, are more developed in 7- to 8-year-old children who are exposed to the natural environment (Schutte, Torquati, & Beattie, 2017). Research reveals that children who spend time in natural environments show lower levels of psychological distress (Wells & Evans, 2003). Additionally, children living in a more natural environment show a higher level of self-discipline, measured by power of concentration, impulse control, and delayed gratification (Taylor & Kuo, 2009). They also show higher levels of self-competence, measured by creativity, motivation, self-dependence, power of concentration, and fluency (O'Brien & Murray, 2005).

Social Effects of Natural Environments

Children who spend time in natural environments have been shown to develop better social competencies such as team work, communication, and social behavior (Dyment, 2005).

Considering the effects and thus the importance of contact to natural environments for children, the tendencies of a modern childhood described above are rather alarming. Children who are not able to play freely in natural environments may suffer serious limitations in physical, social, and cognitive development, and deprivation of natural environments may lead to children developing into adults who lack essential social and personal skills (Blinkert & Weaver, 2015).

Significance of Autonomy for Child Development

Another important factor in healthy child development is autonomy. Due to societal changes, action spaces for children – spaces in which children can move freely and without supervision – have begun to disappear. Blinkert distinguishes between autonomous and heteronomous forms of childhood (Blinkert, 2016). An *autonomous childhood* is defined by indicators of independency, namely, when children play outside for long periods of time without supervision and little time in institutions in the afternoon. A *heteronomous childhood* is defined by indicators of little independency, namely, when children play outside rarely without supervision. They are often accompanied by parents and take part in afternoon child care, providing few affordances to experience the natural environment.

The most important condition for a positive autonomous childhood is the quality of the action space of a child (Blinkert, 2016): the time spent outside correlates with quality of children's residential environments. Children living in a high-quality residential environment have a higher potential to access action space autonomously (Blinkert, 2016). Interestingly, when children had the possibility to choose their spare time environment, they preferred a large number of various locations where they were not being controlled or supervised, while they avoided playgrounds which were especially designed for them (Beach, 2003). However, we have to be aware that natural environments are not always positively associated by children, and it might arouse negative effects as well (Malone, 2016). Children name natural environments often as locations where they feel insecure, e.g., because of darkness, loneliness, and fear of crime or threatening interactions with adults (Hallmann, Klöckner, Beisenkamp, & Kuhlmann, 2005).

Thus, natural high-quality action spaces for children have to meet specific requirements in order to increase the willingness of parents to allow their children to play outside. The action space should be characterized by:

1. Safety – while yet accepting that danger can be perceived and handled by children. There is no complete safety.
2. Accessibility of appropriate play locations in the neighborhood without insuperable barriers
3. Possibilities for creation, which describes the practical value of a location
4. Possibilities to interact with each other (Blinkert, 2016).

Especially in large cities, it is often difficult to provide open spaces for children for unsupervised play. The barriers include dense traffic as well as fewer play locations in the neighborhood and parental fear that their children might hurt themselves (see ▶ Chap. 47, ""She's Only Two": Parents and Educators as Gatekeepers of Children's Opportunities for Nature-Based Risky Play" by Laird and McFarland). Still, children need a daily contact with natural environments to encounter other species, risk, and free play (Richard-Elsner, 2016).

Learning Environments and Nature Experience

Most urban centers tend to be denaturalized and dehumanized. For children it is difficult to engage with natural environments in daily life, especially if they are not allowed to move independently. Thus, children's opportunities to develop literacy, risk assessment skills, and resilience are limited (Malone, 2016). There are research approaches which explicitly or implicitly have identified this problem and are addressing the interaction between child and non-human nature, trying to design environments which are supporting imaginative and creative play. These approaches include the development of schoolyards (Raith, 2015; Tsevreni), preschools (see ▶ Chap. 23, "Child-Nature Interaction in a Forest Preschool" by Kahn), and child-friendly urban structures in general (Broberg, Kytta, & Fagerholm, 2013). In Scandinavia, there is a long history of outdoor education. "Utescole" in Denmark is the concept of school taking place outside, growing stronger since 2000. This "outdoor school" is defined by context-based learning, working outside the classroom and a multi-sensual approach to practical and guided activities, including group work (Jordet, 2010). This meets the call for a place-responsive outdoor education (Mannion & Lynch, 2016). Outdoor learning and education opens up space for physical activity such as play and games, communication, teamwork, experiences, curiosity, and imagination. These aspects are the basis for nonformal learning processes. Outdoor learning and education aims to integrate advantages of school inside and outside and merges the need of a holistic development using the affordances of natural environments. As a result, children are enabled to achieve an interaction with natural environments on a daily basis to reduce nature deficit disorders (Louv, 2011; see ▶ Chap.80, "Childhoodnature in Motion: The Ground for Learning" by Eddy and Moradian).

The self-organized autonomous contact of a child with natural elements such as soil, water, and plants has a high importance for healthy physical and psychological development (Gebhard, 2014; Schemel, 2002, 2008). Thus, nature experience areas could substantially contribute toward learning by immediate, multisensory, affective prescientific learning experiences. Some examples for meaningful activities in the natural environments are given in Table 1 (Reidl, Schemel, & Blinkert, 2005).

Nature experiences include a direct, multisensory, affective, and prescientific learning opportunity a child receives through her or his contact to nature (Bögeholz, 1999).

Table 1 Activities and examples for nature experiences

Activity	Natural element: nature experience
Soil activities Walking in mud puddles	Feel soft, wet soil, interaction of soil and water (see, hear, smell, touch)
Water activities Impound water	Experience water on own body Perceive running water
Activities with plants Harvest and eat fruits Cut and carve parts of plants	Perceive with all senses: see, taste, smell, touch, hear Creatively modify plants
Activities with animals Follow and catch animals	Experience the behavior of animals
Overall activities Run, walk	Experience the variety of the terrain

It includes opportunities for the child to have an embodied experience in a living environment (Meske, 2011), which are made by actively perceiving the environment through observation, smelling, tasting, touching, enjoying, researching, grasping, and recognizing (Renz-Polster & Hüther, 2013).

Playing as a Learning Process

As we can see, one important factor of learning is exploration and play. Play enables development and education. It is an innate behavior in humans enabling a variety of different experiences which are valuable throughout life. Playing offers the opportunity to develop competencies such as creativity, social competence, and executive control (Renz-Polster & Hüther, 2013). According to the definition of nature experiences and play, we consider play behavior as a learning resource for children. In order to contribute to this, some countries adopted the children's right to play in their laws according to the UN Convention on the Rights of the Child (e.g., Bundesministerium für Familie, Senioren, & Frauen und Jugend, 2014).

In contrast to purposeful, planned work, play is the purposeless, spontaneous, voluntary action, which is intrinsically motivated, pleasure-oriented, led by imagination and follows specific rules. Depending on the developmental stage a child is in, play behavior shows a different complexity (Hegemann-Fonger, 1994; Oerter & Montada, 1998). The research is based on the following classification of play behavior.

Play behavior	Description	Authors
Psycho-motor play or exercising play	First occurrence in nursing age Surroundings get integrated, e.g., being outside and playing with sand, moving objects and playing in puddles	Hegemann-Fonger (1994)
Exploration	This looks much alike psycho-motor play in nursing age. However, it is a *conscious* exploration of objects. Again, the surrounding environment plays a major role	Bögeholz (1999)

(*continued*)

Play behavior	Description	Authors
Imagination and role-play	It develops from the age of about one and a half years. Familiar situations as fictional scenes get reenacted. Children pretend to do something, e.g., sociodramatic play adopting roles from family life	Hegemann-Fonger (1994)
Construction play	A specific purpose is apparent, thus overlapping with work: there is an aim to build something. Construction play includes handicraft, painting, and reparation Construction and role-play often depend on each other, e.g., the construction is used to illustrate a role scene	Hegemann-Fonger (1994)
Games	Games integrate various play activities, e.g., "pretending," motor skills or competition Games provide specific rules and often have a name	Hegemann-Fonger (1994)
Movement play	Movement play does not follow specific rules. Children have a strong need for movement, which provides the motivation for their own experiences and physical strength development. The movement as such is the aim, e.g., running, jumping, or swinging. Often, it is repetitive. Movement play does not necessarily involve strong active movement of children, e.g., swinging can be played with little physical activity	Hegemann-Fonger (1994)
Communication play	With increasing age of children, communication play becomes more important. It is rather quiet and with limited movement, e.g., watching, listening, talking, and making music	Bauer (2001)

All play activities can provide parts of others, e.g., games often include communication and movement play, and construction play often includes movement and role-play. The classification serves to differentiate the complexity of play by the main aspect addressed in the apparent play behavior. All these play activities need a location where they can take place and affordances to be activated. Besides structured programs such as outdoor school or the design of playgrounds, nature experience areas could serve to activate children to broaden their play behavior.

Nature Experience Areas: A New Concept to Enable Children's Interactions with Natural Environments

While the concepts mentioned above address institutionalized play areas, free accessible areas for children are still rare. Natural experience areas close this gap and focus on free play for children in their neighborhood and can be reached by children aged 6–12 years without supervision of adults. Natural experience areas, which are located close to the living environment, are unstructured and design-free natural open spaces for children to play and

experience natural environments in an autonomous, spontaneous, and unsupervised manner (Schemel, 1998). Thus, natural experience areas might provide a naturally managed area addressing the loss of non-human nature contact of children. They provide hardly any artificial play elements such as slides or swings. Still, their main purpose is recovery for children. Table 2 summarizes the concept of nature experience areas for large cities.

Empirical research on nature experience areas has been conducted in the German-speaking area in particular. Using observations and interviews, previous empirical studies show that children play in larger groups and the age group of children playing together showed a greater variety in a rural natural experience area (Reidl et al., 2005). Also, children's play is more complex and continues for a longer time in the nature experience area compared to a playground and parental supervision was lower (Berglez, 2005). The play behavior included the creative production of things and play elements such as huts or earth dams. Thus, the play behavior included more planning and setting goals (Blinkert, 2005; Reidl et al., 2005). Additionally, children showed an interest for their physical surroundings and animals (Lude, 2001; Meske, 2011). These reported studies took place in small cities, and a generalization to children living in large cities needs to be questioned. We will now introduce an interdisciplinary project, supported by the Federal Agency for Nature Conservation in Germany. In this context, three nature experience areas in Berlin are supervised by ecological, planning, and social research. Here, we question the effects of nature experience areas on children growing up in an urban context. Results are shown from the initial phase of one of these recently initiated urban nature experience areas in 2016, connecting play activities and nature experiences for children who have fewer

Table 2 Characteristics of urban natural experience areas (Stopka & Rank, 2013, adapted to Schemel, 1998)

Use	Primarily recovery
Character	Min. 50% natural, untreated areas, other areas extensively cultivated Natural development of plants (natural succession) Natural attraction (e.g., mound, puddle), no play tools or other infrastructure
Size	0.5 ha with minimal width of 20 m
Maintenance	Extensive care in order to preserve open views in some parts Development of care plan with organizers and users Control of areas in order to avoid hidden safety risks
Location	Integrated into the living environment in the range of 500 m
Target group	Children in the age of 6–12 years
Assistance	Play actions to get to know location and lose a fear of "wild" nature Extracurricular offers, offers for child care institutions Work in public relations Enable unobserved, free play on a daily base
Regulation	Considering safety issues (according to insurance) All activities allowed except for motor sports
Protection by planning	Initiation in given space category without additional protection Initiation of separate greenspace category possible

opportunities to be in natural environments than children in small cities. We are focusing on the following research questions: **How do children growing up in an urban context experience nature experience areas? What kind of play behavior do nature experience areas arouse in children growing up in an urban context?**

Structure of the Reported Methods

In order to address this research question, we decided to opt for a two-stage empirical approach, including a quantitative and a qualitative part (see Fig. 1). In study 1 we conducted observations in order to see how many children were present, analyzing play behaviors in the natural experience area. A conventional playground served as the control area (see section "Study 1: Observational Study on Utilization and Play Behavior in a Metropolitan Nature Experience Area"). Subsequently, in study 2 we carried out media-supported interviews with children, a hands-on research method in order to analyze in detail what kind of activities children are involved in the nature experience areas (see section "Study 2: Media Supported Interviews with Children: A Photo Ramble"). Figure 1 gives an overview about the mixed-method approach.

Study 1: Observational Study on Utilization and Play Behavior in a Metropolitan Nature Experience Area

In Berlin, Germany, a city with roughly 3.5 million inhabitants, a new nature experience area was initiated in June 2016, located in the periphery of the city with a mixed sociodemographic infrastructure. Results from an analysis of data on the experience of the use of this nature experience area will be presented. In order to compare the play behavior of children, we chose a conventional playground in the direct neighborhood as a comparison site. Thus, there were two different research areas – the nature experience area and the conventional playground – where behavior observations took place.

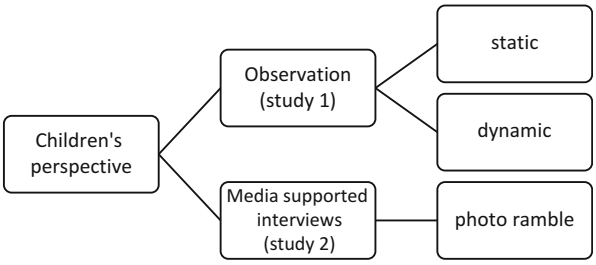

Fig. 1 Structure of the reported methods

Nature Experience Area

The nature experience area is a public space, thus accessible 24 h a day without restrictions. It consists of 0.64 ha of natural vegetation with a high variation between open, partly covered, and covered spaces. The design of the area took place in participation with children from schools and child care institutions in the surrounding neighborhood, starting in December 2015. After visiting and playing in the area, planners asked the children about their ideas and requests concerning the design of the area. Children built models and discussed their implementation. The planners integrated the children's considerations into the design of the area, including work on the space with children. The area was opened for play on June 6, 2016, in an official ceremony. Figures 2, 3, 4, and 5 gives an overview of the nature experience area.

In order to inform neighbors and decrease a possible fear about accidents, a trained child care worker was employed. This employee is in charge of perceiving and removing possible sources of dangers for children and to talk to neighbors, parents, and teachers in order to introduce the concept of a nature experience area.

Playground

As a comparison site apart from the nature experience area, a playground in the direct vicinity was observed. This site was chosen as a comparator since it had the same size and accessibility as the nature experience area. It was located about 100 m away from the nature experience area but served the same neighborhood. The playground has been designed in 2002 and provides play elements in play sand which has a natural appearance due to sandstone elements (see Fig. 6).

Fig. 2 Impression of the nature experience area with entrance area

Fig. 3 Impression of the nature experience area with headge structure

Fig. 4 Impression of the nature experience area with constructed hut

Procedure

Four weeks after the opening, the observation of usage started. A randomized time scheme for the observations was put up to avoid bias due to time, observer, weather, season, and school or holiday season. Fridays were excluded due to special activities conducted on these days before the weekend, thus not being representative for daily

Fig. 5 Impression of the nature experience area with trees

routines (Bauer, 2001). The observations were alternated from 10 a.m. to 4 p.m. and from 2 p.m. to 6 p.m. alternatively in order to include morning activities as well as evening activities in the areas.

The observations were divided into two different procedures: a static and a dynamic observation (see Fig. 1).

- In the static observation, children were counted on various days, differentiated by age and gender. This served the purpose of usage of nature experience areas and playground as a control in general.
- In the dynamic observation, consisting of 1093 time slots, one randomized chosen child was observed in detail for 4 min, including the play behavior according to Hegemann-Fonger (1994).

Observers were trained for 1 day in the given areas, which included obtaining examples for children's play behavior and conducting observation in teams. Results have shown a high consistency between different observers. Two persons were present each day of observation: one person observing the nature experience area, the other person observing the playground. The distribution toward the starting observation area was randomized in order to avoid observers' preference or time effects. After 2 h, they changed locations in order to avoid observation biases due to fatigue. The frequencies of visits in different defined parts of the nature experience area were counted every 15 min. All children were counted, grouped by age and gender, both on the playground and the nature experience area. Additionally, adults were taken into account and served as an indicator for autonomous or heteronomous childhood of the present children.

Fig. 6 Impression of the playground with slide and climbing elements

A pretest of 2 weeks from July 5 to 17 served to evaluate the given sketches of the areas, the measurements, and the research procedure. After analyzing the data and experiences with the procedure, small changes were adopted. The pretest was excluded from subsequent analysis.

The main study took place from August 22 to September 25 on a daily basis which included 2 weeks during school season and 2 weeks during holiday season. Due to low case numbers in the nature experience area, an additional week in September was added.

Sample

The sample of the static observation consisted of all children who were present in the areas when observers were present, either on the playground or the nature experience area. Since the children were not randomly distributed to one of these areas, we worked in a quasi-experimental design, leading to $n = 439$ children in the natural experience area and $n = 2866$ children on the conventional playground for static observations (see Table 3).

Additionally, we had a total of 1093 time slots observing detailed play behavior of children for 4 min in the dynamic observation. Including the additional week of observation in the nature experience area, we had observation data for 380 children in total, consisting of 58 cases in the nature experience area and 322 cases on the playground (see Table 4).

Table 3 Frequencies of children present and no children present in the natural experience area and the conventional playground

Area		Frequency	Percent
Nature experience area	No children present	397	47.5
	Children present	439	52.5
	Total	836	100.0
Playground	No children present	101	3.4
	Children present	2866	96.6
	Total	2967	100.0

Table 4 Gender distribution in the play areas

Area		Frequency	Percent
Nature experience area	Female	25	43.1
	Male	33	56.9
	Total	58	100.0
Playground	Female	167	51.9
	Male	148	46.0
	Missing	7	2.1
	Total	322	100.0

Measures

The observers had a structured protocol to follow and marked how many children were present and what they played, separated by age and gender. Additionally, the observational protocol included weather and temperature in a three-part scale (sunny, cloudy, rain) and the temperature, as well as time, date, school or holiday season, the name of the observer, and the number of children and adults.

Results and Discussion of the Observational Study (Study 1)

In the next sections, results of both parts of the observation study, the static and the dynamic observation, will be provided and discussed.

Static Observation: Number of Children in the Play Areas and their Age

Static observation data show that far more children were visiting the conventional playground than the newly opened nature experience area. In the time span of observations, 78% of the observed children were present on the conventional

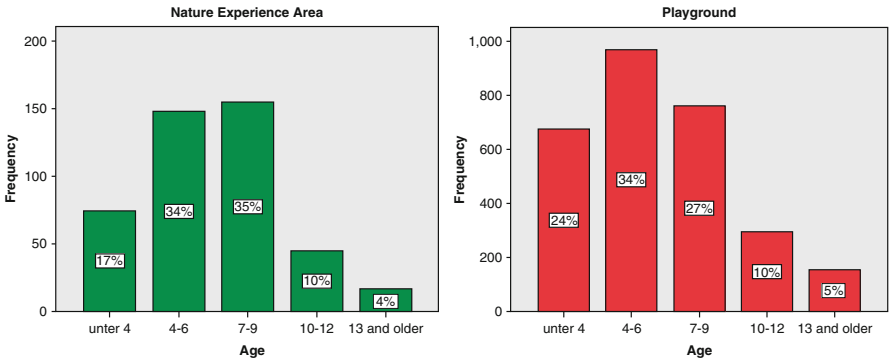

Fig. 7 Frequencies of children present on nature experience area (left, green columns; $N = 439$) and playground (right, red columns; $N = 2865$)

playground. Consistent with this, the times of children present varied between both areas (see Table 3). The nature experience area had more time slots with no children at all (47.5%) than the playground (3.4%).

The age distribution of children in the nature experience area and the playground differs as well. The majority of children (69%) in the natural experience area ranged within an age group of 4–6 and 7–9 years. On the playground, almost one quarter of the children was under 4 years old; most children were between 4 and 6 years old (34%). With 27%, the age group of 7–9 year olds was less represented on the playground than in the nature experience area. Children over 10 years and over 13 years used both areas the least amount of times (see Fig. 7).

A slightly lower percentage of girls (43%) were observed in the nature experience area compared to the playground with 51%. The number of adults supervising children was higher on the playground. The peak of present adults was 26 persons on the playground, while in the nature experience area, in most cases three adults were present, with a peak of 12 persons at the same time.

Discussion of the Utilization of the Play Areas

Results show clearly that a higher number of children were present at the conventional playground than in the nature experience area. This might be due to familiarity since the playground existed for some years already, providing the opportunity to get established for parents to go there with their children or send their children off to play. The nature experience area opened up 6 weeks before the main observation was taken; thus, it is possible that the majority of people from the neighborhood did not know about it yet and therefore have not visited it yet. Furthermore, the nature experience area with dense vegetation might not be inviting for some people due to esthetical considerations (Martens, Gutscher, & Bauer, 2011). Parents might fear their children would hurt themselves in such an area. Watching their children at all times is

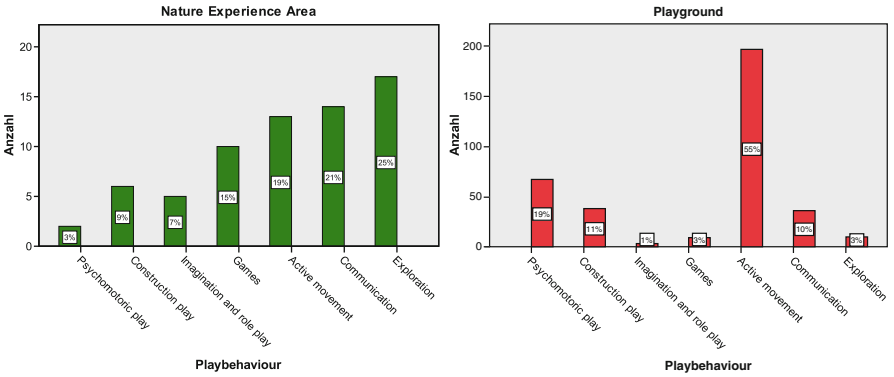

Fig. 8 Play behavior in the nature experience area (left, green columns, $n = 58$) and on the playground (right, red columns, $n = 322$)

not possible in the nature experience area due to the dense vegetation unless parents moved with their children all the time. However, the dense vegetation might be one of the driving factors of children playing freely and learning in the nature experience area. The person employed in order to take care of the area and inform parents and neighbors about the usage of the area could lower this obstacle in the long term. Mostly, children were accompanied by their institutions such as school or preschool on the nature experience area.

The observation data shows that the natural experience area meets the target group of children aged 6–12 years. However, the nature experience area seems to be quite relevant for younger children as well, considering that 17% of the observed children were younger than 4 years old. These children possibly came with an institution, and child care educators have been chosen the area for their play. These groups should be focused in further research, questioning the effects of nature experience areas in early childhood development.

Dynamic Observation: Play Behavior in the Play Areas

Our data show a different pattern of play behavior in the nature experience area and the playground, respectively (Fig. 8).

The comparison between the nature experience and the playground shows some interesting differences: While movement play provides the main play behavior on the playground with 55% of the observations, followed by psycho-motor play with 19%, the play behavior in the nature experience area is more diverse, representing all groups of play behavior to a relevant extent.

The dominant behavior in the nature experience area was exploration (25%), followed by communication (21%), active movement (19%), and games (15%). Activities like construction play (9%), imagination and role-play (7%), and psycho-motor play (3%) are represented less often.

The dominant behavior in the control group on the conventional playground was movement play with 55%. Psycho-motor play was observed in 19% of the cases, while other play behaviors appear in less than 12% of the observed cases (see Fig. 8).

Discussion of Play Behavior in Play Areas

Not taking into account the different group sizes between nature experience area and playground, we analyzed the percentages of play behavior in each area in order to show the relative distribution. Overall, the play behavior in the nature experience area shows a much broader variety, ranging from simple and repetitive movement play to complex imagination and role-play. The dominance of movement play on the playground does not necessarily indicate more physical activity, because more complex play behaviors include movement as well, e.g., creating a hut, which is considered to be construction play, includes running around looking for movable material, carrying it, and moving back to the initial construction site. This can be physically just as challenging as swinging for a longer time. The play classification we used does not aim to make any suggestions to the amount of movement in play but to differentiate the complexity (Hegemann-Fonger, 1994).

The apparent play behavior is more complex in natural areas, consistent with earlier studies carried out in a more rural context (Reidl et al., 2005). We assume that the natural environment stimulates the children with the variety of bushes, trees, and shrubs and thus provides affordances to play (Jansson & Mårtensson, 2012). The playground provides affordances to play as well, but often it is a single function arousing specific play behavior, e.g., the slide to slide, the sandbox to play with sand, and the swing to swing. The natural environment offers opportunities without a given obvious function, e.g., the tree can be used to climb on, to hide behind or as a part of a hut. It challenges the children to develop their own ideas and functions of the elements and thus could stimulate a broader variety of play behavior. Another aspect present in the natural experience area is movable material, such as sticks. Movable material can be put into different locations and be used in a multifunctional way, again supporting a more complex play behavior (Maxwell, Mitchell, & Evans, 2008). Our analysis suggests that the variety of play behavior is an effect of the given environment: a natural environment provides continuity on the one hand, e.g., by a slow growing and changing process, and change on the other hand, e.g., by the different appearance due to season or weather, at the same time. These antipodal trends apparent in the natural environment meet the need of children for routine and excitement at the same time, thus supporting their cognitive development (Gebhard, 2014).

Since children's play in the nature experience area is more complex, they are likely to have diverse experiences, such as social interaction, psycho-motor perceptions, and the exploration of natural elements; it provides a basis for more complex learning processes (Edelmann, 1996). Exploration was the dominant play behavior in the nature experience area, shown in 25% of the observed cases. This is especially interesting in comparison with the conventional playground: exploration

does not play a significant role on the playground representing 3% of the play behavior only. On the playground, movement play such as sliding, swinging, and running is the dominant play behavior which is often repetitive. The cognitive stimulation is higher in more complex play behaviors such as exploration. Exploration of the surrounding environment includes a prescientific experience and understanding (Bögeholz, 1999). Opportunities for various play behaviors enable complex learning in children (Lau, Nerger, & Schreiber, 1997) which could be increased by the implementation of nature experience areas.

One aspect that needs to be further analyzed is the age distribution. Younger children tend to play in less complex ways. Psycho-motor play appears at the age of 4–6 years especially, which was the second most frequent age group on the playground.

Our results suggest that natural experience areas have a stronger affordance character to show different and complex play behavior, while the playground has a strong affordance to show the predetermined play behavior such as sliding or swinging. Thus, it seems nature experience areas stimulate a greater variety of different play behaviors. This may be due to the possibilities of active involvement by modifying the environment themselves, e.g., by creating huts, breaking sticks, or designing pathways. This result is consistent with research on the positive effect of movable objects in outdoor play areas (Maxwell et al., 2008; Moore, 2014) and the importance of space for learning is apparent in general (see ► Chap.7, "Outlining an Education Without Nature and Object-Oriented Learning" by Bengtsson). Results of study 2 will pick up these considerations in detail.

Study 2: Media-Supported Interviews with Children: A Photo Ramble

In order to give a deeper insight into the play behavior in the nature experience area, an explorative procedure questioned the children's view of the area and play opportunities. This served to explore the specific behavior in nature experience areas, which had not yet been analyzed in detail. Due to this focus and the explorative aim, no control group was implemented (Kuckartz, 2012). We were interested in what places children preferred, which ones were avoided, and what kind of activities children were involved in the natural experience area, thus using a playful method (see ► Chaps.17, "Unplanning Research with a Curious Practice Methodology: Emergence of Childrenforest in the Context of Finland" by Vladimirova & Rautio and ► 39, "Embodied Childhoodnature Experiences Through Sensory Tours" by Green). Media-supported interviews serve to address children in a playful, understandable way and place-responsive way (Bauer, 2001; Lynch & Mannion, 2016). The natural experience area was the same as described above (Figs. 2, 3, 4, and 5); the conventional playground was excluded for this study. The interviews took place during early autumn; thus, there were ripe blackberries next to the stinging-nettles and trees full of ripe large and small plums.

During summer break 2016, we contacted organizers of school holiday activities in the neighborhood, supported by the pedagogical staff of the nature experience area. The elementary school holiday institutions were located in the radius of at most 3 km from the nature experience area. From August 15 to August 22, 2016, we conducted 20 media-supported interviews with elementary school children, aged 6–12 years.

Children were informed and offered to take part in the media-supported interview called "photo ramble." Children carried an informed consent letter to be read and signed by their parents. When the children arrived at the area with their holiday institution, they handed in the informed consent sheet. Children took part voluntarily. Some children decided not to take part in order to just play in the area. Children who took part were given an easy to use camera. The researcher explained how to use the camera. The child took a picture of the feet from child and researcher as a first picture to indicate the beginning and to test the usage of the camera. Then, the child was instructed to take five photographs in total, with the following aims:

1. A favorite place
2. A place to be avoided
3. A place to be alone
4. A place to be with others
5. An object that is particularly fascinating to the child

The child received a little flag to put up at each photo to indicate the location in question. As a reminder, the five different photo aims were written on the backside of the flag. Then one child at a time strolled through the nature experience area and took five pictures. No time limit was given.

After taking the pictures, the child came back to the indicated location where a researcher waited. The pictures were put onto an 11-inches-screen in order to present the photos to child and researcher. The interview took the photos one-by-one as prompts (see photo-elicitation, e.g., Briggs, Stedman, & Krasny, 2014). The interview consisted out of five blocks of open questions according to the selected and photographed locations. The first question was "Why did you pick this location as your favourite place?" (place to be with other children, to be alone, respectively), followed by "What do you do there?". Further questions were developed in case an answer was not detailed enough for research reasons. Additionally, we asked for age, gender, and independent activities in a daily context of the children, e.g., the way they get to school (accompanied or by themselves), spare time activities, and distance to the nature experience area. After the interview, we thanked each child for their expertise and handed out a certificate of participation.

The interviews were recorded, and a transcript was written. The interview text was analyzed by content analysis (Mayring, 2003). The first step, the coding, was done very close to the interview material. In the second step of analysis, the codes got reduced, reaching ten categories. These categories were then, in the third step, generalized into four head categories, which aimed to analyze the research question how children perceive nature experience areas.

Results and Discussion of the Interviews (Study 2)

Twelve girls and eight boys at the age of 7–12 years took part. More than half of them (11 children) were accompanied by one of their parents to school, while 9 children went by themselves or were accompanied by siblings. The walking distance to the nature experience area was estimated by most children to more than 20 min from home. Only six children reported a walkable distance of 10 min.

The coding system (see Table 5) derived into a categorization of the whole interview material on the perception of urban children perceiving the nature experience areas. The four head categories adventure and creativity, retreat, instrumental use, and threat, which are shown to be meaningful to the children, will now be reported and illustrated by anchor examples (Mayring, 2003). The anchor examples were translated by the authors from German into English. Results are discussed directly after each head category.

Natural Environment as Location for Adventure and Creativity

The nature experience area was described as a location for playing, climbing, and creating in particular. Adventure was a major aspect children mentioned. Children enjoyed free play and role-play: "In this area, I play with my female friends and pretend to be pirates – or police women" (D1, girl, 10 years old).

Physical activity is an important factor mentioned by the children: "We can run and create uproar. I have to find (my friend) all the time since he is hiding from me. And then I run after him and run through the whole area" (D10, boy 10 years old).

Places to be alone stimulated needs and different play behavior, including role-play: "Here, I can play nicely alone. I'm a dancer and dance... and nobody can disturb me" (D1, girl, 10 years old). Favorite places often had a variety of climbing opportunities: "I like to climb. And this was the location, where you can climb trees" (D7, girl, 9 years old).

Table 5 Categories and head categories of nature experiences

Category	Head category
Possibility to climb	Nature as location for adventure and creativity
Possibility to create	
Possibility to observe	
Possibility to hide/shelter	Nature as retreat location
Esthetics	
Quietness	
Possibility for nutrition	Instrumental use of nature
Darkness	Nature as threatening location
Derangement	
Painful experiences	

Another important activity reported is creating. Building something played an important role for fascination and identification: "This is my favourite place, because I have built it with my friends (. . .) We found a tree. We put sticks onto it, and a hole appeared. And then we could sit in there. (. . .) I built it together with my friends and we had a lot of fun looking for the sticks" (M7, boy, 9 years old).

An important aspect which was reported by several quotes is the explorative character of the area. Children reported observing and thus discovering things as a fun activity, either observing natural phenomena such as animals or other children in play: "(We) look if somebody attacks us in our play, or we look for animals or something else" (M1, boy, 9 years old).

Possibilities to climb and adapt the area were mentioned to be very important. Children enjoyed climbing trees, including the perception of dangerous action as well as the appreciation of a challenging task. These results confirm earlier studies (Reidl et al., 2005) and open up a more detailed picture. The adventure and creativity aspect reflects the explorative nature experience dimension facing the examination of animals and plants (Bögeholz, 1999). Consistent with previous results on the design of play areas, it needs to be considered that children enjoy natural elements, which they are able to utilize in new ways (Maxwell et al., 2008). This is possible to a stronger degree in the natural experience area and might be an explanation for the higher variety of play behavior that we reported in study 1. The learning aspect is assumed to be stronger due to this category, because the possibility to hide plays an important role for children and their learning processes (Renz-Polster & Hüther, 2013). The creative leeway was wider in the nature experience area as results show here, indicating that we need to move away from telling children how things should be to enabling their climbing and creating needs instead. Hiding places, hand-made or given by designed structure, enhance the adventure-orientated dimension of natural environments and need to be considered in terms of design. Creative play and design of the area have to be enabled deliberately in order to support childhood development. This is a main difference to conventional playgrounds, which often provide given elements only and few possibilities for children to change the area.

Natural Environments as Retreat Location

Children reported finding quiet places for retreat or creating places like that, such as huts or walls with little possibilities to be observed. They purposefully sought out such places, e.g., when they are angry or had an argument: "There, I'm always alone, for example when someone beat me or I'm not doing well or so on. Then I sit down there. (. . .) I can calm down, (. . .) because usually there is nobody. Because, when I was there, nobody disturbed me" (M9, boy, 12 years old). They purposefully sought out areas with high vegetation in order to find quietness for themselves: "I went into the shrubs very, very deep. And thus, you do not hear any voices" (M7, boy, 9 years old).

They also looked for quiet areas in order to plan and talk to others: "We are there to make plans what to build" (D3, girl, 8 years old). Imagination and role-play were

part of exclusive locations as well: "I have a secret path to this location (...) and nobody can reach it except for me" (D8, boy, 8 years old). Quietness and esthetic pleasure are enjoyed: "Because it's pretty there (...) and sometimes so quiet, too" (D6, girl, 7 years old).

In a very instrumental way, children expect specific characteristics of the natural area, which they use, e.g., recovery. This is consistent with the recovery-oriented dimension of nature experience including the restorative effects arousing by a stay in a natural environment (Lude, 2001). The data show that dense vegetation structures meet the need for quiet time well. The mention of recovery was probably primed by the research design since the media supported interviews included one question on the location where children liked to be alone. Thus, our results give important additional information about the need of children for quiet areas. Children seeking quietness often perceive the beauty in the natural environment, which is a strong pattern in the esthetical nature experience dimension (Bögeholz, 1999). Planning should include spaces for recovery such as hiding places or areas which are not accessible for adults.

Instrumental Use of Natural Environments

The instrumental dimension of natural environments was apparent especially as it was early autumn and there was an abundance of ripe fruit, which were present during the interview period. Locations with fruit were photographed as favorite places as well as places to be alone: "Because there are so many fruits and you can eat them. (...) small plums and plums. I like to play there or eat (...) the plums I picked" (M1: boy, 9 years old). Collecting fruit was a favorite activity for some children: "There are small plums which I collect and eat. And blackberries" (D9, girl, 9 years old).

A third aspect apparent in our interview data was the instrumental dimension of nature experience, shown by the use of ripe fruit. Our data show the instrumental dimension consistent with earlier research of Bögeholz (1999), including the cultivation of plants and the care for animals. In our case, this dimension was apparent due to the collection and consumption of fruit; children show a fascination to pick and eat fruit. A very intense and positive contact to natural environments was apparent through the consumption of fruit.

Natural Environments as Threatening Location

As we did not limit our perspective on positive effects of natural environments, the interviews asked for avoided locations, too. Children took pictures of negative aspects of the nature experience area. Especially esthetical assessment, such as an untidy appearance, darkness and the lack of climbing opportunities were mentioned. One boy disapproved the change of things he had created earlier, again a sign for identification with the location. "Earlier I liked this (location), there was a

hut, and now it is destroyed, everything, and I dislike it strongly. (. . .) When I came back, everything was broken" (D10, boy 10 years old). "I dislike that it is so narrow and dark" (M2, boy, 7 years old).

Additionally, the children reported threatening and painful experiences. They report a strong sensory-physical perception. "There are thorns and they sting" (M4, girl, 9 years old).

Some children were additionally afraid of getting dirty. "When I run (through the fruits on the ground), my shoes get messed up. And sometimes I fall down, when I run there" (M8, boy, 9 years old).

The threatening dimension of nature experience found in our data is a new aspect, which has not yet been focused in research on nature experience of children (Bögeholz, 1999; Lude, 2001; Reidl et al., 2005). We took it into consideration due to the fact that it was represented in the photo ramble. The threatening nature experience dimension addresses the inconveniences in natural environments, which are perceived by children. These consist of the risk to be hurt as well as esthetical assessment of the area. The threatening dimension addresses an esthetic nature experience dimension (Bögeholz, 1999) but in a negative way. Children cope with it in different ways, such as avoidance or practice. It could provide an important challenge for the children to learn how to deal with new or complicated situations and control them. Thus, it provides an important additional aspect, which could be a key factor for the positive influence of natural environments on children's development.

Limitations of the Research

The studies presented show some potential for the planning and design of children's play areas in an urban context. Nature experience areas were researched regarding their affordances for children and their play and learning behavior.

Study 1 focused on the usage of a nature experience area and a conventional playground as well as a comparison of play behavior. As we used a quasi-experimental design, not randomizing the children to either area, we could not exclude systematic effects here: it might be that a different selection of children visits each area, e.g., very fearful parents prefer the playground, while nature-oriented parents are more open for the nature experience area. These aspects – fearfulness, nature orientation, and environmental literacy, just to name some – might influence the effects of play behavior, too. This could be addressed in further research.

Study 2 with an explorative approach gives a deeper insight into the perspective of the children, showing the importance of complex and creative play in the nature experience area. However, generalizing from these results was not an aim of the research and is not possible. Further research could address the findings and test them for generalization.

The main weak point of this research is the cross-sectional design, allowing innovative results in one point of time only. If we want to make suggestions for planning processes, the studies need to be repeated in a longitudinal design in order to gain results about the development of the site and the development of children's

use of the site. Further work addresses this lack in the context of an interdisciplinary research project.

Conclusion

With an increasing consumption of media and decreasing contact with natural environments for children living in urban areas, the meaning of free play (Skår & Krogh, 2009) and the contact to natural environments (Bögeholz, 1999) are the focus of the two studies about nature experience areas, which were conducted in the metropolis Berlin, Germany. In order to analyze the specific effects of an extensively designed "wild" nature experience area for children, the main research questions addressed the experience of children and their play behavior in nature experience areas. Two studies, using quantitative and qualitative methods, show that playing in natural environments provides important opportunities for children to both play freely and experience natural environments. The results show important nature experience dimensions, which serve the cognitive development of children and influence their attitude toward nature (Bögeholz, 1999).

Nature experience areas in an urban context provide possibilities for contact with natural environments. Thus, they could counteract the recent trends of childhood such as institutionalization and media consumption (Blinkert & Weaver, 2015; see ▶ Chap. 25, "Children in the Anthropocene: How Are They Implicated?" by Malone). However, in order to reach this effect, children need to visit nature experience areas. We compared the usage of a newly initiated nature experience area and a conventional playground and showed that the natural experience area was much less frequently visited. It may be that the new installation needs some support in usage in order to promote the positive effect on children. The improvement of familiarity could well support the visits of children to the natural experience area. Other strategies could be initiated to meet the parents' needs for comfort and child safety. One possibility for this is a design solution: the appearance of a well-tended play area in the front can be inviting also for fearful parents since they can see the purpose and care of the area. Another possibility is a human resource solution: an employed mentor or supervisor of nature experience areas could take care of the area and inform about the potential. This has been the case at the research site and needs to be analyzed in future research over a longer time span. This can reveal whether the usage of nature experience area increases over time due to increasing familiarity or decreasing parental fears. A third solution, again by design, is to create opportunities for parents to sit and socialize. There were not many obvious places to sit down and meet other adults in the nature experience area. More comfortable seating could motivate parents to accompany their children, especially younger ones, into the nature experience areas. Parents' acceptance and willingness to let their children play in nature experience areas is strongly needed and could be supported by opportunities for parents to have a say in further planning of nature experience areas. Still, these need to be designed in a way that the children have the opportunity to play freely and without supervision.

Nature experience areas help to promote a more complex play behavior compared to a conventional playground. This is consistent with earlier studies showing that children develop diverse motion patterns in the natural environments (Fjørtoft et al., 2009). Children show various different play behaviors and thus enable the development of different competencies (Meske, 2011). The nature experience area enables a contact to natural environments for children and complex play behavior, which is very meaningful in their development and learning process (Louv, 2011; Renz-Polster & Hüther, 2013), a nonformal learning process in particular. Both studies show that children find continuity and change at the same time in the nature experience area, a basic need for their cognitive development (Gebhard, 2014). As our data show a broader variety of play behavior in the natural experience area compared to the conventional playground, we show that the learning process is strongly influenced by space itself (Mannion & Lynch, 2016): we assume that children will develop higher creativity and motivation as well as a stronger variety of motion patterns in the long run, thus initiating a more intense learning process (Reidl et al., 2005). Our analysis of interviews on the perspectives of children support these findings, showing creative and complex play behavior in the nature experience area. Also the importance of physical activity for the children becomes apparent in the interviews. Natural environments allow children to engage in independent mobility and thus develop environmental literacy and risk assessment skills (Malone, 2016), and nature experience areas could provide the independent engagement with natural environments (Blinkert, 2016). Our photo-elicitation interviews show that adventure and creativity are important dimensions for the children: they actively adapt and design the areas visited, e.g., by building huts. Such behavior is important for a healthy cognitive development (Oerter & Montada, 1998). Thus, possibilities to climb and to create and design the area should be taken into consideration in the planning process of not only nature experience areas but play areas in general. The interest for physical surroundings was quite apparent in the nature experience area. Affordances in the environment, shown in the reported study by a diverse vegetation and movable material for multifunctional use, can support independent mobility (Broberg et al., 2013). In this context, nature experience areas can play a key role in incidental learning processes in an urban context. The utilization of such areas needs to be carefully looked at as mentioned above over a longer time span in order to promote more regular and established use.

Learning by playing is possible in both of the research areas: a variety of play behaviour was observed in the nature experience area and the playground. However, since the variety of play behavior is much broader in the nature experience area (showing less repetitive movement play and a more diverse and complex play behavior including exploration), the learning effect promoted is stronger. Children engage in a variety of play from simple psycho-motor, construction, imagination, movement and communication play, and exploration behavior. This variety does not appear on the built playground. This result supports earlier studies on nature experience areas in smaller cities (Reidl et al., 2005). Variations of play in the nature experience area arouse more diverse experiences across many levels such as

movement, social interaction, and cognitive challenges, thus supporting the development of different competencies and learning processes. The stronger learning process involved in nature experience areas could be due to the affordance character for children to play and experience their environment (Jansson & Mårtensson, 2012). Qualitative data support the learning process by showing the importance of creative, free, and complex play children reported. Additionally, daily experiences in natural experience areas can contribute toward a better understanding of natural interrelations and to an enhanced environmental awareness (Bögeholz, 1999) and a better subjective importance of nature conservation (Hallmann et al., 2005) (see ▶ Chap. 24, "Childhoodnature and the Anthropocene: An Epoch of "Cenes"". by Cutter-Mackenzie, Krasny, Malony, and Whitehouse).

Our results suggest that nature experience areas should be included into urban planning processes on a regular basis in order to create affordances to enable complex play behavior of children, which are the basis for various learning possibilities. More generally, further design of play areas, traditional playgrounds, as well as nature experience areas needs to consider the positive effect of movable play elements and of play elements which are not predetermined in their function.

Considering the *characteristics of nature experience areas*, our observational and interview data show some interesting results. There is some divergence to the basic concept of the nature experience area according to Schemel (1998). So far, there is no area that remains undeveloped. This was due to the initial design phase, which has been realized with the participation of children in 2016. The derelict brownfield site chosen before the project started is most likely not to be favored by people in an esthetical way (Tenngart Ivarsson & Hagerhall, 2008). Since this subjectively rather unattractive area has been turned into a play area for children, it may take some time for visitors to become familiar with the setting. Signs of setting care effect people positively (Martens et al., 2011) and could lead to an acceptance of the rather wild natural concept for parents and neighbors over a longer time span. For example, could a tended entrance area provide a needed perceived sense that the area is being taken care of, providing a greater acceptance for the more valuable "wilderness" behind?

The size of the nature experience area has been rather small with 0.64 ha. With the use of playing children, the ecological development needs to be focused in longitudinal research: is the area dedicated to play for children sufficient for ecological development in the long run? This should be focused in further research and is part of our interdisciplinary research including ecological development of nature experience areas. Also, safety issues need to be addressed in the maintenance of natural experience areas, especially when trying to promote positive learning effects and autonomous activities in these complex environments. The advantages of nature experience areas in child development shown in the reported studies need to be harnessed into planning processes of an urban child-friendly environment and place-conscious education. Such places need to be created and used for outdoor education in order to enact place-responsive education (Mannion & Lynch, 2016). The value of implementing nature experience areas could possibly simultaneously increase the

opportunities for children to learn in the urban environment while also addressing the need for nature conservation.

Abstract

Place-based education – an approach to learning which engages young people in meaningful investigations taking place in their local community – shows great promise in advancing the concept of childhoodnature. Through sustained and thoughtful engagement with the natural and social worlds of which they are a part, young people can be supported in the development of agency, or the ability to make a difference in the world. This Chapter argues that place-based education projects can best realize this potential by building on culturally and ecologically responsive experiences informed by a fusion of David Greenwood's framing of place consciousness and Steven Fesmire's articulation of ecological and moral imagination. Specific program design recommendations are then made to ensure age-appropriate youth leadership of the work, support continuous development of skills and dispositions, nurture interest and commitment through maintaining

connection to place, and foster depth of engagement through the enhanced interest that comes about through meaningful participation in the world.

Place-based education · Agency · Moral imagination · Ecological imagination

This Chapter takes a critical look at conceptions of agency that are often implicit in descriptions of place-based education, with a goal of developing greater understanding of the challenges and opportunities involved in fostering youth agency. As a curriculum design strategy, place-based education has great potential which emerges directly from its local focus. Owing to the smaller scale and close proximity, students participating in a place-based education project have a better chance to observe and understand what is happening and to have opportunities to effect change. Viewed more broadly, early experiences with meaningful local engagement nurture a lifelong disposition to be an active, committed member of the community (Coulter, 2017). As desirable as these outcomes may be, however, they are not simple to achieve. If place-based education is to realize its potential to connect young people with their community and equip them to be contributing members, we need to be sure we bring our best wisdom to the design and implementation of each project.

In this chapter, I highlight one of the most common limitations found in designs for place-based education: the need for better articulation of the ways in which we support meaningful agency among the participants. Many projects are overly scripted by the adults in charge, which limits opportunities for young people to truly connect with their local space. Imagine, for example, the all too common scenario where a teacher decides on a nature improvement project and gives each student a specific direction to follow, and then everyone goes inside having completed their work. I've actually seen this, where more than 100 students have planted a garden in just over an hour with two students assigned to each plant, which is dropped in the teacher-assigned space. Once all the plants are in the ground, everyone goes back inside; having done what the teacher decided was their part for the environment. While these projects are technically rooted in place, there is not much that motivates student engagement aside from a chance to get out of the classroom. Other more fully developed projects might have a level of shared authority appropriate for the students' age, but as with the first scenario, if that project is not part of a sustained effort to connect young people to their community, it still falls short of what is needed. For example, an isolated ecology or local history unit sandwiched between unrelated studies might engage students for a time, but it has limited potential to foster lasting connections to students' lives. Place-based education works best when it supports the development of effective agency, which in turn requires sustained opportunities to develop skills and dispositions in the context of ongoing engagement with the local community. When we do this, we can be more confident that young people are growing toward responsible citizenship in tune with their social and ecological communities.

As we move forward, I will illuminate these concerns working from the position of a "pracademic," a creative term offered by Badgett (2015) to describe a practicing, publicly engaged academic. I will be drawing on the research literature and my own 30+ years of experience in the field, including 12 years as a classroom teacher leading place-based education programs with students ages 7–12 and more recently as an educator responsible for mentoring teachers in their use of the local community as a learning resource. Even though I have transitioned away from the classroom as my primary responsibility, I continue to have direct contact with preteen students most days of the week. Their work deeply informs the perspectives offered here, as illustrated in a series of short vignettes illustrating key ideas.

What follows is a synthesis of empirical data that has been collected both formally and informally in a variety of contexts, presented in the context of a philosophical reflection on the state of place-based education and its potential to support the growth of agency among participants. My hope is to meet the standard offered by Daniel Dennett for a useful work of philosophy: "A scrupulously reasoned argument that opens our eyes to a new perspective, clarifying what had been murky and ill-understood, and giving us a new way of thinking about topics we thought we already understood" (Dennett, 1999, quoted in Dawkins, 2015, p. 334). Here, the focus is on making an argument for place-based education as an essential curriculum design strategy, bringing attention and clarity to the all-too-often tacit role which youth agency plays in the most successful programs. Lest the philosophical framing of the chapter turn you away, please know that (consistent with being a "pracademic") my focus will be on the practical implications of what we do, rather than on abstract argumentation. Also, to be clear about my own biases as an educator and as a researcher, I am working from a Dewey-inspired, pragmatist point of view. To borrow from Ben Minteer (2009, p. 6), who in turn acknowledges an intellectual debt to Ian Hacking: "pragmatism suggests less the image of the philosopher's armchair than it does the craftsman's [sic] workbench. Ideas, as well as values and moral principles, are not abstractions; they are tools for social experimentation with the goal of bettering the human condition and enhancing our cultural adaptation to the environment." I largely concur with Minteer in this, though I will offer a friendly amendment proposing that our work needs to better more than just the human condition.

I will start building my argument by offering an overview of place-based education as a curricular strategy. With this, I describe key learning benefits, highlighting the ways in which place-based education helps us to address long-standing educational goals such as engaging students' interests and promoting authentic inquiry. The central portion of the chapter develops an analytic frame which allows us to take a close look at the role of agency within place-based education. This section builds on two existing conceptual structures and proposes a synthesis. First, David Greenwood (2013) describes place-conscious learning as a foundational aspect of place-based education. He frames this argument by offering three questions which ground place-based education deeply within the local ecological and cultural space. Following immediately after that, I argue that Steven Fesmire's (2010, 2012) descriptions of ecological and moral imagination give us the tools through which

we can develop well-considered responses to Greenwood's questions. This process of grounding our ecological and moral imaginations deeply in our local space gives us a powerful framing as we consider the role of agency in place-based education. Consistent with overarching principles of childhoodnature, we need to develop a mind-set that works against separating humans from their local environment and, from that basis, continue to develop and refine a set of educational principles to guide our work. To that end, the Chapter closes with reflections on how we might better frame the role of agency within place-based education.

What Is Place-Based Education?

At the outset, we need to be clear on what place-based education offers as a curricular approach. Many teachers I work with at our ecology center have the initial misconception that if it's outdoors, it's in a place, and thus it "counts" as place-based education. While this is minimally true, we need to reach higher. The Place-based Education Evaluation Collaborative (2010) offers a helpful definition when they describe it as an approach to education that "immerses students in local heritage, culture, ecology, landscapes, opportunities, and experiences as a foundation for the study of language arts, mathematics, social studies, and other subjects." When compared with generic "could be anywhere" placeless curriculum, rooting learning in places where students can have recurring firsthand experience offers great potential for educative growth (Place-based Educational Evaluation Collaborative, 2010). First, working directly within the communities and local ecosystems that are close at hand offers real potential – amply supported by research evidence collected by PEEC and others – for young people to be more connected to their work and each other than they would be if their learning were limited to reading text and trade books or using other mediated representations. With this deeper involvement, place-based education enables multifaceted inquiry which transcends traditional curriculum boundaries to encompass historical, ecological, social, and cultural perspectives.

For an example of a more fully articulated project based on ideals of place-based education, consider the work two 11-year-old former students of mine did for their science fair project (Coulter, 2000a). Nathan Strauss and Nate Litz were interested in studying water quality, but they didn't limit themselves to simple "kitchen chemistry" testing of key parameters. Rather, they worked with me to design a project where they field-tested the water at four different locations along the same urban/suburban creek, at roughly monthly intervals from late fall to early spring. By design, they tested the water quality as it coursed from leafy suburbs to more highly urbanized spaces. This spatial perspective offered interesting points of contrast for their data analysis. The geographic spread also helped to bring the boys' attention to one of the many socioeconomic divides in our community – a useful perspective for students in a comparatively privileged private school. I'll have more to say about this project later in the chapter.

To be clear, creating rich local learning spaces is not easy, and it usually requires much more effort on the part of teachers and students than does reliance on

prewritten, heavily sequenced curriculum. If the teachers or group leaders are able to foster age-appropriate engagement in the community in ways that students find meaningful, the value of place-based education as a curricular strategy can be realized. Investigation of local historical or ecological events supports a range of mathematics and language skills including description, measurement, organization, and representation of data, as well as the use of evidence-based reasoning throughout the process as participants work toward understanding. While this same sort of work could be done with artificial data (or even authentic data from distant locations), inquiry that is grounded in the local context makes the work more real for the students and less of a textbook exercise.

Some may counter that focusing on the local risks the students developing a parochial point of view in an increasingly global world, but my experience is just the opposite. A number of projects I have led (or supported others in leading) have been able to cultivate a wider point of view precisely because of the intensive grounding in the local. For example, a project I did with my 9- and 10-year-old students started with intensive field investigations of the woods across the street from our school. The goal at this stage of the project was to help them develop an understanding of our local temperate deciduous forest ecosystem and how the plants and animals they found there are suited for the temperature and precipitation patterns typical in our region. From there, the students investigated a self-chosen distant ecoregion such as the desert or rainforest, exploring how the plant and animal life that flourished there reflected local climatic conditions (Coulter, 2000b). By pairing the local and the distant, students' understanding of key ecological concepts including adaptations, form and function, and survival strategies improved considerably. Comparisons involving what can live where (and why) fostered an awareness of how sensitive plants and animals are to different abiotic conditions – an essential understanding as they wrestle with more complex topics such as climate change. Taken together, this effort built interest as well as a depth of understanding, both of which served as the catalyst for the students' looking further afield in their efforts to understand the world they are a part of. As with the creek project, I will be revisiting this project later in the Chapter to illustrate key ideas.

In conjunction with the academic benefits of place-based education projects, there are opportunities for students to develop and exercise agency, which can lead to personal growth as well as improvements to the ecological and social fabric of the community. As a concept, agency has taken on increasing significance in the sociology of childhood (Mayall, 2002) and childhood studies fields (Qvortrup, 2005). This evolution in stature grows out of an effort to better describe the ways in which young people act capably and with intention to influence their world. The emphasis on agency draws a notable contrast with earlier sociological framings of childhood which largely assumed that passive children could be socialized into being productive future members of their community (Leonard, 2016). As we will see later in the Chapter, recognizing and supporting agency is an important educational goal. Giving young people a voice – metaphorically and literally – sets them on a path toward engagement and responsibility that cannot be traversed if we settle for passive training for some future role as a citizen. The trick here is in finding the

right balance for the intensity and scope of engagement. Consistent with Aristotelian philosophy (Kristjansson, 2015), the virtue is in finding the curricular version of the golden mean – in this case, the spot that is right for a particular group of learners at a particular stage of their development. We need to encourage a level of ambition where students do not settle for a quick "one-off" foray into the community before retreating to the classroom (like the "express garden" installation I referred to earlier). At the same time, we need to ensure that young people do not feel the need to solve the world's environmental problems themselves (Sobel, 1999). Teachers need to find a way to foster a level of sustained engagement which ensures that students come to feel that they are part of larger socioecological systems and that they can make meaningful contributions. Implicit in this mind-set is the need to work with cultural sensitivity and a sufficient level of engagement with community stakeholders to avoid imposing ideas to the detriment either of marginalized cultures and/or the non-human parts of our world.

Before we go too much further in scoping out place-based education, I feel compelled to offer a brief context note. While place-based education may sound very innovative when compared to standard classroom practice, we should remember that what we are discussing here is a time-honored tradition found in most cultures. Perhaps owing to the modern propensity for newness, place-based education has become one of those terms the schooling business has a way of reinventing and turning into something new. (For another modern example, consider the ways in which the maker movement has become trendy, in school and out. Imagine the radical idea that people can make things instead of buying them! Sadly, as we know, making things – like going out into the community to learn – has become so devalued in schools that even perfunctory efforts to do this make it an innovation.) Specific to place-based education, for most of human history young people have learned through their experiences in and around the home and neighborhood. In fact, many traditional cultures still place great emphasis on the highly localized, contextually rich approach to learning that many in Minority western contexts now see as an innovation (see, e.g., Hart, 1997 or Bolin, 2006). Even within a Minority western context, we need to recognize that the approach is hardly new. More than a century ago, John Dewey (1900) raised a concern about the split in more industrialized countries between children and their community, arguing that educators need to find ways to reintegrate the two if education is to achieve its goals. Not surprisingly, the curriculum at Dewey's laboratory school at the University of Chicago had this as a central focus (Tanner, 1997). From there, progressive schools founded on similar goals have continued to flourish as a subculture within the larger educational landscape. All of this is not meant to be critical of place-based education as a learning strategy so much as to point out that what we have before us isn't entirely innovative. Rather, it's a variation on a theme that has maintained a small but persistent thread in the history of education. I will be looping back to this often unacknowledged legacy toward the end of the Chapter when I argue that restoring place within educational designs is our best plan for helping young people remain connected (or perhaps become reintegrated) with nature and society. For now, it's sufficient to note that the very idea that we might need place-based education is a

reflection of the poverty of our collective vision that has allowed schooling and other educational ventures to become detached from the world in which we live.

Be that as it may, it is still worth looking briefly at the emergence of current forms of place-based education. Since others (Smith, 2013) have traced the history of modern place-based education, I will only touch on some of the highlights here as they are relevant for the focus of this Chapter. As a formal approach to curriculum, many consider Gerald Lieberman and Linda Hoody's (1998) report *Closing the Achievement Gap: Using the Environment as an Integrating Context for Learning* to be one of the founding documents of the contemporary place-based education movement. In this report (often known as the "SEER Report" since it was published by the State Education and Environment Roundtable), the authors report on research conducted in schools which used the "environment as an integrating concept" (EIC) as an organizing principle. This term – coined by the Roundtable – makes a careful differentiation from traditional approaches to environmental education. As Lieberman and Hoody (1998, p. 1) argue, "EIC-based learning is not primarily focused on learning about the environment, nor is it limited to developing environmental awareness. It is about using a school's surroundings and community as a framework within which students can construct their own learning, guided by teachers and administrators using proven educational practices." Based on their study of 40 schools in 13 states, Lieberman and Hoody found a number of traditionally defined academic benefits (such as higher standardized test scores) as well as a lower frequency of behavioral issues and higher levels of student engagement. These findings recur in the literature, indicating that – despite some peoples' fears – using place-based educational strategies doesn't detract from test-based accountability efforts, and it can often help.

Building from there, David Sobel, a senior faculty member at Antioch University New England, led what was initially a regional effort in New England to promote place-based education. This grew into the Place-based Educational Evaluation Collaborative (PEEC) which led a joint research and evaluation effort over the course of several years working toward a synthesis of what was known at the time about place-based approaches to learning. Summarizing the findings in a briefing report intended primarily for school administrators and board members, PEEC (2010) found empirical evidence across a wide spectrum of programs that place-based education:

- Helps students learn
- Invites students to become active citizens
- Energizes teachers
- Transforms school culture
- Connects schools and communities
- Encourages students to become environmental stewards.

As these examples illustrate, over the past 20 years place-based education has developed a clear (if not large) presence on the educational landscape in the United States and elsewhere. Perhaps a sign of it "arriving" is the fact that books are now

being produced at a level intended to support classroom teaching practice (Demarest, 2015; Lieberman, 2013), whereas early documents were more theoretical and conceptual pieces.

Reflecting on the movement, there is a lot to appreciate, though one can easily turn a critical eye as well. On the one hand, there is an intuitive appeal. It is hard to get excited about schooling which aims for the opposite of the six research outcomes summarized in the PEEC report. An approach to education that helps students to learn less and become passive citizens led by disempowered teachers is hardly a strategy to get behind, even if that is the de facto outcome of typical neoliberal approaches to education. Still, a couple of clarifying considerations are in order. First among these, as Greenwood (2013) points out, is the fact that there are fundamental mismatches in pedagogic goals between a place-based approach to curriculum and the more corporate-driven, highly standardized approach to education which is the norm in the United States and which has a strong hold in many other Minority western societies (Blossing et al., 2014). Also, there are serious questions about whether classroom teachers locked in a standardized approach to teaching based on a "deliverology" mind-set (Pring, 2013) have the requisite skills, capacities, and pedagogic vision needed to design and carry out complex, locally based investigations (Coulter, 2014). While these facts do not devalue the noble ambitions and good work that has been done in the field, it does suggest rather strongly that a host of obstacles stand in the way of place-based education ever becoming "normal" practice in schools.

A Closer Look at Agency

As an educational concept, the term agency seems to have little presence outside of academic circles, yet the underlying concept is fundamental to the day-to-day life of every classroom, after-school program, or free choice activity. Sociologist Berry Mayall (2002) provides a useful distinction between a person merely taking action and one who is acting as an agent: "A social *actor* does something, perhaps something arising from a subjective wish. The term agent suggests a further dimension: negotiation with others, with the effect that the interaction makes a difference – to a relationship or to a decision, to the workings of a set of social assumptions or constraints" (p. 21). This framing moves us in the right direction as it captures elements of strategic intention and impact rather than just carrying out an activity or acting on an unconsidered or unregulated impulse. In a similar vein, Matthew Crawford (2015) argues that our best thinking and acting do not occur in a world free of constraints. Rather, real creativity emerges through our constructive engagement with the world.

If we apply concepts of agency to a school context, we see that students exercise some degree of agency as they navigate each school day, though the extent to which they are allowed to do this varies quite a bit. In free schools like Summerhill in England (Neill, 1995) or the Sudbury Valley School in the United States (Gray, 2013), young people's opportunities for agency are quite extensive, as they construct

learning opportunities alone or in collaboration with others. Consistent with this open framing, restrictions on their bodily movement are quite minimal. On the other end of the continuum, many students attend regimented "no excuses" schools where behavior is tightly regulated and enforced with harsh consequences (Nathan, 2017). Even in these spaces, however, students find ways to exercise agency within the cracks or as instances of "interstitial agency" (Oswell, 2013). Examples here include students texting each other surreptitiously or creating original games during the limited free time they might enjoy during recess.

As the rest of the chapter unfolds, I will work from a definition of agency consistent with Mayall's framing, where an agent takes actions that are designed and structured to make a difference in the situation at hand. Two important corollaries follow from this: first, agency captures a particular stance reflecting adult-child relationships where there is a high degree of respect and autonomy afforded to the young. With this, there is an assumption that the young actually take up this expectation of agency and make increasingly good use of it as they grow. Both of these corollaries challenge traditional classroom-based models of education where shared authority is rare, as is the assumption among students that they are to take active ownership of their work.

One of the most useful framings of developmental growth toward agency is offered by Roger Hart (1997) in his Ladder of Participation. Encompassing eight rungs, people work up the ladder as they exercise increasing agency:

8. Child-initiated, shared decisions with adults
7. Child-initiated and directed
6. Adult-initiated; shared decisions with children
5. Consulted and informed
4. Assigned but informed
3. Tokenism
2. Decoration
1. Manipulation

I have found it useful in planning programs to discern where a group of students would be placed on Hart's ladder and then provide the scaffolding within the project to support growth toward the next level. So, for example, in working with Nate and Nathan on their water quality project, I had two very self-directed students. They knew I had recently taken a job with the Missouri Botanical Garden focused on using geographic information system (GIS) software to support environmental education. Still, as students who were just approaching their 11th birthdays, they had comparatively limited understanding of what would be possible, which meant that I had to do some groundwork to scope out possibilities for them. From there, they chose to do water testing, and we jointly developed timelines and strategies to make a project they found interesting and which met the requirements of the science fair they would be entering. In terms of Hart's ladder, I'd place it at level 6, where I initiated a good bit of the work, but the boys had substantial involvement in a series of decisions to select and refine the topic selection and procedures. In terms of scaffolded growth,

Nathan went on to complete a largely youth-directed project (Hart's level 7) in middle school as he and a different partner used GIS and an assortment of local historical resources to investigate the ecological impact of the proposed relocation of a sports stadium.

The other project I noted a while ago linking local and distant ecosystems would rank lower on Hart's ladder, due primarily to the lack of experience most students had with taking on self-direction in their work. They were used to highly structured, teacher-led lessons with little student input. Given this, we started the field study in the woods at Hart's level 4 (teacher assigned, students informed), but with a clear agenda on my part to scaffold more involvement as we moved forward toward the comparisons with distant ecoregions. As we jointly developed the project, I had to guide the discussion quite a bit at first, but the format and criteria for the final projects had a good bit of student input. Given this, I would describe the later work in the range of level 5, with much more student consultation on the scope and expectations for the work than we started with.

I will be revisiting Hart's ladder later in the Chapter, but for now, two more items are worth noting. First, Hart argues (correctly in my opinion) that the bottom three rungs are best considered nonparticipation, as there is little value (or virtue) in young people being manipulated into an activity, used as decoration on behalf of a cause or as token actors. Young children holding signs in a political demonstration advocating on behalf of a cause for which they have no understanding would be a good example of nonparticipation. Agency implies a much more intentional and strategic focus, which is captured as young people move up the ladder beyond the nonparticipatory levels. At the higher end of the ladder, notice the apparent juxtaposition in the top two levels. Intuitively, work that is fully youth-directed would seem to be the ideal end point. However, positioning shared adult-youth decision making at a higher level captures an important point. In many ways, it is a more significant achievement for young people to work as equal partners in a cross-generational effort than it is for them simply to have a youth-led project. By taking on the extra challenge of negotiating work across generational boundaries, they are growing toward increasingly responsible citizenship.

Building Connections to Place

If our goal is to connect young people with their local community in ways that build agency, how can we best conceptualize the effort? I find David Greenwood's (2013) framing of place-conscious learning to be an excellent place to start, since the questions he asks enable us to better frame considerations of place-based agency. Drawing on previous work done with Marcia McKenzie (Greenwood & McKenzie, 2009), Greenwood argues that two closely interrelated efforts need to underlie our relationship with place: decolonization and reinhabitation. To that end, he argues (2013, pp. 96–97) that "political decolonization/reinhabitation involves the process of resisting or transforming relationships of domination and control that limit people's possibilities to direct their own life circumstances. Political decolonization/

reinhabitation also implies the space needed to maintain, renew, and create ways of being and knowing that serve the people and places in which they live." With this, he continues by advocating that we pursue opportunities for "(a) maintaining, recovering, or creating ways of knowing and living in relation to place that are threatened or have been lost or silenced, and/or (b) unlearning patterns of thought and action that limit potential for experience and learning in relationship to places" (p. 97).

What I appreciate most about Greenwood's framing is the way in which it provides a structure through which we can bring deeper meaning to our efforts. Decolonization and reinhabitation challenge us to resist control, dominance, and exploitation; instead, we are called to reconnect with the social and ecological community in a more collaborative and respectful engagement. This framing might seem to work against notions of agency if we are being called to turn away from an impulse toward power and influence. Viewed in a different light, however, we do not have to surrender agency as we embed ourselves in our socioecological community in ways that are consistent with childhoodnature. In fact, we can work toward a higher form of agency by moving past control and directing our efforts toward mutual accommodation with the human and nonhuman, living and not-living parts of our surroundings.

Continuing to draw from Greenwood's insights, we can explore three "critical questions" he proposes for place-conscious learning:

- What happened here?
- What is happening here now and in what direction is this place headed?
- What should happen here?

The first of these questions – *What happened here?* – opens us to looking backward. Like many great questions, it can be approached from several directions. It can be answered by reading the landscape surrounding us, as well as through a broad, culturally inclusive reading of human history in the land. In the ecological sense, it challenges us to develop an ability to see what is in front of us in terms of the forces and factors that led up to this point. Common examples here might include observing evidence of bank erosion that has degraded water quality over time or using historical maps and photographs to see how a community has changed. One of the aspects Nate and Nathan found interesting in their creek study was to note the changes over the course of the twentieth century as what was once a heavily wooded riparian corridor was transformed into a concretized channel broken up in places by the creek being totally submerged underground. Historic photographs paired with field investigations made suburbanization very real for the young researchers. If we are to leverage the benefits of being rooted in place, we need students (and the rest of us!) to develop this foundational ability to see nature and communities as processes in flux and to understand that what we are seeing now came to be because of a set of previous natural conditions and social choices. So, we should always have before us the key question: What happened here that got us to this place? It is important to remain cognizant that we are not the only people who have lived on this land. Indigenous communities may or may not still have an immediately noticeable

presence in your community, but the fact remains that our community life today has both continuities and differences with the ways in which others have lived in the same space. This in turn opens the door to considering cultural differences in how people have interacted with the environment to meet their needs. With this, it is good to look for similarities in cultural practices that are driven by factors such as the climate and natural resources within your ecoregion. This effort reinforces the idea that we live *within* and not *above* nature, though modern technology does let us avoid constraints in this regard, at least for a time. All of these strands offer very fertile spaces for inquiry, leading to deeper ways of knowing our place that transcend traditional academic subjects.

The second question – *What is happening here now and in what direction is this place headed?* – challenges students to engage in systems thinking as they look at both the natural and social systems at work. Rather than seeing their local place as a static painting, students need to see themselves within active and ever-changing ecosystems and communities, with components linked by a number of competing and complementary processes. In many ways there is considerable overlap with the previous question, in that both require an ability to "see" the landscape. Here the focus is less on seeing change over time and more on what is happening in the moment. How are animals meeting their needs? Are fluctuations in weather conditions influencing local plant growth? To understand what is happening now, students need to improve continuously their ability to see how multiple factors interact, supporting some processes and limiting others. From here, trying to predict the future requires the ability to see how processes play out over time. I will consider the normative "what if" questions in a moment, but at a simpler level, if the local community is left to itself, what will happen as the core social and ecological processes play out? Systems thinking skills are essential here as students interweave understandings of how cultural, biotic, and abiotic factors interact and how feedback loops can maintain the status quo or create long-term destabilization.

As young people investigate and reflect on current conditions and potential future directions, they should look at the role of humans as an integral part of this process. To guard against seeing ourselves as separate from nature, we need to be very aware of how we draw from the land to meet our needs and how our choices impact the land, both locally and far away. Key questions relate to who is working to be in harmony with the land and how are they doing it? Who is improving the land? (With that, what do we consider an improvement?) Who is making choices that separate us from the land? What motivates these choices? All of these are important considerations at any age, though the degree of sophistication brought to the questions will vary with the students' capabilities. Our task as educators is to foster the kind of experiences that nurture growth over time. Here, Dewey's (1916/1966) description of experience as an interplay of "an active and a passive element peculiarly combined" seems particularly apt, as we foster synthesis emerging from students' direct engagement with the world, coupled with opportunities for both structured and informal reflection on that engagement. Over time, these rich experiences support growth in the sense of an increased ability to learn from future experiences.

The third question – *What should happen here?* – raises interesting moral and ethical questions that have potential to support young people's growth and identity development in ways not often supported in traditional curricula. If students' engagement with the first two questions has anchored them in the full history of the land – the living and non-living, social and ecological, past and present – they will be well equipped to think creatively and critically about future possibilities. As they do this, they will need to be able to draw on an age-appropriate set of skills and perspectives on the land as they consider the future. While the scope of Greenwood's third question is primarily moral, we need to be careful not to lose a grounding in the social and ecological dynamics we hope to see emerge from (or perhaps be maintained in a manner consistent with) the current conditions. Given that both biological and social ecosystems have inherent continuities, there is little value in visioning exercises that happen in a vacuum. They often devolve into fits of wishful thinking, as exemplified by a teacher we worked with who wanted our maple syrup program to be offered in the late spring since warmer days would make for a nicer field trip.

To be effective, moral visioning needs to draw upon the history of what has come before and an understanding of how things got to the place they are today. So, the many (often contested) stories of the land need to be factored in, as does an analytic look at how the interplay of different biotic, abiotic, and social factors contributed to developing the current reality. With that, we also need a healthy dose of humility in recognizing that we do not know everything, and there is much that is beyond our control. Former US Defense Secretary Donald Rumsfeld (US Department of Defense, 2002) inadvertently captured a fundamental conundrum when he made his often-maligned comment about there being knowns, known unknowns, and unknown unknowns. Part of this uncertainty is the inherent, somewhat random variation in the world. Weather patterns fluctuate, and climate change will almost certainly lead to new ecological and social structures. Viewed in a much longer term, species will change. While evolutionary theory offers interpretive frameworks that are quite useful in understanding how we got to this place, there is no way to be certain that what we have is the only possibility or even the most likely one. While it takes place in a fictional setting with parallel worlds, Philip Pullman's *His Dark Materials* trilogy (1996) offers a useful reminder that evolution could lead to quite different outcomes that address the same survival need. In sum, we are better equipped to project future visions if we understand how we arrived where we are, but we need to be fully aware that we always operate with limited information and in a largely probabilistic world where future outcomes are hardly guaranteed.

Fostering Imagination

Moving forward in our analysis of agency, if young people (and the adults in their lives) are going to develop the capacity to engage deeply in a consideration of the past, present, and future of their community, they will need a fusion of what Steven

Fesmire has framed as ecological and moral imagination. Starting with ecological imagination, Fesmire (2010) defines it as:

> An outgrowth of our more general deliberative capacity to perceive, in light of possibilities for thinking and acting, the relationships that constitute any object. Such imagination is of a specifically ecological sort when key metaphors, images, symbols, and the like used in the ecologies shape the mental simulations we use to deliberate—i.e., when these interpretive structures shape what John Dewey calls our 'dramatic rehearsals.' (p. 183)

To clarify the context here, these dramatic rehearsals focus on how we might respond to a situation before us. When we act intentionally (and not impulsively), we choose from among these rehearsals. Continuing, Fesmire argues that ecological imagination lets us "zoom in on things, events, concepts, institutions, and persons without losing sight of their relational context—say, a child in relation to family, a sunrise in relation to the solar system, a statement in relation to its interpersonal, sociocultural, or literary context" (p. 184). Thus, a well-developed ecological imagination can help us to better understand the natural processes and webs of cultural beliefs which help to form the world around us and to appreciate the often-contested interplay of perceptions and beliefs that go with this. All of this holds promise for a more deeply engaging educational space, giving young people a better chance to cultivate over time the imaginative capacity to see the past, present, and future of our places.

While I find the concept of ecological imagination compelling, it is clearly not enough, since by itself it is value-neutral, and thus it could be used for exploitative purposes. Viewing the same issue from a broader vantage point, Dewey (1916/1966) is clear that growth by itself is not sufficient as a goal. One could get very good at being very bad. Imagine, for example, a real estate magnate using a highly developed ecological imagination to understand the processes by which he or she can extract the most revenue from the land. To fully realize the educative potential of place-based education, ecological imagination is needed, but we also need to draw upon (and continue to nurture) the development of a strong *moral* imagination. To do this, Fesmire (2006) lays out a challenging path, calling us to move beyond the somewhat simplistic notion of our values being nothing more than doing what we claim to prefer at the moment. Instead, we need to support students' progress in undertaking the fundamental human quest toward combining what we enjoy doing and what serves the greater good. Many consider such a fusion to be an essential part of living a meaningful and fulfilling life (Baggini and Southwell, 2012). Keeping our focus on place-based education, working to support personal fulfillment without also considering how our choices affect the greater good of the community has a risk of fledging rather narcissistic people.

Alas, the opposite end of the moral values spectrum is equally problematic. An expectation that we can rely on fixed moral commands to tell us what to do is likely to leave us wanting, since by their nature such dictums can be inflexible and thus inappropriate for the situation at hand. Here, Fesmire (2006) argues:

> When we turn to life experiences, we discover that moral decision making at its best has little to do with ready-made rules singling out the right thing to do. Principles are helpful summaries of past moral experiments, but letting them dictate behavior saps our ability to respond intelligently to unique situations that cannot fit prefabricated rules. And all situations are unique: just as you can't put your foot in the same river twice, you can't apply a rule to the same situation twice. Deliberation is more a matter of imaginatively scoping out what would happen if we acted on this or that alternative. In other words, moral rules cannot substitute for moral imagination." (pp. 255–256)

If we are to help young people build a life founded on ecological and cultural sensitivity, we need to do better than relying on their impulsive whims or on imposing fixed moral dictates. Developing moral imagination is complex work, indeed, but it is quite important nonetheless.

Pulling all of this together, Fesmire (2012) argues for the need to develop an "ecologically responsive moral imagination." This becomes imperative, he believes, when we recognize a number of interrelated premises. In making his case, he notes that "there is rarely a single right thing to do," and for that matter, "[w]e can rarely if ever do a single thing" (Fesmire, 2012, p. 215). If we embrace an ecological metaphor, it's hard to disaggregate the many interrelated connections involved. Hence, the options before us are inherently not simple choices. Further, he notes that "we cannot respond to everything that makes a legitimate demand upon us" (p. 216), which necessitates making difficult choices in a complex and perhaps murky environment. With that, we also make choices to leave things undone and perhaps even make choices that we know are ecologically unsound in the moment that we hope have a greater benefit in the long run. Those of us who have ever flown to an environmental conference should appreciate the irony. Navigating this space with a suitable degree of ecological and moral sensitivity requires an imagination that can see and respond to connections. Here Fesmire (2012) offers a vignette from his own life that should resonate with each of us: "To take a simple ecological example, many migratory songbirds I enjoy in summer over a cup of coffee are declining in numbers in part because trees in their winter nesting grounds in Central America are bulldozed to plant coffee plantations. Awareness of this amplifies the meaning of my cup of coffee" (p. 212). I am sure we can each add our own examples.

To recap the role of imagination as it relates to Greenwood's questions: If we are to see the past, the present, and the future of a local place and, with that, if we are to understand the underlying ecological forces and sociopolitical choices that led to current conditions, we need a well-developed imagination. This represents a significant point of departure from instrumental approaches to education that were satirized by Charles Dickens when he created Gradgrind, the school master in *Hard Times*, who wanted only facts: "Facts alone are wanted in life...You can only form the minds of reasoning animals upon Facts; nothing else will ever be of any service to them" (Dickens, 1854/1998, p. 7). Narrow approaches to education were also, of course, criticized in the late nineteenth and early twentieth century by John Dewey when he developed his arguments for a more progressive approach to education. Specific to the role of imagination, Dewey observed that "imagination is as much a normal and integral part of human activity as is muscular movement" (1916/1966,

p. 251). Today, instrumental goals still predominate in neoliberal approaches to education, which favor fidelity to prescribed curriculum paths and which reward assessment results showing an ability to reproduce approved truths on schedule.

By way of contrast, imagination as it is articulated by Fesmire requires a more open-ended approach to thinking which is able simultaneously to apply critical and creative readings to what is known and to fill in the gaps in knowledge where necessary. Phrased differently, to understand place and to exercise agency within it, we need the capacity to engage in a level of integrative thinking and to be comfortable working with Rumsfeld's "known" and "unknown" unknowns. Imagination in this context is a sophisticated, flexible cognitive process, not the fluff version that is often derided by modern-day Gradgrinds. Here Fesmire (2003) draws on Dewey when he remarks that "Dewey cautions against the custom of identifying the imaginative, which is interactively engaged and rooted in problematic conditions, with the imaginary, which is subjective. Neither the imaginative nor the imaginary occurs *ex nihilo*, independent of a bio-cultural matrix, but only the imaginative necessitates courage to engage the present and stretch" (Fesmire, 2003, p. 65).

Toward Effective Agency: Challenges and Opportunities

As the Chapter comes to a close, we are now well positioned for a critical consideration of place-based agency. Many projects, including those shared in this Chapter, illustrate the great potential for learning based in the local community. These individual ventures can be very meaningful in the moment, but we need to be more intentional about sequences of experience if we want to scaffold growth in agency. As noted at the outset, there is little explicit guidance in the place-based education literature concerning how we can structure and sustain youth engagement in ways that build agency. In this closing section I argue that we can best support this growth through long-term commitment and identity development attached to place.

As the broadest level, simply having young people "do something for nature" as part of an ecology unit before moving back inside serves to reinforce human separation from nature. Instead, we need to build from a fusion of Greenwood's articulation of place connection (past, present, and future) and the moral and ecological imagination Fesmire advocates. Deep, imaginative connection to place is the foundation of agency and, arguably, of growth more broadly. If students have a suitable grounding in their local space, they are well equipped to start thinking about next steps, building from a moral and ethical vision of short- and long-term futures. To do this, four design principles are integral to agency-supportive place-based education:

Age-appropriate youth control: Recalling Hart's Ladder of Participation, we need to scaffold ongoing growth toward increasing levels of youth engagement. One might think of this as a continuum from projects which are *assigned* to those that are (youth) *designed*. Implicit in this, of course, is the premise that the intended scope of youth engagement is developmentally grounded to ensure that their efforts are positioned at a level where participants feel competent in the moment and are

supported in their growth. Two simple examples that I have seen include a poster campaign undertaken by students at a local middle school to remind people not to idle their car engines and a second effort done in partnership with local convenience stores to let people buy drink refills with reusable drink containers. While middle school students are not equipped to take on the automotive or soft drink industries, these two efforts are well scaled to sustain youth involvement and serve as building blocks for more ambitious future projects.

Continuous development of skills and dispositions: Too often, we hold back on student involvement and focus on developing skills for some unspecified later use. Whether this is driven by a need to "cover" the curriculum or by a fear that students just do not know enough to make a difference, the lack of authentic engagement endemic to many learning contexts in and out of school reduces motivation to develop needed skills and dispositions. I often find a basketball analogy useful here. If students never play a game, developing skill in making free throws is tedious at best. However, once students have game experience, they can see how the ability to sink free throws is an essential skill, especially when the game is on the line. While truisms can be overused, it might be good to focus on learning what is needed "just in time" and not "just in case" it is ever needed.

Nurturing interest and commitment through connection: Along with providing a context for ongoing skill development, sustained connection to place nurtures interest and commitment. Quick one-off projects such as the "express garden" installation I described earlier, or programs for scouts where a badge can be earned in a day, simply do not have this capacity. Instead, we fall back on vague hopes that something has been sparked for the participants that they will carry forward on their own. While this may happen in some cases, I am skeptical that it is the norm either for over-scheduled suburban youth who are all too quickly on to something else or for the many urban youth we work with who do not have the resources or mentorship to scaffold sustained interest and commitment. Instead, we need to design for this level of connection by fostering sustained involvement with increasing levels of engagement and sophistication.

Fostering depth through enhanced interest: With sustained interest and commitment, participants can achieve a depth that is virtually impossible to achieve with one-off, disconnected projects. If instead we are able to nurture interest through sustained commitment to a project, participants are well positioned to develop both a depth of understanding and an expanded tool kit of skills, both of which are essential to developing agency. If we are to make a difference in the world, we need to see things with a level of detail and complexity that goes beyond headlines or immediate impressions. As we move toward deeper and more nuanced engagement, we come to understand more and want to learn more. It's a virtuous cycle that cannot happen if everything stays at a surface level. Educationally, this depth fosters capacity in reading and writing increasingly complex texts and in effective use of data. These foundational skills are part of most school curricula, but they often wither for lack of authentic use contexts.

Taken together, these four intertwined design principles let us build on the base of connection and imagination. In my experience, this can happen even with young

students, which lets us support place-based work at a level well beyond simple projects like cleaning up litter. For example, my staff and I often partner with local schools to support the development of native plant gardens. While each project has its own features, the ideal baseline is that the students have an age-appropriate say in determining what project they undertake. From there, if they choose to develop a native plant garden, we help them learn in more detail about the ecological benefits of native plants. We also help them to investigate the location where they will be planting. As planning for their garden continues, they learn the specifics of different plant options, including the botanical and ethnobotanical background of each plant. From there, the students design, build, and maintain their garden with our support and the help of their teachers and others in the community.

Projects like this capture (on a school-friendly time and space scale) the potential young people have to envision ways their community could be improved and to act on that impulse in a productive way. Key outcomes in this process include (1) connecting the students to a patch of land which is "theirs," at least for the time they are at the school, (2) giving them a chance to envision alternative uses that are informed by scientific and cultural knowledge, and (3) providing the space for a sustained experience of being better connected to the community. While the ecological benefits of small-scale projects like this may well be negligible, as an educational practice the work has much more potential for lasting impact than would be realized if students simply read about the benefits of native plants. Too often, those latter experiences amount to an implied exhortation that an unnamed *some*one should do *some*thing *some*time. Even though the scale of most place-based projects is small, giving young people a chance to envision the future and act on it has much more potential to build a disposition toward productive agency in the world.

Conclusion

The consistent element in all of this work is seeing ourselves as powerful but not autonomous agents. The legacy of human impact on the land shows an enormous capacity both for destruction and for care. By positioning ourselves within – and not separate from – the nested ecological and social systems we are a part of, we can best realize our place in the world and act as a citizen of the communities we find there. Helping young people grow toward this level of collaborative agency requires care and wisdom that is responsive to their needs and interests. It cannot be scripted or limited to a single curriculum unit. Still, there are paths that can help us get there. Viewing the land and all of its living and non-living elements from the perspectives of the past, present, and future helps to situate us more fully than if we simply go to nature for a service project. As we take on this larger effort and embed ourselves ever more deeply in our local community, we need to work continuously to develop the ecological and moral imagination that allows us to see the world before us and envision what we are called to do. Together, vision and imagination enable us to take on increasing responsibility, equipping us to live as an agent in harmony with the land and each other.

Abstract

Reflecting the growing momentum around childhoodnature, there has been enormous interest in increasing opportunities for young children to experience nature-based play. This has resulted in considerable efforts by early years' settings to naturalize their outdoor play areas, introducing polymorphic natural features,

such as pebbly creeks, mud pits, and willow arches. Inherent in these efforts is an assumption that children will connect with and become immersed in nature as they play. However, there has been little research exploring *how* young children experience nature through nature-based play, particularly when it occurs within the confines of an early childhood (EC) setting. Further, little is known about what might influence their experiences in this context.

This Chapter draws upon qualitative data from Australian preschool children and their educators to build these areas of knowledge. Informed by sociocultural theory, along with notions of flow, the data indicate that children's experiences of nature and nature-based play in EC settings occur across a continuum, from immersion in nature-based play to nature acting as a backdrop to play. Critical to this section of the Handbook, it is educators' pedagogy that emerges as playing a central role in shaping these experiences. In examining the data, this chapter explores the facets of pedagogy – educators' values, beliefs, and behaviors – that appear to best afford children the opportunity to become *immersed* in their nature-based play.

Nature play · Nature-based play · Early childhood pedagogy · Nature pedagogy · Flow

Introduction

The thesis of childhoodnature – that children *are* nature – is perhaps most readily apparent in babies and toddlers who tend to be uninhibited in engaging with nature in an "embodied" manner – they are active, sensory, experiential, and situated in their interactions (Hyun, 2005; Payne, 1997). Over time, a wide range of sociocultural factors – implicit social messages about dirt, transfer of fears or disinterest in the outdoors, and lack of opportunities for extended interaction in naturalized, outdoor environments – can act to socialize children away from nature and its processes (Hyun, 2005; Orr, 1994). The preschool years, when children increasingly grasp social nuance and language, may potentially be one of the key turning points in this process of dissociation from nature, particularly within affluent countries such as Australia.

There is a now established interest in nature-based play within early childhood research and practice worldwide, a trend that has been proliferating in Australia in recent years (Elliott & Chancellor, 2014). This interest responds to concerns that many children in countries such as Australia are being denied of extended outdoor play opportunities at a cost to their health and wellbeing (Bowden, Band, & Gray, 2011; Waller et al., 2017). Through nature-based play, educators seek, sometimes somewhat romantically, to offer children a sense of joy, creativity, and adventure but also to capitalize upon the reputed wellbeing and learning benefits it offers (Waller et al., 2017). These can be fairly anthropocentric (Cutter-Mackenzie, 2010), including learning to negotiate risk and challenge, opportunities for more complex,

imaginary play, advanced motor skills, and the development of social and emotional abilities (Waite, Passy, Gilchrist, Hunt, & Blackwell, 2016), but of particular importance to this Handbook are also desires to foster a deeper connection to the natural world with its intrinsic links to mental and spiritual wellbeing (Waite et al., 2016; Waller et al., 2017).

The nature kindergarten and forest school models of Europe have been a strong influence behind the nature-based play agenda in Australia (Elliott & Chancellor, 2014). These models have offered a nature pedagogy of sorts in that identifiable aspects of the approach remain consistent across settings and countries, with accredited training available in some countries, such as in the UK (Knight, 2009). However, the majority of research has been evaluative, highlighting the benefits rather than critically examining pedagogy in the context of nature-based play. This has created a knowledge gap, which has become particularly apparent as the grassroots nature-based play movement has expanded into other spaces, as well as other cultures (Waller et al., 2017; Warden, 2015). This knowledge gap has only very recently begun to be engaged with, and notions of "nature pedagogy" (Warden, 2015) in early childhood education are still very much in their infancy.

This Chapter reports upon a study that sought, in a broad, open-ended way, to explore children's nature-based play within everyday outdoor green spaces. It draws upon the data from two early childhood settings in NSW, Australia, which had been inspired by the nature-based play movement to re-naturalize their outdoor playgrounds. While the study was exploratory, aiming to examine *how* children experience nature and play within the confines of these familiar settings, educator pedagogy emerged as the strongest and most critical component of the findings and analysis. Correspondingly, the focus in this Chapter is on the interplay between children's *experiences* and educator *pedagogy*, with exploration of the facets of pedagogy that appear to best afford children opportunities to become *immersed* in their nature-based play within the confines of naturalized playgrounds of EC settings.

Early Childhood Pedagogy in Australia

Pedagogy has come to be commonly, albeit somewhat elusively, defined as the art or science of teaching (Alexander, 2008). While it is an expanding concept, it is often narrowly applied in terms of action rather than theory – the professional *practice* of teaching. For the purposes of this Chapter, I take a broader conceptualization, aligning with Alexander's (2008) assertions that pedagogy encompasses a teacher's underlying beliefs and values about their students, about the process of learning, and in this case perhaps about children and nature, *as well as* the ways in which these beliefs and values influence their approach in practice.

In Australia, the Early Years Learning Framework (EYLF) (Department of Education, Employment and Workplace Relations, 2009a) aims to foster shared national beliefs and values among early childhood educators regarding children and the process of learning. The accompanying educators' guide (Department of

Education, Employment and Workplace Relations (DEEWR), 2010) argues that without this, "Educators' individual images, beliefs and values about what children should be and what they should become influence both the planned and unplanned curriculum experiences and learning of children and can lead to wide differences in outcomes for children" (p. 14). The foundational beliefs and values advocated in the guide are as follows:

- Children are capable and competent
- Children actively construct their own learning
- Learning is dynamic, complex, and holistic
- Children have agency – they have capacities and rights to initiate and lead learning and be active participants and decision-makers in matters affecting them (Department of Education, Employment and Workplace Relations, 2010, p. 14).

Clear within these beliefs and values are connections to children's participatory rights, as afforded to them under the United Nations Convention on the Rights of the Child (United Nations, 1989), as well as to sociocultural understandings of learning and development (Rogoff, 2003; Vygotsky, 1978). Given this participatory and sociocultural basis, the EYLF (DEEWR, 2009a) does not include any predefined areas of knowledge that children must learn. Rather, educators are encouraged to foster a collaborative and playful dynamic between themselves, the children, and relevant learning content, based around the daily routines, arising interests, and community context of the EC center. Within this collaborative process, the children's general knowledge, understanding, and skills will expand, but the focus for educators is on intentionally nurturing five key attributes. These attributes, referred to as "outcomes," are positioned as socioculturally relevant to children both in the present and for the future. They include their sense of identity, their sense of connection and capability to contribute to their world, their wellbeing, their confidence and involvement as learners, and their ability to communicate effectively (DEEWR, 2009a).

Despite the above, Australian research conducted just prior to the launch of the EYLF highlighted that sociocultural theory is poorly understood by EC educators (Edwards, 2006), and even when it is understood, making the necessary mindset shifts to fully adopt the beliefs requires considerable time and commitment, particularly for these beliefs to become actualized in pedagogical practice (Edwards, 2007). Further, following the launch of the EYLF, increased research attention surrounding how best to collaborate with children appeared to lead to a "cognitization" of early childhood theory in Australia (Fleer & Peers, 2012). This referred to a preoccupation with how to most effectively expand children's cognitive understandings, rather than focusing on the EYLF outcomes (DEEWR, 2009a), and a resultant shift away from child-led play. This slippage resonates with worldwide concerns about the "schoolification" of early childhood education (Waller et al., 2017). It also echoes findings from practice-focused research in the UK, which identified that many educators struggle to "contribute to, without commandeering"

collaborative interactions with children (Waite, 2011, p. 75), running the risk of diluting children's sense of participation and their subjective sense of the activity as play (Waller, 2007; Waters & Maynard, 2010).

In an effort to redress these issues in Australia, Fleer and Peers (2012) argued that educators have important collaborative roles in children's imaginary play, such as fostering the "collective imagination" by engaging in imaginary conversations with the children (Fleer & Peers, 2012, p. 423). This resonated with the Vygotskian-based "Tools of the Mind" approach in the USA, in which a key role of the early childhood educator is to scaffold purposively increasingly mature play skills, such as assigning a role to open-ended props, taking on and sustaining attributes consistent with a specific character, and adhering to the implicit rules of the established play scenario (Bodrova, 2008). Bodrova (2008) has proposed that in previous generations, when children played more regularly in mixed age groups (often outdoors), this process likely occurred effortlessly, with older siblings or neighborhood children modeling these sorts of play skills.

What is evident then is that collaborating with young children offers the *potential* to bridge dichotomies between play and learning and between cognition and imagination. Further, when practiced well, it can offer added benefits for children, through the intentional modeling of skills and behavior relating to wellbeing, rights, positive relationships, and respect for others and the environment (Waller et al., 2017). Yet, considerable tensions remain around the actualization of effective collaboration in practice.

Pedagogical Values Relating to the Outdoors

Naturalizing the playground of EC settings offers the opportunity to expand opportunities for collaborative play and learning (Blanchet-Cohen & Elliot, 2011; Waters & Maynard, 2010). Naturalized spaces offer scope for new daily or seasonal routines (from managing a worm farm to sweeping fallen leaves). Natural features also provide changing loose materials and interesting affordances to capture children's curiosity (Blanchet-Cohen & Elliot, 2011; Waters & Maynard, 2010), which can stimulate open-ended "joint attention" (Smith, 1999), "sustained shared thinking" (Siraj-Blatchford, 2008), and imaginary play (Waller, 2007). However, competing values regarding children and nature, and about children's outdoor play more generally, create added complexity for educators around collaborating with children outdoors (Ernst & Tornabene, 2012; Mawson, 2014; Waller et al., 2017).

In Australia, the EYLF (DEEWR, 2009a) offers a starting point in considering values and purpose for outdoor play and learning. Nature and the outdoors are not a primary focus in the document, but there is a scope for nature-based play within several of the outcomes, including:

- Outcome 2: Children are connected with and contribute to their world (particularly the sub-outcome, "children become socially responsible and show respect for the environment") (DEEWR, 2009a, p. 29).

- Outcome 4: Children are confident and involved learners (in the sub-outcome entitled, "children resource their own learning through connecting with people, place, technologies and natural and processed materials") (p. 37).

Within these, it is notable that, while there is reference to connection, nature is positioned largely in an anthropocentric way, as an environment to be cared for and a resource to be utilized for learning and play. Further, the dual emphasis on caring for *and* utilizing nature offers little pedagogical guidance in finding a balance between fostering environmental values (and/or preserving natural features in the preschool grounds) and affording rich, exploratory experiences.

In turning to the field of environmental education more broadly, this tension between preservation and exploration has long persisted and is embroiled in issues around the role of adults. On the one hand, adult mentors are positioned as playing important sociocultural roles in validating children's connections to nature as well as more purposively fostering sustainable mindsets (Asah, Bengston, & Westphal, 2012; Chawla, 1999). On the other hand are concerns that children are predominately experiencing outdoor, naturalized environments in supervised, structured, and programmed ways (Kellert, 2002). There is apprehension that this risks a "look, don't touch" approach (Sobel, 2012) that may disconnect children from nature (Hyun, 2005) and even foster feelings of "ecophobia" (Sobel, 1996).

Educational research on outdoor play and learning tends to be fairly consistent in advocating that educators need to be purposeful in modeling interest and enthusiasm for nature and the outdoors, intentional in helping children nurture and maintain their connection to nature, and to consciously challenge themselves as educators with regard to allowing children to experience risk (Sandseter, Little, & Wyver, 2012; Waller, 2011; Waller et al., 2017). Existing educational research indicates that these practices seem to occur most effortlessly in Scandinavian nations, where cultural priority is attached to being connected to nature (Maynard & Waters, 2007; Sandseter et al., 2012). In Australia, connection to country is central to Indigenous cultural heritage and identity, yet like other anglicized countries, nature is not so central to Australian cultural identity at national level (Fargher, 2012). Therefore, like other anglicized nations, educators may lack a sense of purpose toward nature-based play, and hold varying levels of commitment to outdoor play and learning (Maynard & Waters, 2007; Waite, 2010).

Those educators most likely to make intentional use of natural outdoor spaces tend to have a deep personal connection to nature and hold a strong belief that the experiences are important for children's health and wellbeing (Ernst & Tornabene, 2012). However, these intentions can be complicated pedagogically by a sense of romanticism toward outdoor play (Waite, 2007; Waller et al., 2017). Indeed, one of the most consistently identified values among educators toward outdoor play and learning is a desire to offer children a sense of freedom and discovery, and this can leave educators feeling reluctant to seek opportunities to involve themselves in children's play outdoors (Mawson, 2014; Maynard & Waters, 2007; Waite, 2011). Overlaid upon this are practical issues, particularly tensions around risk (see, e.g., Little & Wyver, 2008), which can again lead them to focus on general supervision

rather than seeking opportunities to collaborate outdoors (Blanchet-Cohen & Elliot, 2011; Maynard & Waters, 2007). Given such complexities arise alongside existing tensions around the actualization of collaborative pedagogy in early childhood education in Australia, there has been increasing interest in the notion of "nature pedagogy" (Waller et al., 2017; Wynne & Gorman, 2015).

Nature Pedagogy

Insights into the sorts of beliefs and values that might underlie nature pedagogy can be drawn from existing place-based pedagogies (Wattchow & Brown, 2011) or ecopedagogy (accredited to Paulo Freire but further developed by others, particularly Kahn (2010)). However, in EC education in Australia to date, it has been the nature kindergarten and Forest School models of Europe that appear to have achieved the greatest traction (Elliott & Chancellor, 2014). These offer a pedagogy of sorts in that aspects of the model have remained identifiably consistent even it has spread to different countries and environments (Elliott & Chancellor, 2014; Knight, 2009). Notably, this includes the practice of utilizing a small naturalized area, often within a larger "wild" environment such as a forest, park, or beach, which becomes a familiar "base camp" for activities. In this space, basic boundaries are established, and then emphasis is placed upon child-initiated play and learning, including the facilitation of healthy risk taking. The model tends to promote utilizing the resources nature provides rather than adding toys or additional resources, and as such collaboration tends to occur democratically and spontaneously. Many beneficial outcomes have been identified in evaluations worldwide, including notably the strengthening of relationships between children and educators as well as among children (Elliott & Chancellor, 2014; O'Brien & Murray, 2007). However, beyond Scandinavia, nature kindergarten-style experiences tend to be weekly visits to a nearby forest, park, or beach and as such may be a time when an alternative pedagogy is consciously adopted. Outside of Scandinavia, it is unclear to what extent the pedagogical-type tenets of the nature kindergarten model would be sustained within the more limited confines of everyday early childhood playgrounds.

Recently, influential and entrepreneurial Scottish educator, Claire Warden, has been promoting the need to articulate a natural pedagogy that can cross context, environment, and cultural boundaries (Warden, 2015). In 2016 she founded the International Association of Nature Pedagogy (www.naturepedagogy.com), and her ideas have gathered particular interest in Australia (Wynne & Gorman, 2015). Warden defines nature pedagogy as "the art of teaching and learning *with* nature inside a classroom, outside in nature and then beyond in wilder spaces" (emphasis added) (www.naturepedagogy.com). Her ideas are aligned with notions of childhoodnature, positioning children as part of the earth's natural system. She identifies five environmental and social aspects that shape experiences of outdoor play and learning: topography, space, resources, time, and the adult role (Warden, 2015). Each of these is positioned as a continuum, generating a vivid image of dialing up and down the various aspects. However, despite grassroots momentum,

little research has explored the concept of early childhood nature pedagogy. This chapter seeks to contribute to this emerging area of interest, by reporting on a study that offers nuanced insights into the inherent tensions surrounding the adult role in nature-based play.

Background to the Study

This study was explorative, with an overarching aim to examine how young children experience nature-based play within everyday green spaces. It involved two mainstream Australian early childhood centers, approached for involvement because both were known to have made changes to their playgrounds in an effort to expand opportunities for the children to experience nature-based play. The overarching method for the study was the customizable Mosaic approach (Clark & Moss, 2001), which offered the opportunity to bring together elements of ethnography and the participatory paradigm (Clark & Moss, 2001; Heron & Reason, 1997). Ethnographic-style observation encouraged the formation of interpretive understandings of nature-based play and attention to culture – children's culture, the culture of EC education, sociocultural shifts regarding children, nature and risk, as well as the individual culture of each center. A participatory approach allowed these interpretive understandings to be explored with the participants and for their reflections and meaning-making to contribute further insight. This combined approach was particularly valuable in relation to the concept of nature, a word initially unfamiliar to the children. It also became incredibly fruitful in helping to uncover some of the values and beliefs underlying the observable aspects of the educators' pedagogies.

The study took place in 2013 during a period of considerable reform for EC education and care in Australia. In 2009 a seminal national Early Years Learning Framework (DEEWR, 2009a) (as described above) was introduced, followed by a system of national quality standards (Australian Children's Education and Care Quality Authority, 2011), which includes assessment of outdoor provision. Then, in 2013 all children in their final preschool year (typically aged 4–5 years) were guaranteed access to an EC education and care program for 15 h per week, across 40 weeks of the year, delivered by a degree-level trained educator (DEEWR, 2009b). This could be delivered in a wide range of existing settings, including long daycare centers, dedicated preschools, or in preschools attached to primary schools. This study involved children in their final preschool year (hereafter referred to as "the preschool children") and their educators, at a long daycare center and a community preschool. Given the standardization implied by national reforms, the initial intention of the study was to explore nature-based play in a fluid way across both centers. However an unexpected level of disparity emerged, and as such the two settings came to be examined in a way more akin to two case studies. They are presented largely in this manner throughout this Chapter.

Theoretical Frame

The study was informed by a theoretical frame combining sociocultural theory (Vygotsky, 1978) and the concept of flow (Csikszentmihalyi, 1997). As signaled earlier, sociocultural theory is central to contemporary early childhood theory and practice and foundational to the Australian EYLF (DEEWR, 2009a). The theory stems from the ideas of Vygotsky (1978) who questioned assumptions that competency and ability were determined solely by biological ages or stages. He viewed learning and development as a culturally embedded process, occurring in response to situation and through interaction with others. This dynamic process is understood as being influenced by the child's engagement in their world and the expectations, opportunities, modeling, and requirements they encounter, along with and the nurturing and guidance they receive (Rogoff, 2003; Smith, 2013; Vygotsky, 1978).

As the values laid out in the EYLF (DEEWR, 2009a) indicate, applying sociocultural theory to education requires viewing children as inherently capable – to focus on their *capacity* for competency and to gently scaffold them to extend their abilities progressively, rather than being limited by predetermined ideas about what they can or cannot do (Edwards, 2007). However, dominant societal assumptions and beliefs about children and childhood, such as in relation to safety and protection, or expectations of supervision, may bear influence upon children's opportunities for nature-based play within early childhood settings (Lupton, 1999; Smith, 2013). Therefore, a sociocultural lens drew attention to the dynamic, social, relational, and cultural processes surrounding the nature-based play movement. It encouraged examination of *how* nature-based play was encouraged, facilitated, or otherwise within the socio-relational milieu of each individual center and in particular the social and pedagogical interactions surrounding and integral to this play.

Where sociocultural theory offered insight into the processes surrounding nature-based play, the concept of flow (Csikszentmihalyi, 1997) offered a way to consider the children's lived experiences. *How* did they experience nature-based play – as play or as work, as free or restricted, or as something enjoyable, relaxing, or boring? Csikszentmihalyi (1997) describes the experience of flow as "the state in which individuals are so involved in an activity that nothing else seems to matter" (p. 4). Although flow requires the conscious directing of attention, it is understood as resulting in a relaxation of the brain from full arousal to a focused state of peak efficiency. Therefore, flow is described as "optimal experience." It is linked to happiness, an intrinsic sense of satisfaction and personal growth, with growth occurring both in the skills of the activity and in higher consciousness (Csikszentmihalyi, 1997).

Flow is of particular interest to learning as it taps into students' intrinsic motivation to enhance their skills and to continually repeat this experience of growth. The EYLF makes reference to flow in describing it "as a state of intense, whole-hearted mental activity, characterised by sustained concentration and intrinsic motivation" (DEEWR, 2009a, p. 45). It is suggested that educators can recognize the flow state by children's "facial, vocal and emotional expressions, the energy, attention and care they apply and the creativity and complexity they bring to the situation" (DEEWR, 2009a, p. 45). Notably though, no guidance is offered on how to facilitate these

experiences. Utilizing the concept of flow in this study allowed for exploration not only of the children's experiences but also to consider how educators might balance the delicate task of extending children's learning through collaboration while not destroying the essence of children's self-directed play.

The Early Childhood Settings

The study involved two EC centers situated in similarly demographically diverse, medium-sized towns, in NSW, Australia. The centers were intentionally approached for involvement because both were known to have a keen interest in expanding opportunities for children to experience nature-based play. One was a private long daycare center (referred hereafter as "the daycare"), which operated daily from 8 am to 6 pm all year round and accommodated approximately 80 children between birth and 5 years of age. The daycare grouped children according to age, with each group having their own room indoors. The large outdoor playground was shared, and children between the ages of 2.5–5 years often played outside at the same time. However, only children from the oldest group (aged 4–5 years) and their educators were involved in this study. The second setting was a not-for-profit community preschool (referred hereafter as "the community center"). It operated daily between 8 am and 3:30 pm during school term time and catered to approximately 45 children aged 3–5 years.

The outdoor play space at the daycare was bigger and had greater expanses of grass, but aside from this, the outdoor areas at both settings were comparably naturalized, with mature trees, small bushes, and other vegetation. Both had some landscaping features involving slopes, rocks, and bridges, as well as nature-specific features such as frog hotels (pipe constructions for frogs to hide in). Also, both had areas of patio, large sandpits, cubby houses, and some playground equipment, including swings, which were surrounded by bark rather than artificial softfal surfacing. In addition, the centers had recently added vegetable plots and passionfruit vines. The centers were situated in a subtropical region of Australia inhabited by different species of snakes, including venomous brown and red-bellied black snakes, and many types of spider, including poisonous redbacks, presenting uniquely Australian outdoor risks. At both centers, outdoor playtime tended to be scheduled in the morning from approximately 9 to 10.30 am to comply with sun protection guidelines. At the daycare, another session of outdoor play was sometimes programmed toward the end of the day, although I only observed the morning sessions at both centers.

The Participants

Four educators were involved in the study, two from each setting. These educators worked directly with the preschool children on a daily basis. All of the educators were fairly experienced, although they held a range of qualifications as detailed in Table 1 below. As Table 1 highlights, both centers had already employed degree-qualified educators long before this was mandated by the national reforms.

Table 1 The educators involved in the study

Setting	Educator pseudonym	Job title	Highest relevant qualification	Years of experience at time of study	Length of service at the setting (years)
The daycare	Donna	Room leader (preschool group)	Specialist early childhood degree	16	6
	Danielle	Assistant educator	College-level, workplace-based certificate III in childcare	8	8
The community center	Christina	Center director (and room leader)	Specialist early childhood degree	Unknown	24
	Cath	Room leader	Diploma in early childhood education and care	Unknown	28

Twelve children participated in the study, six from each setting. Eleven of the children were aged 4–5 years and were often some of the oldest at their setting. One child participant at the community center was 3 years old. I aspired to make the research experience enjoyable and playful for the children and invited them to make up their own pseudonyms. I wrote these onto wooden necklaces, like the one I wore when I first attended the center and which the children had admired. We all wore them when we were "doing" our research. At the daycare, the children decided to choose pseudonyms based upon their personal interests. I worked with four boys, Ninja Turtle, Superman, Spiderman, and Surfing, and two girls, Catwoman and the Bead One. At the community center, the children chose to continue the researcher theme and labeled themselves as Dr. and then their first initial. Therefore, at the community center, I worked with Dr. K, Dr. E, Dr. F, Dr. J, Dr. L, and Dr. M. All were girls expect for Dr. F.

Methods

The fieldwork was undertaken several times per week over a 2-month period in late autumn. In line with the customizable Mosaic approach (Clark & Moss, 2001), a range of methods were employed. I began with an initial period of participant observation during which I recorded field notes by hand and interacted with the children mainly following their request or initiation. After 2 weeks of observation, I moved into a more participatory phase with the children and their educators, which involved child-led tours of the playground, child-framed photography, and making collages. These were undertaken in small, child-nominated groups of three and were

undertaken with the aid of a "research assistant," a handmade fictional puppet called Wattle-Pottle. Wattle-Pottle helped to bring a playful feel to the research process and was positioned as being the one with the interest in nature-based play. This additional "persona" afforded the children considerable agency and influence in the research process as indicated further in the section on "Ethics" below.

Toward the end of the fieldwork, I undertook an individual, semi-structured interview with each of the four educators, arranged at a mutually convenient time. Each interview lasted between 30 and 60 min and took a reflective approach to exploring motivations for nature-based play and arising aspects of pedagogy.

The interviews and the participatory activities were digitally recorded via an MP3 player (which I wore on a string around my neck during the more active activities with the children). I transcribed these as soon as possible after each visit, which aided in identifying the voices of the children. The collages were photographed so that the original collages could be left at the centers to share with parents and as a record of the children's work. The field notes were typed up and collated with the photographic material and transcriptions. I took a thematic approach to analyzing this combined data, initially organizing it under overarching headings: childhood, play, learning, nature, and risk (Lofland, Snow, Anderson, & Lofland, 2006). I then used manual coding and memoing to cyclically readjust, collapse, and expand the emergent themes and subthemes (Glaser, 1965).

Ethics

The research was granted ethical approval by the University's Human Ethics Committee (grant number ECN-12-274). In addition, influenced by the ERIC Charter and Guidance (Graham, Powell, Taylor, Anderson, & Fitzgerald, 2013), ethics was approached as an ongoing reflexive endeavor throughout the study. For instance, the settings were recruited for the study through initial contact with the educators. Once they indicated an interest in participating, the directors of the settings were contacted officially to request permission. This aimed to increase the likelihood that the educators would be interested in becoming involved in a participatory way in the study and to reduce the risk that they might feel obliged to participate through workplace hierarchies. Formal informed consent was then sought from each of the individual educators.

The educators were asked for assistance in identifying a diverse range of children based on attendance patterns and likely interest in being involved. They generally suggested the oldest children at the centers, for whom they felt the study would offer a new and different experience. Invitations and consent forms were sent to the children's parents. In addition, in line with contemporary ideas about ethical research involving young children (Ruiz-Casares & Thompson, 2016), a child-friendly information sheet with pictures was enclosed, and parents were asked to discuss it with their child. This information was also reiterated to the children at the beginning of the observation and participatory phases, along with their right to discontinue or

restart their participation should they wish to. The children were also monitored for physical signs of assent or dissent throughout the study (Dockett, Einarsdóttir, & Perry, 2012). Notably, some children choose to briefly stop and restart their involvement during the study, and the youngest child, Dr. M., chose not to participate in the collage-making.

Even in research seeking to be participatory, there can be potentially limiting power hierarchies between the researcher and the children (Graham et al., 2013). The puppet, Wattle-Pottle, acted more powerfully than expected in helping to diffuse some of this. The children used him as a conduit to steer the direction of conversations or activities, to voice concerns, or to indicate dissent. For example, on one occasion Dr. K said, "I think Wattle-Pottle would like to paint now." Conversing through Wattle-Pottle, I was able to clarify that she was suggesting that we all do some painting on the easels on the verandah. This impromptu, child-initiated activity generated some of the richest inter-child dialogue regarding nature and nature-based play.

At the end of the study, summaries of anonymized results were prepared and disseminated to the educators and parents, along with a child-friendly version with pictures suitable to be read aloud to the children. The children were also given their wooden necklaces to take home as a memento of their participation.

Findings from the Study

The study found that the children's experiences of nature-based play could not be uncoupled from the pedagogy of their educators. Accordingly, while this Chapter focuses upon exploring pedagogy, it is necessary to preface this with an overview of the children's experiences. Central to these was the identification of a continuum, from nature providing a backdrop to activities through to the children experiencing "immersion" in nature-based play. Immersion in nature-based play was identified as a twofold experience. It encompassed children's *physical embodiment in nature* (Payne, 1997) – the opportunity to step into the mud, let the rain pour onto their face, hold a lizard in their hand, or experience the risky thrill of climbing a tree. At the same time, it reflected an experience of flow (Csikszentmihalyi, 1997) – children's deep and purposeful *absorption in the activity of play*. Through the links to flow, the experience of being "immersed" in nature-based play can be understood as an "optimal" childhood experience with nature (Csikszentmihalyi, 1997), with potentially important benefits for children's health and wellbeing, their experience of education, connection to nature, and possibly the sustainability of the planet (Bowden et al., 2011; Louv, 2008; Sobel, 1996).

Depending upon the activity they were engaged in, the children's play at each of the study centers could be located at either end of the continuum or somewhere in between, sometimes shifting across the continuum as their play evolved. However, the study children at the community center appeared much more commonly to be "immersed" in nature-based play. This occurred usually through sociodramatic or

creative play based around natural materials, which they often sustained in pairs or small groups for 40 min or more. These observations were reinforced in the conversations with the children and educators who talked extensively and with enthusiasm about this play. By contrast, the study children at the daycare did not often use natural materials or affordances in their play and engaged in much less imaginative or creative play. Instead, they tended to engage in physical play on the equipment (the swings, slides, etc.), in rule-bound games such as "What's the time Mr. Wolf" with the educators, or to walk around chatting to one another. In these activities, the children were rarely, or only fleetingly, observed to be in a flow-like state. Perhaps for this reason, the study children at this center verbally expressed feelings of boredom and frustration several times during the conversations I had with them, emotions that were never mentioned nor identified among the children at the community center.

There is a risk of overgeneralizing the nature-based play experiences of the study children from each center, and it is important to reiterate that the children were not engaged in one form of play experience all of the time. There is also potential to overstate the differences between the centers, although it will be recalled that the initial intention was not to compare the centers – they were chosen for their likely similarity. Indeed, given the similarity in natural affordances and materials in the outdoor areas of the two centers, it was a surprise to find such disparity in the children's nature-based play experiences. This begged further examination and offered an illustrative opportunity to explore the wider influences that might be shaping the children's experiences of nature-based play. Of particular prominence were facets of their educators' pedagogy – varying values, beliefs, and behavior that may have been acting to constrain or enhance the children's opportunities to become immersed in nature-based play. Below, results pertaining to four of these most prominent aspects of pedagogy are presented: values toward nature, parent partnerships, beliefs about children's capabilities, and approach to play and learning.

Values Toward Nature

The educators at both settings described the sustainable practices or wildlife gardening initiatives that were in place at each center, such as small vegetable plots, minibeast habitats, and frog hotels. At the community center, these initiatives had usually been driven by the educators, and tasks such as collecting produce from the gardens, monitoring levels in the water butt, and collecting scraps for the worm farm were particularly well-established within the routines of the center. Both educators at this center described with enthusiasm their personal passion for being in nature, for its beauty and wellbeing benefits, and the importance of preserving the environment for its own sake, as well as for future generations. As such, they appeared to feel deeply connected to nature and to hold the sorts of eco-centric values that resonate with the concept of childhoodnature. It was clear that they felt personally motivated

to foster opportunities for the children at their center to nurture their personal connections with nature.

> Christina: To me it's...the children kicking through the bark and the smell of the bark and...the emotional benefits of being connected with nature that they can take with them through their lives. It's not just the bigger picture [climate change etc.], which is really important, but it's actually something that is important for your emotional wellbeing...that relationship with nature is so important...Well, it is for me, so I suppose I would like that for them as well.

Correspondingly, the educators allowed and actively facilitated the children to have hands-on, full sensory experiences. The children frequently mixed up "potions" in the birdbath using water, petals, bark, and mud. They were allowed to climb low trees and sometimes cut fresh, "springy" branches to play with. There was also a "mud pit" where they could step right into the mud and allow it to ooze through their fingers and toes. As such, at this center, there appeared to be a fairly straight forward link between the educators' personal connections to nature, their values around nature and sustainability, and their rationale for nature-based play.

At the daycare, these connections were a little less clear. It was the owners of the center who had initiated the changes to the grounds, adding circular garden beds, hay bales, shrubbery patches, and a small bridge, as well as introducing the other features such as the vegetable plots. Both of the educators were appreciative of these, and Danielle described the playground as previously being "just blank from one end to the other." However, Danielle did not describe any particular connection to or personal interest in nature, although she did not describe any fears or dislikes either. Donna also did not have a strong personal interest in sustainability, but she did clearly articulate a personal preference for natural spaces:

> Donna: I've worked at a few different centres and [our backyard] always makes me feel better than the fake backyards, like they give me a different feeling. I really feel enclosed by them rather than comfortable...

She also had a fascination with insects, bugs, and spiders, something that was recognized by the children and staff throughout the center. At the same time though, she described that nature could be problematic or aesthetically unappealing, and there was a sense that she liked nature to be managed and under close control: "You just have to kill a few [spiders] and get rid of them." Both her enthusiasm for nature and desire to engage with it in a managed way were further evident in her wish for a professional to add "more adventure" into the playground area and to add natural landscaping features such as "a hill there, and tunnels there." As such, she emerged as having an ambiguous connection to nature, and although she certainly seemed to

value it, this was in a more anthropocentric way. When compared to the educators at the community center, there was much less passion for the messy reality of nature-based play. Indeed, it became apparent that some of the changes to the grounds at the daycare, while ostensibly driven by the nature-based play movement, may have been as much for adult aesthetic appeal as for the children's experiences of nature-based play:

Danielle: I think the circle garden was probably the first thing that they did, because before the garden was there it was just a big mud patch...
Researcher: OK, and so did the kids use to play in that mud?
Danielle: Um, yes and no, but tried to encourage them not to do it because the parents didn't like them getting too dirty, because...as soon as it rained it was just a big slosh pile.

It seemed then that differences in the educators' personal connections and values toward nature were likely contributing to some of the differences in the children's experiences of nature-based play. These values may have been particularly central to educators' commitment to overcome complexities or barriers to nature-based play, such as the weather, dirt, and parental attitudes, as explored further in the following theme.

Parent Partnerships

The interview narratives of the educators also revealed differing levels of parental engagement and rapport between the centers. The educators at the community center described feeling very close to the families who attended their center, often knowing various members of the extended family and sometimes having taught more than one generation. At the daycare, the educators did not feel they knew the children's families so well, something they reflected may have been influenced by the shift work required by long daycare staff, whereby it may not always be the same staff member who is there at drop-off and pickup times. Donna described finding that the same parent could react differently on different days (or to different staff members) to the report that their child had had a small injury or fall. She found this undermined trust in the parent-educator relationship and found it personally quite stressful: "It's like being on a trampoline all the time, you never quite know which way it is going to bounce." To deal with this, she described having to curtail the children in their nature-based play.

Donna: It is never going to be as good as the home environment. . .It's just not really comparable because you do your best, but it is still an environment where you have lots of staff looking after a lot of children who belong to other people. So you do have to reduce the risks as much as possible.

In addition to keeping risk to a minimum, Danielle lamented that parents complained if their children got too dirty or if they learned that their child had been playing outdoors in inclement weather.

Danielle: If it's too cold we're not allowed to take them out, because the parents don't like them being outside if it is cold. Even if it is a sprinkle of rain they have to come in, they're not allowed to stay out in that, because parents don't like them out in the rain.

In contrast, at the community center, Christina mentioned that "parents sometimes check whether the children are allowed to be barefoot as some centres don't allow it," suggesting that, rather than dictating to the educators, the families respected their professional judgment. Indeed, perhaps by virtue of their long-standing, close relationships with the children's families or the educators' personal commitment to nature (as explored earlier), it appeared that the educators at the community center had established themselves as trusted professionals in the context of young children and nature. Consequently, rather than bearing ongoing tensions and worries about parental complaints, there was a sense that the educators had positioned the center as a key site, within the landscape of modern childhood, where the children *could* experience the risks of nature-based play, play out in the rain, and get muddy:

Cath: ...with playing outside, and in the dirt and stuff like the mud pit, sometimes these children go home in quite a state! Anyhow, parents are like, "Oh well, that's what they're here for."

These shared understandings about the experiences on offer at the center seemed to further contribute to relaxed educator-parent relationships, allowing the educators to feel less anxiety about risk or minor accidents. Reflecting upon her long tenure as Center Director, Christina explained, "Generally our community of parents is quite comfortable with what we do. Certainly no one has ever complained that I can think of." It emerged then that the quality of reciprocal trust that the educators were able to build in their relationships with the children's families influenced the nature-based play opportunities they were willing and able to provide for the children.

Beliefs About Children's Capabilities

In addition to the above differences, the educators described varying beliefs about the capabilities of the preschool children in their care. At the daycare, the educators seemed to default to a developmental stage-related conceptualization, largely referring to the children's capabilities in relation to their age. For example, being the oldest group at the center, the children were framed by Danielle as being more

competent than the younger children: "Not so much the young guys, but these guys will know if there is something sharp not to go near it." Along a similar vein, Donna drew attention to the children's limited capabilities in relation to adults: "A child's not going to differentiate [between dangerous and non-dangerous spiders]; I actually find it very hard to differentiate between them."

By comparison, at the community center, when Christina had facilitated the implementation of the EYLF (DEEWR, 2009a), it had resulted in a shift in mindset for Cath in terms of how she understood children and how they learn:

> Cath: It was a big change. . .I just thought, ". . .If we don't have things drawn and they don't learn to cut on a straight line, and then a semi-circle and then a circle, how are they ever going to do it?" And I thought, "Look this is fine. . . we'll start this, but at the end of the year I don't think we're going to have children with skills. . .ready for school." And it probably took a term and I was totally blown away, because I could not believe what they were cutting and what they were doing and it was because it was driven by them. . .I understood then that that was what it was all about, and their skills are amazing and what they can do is absolutely incredible.

Consequently, Cath now felt that children should not be limited by adults' pre-conceived ideas of their capabilities, and throughout the interview, she repeatedly described the children in her care as predominantly capable through statements such as "I think we just learn with them," "You never expect that they can't do it," and "I think sometimes people underestimate children."

In accordance with these beliefs about the children's competence, the educators at the community center worked with the children to develop their understandings of the risks associated with nature-based play and aimed to instill a sense of responsibility toward these. For instance, when talking about the "dry creek bed," a wide hollow at the center filled with large pebbles, Christina described trusting in the children's ability to play safely with the stones. She found that by extending trust to the children, they tended to react responsibly: "They don't tend to throw them. 99% [of the time] they're doing something constructive with them, occasionally someone might throw them, 1% of the time maybe." Through these everyday experiences with risk, Cath believed they could trust in the children's ability to react appropriately should a potentially dangerous creature appear in the playground: "They know, they can identify them [snakes, spiders], and they know that they get an adult."

At the daycare, Donna took a more cautious approach. She preferred not to allow the children to play with sticks, "because they tend to start whacking each other with them." Although, Danielle clarified that it is just the "big [sticks], just because they are quite rough these boys." She explained that they were allowed to play with small sticks as long as they did not "start running around after each other with them," if that happens, then they "encourage them not to play with [the

sticks]." In addition, Donna felt she could not trust the children to react appropriately if they encountered a dangerous snake or spider, something she attributed to their nature as children:

Researcher: How about the children themselves? Do you have a level of trust in them if there was a snake or something in the garden that they would react appropriately?
Donna: No.
Researcher: No?
Donna: No! (laughs).
Researcher: Do you think that is because it has not been tested? Or just through your experience...?
Donna: It's because they are children. They are going to touch whatever they want to touch, they really don't understand risk as such... It's like, "Oh God we just [talked / taught you about] snakes! You're not supposed to chase the snake." No, I don't trust them at all.

Overall then, it was clear that the educators' *beliefs* about children's capabilities influenced the degree to which they were willing to trust them, particularly in relation to navigating the risks associated with nature-based play. In particular, these underlying *beliefs* influenced whether and how the children were allowed to use natural objects in their play.

Approach to Play and Learning

The above themes highlight considerable differences in the educators' underlying values and beliefs between the two centers, aspects that are likely to contribute to their pedagogy outdoors. Further, it became apparent that there were fundamental differences in their approaches to play and learning, with the two centers interpreting the notion of collaboration quite differently.

At the community center, the educators explained that following the launch of the EYLF (DEEWR, 2009a), they made the decision to maintain routines but had done away with much of the structured planning at their center. The educators described with enthusiasm the way in which they actively sought opportunities for spontaneous collaboration with small groups of children, both inside and out:

Cath: You know most days what we think that we'll do, that might flow on from the day before, [well] something else kind of evolves, but...we follow them, listen to them, and follow them. And it's just not how it was, really, but...I think it's very good. It's much more creative.

This occurred in many different ways. On one occasion, Dr. M spotted that the cherry tomatoes were ripe on the vine. After tasting one, she approached an educator

who invited her to fetch the collection basket and helped her to wash them to serve at snack time. On another occasion, a parent dropped off an enormous cardboard box. An educator worked with a group of interested children outdoors to plan what they could use it for, and they spent the morning working together to turn it into a cubby house, carefully cutting windows and doors and decorating it. At other times though, the educators barely seemed to interact with the children at all, leaving them to develop their own play narratives with as little interruption as possible, just occasionally reminding them, for example, to turn off the tap on the water butt if they left it running for too long without using it.

At the daycare, the educators talked about observing the children while they were engaged in free play and drawing upon their interests to develop other activities. However, spontaneous collaboration was not described by either of the educators at the daycare, and none was observed outdoors. Instead, the educators explained that the children's play outdoors would sometimes inform the planning of themes for indoor play:

Donna: If they're collecting sticks outside and making [pretend] fires, we have brought that inside and made [pretend] campfires and added [cool boxes] and chairs and tables and tents and things.

Learning themes were often adopted for a week or more and sustained by the educators through structured art and craft activities, displays in the indoor space, or games and discussions to extend the children's conceptual knowledge. These structured activities were usually arranged for the whole class and planned often a week or more in advance, raising questions about the extent to which an individual child might recognize their contribution or experience a sense of collaboration in the process. Indeed, it was clear that collaborative opportunities were sometimes never followed up:

Danielle: They were quite into collecting those little nut seedy things from the trees, I don't know what they are. . .and we filled up quite a few jars of them last year.
Researcher: What did they do with them?
Danielle: They were going to use them for art and crafts but they never did they just sat in the jars! (laughs)

While the planned, structured activities usually took place indoors, occasionally the outdoor space was used, such as when the class went into the garden to catch spider webs and spray painted them onto black paper. Mainly though, the outdoor space was valued for allowing the children to expend "excess energy" because "it is a very long day when they are inside. . .and they don't like being inside all the time" (Donna). Weather permitting, free outdoor play was scheduled each day, and there

was a sense that being outdoors offered the children a break from the more structured indoor learning activities:

Danielle: It's more free play outside (long pause)...
Researcher: Why do you think you focus more on free play outside?
Danielle: Because normally it is very hard to get them to sit down when they are outside to do something (laughs), yeah they just like to run around. They are just happy doing their own thing rather sitting down doing a task that has been given...

As such, the educators described focusing mainly on supervision outdoors, interacting with the children predominately when they began to get "too unruly" in which case they would initiate structured playground games such as "What's the time Mr Wolf" or invite the children to listen to a story in the cubby house.

Therefore, the educators emerged as utilizing distinguishably different pedagogies: from spontaneous, flexible, collaboration with children indoors and out, to a more planned and bilateral approach delineating largely child-led play outdoors and educator-led learning activities indoors. These divergent pedagogies seemed to influence how the educators conceptualized the outdoor areas and the way in which they engaged with the children in these spaces.

Overall, the educators' values toward nature, their relationships with the children's parents, their beliefs about the children's capabilities, and their collaborative "teaching" behavior emerged as being considerably different between the two settings. While qualitative research conducted in sociodynamic contexts such as EC settings precludes the making of causal connections, the results of this study do strongly suggest that children's experiences of nature-based play within the naturalized playgrounds of EC settings cannot be uncoupled from their educators' pedagogy.

Discussion

The findings suggest that the various facets of educator pedagogy – the educators' values toward nature, their relationships with the children's parents, their beliefs about the children's capabilities, and their approach to play and learning – bear some influence upon children's opportunities for nature-based play within the everyday green spaces of early childhood centers. With reference to the continuum of nature-based play experiences, the various aspects of the educators' pedagogies may act to constrain or enhance the children's agency to reach the outer edge of the continuum and become fully "immersed" in nature-based play should they wish to do so. The scatter graph in Fig. 1 below has been generated as tool to help illustrate the nature-based play continuum and to further discuss the interplay between the children's experiences and the emergent aspects of educator pedagogy.

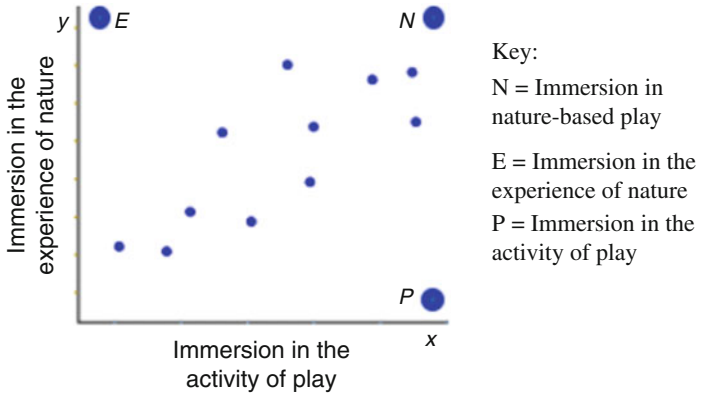

Fig. 1 Example representation of nature-based play continuum. Key: N = immersion in nature-based play. E = immersion in the experience of nature. P = immersion in the activity of play. Note. This graph is purely an illustrative aid for discussion. While the concept of the continuum arose from the findings and analysis, the points on the graph do not correspond to data gathered

As indicated by the x and y axes of Fig. 1, the analysis indicated that the children's experiences of nature-based play are reliant upon two critical conditions: their *ability* to become deeply and purposively *immersed in the activity of play*, i.e., *flow*, and the *opportunity* to become *immersed in the experience of nature.* Reflecting these dual layers, the experience of "immersion in nature-based play" would be situated at point N on the scatter graph and can be understood as an "optimal" childhood experience in nature, potentially offering the myriad wellbeing benefits reputed to be provided by flow and nature connection (Bowden et al., 2011; Csikszentmihalyi, 1997).

Three facets of the educators' pedagogy – their beliefs about the children's capabilities, their investment in relationships with the children's parents, and their own personal values toward nature – were identified as potentially bearing impact upon the extent to which the children were allowed to manipulate nature's polymorphic affordances in a hands-on way (e.g., the use sticks and stones in their play) and to experience nature in an embodied way (getting muddy, experiencing the rain, taking of their shoes, etc.). Therefore, these three facets of educator pedagogy can be understood to act in fairly direct ways upon the y-axis of Fig. 1, potentially influencing the children's opportunities to become *immersed in the experience of nature*.

Turning to the x-axis, the supervisory approach of the educators at the daycare might offer the children the freedom to become *immersed in the activity of play.* Certainly, adults' fond memories of playful outdoor adventures were usually times when they were playing freely and adults were not involved (Louv, 2008; Waite, 2007). However, the children at the daycare were rarely observed to be in a flow-like state in their play and on several occasions voiced frustration or boredom. This could be influenced by the confined nature of the setting, the necessity of certain rules in the group, the length of time the children spent at the daycare, and the absence of

older children to extend their ideas, creativity, and play skills, aspects that differ quite considerably from the play experiences of previous generations (Bodrova, 2008). Yet, frustration and boredom never arose during the fieldwork at the community center, and the children regularly seemed to become immersed (in a flow-like state) in their free nature-based play, something apparent in their creativity, deep and purposeful engagement, and enjoyment of this play (DEEWR, 2009a).

The greater freedom offered to the children at the community center to manipulate natural materials creatively may partly account for the differences in experience, offering them a greater sense of freedom. However, they most commonly used leaves, grass, or bark, which were also readily accessible to the children at the daycare. The difference in the type of setting may also have been influencing the children's experiences. The children at the community center had attended their center for a maximum of a year and a half; many did not attend every day, and opening hours were shorter. By contrast, some of children at the daycare may have attended the center for close to 5 years and may have been attending for full 5 days a week all year round. Yet, the type of setting cannot readily be changed. In fact, arguably it may be more important for children such as those at the daycare to have the opportunity to connect with nature and experience the well-being benefits of flow at their EC setting, given the dominance of this space to their early childhood experience. In a sense then, this places added impetus upon the educators to help facilitate these experiences for the children, pointing to the importance of educators' approaches to play and learning.

In considering the role of educators' approaches to play and learning upon the children's *ability* to become *immersed in the activity of play*, it is important to highlight that while the educators at the community center did sometimes collaborate with the children outdoors, it was not necessarily during these experiences that the children appeared to experience flow. As indicated above, this was most evident in their self-directed, socio-imaginative, or socio-constructive free play. Critically though, autonomously sustaining this play required the children to collaborate with *one another*, so that play narratives could fluidly evolve, and conflict could be resolved swiftly and not interrupt play. Sociocultural theory would suggest that the children at the community center may have been mirroring or reconstructing the collaborative pedagogy of their educators (Rogoff, 2003; Smith, 2013; Vygotsky, 1978). Or put another way, by modeling and engaging with the children collaboratively, Christina and Cath may have nurtured the maturity and self-sufficiency of the children's play skills at the community center, allowing them to remain more purposefully engaged – immersed – during periods of free play. This connection differs slightly from the ideas of Fleer and Peers (2012) and Bodrova (2008) in both intention and timing. Rather than fostering the children's collective imagination (Fleer & Peers, 2012) or ability to sustain characterization (Bodrova, 2008), the facilitation of collaborative skills has wide-ranging social application. It also does not require the educators, necessarily, to involve themselves in the children's free play directly. The skills are acquired (over time) in interactions with the educators and can then be appropriated later in free play, allowing this to be wholeheartedly child-led.

A complex dynamic of beliefs likely underpins this pedagogical approach. For instance, although the educators' beliefs regarding preschool children's capabilities emerged in the findings in relation to access to risky natural materials, implicit within these beliefs is the extent to which the children are recognized as competent partners to collaborate with (Siraj-Blatchford, 2008; Smith, 2013; Vygotsky, 1978). Hence, these beliefs likely underpin the educators' approaches to play and learning (Department of Education, Employment and Workplace Relations, 2009a). Somewhat similarly, while a commitment to a collaborative pedagogy largely supersedes the need for educators to personally value nature, it is likely that personal connections motivate educators to overcome any difficulties or barriers (such as safety concerns, parental resistance, or complaints) and actively seek to position their center as a space where children can experience immersion in nature-based play (Asah et al., 2012).

Educators' personal connections to nature aside, it was somewhat surprisingly that there should be such a divergence in the educators' beliefs about children's capabilities, their investment in relationships with the children's families, and their approach to play and learning. These are key areas in which the EYLF (DEEWR, 2009a) seeks to foster shared beliefs and values among educators nationally. However, as Cath described in her narrative and as existing Australian research has highlighted (Edwards, 2007), making the paradigmatic shift from developmentalism to sociocultural theory and embracing a collaborative approach in practice can be very challenging. Yet, rising to this challenge is critical. Even in something as seemingly innate as nature-based play, the results of this study demonstrate that, within the confines of EC settings, it is not enough simply to naturalize the playground, stand back, and leave the children to play. Educator pedagogy plays a critical role both in affording children the agency to really engage with the natural affordances *and* to develop the skills to achieve and sustain flow-like states in their nature-based play.

Conclusion

While only a small-scale study, the findings shed new light on how contemporary preschool children experience nature-based play within the naturalized playgrounds of EC settings. The results highlight that children's experiences in these environments range across a continuum from "nature as a backdrop to activities" to "immersion in nature-based play." Children's nature-based play experiences shift across the continuum depending upon their interests and the evolution of their play. However, the results of this study also clarify that for children to *regularly* and *consistently* experience immersion in nature-based play at EC settings requires more than just physically naturalizing the playground environment. Two key conditions must be met: (1) children need the opportunity to become *immersed in the experience of nature* (e.g., to freely engage with nature's affordances such as mud, rain, sticks, etc.), and (2) they require the ability to become (and remain) deeply and purposively *immersed in the activity of play*. The findings suggest that sociocultural

influences, in particular educator pedagogy, act to constrain or enhance children's opportunity and agency in both these regards. Specifically, educators' beliefs about children's capabilities, their investment in relationships with the children's parents, and their own personal nature-connectedness influence children's *opportunities* to become immersed in the experience of nature. In addition, educators' approaches to play and learning (underpinned by their beliefs about children) influence the development of children's autonomy to sustain collaborative play – their *ability* to become immersed in the activity of play. Therefore, while making environmental changes to the playground are a critical first step toward affording children opportunities to become immersed in nature-based play, these must be concurrent with a commitment to shifting mindsets and to working with intention to foster the children's autonomous collaborative play skills.

Abstract

Traditional nature-based experiences have gained increasing attention for their ability to foster in children a sense of Connectedness-with-Nature. What is often not acknowledged in contexts of cultural diversity is how nature-based pedagogies often subtly project Eurocentric environmental values onto children, inadvertently colonizing natural spaces. Drawing on a qualitative case study with 37 ethnically diverse children at an outdoor education center in South Africa, this chapter proposes a potentially transformative triad of decolonizing, ethics-led and embodied nature-based pedagogies to address calls for nature reconnection in this context. The tensions and resonances between children's sociocultural-historical value positionings and those of the outdoor education center are explored in relation to the embodied nature of children's on-site experiences which are designed to mediate their developing sense of Connectedness-with-Nature. Through semi-structured interviews with children and instructors, participant observation of two camps, and reflexive journaling, data were analyzed thematically drawing on Cultural-Historical Activity Theory. The analysis highlights the formative role of historically constituted, sociocultural elements in mediating children's material, embodied experiences with outdoor education programs. The authors argue that decolonized/decolonizing, socioculturally and socio-materially resonant, and ethics-led pedagogies are important dimensions in developing children's feelings of Connectedness-with-Nature and opening potentially transformative pathways for (a)mending the perceived human-nature disconnection.

Decolonized nature-based pedagogy · Connectedness-with-Nature · Sociocultural-historical positionings · Socio-materiality

Introduction

This Chapter reflects on the potential of nature-based pedagogies that are (i) decolonizing, (ii) ethics-led, and (iii) embodied, to develop child-nature connections at a South African outdoor education center. These pedagogies are presented as a triad because their potential to create transformative learning processes and develop child-nature connections resides in their interrelatedness rather than in their selective or separate use.

The first section of the Chapter introduces the eco-psychological ideal of Connectedness-with-Nature (Zylstra, Knight, Esler, & Le Grange 2014) and considers how the triad of decolonizing, ethics-led, and embodied pedagogies in structured outdoor education programs has the potential to strengthen children's Connectedness-with-Nature. Throughout the Chapter, the authors draw on Connectedness-with-Nature in acknowledgement of Zylstra et al.'s (2014) work that framed earlier research on which this Chapter is based (Ward-Smith, 2018).

The features and aspirations of Connectedness-with-Nature, applied in this Chapter to children's experiences of nature-based pedagogies, resonate strongly with the book's overall theorization of childhoodnature. These theoretical propositions are elaborated in the second part of the Chapter which presents data from a case study of children's experiences of nature-based pedagogies at an outdoor education center in the Eastern Cape province of South Africa.

"Connectedness-with-Nature"

Calls for people to "reconnect with nature" have become common across various disciplines including Environmental Education, Environmental Ethics, Eco-psychology, and popular environmental discourse (Bonnett, 2004; Louv, 2010; McGarry, 2014; Weston, 2012; Zylstra et al. 2014). The multifaceted benefits of nature immersion and nature-based learning have been well-documented, ranging from enhanced health and wellbeing to self-growth and development and to environmental advocacy (Capaldi, Passmore, Nisbet, Zelenski, & Dopko, 2015; Gill 2011). In response to the cultural dominance of Minority western modernity which values scientific knowledge over intuition, verbal communication over bodily awareness, rational judgment over care, and action over introspection, nature-based experiences may offer a method to recentralize the importance of emotive embodiment through experiences within nature (Akhurst, 2010).

Among the many responses to the increasing challenge of children's disconnection from nature is the eco-psychological ideal of Connectedness-with-Nature which contends that a personal and emotional reconnection with nature is an important predictor of ecological behavior and subjective wellness (Mayer & Frantz, 2004; Nisbet, Zelenski, & Murphy, 2008). This is not to say that all human beings are literally physically or materially disconnected from nature but rather that there is an emotional and psychological disconnection which may in turn mediate a physical and experiential disconnection. The aim is for a steady state of consciousness comprising symbiotic, cognitive, affective, and experiential traits that reflect, through consistent attitudes and behaviors, a sustained awareness of the interrelatedness between one's humanness and the more-than-human world (Zylstra et al., 2014). This may be an evolving continuum comprising of information about nature, experience in nature, and culturally embedded nature-based practices over time, which all combine toward engendering a deeper, more committed connection with the natural world.

A central concern of this chapter is the extent to which outdoor education centers in South Africa (or any setting where nature-based learning processes are influenced by colonial legacies) can contribute to developing children's Connectedness-with-Nature. Below, we look briefly at the dominant cultural history of nature-based pedagogies in outdoor and environmental education centers in South Africa, before elaborating on how a triad of decolonizing, ethics-led, and embodied nature-based pedagogies may potentially develop children's reflexive engagement with their own

experiences in, and connections with, nature. The case study data presented through the lens of Cultural-Historical Activity Theory (CHAT) in the second part of the Chapter foregrounds the importance of pedagogies that resonate with children's lived experiences and traditional bio-cultural constructions of the natural environment.

Socioculturally and Historically Emergent Nature-Based Pedagogies

In South Africa, child-oriented, experiential nature-based pedagogies have tended to foreground environmental behavior change designed from a position of "expertise" where Eurocentric conservationist values are transposed into other contexts. In sketching a sociocultural history of outdoor and environmental education centers in South Africa, O'Donoghue (2007) recounts how nature-based programs in the 1980s emerged from colonially inspired nature conservation campaigns seeking to "create environmental awareness through hands-on learning in wild nature" (p. 144). To this day, children participating in such programs are commonly encouraged to take on environmental values that are external to their sociocultural, historical, and economic contexts, as well as from their everyday understandings of and experiences in nature, and their environmental concerns. Many children hence experience structured nature-based learning programs as contextually disembedded, perhaps even alienating interventions (Masuku van Damme & Neluvhalani, 2004; Muir, 2002; Zazu 2007). Few nature-based pedagogies work "from the ground up," embracing how children's immediate, lived experiences mediate their Connectedness-with-Nature.

Currently in South Africa, little has been researched and published about the role of decolonizing pedagogies in nature-based education. Ashwell (2010) suggests that appreciation for nature-based education in South Africa has receded in recent years as the concept of "nature" has been steadily replaced with more utilitarian or scientific concepts such as "natural resources" or "biophysical environment" in policies and curricula. Part of this diminishing focus on nature in South African environmental education programs may be, she suggests, due to the prominence and urgency of addressing environmental injustices and sustainable development agendas in the democratically emerging state. Additionally, critiques of nature-based education in the 1990s by prominent environmental educators may have also undermined confidence in the relevance and politico-ideological appropriateness of its typical pedagogies in a post-Apartheid setting, especially as nature-based education was historically associated with "whites only" access to nature reserves and national parks (Ashwell, 2010).

The post-Apartheid democratic turn from the 1990s introduced to nature-based education programs a culture of participation and emancipation, with the emphasis often focused on team-building exercises, "icebreakers," and collaborative problem-solving (O'Donoghue, 1999). Pedagogies struggled to break through to any profound engagement with learner's lived experiences and cultural capital. In light of

this complex, politically laden sociocultural history of outdoor and environmental education centers in South Africa, the perspectives and case study data shared in this Chapter are part of a tentative exploration of the role of nature-based pedagogies in mediating young people's connectedness with their natural heritage in ways that are generative and just.

Toward a Triad of Decolonizing, Ethics-Led, and Embodied Nature-Based Pedagogies

This section introduces the idea of a triad of nature-based pedagogies that seek to develop decolonized and ethically imbued child-child, child-adult, and child-nature relationships. This triad requires that we attend more closely to the ways children position themselves during outdoor education experiences in relation to their own historical, sociocultural, and socio-material circumstances and those of the outdoor education program.

Decolonizing Pedagogies

Postcolonial scholars such as Chakrabarty (2000), Santos (2007), and Kayira (2013) emphasize that colonialism's most powerful legacy is not geographical but onto-epistemological. Kayira (2013, p. 107) reflects how many post-independence African countries remain under the hegemonic influence of Minority western cultural and economic standards and "are construed as objects of elite benevolence, rather than as historical subjects possessing their own unique worldviews, interests and passions." These global patterns are echoed at community, classroom, and homestead levels, with the result that even community-oriented, nature-based education programs are commonly framed around Eurocentric accounts of people-nature relationships.

Decolonizing pedagogies refers to approaches to teaching and learning that help learners to recognize and disrupt the structure and powers of colonial influences on their lives and in their communities. Complex legacies of colonial narratives need to be interrogated, where relationships and practices have subordinated and controlled certain groups of people and the natural world. As authors, we use the present-continuous tense here (decolonizing) to signify the incompleteness of the project – nothing is yet truly decolonized. The term also reminds us of the need for expanding spheres of reflexive moral relationships not only with other people, communities, cultures, races, and faith groups but also with subjugated species, ecosystems, landscapes, and more.

Educators writing about decolonizing pedagogies point to the significance of open-ended, generative dialogue, reflexivity, and relationality to enable transformative learning processes. For example, Asher (2005) draws on post-colonial and feminist theories to propose spaces of *in-between-ness* in which children and educators are able to "validate their particular histories/life stories and at the same time to rethink relations of oppression" (p. 1103). Such approaches commonly seek to re-center Indigenous ways of knowing, doing, and relating and support change-

oriented, agentive responses in the world (McGregor, 2012). Decolonizing pedagogies can introduce a critical, reflexive edge to nature-based learning processes that might otherwise risk being little more than environmentally well-intentioned but socioculturally disembedded efforts to reconnect children with the natural world.

Ethics-Led Pedagogies

Educators' understandings of ethics-led pedagogies as open-ended, deliberative processes rather than as static codes of conduct (Olvitt, 2013) are central to this Chapter's proposition of a triad of decolonizing, ethics-led, and embodied pedagogies in nature-based education programs. A relational, dialogical, and contextually responsive foundation to ethics-led pedagogies may help to mitigate the risk of ethical and moral imposition that accompanies colonizing practices (where the colonizer seeks to impress "the right way" upon the other), such as those historically found in many South African nature-based education programs where the educator seeks to instruct children on "the right way" to understand and relate to nature. These ethical tensions, especially in post-colonial settings, are understood by Bauman (1993, p. 97) who cautions that: "'Stooping to' the weak by the self-confident strong is in the end the birth-act of domination and hierarchy: the reforging of difference into inferiority." Nature-based educators must tread a very fine line between pedagogies that unreflexively advance the rightness of a particular way of being with nature and pedagogies that *invite* – but avoid prescribing – ethical engagement with our relationships with nature.

Regardless of the specific form of the wide range of possible ethics-led pedagogies, in general terms these learning processes would be empathetic, care-filled, just, and grounded in relational understandings of the world. Ethics-led pedagogies engage explicitly and reflexively with the range of values and ethico-moral positions that people bring to each situation and seek to create challenging but safe spaces for learners to have ever-deepening conversations about what matters to them, why, and how that affects others, now and into the future (see, e.g., Jickling, 2005, 2009; Olvitt, 2013, 2017).

Embodied Pedagogies

Embodiment and the socio-materiality of nature-based pedagogies are important but often taken-for-granted dimensions of mediating children's Connectedness-with-Nature. Fenwick (2015) explains that learning is fundamentally a socio-material concern and that materials and material settings actively mediate learning as, ". . .there are no clear, inherent distinctions between social phenomena and materiality" (p. 83). As such, the sensual embodiedness and seemingly overt physicality of children's nature-based experiences are inseparable from the sociocultural-historical positionings that children and educators bring to each experience. Shifting from a subject-centered, cognitive view of learning to one that acknowledges how "objects,

bodies, technologies and settings...permit some actions, and prevent others" (Fenwick, 2015, p. 85) necessitates embodied approaches that lead children into relational, holistic, and experiential explorations of their dynamic relationships with the natural world. Further, it would suggest the importance of pedagogies that share and produce understandings of nature *through* (rather than in spite of) children's sensual embodiedness in the world.

A Complex History of Biocultural Diversity in the Eastern Cape

The outdoor education center case study that forms the basis of this Chapter is located in one of South Africa's economically poorest and most rural provinces, the Eastern Cape, where the dominant ethnic group is the AmaXhosa. The province's history reflects ongoing national struggles to transition from centuries of colonial oppression (since the early 1800s) to a fledgling democracy in which people and land can flourish.

Over a century ago, when South Africa was under British colonial rule, black people were restricted to owning a mere 7% of land (Ramphele, 1991). The Nationalist Apartheid government that came to power in 1948 then established reserves (known as "independent homelands" or "Bantustans") to strategically keep black people out of urban areas while providing a steady supply of labor for white-owned mines and farms (Durning, 1990; Ramphele, 1991). Most "homelands" were on marginal, unproductive land bearing the region's characteristic red, fragile topsoil. These "independent homelands" rapidly became places of environmental degradation, extreme poverty, deforestation, overgrazing, and failed crops: places where traditional family structures disintegrated under the economic pull of the commercial farms, factories, and mines to which people departed in search of employment. The pervasiveness of Apartheid rule across social, political, and economic sectors of South African life ensured the institutionalization of environmental racism, which has endured beyond the advent of democracy under black majority rule since 1994 (Olvitt, 2012).

In an extract from a book documenting the history of the Wildlife Society (an environmental NGO with an almost exclusively white membership), Pringle (1982, p. 256) reflects how the organization grappled with these tensions during the height of Apartheid:

> ... [In the late 1970s] the Society told its members. 'It surely behoves us to do all in our power to reach out to this section of the community... the black mind needs to be instilled with knowledge of the mutual benefits to be derived from striving to preserve instead of destroying nature.

This text is illustrative of dominant colonial perspectives in South African outdoor and environmental education centers, which persist (albeit in more nuanced or muted forms) even to today. Well-intentioned strategies to "reach out" to black communities so that their minds can be "instilled with knowledge" about how to live harmoniously and sustainably with nature reflect a deficit view of a perceived ignorant, destructive "other" (Kayira, 2015; Masuku van Damme & Neluvhalani,

2004). Typically, pedagogies associated with such perspectives were (and in many cases still are) transmissive and focused on value change and behavior modification (O'Donoghue, 2007).

The accumulated history of decades of land dispossession, forced removals, inequitable access to natural resources, and dehumanizing denial of access to health and sanitation services presents a picture of a province where people's relationships with the natural world might be characterized by disconnection. However, more recent research into biocultural diversity and nature-culture relationships in the Eastern Cape (Cocks, Dold, & Vetter, 2012; Dold & Cocks, 2012; McGarry 2008) indicates that the AmaXhosa people's close connections to nature remain strong but have until recently fallen outside of the explanatory capacity and implicit values frameworks of mainstream conservation discourses. Cocks, Dold, and Vetter (2012, p. 1) describe how the AmaXhosa people:

> . . . portrayed a strong, although not always easily articulated, appreciation for nature, especially *ihlathilesiXhosa* ('Xhosa forest', vegetation types within the Thicket Biome). Activities such as collecting fuelwood and other resources, hunting and time spent at initiation schools were described as key opportunities for spending time in nature. The benefits of being in nature were ascribed not only to the physical experience of the forest environment. . .but also to the presence of ancestral spirits. Being in nature thus contributes significantly to the physical, mental and spiritual well-being of local people, and is also integral to their sense of cultural identity.

In a similar study, Dold and Cocks (2012, p. 14) describe the importance of local forests and thicket as a learning environment for children: "Children collect fruit, hunt birds, swim, climb trees, make clay toys, carve fighting sticks and ketties (catapults), catch fish, and generally play in the forest."

Researching the role of natural resources in the lives of rural children impacted by HIV/AIDS in the Eastern Cape, McGarry (2008) reported that the quality of children's diets at home was, on average, 60% lower than the Food and Agricultural Organization (FAO) recommendations. However, he found that 62% of the 850 children interviewed supplemented their diets with wild foods, with 30% supplementing over half their diet with wild foods.

These snapshots of culturally and economically imbued people-nature relationships represent the lived realities of many of the rural children who attend camps at the Mystic Mountain outdoor education center. The following section turns to the case data of children's experiences of nature, mediated by activities at Mystic Mountain (Ward-Smith, 2018).

The Case of Mystic Mountain Outdoor Education Center (Name Changed)

The research explored how children from diverse sociocultural, economic, and historical backgrounds learned to connect with nature through experiential nature-based activities during 4-day camps at the Mystic Mountain outdoor education

center (Ward-Smith, 2018). Mystic Mountain is one of South Africa's longest established not-for-profit education centers that provides experiential nature-based learning to children from diverse backgrounds. The center seeks to respond to the concern that increasing numbers of South African children do not have close connections with, or intimate understandings of, nature. The center offers 4- to 6-day camps featuring a host of adventure and nature-based experiences, most of which take place in the natural environment. Activities include swimming in a natural pool, day and night hikes in the indigenous forests and commercial tree plantations, indigenous tree planting, invasive tree ringbarking, as well as a nature-based middle ropes course.

Mystic Mountain's main objective is to provide a safe and natural space for socioeconomically disadvantaged children to explore their identity, their skills, their own personal growth, and the natural environment around them. In recent years there has been a strong push toward experiential environmental education through nature-based activities such as hiking, tree planting, and swimming. Mystic Mountain seeks to provide nature-based learning experiences through which children develop their agency and self-efficacy.

The core values that influence Mystic Mountain's practices are loosely based upon Christian-based ethics of stewardship of care and respect for people and land, illustrating the adoption of a dominant worldview introduced through colonial expansion. Features of the center's core values include sanctity of life (not harming any human or other creatures or plants) and showing respect for the environment, for people, for the learning context, and for oneself. Thus, the experiential learning programs are guided by an explicit set of environmental values that promote colonially inspired conservation values and practices within a context of African cultural diversity.

Many of the camps are externally funded to sponsor children from socioeconomically disadvantaged backgrounds to explore themselves and learn about the natural environment through structured and unstructured nature immersion within a pristine natural setting. These camps are referred to by staff members as "underprivileged camps" or "UPCs" for short. This problematic labelling reflects a deficit understanding of the sponsored children who are perceived to be "lacking" in some way, thereby diminishing their potential assets and alternative everyday ways of knowing.

Research Methods

The qualitative case study that forms the backbone of this chapter draws on data collected over two 4-day camps at the Mystic Mountain outdoor education center in a rural area of the Eastern Cape. Data generation methods included semi-structured interviews and focus groups with instructors, staff, and selected participating children from both camps, participant observations during the camps, and reflexive journaling.

In total, 37 children, 7 volunteers, 3 instructors, and 2 managers were interviewed. Forty-minute pre-camp focus groups were facilitated to gain insight

into the children's unique sociocultural-historical contexts in relation to their descriptions of their Connectedness-with-Nature. Forty-minute post-camp focus groups were facilitated on the last day of the camps to gauge the effect of the camp experiences in relation to their thoughts about Connectedness-with-Nature. With participants' permission, these interviews were digitally recorded with a discreet audio recorder.

Participant observation entails the active and nonintrusive engagement of the researcher in activities in order to gain a deeper understanding of the interplay between participants and the activities they do (Cohen et al. 2007). In this study, participant observation of both camps' nature-based activities and procedures shed light on the instructors' pedagogies and orientations toward the children. Observing the children before, during, and after the nature-based activities provided an important background to their accounts of Connectedness-with-Nature that was discussed in subsequent interviews. The initial observations also provided useful content for shaping the post-camp interview schedules. The detailed handwritten observation notes provided important contextual detail that enabled the study's thick descriptions and underpinned the research findings.

These methods were complemented by reflexive journaling which acted as a stimulus for the researcher (Ward-Smith) to reflect on the camps' interactions, procedures, and dynamics and for a deeper understanding of the research process. Journaling is a strategy for researchers to write freely to examine their personal presumptions, biases, goals, subjectivities, and desires in relation to the research (Ortlipp, 2008). Its value lies in retrospection, generating new insights about researcher positionality and what is being studied.

Gaining Perspective Through Cultural-Historical Activity Theory

In addition to the above, Cultural-Historical Activity Theory (CHAT) provided valuable tools to help make visible the historical, cultural, and socio-material entanglements that require close attention in transformative learning processes. Drawing on Lev Vygotsky's (1978) account of sociocultural mediation, CHAT explains children's engagement with nature-based experiences, such as Mystic Mountain's camps, as processes of mediation through children's and educators' unique contexts and positionings. A CHAT-based analysis of the case study data helped to identify the historically accumulating tensions and contradictions between, for example, the cultural capital of children and the mediating tools used by educators in the activity system of the camp at Mystic Mountain.

Through a second-generation CHAT stance, the nature-based program at Mystic Mountain was conceptualized as an activity system. Second-generation CHAT (applied in Fig. 1 in relation to Mystic Mountain outdoor education center) shows how individual meaning-making and action can be better understood in relation to sociocultural and historical context and how society is in turn acted upon and changed by individual agency. The unit of analysis in second-generation CHAT is the activity system itself. The second-generation CHAT heuristic includes an

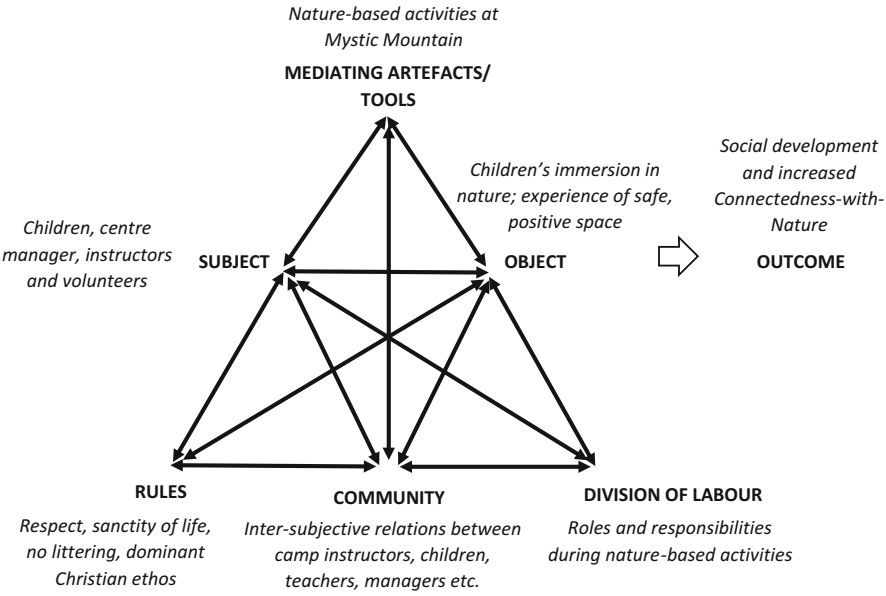

Fig. 1 Mystic Mountain represented as an activity system. (Adapted from Engeström, 1987)

expanded activity system comprising the subject and object of the activity system with mediating artifacts and tools in the top triangle, underpinned by rules and procedures, the community relevant to the activity, and the division of labor for conducting the activity. The subject and the object are interconnected in that the fulfilment of the object depends on the subject's motivation (Popova & Daniels, 2004). The object of activity is transformed through activity into outcomes. Mediating artifacts and tools refer to culturally produced means for changing the environment and achieving goals. The division of labor concerns both the horizontal interactions among the group members and the vertical division of power, resources, and status. The community concerns participants who share the common object, which shapes individual actions and the shared activity. Furthermore, within any community engaged in collective activity, there are formal and informal rules, norms, and established values, which enable and constrain the internal dynamics and accomplishments of an activity system. The subject-object relations of an activity system and their cultural mediation often result in historically accumulating tensions and contradictions which are recognized as the main drivers of learning and change within and across activity systems because actors respond to the disturbances (Cole & Engeström, 1993). As such, identifying and responding to tensions and contradictions within an activity system is integral to CHAT and its transformative potential. Contradictions can occur within a component of an activity system, between two or more components of an activity system or between multiple activity systems. Disturbances are usually the visible manifestations of systemic contradictions and also often provide vital opportunities for learning.

Within the case study context, an activity system analysis allowed for deeper insights into the mediatory relationship between contextual factors and the object of Connectedness-with-Nature (see Fig. 1 below). The components of the Mystic Mountain activity system included the subjects (Mystic Mountain staff), the mediating artifacts (various nature-based activities), the object of the activity system (child welfare and the development of children's Connectedness-with-Nature through experiential nature-based learning), the rules and norms (such as respect and sanctity of life), the community (intersubjective relations between all members underpinned by personal histories of children and the religious/cultural ethos of Mystic Mountain), and, finally, the division of labor (all those who participate in Mystic Mountain function in particular hierarchical roles). Conceptualizing activity in this manner allows for a nuanced, working image of the activity system in a way that highlights the dialectical, interactional, and historical nature of nature-based pedagogy at Mystic Mountain.

Nature-Based Pedagogy at Mystic Mountain

The case study conducted by Ward-Smith (2018) focused on two camps that took place at Mystic Mountain in the middle of winter in 2016. For ease of reference, we refer to the group of children at Camp 1 as "The Mountain Movers" and those in Camp 2 as "The Star Gazers."

Mystic Mountain outdoor education center was managed by two white South Africans (one male, one female) and supported by three instructors, long-term employees, who ran the camps and facilitated the activities. Two were young, black South African males, and the third was a mixed race female from a neighboring southern African country. Of the seven volunteers who assisted on camps (four male, three female), three were black South Africans, one was a white South African, and another three were Eastern European volunteers. Ward-Smith's (2018) initial interviews reported how some of the local volunteers had themselves attended camps as children and had returned as volunteers, due to their transformative experiences there, for example, Volunteer 7 noted: "In [this centre], nature is important to everyone, so since I was little, people were telling me that nature is part of us. . .." All the foreign volunteers had chosen Mystic Mountain as a placement because of their own transformative nature experiences during childhood or because they were passionate about working with children outdoors. Volunteer 2 said: "I have spent quite a lot of time in. . .mountainous environments during holidays. . .So I think I have always sort of had a sort of respect for these environments. And also we learnt a lot about them at school" (Ward-Smith, 2018).

Camp 1: The Mountain Movers

This camp took place in mid-winter. It included 60 children from a well-regarded, fee-paying school from a coastal town. Although the children were heterogeneous in

terms of race and gender, the majority were from middle-class backgrounds. The group was accompanied by two school teachers, and this camp focused on teamwork, confidence-building, and experiential environmental education. The weather was relatively cold but clear, with average daytime temperatures of 15 °C (59 °F), average nighttime temperatures of 2 °C (35 °F). Twelve children were interviewed, ages ranging from 12 to 14 years, with an equal number of boys and girls. Ethnically, six participants were white, four were black, and two of mixed race. (Racial identifications are noted here because, especially in the light of South Africa's Apartheid legacy, racial differences commonly reflect significant cultural and economic differences. This is especially so in the Eastern Cape, one of South Africa's poorest and most rural provinces where the sociopolitical and economic divisions of the country's colonial and Apartheid history have not changed substantively.) All 12 participants were proficient English-language speakers.

Camp 2: The Star Gazers

This second camp also took place in mid-winter. This camp was one of Mystic Mountain's two "UPCs" (underprivileged camps, as they were termed by staff members). Primarily, these camps focus on providing a safe and supportive space for children who are socioeconomically disadvantaged. As a secondary focus, the camps provide opportunities for transformative encounters with nature through experiential, environmental learning. The camps are also structured to develop agency through "self-initiated action plans" (SIAPs). During these SIAPs the children are divided into groups, and they plan what activities to do and when to do them. Thus, the activities become a self-driven competition, to activate the children's agency and develop their time management skills.

The weather during this camp was particularly cold and rainy with only one clear, sunny day. The children's ages ranged from 10 to 14 years, and they had a more limited understanding of English than the Mountain Movers. All of the children were black and either living in formal child care facilities or from socioeconomically disadvantaged backgrounds in peri-urban or rural settings. They were not accompanied by adults with whom they were familiar. Ward-Smith's (2018) observations were that many appeared to have low levels of confidence in this setting and had little access to, or experience in, pristine natural spaces. For many, coming to Mystic Mountain was their first holiday-type experience or their first experience in a nature-based setting. Twenty children who were sufficiently proficient in English participated in the pre-camp focus groups, and from these, five (three boys and two girls) were selected for the post-camp focus group. (Although in practice there were many difficulties during the interviews in terms of the English-isiXhosa language differences.)

It became apparent that the Star Gazers' sociocultural and historical positionings were disadvantaged in terms of finances and basic child rights such as individual care, support, and education. They seemed more inhibited, serious, and much less willing to talk, and they did not behave as carefree children. (We are aware that this

description of the Star Gazers can also be seen as a "deficit" description; however, these factors were noteworthy in terms of their lived realities of socioeconomic hardship and social stress and how that influenced their personal agency and developing sense of *Connectedness-with-Nature*. This is not to deny that the Star Gazers did not have alternative ways of being, doing, and knowing in relation to nature but that, from Ward-Smith's (2018) observations, these children did not appear to be especially playful or relaxed.) This was in contrast to the Mountain Movers who appeared to be more engaged, curious, and willing to converse.

Sociocultural-Historical Mediation of Connectedness-with-Nature

Ward-Smith's (2018) case study highlights the importance of contextual relevance and resonance in mediating Connectedness-with-Nature for the Mountain Movers and the Star Gazers. As will be illustrated in the sections below, the children's intersecting historical, social, economic, cultural, and religious positionings shaped their relations with and understandings of nature prior to attending the camps and influenced the mediation of their Connectedness-with-Nature. Excerpts from interviews are noted in italics, with the code to identify the participant noted after as SG (Star Gazer) or MM (Mountain Mover) along with the respective number to preserve anonymity.

Prior Educational Background

In both groups, it became evident that the form and content of the children's prior education influenced their understandings of environmental issues and their sense of Connectedness-with-Nature. On the one hand, the Mountain Movers attended a well-regarded state-funded school that not only exposed them to environmental knowledge through curricular subjects such as Natural Sciences but also physically enabled them to have mediated nature-based experiences such as camps and educative beach and forest excursions. As such, these children's discussions reflected understandings (albeit rudimentary and age-appropriate understandings) of ecosystems and human impacts on natural systems. These were mostly framed by concepts and terminology in the Natural Science school curriculum, augmented with personal experiences of having visited natural places or talking to a knowledgeable adult about environmental problems. The children in this group were generally able to explain the difference between indigenous forests and exotic plantations and lament the impact of sewage spillage on animal life. For example, one child explained: "…The sewage is…destroying the animal life … [I know about it through] mostly…the teachers, Mr. K talks about it a lot" (MM9), and another explained that: "…the indigenous forest is thicker in ground vegetation than the other one [exotic plantation] and darker at ground level…" (MM5).

The Star Gazers' schools, on the other hand, had provided far fewer opportunities to develop environmental knowledge or experience nature-based activities. The environmental knowledge that they were able to share during interviews was derived

almost exclusively from personal experience of social and environmental problems in their immediate environments (such as substance abuse, littering, and animal welfare). When asked what environmental problems they knew about in their area, several Star Gazers named social anxieties such as: "There are many strangers" (SG5) and "Many children in my areas are smoking drugs and that's a problem" (SG2). Thereafter, when asked specifically about problems concerning *nature*, one child suggested: "Poaching, uh, I think it's poaching" (SG1). When asked if they think their everyday activities such as eating and travelling affect the environment in any way, the same child responded: "No, those things don't affect the environment...." The other group members indicated that they could not answer the question.

A Mystic Mountain staff member suggested that the Star Gazers' environmental knowledge would be, "pretty much non-existent unless they have been to [us] before" but that: "You can't blame the kids [for not caring about the environment]; they don't have any exposure... Equally, the schools aren't teaching them." The educator added that: "The only other exposure that they get is counter [environmental]...If you are growing up in a township [the term used in South Africa to refer to high-density, low-cost, historically black residential areas] you are not going to have a lot of environmental education, or positive influences around you."

The dominance of these deficit accounts of the Star Gazers' prior environmental knowledge and their perceived inability to connect with nature contributed to the outdoor education center's starting point for developing the curriculum of its so-called "underprivileged camp" and its nature-based pedagogies. These stark differences in children's educational experiences, which are rooted in the historical legacy of Apartheid and more recently the post-Apartheid moral imperatives of equity, redress, and social justice, inevitably influence the object of educational activity systems, including those of environmental education and outdoor education programs. For example, the object of the Mystic Mountain activity system was not only the provision of nature-immersion opportunities for children but also the provision of a safe and supportive space for socioeconomically disadvantaged children. However, as crucial as such interventions are, Devlin (2011) cautions that a deficit-based approach may constrain the children's potential learning outcomes by reducing them to what they "lack." Lotz-Sisitka (2009) similarly reminds us not to confuse people's historical contexts with people's power and inherent capabilities for learning, resilience, adaptation, and change. The challenge for nature-based educators then lies in exploring pedagogies that nurture children's own profound and intimate connections with their everyday contexts, promote resonant learning processes, and enhance children's own sense of Connectedness-with-Nature.

Technologies and Everyday Activities

Children's home environments and everyday activities – often involving the use of technology – emerged as another important mediator of Connectedness-with-Nature.

The Mountain Movers, for example, recognized various nature-oriented lifestyles (such as living on a farm) and other more typical, everyday interactions (such as doing homework or socializing with friends) as ways in which Connectedness-with-Nature had been influenced. The children's accounts also included mobile phone technologies and television as significant factors influencing their perceptions of and relationships with nature.

Both groups had strong attachments to their mobile phones and television shows which they exclaimed they were missing while on camp. One Mountain Mover referred to addiction to his mobile phone: "...[Your mobile phone] is like a potion...It has to be right next to you" (MM8); and a Star Gazer exclaimed: "I miss my TV, I miss electricity...my phone, technology...we can't have our phones here!" (SG2). The influence of mobile phones may be addictive, particularly for children, which may constrain opportunities for embodied nature connections (Carbonell, Oberst, & Beranuy, 2013). In contrast, two children from the Mountain Mover group did note the value of prohibiting mobile phone use during the camp as it strengthened opportunities for quality social interactions, for example: "It is awesome without my phone...Because we have more time to communicate" (MM7).

Although some of the children did not have much embodied access to nature in their everyday lives, they had regular access to knowledge *about* nature through television. Some children reflected on how nature-based television programs had contributed directly to their environmental knowledge. These and other technologies are recognized here as historical mediating artifacts in the children's lives, the cognitive and affective legacy of which the children bring with them into the activity system of Mystic Mountain and which continue to mediate the children's understandings of and relationships with nature in indeterminate ways; some might hinder embodied connection with nature, while other technologies enable environmental knowledge acquisition. Sociocultural theories emphasize the impact of context, everyday activities, and practices as pivotal in shaping how and what we learn (Engeström et al., 1999). Everyday activities and technologies mediate our value positionings and modes of meaning-making. As such, our understandings of the environment emerge from our continuous participation in our everyday life-worlds.

Sociocultural and Economic Constraints on Nature-Based Experiences

The risk of crime in natural spaces and potential threats to personal safety mediated the children's willingness to explore natural spaces in their everyday lives. Many children expressed fear around this issue, for example: "You will get raped if you have to walk on the beach late; that stuff happens a lot" (MM9). These fears are quite legitimate in contemporary South Africa, where people visiting certain beaches, parks, forests, and mountain trails are vulnerable to crime. Females in particular are afraid of visiting natural spaces for fear of being attacked and rarely visit isolated places alone. These social realities further compound "human-nature" disconnections.

Some of the research participants' responses indicated that access to natural spaces is often further constrained by finances and/or race. One instructor noted that nature-based experiences are historically perceived by black people as being "white people's stuff" (Ward-Smith, 2018). Some participants highlighted financial means as a pre-requisite to accessing natural spaces and activities like leisure camping. This speaks to the privileged and sometimes idealistic notion of people "getting back to nature" (Mcphie & Clarke, 2015) when hegemonic sociopolitical structures, historical contexts, and modern, consumerist lifestyles constrain access to nature. These prior perceptions of nature as dangerous and as spaces of privilege illustrate how Connectedness-with-Nature can be socioculturally and socio-materially mediated in ways that hinder connection. Decolonizing nature-based pedagogies would need to deconstruct such historically laden notions and open up new spaces for embodied nature connections and ethics-oriented reflexive deliberations around people-nature relationships.

Also significant were the ways in which the children's prior perceptions and understandings of and relations with nature played an integral mediatory role in connecting with nature in their everyday lives. At a surface level, children from both groups perceived nature as something somewhat separate from humans, for example, "I think more of animals and plants and then I think of myself" (MM3). Such perceptions are commonly associated with the notion of the "bounded self," which has been linked to the perpetuation of the human-nature binary and thus the perceived human-nature disconnection (Frantz et al., 2005). However, a closer look at the children's nature perceptions reveals an undergirding link between culture and nature in terms of the ancestral spirits, gathering of foodstuffs and traditional use of plants to sustain the human self. The children alluded to a direct, yet discreetly spoken of, connection between the natural world and the spirit world of the ancestors. For some children, this was expressed as apprehension around occupying certain natural spaces, highlighting a practical, material connection between people and nature that is mediated through spiritual and cultural practices. For children who recognize the powers (and expectations) of the ancestors and traditional healers, natural spaces are sites of negotiation which in turn mediate perceptions of safety in natural spaces. Thus, it is clear that nature is not only an individualized, subjective phenomenon, but perceptions of nature and feelings of Connectedness-with-Nature are socially, culturally, and historically mediated and negotiated (Zylstra et al. 2014).

Religious positionings were also seen to mediate children's sense of Connectedness-with-Nature and associated moral responses to environmental concerns. For example, they believed that the Earth belonged to God or that humans should care for the Earth, as required by God. For instance, one Mountain Mover stated: "God, Adam and Eve said that we have to take care of the Earth...but it doesn't seem like [that's what] we are doing" (MM4). The staff members' environmental ethics were similarly guided by a strong Christian orientation, for example, one manager described: "....having been brought up as a Christian, it's...like: 'you are custodians of the Earth and...everything within it' so you should be looking after it..." (Ward-Smith, 2018). These resonances between the children's and the adults'

beliefs in relation to God and their relationships with the nature established a strong Christian-led value synergy that cut across all aspects of the observed camps. These eco-religious value positionings shaped children's perceptions of and actions toward nature, illustrating the strong sociocultural influence that faith systems can have on environmental values (Biel & Nilsson, 2005).

Empathy in Sociocultural Context

Connecting with nature may also be linked to empathetic processes since it requires perceiving and feeling from the perspective of the "other" (in this case, nature) in ways which require openness to emotion, feeling, vulnerability, sensation, and embodied identification (McGarry, 2014; Zylstra et al., 2014; Jickling, 2009). The Star Gazers and the Mountain Movers had experienced feelings of empathy for nature prior to coming to Mystic Mountain. These were expressed, for example, through concern for the death of an animal (such as a street animal or a carcass) because of its bodily pain or through affection for an animal (such as a pet). The former example speaks to feelings of embodied identification with the pain of a dying animal, highlighting a more ecocentric, material similarity between human and more-than-human animal pain.

In some cases, however, empathetic relations with nature were seen to be constrained by socioeconomic circumstances. For example, one Star Gazer exclaimed that he would feel happy if an animal were to die because its death would give him access to a protein-rich meal: "I would feel happy [to see a dead animal]. . .because I would want to eat it" (SG2). Vulnerable children in the rural Eastern Cape are known to depend more heavily on wild-food sources, including bush meat, for their survival than those living in more advantaged socioeconomic circumstances (McGarry, 2008). This child's socioeconomic circumstances (one of enduring poverty) directly mediated his attitude toward animals as fellow sentient beings.

This section has shared extracts from the case study data to show the significant extent to which the children's developing senses of Connectedness-with-Nature were socioculturally and historically mediated through prior education, everyday activities and technologies, sociocultural and economic constraints, and environmental empathy. These insights suggest the importance of pedagogies that are gently attentive to the sociocultural nuance of children's lives and able to guide children to (re)negotiate their relationships with the natural world.

Embodiment and Socio-materiality of Nature-Based Experiences

This section summarizes data related to the actual physicality of nature-based activities at Mystic Mountain. Factors such as the weather, the terrain, and the overt physicality of nature-based activities are important mediators of nature-based experiences. For instance, in this case study, they directly influenced decisions to

participate in certain activities; they stimulated feelings of fear, humility, inspiration, and frustration; and they influenced memories of the camp experience and the place. Together, these in turn mediated the children's feelings of Connectedness-with-Nature.

The weather was a major determining factor in the children's expectations, experiences, and reflections on their time at Mystic Mountain. The weather might even be regarded as an implicit mediating tool due to its invisible role in mediating the children's engagement with the object of the Mystic Mountain activity system: immersion in nature. Many of the children were apprehensive about the cold weather conditions prior to and during the camps. Rantala, Valtonen, and Markuksela (2011) consider the weather to be an unpredictable material force of nature that can mediate people's experiences and practices in, and connections with, nature. They suggest that the weather affects people's engagement with nature-based activities in three main ways: anticipation of the weather, ways of coping with the weather, and discursive practices related to the weather (narratives and emotions that the weather evokes). In essence, the weather maintains a particular type of material agency (Human agency in relation to the weather can also play an equally strong part in determining nature-based practices.) that can "manipulate human practices by narrowing down or extending opportunities for outdoor activities" (Rantala et al. 2011, p. 285).

In the two camps, some forms of weather (such as snow, which is experienced as a novelty in this region of South Africa) were seen to excite some children's desires for outdoor experiences, while other weather conditions such as wind and rain (commonly perceived as disabling and uncomfortable) remarkably dissipated children's enthusiasm for being outdoors. The perceived and experienced physical strenuousness of the day hikes was another major factor that negatively influenced the children's experiences of hiking in nature. For example, one Star Gazer exclaimed: "The road is way too long for me and there are big hills" (SG3). However, negative experiences were sometimes countered by the experienced beauty of some of the goal-points of the hikes (waterfalls or view sites). Most of the children reflected on these day hikes with a strong sense of physical accomplishment, for example: "It's a beautiful sight...I have now seen a waterfall, it's breathtaking actually...It's just...wow!" (MM4). In terms of the night hikes, the darkness (linked to fear of animal attacks and fear of injury) was a key factor that negatively mediated the children's perceptions and experiences of the night hike. However, upon reflection, some children appeared to have enjoyed the night hike as it encouraged them to use different senses.

These experiences highlight how embodied, socio-material, and sensual encounters with nature can mediate perceptions of nature (Dorwart, Moore, & Leung, 2009). Attending to sight and hearing in natural settings can heighten embodied connections with nature by helping children to build more detailed and exciting understandings of their surrounding context (Gooley, 2014). Johnson (2002) maintains that experiencing a sense of "beauty," through overcoming challenges during the experience, may help to engender spiritual peace, humility, and comfort in natural spaces, in turn contributing to a sense of Connectedness-with-Nature. It

was observed on the hikes with both groups of children that a sense of accomplishment after overcoming the strenuousness of the day hikes and fear of the darkness during the night hikes seemed to strengthen their self-efficacy, agency, and confidence in natural places.

However, only one Mountain Mover appeared to have genuinely enjoyed the overall experience of the day hikes. This she ascribed to the way it triggered positive memories of spending time with her grandparents in nature. Historical resonances, in this case nostalgic memories, can be evoked through experiences in nature (Dorwart et al., 2009) which again emphasizes the importance of emotion in learning to connect with, and perceive, nature (Jickling, 2009).

This section has illustrated how the embodied or socio-material elements of nature-based experiences tacitly but undeniably mediated the development of children's Connectedness-with-Nature. This points to the importance of being more explicit when designing nature-based education programs about the mediating influence of sensual or physically demanding experiences on children's connections with natural places.

Value Contradictions and Resonances Within the Activity System

The previous sections have highlighted how sociocultural-historical and socio-material context influenced the children's developing sense of Connectedness-with-Nature in powerful yet underemphasized ways. This section will now discuss how contradictions or resonances between values and ethico-moral positionings within the activity system also mediated children's learning.

The "rules" of an activity system convey explicit and implicit regulations, norms, and conventions which can both enable and constrain environmentally oriented actions (Olvitt, 2012). When these rules do not align with one another, or with other elements of their activity system, or with other related activity systems, they produce systemic disturbances, tensions, or contradictions. According to Engeström (2001, p. 137), contradictions are the "historically accumulating structural tensions within and between activity systems." They are seen as having generative potential in driving learning and mediating transformation in activity systems.

In the Mystic Mountain activity system, contradictions arose around several of the children's established perspectives and practices of littering and harming animals. Such practices are directly at odds with the "rules" of the Mystic Mountain activity system (such as no littering and respecting the sanctity of life) which are undergirded by nature conservation values. For example, in response to the ongoing problem of children dropping their rubbish around the center and on hikes, one manager described how, for the Star Gazers: "Something like not littering is absolutely new. . .because there [are] very limited refuse removal services where they are." Other staff members highlighted a lack of environmentally conscious role models in the children's communities. This indicates the center staff's efforts to acknowledge the extent to which the children's everyday environmental practices (such as littering) are influenced by their prior sociocultural-historical positionings.

Several staff members described tensions between children's cultural practices or beliefs about animals and Mystic Mountain's values of the sanctity of life. Manager 1 highlighted how killing specific animals, like snakes and owls, is often related to cultural beliefs that are at odds with the values Mystic Mountain promotes:

> Something like snakes, we would obviously never allow them to kill a snake...We would catch it, take it far away and release it. [Also] things like the owls ...for the Xhosa...there are all sorts of stigmas around owls and snakes, even tortoises...The fact that we say, No, tortoises must be protected', this does come as something new to them.....(Ward-Smith, 2018)

Manager 1 believed that the children's sociocultural backgrounds mediated their behavior toward the animal/plant life: "At home...they are encouraged to do it [kill a snake]...Killing something like a locust or...a frog...is *irrelevant* but killing something like a snake...an owl...you are encouraged to do it. [Also]...damaging the plants and the wildlife as you go along..." (JI1, [00:23:00.19]). Further, some of the instructors, from a rural Xhosa background, were able to shed light on the tensions that the Star Gazers might experience at Mystic Mountain: "Like for snakes...like where you grow up [in the township], the first thing you do is, you kill it...Because you don't know...what it is going to do to you!" Further, he described an encounter with a snake while living at Mystic Mountain and how juggling both of his roles was difficult, as an instructor and as a Xhosa man (accustomed to killing snakes):

> [At] Mystic Mountain ...there was a snake, and I was like 'Okay!' I had never thought how to catch a snake [because] ... for the people that grew up in the location, if you see a snake, you have to kill a snake... it's a dangerous animal. So, I was like.....okay now I am wearing another hat [the instructor hat], which means I mustn't kill a snake because a snake can help you with keeping away rats and mice...It's some of the stuff that I have learnt at Mystic Mountain ...Most of the guys who are growing up in the location, they don't *have* that much information [...] Especially with us Black people, [seeing a snake] means something else, like an omen. (Ward-Smith, 2018)

These examples highlight the value tensions between children's and some instructors' cultural beliefs about animals and Mystic Mountain's pro-environmental rule of sanctity of life. Such tensions also highlight some important challenges for Mystic Mountain's continued exploration of decolonized pedagogies. There is a need to engage critically, sensitively, and reflexively with conflicting values and ethical practices in ways that are not impositional and that do not delegitimize either the children's or the center's values, everyday practices, and cultural beliefs. Nature-based pedagogies need to create "hybrid spaces" of exploration and deliberation that help children and instructors to depart from alienating narratives framed by narrow positionings of "right" versus "wrong."

Olvitt (2012) cautions against foregrounding tensions and contradictions in activity systems without giving due attention to continuities or resonances, which also appear to provide traction for ethics-oriented learning. On the Mystic Mountain

camps, there was evidence of eco-religious synergies between the children's religious value positionings and the environmental ethics of the outdoor center. For example, the following prayer is displayed on the dining hall wall at Mystic Mountain and is recited before meals:

> ***Mystic Mountain's Grace***
> *O God who made the pleasant shade*
> *The blazing sun the streams that run*
> *The food we eat the friends we meet*
> *The games we play here everyday*
> *Our heads we bow to thank thee now.*

During interviews and focus group discussions, several children referred to this prayer and the way it resonated with their experiences of nature connectedness. One Star Gazer, for instance, commented: "I really like the grace because it tells everything that happens around Mystic Mountain so sometimes when I want to pray at home I just say, 'Oh God who made the pleasant shade. . .'" [SG1). Instructor 6 also noted:

> It's a nice prayer. . . it accommodates everyone. Most of the words are touching on nature. . . that's what Mystic Mountain is about . . . If you take all those words and align them with everything that you are going through here. . .that prayer, it tell you what is going to happen . . .Also most of us, we are religious people.

Biel and Nilsson (2005) maintain that situational cues (e.g., reciting this prayer before meals) partly determine which religiously imbued values influence environmental attitudes. Like other sociocultural positionings, resonance with religious values may be an important dimension of mediating children's sense of Connectedness-with-Nature.

This section has highlighted how the environmental values and passion of the staff members (which is understood here as an essential underlying component of the activity system's mediating tool of nature-based activities) were another implicit but powerful mediator of the nature-based activities and, by extension, the children's environmental learning and Connectedness-with-Nature. This passion was mediated by the staff members' own backgrounds and the environmental values they promote as well as the environmental values that Mystic Mountain itself promotes (Ward-Smith, 2018).

Conclusion: Toward Resonant, Decolonized Pedagogies

From the vantage point of CHAT, this Chapter has argued for a triad of decolonizing, ethics-led, and embodied nature-based pedagogies, drawing on Ward-Smith's (2018) case study data of two children's camps at Mystic Mountain outdoor education center. The children's Connectedness-with-Nature was shown to be mediated by the dialectical interrelationships of sociocultural-historical, socio-material, and

embodied elements. These included values-based, relational encounters (such as the camp instructors' passion for nature and environmental care), immediate cultural artifacts (such as the nature-oriented prayer hanging in the dining hall), and rules of the outdoor center's activity system (such as the center's rejection of littering and its explicit commitment to the sanctity of life). Larger societal structures (such as politico-economic systems and the inadequacies of the state schooling system to develop children as informed, agentive, and reflexive citizens of the planet) and cultural practices and norms (such as people-animal relationships and how to dispose of waste) were also seen to mediate children's Connectedness-with-Nature. The case study further showed how all of these elements are emergent from the complex sociocultural history of colonialism; Apartheid, democratic politico-economic reform; traditional and contemporary people-nature relationships in AmaXhosa culture; and the cultural history of outdoor education centers and their pedagogies in the Eastern Cape province. Importantly, the children's own positionings in relation to this rich milieu were found to mediate their perceptions of, and connectedness with, nature both prior to and during the Mystic Mountain camps. There, mediating factors included children's prior formal educational experiences; prior environmental knowledge; their familiar, everyday activities; and their direct and indirect experiences of nature.

The case study shared in this Chapter raises important questions about the connections between transformative learning processes, reflexive ethical dialogue, cultural history, and people's connections with nature that are relevant to contemporary global struggles for people and the planet to flourish. The triad of decolonized, ethics-led, and embodied nature-based pedagogies has the potential to open up more nuanced, contextually resonant, and potentially transformative pathways to (a)mending the perceived child-nature disconnection. Some starting points for considering what such nature-based pedagogies might look like include:

- Acknowledging the world's relational complexity
- Acknowledging that children's sociocultural-historical value positionings are multidimensional, interactional, and fluid
- Building on children's everyday lives and matters of concern rather than asking that they adopt external or socioculturally disembedded knowledge and practices
- Avoiding a deficit approach to children and the capital they bring to nature-based learning contexts
- Centralizing and celebrating children's sensual embodiedness in the world
- Adopting a stance of openness and plurality that acknowledges that children from all backgrounds are capable young people with their own socioculturally inscribed ways of doing, being, knowing, and valuing in the world
- Creating challenging but safe spaces to deliberate contradictory and resonant value positionings.

Nature-based pedagogies framed in this way recognize children's lived historically, politically, socioculturally, and socio-materially diverse realities as the *starting point* of environmental learning processes. They can open up vital spaces for

collaboration and ethics-led dialogue that heed the call for nature reconnection in critical, collaborative, and embodied ways.

Abstract

This Chapter explores the dynamics of place as experienced by third culture kids (TCKs) who spend their developmental years in multiple and diverse physical and social contexts. Traditional conceptualizations and assumptions about a singular localized sense of place are not congruent with the changeability of TCK experiences, and so the concept of sense of place is reexamined with TCKs as the focus. Readers are introduced to two research-based case studies on TCKs and their relationships with place. A study from Hong Kong identifies potential differences between TCK and local Hong Kong adolescents in terms of their relationships to nature and place attachment and considers how relocation has influenced TCK sense of place (Urquhart, An exploration into the environmental identities and sense of place of internationally mobile adolescents. Unpublished master's thesis. Retrieved from https://purehost.bath.ac.uk/ws/portalfiles/portal/187944920/Oliver_PICTON_final_Thesis.pdf). A second case study of TCK adolescents in Qatar explores how the "gatedness" of residential contexts can strongly impact TCK experiences of place and sense of place (Picton, International school students' experiences of their local environment: a case study from Qatar. Unpublished PhD thesis, University of Bath, 2016). For TCKs, mobility has the potential to both expand and simultaneously limit engagement and identification with place and non-human nature. This Chapter calls for the recognition that for TCKs, immediate contexts are intrinsically linked to a diversity of places in their past, present, and future. Key aspects of place-based education (PBE) and the potential pedagogical challenges and opportunities are considered within the contexts of international schools. PBE is highlighted as a way to promote relational conceptualizations of place to drive an inclusive and globally minded sense of place for TCKs.

Third culture kids · Sense of place · Place attachment · Nature bonding · Place-based education (PBE) · International schools

Introduction to Third Culture Kids and Place

In an increasingly interconnected world, more and more children and youth are spending their childhood and adolescent years in multiple cities, countries, and environments. Furthermore, they experience diverse cultures and languages in varied geographies and ecologies. This Chapter looks to highlight the ways in which international mobility adds unique dimensions to a young person's sense of place and experiences of place that are worthy of exploration. Mobility and relocation challenge current discourse on sense of place that typically focuses on singular and prolonged places of connection and experience, which is incongruous with the reality of many internationally mobile children and young adults. This Chapter aims to justify an expansion of dominant conceptualizations of sense of place and

experiences of place to be more inclusive of multiple place experiences. We also explore the potential opportunities for place-based pedagogies, particularly within international schools, to help foster a sense of place from a childhoodnature perspective. In the same way the concept childhoodnature rejects anthropocentrism, this chapter rejects notions of TCKs being somehow separate from place, nature, and their environment of residence. If children are nature, then TCKs cannot be viewed as separate from their places of residence.

Who Are Third Culture Kids?

New York to Sydney, Hong Kong to Beijing, and Dubai back to Hong Kong: What reads like the itinerary of a world tour is actually an example of the places of residence and life transitions of an internationally mobile teenager from birth to age 17. Parental career choices are often the reason for childhood and adolescent transience, but changing family dynamics, evolving political and economic climates, and personal choice also impact mobility (Urquhart, 2016, p. 14). Characterizing and studying the lives of internationally mobile children is challenging, as the range of life experiences encompass a world of familial, cultural, ethnic, linguistic, and environmental possibilities and combinations. The term "third culture kid" was first used in the 1970s by Useem (1976) to describe the emerging group of children growing up outside of their "home" passport country and culture, with attachments to multiple cultures rather than one dominant culture. Internationally mobile children and youth are also sometimes referred to as "expatriate children" (Picton, 2016) or "global nomads" (Hayden, 2006), and each term has its own nuances in definition (McCaig, 2011, p. 47; Tanu, 2013, p. 5). To remain consistent with current discourse, this chapter will refer to internationally mobile children and youth as TCKs. It is also important to note that negative factors such as conflict and environmental degradation and change have also driven international mobility. Regardless of the terminology used, common characteristics are shared by these children and youth. Previous studies described the difficulties that TCKs can have in constructing social and cultural identities and in connecting to concepts of home because of their experiences living in numerous social contexts and having relocated multiple times (Fail, Thompson, & Walker, 2004; Grimshaw & Sears, 2008). The significance of this chapter will now be outlined by introducing some of the opportunities and challenges faced by TCKs in international school contexts and how experiences of environments and place can be shaped by mobility. The role of schools and the potentials of place-based practices will also be introduced. Both international education and "international school" are somewhat contested concepts with a number of definitions. International education is often equated with "cosmopolitanism" (Gunesch, 2004) and "global education" (Clarke, 2004). International schools are heterogeneous entities, but some broad generalizations are that they often cater for expatriates, employ teachers from overseas, are fee-paying, and offer international programs of study.

Chapter Significance

Instead of having one primary place of residence to connect with emotionally and cognitively, TCKs have lived in multiple locations and likely have difficulty identifying a singular home location (Nette & Hayden, 2007).This chapter therefore challenges sense of place discourse in environmental education and singular notions of place in place-based education (PBE). Pollock and VanReken (2009) argued that growing up internationally means that TCKs often have an expanded view of the world and strengthened cross-cultural skills (pp. 111–115), both of which are attributes described as having an "important and meaningful contribution to sustainable and tolerant societies" (UNESCO, 2006, p. 8). Yet TCK migrant status can also mean that there are potential language and cultural barriers which could limit TCK voice, community engagement, and ability to effect change within certain contexts. Additionally, TCKs can also live somewhat "sheltered" lives in gated communities or expatriate enclaves which can limit environmental engagement (Picton, 2016; Thieme, 2015). Here we see a duality; international mobility has the potential to both expand and simultaneously limit TCK engagement and identification with "place" and nature.

Research about identity formation in TCKs has previously focused on the social, cultural, and psychological aspects of child and youth identities (Fail et al., 2004; Grimshaw & Sears, 2008). While not independent from these dimensions, this Chapter focuses specifically on environmental and geographical place. Environmental education typically promotes a localized sense of place and has not yet given significant attention to how sense of place differs for those (like TCKs) that do not have a singular sense of home or place. This Chapter looks to address this gap and aims to contribute to a richer understanding of the experiences of TCKs. Specifically, this Chapter calls for an expansion to the "sense of place" concept to be more inclusive of multiple locations concurrently and to de-emphasize a singular and localized understanding of place. Although not directly included in the scope of this Chapter, there are potential implications here for other populations of children and adolescents that experience relocation, including immigrant families and refugees who likely have more limited choice in their relocations than TCK families due to political and social conflict.

The Chapter also explores the dynamics of place as it relates to international schools and pedagogy. The potential of PBE in TCK and international school contexts is outlined. A broad interpretation of PBE is adopted as learning where "lived experience of a local environment and community is a starting point for inquiry into the instability of meaning attributed to an always already mediated experience of the local" (Ruitenberg, 2005, p. 213). The power and value of PBE lies in how it can address "contextualizing knowledge and by resisting imperialist and homogenizing forces of globalized culture" (ibid.). For TCK teenagers who are potentially alienated or differentiated from their wider local community, this has a great deal of potential. PBE is at its core about "experience," placing emphasis on hands-on, real-world learning experiences. As a strategy for learning, PBE has been linked to increased academic achievement, helping students develop stronger ties to their communities,

enhancing students' appreciation for the natural world, and creating a heightened commitment to serving as active, engaged, and contributing citizens (Sobel, 2004).

Author Perspectives and Chapter Outline

Motivation to author this Chapter has been largely inspired by both of our professional careers as educators within international schools and our own personal experiences with international relocation. We have each lived and taught in multiple countries and have had regular contact with children who experience the challenges and joys of growing up as TCKs in multiple places. Both of us are employed at schools that offer the International Baccalaureate (IB) curriculum, and through the courses that we teach, *Environmental Systems and Societies* and *Geography*, students often share their personal stories that contrast their wide range of experiences (or lack of) with all types of environments.

Through our careers in education, we have both developed an interest in fostering environmental awareness and connection to non-human nature in our students. Research on sense of place and place experience has established that having a personal connection to an environment is a significant precursor to the formation of environmental values and pro-environmental behaviors (Kals & Ittner, 2003; van der Werff, Steg, & Keizer, 2013). In her analysis of a range of contemporary environmental philosophy, Heise (2008) summarized that "in spite of significant differences in social outlook, certain features recur across a wide variety of environmentalist perspectives that emphasize a sense of place as a basic prerequisite for environmental awareness and activism" (p. 33). Since a developed sense of place is a commonly referenced requirement for fostering pro-environmental proclivities, then we, as educators, have a responsibility to understand the TCK experience as it relates to place as fully and with as much dimension as possible.

Each of us began our explorations on the dynamics of TCKs and place separately, in the contexts in which we were teaching. Much of this Chapter is inspired by and based on our research case studies conducted with TCK students within international school contexts in Hong Kong (Urquhart, 2016) and Qatar (Picton, 2016). This Chapter will introduce readers to this empirical focus in section "Case Studies of Third Culture Kids and Place." The first study outlines findings about TCK relationships with non-human nature and place attachment in Hong Kong, and the second study examines how in the residential contexts of some TCKs "gatedness" can strongly impact place experience and sense of place. Although distinct studies, both examine TCK relationships with place, place identity, and local environmental experience. Few empirical studies beyond these examine TCK place experience and sense of place, highlighting the need for further research in the field (see, e.g., Sander, 2016). The studies presented both corroborate and conflict, likely in part because of the heterogeneous nature of TCKs, and the geographical contexts in which they live, learn, and play. Section "Third Culture Kids and Place" of this chapter will contextualize the research findings on TCKs and place within current theoretical frameworks. Section "International Schools and Place" then expands on the

dynamics and implications of place within international schools for TCK students. International schools tend to be preferred educational institutions for the families of TCKs, for several reasons that will be outlined. Lastly, section "Conclusions and Place-Based Potentials in International Schools" looks to summarize the potential for PBE in international schools and the pedagogical challenges and opportunities it poses in relation to TCKs. This Chapter concludes by examining how a relational conceptualization of place and environments can drive a more globally minded sense of place for TCKs and richer childhoodnature experiences.

Case Studies of Third Culture Kids and Place

The following two case studies are presented to explore some of the issues, challenges, and opportunities faced by TCKs in their environments of residence. The geographical and sociocultural differences between Hong Kong and Qatar also highlight the ways in which the complexities of place can potentially expand yet simultaneously limit TCK engagement and identification with "place." Discussion of how the findings from both students compare to one another and problematize traditional sense of place concepts will follow.

TCKs in Hong Kong: Relationships with Nature and Place Attachment

The intention with this study was to explore the presence and nuances of potential differences between TCKs and their more "local" adolescent counterparts in terms of relationships with non-human nature and place attachment. The findings for this case study came from mixed methods research on the experiences of secondary school students aged 14–18 residing and attending international schools in Hong Kong (Urquhart, 2016). The key research questions relevant to this chapter were:

1. What are the relationships, if any, between the number of international relocation students experienced and their general relationship to non-human nature?
2. What are the relationships, if any, between the number of years adolescents have lived in Hong Kong and their attachment to Hong Kong?
3. How does being internationally mobile impact TCK sense of place?

The first research stage used empirical analysis to explore any emerging quantitative differences between *local students* who have lived their entire lives in Hong Kong and students who have lived internationally in terms of how both groups relate to non-human nature and how attached they felt to Hong Kong specifically (to address research questions 1 and 2). The survey asked key demographic data and incorporated sections of two preexisting psychometric scales: the Nisbet, Zelenski, and Murphy (2008) *Nature Relatedness Scale* and the Raymond, Brown, and Weber (2010) *Place Attachment Scale*. The survey was distributed to students from five different international schools in Hong Kong which all offered the International Baccalaureate

program and reported a minimum of 30 different nationalities represented within their student population. The survey required students to respond to statements in a Likert scale rating system, and the resulting 213 responses from students with citizenship to 49 countries were analyzed for variance. However, surveys alone could not explain any identified differences between local and internationally mobile participants. The underlying reasons are much more multidimensional than a survey can reveal, and therefore 12 individual semi-structured interviews provided qualitative insight into the survey results in a way that highlighted participant voices. Interviews also addressed research question 3 about sense of place and allowed adolescent perspectives to be shared, which was crucial to understanding personalized constructions of sense of place and relationships with non-human nature.

Hong Kong is an ideal site of study for TCKs as there are a considerable number of international schools which reflects the large population of expatriate families and the desire of local Hong Kong Chinese families to have their children educated at schools with international curriculum and English-language instruction. The images and symbols associated with Hong Kong are often of the urban cityscape; however, Hong Kong also has a diverse ecological landscape with sandy and rocky shores, woodland, open grassland, and mountain ranges with a significant portion of geographical area preserved as country parks or marine parks. While these are accessible public spaces, the extent to which the participants from this study use them for recreation was difficult to determine. Opportunities for immersion into natural environments are available to residents, but conclusions about access cannot be made definitively. The following two sections outline key findings from this case study research.

Third Culture Kids Relationships with Non-human Nature

The question of TCK relationship with non-human nature was formed to address an assumption that this might be limited by mobility because of a suggested sense of being "unrooted," a term used occasionally in TCK literature (Eidse & Sichel, 2004). The Nisbet et al. (2008) *Nature Relatedness Scale* (NRS) is a tool used to empirically describe an individual's connectedness to the natural ecological world and "encompasses one's appreciation for an understanding of our interconnectedness with all other living things on earth" (p. 718). When student scores were analyzed for demographic differences using two-tailed t-tests and ANOVA, minor differences were found between school population and gender. More significantly, when grouped based on the number of relocations experienced in their lifetime from 0 to 3+, the results indicated that respondents who had experienced three or more international relocations were more likely to have a higher nature relatedness score from the survey than their peers. This indicates that the most mobile TCKs were more likely to express an appreciation and recognition of the interconnections and significance of natural systems in their survey responses (Urquhart, 2016, pp. 66–72). It is not possible to prove causation to conclude that high levels of international mobility were the reason for a stronger relationship with non-human nature. These results do, however,

indicate that international mobility does not negatively correlate with an adolescent's relationship with non-human nature as expressed in the survey responses. As research has linked environmental relationships with nature as a requirement to developing environmental values and behaviors (Kals & Ittner, 2003; Nisbet et al., 2008), we can suggest that internationally mobile TCKs have a similar capacity to behave and think in an environmentally conscious way as their less mobile peers (Urquhart, 2016, p. 106). One challenging dimension of this research was the TCK definitions of nature. When asked about their understanding of the term nature, the TCK participants typically shared an understanding of the concept of nature that echoed that of Clayton and Opotow (2003): "Environments in which the influence of humans is minimal or non-obvious, to living components of that environment (such as trees and animals), and to non-animate nature environmental features, such as the ocean shore" (p. 6) (Urquhart, 2016, p. 96). It is recognized that these understandings of nature often distinguish place from humans and are innately anthropocentric; however, TCK conversations about nature did tend to reflect this perhaps dominant human-nature dichotomy that childhoodnature looks to challenge (Malone, 2016).

Interview responses provided insights into TCK experiences of non-human nature, and three themes emerged that suggest potential reasons for a strong nature relatedness score: the significance of early family experiences in nonhuman nature; experiences in diverse environments; and an appreciation of impermanent contexts (Urquhart, 2016, pp. 74–77). Several TCKs who had relocated internationally shared stories of experiencing natural environments with family at a young age and engaging in outdoor activities such as hiking, camping, or going to the beach with parents and siblings. One TCK student shared her perception of her parents: "I don't think my family is the kind of people who are disassociated from the environment that we live in. We are pretty eager to immerse ourselves in the places we live in" (Urquhart, 2016, p. 105). This affinity for families to explore and a desire to fully experience diverse places would likely be values and attitudes transferred along to mobile children and adolescents. This is consistent with the writing of Louv (2005) who identified the significant role that parents play in introducing and normalizing experiences in non-human nature for their children. The role of family in introducing TCKs to such experiences was not an original focus of this Hong Kong case study but is worthy of recognition as a potential reason that TCKs are able to form equally as strong relationships with non-human nature as their peers who have not experienced international mobility.

Another theme which emerged from interviewing the Hong Kong-based TCKs was that life in multiple countries generated a diversity of environmental experiences, through engaging with a range of biomes, witnessing a variety of issues, and seeing diverse approaches and attitudes to environmental management. One TCK participant explained:

> I think actually why it [participant awareness of the environment] has evolved so much is because I have seen so many different environments. I have maybe a deeper appreciation. Had I lived in just one place seeing, for example, a tropical rainforest, then I wouldn't have an appreciation for, like environments with mountains and stuff like that. Because I have

> seen lots of different environments, I think that's something that really explains why I care about the environment. (Urquhart, 2016, p. 75)

A few TCK participants identified that an appreciation for a particular place originates from wanting to savor the experience of that place. Knowing that a location is unlikely to be permanently accessible encourages TCKs to be aware of the place, explore it and revel in it. Another participant shared that as a TCK, "since you move around a lot, you enjoy it [current environment] much more because it's precious time and it won't last for very long. . . You have to take advantage of it and appreciate it that much more" (Urquhart, 2016, p. 76).

Experiencing the similarities and differences between different geographical locations can provide a chance for adolescents to see firsthand the environmental issues and successes in the places they have resided. Thomashow (2002) argued, "Ecological transience offers a perceptual opportunity–a means to observe and internalize the diversity of peoples and landscapes" (p. 164). With the exception of philosophical perspectives like those of Thomashow (2002) above, there is a noticeable lack of research on the potential benefits of mobility as a way to experience environmental diversity and foster environmental concern. If mobility can provide TCKs with the diversity of experiences to conceptually view the world as a larger system, then this could positively impact their relationship with non-human nature. To further this, living in places for short periods of time generated in some TCKs a desire to make the most of their time, and they chose to engage fully with the places around them.

Third Culture Kids Place Attachment (Hong Kong)

The question of TCK attachment with Hong Kong was intended to address the assumption that the number of years of residence in a place will have a direct correlation with an adolescent's attachment to that particular location. The Raymond et al. (2010) *Place Attachment Scale* (PAS) was used to consider if correlations exist between the amount of time that an adolescent has spent in Hong Kong and the levels of connection they feel to Hong Kong. Responses to the PAS were analyzed holistically using a single PAS score and also separately by two of its dimensions: place identity and nature bonding. In reference to the PAS survey tool, place identity is defined as "those dimensions of self, such as the mixture of feelings about specific physical settings and the symbolic connections to place, that define who we are" (Raymond et al., 2010, p. 426). The nature bonding dimension specifically required students to consider their "feelings of belongingness or membership to some part of the non-human natural environment" (Raymond et al., 2010, p. 426).

When student survey PAS scores were analyzed for correlation, the number of years that a TCK had lived in Hong Kong has no statistical influence on how attached they were to Hong Kong as indicated by their overall place attachment scores. To analyze the data further, the subcategories of place identity and nature bonding were analyzed separately using divided groups based on years of living in

Hong Kong to complete a chi-squared analysis. The results indicated that there was sufficient statistical evidence to conclude that there was a relationship between the number of years an adolescent has lived in Hong Kong and his or her place identity score: adolescents who had lived in Hong Kong the longest had the highest place identity scores, and those who were newer to Hong Kong were more likely to have a low place identity score (Urquhart, 2016, pp. 81–83). While this trend might not be surprising, what was more surprising was that when the dimension of nature bonding was examined based on length of residence in Hong Kong, there were no discernable differences between those responses from longtime residents versus new residences based on how bonded they felt to the non-human natural environments in Hong Kong (Urquhart, 2016, pp. 83–84). The TCKs that participated in the interviews made statements that aligned with these empirical findings about time and place attachment. One TCK participant shared:

> I think the longer you live in a place, the more you will be attached to it because you have more memories. Locations are better memorized, and you can walk around it with your eyes closed. Since I have been in Singapore more, I feel more attached to it. In Dubai, I was only there for 1 year, so I don't feel attached to it.

Another participant elaborated on the idea of relating to a place and identified a sense of being attached to many places, but not with the same depth of identification:

> I feel like when you move around to so many different places, and you spend a good amount of time between them, in a way you can sort of relate to everything equally, but on the other hand, you can't really relate to them [places] as deeply as someone who has lived there a much longer time.

These two TCK students, along with other interview participants, connected the length of time spent in a place with increased familiarity and intimacy.

However, this relationship between length of time in a place and connection was not found when looking at the subcategory of nature bonding specifically. The following themes emerged through interviews as possible reasons why: the accessibility of Hong Kong for exploration (in both rural and urban contexts); a sense that feeling connected to a place is distinct from nationalism or patriotism; and a perceived difference in attitudes to nature between TCKs and their more local longtime residing peers. Many TCK interview participants felt as though Hong Kong's public transportation availability, relative personal safety, and lack of significant language barrier for English speakers made living and traveling in Hong Kong easy, especially when compared to other places the adolescents have lived prior to Hong Kong. The ease of accessing a place, particularly rural contexts, could explain the nature bonding dimension of place attachment as even adolescents who are newer residents of Hong Kong are not impeded to access natural spaces by barriers that may be present in other places (Urquhart, 2016, pp. 87–88).

A second theme that emerged from TCK interviews was an articulated dislike for perceived nationalism and patriotism. One participant shared, "I can't really hold too much of an alliance or love or a patriotism to any single country because they are

all. . . they have all in a way built me up to the person I am today" (Urquhart, 2016, p. 88). Participants made it clear that feeling a sense of loyalty to a place is not necessarily linked to being influenced or connected to a place. Thus, TCKs are able to experience, appreciate, and connect with a place despite not having a preexisting sense of identification, and perhaps identification is not as significant a prerequisite to establishing place connections as previously assumed.

One final result from the interviews was that several TCKs perceived a difference between themselves and their local peers in that TCKs noted that they themselves had more frequent encounters with the rural and natural place in Hong Kong than their peers who may have been born in Hong Kong. In most cases where this distinction arose, participants saw this to be of concern and expressed interest in encouraging others to engage more with Hong Kong's environments:

> I really think that it is important, for Hong Kong students especially, that they need to get outside more! Out hiking, but not just hiking, but even get to the beach, you know? Get outside. I think that is something that Danish students have but that Hong Kong students lack is that ability to be more alone and just be by yourself. . . Get out hiking or exploring and being in touch with nature.

Exploration of Hong Kong, inclusive of natural areas, is a technique used by TCKs to build familiarity and attachment with Hong Kong. Although participants did not explicitly identify cultural influences as a distinguishing factor, it was hinted at in the interviews. The willingness and interest to experience the natural side of Hong Kong is perhaps a way to compensate for the reduced amount of time mobile adolescents had lived in Hong Kong.

This Hong Kong case study made it evident that internationally mobile lifestyles have impacted TCKs who hold memories and experiences within diverse places. The findings of this research challenge the assumptions that a sense of "unrootedness" automatically limits a TCK's ability to form relationships with non-human nature and shows that mobility does not necessarily negatively impact his or her connection to the natural world. One important reminder is that the context of Hong Kong was likely a significant factor when shaping TCK relationships with non-human nature and attachment to place in this case study. TCKs likely benefit from Hong Kong's linguistic accessibility and internationalism, thus opening opportunities for TCKs to engage and explore. As seen in the next case study on the TCK experience in Qatar, not all international experiences afford TCKs the same level of social and physical access to place.

Third Culture Kids in Qatar: Gated Communities and Third Culture Kid's Experiences of Place

Picton's interpretive case study examines how students aged 13–14 attending an international school located in a large gated company township/compound in northern Qatar experience their local environment of residence. Where Urquhart's study

focused on relationships with non-human nature, sense of place, and place attachment, this study was framed as a study of environmental *experience*. A range of terms are used in literature to describe how people understand and experience their world, and many of these overlap. Some are somewhat "everyday," for example, "understandings," "knowledge," and "perception." Others are more technical and grounded in academia and various epistemologies, for example, "discourse," "representations," and "imaginative geographies." Experience was chosen to frame this study because of its all-encompassing nature, with many of the other ways of understanding the world foregrounded in *experience* of the world.

The research revealed the importance of understanding how "gatedness" impacts environmental experience for some TCKs. A growing volume of research from a variety of disciplines, notably urban planning studies, cultural geography, and anthropology, have started to explore gated communities as a feature of living spaces across the world – often for wealthy nationals and expatriates in countries with more extreme inequalities in wealth distribution (see Brunn, 2006; Glasze, 2006; Low, 2003). There is now also some interest in how these residential forms are impacting children's sense of place and place experience (e.g., Sander, 2016). The significance of understanding gatedness in TCK experiences of place lies in the understanding that physical space produces the preconditions of social space. As previously noted, the lives of many TCKs can be both highly unbounded on a macroscale, experiencing frequent moves and high levels of international mobility, yet in everyday terms be restricted by various types of boundedness or gatedness – real and imagined, physical, and more sociocultural. A range of factors can inhibit or encourage place and non-human nature interactions for TCKs, including safety, language or cultural barriers, family and school attitudes to host environment, climate, and type of home residence.

The research presented here was conducted at a large British international school in the north of Qatar, owned by the national gas companies. The school and students' homes were both located within a walled and gated housing community with over 10,000 expatriate residents from over 60 different countries. Using qualitative methods – map drawing, concept mapping, walking as method, and focus groups – and a participatory data analysis framework with 58 Year 9 (13–14 year old) students over 2 phases of research, the study revealed the importance of acknowledging how gated living can impact place experience and sense of place for TCKs. Although such levels of physical gatedness are not universal for TCKs, it is common for migrants and TCKs to live in gated complexes, apartments, or compounds all of which restrict entry/exit and act as a semipermeable residential form. This may be for safety, convenience, or cultural reasons. The research used a process of co-analysis with participants to develop categories of place experience. Across two phases of research, the participants themselves developed 13 "categories" of place experience, encompassing a range of physical environments, imagined spaces, and types of experiences. These are summarized in Table 1.

Using a process of co-analysis and researcher theorizing five key findings emerged in the research. These have implications for understanding childhood place experience for TCKs, in particular those living in similar geographical and

Table 1 Categories of place experience identified by third culture kids in Qatar (Picton, 2016)

Category of place experience	Examples and detail
People and cultural places	Encompassing the territorialization of space and ethnic stereotyping in the community, as well as territories based on company (employer) allegiances
Economic places	The social importance of shops as sites of socializing
Gates and walls	Physical boundaries and the importance of gatedness. Children noted feelings of imprisonment but also more positive notions of gatedness including sense of safety and security. Some gates were more imagined with nonphysical boundaries also perceived. Walls were also used as sites for play
Religious places	Both formal religious sites (mosques) and more metaphysical places with spirits
Social places and recreation	The street, youth clubs, sports facilities – all often gendered in their use and perception
Transport and roads	The physical morphology of roads and transport. The impact of car dependency in the community was reflected with many having a very nodal sense of place – disparate locations experienced and connected by car transportation with little understanding of their relative locations
Health	Health center (local clinic) and healthy places
Home and homes	Understood on many scales from bedrooms and belongings to home as homeland or place of belonging
School	Experienced as a place of learning, friendship, and socialization. Valued but also often disliked
Time	The *process of place* – time of day, seasons but also related to time perception. Notions of time being experienced at different "speeds" in different places. Also encompasses change and continuity of environments more generally
Online world	Online lives and their significance for identity formation and maintenance for TCKs were noted
Safe places	Spaces of fear and comfort, as well as the presence of security personnel, were significant. In many senses this category is linked to "gates and walls"
Environment/the outdoors	The importance of nature, wastelands, secret places, green spaces, and the outdoors more generally. A small minority of participants had strong connections to the physical environment

sociocultural contexts, for example, compounds or expatriate enclaves in the Middle East.

1. **Gatedness impacts children's experiences of local environments**: the research found that the everyday lives of TCKs were impacted by the presence of gates, walls, and security patrols. These limited independent mobility and as a result severely limited knowledge, understanding, and experience of wider nature beyond the immediate area of residence.
2. **Binaries matter**: the local environment was often experienced and understood in binary terms between the "real" and "imagined," oppositional understandings of

"us" and "them," "natural" and "unnatural," and understandings of the known and unknown in spatial terms. Such binaries would support notions of children being separate from nature.

3. **Borders and boundaries lead to transgressions**: areas such as wastelands and other derelict spaces were often special and hidden places for participants in the study. The children created their own microgeographies, challenging power structures and dominant uses of space and place. The appropriation of space and subversive use of places was a means of challenging inherent power structures.
4. **Othering needs challenging**: in the multiethnic and multicultural community under study, the children developed "territories" based on a range of factors, most notably nationality and company allegiances (parent employers). Some evidence of xenophobic attitudes emerged in data from some participants, highlighting the wider issue of cultural conflict in international communities, and international schools.
5. **Environmental experience is inherently temporal**: experiences of place, nature and sense of place, were found to be time dependent. Experiences of places changed depending on time of day and season. Notions of the passage of time itself being experienced differently in different places (slow time vs. fast time) emerged. Children also noted change and continuity in the environment, acknowledging landscape changes both in physical and human terms. Here it is useful to conceptualize place as process, where place is "made up of the social constellations (local as well as global) that unfold at a given location at a given time, which entails that places *do not hold stable identities*; rather, they are continuously reconstructed through the social processes that intertwine in a given location" (Christensen, Mygind, & Bentsen, 2015, pp. 591–592 own emphasis added).

There are multiple implications of these findings for understanding childhoodnature. Certainly binary understandings of place and othering need to be challenged, with more opportunities for TCKs to deconstruct binaries of place, for example, through critical place-based pedagogies in their local area of residence. Similarly, acknowledging the potential difficulties that TCKs have in voicing concerns and ideas about their environment of residence needs consideration. These challenges emerge from their frequent moves, which can lead to loss of "voice" because of lessened community knowledge and embeddedness – both prerequisite for developing voice and having it heard. In some TCK contexts, the controversial politics and power geometries of "indigenous," "hybrid," and "non-indigenous" voices add, potentially, a further problematic dimension to listening to TCKs. If their voice represents, and is perceived as one that is "nonlocal" or even colonial, this is a huge challenge to placemaking and place-engagement. Despite these obstacles, which are likely both real and perceived, the importance of TCK voices in the creation and maintenance of child-friendly environments is an important theme.

Bridging the Findings

Both the Hong Kong and Qatar case studies highlight the complexities of mobility and the implications for place that are inherent in the experiences of TCKs. Initially, they may seem to contradict: the Hong Kong participants expressed equal if not elevated relationships with non-human nature and nature bonding, whereas the TCKs in Qatar felt their experience of place and non-human nature was limited by gatedness, borders, and "othering." However, both findings can coexist. The point remains that the TCK experience and sense of place come from a unique perspective that may be simultaneously limited and expanded due to their circumstances. The heterogenous nature of TCKs and their environments of residence means that further investigation into their experiences and everyday lives in different contexts is needed and encouraged. The remaining sections in this Chapter aim to consider these findings within current theoretical frameworks on place and then highlight the potential of place-based pedagogies for TCKs.

Third Culture Kids and Place

Conceptualizing Place

As we consider the experience of places by TCKs in the above case studies from Hong Kong and Qatar, reviewing the concept of place itself is of great importance. Place is a useful lens through which environments, and experiences like those of TCKs, can be viewed. Somerville and Green (2015, p. 36) note:

> as a conceptual framework, place provides a bridge between the local and global, real and representational, indigenous and non-indigenous, and different disciplinary approaches. Place itself is theorised in different ways according to the perspective of each person. Children have their own theories of place… Rather than defining and delimiting what place means, we ask what can place enable in our thinking and empirical research?

This support for place as a conceptual framework for understanding childhood and adolescent experiences touches upon many of the issues central to this chapter: How do the constructs of local and global intersect in the lives of TCKs? How do "indigenous" and "nonindigenous" knowledges intermingle? How do children's real and imagined places combine? While these issues are explored in Urquhart (2016) and Picton's (2016) studies, this is still a neglected field of study requiring further exploration. Massey (1994) is perhaps the first author to challenge the more singular and conventional understanding of sense of place and argued that the character of a place:

> can only be constructed by linking that place to places beyond. A progressive sense of place would recognize that, without being threatened by it. What we need, it seems to me, is a global sense of the local, a global sense of place. (p. 156)

Massey's (1994) call for a broader sense of place has been echoed by Heise (2008). After her critique of the limitations of the sense of place concept in a globalized world, Heise (2008) identified the need to find ways to understand narratives that reveal a "new kind of eco-cosmopolitan environmentalism that might be able to effectively engage with steadily increasing patterns of global connectivity" (p. 210). Although we are not promoting the use of additional ambiguous neologisms such as "eco-cosmopolitan" to be applied to TCKs, we agree with the sentiment of her conclusion: the need to include a multiplicity of places into one's sense of place is becoming increasingly common. This justifies the need to update assumptions about sense of place, and to recognize that for TCKs, immediate contexts are intrinsically linked to those places of an individual's past and future. In this Chapter, place is understood as constructed when an individual attaches meaning to a physical location, and like Malpas (1999) and Massey (2005), we do not wish to neglect the physicality of the environment. Similarly, with our focus on TCKs, we do not advocate a static understanding of place nor a singular one. Instead we want to emphasize the fluidity, openness, multiplicity, hybridity and changeability of place, and thus experiences and perceptions of the environment. We align our understandings of place with those of Massey (2005): place should be understood as relational – as process, unbounded and negotiated. It is when TCKs attach meaning to their physical location that place is constructed and experienced, in multifarious ways. When place and the inner self meet, there are diverse relationships which are constantly in flux – a negotiated process. It is an emotional relationship dependent on the body – hence the significance of embodied geographies of place – this embodiment of place is even more significant for children who often experience the landscape in more physical ways than adults through outdoor play and exploration (Cele, 2006).

Conceptualizing Sense of Place with Third Culture Kids

The discussion about place is inherently linked to sense of place research, which considers the depth to which individuals and societies understand their immediate surroundings and build cognitive and emotional ties with a place. For this Chapter, we propose that sense of place is a key component that contributes to an individual's identity. Philosopher Arne Naess (1985) stated, "The nearer has priority over the remote – in space, time, culture and species" (p. 268). Heise (2008) noted that Naess is not alone in prioritizing the immediate local context. She summarized that many environmental thinkers make associations between the concepts of "spatial closeness, cognitive understanding, emotional attachment, and an ethic of responsibility and 'care'" (p. 33). The limitation of prioritizing one local context is that many TCKs do not associate themselves purely within one physical context. Another challenge is that with emerging environmental concerns spanning across national boundaries, having a sense of place with a particular location may not be enough to provide the impetus to respond to issues that impact the world on a global scale.

Sense of place is a psychological construct that is developed over time with a variety of virtual or physical experiences and is heavily mediated by social contexts. Sense of place is itself a nebulous construct and often incorporates multidimensional experiences. More recent usage of sense of place with a psychological approach considers how connected an individual feels with a certain place (Kudryavtsev, Stedman, & Krasny, 2012, pp. 230–231). Two main components of sense of place are identified: "place attachment" (Kudryavtsev et al., 2012, p. 231) and "place meaning" (pp. 232–233). Kudryavtsev et al. (2012) define place attachment as the bond between people and a place or, in other words, the extent to which a place is important to people (p. 231). Place meaning refers to the symbolic significance that an individual ascribes to a place from their life experiences (p. 231). In other words, "place attachment reflects how strongly people are attracted towards places, while place meaning describes the *reason* for this attraction" (Kudryavtsev et al., 2012, p. 233). Both place attachment and place meaning are highly individual and remain fluid as they evolve through a person's life.

This process of ascribing and renegotiating place attachment and place meaning is ongoing, and an individual's sense of place is the result of an amalgamation of all experiences. For TCKs specifically, this process involves multiple geographical places. It was found that relocation is not comparable to resetting an individual's sense of place back to a blank state of detachment (Urquhart, 2016). Instead, relocation requires an adjustment period in which negotiation processes incorporate the current environments into previous contexts. If authentic attachments begin to form between adolescents and their environments, then that place becomes amalgamated into their overall sense of place (Urquhart, 2016, p. 109). The incorporation of multiple places into a sense of place is distinctly different than the construct of "placelessness" (Gruenewald & Smith, 2010, p. xvi) or "unrootedness" (Eidse & Sichel, 2004) and challenges the suggestion that mobility could weaken the sense of place of TCKs.

When our understanding of sense of place is expanded to include multiple places, this means that we need to let go of the premise that sense of place is experienced only as an immediate singular construct. In his discussion of place-based transience, Thomashow (2002) concluded:

> Yet I am not willing to let go of this place-based philosophy. Not only does it make good pedagogical sense but it speaks to the possibility of ecological fidelity, and lends me a sense of rootedness (however transient) in a world of ceaseless motion. (pp. 176–177)

Here, we both agree and disagree with Thomashow (2002): we challenge the term "ecological fidelity" (p. 176) which promotes singularity and we argue that fostering an individual's engagement and connection with one context essentially strengthens their connection to all of the places that are incorporated into his or her sense of place. If, however, the sense of place concept can be expanded to be inclusive of multiple places all at once, then we agree with Thomashow that it makes pedagogical sense to foster sense of place through PBE, as we will outline in the next section of

this chapter. Sense of place becomes a more holistic concept of understanding oneself in relation to the multiple places that compose identity.

International Schools and Place

Significance of International Schools

TCK's engagement with place in terms of childhoodnature, sense of place, place interaction, and place experience is unique for two key reasons: TCKs experience the *process* of place as they transition from place to place, and their migrant status and potentially "sheltered" lived experiences can lend itself to a lack of community voice or engagement because of language, cultural, or physical barriers. These dynamics of place for TCKs often manifest in the arena of formal education. International schools, international education, and the experiences of TCKs are themselves bound up in complex negotiations of place and different environments. Both international education and "international school" are contested concepts with a range of definitions (Hayden, 2006; Hayden & Thompson, 2013). "National" schools can embrace international education – the term is inclusive. International schools are not homogenous entities – but some generalizations are that they often cater to expatriate families, employ teachers from overseas, are fee-paying, and offer international programs of study. However, in some countries it is now very common for international schools to cater for an almost exclusively "local" market or even to have "international programs" within national schools. Many TCKs attend international schools as internationally mobile families often view international schools as more culturally inclusive in comparison to local public education systems around the world because of student and staff diversity and/or use of international curriculum. English is often a language of instruction (Hayden, 2006; Hayden & Thompson, 2013). Additionally, for highly mobile TCKs, international schools can also provide stability through their common features like values, aims, and curricula, even though country context may have changed significantly. Typically, the students who attend international schools come from families that have a middle to upper socioeconomic status which often has implications of privilege. The two studies presented earlier in this chapter emerged from the context of international schools.

Negotiating Place in International Schools

Both TCK experiences and international schools are bound up in complex negotiations of place and environments. Decisions about place, including curricular decisions, combine to shape the TCK understanding of place. Globally mobile parents and their employers make choices about places to live and travel, while educators and schools also make choices about the places students will study. Through these parameters, TCKs make everyday choices and negotiate various environments.

Place and the local environment in international school and TCK contexts can be explored in three interrelated ways:

1. **Practical pedagogies of place**: the role and potential of PBE, place-situated pedagogies, place-conscious education, and how place is negotiated in the curriculum.
2. **Curriculum places**: the landscape and topography of place and environments in the (written) curriculum itself and different conceptualizations of place in education as linked to different educational ideologies.
3. **School embeddedness in environments** (physical and social; local and global): school interactions and interconnections with the wider local environment and community, as enmeshed in the bundle of trajectories – human and non-human – that make up place. International schools often engage with non-human nature, place, environments, and communities on multiple scales – nearby (e.g., through field trips and local language learning) and much more distant, for example, through membership of regional school organizations and sporting events. Ideologies of community embeddedness are likely to impact both 1 and 2 above.

Practical Pedagogies of Place (Place-Based Education)

PBE is not an uncontested concept, but some of the key features include that it is locally based, student-centered, experiential, and interdisciplinary (Ormund, 2013). As Sobel (2004) notes, "One of the core objectives [of PBE] is to look at how landscape, community infrastructure, watersheds, and cultural traditions all interact and shape each other" (p. 9). PBE is a reaction against what is perceived as "placeless" curricula, decreasing outdoor experiences for children and decreasing attachment with non-human nature. The assumption of PBE, rather like bioregionalism, is that rootedness and attachment to place are preferable to placelessness or weak place attachment, a humanistic understanding of boundedness and the importance of "home" (Picton, 2016). The importance of nature in PBE is central, although PBE is not exclusively reserved for educational experiences in the "wild" and is inclusive of neighborhood and urban exploration. Nature is found in many environments including urban ones. Indeed, PBE in the research literature appears to focus on place-interactive education in primarily (a) "Minority western" contexts and (b) temperate environments – woodlands and wetlands in particular, therefore neglecting the environmental and social realities of many regions of the world where TCKs live. Somewhat romanticized and anthropocentric ideas of getting children "out" into the environment are not universally straightforward for environmental, social, and safety reasons. This does not, however, mean PBE cannot be introduced in the classroom in such contexts, but these challenges must be acknowledged.

David Gruenewald's (2003a, b) articles about place in the curriculum focus on a more critical pedagogy of place. For Gruenewald, the concept and physical reality of place are "profoundly pedagogical… as centres of experience, place teaches us about how the world works, and our lives fit into the spaces we occupy. Further,

places make us: as occupants of particular places with particular attributes, our identity and our possibilities are shaped" (Gruenewald, 2003b, p. 647). Somerville, Kerith, and de Carteret (2009) propose a new pedagogy of place taking Gruenewald's ideas of decolonization and reinhabitation, but with a renewed focus on moving away from binary constructions of thought, something necessary when exploring place with children in schools (Picton, 2008). Further contesting of PBE concepts has come from writers like Malone (2016) and Ruitenberg (2005). Malone (2016, pp. 53–54) has critiqued, from a broadly posthumanist perspective, current conceptualizations of place-based practices and children's interactions with non-human nature, and place more generally, for sustaining nature-culture binary understandings and for being anthropocentric. Here Malone "decenters" anthropocentric and romantic views of "reinserting" children in nature, instead analyzing the complex interactions between children and the "more-than-human" world. The exceptionalism of humans is challenged by Malone, and writers in this Handbook, in favor of viewing humans – including of course children and young people – as part of nature rather than separate from it.

Other critiques have also emerged which are particularly relevant to TCKs. Critically examining concepts of "local" and the privileging of the local in PBE is important. For example, Ruitenberg (2005, p. 218) outlines the concept of a "radical pedagogy of place":

> A radical pedagogy of place is a pedagogy of "place" under deconstruction, a pedagogy that understands experience as mediated, that understands the "local" as producing and being produced by the trans-local, and that understands "community" as community-to-come, as a call of hospitality to those outside the *com-munis*. In a radical pedagogy of place, students are taught to see the multiplicity of and conflicts between interpretations of a place, the traces of meanings carried by the place in the past, the openness to future interpretation and meaning-construction. A radical pedagogy of place does not pretend to offer answers to or "correct" interpretations of hotly contested places.

The critique of the "local" here is significant, in a time when local/global/indigenous/nonindigenous/hybrid forms are blurred. Concepts of "local" are certainly challenged by TCKs and transnationalism, where the "hereness" of the local is inevitably "contaminated," to use the words of Ruitenberg, by the "thereness" of the nonlocal because of globality. These ideas certainly resonate with Massey's (2005) view of place as relational and as a nexus. Where a relational and fluid approach is adopted, it is argued that a richer view of place emerges, as opposed to absolute or relative views – where place is defined and made by their "outsides" as much as by their "insides." Distinctions between people and place are also nicely resolved by Massey in her global sense of place with "bundle of trajectories" where the mix of people (and absence of people) and interaction with physical space and objects is an integral part of place. This brings Massey's theorizing back to the more relevant scale of pedagogies, childhoodnature, and the breaking of nature-child binaries. Here we can apply her ideas to the context of PBE, where emphasis on the local and bounded must not preclude relational understandings of place – where if place is a "collection of stories," PBE should be a reading of these layered stories. This is

reminiscent of Somerville et al.'s (2009) conceptualization of our relationship to place as constituted in stories and other representations. Section "Conclusions and Place-Based Potentials in International Schools" in particular will further discuss the potential of PBE for TCKs.

School Embeddedness in Places: International Schools and Their Environments

Concepts of "local" in international schools attended by many TCKs are blurred by mobility, access, and communication. In some contexts, what is perceived as local and local community may be, in geographical terms, distant and vice versa. International schools engage with their wider environment in a number of ways. Since there is so much diversity in international schools, there is a great deal of diversity in the ways such schools engage with place, some of which may include service learning experiences, fieldwork, host country student enrolment, integration of host country curricula (including language learning), physical structure of buildings, and host country teacher engagement (Picton, 2016). Therefore, TCKs and the international schools many attend do not exist in isolation, but are embedded, to various degrees, in communities of migrants and nationals, often identifying both with internationalism and more locally based identities.

It is clear that PBE and school embeddedness in place are contested but significant fields. These interactions are co-implicated in how TCKs and international schools are themselves "place-situated" through their educational experiences. The relationships between TCKs, school embeddedness in environments, and pedagogies of place impact upon, and are reflected within, each other.

Conclusions and Place-Based Potentials in International Schools

A child's experience with place and non-human nature is fundamental to their learning. Attempting to understand TCK perspectives is required by educators when developing engaging, relevant, and rigorous curricula. Studies such as those presented here as case studies are beginning to explore TCK's sense of place and environmental experiences. The contrasting findings of the two studies from Hong Kong and Qatar presented earlier in this chapter highlight the heterogenous nature of TCK experiences of place. This is also underpinned by the "view that education can happen anywhere: through informal as well as formal experiences; in homes, communities, and environments; through interactions with the human (parents, friends, and classmates) and the nonhuman (physical objects, parks, woodlands, and buildings) world" (Martin & Pirbhai-Illich, 2016, p. 355).

However, there are unique challenges for TCKs and international schools in incorporating place-based practices into the curriculum. International schools

face the challenge of providing education for children, often TCKs, for whom the local environment (physical, sociocultural, political, economic) will often not, at least initially, be known to them through extensive childhood exploration and intergenerational knowledge. In contrast, children growing up in less mobile communities may grow up in the same or similar environment, developing detailed knowledges of the local area and culture, building relationships, observing, and being a part of processes of change. It is not suggested that mobility is limited to TCKs, but their experiences of it are certainly intensified and accelerated. It is argued here that critical PBE, place-conscious or place-situated curriculum, may help international school students know, experience, and value their environments of residence in a more intimate way and therefore provide opportunities to develop attachments to place and develop their own sense of place and place identity – shifting from residing in to inhabiting place.

What is clear, as international educators, is that a place-situated and place-conscious pedagogy for TCKs and internationally mobile children must be especially globally minded and progressive, grounded within a relational understanding of space and place. This involves exploring places not in absolute or relative terms as bounded, isolated, nodal, or disconnected, but as process, negotiated and unbounded. This goes somewhat against the "new localism" of some PBE, with its risks of a somewhat parochial and conservative notion of place. Indeed, for some students, excessive focus on the "local" in international school contexts could be intellectually isolating. Here, it is useful to return to three of Massey's (2005) relational understandings of place – as process, unbounded and negotiated – and how these might shape and influence place-based pedagogies for TCKs. Any place-based practice or pedagogy need to be framed within a clear concept of space and place – place as process, unbounded and negotiated.

PBE for TCKs in international schools should start by considering the students themselves. These are children and youth who are, through their everyday lives, often deeply embedded in multiple places. Place-conscious education in international schools should embrace and celebrate local-indigenous voices on and of place alongside hybrid international-migrant perspectives. Educators should also recognize that sometimes there may be conflict emerging in these dialogues and that this should be embraced. Using PBE as a means to develop a singular construction and identity of place or nature is not desirable since this leads to seeing places as bounded with *insides* and *outsides*. This is a clear challenge to humanistic notions of place as deeply rooted and bounded. It is suggested that focus on home locality in PBE "runs the risk of encouraging parochialism, a loss of solidarity with other places and peoples, and even xenophobia which is inimical to the practice and achievement of global sustainability" (Morgan, 2011, p. 96), although we would hope this would be less likely in the intercultural and cosmopolitan contexts of many TCKs. Instead, as Massey proposes, places should be explored and understood as being relational – defined and made by their "outsides" as much as by their "insides." This has identity implications (where identity for

TCKs is defined by both "outsides" and "insides," however this is conceptualized), and with implications for PBE:

> No longer is identity (on the broader canvas, 'entities') to be theorized as an internally coherent bounded discreteness. Rather it is conceptualized relationally – with implications both internal (in terms of fragmentation, hybridity, decentering) and external (in terms of the extension of connectivity). (Massey, 2006, p. 37)

Therefore, something akin to a "global sense of place" is desirable or a "place-based global curriculum" (Kenway, 2009) which is both inward and outward looking, with emphasis on "links and interconnections to that beyond" (Massey, 1994, p. 5). Educators who work with TCK students need to make conscious and thoughful efforts to prompt students to consider how local learning connects to larger issues that space multiple places. If this is done well, then PBE can be used to support the development of sense of place so that all experiences with place can be carried by TCKs along their mobile journeys.

Although research exploring TCK identity and concepts of home certainly exists, few studies beyond Urquhart (2016), Picton (2016), and Sander (2016) directly examine TCK experiences of place and nature and try to uncover the dynamics of their everyday lives. We hope this Chapter encourages more researchers – from a variety of fields of study – to examine the unique perspectives and experiences of TCKs. It is clearly a challenge to generalize TCK nature/environment experiences because of the inherent heterogeneity of TCKs and their diverse experiences, environments of residence, and mobilities. Indeed, TCKs challenge many theories and understandings of place – sense of place, place attachment, and place identity – by virtue of their mobilities. Additionally, the dynamic nature and evolving negotiation of an individual's environmental identity mean that conclusions about TCK and place relationships may hold true in one place and time but not in another. A consideration moving forward is how to conceptualize child-non-human nature and child-place interactions for TCKs while also deconstructing these very binaries. In particular concepts of local-nonlocal, indigenous-nonindigenous, and attached-detached need exploration – and going further to examine TCK experiences from a less anthropocentric perspective. If children are nature, then TCKs by extension cannot been seen as somehow separate from their communities and environments of residence but as fundamental parts of these.

Abstract

In this final section of the Handbook, we turn to ecological aesthetics in response to radical changes in both *the nature of childhood and the nature of nature* in the contemporary world. Artistic and aesthetic approaches have become increasingly relevant as children encounter a world typified by the acceleration of social, technological, and environmental change, and the mutually reinforcing conditions of planetary instability, inequality, and precarity. Anthropogenic climate change, the mass extinction of plant and animal life, and the chemical contamination of air, food, soil, and water resources are transforming not only what we might think of as "the environment," but also the aesthetic qualities and environmental sensibilities that constitute the experience of *being alive*. For many scholars these changing conditions of Earthly life have taken on the name of

'Anthropocene', an epoch defined by the total imbrication of human life with more than human planetary systems and technologies. The authors in this section take up ecological aesthetics as a relational, experimental, and theoretically adventurous field which aims to grasp the experiential qualities of life under these changing conditions, and to imagine alternatives. With chapters focusing on the role of movement, nature-study, poetry, pattern, sense-awareness, and the creation of experimental works of art, this section highlights interdisciplinary research and pedagogy which attends to richly textured compositions of childhoodnature experience through a diverse range of material, social and conceptual practices. In drawing together a range of Indigenous, speculative, sensory, cultural, empirical, and artistic approaches, the range of chapters collected in this section attests to the diversity and emergent shaping of ecological aesthetics as a field that is still very much in the making.

Introduction: A (Re)turn to Aesthetics

It seems that our world becomes more strange with each passing moment, refusing to settle into any recognizable pattern that might conform with our previous intentions, expectations, or understandings. Is it any surprise that we find ourselves (re)turning to poetry, art, music, dance, and philosophy as ways of feeling, imagining, and thinking the world anew? In this final section of the handbook, we negotiate such a (re)turn to aesthetics in response to radical changes in both *the nature of childhood* and *the nature of nature* in the contemporary world. We live in times, now, where there is growing concern about qualities of life at the planetary scale. Anthropogenic climate change, the mass extinction of plant and animal life, and the chemical contamination of air, food, soil, and water resources are transforming not only what we might think of as "the environment" but also the

aesthetic qualities and environmental sensibilities that constitute the experience of *being alive*. What's more, today's children inhabit a world in which the very nature of life is being reconstituted through biotechnological transformations associated with genetic manipulation, ubiquitous computing, and machine learning, such that the boundaries between human and nonhuman, life and nonlife, and natural and artificial have become eroded if not completely dissolved (Braidotti, 2013; Povinelli, 2016). We (re)turn to aesthetics at a time when we are "living in suspense" among social and environmental catastrophes, a time which calls upon us to develop "new powers of acting, feeling, imagining, and thinking" (Stengers, 2016, pp. 22–23).

For many scholars these changing material conditions of Earthly life have taken on the name of "Anthropocene," an epoch defined by the total imbrication of human life with more than human planetary systems and technologies (Rousell, 2016; Steffen et al., 2015). Other scholars have been hesitant to adopt a term so saturated with the association of "Anthropos" and its aftertastes of human dominance, supremacy, and exceptionalism (Colebrook, 2014). Some have characterized the total subsumption of Earthly processes under a capitalist political economy in terms of "Capitalocene" (Moore, 2017); others have emphasized the chthonic, nonhuman powers of the Earth itself under the terms of "Chthulucene" (Haraway, 2016); and still others reject the Anthropocene as a conceptual and material artifact of Western (mis)thought, which continues to deny the profound insights of Indigenous cultural practices and metaphysical understandings (Demos, 2017; Horton, 2017; Todd, 2015).

Despite their differences in terms of emphasis and approach, a number of arguments are loosely shared across these various accounts of the contemporary moment. First, there is a general consensus that we live in a time that is radically different from previous times on Earth. The illusions of psychic, social, political, and climatic stability have dropped away, and we are faced with a world that is intricately entangled, complex, precarious, unpredictable, and messy (Morton, 2013). Second, there is an agreement that these disorientating conditions call for a complete overhaul of dualistic conceptual categories and onto-epistemological hierarchies which have dominated Western thought for millennia. Any kind of a priori separation between nature and culture becomes untenable under these new conditions. This has led to renewed engagement with Indigenous and non-Western philosophies, as well as a growing series of rapprochements between the environmental arts, humanities, and sciences (Cajete, 2006; Haraway, 2016). Third, there is an emerging sense that a more expansive, experimental, and theoretically promiscuous account of *aesthetics* is necessary if we are to grasp the experiential qualities of life under these changing conditions and to imagine alternatives (Shaviro, 2014). This makes such a (re)turn to aesthetics intrinsically ecological, as it is concerned with an aesthetic of relation and coexistence. In other words, it is an aesthetic that is concerned with the sensible qualities of relations between and among bodies, environments, societies, and technologies within complex assemblages that exceed the limits of human cognition and knowledge. The (re)turn to

aesthetics is thus a (re)turn to the wonder of felt relation and to the sensibly distributed *nature* of experience as entangled with the wild variety of other creatures with whom we share our ecological worlds.

In some ways this movement constitutes a return to the ancient Greek roots of the word "aesthetic":

1. *Aisthetikos*, meaning "of or pertaining to αἰσθητά, 'things perceptible by the senses, things material', as well as 'perceptive, sharp in the senses'"
2. *Aisthanesthai*, meaning "to feel, apprehend by the senses" (Oxford English Dictionary, 2017, n.p.)

In these two ancient definitions of aesthetics, we see the original inclusivity of meaning which combines the material causality of the empirical world with the subjective experience of feeling and sensuous apprehension. *Aesthesis*, in this originary sense, includes both the subjective act of perception and the objective nature of that which is actually perceived. To take up aesthetics in this key is to resist what Alfred North Whitehead (1967) diagnosed nearly a century ago as "the bifurcation of nature." This is the bifurcation that separates the objective world of natural causality out from the subjective world of qualitative experience, imagination, and interpretation. "Everything perceived is in nature," Whitehead writes. "We may not pick and choose. For us the red glow of the sunset should be as much a part of nature as are the molecules and electric waves by which men of science would explain the phenomenon" (2004, p. 20). In resisting the bifurcation of nature, the red glow of the sunset is both *what* it is objectively and *how* it appears subjectively, at one and the same time. The color red, the sensation of red, the feeling of red, the intensity of red, the idea of red, the molecular materiality of red, our past associations with red, and the way that a certain shade of red appears at this particular time and place: these all become elements of nature as inseparable from aesthetic experience or *aesthesis*.

In the seventeenth century, the study of aesthetics came to be associated with dualistic theories of cultural "judgment" and "taste" and was relegated (at least in mainstream Western philosophy) to specialized subfields associated with the philosophy of art. However, over the last 10 years, there has been a veritable revival, what some have even called a *renaissance*, of interest in aesthetics as the basis for speculative realist and materialist theorization (Debaise, 2016; Hansen, 2015). Often drawing extensively from philosophers such as Whitehead, Deleuze, and Guattari, scholars and artists associated with the current speculative turn have brought aesthetics back into the center of philosophical thinking and inquiry (Debaise, 2017; Kolazova, 2016; Shaviro, 2014). This speculative expansion of aesthetics to encompass both the cultural and the natural, the subjective and the objective, and the artistic and the scientific is what we name an "ecological aesthetics." It is an aesthetics that operates across scales of space and time, from the microtemporal entanglement of quantum events to the geo-social movements of planetary epochs and evolutionary life processes (Yusoff, 2015).

The Indigenous and the Speculative

We concur with scholars such as Protevi (2013), Haraway (2016), and Debaise (2017) who have argued that the geo-eco-onto-biocultural transformations of contemporary life call for an aesthetics that is radically environmental, speculative, empirical, relational, and inclusive of all forms of life and modes of existence. We also note the particular resonance of such a (re)turn to aesthetics with Indigenous ontologies, cosmologies, and practices that have been in existence for millennia. Geo-ontological analyses of Indigenous art, philosophy, and culture by feminist scholars such as Grosz (2008) and Povinelli (2016) highlight an emerging sense of compatibility between the "traditional" aesthetics of Indigenous peoples and the "new" aesthetics proposed by today's speculative theorists, artists, and scientific practitioners. We acknowledge that many Indigenous cultures have already been thinking and working through such an ecological aesthetics for millennia and offer a plethora of place-based and culturally responsive resources for grappling with the challenges of social and ecological crises at the planetary scale. We can also thread a speculative history of ecological aesthetics back to prehistoric cultures and the territorial behaviors of the animal world, including the cave art of early hominids and the ritual performances and habitat constructions of mammals, birds, and myriad other forms of life. And yet we also acknowledge that the material conditions of the contemporary world are *undeniably new*. As Hansen (2015) notes in his analysis of the experiential impacts of twenty-first century media technologies, "we literally live in a new world, a world characterised by a vastly expanded and deterritorialised sensorium" (p. 161). There is no place on Earth that is unaffected by human enterprise and technological expansion. The sheer number of human bodies continues to grow, even as the numbers of other Earthly creatures continues to decline. The cumulative sensing capacities of micro-computational media networks have become powerful agencies and elemental components of everyday existence. Nobody has ever experienced anything like what we are experiencing at present. So what do we do? Can we (re)turn to the past and the future at the same time? Can we collectively craft an old/new ecological aesthetics that co-implicates the Indigenous and the speculative?

While there are strong resonances between the theoretical positions of speculative and Indigenous thought, their modes of aesthetic actualization can also appear to be in tension. Some of these tensions become palpable in reading across the chapters that make up this section. We find tensions, for instance, between rapid acceleration and deceleration, between acknowledging the past and imagining the future, between symbolic representations and worldly sensibility, between cultural traditions and technological mediations, between biographies and multiplicities, between practical engagements and theoretical speculations, and between the "Great Mystery" (▶ Chap. 76, "Eco-aesthetics, Metaphor, Story, and Symbolism: An Indigenous Perspective") and the "aesthetic order of nature" (▶ Chap. 74, "Uncommon Worlds: Toward an Ecological Aesthetics of Childhood in the Anthropocene"). Rather than setting up these terms as binary distinctions between categories, we would like to think of them as tensions that produce new potentials for aesthetic experience. We would like to think of them as *productive tensions* that stretch and blur the "frictional spaces" between different modes and manners of existence.

Rehabilitating the Concept of "Nature"

What remains central to our approach to this section is a focus on aesthetic modes and processes, rather than on ontological substances or essences. We are specifically interested in how this theoretical shift can provoke renewed or rehabilitated concepts of "nature." As Rousell and Cutter-Mackenzie write in ▶ Chap. 74, "Uncommon Worlds: Toward an Ecological Aesthetics of Childhood in the Anthropocene" (this volume, p. 5), ecological aesthetics is concerned with "differences in 'becoming' (as the aesthetic mode or manner of existence) rather than differences in 'being' (as the ontological essence or substance of existence)." This shift in register recognizes the primacy of embodied experience as a constitutive process, a movement that finds resonance with many Indigenous traditions as well as recent findings in the life sciences. Postgenomic research in contemporary biology, for instance, reveals the ways that environmental and social conditions have transgenerational impacts on biological functioning, cultural development, and gene expression (Frost, 2016). This means that place-based and culturally situated experiences have effects on the biological constitution of living bodies not only over the course of a single lifetime but across generations and also across species. Recent findings in embodied cognitive science further reveal the ways that sentient, perceptive, cognitive, emotional, and social experiences are inseparable from biological processes, such as sensorymotor activity, directional motility, biochemical gradients, and precognitive affective responses (Protevi, 2013). These findings gesture toward the capacity for entire bodies and societies to sense the world aesthetically, including the ability for cells, proteins, and even genes to sense and dynamically respond to the environments and milieus within which they are embedded.

However, if we are to maintain a commitment to a *speculative* ecological aesthetics, then even our embodied, culturally situated, and sensory experiences can't reveal the whole story. If ecological aesthetics is to graft onto "nature" as the immanent ground, plane, or continuum for all experience, then it must also account for the speculative conditions under which experience occurs, conditions which *are never directly perceived or experienced* by humans (Debaise, 2016; Hansen, 2015). Perhaps it is in the speculative space of pure potential that the concept of "nature" might be rehabilitated for our times. Nature would, in this sense, simultaneously compose, sustain, and vicariously exceed experience in every direction. As Cajete and Williams discuss (▶ Chap. 76, "Eco-aesthetics, Metaphor, Story, and Symbolism: An Indigenous Perspective"), nature is *intrinsic* to all experience even as it remains "the Great Mystery" of existence itself. Whitehead, Rousell, and Cutter-Mackenzie (this section) theorize nature as the "aesthetic order" of the universe, an extensive continuum of vibratory intensities and potentials that includes all things and their felt relations. Phillips (this section) describes feeling the "infinite alterity and ethicality" of nature in the touch of a child's hand in the streets of Chiang Mai, Thailand. In each of these speculative accounts, we encounter a "nature" that is never static, passive, or predictable but always changing *as our experiences change* (along with the experiences of all other creatures, cultures, places, and times). The speculative conditions under which life takes place are revealed to be just as contingent as life itself, just as permeable, malleable, and intricately enmeshed. Perhaps the

Indigenous and the speculative have always been intertwined within the aesthetic "matrix that embeds" us all (▶ Chap. 77, "CineMusicking: Ecological Ethnographic Film as Critical Pedagogy"). And maybe the emerging field of ecological aesthetics can offer a nexus or meeting place for conceptualizing and working with this matrix, for bringing a speculative metaphysics of nature into direct and consequential contact with embodied, sensorial experience – in all its wild proliferations and potentials.

Ecological Aesthetics, Childhood, and Learning

This brings us to the focus of this section of the Handbook, which is the intersection of ecological aesthetics with childhoodnature relations, encounters, and learning experiences. To our knowledge this is the first book-length treatment of ecological aesthetics as applied to the learning experiences of children. As demonstrated by the chapters collected in this section, ecological aesthetics provides fertile grounds for interdisciplinary research and pedagogy which attends to richly textured compositions of childhood experience through a diverse range of material, social, and conceptual practices. Such approaches have become increasingly relevant as children encounter a world typified by the acceleration of social, technological, and environmental change and the mutually reinforcing conditions of planetary instability, inequality, and precarity. In attending to the sensuous, creaturely, and affective qualities of children's encounters with and *as* nature, multiple sites are opened up as vital spaces for children to respond to these changing material conditions of everyday life. As the chapters in this section attest, these sites expand beyond places commonly associated with "nature," such as national parks, remote wilderness areas, nature schools, or community gardens. They also include art galleries, museums, urban landscapes, everyday domestic spaces, science laboratories, and digital environments, among many other settings. Each of these sites of encounter can be considered intrinsically ecological and aesthetic environments that condition the very possibilities for children's movement, learning, sensation, perception, imagination, feeling, and thought.

While this ecological aesthetic perspective supports methodological turns toward artistic, creative, and sensory practices across diverse educational and research contexts, it should not be confused with an advocacy for "arts-based methods" as narrowly and instrumentally defined in relation to "nature." Rather, this section works to expand the purview of aesthetics to encompass the rich histories of the environmental arts, humanities, and sciences, along with Indigenous practices of making and knowing that are associated with bioculturally embedded understandings of place. Hence, we see the turn toward ecological art and aesthetics as a turn toward environmental awareness as a mode and manner of sensory attunement and response. To become attuned to one's environment is to inhabit an artful disposition, a sensory apprenticeship with the naturalcultural environment that establishes the very conditions under which learning becomes possible. This is to embrace nature itself as a creative force that is embodied in the fearful wonder of a child as a lightning storm approaches or the subtle adjustments of a child's body to catch a

different perspective on a vista or a painting or a science experiment. Such an ecological aesthetic lurks everywhere, in the potentials for a more artful attunement to the everyday experiences of children, and indeed, to all forms of life.

Drawing Together the Seed Bag

In drawing together the chapters for this section, we sought contributions that put aesthetic experience at the center of childhoodnature research. We saw this as a process of gathering experiential seeds of potential to spread with the wind, akin to Haraway's (2016) "seed bag" approach to collecting and crafting new figurations, tropes, and concepts through speculative philosophy, science, art, biography, and fiction. Rather than delimiting the field through preestablished criteria and boundaries, we wanted to see how ecological aesthetics might sprout new possibilities for understanding the interconnectedness of childhood and nature through sensory, affective, and creative practices. We cast our net as widely as possible and were fortunate to receive submissions from scholars, artists, educators, and practitioners hailing from diverse cultural and geographical locations. The authors of the chapters in this section also represent a wide range of academic career stages, including early- to-mid-career researchers, artists, and educators as well as substantially established scholars and internationally recognized experts in various fields. The range of chapters collected in this section attests to the diversity and emergent shaping of ecological aesthetics as a field that is still very much in the making. We feel that this incipient curiosity for what the field might become stirs at the heart of each of the chapters to follow.

The section opens with ▶ Chap. 72, "Sticky: Childhoodnature Touch Encounters," as Louise Phillips presents a series of eco-aesthetic encounters with *touch* drawn from her lived experiences of child-led walks in Chiang Mai, Thailand. "The Walking Neighbourhood Hosted by Children" is a project that has been held in several countries across three continents and is designed by a team of artists to rethink the geography of fear that limits children's access to public spaces and that devalues children's capacities and competence. Phillips shares her sensory ethnographic research by bringing to life a series of "human-plant-place relations" as she is led by children on three walks. Through her embodied and emplaced sensorial research, she captures how children's attention to the sensuous and affective qualities of nature comes to matter through material affordances and constraints. She develops an eco-aesthetic account of childhoodnature touch in relation to Karen Barad's quantum physics-informed theory of agential realism, in which "all particles are entangled in the void, so that every degree of touch is touched by all possible others," (▶ Chap. 72, "Sticky: Childhoodnature Touch Encounters"). As we walk with Louise and the children, we are invited to imagine their entanglements and appreciate the stickiness of touch.

In ▶ Chap. 73, "Rachel Carson's Childhood Ecological Aesthetic and the Origin of *The Sense of Wonder,*" David Greenwood traces the history of Carson's development of a "sense of wonder" through her immersion in nature and in the nature study movement, as well as in early twentieth century children's literary magazines

such as St. Nicholas. He invites us to consider two of Carson's most significant teachers: her mother and a 64-acre rural property that had "orchards and gardens, groves and fields, hills and hollows," with ample room to wander. While known for *Silent Spring* (1962), in prior years Carson had published *Under the Sea Wind* (1941) and *The Sea Around Us* (1951) and published her final book, *The Sense of Wonder*, in 1965. Examining the evolution of her works, Greenwood finds that "what made Carson's nature writing unique was not her politics, but her rare ability to combine the skills, gifts, and discipline of a scientist with those of a literary artist." For Carson, books of nature study encouraged not just curiosity for natural objects but also immersive experiences as well as aesthetic and ecological imagination. He points to the significant role of an adult (her mother) in facilitating her sense of wonder even as opportunities were available to Carson "to combine recreation, environmental learning, and an ethic of reverence toward the natural world." In asking, "What does Rachel Carson have to teach us that we might have to remember?" this chapter foregrounds the significance of *aesthetic experience* in evoking a sense of wonder.

In ▶ Chap. 74, "Uncommon Worlds: Toward an Ecological Aesthetics of Childhood in the Anthropocene," David Rousell and Amy Cutter-Mackenzie draw upon Alfred North Whitehead's (1978; 1967) speculative philosophy of nature to develop an alternative theoretical approach for posthumanist studies of childhood. In the first part of the chapter, the authors make the case for a new aesthetics of childhood that is responsive to the environmental changes of the Anthropocene epoch, highlighting the need for a more intensive and affirmative engagement with non-Anthropocentric and non-representational aesthetic theories and practices. Combining Whitehead's philosophy with recent research in the life sciences and media studies, the authors theorize the relationship between the "common world of nature as a vibratory continuum" and the "uncommon worlds" of children as "creatures of becoming." The second part of the chapter extends this theorization through the analysis of children's photographs produced during the 3-year *Climate Change and Me* project undertaken in regional NSW, Australia. Rather than working with images as "representations or analogic signifiers for children's experience," the authors explore how each photograph "co-implicates children's bodies and environments through affective vectors of feeling." The chapter concludes by considering the pedagogical implications of children's photographic practices, focusing on Whitehead's (1967) concept of the "art of life" as a guiding proposition for the aesthetic cultivation of environmental awareness.

Lucinda McKnight's ▶ Chap. 75, "Tin Shed Science: Girls, Aesthetics, and Permeable Learning" further develops a relational and diffractive approach to environmental learning in the suburbs of Melbourne, Australia. Combining "fragments of original pedagogical intent" with the polyphonic voices and material agencies of a backyard science club, the chapter works to assemble a posthumanist conceptualization of learning that emphasizes the radical permeability of human and nonhuman bodies and environments. The chapter not only draws on new materialist theories of embodiment, aesthetics, and agency but also puts these theories to work in the construction of a multilayered and diffractive account of learning that "is

always about the earth, and an awareness of the processual making of earth through intra-action." In doing so, McKnight works creatively to disrupt her own authorial voice and pedagogical intentions with "the voice of the earth," including the geological ruptures of poetic utterances and strange theoretical "unearthings and blendings." The chapter thus offers a strikingly original take on what science education might become if exposed to the wildness of posthumanist aesthetic practices, as the "becomingearth" of the child provokes a (re)turn to dirt and the permeability of organic bodies.

Discussions of Indigenous ecological knowledge and aesthetics are largely missing from mainstream sciences education, arts education, and environmental education. ▶ Chap. 76, "Eco-aesthetics, Metaphor, Story, and Symbolism: An Indigenous Perspective" presents a conversation between Tewa scholar, educator, and artist Gregory Cajete and eco-educator Dilafruz Williams of East Indian origin, about the nature of eco-aesthetics, metaphor, story and symbolism in Indigenous thought and reality. Aspects of the Indigenous mythopoetic tradition are discussed as part of the traditional education practices of Indigenous cultures. The conversation draws upon the lived cultural experiences of the authors as they discuss the rich use of metaphor, story, symbols, and art to convey notions of eco-aesthetics in the teaching and learning process and the education of children. Acknowledging that oral traditions "used stories for millennia to evoke a sense of place and a deep understanding of interconnectedness of all life," they point to stories also as a means for "connecting past with the present and encouraging imagination." Exploring the environmental, mythic, visionary, artistic, affective, communal, and spiritual dimensions of Indigenous education through Cajete's writings, the conversation concludes with a discussion of how Indigenous ecological thoughts may be expressed through contemporary art forms to show possibilities for childhood and nature as interconnected.

The section's engagement with Indigenous ecological aesthetics continues through the contribution of filmmaker and ethnomusicologist Michael MacDonald. In ▶ Chap. 77, "CineMusicking: Ecological Ethnographic Film as Critical Pedagogy," MacDonald develops "Cinemusicking" as an ecological approach to ethnographic filmmaking that he has developed through film projects with Indigenous elders and urban youth. Drawing on theories of biosemiotics and "the matrix that embeds" from ecological thinkers such as Bateson, Luhman, Maturana, and Varela, this chapter offers both theoretical and practical insights into ecological aesthetic education as a transformative process of co-creation and interpenetrating systems. A series of richly drawn examples are portrayed through MacDonald's ethnographic descriptions of musical and cinematic engagement, including the rhythmic ciphers of inner city "hip hoppas" and the traditional ecological knowledge (TEK) practices of Cree peoples in Northern Canada. In linking systems theories with critical pedagogy and Indigenous philosophies, MacDonald writes that "the process of engaging with the *matrix that embeds* is part of the practice of life called *Pimachihowan*, experienced as sacredness." This chapter thus offers a fresh vision of ecological aesthetic education that links the sacred with everyday embodied experience and aesthetic practices of life-living.

Teacher educators Shelley Hannigan, Anna Kilderry, and Lihua Xu bring their diverse disciplinary lenses from arts education, early childhood education, and STEM to challenge the dominant anthropocentric view and paradigms in education as they explore ▶ Chap. 78, "Patterning in Childhoodnature". Critiquing the discipline-based compartmentalization of education, they conceptualize childhoodnature through patterning as a transdisciplinary approach for exploring the intricate relationships between organisms and their environments. Patterns, for them, are the "regularities and repetitions of actions, units, or shapes in space, time, and/or behaviour." They discuss how children's bodies are physically made up of biological structures and patterns, as are children's behavioral patterns, movements, and cognitive schemas. Highlighting patterns of sameness and difference through examples from Indigenous culture and contemporary art, they propose a biophilic and transdisciplinary approach to pedagogy and curricula to revive the aesthetic knowledge of patterning among children. For these authors, knowledge about patterning could enable children to make complex connections with their selves and the environment as ecological and aesthetically engaged learners.

Questioning the educational trend that considers the child and nature as a narrowly constructed dichotomy, Patti Pente offers alternative configurations of childhood in education by theorizing how the nanoscale can expand the imagination of what our human relationship with the planet might become. In ▶ Chap. 79, "Nanotechnology, Anthropocene, and Education: Scale as an Aesthetic Catalyst to Rethink Concepts of Child/Nature," she invites us to consider "what we might create with our bodies in space and time if the perceptions of the world stretch to the nanoscale and geological time." Jogging our memories, she reminds us of scale, explaining that nanotechnology is the study and use of materials at the small range of 1–100 nm, where 1 nm is equal to 1 billionth of a meter. With this awareness of the invisible nano-world, we are encouraged to consider how, "through a shift in scale to include the very large and the very small, dichotomous thought is eschewed for a concept of life understood as continual, material process." Pente posits that nanotechnology can surface the relationship of "invisible" materials at the small nanoscale with the visible character of the human-scale, offering a challenge for educators to enlist the creative imagination in order to confront our taken-for-granted Anthropocentrism. Scale therefore serves as an aesthetic catalyst to rethink childhood and nature concepts and relationships for education, art, and research.

Exploring concepts of childhood and nature in motion, Martha Eddy and Ann Moradian propose an aesthetic of embodied movement as both the physical and metaphysical ground for learning. In ▶ Chap. 80, "Childhoodnature in Motion: The Ground for Learning," they advocate the moving body as critical to celebrating and deepening childhoodnature relationalities. In proposing a life-long somatic relationship with our bodies in motion, they support a reclaiming of wholeness that "intensifies not just self-awareness, self-knowing, self-care and self-regulation, but also moves us to act and interact with greater awareness and care for others and our world, including the places we inhabit and share." The role of movement is crafted as a reminder that the body itself holds many of the lessons in establishing life-affirming relationships. Through a series of vignettes, they offer examples of

problems, solutions, and research through an analysis of intervention into bodily disassociation and disembodiment and propose an ecological revitalization of thinking, feeling, and living through the body *in* and *as* movement. Their deep and wide-ranging treatment of an ecological aesthetics of movements provides a valuable resource for educators and researchers interested in childhoodnature studies and embodied practices.

Movement also serves as the basis for inquiry in the section's final chapter, entitled ▶ Chap. 81, "Propositions for An Environmental Arts Pedagogy: A/r/tographic Experimentations with Movement and Materiality". In this chapter, authors David Rousell, Lexi Lasczik, Rita Irwin, and Peter Cook undertake a series of creative experimentations that investigate the relations between movement and materiality in the development of an environmental arts pedagogy. Drawing on new materialist theories of matter and movement as vibrant and creative forces, the authors devise a series of four experimental art processes that "explore the relational spaces between art, environment, and pedagogy." As a methodology that operates through relational practices of artmaking, researching, and teaching/learning, they take up a/r/tography as "an ecology of practices in which human and non-human agencies are always entangled with distributed processes of co-composition, negotiation, and constructive functioning." Through a/r/tographic renderings that combine elements of speculative theory, poetics, and visual imagery, the authors put the concepts of "corridor," "flight," "viscosity," and "construction" to work in ways that connect "movement with matter, body with environment, and imagination with empirically-observable phenomena." Bringing together creative practices associated with choreography, drawing, installation, and social practice art, the authors conclude with a series of speculative propositions for an environmental arts pedagogy.

Frictional Spaces and Relational Overlaps

The editorial process of drawing together this fertile "seed bag" of chapters has revealed to us the rich diversity of theories and practical engagements that are currently being undertaken to shape the field of ecological aesthetics in relation to childhoodnature studies. As mentioned in the opening sections of this introduction, we have welcomed the relationships and the tensions that have emerged between and among these diverse offerings. Indeed, we have endeavored to actively multiply the possibilities of how ecological aesthetics might transform studies of childhoodnature rather than attempt to achieve a consensual framework or agreed-upon set of parameters. In closing this section introduction, we highlight some of the dynamic frictions and discontinuities, along with relational overlaps, that have emerged through the differential concepts of childhood, empiricism, sensation, pattern, and movement.

We can see various relationships emerging in the spaces between Greenwood's biographical treatment of Rachel Carson's early twentieth-century childhood and the diffractive multiplicities of twenty-first-century childhood that we encounter in

McKnight's "Tin Shed Science club." In the "frictional spaces" between these two chapters, we see onto-epistemological differences being multiplied across decades, as civil rights, literary, artistic, and environmentalist movements coincide with radical technological revolutions and catastrophic ecological destabilizations coincide with post-truth political regimes. While the early twentieth-century world of Carson's childhood may no longer exist, the transformative power of her sense of wonder lives on in McKnight's Tin Shed Science club, even as the authorial control of the human(ist) voice "collapses into soil, understands the child as soil." We are reminded that there is no going back after each turn. The environmental turn, the feminist turn, the material turn, and the ontological turn: each of these turns is not simply a shift in human ideology and ethics but a turning of the Earth itself that never turns back.

The frictional spaces between the speculative and the Indigenous also begin to coalesce over the course of reading this section to inform different variations of an ecological aesthetic **empiricism**. Rousell and Cutter-Mackenzie's speculative account of nature as a vibratory continuum both resonates with and disturbs the traditional ecological knowledge (TEK) systems invoked by Cajete and Williams and in MacDonald's account of the "matrix that embeds." Each of these ecological aesthetic accounts pivots relationally on the centrality of embodied and enactive engagement with the world as empirically experienced. The friction between these approaches emerges in the different ways that they resist reductive understandings of empiricism rooted in Western scientism. For Rousell and Cutter-Mackenzie, the development of a "speculative empiricism" allows them to account for the virtual, immanent, indeterminate, and unknowable elements of potential that form the underlying conditions for childhoodnature experience. Cajete, Williams, and MacDonald, on the other hand, evoke the "Great Mystery" of nature through Indigenous spiritual beliefs and practices that are intimately connected with trans-generational experiences of place, community, art, and ritual. These authors describe what might be called a "sacred empiricism" that infuses everyday aesthetic practices such as breathing, walking, and noticing with a profound spiritual significance and connection with the whole of nature.

Another frictional space can be found in the ways that various chapters focus on the role of **sensation**, a space where sensory experiences of childhood and nature make aesthetic contact. Phillips writes of the "sticky sensation" of holding a child's hand while walking through the streets of Chiang Mai, while Rousell and Cutter-Mackenzie describe the "ecologies of sensation" that emanate from the surfaces of children's photographs. In thinking the sensation of childhoodnature beyond the human, these two chapters provide alternative perspectives on the ways that nonhuman senses and sensors are entangled with childhood experiences, including the sensorial agencies of plants, buildings, mushrooms, and digital cameras.

Pattern also emerges as a frictional space that problematizes aesthetic issues of scale, complexity, and differentiation, as emphasized in chapters contributed by Pente and Hannigan, Kilgerry, and Xu. Pente brings our attention to the nano-scale as a potential catalyst for childhoodnature pedagogy and artistic practice, while Hannigan, Kilgerry, and Xu draw out the life-size implications of patterning across

biological, cultural, and ecological systems. These chapters offer productive tensions between patterns of repetition and patterns of difference, revealing the ways that patterns operate across multiple levels and scales of organizational complexity, many of which are ordinarily hidden by habitual modes of perception and thought. Both chapters share a commitment to extending the connections between science and art, using pattern and scale as conceptual figures that can transform the ways that children learn through aesthetic engagement with the elements and forces of the natural world.

The final two chapters in the section each contribute to a frictional space concerned with the ecological aesthetics of **movement**. Both chapters acknowledge the primacy of movement in matters of life, learning, aesthetic experience, and environmental awareness, but the differential contrasts between their approaches also generate a series of productive tensions. Focusing on the centrality of the moving body as the experiential locus for environmental learning, Moradian and Eddy offer a complex range of theories and empirical examples that link embodied self-awareness with ecological sensibilities and capacities for interconnection. For these authors, the body operates as a phenomenological conduit and interface for engaging with the whole of nature through movement, leading them to propose a somatic pedagogy predicated on the dynamic balancing of psychological, social, and ecological systems. Rousell et al., however, take an alternative approach that experiments with movement as a distributed environmental force that is inextricably linked to dynamic material processes and interactions. Rather than emphasizing the conscious movement of the individual human body, these authors foreground the intercorporeal materiality of choreographic movements that come to compose an environmental arts pedagogy.

We hope that this brief introduction to the section's core components has provided a helpful series of entry points for thinking within, across, and among the various chapters collected here. We conclude by extending our deep gratitude to all of the contributors who have made this section possible, as well as the lead editors who have supported our efforts to bring a fresh, experimental, and, in many ways, untested approach to childhoodnature studies.

Abstract

Children's attention to sensuous and affective qualities of nature-matter affordances and constraints is the focus of this chapter, along with related possibilities for movement, learning, and thought. An eco-aesthetic account of childhoodnature touch is developed in relation to Barad's quantum physics-informed theory of agential realism. By this account, all particles are entangled in the void so that every degree of touch is touched by all possible others. Encounters of childhoodnature touch are drawn from the author's lived experiences of child-led walks in Chiang Mai, Thailand. These are performative walks from "The Walking Neighbourhood Hosted by Children" project, in which arts workers supported primary school-aged children to locate places of connection in urban landscapes for curating and leading walks as public performance. Sensory

ethnographic attention to the encounters were privileged due to limited mutual language sharing. The eco-aesthetics of childhoodnature touch encounters in three child-led walks of Chiang Mai are storied from the author's lived encounters to invite "possibilities of engaging the force of imagination in its materiality" (Barad, Differ J Fem Cult Stud 23(3):206–223, 2012). Poetics and storying are purposefully offered to entice readers to imagine sensing the insensible – the indeterminacy of the entanglement of matter. By doing this, experiences of childhood connections with nature can be (re)imagined, foregrounding the affect of eco-aesthetics in provoking appreciation and care for the entangled other.

Kraing (age 11) is leading me with a group of about eight adults and children down an alley lane in Old Chiang Mai; I wonder where we were headed. The only clue I hold is "sticky," as *Sticky Duang Dee* is the name of Bai Bua (9), and Kraing's walk and Bai Bua had already taken us to Wat Duang Dee. Suddenly, Kraing stops near a large concrete wall bordering a hostel. He invites us to admire an ivy vine that was growing all over the wall (Fig. 1).

Kraing is fascinated by how it *sticks* to the wall. He invites us to stop and marvel at the beauty of the vine and wonder at its capacity to cling and adhere to the wall – as if we are encountering vines for the very first time. I have seen this vine before; in fact, something similar grows on a wall in my own garden. But, in this moment, following Kraing's invitation, I notice how the leaves diminish in size toward the end of a branch, reaching out with fine tendrils and how the branches grow over each other sticking with fine stem roots clinging to other leaves as well as the wall. I marvel at the aesthetic of its irregular tangled quite flattened form – noting the relationship between vine (nature) and concrete (manufactured). Nature pervades urban development, discretely crawling and clinging to its surfaces. However, it is not as simple as that – the binary of nature and development are troubled and diffracted.

English ivy is an introduced plant to Thailand. Though Thailand was not claimed as a colony, the colonizing forces of the British and French Empires surrounded it and so introduced species surreptitiously crept in – the metaphoric entanglements of past-present colonialisms. Along with the historical questions of how the vine came to be, I searched for scientific explanations on how the tiny stem root hairs thread into fine cavities in walls, learning how the root hairs grow in a spiral-like locking formation with hooklike ends fastening the connection (Bourton, 2010). Ivy vines are known aggressive invaders, just as concrete invades nature. The concrete wall conquers space as a divider between private and public property. Though the vine has an aesthetic appeal, and this is what Kraing notices and wants others to notice, recognizing the histories of both matters, it is not as simple as nature permeating the manufactured; both are in response to the other and both are in tension to the other, as

Fig. 1 Sticky vine

what Barad (2007) refers to as intra-acting. These diffractive readings collide in and out of my mind – visual and tactile wonderings that would not have occurred, without Kraing's invitations to notice and wonder. I came to notice human-plant-place relations in the everyday lives of children through immanent materialized connections (Bellacasa, 2009). Through heightened sensory awareness, ethicality in being and knowing is awakened, alerting my recognition of entanglement of alterity, vine, concrete wall, of child and adult, and of past and present, as what Barad (2007, 2010) names as spacetimematterings. These different relations provoke a rethinking of human-plant-place relations, of colonizing entanglements, to be emplaced differently, as Nxumalo (2015, 2016) too experienced in her childhoodnature encounters. Kraing invites attention to the vine – a caring appreciative relation that emerges in the ordinary to consider the inherent material connections between each tendril of the vine and its chosen habitat.

I open with this story, as it was this encounter that inspired this chapter and my ponderings on the stickiness of childhoodnature touch. Kraing chose the ivy-vined wall as his walk destination for the social practice (or participatory) arts (see Bishop, 2012) project *The Walking Neighbourhood hosted by Children* (To date *Walking Neighbourhood hosted by children* (http://thewalkingneighbourhood.com.au) has taken place in Brisbane, Darwin, and Sydney in Australia, Chiang-Mai in Thailand, Seoul in Korea, and Kuopio in Finland.) when it took place in Chiang Mai, Thailand at the Chiang Mai City Arts and Cultural Center in May 2013. *The Walking Neighbourhood* was designed by Lenine Bourke (Artistic Director) and a team of co-artists to provoke rethinking of the geographies of fear (Valentine, 2004) that control children's limited access to the public sphere (e.g., see Gill, 2007, Malone & Rudner, 2011) and perpetuate commonly held perceptions of children as incompetent becomings (e.g., see Coady, 2008). *The Walking Neighbourhood* arts project confronts the public imaginary through public performance of child-led neighborhood walks that foreground children's visibility and independence in public spaces. However, the politics of children in public spaces is not the focus of this

chapter; instead I zoom in to diffractively read intra-actions in childhoodnature touch encounters that emerged in the child-led walks in Chiang Mai in May 2013.

Following Kraing's invitation, I savor the eco-aesthetic appreciation of stickiness in childhoodnature touch. And like the growing body of work in more-than-human geographies (see, for instance, Ginn, 2014), I examine how heterogeneous materials become sticky and cohere into broader webs of relation. To explore and tease out the entanglements of a sample of childhoodnature touch encounters, I first briefly explain Karen Barad's (2007) feminist quantum physics theory of agential realism to consider what happens with the action of matter touching itself. Key concepts and understandings of intra-actions, agential cuts, and spacetimemattering are explained with reference back to my sticky encounter with Kraing. I then define the focus of touch in childhoodnature and the applied methodology of diffractive analysis through sensorial ethnographic storytelling. These explanations set the scene for further sensory readings of another two childhoodnature touch encounters in Chiang Mai. I then close the chapter with childhoodnature touch offerings on eco-aesthetics, responsibility, and indeterminacy toward ethico-onto-epistemology.

How Matter Matters in Intra-actions and Agential Cuts

I look to Barad's (2007, 2010, 2012, 2014) writings because she seeks to "understand the nature of nature and the interplay of material and discursive, the natural and cultural, in scientific and other social practices" (2007, p. 42). Her work offers a commitment to the material nature of practices and how they come to matter. In her theory of agential realism, matter is an active participant in the world, which "is a dynamic intra-active becoming that never sits still" (2007, p. 170). So to understand the tensions, possibilities, and dynamics of childhoodnature touch, I look to materiality at play to broaden understanding and insight. More specifically, I look at what Barad refers to as intra-actions.

Contrary to the concept of interactions, *intra-actions* do not assume prior existence of independent entities. Emphasis instead is on what emerges from actions, not on the preexistence of child, adult, vine and wall, and all predetermined meanings ascribed to these constructs. Intra-actions involve all types of matter: natural, synthetic, corporeal or incorporeal. When examining intra-actions the primary ontological units are not things but "phenomena – topological reconfigurings/entanglements/relationalities/ (re)articulations of the world" (Barad, 2007, p. 141). The phenomena of attention in this chapter is the eco-aesthetics of childhoodnature touch. Through intra-actions "the boundaries and properties of components of phenomena become determinate and particular concepts (that is, particular material articulations) become meaningful" (p. 139). Attention to intra-actions reads distinct entities, agencies, and events as emerging or materializing through or from the intra-action, rather than existing in their own right prior to the intra-action (Barad, 2010). Entities do not preexist; they are agentially enacted and become determinately bounded and propertied within phenomena. Agencies are only defined in relation to their reciprocal interconnection. The vine and the wall and their relationship only

became defined when Kraing invited my attention to them. The boundaries and properties of the vine and wall became determinate, and specific articulations of the world became meaningful through Kraing's invitation. Others engaging in this childhoodnature touch moment would sense different intra-actions producing different phenomena. "The dynamics of intra-activity are non-linear, causal and non--deterministic" (Barad, 2007, p. 240). No individual agents cause change; rather it is in the intra-action that change can emerge. It was the coming together of Kraing's aesthetic appreciation of vine and wall and my openness to wonder that the everyday vined wall became a provocation for recognizing the entanglement of children, aesthetics, subversive invasions, nature, and urban development. The storied intra-actions of childhoodnature touch encounters in child-led walks that I share in this chapter invite differing meanings regarding children, nature, place, and touch to emerge.

Intra-actions enact agential cuts, that is, the subject and object within the phenomenon become determined. It does not produce absolute separations but rather a "cut together-apart (one move)" (Barad, 2014, p. 168), the quantum entanglement of matter, in that matter can be both together and apart with one move. It is through material intra-activity that concepts "enact the differentiated inseparability that is a phenomenon" (2010, p. 253).

In agential realist ontology, neither materiality nor discursivity takes priority, welcoming both material and discursive readings of phenomena that emerge in intra-actions. The primary units of analysis are thus material/discursive practices (e.g., walking, touching), not words. Outside of agential intra-actions – things are indeterminate. Through attention to what happens and what matters in the intra-activity (Barad, 2007) of childhoodnature touch, I see and feel what sticks, that is, what retains as a resonant memory – what lasts and what is sticky as in troubling because of its viscosity – it clings and lingers.

Childhoodnature Touch

In attending to this handbook's focus on childhoodnature, I have chosen to specifically look to what happens in children's touch encounters with nature, that is, moments when children initiate attention to touch in and with natural matter. I look to what emerges (intra-actions) in childhoodnature touch encounters, because "[s]o much happens in a touch: an infinity of others—other beings, other spaces, other times—are aroused" (Barad, 2012, p. 2006). The entire history of physics "can be understood as a struggle to articulate what touch entails," pursuing a myriad of questions, such as "How is a change in motion effected?" (p. 208). Kraing named his walk destination "sticky." It was how the vine stuck to the wall that intrigued him. In classic physics, all touching is repulsion; the electrons of the atoms that make up whatever is touching and being touched electronically repulse each other. The sensation of touch is an effect of electromagnetic repulsion. Matter is made up of particles that repel each other – mutual repulsion that to the naked eye looks like they are sticking together. While I am not a physicist, Karen Barad (2012, 2015) offers

these explanations as a base to build and contrast quantum physics explanations of touch. In quantum physics, particles act and react in the void; they are entangled with the void so that "all material 'entities', are entangled relations of becoming . . . materiality 'itself' is always already touched by and touching infinite configurations of possible others, other beings and times" (p. 215). What this means is that "[e]very level of touch, then, is itself touched by all possible others" (pp. 212–213) so that "[a]ll touching entails an infinite alterity" (p. 214). To contemplate the expansiveness and complexity of the entanglement of all matter magnifies the profundity of touch beyond imagination and measurement.

This notion of infinite alterity also defies classical definitions of space and time. What Barad refers to as spacetimemattering invokes the differential patterns of mattering across different times and spaces (Barad, 2010). History (spacetime) is understood as a linear unfolding. In spacetimemattering, past, present, and future are threaded through one another – "a topology that defies any suggestion of a smooth continuous manifold" (p. 244). Time, instead, is understood as diffracted. Take a moment to contemplate, sensing touch of multiple times and places at once, the spiralled hook grasping of vine root hairs interlocking with rock, sand, and gravel taking place in millions of places over Earth across thousands of years and the millions of children across times and places wondering how vines stick.

Barad (2010) further explains that relations define responsibility as the ability to respond, that is, a matter of inviting, welcoming, and enabling the response of the Other. Attention to specific intra-actions in childhoodnature touch in child-led walks acknowledges and makes such *relata* (potential preceding components of relations). "Responsibility is not an obligation" and "is not a calculation to be performed. . .It is an iterative (re)opening up to, an enabling of responsiveness" (p. 265). What Barad calls response-ability "is a relation always already integral to the world's ongoing intra-active becoming and not-becoming. . .an enabling of responsiveness. . .an iterative reworking of im/possibility; an on-going rupture" (2007, p. 265). Response-ability flows out of the cuts that define phenomena in intra-actions. Through attention to how matter relates and intra-acts in childhoodnature touch, irreducible relations of response-ability are read as entanglements with others: not as mere connections but rather as indebtedness to difference and how such debt permeates our sense of self. An ethico-onto-epistemology (ethically knowing through being) of entanglement with all others provokes an ethic of care for all others. It is through widespread embracement of such an ethico-onto-epistemology that I see offers hope for sustainability of Earth.

Diffractive Sensorial Storying

The multiplicity of difference in intra-actions can be read through diffractive analysis (Barad, 2007). Agential realism enquires "into how differences are made and remade, stabilized and destabilized as well as their materializing effects and constitutive exclusions" (Barad interview with Kleinman, 2012, p. 77). To move away from Cartesian/positivist representation and reflection, I explore diffractive readings.

In physics, diffraction is a process in which light or waves spread in multiple directions once they pass through a narrow aperture. Barad proposes that the concept of diffraction in analysis is applied to produce multiple and diverse perspectives elicited through differing meaning-making, such as through narratives, graphics, poetics, the political, the spiritual, the sociological, and so on. Diffractions map where the effects of differences appear, to study how differences are produced, how they matter, and the entangled effects these differences make. In this chapter, I apply diffractive analysis to explore different ways of childhoodnature touch and being with touch "and sensing the differences and entanglements from within" (Barad interviewed by Kleinman, 2012, p. 77).

I share diffractive analysis of intra-actions of matter in child-led walks through diffractively storying performative accounts of material bodies (human and non-human), because I agree with Cronon (1992) that narrative is "our best and most compelling tool for searching out meaning in a conflicted and contradictory world" (p. 1374) and with Cameron (2012) that telling stories "can move, affect, and produce collectivities" (p. 575). Through a storied approach to inquiry (Denzin, 1997), I seek meaning in the stories and encourage active reader engagement with the stories. I hope, as Haraway (2008) proposed, for readers to be touched by these stories so to inherit different relations and begin to live different histories and provoke alternative worlds and new realities as Gibson-Graham (2006) proposed for geographical storytelling.

Performative accounts place our "thinking, observing and theorizing as practices of engagement with, and as part of, the world in which we have our being" (Barad, 2007, p. 133), as opposed to above or outside in a representational view. A performative account advocates for "relationality between specific material (re) configurings of the world through which boundaries, properties and meanings are differentially enacted (i.e., discursive practices in my posthumanist sense) and specific material phenomena (i.e., differentiating patterns of mattering)" (p. 139 – italics as per original). Phenomena are thus read as an ontological entanglement of intra-acting agencies, with openness to indeterminacy so that differing ways of seeing and understanding can emerge, pushing aside or muffling preconceived notions through attention to being. Knowing through being is studied, that is, an "onto-epistem-ology" (Barad, 2007, p. 185). I am looking to understand what differences matter in nature touch proposed by children, how they matter, and for whom within a shifting entanglement of relations while acknowledging that I am part of the differential becomings. Attention to these differences includes the aesthetics, affects, sciences, and politics of touch.

With limited knowledge of Thai language, I let go of privileging meaning-making through words and actively heightened my sensory awareness to make meaning through visual, auditory, tactile, gestural, and olfactory modes. Following Ingold's (2011) proposition, I draw from animist ontologies and embrace openness to being "alive and open to a world in continuous birth" (p. 64), engaging with the world as a source of astonishment. Such a way of being is curious and welcoming of the new and unknown. It could be argued that many children readily embrace such an ontology, whereas adults have experienced years and years of cannons of Western

thought conditioning, to be "sealed by an outer boundary or shell that protects their inner constitution from the traffic of interactions with their surroundings" (p. 68) as we consistently define, construct schema, classify, and set parameters of how we know the world. Through a more open (animic) and sensorial way of being, I endeavored to welcome all that the children wanted to share to experience new ways of sensorially being in neighborhoods of Chiang Mai with others.

When I accompanied the children on their walks, I recorded video and embodied memories of which I journaled later the same day. I drew from Pink's (2009) principles for sensory ethnography (perception, place, knowing, memory, imagination) as a framework for engaging with sensory data gathered through walking. My sensory *perceptions* were read as interconnected in alignment with the ontology of agential realism, with no one sensory modality dominating and multiple socially, culturally, and biographically specified meanings intersecting. These sensory perceptions defined *places*. The children's nature touch encounters were very much emplaced, with the intra-actions in space defining *places* of meaning (Creswell, 2004). I drew on my sensory memories of previous visits to Thailand, of previous walks with children, of previous walks in general, and of previous lived experiences. My embodied sensory *memories* of ethnographic data of childhoodnature touch were not merely reported but rather reactivated, imagined, mused over, and linguistically played with. Insights (*knowings*) were generated through the creation and sharing of stories of emplaced sensory memories of children's nature touches. "'Imagination' is implicated in everyday place making practices" (Pink, 2009, p. 39), not just visual imagining but multisensory imagining. I imagined each child's experience of the walk, and their previous experiences of the walk, imagining what she/he was interested in, thinking, and feeling. Collectively, these principles guided my attendance to the sensoriality and materiality of another's way of being in the world, by aligning my body and rhythms and ways of seeing and listening with theirs so that I could become similarly emplaced to come to be with the children's sensations, understandings, and imaginings.

Through embodied and emplaced sensorial research of *The Walking Neighbourhood hosted by Children*, I have been alerted to the ongoing responsibility to the entangled other (Barad, 2007, 2010) that I am entangled with other people, animals, plants, things, and places. I am affected; I am not separate from but rather blurred with others. Such heightened awareness of whole of body in place with others invokes relationality. Allow me to take you on two further walks with children in Chiang Mai.

Childhoodnature Touch that Initiates Movement

As we walked down Ratvithi Road, Pang Pound (9) asked us to stop and to notice hundreds of golf ball-sized seedpods on the ground. She then invited us to roll on them like a skateboard or roller skates. The walking tour group of about 15 then experimented with rolling on seedpods, skating along the footpath of Ratvithi Road. Rather than be bothered by the slippery hazard of seedpods interrupting the

path designed and made for humans to walk along, Pang Pound invited us to relish the very quality considered as a nuisance by pedestrian safety auditors. As Ranciere (2010) noted, urban design and civil services commonly demand that pedestrians "move along" so that the only permissible activity is walking through public spaces. Being spherical invites diverse movement. We played with moving differently – sliding rather than stepping. Pang Pound invited us to notice what can happen if we work with the touch of our shoe-clad feet on the spherical seedpods. We worked with the offer of the seedpods. They scattered, and many crunched, cracking the pod open – a necessity to perpetuate the dispersal of the seeds and the ongoing life of the tree. Wajuppa Tossa (Thai co-researcher) relayed in her version of the walk that Pang Pound said, "I don't want to leave this place. It's so much fun" (Phillips & Tossa, 2017, p. 22), reflecting childhood's stickiness with nature.

As we turned the corner to Khang Ruan Jum Road, Pang Pound and her accompanying walk hosts Jenny (age 7) and Kwan (age 9) warned us with nose blocking gestures that we were passing open rubbish bins. With the intense damp heat, the rotting organic matter was pungent. For a moment, through embodied sensation, the pervasion of the odor and suffocating humidity felt like being in literally a compost bin, being with organic matter in the slow lingering process of decay, like Haraway (2016) invites us to be with in *Staying with the Trouble*. This sensation was only fleeting as we did not stay with the decomposing matter for long but turned the corner to be refreshingly aroused with the fragrant aroma of Thai cooking from street stalls.

Pang Pound then led us to the Mueang Chiang Mai District Office, a place where she played when she was little, when her Dad worked there. In the open space to the left of the office building, Pang Pound pointed to a statue of the King of Thailand, her embedded dutiful practice. She then invited us up the front steps of the office building to collect leaves from the ground under a large overhanging yellow India tree and throw them in the air. The leaves were like feathers with an embedded pealike seed at one end. "It falls like rain," exclaimed Pang Pound. No government officials were to be seen. The grounds were quiet aside from our group playing with leaves on the front step. It was Saturday. There was much laughter and chatter as we delighted in throwing leaves in the air in the forecourt of government offices. This was a space of power and authority, yet Pang Pound invited us to contrast this with the carefree action of throwing leaves in the air. Her association with this space was as an open play space. There are no playgrounds in Chiang Mai, so the car park and forecourt of the government offices were to Pang Pound a space to move and explore. The regulatory space was disrupted by a child's invitation to hold and throw leaves and admire the beauty of their wafting drift to the ground.

Pang Pound invited us to see and experience an institutional space differently, by not permitting its authoritative nature to feature or intercept with aesthetic sensory pleasures. Pang Pound could have asked us to throw leaves in the air at any site, but this wasn't any site. I indulged in the playfulness of throwing leaves in the air against the backdrop of the sterility of government offices. The exquisite irony was not lost in this moment of childhoodnature touch.

Pang Pound's provocations of seedpod sliding and leaf throwing were delightful playful offers to enjoy and appreciate qualities of these plant parts. What emerged in these intra-actions was an honoring and celebration of the seedpod and leaf's qualities – how they can bring joy and wonder while at the same time enacting their dispersal to perpetuate the life cycle of the plant. The entangled effects of noticing these differences with adult sensibilities of the typical patterns of human privileged and policed usage of public spaces sparked readings of the politics of space and how childhoodnature touch can provoke the reconfiguring of spacetime-matterings with playful humor. Pang Pound's childhoodnature touch provocations furthered my embodied commitment to ethico-onto-epistemology – I sensed the differences of child, adult, seedpod, footpath, decaying organic matter, leaves, and offices and their entanglements from within.

Human and Nonhuman Touch

A couple of days earlier, Seemie, all of 6, with a sparkling smile, dressed in a pink dress topped with a crocheted white bolero and wide koala-shaped thongs (globalization is alive and well), held her hand out to accompany me. I entered the walk with a post-humanist ontology of openness – letting go of preexisting conceptions of Seemie as child and me as adult, of me as foreigner (farang), and of Seemie as a local; rather we were beings engaging with the streets of Old Chiang Mai. Seemie wrapped her hand in mine to take me on the walk.

I felt the delicate nature of Seemie's small hand in mine. My senses alerted to the weight, texture, and warmth of her hand that is neither a subject (i.e., to be used for a purpose, e.g., guide me in direction of walk) nor an object of observation. I sensed a "proximity of otherness that brings the other nearly as close as oneself. Perhaps closer… an infinity of others—other beings, other spaces, other times" (Barad, 2012, p. 206).

Her hand is matter intertwined with the matter of my hand, engaged in the intra-activity of handholding. The affect of connection to another was created. My embodiment was integrally entangled with Seemie's. *This is not to say that I experience this when I hold hands with anyone or that the act of holding hands automatically produces such; that is too simplistic an application of agential realism. I am sharing my perceptions and sensations of this moment of being with participant and with data. My predefined identities as mother and early childhood teacher that would be readily socially welcomed in the action of adult woman holding young girl's hand are not foregrounded in my perceptions. The moral panic of adult and child touch that has risen in recent decades* (Tobin, 2004) *was not present in the moment; rather, I, like Tobin, am willing to state publicly that I appreciated being affectionately touched by a child. By examining intra-actions, our entities were not predetermined; they emerged from the action. Instead I am attending to the wave of sensations: warmth, softness, tenderness, and delicateness.* In that moment of my hand being taken in Seemie's, I had an ethico-onto-epistemological awakening, that is, in caring in knowing, and in being, which opened corporeal

awareness of connectivity and entanglement: entanglement of alterity, of generations, of child and adult, and of interculturalism.

Seemie was leading the walk; she was responsible for me. Or as an adult, does the default for responsibility always defer to me? *In agential realism I am embodied, I am with Seemie, I am not an outsider observing in, I am in the moment with Seemie. I am engaged in walking along streets of Old Chiang Mai with Seemie. I am adult and child at the same time; binaries blur.*

Our only shared words were greetings (sawatdee-ka) and gratitude (korp-kun-ka). By not sharing a language – the emphasis on words diminished; materiality and performativity claimed more space. My senses heightened to the new urban landscape. All I knew from an adult's explanation before we set off on the walk was that Seemie was taking us to a mermaid house. Fresh to a foreign city with sensory ethnographic sensibilities, I existed in the indeterminacy of quantum causality at the heart of Barad's (2007, 2010) concept of intra-actions. With openness to instability and impossibility, I searched for some threads of stability and possibility in my sensory memories for balance and for meaning. A mermaid house, what could that be? I imagined what a mermaid house might be. Is it a museum where Thai folklore of mermaids was stored and documented? Was it someone's home inspired in design by mermaids? Is it a building with a mermaid painted on it? Being in touch with more-than-human imaginings in intercultural folklore, images of half-fish-half-human beings across cultures floated in and out of my mind as Seemie led us onward.

As we walked down narrow footpaths frequently obstructed by obstacles, such as electricity poles, trees, and rubbish, I wanted to engage with Seemie to make conversation, such as "How much further?" and "Where is the mermaid house?" I guess driven by previous patterns of walking with another, you converse. Without Thai, all I could do was point, and Seemie smiled and nodded. Committed to holding my hand, Seemie led the way. With the anticipation of the unknown and unfamiliar and the rising temperature and humidity, sweat slipped between our hands, yet Seemie continued to carefully attend to holding my hand. Beads of sweat developed on her petite forehead.

> . . .touching, sensing, is what matter does, or rather, what matter is: matter is condensations of response-ability. Touching is a matter of response. Each of "us" is constituted in response-ability. Each of "us" is constituted as responsible for the other, as the other. (Barad, 2012, p. 215)

I felt from Seemie a commitment to being responsible for me and the group. She was diligently committed to holding my hand and leading the walk to her desired mermaid house. I wondered if she was perspiring from the heat alone, or was she anxious about leading the walk and having responsibility for a *farang* (foreigner)? She continued to smile sweetly at me and carefully hold my hand.

The entire group of 11 followed Seemie's lead. I had no idea where we were going yet was comfortable in the adventure of being led to the unknown by a young child, well, aside from prickly discomfort of the heat. We crossed the road and turned

Fig. 2 Mistaken mermaid house

into another road where Seemie stopped across from a carpentry workshop; let go of my hand to approach the translator, Kimmim; and spoke in Thai, which Kimmim relayed as "It's not there!!" (Fig. 2)

An agential cut, the indeterminate phenomena of the mermaid house became determined through local causal structure (Barad, 2007). Though determined as absent – as missing! – our willing curiosity to see the mermaid house was stumped. Could this, what appeared to be a manufacturing workshop, be differently materialized as a mermaid house at another point in time? Spacetimemattering, that is, the differential patterns of mattering across different times and spaces (Barad, 2010), rearticulated this workshop as the mistaken mermaid house. A few of us took photos to archive this puzzle.

I responded with empathy to Seemie's disappointment through a convivial offer of a grimace. She shyly smiled, seemingly un-phased by not locating her mermaid house. The workshop to which Seemie had led us had a panel near the roof, with a shadowed mark suggesting a previously adhered decorative piece, but it was dirty and well-worn and looked like a well-established workshop for construction. It was puzzling that it could have changed from a young girl's perception of a mermaid house within 2 days. The accompanying translator and Australian arts worker (Nathan) talked about what to do. Nathan suggested they talk about it at the group debrief on return.

Sai then led the group onto his destination. Seemie retrieved a camera from her cloth shoulder bag. We then shared intra-activity between human and nonhuman apparatuses (i.e., cameras). This became our new way of interacting, a shift from the physical connection of hand holding to sharing visions of interest. Seemie photographed lotus flowers in a decorative pond on the footpath, sparkly signs, gates, and flowers. . .flowers and more flowers all within two blocks. Like Hultman and Lenz Taguchi (2010) who diffractively read photos of preschool children in an outdoor playground using a relational materialist methodology to enable shifts in habits of seeing children, I too focussed on visual data with a view to glean insight to Seemie's

Fig. 3 Seemie taking photo of flowers

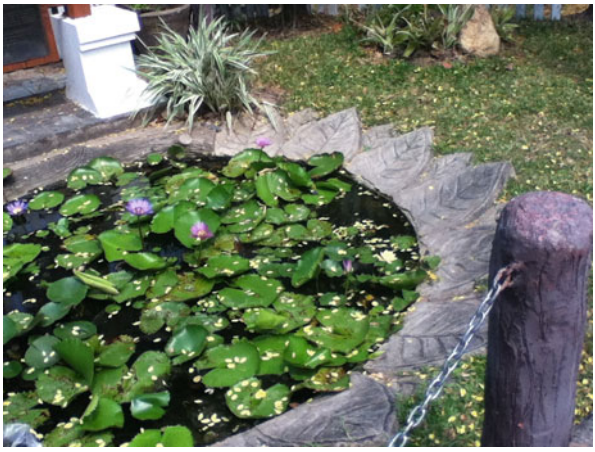

Fig. 4 Lotus flower pond that Seemie photographed

interests and to know her connections with matter in public spaces. I photographed her photographing and what she aimed her camera at, noticing her connections with places, to build understanding of the phenomena of inquiry: children in public spaces (Figs. 3 and 4).

I regarded matter that I would have otherwise passed. Seemie taking photos of matter in the urban environment physicalized her connection to the neighborhood, and I taking photos of Seemie connecting to matter drew me in as another thread in a web of entangled connections with Seemie and with lotus flowers so that I became with the data (Hultman & Lenz Taguchi, 2010, p. 534). I visually honored with Seemie what she deemed worthy of archiving.

Then we crossed the road and turned up a narrow road, and Seemie suddenly stopped. I saw her looking at a large copper mermaid painting on a black wall behind a gate. “Is this the mermaid house?” I asked and she nodded affirmatively (Fig. 5).

Fig. 5 Seemie with her sought-after mermaid house

The open arms and curving body of the mermaid were alluring. Seemie smiled delightedly, yet she dutifully did not pass the gate. Seemie knew the boundaries of space; even the tantalizing enticement of her object of desire (the mermaid) did not intercept her compliance with the public/private space divide (adapted from a version of Walking with Seemie previously published in Phillips, 2016).

My walk with Seemie produced attention to intra-actions of childhoodnature touch between human and human, between human and more-than-human, and between human gaze and flowers. In the child-holding-adult-hand emerges appreciation of the sensations of warmth and tenderness, commitment to reciprocal responsibility (in a Baradian sense of inviting, welcoming, and enabling the ability to respond to each other), and the politics of adult-child touch. The boundaries of each other's being blurred to be entangled in pursuit of the mermaid's house. Being in touch with the pursuit of the mermaid house invited the spirits of mermaids across cultures to accompany the walk. As a storyteller of more than 25 years, I have read, heard told, and told myself folktales of mermaid encounters. A dear friend, Narelle Oliver, published a book "Mermaids Most Amazing" (2001), which collates the folklore of mermaids for child readers. In the book, Narelle recounts half-human-half-fish creatures in the mythology and folklore from Arnhem Land, Babylonia, Polynesia, Native America, the Philippines, Mexico, Japan, Ukraine, Scotland, Ireland, Ghana, and Germany. These images and stories along with many others that I had read and heard were aroused and present as I was held in suspense as to

what and where Seemie's mermaid house was. The intrigue of indeterminacy was enticing. The questions of whether mermaids exist did not surface. The commitment of the search for the mermaid demonstrated an enduring commitment for a mixed group of children and adults to support Seemie's desire – her wish. Does childhoodnature have to be only about what is scientifically proven? It was the aesthetic – the beauty of the mermaid that – Seemie appreciated, just as she appreciated the beauty of the lotus flowers, as too have been appreciated across mythology.

Childhoodnature Touch Offerings Toward Ethico-onto-Epistemology

These diffractively storied encounters of childhoodnature touch are shared not to idealize or romanticize childhoodnature touch but rather to witness the possibilities of awakenings that emerge. The children did not offer these childhoodnature touch encounters because of an explicit focus on nature; rather these encounters were entangled and located within what sparked their interest in their neighborhood walks of Chiang Mai. What is at stake is "what counts as nature, for whom, and at what costs" (Haraway, 1997, p. 104) and how. Through animic openness and heightened sensorial awareness to the childhoodnature touch provocations of my child walk hosts, the children alerted me to what matters – to what counts as nature. It is not the untarnished wilderness but rather in the everyday – the ordinary (vine on wall, seedpods underfoot) but also in the extraordinary – the (im)possible (mermaids). Emerging from these childhoodnature touch encounters is attention to eco-aesthetics and the feeding of responsibility toward others, through openness to indeterminacy for an ethico-onto-epistemology. The following discusses understandings gleaned on these three concepts emerging from the above diffractive storying of childhoodnature touch encounters.

Eco-Aesthetics

Kraing, Pang Pound and Seemie invited sensation with nature: not with what is readily visible and visceral but with that which creeps into crevices, rolls underfoot, hangs to the side, and hovers on the boundaries of existence. The stealing of surreptitious moments to sensorially connect illustrates the inseparability of children and nature. With fewer years of Western conditioning to separate mind from body, Kraing, Pang Pound, and Seemie did seem to have an enhanced attunement to sensorially read and be with organic matter. Or was it simply that they were given the luxury of time to walk and wonder in their local neighborhood as a source of astonishment (Ingold, 2011), as opposed to traversing through spaces, to get to a predetermined destination?

The Walking Neighbourhood hosted by Children involved arts workers facilitating workshops with primary school-aged children who self-volunteered (or their

parents volunteered them) to participate. The series of workshops involved drama games for the group to get to know one another and build rapport with one another, lots of observational neighborhood walks, photo documentation of the walks, collecting artifacts on the walks, interviewing neighborhood residents, and group meetings to reflect and debrief on walk experiences and the process of developing a curated walk for adult audiences. The arts do invite us to look closer – to observe – to explore. The whole project invited relational aesthetics (Bourriaud, 2002), through artists and audiences manipulating everyday practices to provoke (re)thinking about these practices so that the everyday is engaged with not as predetermined but rather as indeterminate.

The experience of the aesthetic is an intangible, emotive experience that humans struggle to shape into words. By referring to the Greek root *aisthe*, which means to feel or apprehend through the senses, Baumgarten coined the term in 1750 (Abbs, 1987; Barilli, 1993). Sensorial meaning-making is at the core of aesthetics, so it is not just sensory perceptions alone but rather how they are combined with our interpretations or readings of our sensory perceptions (Diaz, 2004). To explain the aesthetic experience, Dewey (1934) applied the metaphor of a stone rolling down a hill that is looking forward to the journey, relishing the encounters along the way, and relates the end of the journey to all that went before. This explanation breathes more-than-human sensibilities, inviting a stone and inclined landform to illustrate interconnected and relational qualities of aesthetic experiences. Though rolling down the hill implies speed, I suggest that slow lingering is far more desirable for the relishing of aesthetic encounters. And it is in these moments of relishing, of savoring, that shifts in understandings can be provoked cultivating a sensuous, analogical, and poetic mode of knowing (Abbs, 1989; Greene, 1995). The symbolism and sensuousness of the aesthetic encounter possess great power for new insight, especially when time is allowed for musings over the sensory perceptions (Marcuse, 1978). The language of aesthetics makes "perceptible, visible, audible that which is no longer or not yet perceived, said, and heard in everyday life" (p. 72). By this Marcuse claimed that the language of aesthetics can communicate what is not communicable in any other language.

The childhoodnature aesthetic encounters of Kraing, Pang Pound, and Seemie's walks communicated beyond what I have been able to share through words in a linear chapter. Though these encounters may seem a simple, small gesture, they are imprinted within, as I can so viscerally reimagine being in each encounter. Although they occurred more than 4 years ago, they continue to provoke sensuous, analogical, and poetic knowing. They provoke what Maxine Greene (1995, 2004) referred to as wide-awakeness, arousing vivid, reflective experiential responses by releasing imagination through the arts. This state of wide-awakeness is not about sudden or short bursts of shifts in consciousness but rather an ongoing deeper awareness of what it is to be in the world. These childhoodnature touch encounters aroused an openness to be with child, to be with vine, to be with seedpods, and to be with mermaid – to sense their pulses. The addition of eco to aesthetics brings the aesthetic attention to nature or ecological concerns (Miles, 2014), "to cross the contested terrain that makes up the natural world and humankind's relationship

with it" (Finley, 2011, p. 312). Though Kraing, Pang Pound, and Seemie did not communicate any explicit sustainability agenda in their childhoodnature touch encounters, the experience of each certainly aroused a deepened sense of responsibility for the other, for which I am eternally grateful for their invitations to admire the beauty of vines, the movement of seedpods, the touch of skin to skin, and the welcoming of mermaids. And it is through cultivation of appreciation that we then care, that we then have the ability to respond to another, that we ethically know through being with others (ethico-onto-epistemology).

Response-Ability: Having the Other in One's Skin

From such an ethico-embodied position, one cannot escape responsibility to all other beings – an ethics of worlding – by bringing the sciences into democracy, acknowledging the politics of nature, flattening the hierarchy of human privilege, and recognizing that all beings share common worlds (Latour, 2004). By reading intra-activity in childhoodnature touch, all bodies came to matter – the tenacious claws of the vine come to matter; the ambiguous and elusive mermaid comes to matter; and the playful movement possibilities of seed pods and seeded leaves come to matter. It is about being entangled with all matter—"having-the-other-in-one's-skin" (Barad, 2007, p. 392). From an agential realist position, "we (but not only "we humans") are always already responsible to the others with whom or which we are entangled, not through conscious intent but through the various ontological entanglements that materiality entails" (p. 393). Kraing, Pang Pound, and Seemie brought conscious attention to our entanglement/stickiness with nature. Although much of the human project has tried to disconnect us from nature, vines continue to creep into manufactured structures, seedpods continue to roll underfoot, mermaids continue to hover on the peripheries of existence, and children seize these surreptitious moments to connect.

Whole of body sensing of interconnectedness/interrelationality evokes ethicality, that is, "hospitality to the stranger threaded through oneself and through all being and non-being" (Barad, 2014, p. 163). In this space, self-interests dissipate, and the attention is to "being with." Such responsibility entails "an ongoing responsiveness to the entanglement of self and other, here and there, now and then" (Barad, 2007, p. 394). In the shift from humanism to post or more-than-humanism, the ongoingness of responsibility is hard to sustain especially in our age of extreme consumerism and social media-fuelled narcissism. And it would be idealistic to suggest that Kraing, Pang Pound, and Seemie sustained responsibility to the organic matter of their touch encounters. It is difficult to say. There was certainly a desire to linger as expressed by Pang Pound about the seedpod rolling touch with "I don't want to leave this place." But they also quickly moved on, though probably in response to adult corralling to keep to predetermined time schedules. As Ginn (2014) expressed, "the aim of more-than-human geography to rethink the ontological and ethical entanglement of life is long term and ambitious" (p. 541). The awareness of the responsibility to all others is a beginning of "facing our responsibility to the infinitude of the other,

welcoming the stranger whose very existence is the possibility of touching and being touched, who gifts us with both the ability to respond and the longing for justice-to-come" (Barad, 2012, p. 219). It is hoped by those of us who have begun to sense, and those for whom such sticky, entangled ethicalities are deeply rooted in our cultural DNA, that response-ability to the infinitude of the other is contagious and spreads and heals the vast injuries of human privilege.

Conclusion

To close, I propose that it is through openness to indeterminacy that holds the space for ethically knowing and being with others: an ethico-onto-epistemology. As Barad (2012) asserts, "being in touch with the infinite indeterminacy at the heart of matter, the abundance of nothingness, the infinitude of the void that is threaded in, through and around all spacetimemattering opens up the possibility of hearing the murmurings, the muted cries, the speaking silence of justice-to-come" (p. 216). To sit with the unknown/the ambiguous/the indeterminate is a core attitude for creative practice (Piirto, 2011). It is the ambiguity that invites exploration – which invites openness to see the hidden, to hear the murmurings, to feel breath on skin, to smell ghosts, and to taste the notes of earth in water. And it is through the imagination that the arts and aesthetics put "us in touch with the possibilities for sensing the insensible, the indeterminate" (p. 216). I invite you to embrace indeterminacy in childhoodnature touch encounters that are offered your way, to relish and linger with sticky sensations and to embody touching infinite alterity and ethicality.

Abstract

From early childhood onward, Rachel Carson's relationship to nature was both imaginative and scientific, involving both literature and firsthand investigations of her homeplace. Later in life, Carson shared in a speech that, "I can remember no time, even in earliest childhood, when I didn't assume I was going to be a writer. Also, I can remember no time when I wasn't interested in the out-of-doors and the whole world of nature. Those interests, I know, I inherited from my mother and have always shared with her" (Carson, Lost woods: The discovered writings of Rachel Carson. Beacon Press, Boston, 1999, p. 106). Carson's mother recognized her daughter's gifts and surrounded her with opportunities to learn in two complementary directions: creative writing and nature study. This chapter examines the development of Carson's famous "sense of wonder" through her own childhood immersion in the early twentieth-century nature study movement, as well as through her relationship with children's literary magazines, particularly *St. Nicholas*. Like other exemplars of literary environmental history, Carson's

early childhood experiences nurtured the development of an artistic sensibility as well as a responsiveness to, and curiosity about, the more-than-human world. Carson's aesthetic made her a best-selling author who catalyzed the modern environmental movement with *Silent Spring*. But her success as a writer and legacy as an activist were rooted in "the sense of wonder" – a phrase that would become the title of her last, posthumously published book. Today, *The Sense of Wonder* remains an ecological manifesto that summons learners and educators of all ages to keep alive this vital sense in our own lives.

Introduction: The Past Is Not over

> All history becomes subjective; in other words there is properly no history, only biography.
> – Ralph Waldo Emerson (1982, p. 153), from his 1841 essay, "History"

Why bother to look at the past? What can we learn from the elders – the *ancestors* of the environmental movement? Where, in the life of someone like Rachel Carson, was the meeting ground between the aesthetic and ecological imagination?

People who know of Rachel Carson most often remember her as the author of *Silent Spring*, her 1962 classic exposé of chemical pesticides, and the industry behind them, that helped launch the modern environmental movement. *Silent Spring* did in the 1960s what no one book had ever done before and will likely ever do again: it radically changed the terms of the conversation between people and nature in the public imagination, in media, in science, in business, and in government. It galvanized a massive public outcry about the impacts of technology on human and nonhuman health, it led to a series of national policy shifts around environmental regulation (in more than one country), and it became an enduring symbol of the need for citizens to both heighten our awareness of ourselves as environmental watchdogs and also to recover our sacred obligations and connections to the earth. Translated into many languages, *Silent Spring* quickly became an international best seller and signaled a new era of global environmental politics. Technological "progress" and the interests of business would from then on be questioned on a planetary scale by a growing group of concerned citizens, scientists, and policymakers who would become known as environmentalists.

What most people do not remember today, however, is that *Silent Spring* did not make Rachel Carson's reputation as a writer and household name. She was already the beloved author of three best-selling, and largely apolitical, natural histories of the oceans. Carson's popularity as a nature writer, her status as a much-loved observer, and scientific interpreter, of the natural world, put her in a unique position to become an international spokesperson for the environment. Her notoriety, and, from her publisher's perspective, her marketability, ensured that *Silent Spring* would be published, publicized, and widely read and that its charges against chemical pesticides would be seriously considered.

It is hard to imagine the environmental movement as we know it without *Silent Spring*. And it is impossible to imagine *Silent Spring* without the success of her Carson's previous three books: *Under the Sea Wind* (1941), *The Sea Around Us* (1951), and *The Edge of the Sea* (1955). The most important of these was *The Sea Around Us*. Published over 10 years before *Silent Spring*, this is the book that changed her life and that made Carson's reputation as a major nature writer. Sales from *The Sea Around Us*, along with the constant stream of requests for new writing and speaking engagements, gave Carson the financial freedom to quit her government job, build her cottage on the coast of Maine, and become a full-time writer – her lifelong dream realized. She benefitted from the massive publicity behind the book, which included serial prepublication in *The New Yorker* (*Silent Spring* would receive the same privilege), a Book of the Month Club selection (ditto for *Silent Spring*), the John Burroughs Award, and the National Book Award. The accolades and awards were the fruition of a long effort to write while holding down a government job as a scientist and supporting her extended family. But most of all, Carson's success reflected her literary gift to communicate her own sense of wonder through poetic prose that somehow married imaginative vision with vivid natural history, unbridled enthusiasm, and the careful reasoning of science.

In today's intellectual environment, postmodern, ecocritical, and critical humanist scholars are sometimes hasty to condemn the writing of canonical environmental thinkers. Often, writers such as Henry David Thoreau or John Muir are dismissed as expressing a narrow, white, male, and privileged view of romanticism that does not reflect the cultural diversity of thought and experience in today's environmentalism. Though such critiques are of course sometimes warranted, they are less convincing when they become ad hominem attacks on personalities (often based on excerpted or "cherry-picked" passages) that lack careful engagement with an author's biography and his or her larger body of work in its historical context. This is especially true with Thoreau, who was recently lampooned in *The New Yorker* in an article titled "Pond Scum" (Shultz, 2015). While this chapter does not seek to enter into a debate about the relative merit of canonical environmental literature in the context of today's intellectual trends, it does explicitly focus on the biography of Rachel Carson as related to her writings that still resonate with large audiences. What does Carson still have to teach us that we might need to remember?

At a time when "nature writing" is sometimes critiqued for not being critical enough to address the enormity of today's cultural and ecological crises, it is worth remembering that the transformative power of Carson's *Silent Spring* had its origins in an *aesthetic*, rather than a *political*, genre. In both academic and political contexts, aesthetic experience and expression are often marginalized in favor of discursive and rational argumentation. From the perspective of the arts and humanities, such marginalization limits the possibilities of what it means to be an imaginative and creative human being, just as it frequently excludes imaginative thinking from politics. The life of Rachel Carson – as artist and activist – demonstrates the vital necessity of aesthetics to political life and to the environmental movement. What made Carson's nature writing unique was not her politics, but her rare ability to combine the skills, gifts, and discipline of a scientist with those of a literary artist. While she developed this ability throughout her life and career, it started with a

childhood steeped in both natural history and literature. Examining the confluence of these twin passions in Rachel Carson's early life illustrates what kinds of learning experiences undergirded Carson's celebrated environmentalism. It also serves as a reminder that literature and nature study remain valuable ends in themselves and that they are essential to children's learning as well as to contemporary environmentalism.

Rachel's First Teachers

> I can remember no time, even in earliest childhood, when I didn't assume I was going to be a writer. Also, I can remember no time when I wasn't interested in the out-of-doors and the whole world of nature. Those interests, I know, I inherited from my mother and have always shared with her. – Rachel Carson (1999, p. 106), from her 1954 speech, "The Real World Around Us"

Born in 1907 in Springdale, Pennsylvania, Rachel Carson's early childhood was guided by two of her most significant teachers, her mother Maria McLean Carson, and a 64 acre rural property that featured orchards and gardens, groves and fields, hills and hollows, and plenty of room to roam. Linda Lear (2009), Carson's principal biographer, offers this description of the famous naturalist's mother:

> Maria was an avid reader and believed in using her leisure time to improve the quality of her children's lives as well as her own. One of her keenest interests was natural history. She was not alone in this passion, for botanizing, bird-watching, and nature study were interests avidly pursued by amateur naturalists all over the country at the turn of the century, particularly among middle-class, educated women. (p. 13)

Maria McLean was highly educated for her time. The daughter of a Presbyterian minister, she attended the elite Washington Female Seminary, excelled in music, and was trained in a classical curriculum which included Latin. After taking advanced courses at Washington College, Maria taught school and gave music lessons until she married Robert Carson, as marriage was then taboo for female teachers. Robert was neither rich nor well-educated, and the family always struggled financially. But with their initial purchase of the property in Springdale, Robert and Maria were able to provide Rachel and her siblings with an expansive homeplace filled with daily wonders. Eventually, the young naturalist would learn to study her immediate environment systematically with her mother and discover that she had a passion for writing about it for herself as well as for other young readers (Lear, 2009, pp. 8–20).

The Nature Study Movement

Maria Carson and her daughter Rachel wandered the woods and fields around their home at a time when nature study had become one of the country's chief recreational and leisure activities for people of all ages. When considering the history of environmentalism and environmental education, the nature study movement in the

United States in the late nineteenth and early twentieth centuries stands out as an extraordinary phenomenon. It enjoyed enormous popularity among ordinary citizens, and it had deep impacts on children through the widespread adoption of nature study curricula in schools. The movement emerged and flourished during a time when naturalists – from Louis Agassiz to John Burroughs – were highly respected people and when the knowledge of the natural world, including a basic acquaintance with local flora and fauna, was considered fundamental to a proper education (Pyle, 2001). Historically, the popularity of the nature study movement owed much to nineteenth century Romanticism and the cult of nature that followed the American Renaissance. The difference was a departure from the mere idealization of nature by elites to firsthand experience of it for the masses, as a subject of both aesthetic appreciation and scientific inquiry (Armitage, 2009).

As a former schoolteacher herself and as a parent actively involved with the schooling of Rachel's older siblings, Maria would have been familiar with the many books then available to teachers to help guide their students in nature study. The most famous of these was Anna Botsford Comstock's, the *Handbook of Nature Study*, first published in 1911, 4 years after Rachel's birth. Like the larger movement and its advocates, such as Comstock's Cornell University colleague, Liberty Hyde Bailey, the *Handbook* encouraged not just curiosity for natural objects, but immersive experiences, as well as emotional and spiritual connections, which combined recreation, environmental learning, and an ethic of reverence toward the natural world. The subtitle of Liberty Hyde Bailey's 1909 book communicates the humanistic agenda for a nature study movement focused on school-aged children: *The Nature Study Idea: An Interpretation of the New School-Movement to Put the Young into Relation and Sympathy with Nature*. For Bailey and other advocates of nature study, the point was to connect the learning of the science of natural history to the experience of excitement, joy, and wonder. Later in her own life, as we will see shortly, Carson would restate this precise goal with its most memorable expression in her writings on "the sense of wonder." Well before she wrote about it as an adult, however, she experienced it as a child through the everyday contexts of family, home, and turn-of-the-century educational culture.

The nature study movement was the earliest example in the United States of widespread environmental education. By 1939, in its 24th edition, Comstock's *Handbook* had been adopted in schools throughout the country and had introduced two generations of children to natural history through the direct experience of their local environments. Before World War II, mainstream American culture included within it a strong affirmation of nature study as both a societal good and as a benefit to the education of the nation's children. Today's environmental movement is deeply indebted to the success of the earlier nature study movement. And some of the current movement's inadequacies, such as the diminishment of natural history within a broadly diffuse mission fractured by specialization, reflects the earlier movement's demise (Pyle, 2001). But in the second decade of the twentieth century, nature study flourished. Maria Carson devoted herself to mentoring the young Rachel in the wonders found in the family woods, hillsides, and orchards and made full use of the Comstock readers that her two elder children brought home from school. Rachel was surrounded from birth by birds, insects, fruit trees, vegetable gardens,

wildflowers, hedgerows, woodlots, and meadows. She was mentored from an early age to experience nature and her own backyard, as a vast laboratory for learning about life's miracles. While many rural children of Carson's era had open access to natural environments, few had the encouragement of committed college-educated parents like Maria Carson, whose persistent tutelage would help to fuse Rachel's experience with her developing senses of curiosity and wonder.

Maria Carson's guidance, like the nature study movement itself, went well beyond the taxonomical naming of the diverse creatures she and her daughter would regularly encounter on their property and the surrounding landscape. According to Lear (2009):

> Maria impressed her respect and love for wild creatures on all her children. When they returned home from their woodland adventures with treasures to show her, Maria instructed the children to return them to where they had been found. This kind of care for the natural world had a spiritual dimension that at least her youngest daughter [Rachel] embraced and would practice all her life. (p. 15)

However Rachel Carson experienced her own spirituality, her writings are alive with expressions of love, care, wonder, and awe – emotions that kindled her aesthetic imagination and enthusiasm. In her biography, Lear (2009, p. 8) describes how Springdale residents recount the story, "perhaps true, perhaps apocryphal," of Carson's early fascination with the ocean. As local lore has it, 1 day Rachel found a large fossilized shell in the rocky outcrops of the hillsides surrounding the Carson property. She wondered where it had come from, what kind of creature had made it and lived in it, and what finally happened to the animal and the sea in which it lived. Whether myth or fact, one can easily imagine these kinds of questions coming up regularly on Rachel and Maria's many rambles on their land and during Rachel's adventures with other Springdale children, who collected many fossilized shells on the Carson property. Later as an adult, Carson would write of her love of the sea: "Even as a child – long before I had ever seen it – I used to imagine what it would look like, and what the surf sounded like" (Carson, 1999, p. 54).

Her mother Maria, the family land, and the nature study movement helped to nurture in Carson an acute awareness of her imaginative powers, her sense perceptions, and her powers of expression. The nature study movement promoted reverence for nature's wonders *and* a reverence for nature's beauty. In his history of the nature study movement, Kevin Armitage (2009) emphasizes the importance of aesthetics to many of the movement's advocates:

> The nature study movement provided thinkers. . . with a working model for using education to inculcate the public with aesthetic sensibilities and a consciousness for conservation. One result of sympathetic contact with nature was to bring beauty into people's lives. Nature study advocates disavowed the idea that the experience of beauty should be a distinct and specialized component of a well-rounded education. They preferred to see beauty as continuously integrated into all parts of life. Sympathy with nature and the aesthetic pleasure derived from it affected every part of being. Rather than existing in things, aesthetic pleasure arose from human experience – especially experience with nature. (pp. 150–151)

So prevalent was the idea that the aesthetic experience in nature was a valued educational aim in itself that in 1902 the *Nation* magazine would opine that nature study and artistic seeing "have the same enemy – lazy and abbreviated habits of vision; both fight the same battle – to intensify the powers of observation" (cited in Armitage, 2009, p. 152).

The nature study movement had many advocates and practitioners. Dignitaries such as Harvard University President Charles Eliot promoted a new education for public happiness through the experience of the beautiful in nature (Armitage, 2009, p. 148). John Dewey's theories of learning and aesthetic experience provided theoretical support for new ventures into the field. Dewey's ideas of education and art were that they depended primarily on experience or forms of communication that were not reducible to subject or object. That is, experience, or art, is to be conceived as the continuous interplay between subject and object, between the viewer and the viewed, and between children and their environment (Dewey, 1997, 2005). It is this interplay that the nature study movement sought to enhance through direct contact with nonhuman phenomena and with opportunities for reflection and expression – key components of experience, according to Deweyan theory. Scientists, naturalists, writers, and photographers such as Liberty Hyde Bailey, Anna Comstock, and Gene Stratton-Porter inspired young people and their mentors to experience nature directly, out-of-doors, as a basic part of what it means to be alive in the world. All of these themes would become central to Carson's identity as a writer and environmentalist. Whatever Carson's innate gifts were as a child, it is hard to imagine the path she followed without the influence of the nature study movement and her opportunity to experience its credo daily, on the land, with her mother as her enthusiastic guide.

St. Nicholas Magazine

While art and writing were central to the nature study movement – Comstock's (1967) *Handbook of Nature Study* included correlations with drawing, story, and "language work" (p. xv) – Maria Carson also subscribed to several children's magazines to support her daughter's enthusiasm for reading and the art of writing. Rachel's favorite was *St. Nicholas*. Lear (2009) writes, "No other juvenile magazine of the period adopted the values of the nature study movement more completely than *St. Nicholas*" (p. 18). While *St. Nicholas* reflected the turn-of-the-century nature study movement, it also inspired other young writers who would eventually help shape American literature. William Faulkner, F. Scott Fitzgerald, Edward Estlin (e. e.) Cummings, Edna St. Vincent Millay, and E. B. White, among other notables, all contributed to *St. Nicholas* as child authors.

Like the bounty of resources produced for schools, teachers, and families during the nature study movement, *St. Nicholas* was geared toward children. First published in 1873, the magazine emphasized beautiful illustrations, high-quality writing, stories, poetry, and a section on letters from readers. The magazine was also designed

to motivate its young readers toward intellectual achievement and high ideals. In 1889 it began publishing work by children themselves and holding contests for the best poems, stories, essays, drawings, and puzzles. Each month, winners were awarded prizes and inducted into the St. Nicholas League; the highest achievements were for honor members who were awarded cash prizes. Before she was thirteen, Rachel submitted four stories to the magazine, all of which were published. This early literary success, which twice included actual payment from *St. Nicholas*, inspired Carson to think of herself as a writer of some ability, and it commenced what would later in her life become an assiduous business practice of identifying potential publishing opportunities and submitting work for review – usually with the expectation of remuneration (Lear, 2009, pp. 18–26).

Rachel Carson sent the magazine her first story contribution at age ten. It was immediately published and given a prize, as were several other articles, the last of which described her "favorite recreation" – which was a special section in the magazine devoted to the subject. Carson's story of going birds'-nesting (her favorite recreation) with her dog, Pal, is worth quoting here at length as it illustrates the convergence of her skills as a sensitive young naturalist and writer of some accomplishment:

> The call of the trail on that dewy May morning was too strong to withstand. The sun was barely an hour high when Pal and I set off for a day of our favorite sport with a lunch-box, a canteen, a notebook, and a camera. Your experienced woodsman will say that we were going birds'-nesting – in the most approved fashion.
>
> Soon our trail turned aside into deeper woodland. It wound up a gently sloping hill, carpeted with fragrant pine-needles. It was our own discovery, Pal's and mine, and the fact gave us a thrill of exultation. It was the sort of place that awes you by its majestic silence, interrupted only by the rustling breeze and the distant tinkle of water.
>
> Near at hand we heard the cheery "witchery, witchery," of the Maryland yellow-throat. For half an hour we trailed him, until we came out on a sunny slope. There in some low bushes we found the nest, containing four jewel-like eggs. To the little owner's consternation, we came close enough to snap a picture.
>
> Countless discoveries made the day memorable: the bob-white's nest, tightly packed with eggs, the oriole's aërial cradle, the frame-work of sticks which the cuckoo calls a nest, and the lichen covered home of the humming-bird.
>
> Late in the afternoon a penetrating "Teacher! *teacher!* TEACHER!" reached our ears. An oven-bird! A careful search revealed his nest, a little round ball of grass, securely hidden on the ground.
>
> The cool of approaching night settled. The wood-thrushes trilled their golden melody. The setting sun transformed the sky into a sea of blue and gold. A vesper-sparrow sang his evening lullaby. We turned slowly homeward, gloriously tired, gloriously happy! (Carson, 1999. p. 10)

In these few short paragraphs, we can witness several of Carson's attributes, so early embodied, that would develop throughout her life and work. The first sentence reflects the pull of the trail felt by so many nature lovers. This particular adventure

was not a special occasion, but a daily experience for Carson. She would embark alone or with her dog for an entire day prepared with food, water, and the tools of her nature study craft: a notebook and camera. Her language may seem somewhat cliché to today's readers, yet it is quite descriptive for a girl of thirteen. And while any decent young writer might pen the phrases "majestic silence," "rustling breeze," and "distant tinkle of water," Carson's prose is most evocative when she describes the birds' nests she finds in closer detail: the "four jewel-like eggs" of the yellowthroat, the oven birds' nest, "a little round ball of grass," and the extended list: "the bob-white's nest, tightly packed with eggs, the oriole's aërial cradle, the frame-work of sticks which the cuckoo calls a nest, and the lichen covered home of the humming-bird." That Carson even knew how to identify the nests and birdsongs of these local breeding birds reflects a process of learning the natural history of her homeplace, a process that had evolved over time to the point where she is clearly very confident and capable. That sense of confidence and ability is, likewise, reflected in the sure-footed phrasing and description of a talented writer. *St. Nicholas* was the perfect outlet for young Rachel. It was a public place where she could test and display her aptitude as both naturalist and writer.

Together, the nature study movement and the literary opportunities presented by *St. Nicholas* magazine created a rich milieu in which Carson's aesthetic sensibilities could be awakened. Nature's mysteries inspired Rachel on a daily basis, kindled her imagination, and led her to learn more about the plants, animals, and places of her home range. *St. Nicholas* offered a space where her voice could be seen and heard and where she could begin to identify herself as a serious writer with a publication record – all before entering high school. And perhaps most important to Carson's learning was the near constant presence of her mother, Maria McLean Carson. Maria recognized her daughter's gifts and made it her business to nurture them. The nature study movement and children's literary magazines provided them both with plenty of resources. Yet it was also more than that. These two pillars of Carson's childhood – nature study and literature – were highly visible and valued expressions of culture at the time; among the educated classes, reading, writing, and nature study were respected activities for everyone's self-development. Maria and Rachel Carson must have felt that support. They flourished under its influence.

The Sense of Wonder

If we were to examine Carson's major publications in reverse order, we would need to begin not in 1962 with *Silent Spring*, but in 1965 with her posthumously published, essay-length book, *The Sense of Wonder*. This may be her most timeless book: the one that, because of its brevity and broad appeal, may be the most widely read today and the one that will still be read for its freshness decades, perhaps centuries, into the future. Unlike her other books, which, though poetic, dramatic, and profound, depend largely on a science that may seem outdated, *The Sense of Wonder* captures a profound human experience that the environmental movement and all of its advocates consistently need to return to for sustenance.

As we have seen, Carson's professional success as nature writer was nurtured in childhood through intensive exposure to natural history and the craft of writing. Long before environmental educators would begin researching, writing, and discussing the impact of "significant life experiences" on environmental attitudes and behaviors (e.g., Tanner, 1980; Chawla, 1998), Rachel Carson wrote a powerful literary manifesto advocating childhood experience in nature. Just as the politics of *Silent Spring* sprang from an imaginative writer rather than a seasoned political activist, the pedagogical wisdom of Carson's book, *The Sense of Wonder*, arose not from formal research into childhood learning, but from the perceptive reflections of a naturalist and literary observer. Carson was, of course, well trained as a biological researcher, but her writing about childhood was biographical and imaginative. *The Sense of Wonder* describes her relationship with one child – her grandnephew, Roger. Today the phrase "the sense of wonder" is probably better known than "silent spring." Both phrases are iconic to the environmental movement; both emerged from a now historical figure whose primary identity was that of a writer. In a research handbook such as this, it is worth noting the value of imaginative writing as a legitimate form of knowledge production. The marginalization and exclusion of aesthetic expression from many academic conversations privileges one way of knowing over others and severely constricts the possibilities for human communication and understanding. The limits of space restrict elaboration on this point. Suffice it to say that an emphasis here on Carson's literary achievements, and their impact on environmental education and the entire environmental movement, points to the need to revalue literary and artistic contributions in every field of study.

The Sense of Wonder was first published in 1956 as a feature article in the popular magazine, *Women's Home Companion*, under the title, "Help Your Child to Wonder." Carson never had children, but she was very close to her grandnephew, Roger Christy, who she would eventually adopt when his mother, Rachel's niece, died. Carson's biographers and her own letters tell us of her struggles with her maternal role. Throughout her adult life, she had been the chief caretaker – and breadwinner – for her entire extended family, including Roger and his single mother. The burden, in terms of time and money, that this placed on so ambitious a writer as Carson was significant, and it forced her early in her career to develop strict work and business habits. Hard pressed to find space and time to write, she also always wrote with the aim of making as much cash as she could from her efforts. As mentioned earlier, Carson's blockbuster success with *The Sea Around Us* lessened the financial burden and also allowed her to build a cottage, a sort of writing retreat, on Southport Island on the coast of Maine. Even so, adopting 5-year-old Roger at age 50 added pressure to a host of family obligations she had begun to refer to as "the emergency" (Lear, 2009, p. 300). But even before she adopted him, Carson was very fond of her little nephew. Her relationship with Roger and their adventures near the sea at Southport are what inspired "Help Your Child to Wonder" and gave the public a closer look at the private, feeling life of the best-selling author.

This world of feeling, the intense world of sense perception and wonder at even the smallest parts of creation – this has always been the cornerstone of American environmentalism and its nature writers. Walt Whitman may have said it best in

Leaves of Grass when he exclaimed, "and a mouse is miracle enough to stagger sextillions of infidels" (Whitman, 1980, p. 73). English romantic poets like Wordsworth and Blake and American transcendentalists like Emerson and Thoreau all celebrated the mysterious forms, energies, and relationships between each part of the living earth and the entire cosmos, as did dozens of other writers Carson admired. From its earliest beginnings, American environmentalism was promoted and shaped by its nature writers. Intimacy between people and nature, however, and the meaning one makes of it, depends largely on place and time, on the conditions that either invite or inhibit the development of such a relationship. In their seaside adventures in Maine, Rachel witnessed Roger's bond with the world develop; her observations and reflections stand up today as a poignant plea on behalf of all of us to protect and reclaim our own sense of wonder.

The Sense of Wonder: A Brief Textual Analysis

This chapter views Rachel Carson – both her biography and her writings – as a necessary part of contemporary environmental education, especially with respect to aesthetics and children's learning. Examining the significance of Carson's own early learning experiences was the subject of earlier sections. This section aims to demonstrate, through close reading, how *The Sense of Wonder* (Carson, 1965) functions as a literary text imbued with particular pedagogical, ecological, and aesthetic insight – for children and adults.

The essay opens with the image of Carson wrapping up a small child to introduce him to the sea for the first time (citations are from the original 1956 version titled, "Help Your Child to Wonder" though both titles will be used):

> One stormy autumn night when my nephew Roger was about twenty months old I wrapped him in a blanket and carried him down to the beach in the rainy darkness. Out there, just at the edge of where-we-couldn't see, big waves were thundering in, dimly seen white shapes that boomed and shouted and threw great handfuls of froth at us. Together we laughed for pure joy – he a baby meeting for the first time the wild tumult of Oceanus, I with the salt of half a lifetime of sea love in me. But I think we felt the same spine-tingling response to the vast, roaring ocean and the wild night around us. (p. 25)

"Help Your Child to Wonder" was Carson's first magazine publication after the runaway success of *The Sea Around Us* (1951). Readers of the *Women's Home Companion* (1956) were excited to learn more about the private life of the famous author. Lear (2009, p. 280) reports in her biography that the original commission from the magazine was for Carson to write more of a personal profile of herself for admiring readers. But Carson gave readers something that even more women, as well as men, could relate to: the image of a motherly figure introducing a child to the all-encompassing embrace of Oceanus, Carson's mythopoetic name for the subject of her three previous books.

With the opening paragraph, Carson establishes several themes developed throughout the essay: the importance of sensory impressions, emotions, a sense of

mystery, and the shared experience of adventure. The night is stormy; the ocean is roaring; the waves are thundering: "I think we felt the same spine-tingling response," Carson writes. She describes an emotional scene of laughter and "pure joy," as she shares her "half a lifetime of sea love" with her nephew. But it is not just the sheer physicality of the sea throwing "great handfuls of froth" that produces the emotional response. This prelude paragraph is also steeped in a sense of mystery – the unknown. They go "down to the beach in the rainy darkness. Out there, just at the edge of the where-we-couldn't see," where "dimly seen white shapes. . .boomed and shouted." On this dark and "wild night," the child meets for the first time the "wild tumult of Oceanus." This is far from a tame nature walk. Carson introduces the child to creation itself and imaginatively invokes the gods. And suffusing the entire scene is the image of intimacy and togetherness. The adult guide is there with the child to share the joy, wonder, and awe of the experience.

Throughout "Help Your Child to Wonder," Carson describes diverse experiences in nature as enchanted "adventures" capable of producing deep feeling. She emphasizes the significance of the adult-child relationship in these adventures and insists that they are "based on having fun together rather than on teaching" (p. 26). She also points out that a natural outcome of such shared experience is a growing curiosity and knowledge of nature's parts and how they work together. Of Roger's developing ecological literacy and his ability to identify individual species, Carson remarks, "I am sure no amount of drill would have implanted the names so firmly as just going through the woods in the spirit of two friends on an expedition of exciting discovery" (p. 26). Such a reflection echoes Carson's own natural history exploits around Springdale with her mother and her dog Pal.

The heart of the essay communicates a profound sensitivity to the child as a person to be respected. In this, Carson shows herself to be a child-centered pedagogue in the tradition of Rudolf Steiner, Maria Montessori, or John Dewey. For Carson, this was not the result of formal educational training, but an extension of her sensitivity, as an artist and naturalist, to the experience of another being. Bridging the usual divide between the child and adult world, Carson (1956) writes:

> We have let Roger share our enjoyment of things people ordinarily deny children because they are inconvenient, interfering with bedtime, or involving wet clothing that has to be changed or mud that has to be cleaned off the rug. We have let him join us in the dark living room before the big picture window to watch the full moon riding lower and lower toward the far shore of the bay, setting all the water ablaze with silver flames and finding a thousand diamonds in the rocks on the shore as the light strikes the flakes of mica embedded in them. I think we have felt that the memory of such a scene, photographed year after year by his child's mind, would mean more to him in manhood than the sleep he was losing. He told me it would, in his own way, when we had a full moon the night after his arrival last summer. He sat quietly on my lap for some time, watching the moon and the water and all the night sky, and then he whispered, "I'm glad we comed" [*sic*]. (pp. 26, 46)

Not only does the prose here reflect a respectful attitude toward children, but it flickers with the aesthetic beauty of "silver flames." Just as she approached nature with amazement as a child and felt compelled to write about it, the mature writer makes the natural world shimmer with the imminent presence of some miracle.

After focusing on her relationship with Roger for the first half of the essay, in the second half, Carson begins to generalize about the nature of experience and learning. Although these general insights about learning are the most frequently quoted passages from *The Sense of Wonder*, it is worth remembering that they were nurtured in a relationship with Roger at Carson's cottage by the sea. In other words, her profound philosophy of environmental learning, which resonates with many diverse people today, originated in relationship with a specific place and a specific child. One of the lessons of the essay, therefore, is that environmental learning depends first of all on establishing and nurturing such relationships.

The following three paragraphs are the most famous passages from *The Sense of Wonder*. They are worth quoting at length because of their continued relevance and because of how they present a challenge to environmental learning programs for children that may not measure up to Carson's vision:

> A child's world is fresh and new and beautiful, full of wonder and excitement. It is our misfortune that for most of us that clear-eyed vision, that true instinct for what is beautiful and awe-inspiring, is dimmed and even lost before we reach adulthood. If I had influence with the good fairy who is supposed to preside over the christening of all children I should ask that her gift to each child in the world be a sense of wonder so indestructible that it would last throughout life, as an unfailing antidote against the boredom and disenchantments of later years, the sterile preoccupation with things that are artificial, the alienation from the sources of our strength.
>
> If a child is to keep alive his inborn sense of wonder without any such gift from the fairies, he needs the companionship of at least one adult who can share it, rediscovering with him the joy, excitement and mystery of the world we live in. Parents often have a sense of inadequacy when confronted on the one hand with the eager, sensitive mind of a child and on the other with a world of complex physical nature, inhabited by a life so various and unfamiliar that it seems hopeless to reduce it to order and knowledge. In a mood of self-defeat, they exclaim, "How can I possibly teach my child about nature – why, I don't even know one bird from another."
>
> I sincerely believe that for the child, and for the parent seeking to guide him, it is not half so important to know as to feel. If facts are the seeds that later produce knowledge and wisdom, then the emotions and the impressions of the senses are the fertile soil in which the seeds must grow. The years of early childhood are the time to prepare the soil. Once the emotions have been aroused – a sense of the beautiful, the excitement of the new and the unknown, a feeling of sympathy, pity, admiration or love – then we wish for knowledge about the object of our emotional response. Once found, it has lasting meaning. It is more important to pave the way for the child to want to know than to put him on a diet of facts he is not ready to assimilate. (p. 46)

Preserving "one's instinct for what is beautiful and awe-inspiring" is Carson's primary pedagogical concern. The urgency of this concern is made more poignant in the first paragraph by her modernist acknowledgment of widespread adult boredom, disenchantment, and sterile preoccupation with what alienates us. She also claims that a dimmed adulthood can be avoided by keeping alive our sense of wonder. Carson's comments on adult life are instructive to educators whose curricula and programs focus only on children and youth and rarely recognize, at least publically, the reality of adult challenges and the impact that adult affect can have on young

learners. The sense of wonder, she claims, is something that must be kept alive in children. In order for that to happen, she implies, adults must also keep it alive in themselves as an "antidote" to what robs us of the sources of our strength. Carson's vision here is for lifelong learning though lifelong immersion in, and lifelong appreciation of, nature's wonders.

The second two paragraphs rephrase, highlight, and refine some of the themes illustrated earlier in her anecdotes about Roger. First, she reasserts the importance of adult guides: "If a child is to keep alive his inborn sense of wonder. . .he needs the companionship of at least one adult who can share it, rediscovering with him the joy, excitement and mystery of the world we live in." Second, she stresses the primacy of the emotions over the intellect alone: "it is not half so important to know as to feel. If facts are the seeds that later produce knowledge and wisdom, then the emotions and the impressions of the senses are the fertile soil in which the seeds must grow." As a creative writer tuned to the aesthetics of experience, Carson reveals herself as an early champion of "affective experience" in environmental learning. Here it is helpful to remember that Carson's own education, steeped as it was in the nature study movement and in literature, was saturated with affect and creative expression. She knew from her own experience of learning that "it is more important to pave the way for the child to want to know than to put him on a diet of facts he is not ready to assimilate" (p. 46).

For Carson, facts, knowledge, and, most importantly, the desire to learn are nurtured through experiences of adventure, discovery, and curiosity, rather than from some predetermined educational curricula. The remainder of the essay, however, provides adults with specific guidance on how to help children wonder. Her message is simple: enliven the senses and focus on the living things found in one's home environment, whether that environment be rural or urban: "Exploring nature with your child is largely a matter of becoming receptive to what lies all around you. It is learning again to use your eyes, ears, nostrils and finger tips, opening up the disused channels of sensory impression" (p. 47). For her mostly female readers in mid-twentieth century America, Carson provides vivid, everyday examples for awakening sensory perception for both adults and children. Recreating the sense of wonder through her prose, she reflects on a multisensory experience stargazing with an adult friend:

> It was a clear night without a moon. With a friend, I went out on a flat headland that is almost a tiny island, being all but surrounded by the waters of the bay. There the horizons are remote and distant rims on the edge of space. We lay and looked up at the sky and the millions of stars that blazed in darkness. The night was so still that we could hear the buoy on the ledges out beyond the mouth of the bay. Once or twice a word spoken by someone on the far shore was carried across on the clear air. A few lights burned in cottages. Otherwise there was no reminder of other human life; my companion and I were alone with the stars. I have never seen them more beautiful: the misty river of the Milky Way flowing across the sky, the patterns of the constellations standing out bright and clear, a blazing planet low on the horizon. Once or twice a meteor burned its way into the earth's atmosphere. (p. 47)

Other examples include Roger honing his sense of smell for the wood smoke and sea air that surround their experience at Carson's cottage and listening with her nephew as "the sound of the insect orchestra swells and throbs night after night" (p. 47).

Near the end of her essay, she also shares for her readers her enjoyment, as a scientist and naturalist, of using simple technologies, such as binoculars or a magnifying glass, to enhance outdoor experience. Carson herself made frequent use of a microscope at her cottage, often carrying home specimens from her beach for closer examination. But again, her emphasis in this essay is not primarily taxonomical or even descriptive, but rather to use the simplest equipment of nature study to deepen the experience of wonder. In a passage evocative of the theme of mystery that opens the essay, she suggests sitting together with a child, binoculars trained on the moon to observe the wonder of night migration:

> Seat yourself comfortably and focus your glass on the moon. You must learn patience, for unless you are on a well-traveled highway of migration you may have to wait many minutes before you are rewarded. In the waiting periods you can study the topography of the moon, for even a glass of moderate power reveals enough detail to fascinate a space-conscious child. But sooner or later you should begin to see the birds, lonely travelers in space glimpsed as they pass from darkness into darkness. (p. 47)

Finally, after providing adults with a host of ideas for easily accessible and aesthetically rich nature excursions with children, Carson concludes *The Sense of Wonder* with a memory of her friend and mentor Otto Pettersson. When he knew that he had little time left on earth, the 93-year-old Swedish oceanographer revealed, "what will sustain me in my last moments is an infinite curiosity as to what is to follow" (p. 47). Carson's faith in a sense of wonder was bolstered throughout her life with fellow scientists who shared it. And as she herself faced an early death from cancer and related ailments, Carson never lost the ability to be amazed and enlivened by her perception of the natural world. As if prefiguring her own decline and the eventual passing of everyone, even children, Carson departs *The Sense of Wonder* with an abiding love for a mysterious world in constant flux:

> Those who dwell, as scientists or laymen, among the beauties and mysteries of the earth are never alone or weary of life. Whatever the vexations or concerns of their personal lives, their thoughts can find paths that lead to inner contentment and to renewed excitement in living. Those who contemplate the beauty of the earth find reserves of strength that will endure as long as life lasts. There is symbolic as well as actual beauty in the migration of the birds, the ebb and flow of the tides, the folded bud ready for the spring. There is something infinitely healing in the repeated refrains of nature – the assurance that dawn comes after nights, and spring after winter. (p. 47)

Always the poet scientist, Carson's ecological aesthetic embraces the power of nature to teach, to heal, and to transform.

Conclusion: Wonder in Life and Death

Rachel Carson's sense of wonder endured to the end of her too short life. Throughout the writing of *Silent Spring* and especially in the aftermath of the sensation it caused, Carson struggled with cancer, surgeries, and the debilitating effects of multiple

illnesses. The peak of her literary success in 1962 corresponded with suffering and physical decline that would lead to an early death in 1964 at the age of 56.

During her final 2 years, with her limited energy for work, she had more requests from publishers for writing projects than she could handle. But there was one project that she consistently voiced her commitment to complete. She called it "the Wonder book." Contracted with Harper and Row, this was to be an expansion of the 1956 essay, "Help Your Child to Wonder." When her illness worsened in 1963, she wrote in a letter to her close friend, Dorothy Freeman:

> Oh, I don't deny there are periods of depression and of dark thoughts. There is still so much I want to do, and it is hard to accept that in all probability, I must leave most of it undone. And just when I have attained the power to achieve so much I feel is important! Strange, isn't it? And there are times when I get so tired of the pain and especially the crippling that if it were not for those I love most, I'd want it to end soon. But I seldom feel that way.
>
> I want very much to do the Wonder book. That would be Heaven to achieve. (Freeman, 1995, p. 490)

In what she knew would be her final project, Carson made the very conscious decision to focus her energies on what she thought was most important: keeping alive the sense of wonder that had animated her passion for the natural world and her gift as a writer. At the very end of her life, with whatever power she had left, she wanted to return to this theme as a final act of service to all people, especially the children she knew would inherit a very uncertain environmental future.

The uncertainty of life, and the certainty of death, is part of what makes the sense of wonder such a universal experience. Wonder is the natural human response to the mysterious, the unknown, and the miraculous – the unfinished business of the universe. Unfortunately, Rachel Carson died before she was able to expand "Help Your Child to Wonder" into a longer book on the theme. But her wonder book – *The Sense of Wonder* – a reprint of the original essay with new photographs by Charles Pratt, was published in 1965. It was dedicated to her grandnephew, Roger Christy (Lear, 2009, p. 483).

The Sense of Wonder is among Carson's shorter works. Originally published in a popular magazine as a guide for women, it was not at first intended as the ecological manifesto it has become. But in this brief masterpiece, we can see the influence of Carson's own ecological education: the development of an "indestructible" sense of wonder. Like Carson, the nature study movement advocated not simply for a scientific stance toward children's learning, but for one steeped in the spirit of discovery, where the whole child – emotions, spirit, body, and mind – would be drawn into a relationship of intimacy with the natural world. The movement steered adults toward experiences, activities, and resources and encouraged mentors to become the kind of guide that Maria Carson was to Rachel and that Rachel would become with Roger. Rachel's early exposure to literature in magazines like *St. Nicholas* motivated the young creative writer to publish at an early age and to develop a lifelong identity as a writer. Over time Carson would hone her skills as a naturalist and her craft as a writer, eventually producing four best sellers. The last of these, *Silent Spring*, significantly changed the political environmental landscape. But

it was her sense of wonder, and her ability to express it with poetic prose, that positioned Carson to catalyze the new environmentalism.

At a time when children are often over-scheduled with educational activities and overloaded with media, Rachel Carson's early life, and her essay *The Sense of Wonder*, can serve educators as a touchstone for educative experiences in nature. The lessons for today are deceptively simple. One: children thrive when they can share the joy of discovery with adults who feel and express that joy and who do not rush to put children on a "diet of facts" they are not ready to assimilate. This precept presupposes something that cannot be assumed: that is, a joyful adult who gives children room to roam and who is eager to share the experience. Two: children whose emotional and aesthetic faculties have been sparked in relationship with nature should be given a chance to express that relationship in some creative form. Again, this is not so simple to achieve, especially in formal educational environments where individualized learning is often more rhetoric than reality. Maria Carson, however, regularly provided Rachel with opportunities to explore both of these powerful avenues of learning. All of us are their beneficiaries.

In the age of digital media, direct aesthetic experience with the natural world may seem like a simplistic, or even unrealistic, educational touchstone. Many educators today are encouraged to engage children with the wonders of technology rather than the wonders of nature. It is also true that the imagination and aesthetic sensibility even of today's preschool learners is often mediated by interactions with computers rather than oceans or forests. For many children, as well as adults, computerized attention is the dominant mode of experience in the development of their social and ecological awareness (whether this is an evolution or devolution is the subject of another essay). Gone is the day when a child waited impatiently for the new issue of *St. Nicholas* to appear in the mailbox. Steeped in the technological milieu and bounded by urban environments and regulated green spaces, children may seem to lack access to the everyday wonders of field, forest, and ocean that surrounded Maria, Rachel, and Roger.

In "Help Your Child to Wonder," Carson reminds parents and other adult mentors of some fundamental experiences still available to everyone: the sensory experience of sunrise, dusk, and dark; the revelations of the limitless night sky; the near or faraway voice of one particular bird waiting to be found and named; the power of a thunderstorm and other weather events as they move through and transform a place; the mystery of seasonal migration just overhead or in the distant horizon; the intricate beauty of a snowflake, or a grain of sand, or the wing of a housefly under a magnifying glass; the odors of the seasonal change as organic matter photosynthesizes or decomposes; and the music of insects on a summer night. Of the thrill of these everyday discoveries, Carson (1956) writes, "the game is to listen, not so much to the full orchestra, as to the separate instruments, and to try to locate the players" (p. 47).

Finally, whatever one's opportunities are for direct experience with flora, fauna, and the always changing physical environment, Carson reminds educators of our most potent resource with respect to the development of children's sense of wonder:

> If a child is to keep alive his inborn sense of wonder. . .he needs the companionship of at least one adult who can share it, rediscovering with him the joy, excitement and mystery of the world we live in. . . .I sincerely believe that for the child, and for the [adult] seeking to guide him, it is not half so important to know as to feel. (p. 46)

However we imagine best guiding children, Carson insists that an indispensable part of the program is preserving and cultivating our own sense of wonder. This, the great naturalist and writer contends, is the most precious and educative gift we can offer those who will follow.

changes of the Anthropocene epoch. Our approach foregrounds the singularity of children's aesthetic experiences as relational-qualitative "intensities" that alter the fabric of nature as an extensive continuum held in common. We therefore argue that every moment in the life of a child is an uncommon and unrepeatable occasion through which the common world of nature is felt, perceived, and experienced differently. In the second part of the chapter, we use this eco-aesthetic framework to analyze a series of photographs taken by children as part of the Climate Change and Me project, which has mapped children and young people's affective responses to climate change over a period of 3 years in New South Wales, Australia. Rather than working with images as representations or analogic signifiers for children's experience, we analyze how each photograph co-implicates children's bodies and environments through affective vectors of feeling or "prehensions." In doing so, we actively work to reframe aesthetic notions of image, sensibility, perception, and causality in relational terms while also acknowledging the individuation of childhood experiences as "creaturely becomings" that produce new potentials for environmental thought and behavior.

Introduction

> We must think of Nature without any residual anthropocentrism: that is to say, without exempting ourselves from it, and also without remaking it in or own image. (Shaviro, 2015, p. 216)

In addressing the need for a more robust engagement with aesthetics in posthumanist studies of childhood and nature, this chapter aims to make some tentative steps toward an ecological aesthetics of childhood that is grounded in Whitehead's (1978) speculative philosophy. By integrating Whitehead's philosophy with posthumanist approaches to the life sciences (Frost, 2016) and media studies (Hansen, 2015), we work to establish the contours of an ecological aesthetics that is both attuned and responsive to the rapidly changing material conditions of contemporary life. In doing so, the chapter takes an alternative theoretical approach from much of the "common worlds" scholarship that has emerged in recent studies of childhood and nature (see, for instance, Malone, 2015; Rautio, 2014; Taylor, 2013; Taylor & Pacini-Ketchabaw, 2015).

In the first part of the chapter, we begin by making the case for a new aesthetics of childhood that is responsive to the accelerating social, technological, and environmental changes of the Anthropocene epoch. We consider the recent turn toward "common worlds pedagogies" in environmental education and childhood studies while also highlighting the need for a more intensive and affirmative engagement with non-anthropocentric and nonrepresentational aesthetic theories within these

fields. Taking Whitehead's aesthetic order of nature as our starting point, we begin to develop an ecological aesthetics that is orientated toward the "uncommon" dimensions of children's experience in and of the Anthropocene epoch. This allows us to foreground the singularity of children's aesthetic experiences as relational-qualitative "intensities" that alter the fabric of nature as an extensive, vibratory continuum held in common. In doing so, we actively work to reframe aesthetic notions of image, sensibility, perception, and causality in relational terms while also acknowledging the individuation of childhood experiences as "creaturely becomings" that produce new potentials for environmental thought and behavior.

In the second part of the chapter, we develop this eco-aesthetic approach to childhoodnature scholarship further by analyzing a series of photographs taken by children as part of the Climate Change and Me project. This project has mapped children and young people's affective responses to climate change over a period of 3 years in Northern New South Wales, Australia. Elsewhere we have analyzed the political and ethical implications of children's embodied participation in the project (Cutter-Mackenzie & Rousell, in press-a), the emergence of speculative fiction as research method (Rousell, Cutter-Mackenzie, & Foster, 2017), as well as the project's methodological innovations and insights (Cutter-Mackenzie & Rousell, in press-b). Here we focus specifically on the speculative analysis of photographic images created by children over the course of the project. Drawing on Whitehead's (1978) theory of prehension in conversation with biocultural insights from the life sciences (Frost, 2016) and media studies (Hansen, 2015), we analyze the sensuous, causal, and virtual elements of children's photographs as occasions of felt relation and environmental encounter. Rather than working with images as representations or analogic signifiers for children's experience, we explore how each photograph co-implicates children's bodies and environments through affective vectors of feeling or what Whitehead (1978) calls "prehensions." This leads us to propose an ecological aesthetics of childhood that affirms both the "common world" of nature as an extensive continuum and the "uncommon worlds" through which children make aesthetic contact with other creatures, environments, and modes of existence. The chapter concludes by considering the pedagogical implications of children's photographic practices, focusing on Whitehead's (1967a) concept of the "art of life" as a guiding proposition for aesthetic cultivation and bodily engagement.

A New Aesthetics of Childhood

Recently there has been a turn toward more relational, collective, and distributed conceptions of children and childhood in the social sciences (Lee, 2013), the environmental humanities (Taylor, 2013), and environmental education (Malone, 2015). In many cases this turn has emerged in response to posthumanist concerns regarding the onset of the Anthropocene epoch, a time in which the very nature of childhood is being transformed by anthropogenic climate change, species extinction, resource contamination, ubiquitous computation, and biotechnological mechanisms

of social control (Lee and Motzkau, 2013). Scholars working the intersections between the fields of childhood studies and environmental education have proposed that the onset of the Anthropocene calls for new conceptualizations of children and childhood (Malone, 2016; Somerville, 2017), along with new research methodologies and techniques that are attuned to the complex dynamics of children's social and ecological worlds (Cutter-Mackenzie & Rousell, 2014). As the relentless acceleration of social, technological, and environmental change continues to erode the humanist foundations of dualistic Western thought, we are now witnessing a proliferation of biosocial (Lee, 2013; Youdell, 2017), posthumanist (Lenz-Taguchi, 2010; Malone, 2016; Rautio, 2014), Indigenous (Cajete & Pueblo, 2010), socioecological (Payne, 2010), and post-developmental (Blaise, 2014) framings of childhood. While these approaches tend to share a commitment to reconceptualizing childhood within more-than-human environments, assemblages, societies, and worlds, they have tended to focus predominantly on the ethical, political, and pedagogical implications of such radically inclusive ecologies of childhood. As such, the aesthetic, imaginative, and experiential qualities of children's environmental sensibilities have often been backgrounded by "ontological" shifts from individuals to collectives, binaries to hybrids, and constructivisms to materialisms. In many cases, this has involved a reinvigoration of the concept of the political collective or "commons" as an assemblage of human and nonhuman constituents that compose the messy and entangled worlds of children and childhood (Taylor, 2013). This backgrounding of aesthetics has been particularly evident in the recent flurry of scholarship under the rubric of "common worlds pedagogies," many of which have drawn extensively on the work of Latour (2004) and Haraway (2008) to account for the common worlds that children inhabit with myriad other agencies and forms of life (Taylor, 2013; Taylor & Pacini-Ketchabaw, 2015).

While we acknowledge the rigor and timely significance of the work currently being undertaken to reinvigorate a more-than-human commons, in this chapter we argue that such turns call for a new aesthetics of childhood as much as they require a new politics and ethics of relationality. It has been widely acknowledged that environmental education has not adequately engaged with the aesthetic dimensions of experience (Eernstman et al. 2012; Ingram, 2012; Inwood & Taylor, 2012; Stables, 2001), while an Internet search at the time of writing revealed no substantive treatment of aesthetics within published literature associated with "common worlds pedagogies" and related research. The reason for this eschewal of aesthetics is not entirely clear. One possible reason could be the distancing of posthumanist studies of childhood from Enlightenment and Romantic aesthetic traditions which have perpetuated purist, progressive, and sublime images of childhood and nature as idealized forms (Taylor, 2013, p. 13). We concur that such a distancing is both timely and necessary, as the humanizing influences of Romantic idealism are often the default philosophical touchstones for contemporary environmentalist movements (Morton, 2007), as well as the "child in nature" movements associated with forest schools and related environmental education initiatives (Malone, 2016). In resisting the dominant tropes of such humanistic ideals in environmental education and childhood studies, critical posthumanist studies have shown how representations of the "natural child" have been used to perpetuate political regimes of anthropocentrism and

human exceptionalism, effectively legitimizing the very social and environmental injustices which they seek to avoid (Malone, 2015; Taylor, 2013). The dominant cultural logic of Kantian aesthetics has also used ideal qualities (such as beauty) and capacities (such as art, language, and technology) as criteria for placing humans above other creatures, consequently positioning the external environment or "nature" as an objective correlate or backdrop for human progress, cognition, and knowledge (Morton, 2013; Shaviro, 2014).

As Morton's (2007) meticulous deconstruction of the lingering dominance of Romanticism has shown, the dismantling of such idealist aesthetic regimes has been a core project of the arts for over two centuries. While Kantian aesthetics continues to exert a stultifying influence on studies of childhood, education, and environment (Prout, 2005; Taylor, 2013), in the art world, these idealisms have long since been replaced by the austerities of social realism, the machinic abstractions of modernism, the anti-humanist deconstructions of postmodernism, and the relational assemblages and spatiotemporal mobilities of much contemporary art (Groys, 2008). Equivalently, contemporary works in art theory, cultural studies, and media studies have been largely influenced by Deleuzian, Whiteheadian, and new materialist aesthetics of immanence, sensation, relationality, affectivity, animality, and becoming (see, for instance, Hansen, 2015; Massumi, 2011; Shaviro, 2009). As Kennedy (2000, p. 30) notes, the materialist turn in aesthetics means that beauty is no longer "consilient with goodness, the romantic, or transcendent notions, but to a feeling of duration, movement, and continual process." Rather than a disavowal of outmoded idealist aesthetics, posthumanist childhood studies could benefit from a more affirmative engagement with the relational and materialist turns in aesthetics in art, media, design, architecture, technology, and film studies over the last three decades. Haraway's (2016) recent work could provide a catalyst in this regard, as she advocates the development of a "new new synthesis" between the environmental arts, humanities, and sciences which would tie "together human and nonhuman ecologies, evolution, development, history, affects, performances, technologies, and more" (p. 63).

Haraway's new synthesis of life sciences, environmental humanities, and relational arts shows the potential for a transdisciplinary ecological aesthetics to transform studies of childhood in ways that are responsive to the Anthropocene's most pressing challenges. By drawing on the vigorous development of posthumanist aesthetic theories in such diverse enterprises as philosophy, art, cultural studies, and the biological sciences, a new aesthetics of childhood becomes both possible and necessary in reconfiguring our understandings of children's learning experiences and environments. This is not to argue that posthumanist studies of childhoodnature need to become *more* aestheticized or artistic (though this may also be the case) but rather that the aesthetic dimension of such work is inseparable from the political and ethical issues that appear to necessitate an "ontological" reappraisal of childhood in relation to nature. We therefore argue that the posthumanist and post-anthropocentric turns toward relationality, collectivity, biosociality, affect, process, emergence, becoming, entanglement, and "common worlds" need to be understood as *aesthetic movements*, prior to their instantiation as movements in ethics, politics, or pedagogical practice.

What these posthumanist turns both instantiate and require, we suggest, is an ecological aesthetics that reconfigures how children's bodies, environments, spaces, places, times, and relations are composed, felt, sensed, and experienced. Such a new aesthetics could be located in the *creatureliness* of children's felt relations and bodily capacities while remaining attuned to incipient ethical and political ecologies as they emerge with/in environments that simultaneously surround, permeate, sustain, constrain, and animate children's everyday lives (Frost, 2016).

The Creatures That Become

In developing an alternative approach to posthumanist studies of childhood in this chapter, we negotiate a (re)turn to Alfred North Whitehead's speculative philosophy as an ecological aesthetics of becoming and felt relationality. Whitehead's philosophy has undergone a renewal in recent posthumanist scholarship, as the relational system of thought he developed nearly a century ago offers a visionary alternative to dualistic and anthropocentric philosophies that have dominated Western philosophy for millennia (Shaviro, 2014; Stengers, 2011). In Whitehead's (1978) speculative philosophy, every actual occasion of experience is understood as a "creature of becoming" that sustains its own existence through affective encounters with other creatures. "The actual occasions are the creatures which become," Whitehead (p. 35) writes, "and they constitute a continuously extensive world." In other words, everything that exists is a *creature* because all actual entities are, more or less, capable of *experience*. All things are creatures of experience. The differences between entities are therefore considered aesthetic differences of degrees, qualities, speeds, manners, and intensities of experience, rather than ontological differences in kind. A stone, for instance, may have a relatively dense, slow, and contracted quality of experience compared to the experience of a child. A child will likely have a more intense experience than the stone, with greater degrees and capacities for sensitivity, contrast, and transformation over a shorter duration. This means that the difference between the experience of a stone and the experience of a child is aesthetic, rather than ontological (Robinson, 2009). In other words, creaturely experiences are distinguished by differences in *becoming* (as the aesthetic mode or manner of existence) rather than differences in *being* (as the ontological essence or substance of existence).

For Whitehead, this differential quality of experience as becoming extends from the cosmological to the quantum, making his philosophy a form of "pan-experientialism" compatible with process thinkers such as Bergson and Deleuze. As Robinson (2009, p. 22) writes, each of these three thinkers foregrounds "the implicit aesthetic genesis, order and creative organisation of experience, with experience here understood as enlarged and not simply equivalent to human experience." We also note the compatibility of Whitehead's philosophy of organism with recent insights from the life sciences, which have revealed the extent to which genetic, cellular, and bodily activities are dynamically modulated by both immediate and transgenerational changes in social and ecological conditions (Frost, 2016). As

Protevi (2013) argues, contemporary advances in the biological, computational, and cognitive sciences provide empirical support for the process philosophies of Whitehead, Bergson, Simondon, and Deleuze while also demanding a posthumanist aesthetics that acknowledges the environmental porosity, plasticity, and permeability of sensing organisms and the environments they coinhabit with other creatures (see also Alaimo, 2010). We therefore take the lead from Frost (2016) in conceiving of children as "biocultural creatures" and the environments they populate as "biocultural habitats," to the extent that the term "biocultural" "encapsulates the mutual constitution of body and environment, of biology and habitat" (p. 4). Within this assemblage of biocultural creatures and habitats as the mutually conditioning elements of life, the element of "culture" is understood as a process of cultivation which provides a medium and milieu through which bodies and environments emerge, grow, develop, interact, and eventually perish.

We can now return to the example of the stone and the child in order to better understand what Whitehead means by the "creatures that become." The child picks up the stone on the riverbank, feeling its weight in the hand, the pock-marked texture of its surface, the way it catches the light as she turns it over. Both child and stone are *creatures*: they are accretions of all the relations they have experienced since they came into existence, including the auto-affective experiences of their own bodies, spaces, and times. They are distinct creaturely entities, each with their own "routes of inheritance" (Whitehead, 1978), and yet they inhabit, if only for a moment, a shared "biocultural habitat" (Frost, 2016). And in this imagined moment of encounter, as the child handles the stone and then skims it across the surface of the water, an event occurs that is not of the child or the stone but of the *aesthetic relation between child and stone*. This felt relation between creatures of becoming is what Whitehead refers to as "prehension." Prehension is the way that creatures sense, perceive, and incorporate the experiences of other creatures through the aesthetic *feeling* and *intensity* of relation. This also means that creatures become *what they are* by prehending other creatures, including themselves (Shaviro, 2009). We can attempt to encapsulate this in a rather simple formulation: *creatures are what they feel.*

Common and Uncommon Worlds

In order to make sense of Whitehead's "common world" pan-experientialism, we need to expand our understanding of aesthetic experience to encompass what he refers to as the "aesthetic order" (Whitehead, 1985). Indeed, we find within Whitehead's radically non-anthropocentric philosophy a system in which all orders of existence (including the biological, the social, the conceptual, the epistemic, the semiotic, the political, the ethical, the spiritual, the actual, and the virtual) are circumscribed within the aesthetic order of *nature.* As Jones (1998, p. 20) notes, this conception of aesthetic order is coextensive with the weight of causal complexity as it emerges through natural processes and accretes over time. For Whitehead (1967b, p. 53), the aesthetic order refers to a common world of nature as it is collectively experienced with each passing moment, along with all of the historical

data, virtual potentialities, and entangled sensibilities that each creature inherits from previous events. "The actual elements perceived by our senses are in themselves the elements of a common world," Whitehead (1967a, p. 88) writes. Every creature that exists is always already immersed "within a world of colours, sounds, and other sense-objects, related in space and time to enduring objects such as stones, trees, and human bodies. We seem to be ourselves elements of this world in the same sense as are the other things which we perceive" (p. 89).

The way that creatures become sensible elements of each other's worlds is crucial to understanding the distinction between common and uncommon worlds that we wish to unfold in this chapter. Whitehead's formulation of a common world is the vibratory continuum of nature that extends from subatomic to cosmological proportions and timescales. This common world is extensive, continuous, and objective to the extent that it includes every creature and occasion of experience that actually exists. This world is common because it includes all possible elements, actualities, and potentialities of experience. And yet these elements, actualities, and potentialities of experience are also changing, with every moment, in ways that are not reducible to anything common. These are what Whitehead calls the "actual worlds" of the creatures who become, what we might call, the biocultural habitats and intensive milieus of creatures and the societies they populate (Frost, 2016). While these uncommon worlds are not isolated from one another, we would not consider them "common" because they are always being felt differently by the particular creatures who actually experience them. Hence every creature (from a child, to a stick insect, to a mushroom, to an asteroid) feels its actual world differently. This gives every creature its own relational intensity as an individual, with its own *uncommon* world that is determined by *how* creatures prehend their interpenetrating worlds in different ways. Indeed, this privacy of subjective experience is what makes the assemblage of a heterogeneous society, ecology, or collective of creatures possible.

Based on this differentiation between common and uncommon worlds, we can tease out some initial propositions for reconceptualizing children and childhood. Firstly, as biocultural creatures, children never experience the same actual world twice because each experience constitutes a novel synthesis of relations from a series of disjunctive elements (molecules, bodies, societies, places, times, materials, concepts, feelings, perceptions, discourses). This fits with Taylor's (2013) assertion, drawn from her work with Arrernte peoples of Central Australia that "children *are* their worlds. It is the particularities and distinctive features of these worlds that makes children who they are." However, we suggest that the very distinctiveness of children's actual worlds is indicative of their *uncommonality* as individual creatures with their own private intensities of feeling and bodily capacities for aesthetic experience. Every moment in the life of a child is an uncommon and unrepeatable instance through which the common world of nature is felt, perceived, and experienced differently.

Second, and as Whitehead (1978, p. 35) makes clear, the common world of nature is not continuous in itself (or causa sui) but rather *becomes* continuous through the ongoing proliferation of uncommon worlds in all their teeming intensities and

entanglements of creaturely relations. In other words, the common world of nature relies on uncommon occasions of experience to continue its extension. This means that a child's process of becoming (or what Haraway calls "worlding") is fundamentally creative: the child feels the actual world in a way that is *qualitatively* different from any other occasion and, in doing so, adds her experience to the extensive continuum of nature. In this way, the extensive continuum of nature both *produces and is produced* by the intensive qualities of experience that constitute children as "creatures that become." Put another way, everything that a child experiences contributes to the continuity of nature while at the same time irrevocably changing what nature can be.

The Whir of Worldly Sensibility

In a common world in which everything both senses and is sensed through differential qualities of aesthetic experience, what comes to matter is the distribution and processing of aesthetic sensibility within more-than-human political ecologies and collectives. Whitehead describes how "we find ourselves in a buzzing world, amid a democracy of fellow creatures" (1978, p. 50). This buzzing world of creaturely activity "expresses the relation of causal interaction between entities and their actual worlds" (Jones, 1998, p. 20). As we described in the section above, the causal interactions between creatures and their habitats constitute the aesthetic order of nature as an extensive, vibratory continuum or common world. The idea that the very consistency, order, and causal infrastructure of nature is altered and redistributed by the aesthetic experiences of creatures (such as children) offers a basis for a new ecological aesthetics of childhood. It means that children literally reconfigure the virtual structures of nature through intensive processes of individuation, creating new potentials for life through the dynamic relations between "a milieu of interiority and a milieu of exteriority" (Simondon, 2017, p. 223). Whitehead (1978) describes this process of individuation as "constructive functioning," whereby the trafficking between intensive and extensive milieus, between bodies and environments, involves a creative synthesis of differential elements that produces the singular (uncommon) world of a living organism or creature (see also Deleuze, 1994; Protevi, 2013).

In taking this proposition a step further, we suggest that the molecular, metabolic, semiotic, perceptual, conceptual, and technological trafficking between children's bodies and their biocultural habitats is a function of what Hansen (2015, p. 3) calls "the distribution of worldly sensibility." For Hansen, worldly sensibility refers to the causal infrastructure of the vibratory continuum that operates above, around, and below the thresholds of human sense perception and consciousness (p. 2). The cells of our bodies, for instance, are constantly responding to the surrounding environment in ways that we are only vaguely aware of at the conscious level, if at all. These processes operate through what Whitehead (1978, 1929) calls the mode of "causal efficacy," which he contrasts with the perceptual mode of "presentational immediacy." Where the mode of presentational immediacy involves the sensuous perception

of vivid values as experienced through qualia such as colors, sounds, textures, tastes, and smells, causal efficacy is a function of the underlying causal infrastructure of nature as a vibratory continuum (Hansen, 2015). Presentational immediacy gives us access to the sensuous qualities of our external environments to reveal clearly recognizable objects of perception, but it lacks temporal duration, thickness, and subtlety. In this sense, presentational immediacy is only the province of sufficiently complex creatures, such as humans and other animals, who are capable of experiencing "the clear and distinct representation of sensations in the mind of a conscious, perceiving subject" (Shaviro, 2014, p. 23). Although Whitehead (1985, p. 23) describes such perception as "vivid, precise, and barren," it is through this representational mode of perception that "the world discloses itself to be a community of actual things, which are actual in the same sense as we are" (p. 21).

Causal efficacy, on the other hand, refers to the "vague (nonrepresentational) way that entities affect and are affected by one another through a process of vector transmission" (Shaviro, 2014, p. 23). It is thus more accurately described as a mode of *sensibility* than a mode of perception (Hansen, 2015). Causal efficacy opens the range and distribution of sensibility to the entire aesthetic order of nature and places all things that exist on the same ontological footing. For human creatures, causal efficacy means that even our most clear and distinct perceptions are mediated through complex causal processes that lie above, below, or beyond our consciousness, including those processes associated with our own bodily capacities. "We see the picture, and we see it with our eyes; we touch the wood, and we touch it with our hands; we smell the rose, and we smell it with our nose; we hear the bell, and we hear it with our ears; we taste the sugar, and we taste it with our palate" (Whitehead, 1985, p. 50). In these examples, causal efficacy is associated with what Whitehead (1978, p. 81) calls "the withness of the body," a position which implicates the body and its capacities within the elemental distribution of *worldly sensibility* across the whole of nature. In the mode of causal efficacy, "the inflow into ourselves of feelings from enveloping nature overwhelm us . . . the presentations of sense fade away, and we are left with the vague feeling of influences from vague things around us" (Whitehead, 1978, p. 176). As Hansen (2015, p. 49, italics in original) explains, the vague, haunting sensations of causal efficacy are indexed to "the *material causal linkages* that exist and have force outside of the realm of impressions, ideas, and ideas of impressions – outside the domain of sense perception proper." Underneath the incessant whirring of cicadas on a summer afternoon is the imperceptible whir of worldly sensibility, a whole buzzing world of nature seething just below the threshold of conscious, sensory perception.

In bringing the vibratory continuum of nature into contact with the perceptual impressions and affective intensities of individual creatures, Whitehead's theory of prehension effectively fuses aesthetic experience with the material causal infrastructure of nature's spatiotemporal dynamisms (see also Protevi, 2013). As Manning and Massumi (2014) further note, both presentational immediacy and causal efficacy are present to varying degrees in human experience, and it becomes a matter of how these modes of perception and sensibility achieve various fusions, syntheses, and vicarious interchanges. In the following sections, we focus more specifically on how

children's photographs can embody these kinds of bioaesthetic fusions and syntheses, which bring together the subjective experiences of children with the vibratory continuum of worldly sensibility.

Pieces of the Earth

Over the last 3 years, the *Climate Change and Me* project has mapped children and young people's affective, creative, and theoretical responses to climate change through participatory ethnography and socially engaged art practices. This has involved working with 135 children and young people (aged 9–14) from across Northern NSW, Australia, as co-researchers who were directly involved in all phases of the research. The artworks, essays, videos, photographs, poems, and fictional works created through this research were assembled into a public touring exhibition called Past Now Future, which was viewed by over 8000 members of the public over an 8-week period. This material also provided the resources for a transdisciplinary climate change curriculum, which is currently being implemented in regional primary and secondary schools across Northern NSW (see www.climatechangeandme.com.au). Over the course of the project, photography emerged as a creative research method that opened up spaces for children and young people to think and act differently in relation to climate change. This process was set in motion through the project's emergent research design and child-framed methodology, which allowed us to work collaboratively with children and young people within a "co-research playspace" (Cutter-Mackenzie & Rousell, 2014; see also Cutter-Mackenzie & Rousell, in press-b). Initially this involved hosting research training workshops in local schools, where students were introduced to the concept of the Anthropocene epoch and learned to conduct ethnographic interviews and observation, take field notes, and use creative practices such as drawing, photography, and video as educational research methods. We also developed a customized and secure social media interface that enabled the young researchers to post and comment on each other's photographs, as well as initiate their own small projects, discussions, and games within a blogspace we called the "CC + Me Hangout."

We found that many of the co-researchers tended to gravitate toward the medium of photography, as we witnessed an inundation of over 4000 images uploaded to the project website in the 1st year of the project alone. As we progressed through the analytic stages of the project, we hosted a series of creative ThinkTank workshops where the children worked through the data en masse. This included a process of collectively curating the photographs down to a series of 200 images that the children felt expressed their experiences of climate change and of life in the Anthropocene more broadly. The children also wrote messages on the backs of the photographs at this time, with a combined function of interpreting the affective qualities of the images while also translating those feelings for a public audience. At this point we worked closely with the children to design and assemble a collaborative artwork for the touring exhibition which involved transferring the photographs onto plywood tiles coated in beeswax. This process effectively archived the images

Fig. 1 A photograph submitted by Grace (age 11) with the subtitle "The little worlds that exist around us"

in an encaustic wax medium that would preserve them for millennia while also transforming the image from a reproducible digital file into a unique work of art. As shown in Fig. 1, the wax transfer process altered the color, texture, and form of the image to achieve a ghostly rendering encased in the surface of the wax. These rematerializations of the children's photographs were then fitted with magnetic strips, allowing them to be mounted on the surface of a whiteboard and iteratively rearranged in the manner of a fluid montage. This work was entitled "Pieces of the Earth" and formed one of the three major works in the Past Now Future exhibition, along with a series of video installations and a book of the children's poetry, photographs, critical essays, and speculative fiction (see Rousell & Cutter-Mackenzie (ed.), Handbook Companion) (Fig. 2).

Theorizing the Image as Surface

In this section we analyze how different images were materialized in the Climate Change and Me project through children's aesthetic engagements with their changing environments. Rather than interpreting the images as representations of what children think or know about climate change, we follow the intensive transformations of images as immersive surfaces within which children are implicated as biocultural creatures. We understand the surface of the image to be a composition of creaturely prehensions, or what Whitehead calls "vectors of feeling," as well as an

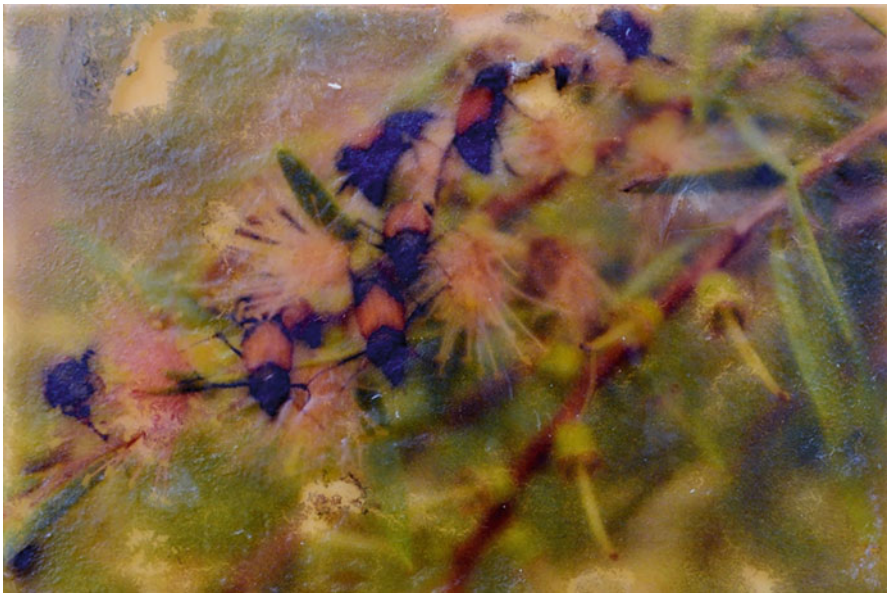

Fig. 2 Grace's wax transfer of the "little worlds" image using encaustic medium on plywood

interface that opens onto the vibratory continuum of nature. Our intention is to plumb the immersive depths of the image's surface, moving away from linguistic and optical frames of reference to embrace a tactile materiality that fuses the immediacy of aesthetic feeling with the vague penumbra of worldly sensibility. Through our focus on images as sites of aesthetic contact and felt relationality, our research essentially comes to involve "the production of surfaces, their multiplication and their consolidation" (Deleuze, 1990, p. 125). In this way, we see the surface of the image as a nexus between the uncommon worlds of children as biocultural creatures and the vibratory continuum of nature as a common world of material causality, relationality, sensibility, and extension.

Our analysis begins with a series of digital photographs taken by children, which we understand as prehensions of children's actual worlds as they exist (ed) in the places and times of the photographs. The first photograph was taken by an 11-year-old girl named Grace, who walked alone in the wet sclerophyll forest near her grandmother's house in a remote area of Northern NSW (Fig. 3). Moistened by a heavy rain that had fallen over previous weeks, the forest was teeming with fresh explosions of fungi, vegetation, and insect life as Grace collected a series of highly detailed and saturated images. The second photograph was taken by 12-year-old Kairo, who made her way to a remote coastal location in Northern NSW just before dawn (Fig. 4). Her images capture the Pacific Ocean's horizon in the liminal moments between night and day, such that the surfaces of water and sky become washed with color values too subtle and blended to name.

Fig. 3 Photograph taken by Grace (age 11) during a morning walk in wet sclerophyll forest

Each of these images emits a certain dark brilliance, a gradient of contrasts that results in a particular intensity of aesthetic feeling emanating from the surface of the photograph. In this first analytic pass over the images, we are aware of values of color, light, shadow, and texture resolving into recognizable forms on the surfaces of the photographs. The presentational immediacy of atmospheric qualities within a distributed environmental field resolves into clearly delineated spatial relationships: mushrooms growing on a branch and an ocean reflecting the sky. As Massumi and Manning (2014) note, there is a certain aesthetic enjoyment or "entertainment" that accompanies presentational immediacy prior to the resolution of the field's surface effects into forms and spatial relations. Entertaining the immediacy of the image also brings our attention to the contemporaneous nature of events that occur relationally, and yet independently, within the field of experience (Whitehead, 1927). There are interpenetrating values, such as color and moisture, which are shared between the ocean and the sky in Fig. 4, a resonance between surfaces. This is to entertain the surface effects of the relational field itself as an elemental *environment*, a mode of perception closer to the experiences of autistic people or of hallucinogenic states than to neurotypical consciousness.

Yet even before the surface resolves into recognizable forms and affordances (a mushroom you could pick, an ocean you could hear, smell, and dive into), our awareness of the image has been influenced by a more vague mode of sensibility associated with causal efficacy. The mode of causal efficacy reveals that there is much more occurring in these images, both perceptually and causally, than what can be seen within the frame of the photograph. In the first image, we can barely sense

Fig. 4 Photograph taken by Kairo (age 12) just before dawn at Angel Beach, NSW

Grace's damp foray into the rainforest and share in her increasing wonder as she photographs the wild variety of fungal constellations appearing at her feet. In the second image, we catch a vague, penumbral sense of Kairo knee-deep in the waters of Angel Beach at dawn, trying to steady the camera as she darkly contemplates rising sea levels and human failures. In each of these images, we see what the child sees and what the lens of her camera sees, at a particular moment in time and space that occurred 2 years ago at the time of writing. Attending to causal efficacy gives us a haunting sense of what lies beyond the perceptible objects within the frame of the image, the weight of multiple spaces and times that condition the image directly, aesthetically, materially, and causally.

The sensing body of the camera is crucial in this mediated configuration of child and environment, as it captures and renders the sensory data of the occasion in ways that no human can do. As Hansen (2015, p. 24) argues, such media technologies are able to "capture a wealth of data from worldly sensibility- including data about our own implication in it- and feed this data forward into a future or just-to-come moment of conscious perception." In other words, digital cameras give us access to nature itself in ways that conscious, human perception does not. We understand the extrahuman sensing capacity of the camera as a function of what Whitehead (1978) calls the "vector-character" of prehension. The camera renders the image as a conduit or channel for vectors of feeling that extend from one unique perspective on the universe to another: sunlight falling on the forest floor, the roiling ocean at dawn,

the wind-swept eyes of a child, and the ink-saturated pages of a book. All of these and more are events within an ecology of sensation that proliferates through an intricate meshwork of aesthetic prehensions. This sensory ecology is what makes it possible for you to the encounter these images and words as you flip the pages of this handbook. In this way, each image expresses a capacity to "channel the force of worldly sensibility" as the "pure potentiality" of the vibratory continuum of nature as the "total environment" (Hansen, 2015, p. 238). In prehending the image, we also grasp a vague sense of the whole of nature seething in the depths of its surface.

Through this speculative analysis of the image as a conduit for vectors of feeling and worldly sensibility, we find that it is no longer the human/nonhuman distinction that really matters, or maybe even that this distinction is no longer possible. The images themselves show nothing human, and yet the body of the child is *felt* as a living creature, invisible and yet implicated in the surface of the image. The sensible appearance of the image and the material conditions of its appearance are inseparable, such that the surface enables sensing bodies to make aesthetic contact with one another *at a distance* (Shaviro, 2014, p. 148). This fusion of presentational immediacy with causal efficacy opens the image beyond any representational or discursive function. What we are dealing with instead are the differential relations between the forces of aesthetic appearance and material causality, between the resolution of perceptual elements within a sensory ecology and the material conditions through which that whole sensory ecology operates. Child-environment prehensions contract the elemental qualities of worldly sensibility into an image, narrowing the field of potential experience to produce an intensity of contrast that is felt on the surface. This is what we mean when we say that the surface of the image has depth: it has depth of contrast, depth of feeling, depth of intensity, depth of sensibility, and depth of potential.

Rematerializing the Image as Surface

Having established the surface of the image as a site of aesthetic contact between sensing bodies and environments, we now consider the transductive potentials of the image through its capacities for material transformation. As described in the preceding section, the children selected 200 images for the exhibition which they transferred onto tablets covered with an encaustic medium (beeswax and damar resin). The digital images were printed out in high-resolution using a laser printer and then pressed into a molten layer of encaustic medium on the surface of the tablets.

After applying extensive pressure to the image with the back of a spoon, the paper from the original print could be removed by repeated rubbing with fingers (see Fig. 5). The tablet was then carefully reheated to a molten state in order to lift the underlying medium to the rippling surface, thus fixing the image within a translucent layer of wax and resin. What appears on the surface of the tablet is a ghostly monoprint of the digital image, as the printing ink is suspended within an archival medium that can, under certain conditions, preserve the image for thousands of years (see Fig. 6).

Fig. 5 Rubbing the paper off the surface of the wax transfer once the ink has been embedded

Fig. 6 An example of a wax transfer image that creates a fusion of body and environment

The wax transfer process demonstrates how the image can function not as a representation of childhood but as a surface that channels vectors of childhoodnature sensibility through material transduction and transformation. The image is seen to slide

Fig. 7 Children engaging with the collaborative artwork *Pieces of the Earth* as a fluid montage of surfaces

from one medium into another, as the transfer process effectively *resingularizes* a digital image through its deformation and reformation as an analogue image (see Guattari, 2008). In other words, the transfer process unleashes the virtual potentials of the image to become something else, something new, within a topological field of near-infinite possibilities. "Think of each image receding into its deformation, as into a vanishing point of its own twisted versioning," Massumi (2002, p. 133) writes. Paradoxically, we see the image become more singular by differentiating, by resingularizing back on itself as "matter in analogue mode" (p. 135). The wax transfer is a process of transduction from one medium to another, from a medium of digital code to a medium of analogue materials and bodily sensations. The precarious virtuality of the image is brought to the fore, as its rematerialization in analogue form is scarred by the process of deformation or sensible qualities that were lost in the process of transfer. "A feeling bears on itself the scars of its birth," Whitehead (1978, pp. 226–227) writes. "It retains the impress of what it might have been, but is not."

In becoming analogue, the image implicates the body of the child more thoroughly into the depths of its surface. The fusion of bodies and environments that we discussed in the previous section becomes even more palpable, more intricately embedded and folded together through a renewed tactility of the child-environment nexus. Perhaps the digital code of the photograph was only a temporary holding pattern between the child's environmental experience and the rematerialization of the analogue image on the wax tablet. As a medium for making aesthetic contact with children and their biocultural environments, the transfer process replaces the

representational ocularity of vision with a tactility that crosses temporal and spatial divides. We can touch the child's sense of the forest on the surface of the wax tablet, revealing what Hansen (2006, pp. 70–71) calls an "infratactility" or primordial tactility, operating at the very "heart of the sensible." The wax transfer process intensifies the tactility of the photograph and, in doing so, enables a more thorough melding of children and their environments on the surface of the image (see Fig. 6). While there is a loss in clarity and resolution, there is a gain in analogue sensation and worldly sensibility. The images become more permeable, taking on the biocultural tactility of skin, flesh, and membrane, as they come to embody the "sometimes fluid and sometimes disjunctive processes of responsive development, dissipation, intensification, and transformation" (Frost, 2016, p. 149). The images become, quite literally, *Pieces of the Earth* rendered from the biocultural interactions between children's bodies and their changing environments (Fig. 7).

Conclusion: Cultivating the Art of Life

In this chapter we have taken some steps toward the development of an ecological aesthetics of childhood that is responsive to the challenges of the Anthropocene epoch. We began by outlining the need for a more robust engagement with aesthetics in posthumanist studies of childhoodnature as part of the broader call for a "new synthesis" of the environmental arts, humanities, and sciences (Haraway, 2016). Drawing on Whitehead's speculative philosophy in conjunction with insights from the life sciences and media studies, we proposed a series of relationships between the common world of nature and the uncommon worlds of children as biocultural creatures. This led to a further series of distinctions between presentational immediacy and causal efficacy as modes of perception and worldly sensibility, with an emphasis on the fusion of children's perceptual experiences with the causal infrastructure of natural systems and dynamic spatiotemporal processes. We then extended this ecological-aesthetic framework through an analysis of children's environmental photographs as part of the Climate Change and Me project, including the analysis of digital photographs in relation to the analogue rematerialization of images through a wax transfer process. Using aesthetic concepts of intensity, contrast, sensibility, and surface, our analysis focused on developing the image as a site for making aesthetic contact with the embodied relationships between children and their changing environments.

This brings us to the perennial question of whether, and how, an image becomes a work of art. Does the child's photograph become art when it is curated and exhibited as such? Does the transductive process of the wax transfer qualify the image as art through its material transformation? While we do not offer a definitive answer to these questions here, we suggest that the transfer process intensifies both the elemental and aesthetic qualities of the image and, in doing so, pushes the image to the threshold at which image becomes art. To the extent that the image becomes more singular through an artful process and that this process introduces qualitative changes into biological, social, and material processes, then we would say that it

becomes art. Hence, it is not so much the image itself that we advance as art but the transformative processes that are both attributed to and unleashed by the image through forces of material production and the intensities of affective encounters. It is in this sense that we associate art with *artfulness*, as an aesthetic way or manner in which life is lived and experienced within an ecology of sensation (Manning, 2016).

We also recognize artfulness as the way in which the aesthetic becomes pedagogical, inasmuch as a work of art is able to redistribute worldly sensibility at the levels of the social, the ecological, and the planetary. We therefore conclude with a pedagogical perspective, as we position artfulness as the cultivation of aesthetic sensibilities and capacities for practicing what Whitehead (1929) calls "the art of life." We see the art of life as a pedagogy for cultivating environmental awareness through the aesthetic selection and recomposition of sensory elements in relation to bodily movement and perception. "For example," Whitehead (1929, p. 200) writes, "the mere disposing of the human body and the eyesight so as to get a good view of the sunset is a simple form of artistic selection. The habit of art is the habit of enjoying vivid values." Whitehead positions the body as the pivot point for the art of life, an aesthetic practice of enjoying the sensible intensities, values, and contrasts that emerge in the relations between interior and exterior milieus. "Each individual embodies an adventure of existence. The art of life is the guidance of this adventure" (Whitehead, 1967a, p. 39). The art of life is the art of the creature, the art of the organism, and the art of attuning one's biocultural body to an ecology of sensation through aesthetic techniques of existence. These are techniques that meld the aesthetics of beauty with environmental sensation, such that the beautiful is no longer associated with taste or judgment but with 'a felt "immediacy," "force," or "intensity" in process' (Kennedy, 2000, p. 31).

In this chapter we have proposed an ecological aesthetics of childhood drawing from speculative philosophies of nature, media, and the body. We have analyzed the sensory practices of children as embodied techniques for cultivating environmental attunement through aesthetic experience. Grace walking in the forest finding mushrooms at her feet or Kairo wading into the waters of Angel Beach to take photographs at dawn, these are moments in which creatures are guided by the art of life, such that body and environment become fused in the production of life itself as a work of art (Rousell & Fell, 2017). These are occasions of vivid experience never to be repeated; they are the uncommon worlds of children as biocultural creatures, each a unique perspective on the universe as it is felt differently and yet together, with each passing moment.

Abstract

This chapter provides a partial account of an intimate case study of an after-school science club for young girls in a garden shed in suburban Melbourne, Australia. While hybrid learning spaces merging home and school have been described before (Moje, Ciechanowski, Kramer, Ellis, Carrillo, and Collazo, Reading Research Quarterly 39(1):38–70, 2004), particularly in relation to girls and science (Barton, Tan, & Rivet, American Educational Research Journal 45(1): 68–103, 2008), such descriptions are limited to the hybridity of discourses and do not acknowledge the aesthetic, material, or sensuous dimensions of scholarship. Instead, the study on which this chapter is based involves diffractive artworks

taking place notionally some years "after" the science club, forming this chapter assemblage.

The chapter combines images of the science club shed with further assembled fragments of original pedagogical intent via planning documents and other arts-based interventions by the organizer/writer. Emerging with this work is the concept of permeable learning, based on understandings that design is multiple and human intentionality as curriculum is a thin-skinned and fragile fiction despite humanist insistence, particularly in neoliberal contexts, that it is otherwise. Permeable learning incorporates intra-action (Barad, Meeting the universe half-way: Quantum physics and the entanglement of matter and meaning. London: Duke University Press, 2007) as both human and nonhuman entities merge, thus calling each other into being. So students and the gases they create and breathe in their experiments become new entities of indiscernible boundaries, as do school and home, art and science, mud and hands, public and private pedagogies, teacher and student, memory and experience, girl and bird, and shed and garden.

Introduction: Questioning Boundaries and Binaries in Childhoodnature

French poet Jacques Prévert dissolves the mathematics classroom in his famous poem *Page d'écriture* (1972), or *Page of writing*, in which a child at a desk imagines a lyrebird in the sky. The bird enters the classroom, and as if by magic:

> Les murs de la classe
> *S'ecroulent tranquillement*. (1972, p. 211)

The original French language retains the long vowel sounds of reverence, of wonder unfurling, as the walls (*les murs*) of the classroom fall away peacefully. The tiresome lesson of multiplication table chanting is transformed: windows are again sand, ink is water, desks are trees, and chalk reforms a cliff. In the last two lines of the poem, the *porte-plume*, the quilled pen, is once again a bird. The hard boundaries between what things are and what they have been melt away, meanings are playfully blurred, and the words of both poem and rote chant fly free.

The traditional classroom's discursive triumph over the material, its performance of humanist supremacy, is exposed as fiction. Prévert's surrealist intervention allows eco-aesthetics to bubble through the membranes that keep things apart that maintain boundaries of space, time, and sense. Things are more than tools for humans; here they flow back into their origins and form genealogies that reinstate them in the abject natural world. This release echoes the concept of childhoodnature and

the merging of human and other. The dry world of abstract mathematical sums, of dreary adult domination of the child, and of the illusion of mastery over nature no longer holds.

This chapter argues that while all learning spaces have their ecologies and materialities, as Prévert reminds us, some spaces are less devoted to suppression and oppression. They are less intent on the rigid maintenance of boundaries and binaries such as those between adult and child, teacher and student, school and home, mathematics and art, human and animal, and nature and culture. Some spaces are more open to the aesthetic dimensions of learning encounters, and these spaces, with their own particular affordances and constraints, can assist us in imagining what education might be in the Anthropocene. This is the period in which human activities are recognized as having a permanent impact on the Earth's strata, becoming "a geological force capable of affecting all life on the planet" (Braidotti, 2013, p. 6). By exploring what happens in these more fluid and permeable spaces, such as the garden shed as science club (Fig. 1) described in this chapter, we may reconnect with the ecological and aesthetic dimensions of learning, to more readily enact Prévert's literary dissolution and transformation. So childhood and nature become childhoodnature, and discourse and the material become discursive material as formally discrete concepts slide together.

The chapter considers the dissolution of binaries by describing part of an intimate case study of an after-school science club for young girls held in this shed in suburban Melbourne, Australia, in 2014. While hybrid learning spaces merging home and school have been described before (Moje et al., 2004), particularly in relation to girls and science (Barton et al. 2008), such descriptions are limited to the hybridity of discourses and neglect the aesthetic, material, or sensuous dimensions of scholarship. Instead, the study on which this chapter is based involves diffractive artistic provocations that work ecologically throughout this chapter text's words and images, forming myriad connections and echoes with discursive-material appeal.

Combining photographs of the science club architecture and detritus taken in 2017 with further assembled fragments of original pedagogical intent via planning

Fig. 1 Garden shed

Fig. 2 Science club table

documents, and other arts-based writerly interventions by the organizer/writer/researcher, the chapter takes an experimental approach. Emerging with this work is the concept of permeable learning, based on understandings that design is multiple and human intentionality as curriculum is a thin-skinned and fragile fiction despite humanist insistence, particularly in neoliberal contexts, that it is otherwise. Permeable learning incorporates intra-action (Barad, 2007) as both human and nonhuman entities merge, thus calling each other into being.

So students and the gases they create and breathe in their experiments become new entities of indiscernible boundaries, as do school and home, art and science, mud and hands, public and private pedagogies, teacher and student, memory and experience, girl and bird, and shed and garden. Permeable learning incorporates attention to the vibrancy of matter (Bennett, 2010) and the sensory aridity of learning spaces reliant on the Cartesian split. Permeable learning recognizes creatures as teachers, acknowledges discursive materially realized gender, and challenges persistent humanist preoccupations in both teaching and research. These anthropocentric notions include custodianship of nature and nature or art as tools serving the scientist (as in many manifestations of STEAM – Science, Technology, Engineering, Arts, and Mathematics as curricular orientation) and the lens as a way to conceive of research (McKnight & Whitburn, 2017). Both the study, and this chapter, form richly textured compositions (Fig. 2.) of what learning and research might be if children and nature are understood to be inseparable.

Forming the Chapter

The chapter therefore delays a linear humanist narrative account of the science club and seeks new ways to share concepts as practice. This *page d'écriture* is loosened from its positivist research output moorings of literature review, methodological framework, findings, and conclusions, moorings that create hierarchical thinking

(Braidotti, 2013, p. 86) imbued with human arrogance. Instead, imagination and critical intelligence are called into play (Braidotti, 2013, p. 82). Inspired by Prévert and the capacity for the lyric and aesthetic to mediate between concrete reality and abstract ideas (Bristow, 2015), a series of visual, textual, and theoretical vignettes leak into each other, and theory seeps through, concentrating here or there, where it is needed. The photographs are not merely illustrative of the text but do their own work foregrounding matter and insisting on the surprising agencies of insects and plants – the spider web strand or climbing geranium stem that participates in new assemblages in the making.

So the tidy story of a science club for girls run in a garden shed, relayed by a researcher voice and persona do not dominate this telling, although they become folded in. Instead this chapter remains alert to other voices, stories, unearthings, and blendings; the reader is invited to enter into the spirit of this reading and suppress impatience at the complications of collapsing concepts. The writing has not started, for example, with locating the researcher or theoretical resources (although these are important components of research assemblages) but with lines from a poem that embodies childhoodnature. Similarly, in a new materialist and posthumanist paradigm, the child is not foregrounded here, through a Rousseauian fantasy of virtue, but is part of childhoodnature's becoming. The category of "child" as in "child-centered learning" is, despite its employment in progressive education, exhausted. To focus on the child is to focus on the human, and the human custodian is a concept much depleted by planetary crisis, in relation to, for example, climate change, accelerating species extinction, and nuclear proliferation.

Instead of research questions that seek to establish what humans did, what the educational outcomes for them were and how, on reflection, things could be different; the questions raised here are those which do not revere a reflective practitioner already suspect in a relational ontology (McKnight, 2016). How can one look back at something fixed, when entities are created through intra-action (Barad, 2007) and call each other into being, rather than existing prior? In this instance, research takes the form of diffractive analysis (Barad, 2007), in which things are read through each other. This is not a mirror held up to science club and an account of what it was but an imagining of what it could be, if diffracted with theoretically informed arts-based inquiry. The study asks:

What dimensions of learning emerge through this project?

It also considers:

- How does an arts-based approach assist with understanding what learning is?
- How does the concept of diffraction provide alternatives to reflecting on learning/evaluating learning?
- How does this study assist in conceptualizing and critiquing STEAM (transdisciplinary Science, Technology, Engineering, Arts, and Mathematics) education?
- How does this study work to disrupt humanist and gendered notions of education?
- How can this study contribute to the development of new theory in relation to learning?

As the study is still in progress, this chapter shares the writing and assembly as inquiry and analysis that are currently in play, which attempt to respond to these questions and also flow beyond them, regarding them as permeable as well, as a discursive sieve of predetermined humanist constructs that are difficult (but not impossible) to think beyond and do research without (St Pierre, 2014). The *pages d'écriture* that are the project proposals and ethics applications compulsory for conducting empirical research are themselves of paper pulp, toner, traces of other studies, conventions, expectations, and fonts, if we imagine them as transparent, or permeable.

So rather than humanist rationales, whether for research or learning, we invoke the material (Alaimo & Hekman, 2008, p. 9) and become earth (Braidotti, 2013). Perhaps all experiments, all lessons, should begin with the question "how is the earth?", much as the common greeting in Mandarin asks "Have you eaten?" If we begin with a conceptualization of earth, and awareness of earth in the making within all assemblages, including that of childhoodnature, we may start to shift our understandings of what learning is.

Science Club as Earth

How does earth write? What is the voice of earth? What story would the earth tell about science club? How far can personification take us, as we "benevolently" (Braidotti, 2013, p. 79) incorporate others into the human category and reinforce presumed superiority? How can anthropomorphism always acknowledge its biases and limits, when humanism is inherent even in the grammar of our sentences and constructs of subject and object? It is even present in the portrait format of this page, which echoes the dimensions of the human body as convention. These are questions that feel urgent, in any project that seeks attention to nonhuman bodies.

The foundations of this study, of science club, of curriculum, and of my academic career are in earth. The structure of the shed forming part of science club's assemblage is impossible without earth, the earth of the Wurundjeri people: its contemporary local district name, "Boroondara," is drawn from the Woiwurrung language spoken by the Wurundjeri and means "shady place," although the trees in this area were cleared for colonial agriculture more than 100 years ago. I pay my respects to the elders of the Wurundjeri people, who are recognized as the traditional owners of these lands, despite this imported White, Western concept's inadequacy for describing the Indigenous melding of human and earth.

Humans are always in the making as human being earth or perhaps, preferably, human becoming earth, although I note critiques of children as "becoming" rather than "being" (Uprichard, 2008) as resigning them to an always inferior and incomplete status. Even rock is always forming, is always changing, and is far from a discrete entity. Water flows through rock. The slough of our skin cells is earth, as is the mud under our nails and ingrained in the whorls of our fingertips, as is the decomposition of our bodies in living soil (Williams & Brown, 2012), and the

inhalation of chalk dust. We have cliffs in our lungs. Our practices form the strata of the earth. We eat earth, on garden-sourced tubers, themselves made of nutrients taken up from soil. Where does one thing begin and another end?

If we understand that learning is always about the earth, and an awareness of the processual making of earth through intra-action and of temporary and permeable boundaries forming around coalescences of agencies, we enter new territory. Traditional curriculum theory requires educators to think of aims, objectives, and, more lately, outcomes, on a trajectory away from earth, from the lesser-than-human as designated by being other than White, able-bodied male (Gaztambide Fernandez, 2015). Education is designed to remove children from the abject, from soil, feces, and dirt, as exteriorities of the body that define subjectivity (Kristeva, 1982). Childhoodnature collapses the child into the soil and understands the child as soil. There are however risks here that those considered close to nature (children, women, people of color) are denigrated (Alaimo, 2008; Gaztambide Fernandez, 2015); a remedy for this is to emphasize that childhoodnature is part of personhood nature.

Templates for practical reports, curriculum planning, and research funding applications ask limited questions, with their focus on aims, materials, and methods. We are not best served by seeking ever Whiter, more ideal, more perfect, more educated humans. Instead we need to ask what is changed, decomposed, accumulated, preserved, eroded, and contaminated through our practices. These are the phenomena (Rotas, 2016, p. 180) of becoming earth happening and forming here, as soil "actively promotes life and is itself alive" (Williams & Brown, 2012, p. 43). Writing about science club is not about triumphantly performing set piece demonstrations of human mastery over matter with children, so that abstract concepts might be introduced and remembered. Science club could be a shivering, as worms turn us over in our graves-to-come, an awakening to the vibrancy of matter, rather than to our power over it. Science club could be a sensitivity to the material world, rather than relegating it as a backdrop to human actions.

The foundations of science club in becoming earth are made most obviously as we add our weight to the concrete slab of the shed floor, so that we are aware of the material beyond/below the neat list of apparatus and materials required for the first science club: nappies (diapers), water beads, water, Ziploc bags, and salt. Diffracted with new materialist and posthumanist theory, pushed through the narrows of becoming earth, this list, emulated in countless classrooms, might always begin with "earth." This would be an acknowledged materiality more fundamental than simply that required for an experiment as performance of human control.

The material turn in theory might also be described as the turn to dirt. This is not a turn as in an oscillation of a human figure but of the turning of dirt by multiple organisms, such as the plumules rearing from a seed or an ant collecting tiny particles of soil. This is how we might turn ideas and materials in science club, inspired by Braidotti, who draws on Gilles Deleuze, Jane Bennett's (2010) assemblages of vibrant gutter matter, Ladelle McWhorter's (1999) concept of dirt and flesh as cousins, Diana Coole's attractive and repulsive dirt (2015), Jussi Parikka's (2012) dirty media discourse, and the work of further feminist materialists such as Stacey

Alaimo (2008). These are the theorists informing this writing as diffractive practice (Barad, 2007) remaking science club, rather than reflecting on its outcomes.

This new science club does not begin with an experiment title for an activity, as the other science club did, with:

- Fizzy sherbet
- Elephant toothpaste
- Water beads
- Silly Putty
- Chromatography
- Birds' nests
- Christmas crystals

Such titles elide a bigger picture. Instead we flow into a kind of "*ca va*?" of the earth, a "how're we going," a return to recognition that we (human and non-human) are constantly making the earth and each other. Common sense informed the original science club that the happening that mattered was doing experiments in a pop-up shed lab and that the only materials that mattered were those of the equipment lists on the handouts. This demonstrates the extraordinary tunnel vision of conventional science. We were also, for example, simultaneously contributing to the compaction of topsoil under concrete, in a flesh-cement-soil assemblage.

To dare to write these words is not science happening as we allow it, but science as "knowledge making" – the etymological derivation of the word in another, more open way, based on another kind of heightened, multisensory "observation." The primacy of this looking word in science is another humanist trope that is difficult to avoid (McKnight & Whitburn, 2017). There is science beyond the predetermined demonstration of human management of natural phenomena that begins and ends with the donning and doffing of our disposable gloves; I have written about the notion of the "manager" elsewhere (McKnight, 2016). This is science as always already becoming, not what we are or know in a fixed sense, but what is in the making. This is science in which the researcher is always becoming the matter being investigated, rather than studying it at a distance.

Intra-action of various agencies, including children's bodyweight, reduces the pore spaces of the soil under the science club shed, so that microorganisms struggle to move through it; makes it hydrophobic, so that water moves away from it; and prevents the formation of leaf litter, with all its regenerative vibrancy. I refer to a children's book here: Rachel Tonkin's *Leaf Litter: Exploring the mysteries of a hidden world* (2006) illustrates this beautifully and interactively, with each page a fabulous assemblage of layered and living matter. The soil is already changing over time, with old cement dust from the laying of the concrete altering its pH. Standing on this concrete soil compaction makes our human bodies too, its hardness locking out our knee joints and testing the fluid-filled discs cushioning our vertebra, so that we ache.

Leaves blow in under the loose doors, slowly forming new drifts of soil in concrete corners. Our shoes break up these leaves and make dust that we breathe in windy gusts. This making cannot be disentangled from the cultural practices of further waves of migrants, who have removed Boroondara's vegetation in another cycle. Most of the mature canopy trees in the area, largely deciduous trees reminiscent of Britain and planted in the mid-twentieth century, have now been removed. Nor can the soil's composition be disentangled from the recent Australian drought, which killed many trees and has changed the nature of the soil. What we are becoming, breathing and breaking down into in the shed, is part of migration policy and global shifts in human traffic, nostalgia, climate, and more.

The chalk dust from drawings on the shed walls speaks of the educational play regimes of the middle-class mother; rust particles from disintegrating corrugated iron are endless products of the pickling liquor of galvanization and evidence of the contamination of other soil in the process. The ivy that penetrates the flimsy shed structure mocks the inside/outside, home/garden binaries, and its carapace of hairy stems diffracts the human intentionality of shelter design, growing to its own thick imperatives and necessities, blurring and remaking the shed, and allowing birds to build their nests there. The shed is also inseparable from its original purpose; it is a tiny garage for an early automobile. We are not so far away from a busy main road, and if we listen, we can hear, like George Eliot's roar of the universe that Braidotti reminds us of (2013), the cars' engines and taste the heavy metal particles we ingest.

None of the above is mentioned in the first science club.

This account describes the vitality of the shed, not as a container space for activity – this is problematic (Barad, 2007; Snaza et al., 2016) – but as a happening metaphor for learning and life as intra-action, of agencies calling each other into being, forming as they move through each other. Invisible, contingent membranes form too, like the skins on liquids, but these are always more or less permeable. Child and nature, child and car, and child and soil are only separated by conjunctions. Even childhoodnature is only separated by the kerning conventions of this font. Yet semiotics still insists on the binary; readers perceive two signs here. Perhaps we need a new combined word, a "chanterduil," perhaps, interweaving these signs to enact entanglement.

I thought none of this, running science club or, at least, imagining I was running a science club rather than participating in a teeming shed ecology, being made by it myself. Humanist teacher as mythmaker and proponent of impermeability, I was secure in the repeatability of routine and the shoring up of Cartesian logic. I had not even begun my new materialist and posthumanist reading or encountered any of the ideas that shape the diffractive narrows of this new version. As a writer, researcher, mother, and student, I too am always in the making, with ideas leaching into and out of me, with new thought and movement patterns flowing. Recognizing the human in posthuman, I turn now to the account of science club that well-trained readers might have been expecting, which serves to provide missing discursive elements that also form part of this assemblage. Yet it is read now, if the chapter has been followed sequentially, through the insights of the alternative, diffracted account above.

Science Club as Narrative

There is another story of science club, a neat narrative that puts dirt in its proper place, in the materials list of Experiment Seven: Birds' Nests. In 2014, my 9-year-old daughter's local state primary school obtained funding for specialist science training for two teachers and offered a lunchtime science club for students. This was so popular that attendance had to be carefully managed, and my daughter had to wait some months until the Grade Twos were allowed to go. During this time, her enthusiasm waned, and she told me she had realized that science club was just for boys. I did my best to persuade her otherwise, and by the time the form came home to be signed, she intended to participate. Alas, again the club was hugely oversubscribed, and by chance, all the female applicants in my daughter's class were not accepted.

As a PhD student in gender and education, who had just submitted a thesis on gendered bias in coeducational curriculum design, I had time and the inclination to create an alternative science club with my daughter. I had no intention to do research in relation to the club; this was an entirely domestic project to correct a perceived gender politics injustice and, as an aspirant middle-class mother, to ensure that my daughter did not miss out! The science club I refer to in this chapter from this point, providing the focus for this research, is this alternative club.

The school provided me with a list of topics their science club covered, and I used the Internet to find and design activities, supported by sites such as GEMS.org (Girls Excelling in Math and Science) and my own collection of child-rearing books. My previous studies had involved art, literature, biology, and physiology, so I was able to put this transdisciplinary aesthetic and scientific background to use. I wrote a lesson plan for each of 8 weeks, which also functioned as a handout for the children, and we invited all the five girls from my daughter's class who had missed out on selection for the school club. Parents paid a small sum to cover the cost of materials and refreshments: I made an after-school snack cake each week. The club took place after school, in our garden shed, an old tin structure four by six meters, in which we installed a central table for experiments. I wrote up each week's title on an old child's chalkboard (Fig. 3). I knew the experiments would be messy, and I wanted the girls to play and explore freely, so the shed seemed an ideal location. I did not want dirt in the house.

For reasons of insurance, this was construed as an informal, playgroup-type activity, located in the community and not in any way related to the school. It was not informed by mandated national curriculum, but by my own feminism and desire for girls to enjoy science. I designed and printed off posters of young female scientists, for example, Aynur Askin, who has developed a system for using the wings of butterflies in textiles (Celikkan, 2014), that played up the interrelationship of arts and science in a girl-friendly way.

As a poet and an artist, I was interested in the concept of STEAM, incorporating art into science, technology, engineering, arts, and mathematics, and had long encouraged the preservice teachers I lectured to design transdisciplinary curriculum,

Fig. 3 Chalkboard

Fig 4 Vases

for example, blurring physics and science fiction. I had a strong sense of enacting this through science club, of creating a sensorily delightful experience and an aesthetically pleasing space that blurred studio and laboratory (the space had been used by previous owners as a picture framing workshop) and also natural world, as the shed was sited in the garden and had windows and views on to greenery. I put a derelict antique cabinet along one wall and set up a collection of old glass vases (Fig. 4.) and flasks where they would catch the light.

I was wary of falling into the trap of making girls' science all about makeup and bath bombs but also wanted to complicate the masculinist precision of the lab, both physically and through the experiments; for example, we used our chromatography strips to make colorful butterflies (Fig. 5.) that we suspended from the shed frame. This was a science club initiated by a feminist artist, predicated on owning a suburban block big enough for a garden shed and only working part time.

Fig 5 Filter paper butterflies

Science club was a lot of fun, but sometimes I became concerned that my carefully planned procedures were not being followed. The girls were just as interested, if not more interested, in moving between the shed and the surrounding garden, picking and eating snow peas and checking on the baby birds in the nest made in the ivy surrounding the shed. As an experienced teacher, I felt the familiar impetus to keep my students on task. How much were they learning about scientific concepts? If I tested them, would they be able to remember the chemical equation of our citric acid/bicarbonate of soda fizz? Explain how polymers get bigger? Describe the properties of fluids? What knowledge would they be able to demonstrate to their parents? There were, of course, no tests. At the end of science club, I received some lovely thank you cards from the students – whatever they had learnt, they had certainly enjoyed and appreciated the opportunity.

What are the inadequacies of this account? What of the proliferation of "I"s, as the human and its intentions come to the fore? Despite my interest in the embodied experiences of the children (or, rather, my plans for these), this account situates us all in a discursive bubble, in which we are insulated from the materials surrounding us, unaware of and impervious to the myriad connectivities and complexities of existence. Science club performed the illusion that chemistry happens when we let it.

I received my doctorate just as science club ended. I was fortunate to have Bettie St Pierre as one of my thesis examiners, and she advised me to read in directions my own doctoral supervisor had been reluctant to take. Over the last few years, since the first science club, I have read until my eyes are sore as advised (St Pierre, Jackson, & Mazzei, 2016), absorbing new materialist and posthumanist theory. Science club has been constantly in the making with this reading, reforming through acts of both memory and imagination. Concurrently, the fields of childhood studies and curriculum studies have begun to move in similar ways (Snaza et al., 2016, p. xv), so that there is even more to read. In the following section, I turn to the theoretical resources that I draw on in creating the versions of writing as inquiry above.

Tin Shed Theory for Permeable Learning

This chapter is not a call for environmental education, for forest or bush schools, or for shed schools. This work is not related to the teacher practice of "porous learning" understood as enabling digital delivery of school curriculum at home (Jesson, 2016). This chapter does not simply describe the ecologies of a particular educational site but seeks to advance a theory of permeable learning that emerges from the accounts above (and following) and the particular materialities of the shed as happening. This is in stark contrast to an evaluation of science club, and an assessment of what learning its participants have retained so that its outcomes and impact may be determined (as if these things could in fact be known).

Instead the chapter shares a material and arts-based research and curriculum strategy that are conspicuously in the making in this writing, not something executed in the past that is being unproblematically reported on. The tissue-thin page membranes that separate the chapters and sections of this handbook are themselves permeable, so that what the collection has to say about, for example, "pedagogy," flows through and becomes concentrated here or there, as it is taken up into new assemblages shaped by digital search functions, white space, interests, time constraints, eyeballs, or ears.

The notion of pedagogy as place of purposefully creating particular kinds of learning environments with attention to their aesthetic dimensions has been a recurring theme in educational literature. This has been realized, during my teaching career, by theorists drawing on John Dewey and Maxine Greene's earlier work on experience and embodiment, still with a focus on the nurturance of the human. This work pays attention to "nonschool settings" (Schubert, 2004, p. ix) such as science club as backgrounds for learning but also gestures toward the material, if only through metaphor, to the need for "fertile educational ground" (p. xiii). This metaphor may, however, serve to reinforce a nature/culture binary through its oxymoronic tension between dirty agriculture and pristine school.

Julian Sefton-Green has recently undertaken a review of learning at nonschool, defined as "contexts where teaching and learning aren't usually understood to be the primary purposes of place" (2013, p. 20). He describes these kinds of learning spaces as traversing boundaries, where school and out-of-school intersect, and as underresearched, unless via project evaluations which ignore larger questions around learning. Sefton-Green does acknowledge other nonhuman participants in these spaces, such as tools and affect, but as context for human practices, not agentic intra-action.

I also acknowledge the work of Elizabeth Ellsworth. Her *Places of Learning* (2005) begins with William James' quotation about things not made, but "in the making" (p. 1). She is already moving toward a kind of permeable learning, with her desire for a "reciprocal opening" (2005, p. 9) between learning and the aesthetic and her call for investigations not models; this is the gist of Prévert's poetic critique of multiplication table rote memorization in *Page d'écriture* and of my writerly interrogation of the science club curriculum. Ellsworth describes encounters with artworks, and the material's capacity to know, as she draws on Winnicott's transitional

space and pedagogy as a "web of interrelational flows" (Kennedy in Ellsworth, 2005, p. 24). These concepts shift our sense of the boundaries and siloes of education, as bodies dissolve into and out of what we were and what we will be, with insides and outsides related not opposite, and receptivity to "encounters with the unthought" (2005, p. 37). This creates new possibilities for shed and garden, home and school, and gut and skin.

Her understanding of intent as agency distributed across multiple bodies is also helpful and reinforced by Barad (2007) who writes of intentionality as entangled human and nonhuman agencies. I aimed to stick to the school's sketched-out science club curriculum list, but the purchase volumes, volatility, and storage requirements of carbon dioxide meant that we had to skip the week on dry ice bubbles. What happens is not simply what I want to happen: matter really matters and has the capacity to blow the door off my refrigerator!

The diffracted science club's attention to matter, and to transversality, also flows from the work of material feminists over the last decade or so, and the realization of the ontological turn, in which things are understood to have the capacity to speak back (Lather, 2016). Concepts of intra-action and assemblage (Barad, 2007) and of vibrant matter (Bennett, 2010; Coole & Frost, 2010) are vitally important to this work.

Viscous Porosity and Permeable Learning as Related Concepts

Nancy Tuana's work is also closely linked, as she has developed the conceptual metaphor of viscous porosity (2008, p. 189), to understand how subjects are constituted through relationality and to explore the intersections between things, people, biology, and culture. Her planned feminist essay on embodiment shifts, via the forces of Hurricane Katrina, to an encounter with "levees, hurricanes and swamps" (2008, p. 189) in a manner similar to my emergent awareness of science club as more than a planned list of experiments. Instead of a discursive account, my accounts, even the more traditional one, become shot through with dirt, rust, birds, snow peas, and corn flour. Tuana prefers "porosity" to "fluidity," as she feels it indicates resistance and complicates interrelations. In contrast, I have chosen "permeability" as guiding metaphor, in part to distinguish this work from that of developing digital learning strategies as porous learning.

Permeability and porosity are related concepts. Permeability, in relation to earth and soil sciences, is a measure of how readily fluid passes through rock and, in chemistry, describes how things may pass through membranes. Porosity is a ratio, describing the fraction of void space (the space between particles) in a given material. Something that is porous has more space and less matter and is described by the mathematical relation of these comparable volumes. For my purposes in seeking a metaphor for learning that fits new materialist and posthuman sensibilities, "permeability," as capacity rather than state, has a stronger sense of movement across and through, and this encompasses the sense that things may be more or

less permeable. Borrowing from chemistry, the membranes that create ostensibly separate entities are themselves not fixed but better understood as a "fluid mosaic" (Nelson & Cox in Frost, 2016, p. 65), always shifting and in composition. Yet these membranes are enough to allow the perception of contingent and ephemeral entities and prevent the dissolution of all into universal soup.

In permeable learning, things are recognized as mutually co-constitutive, moving through each other, becoming anew as they intra-act. Membranes, both physical and discursive, form through coalescing forces of nature-culture, temporary boundaries that are never solid but are open to possibility and to continuous becoming. Curriculum or planning might be understood as membranous, textual assemblages of words, spaces, politics, and passions – I am reminded here of Ted Aoki, cutting holes in the curriculum (described by Pinar, 2011, p. 1) to open it to possibility. If curriculum is a perforated, gelatinous membrane, not a straightjacket or order, what might flow through it? This is curriculum as described in one of Yoko Ono's Instruction Paintings, in which she advises the reader to put a hand up to the light, "until it becomes transparent/and you see the sky and trees through it" (Ono, 2012, p. 36). What can we see through curriculum? Or if we can put aside this humanist preoccupation with vision as perception, what do we sense through curriculum? What can filter through this grid of intelligibility reimagined as fluid mosaic?

Curriculum and Childhoodnature

This different orientation immediately throws up radical transversalities; this is much more than the oft-described gap between planned and enacted curriculum. Suddenly curriculum does not just work one way. Things flow in all directions. Animals can teach. Children are nature. Science no longer starts and stops in the linear temporality of school but is always already forming as questions, as art and as matter. So we might ask of any curricular project:

- What are we pretending is discrete?
- What are the contingent boundaries, layers, or membranes we perceive forming? How have they formed (Barad, 2007, p. 23)? What is called into being through their formation? What do they attempt to prevent and enable? How readily do other things pass through them?
- What strategies can we use to disrupt the representational logic of curriculum documents, like the science club handouts?
- How is matter co-composing this learning phenomenon?
- How can we break down the boundaries between disciplines in this event?
- Who or what is participating in the choreography of the encounter (Coole & Frost, 2010, p. 36)?
- How are we performing binaries in planning, in particular that of nature/culture?
- How are we contributing to both bewilderment (Snaza, 2013) and wonder (Snaza & Weaver, 2015, p. 7)?

- How are we flattening the human and challenging humanism?
- What constitutes the materiality of places-as-happenings here? How can we think-act ecologically? What are the notional waste products of this learning act? What will happen to them?

Other educational theorists' ideas infuse these questions. In recent publications, there are calls for the borders between pedagogy and curriculum, nature and culture, and human and nonhuman to blur (Snaza et al., 2016; McKnight, Rousell, Charteris, Thomas, & Burke, 2017). There are demands for "a new politics of attention" (Snaza & Sonu, 2016, p. 30) echoing Bennett's "new regimes of perception" (2010, p. 108). If we turn this to science club, we perceive new phenomena, perhaps a colonial fantasy of subjugation of the land/Indigenous peoples? There was no acknowledgment of country at science club. The municipality of Boroondara, the shady place, no longer requires it at council meetings (Masanauskas, 2017), in a related performance of ignorance and forgetting. Do we perceive a performance of the "narrow governmentality of scientificity" (Lather, 2013, p. 645)? The reproduction of capitalism as "the engine of environmental degradation" (Miles, 2014, p. 8)? The excess materials I purchased for science club lie discarded in the shed. One week I put around 15 swollen disposable nappies (diapers) in our rubbish bin, after the girls had tested the superabsorbent polymers lining them by filling them with water.

Is science club the product of a struggling education system that channels scarce material resources toward boys? And/or is it a mechanism of exclusion reliant on middle-class cultural and economic capital, despite my feminist pretensions? Do we perceive a shoring up of the boundaries between child and nature, as children follow adult instructions to manipulate natural phenomena?

What would a science club be that "challenges assumptions towards cognitive and practical mastery over the world" (Frost, 2011, p. 78)? How could we resist the tyranny of the topic and honor the concept as creative agent (de Freitas & Sinclair, 2013, p. 466)? Through all these questions, further science clubs are forming, clubs that may follow Barad's advice that we should not take for granted what needs to be investigated (2007, p. 26) and that there are outcomes other than those defined by the "thrust called intent" (p. 32). In this way, science club can challenge what has been described as fascistic curriculum (Pinar, 2011; Helmsing, 2016).

This is therefore not a template for permeable learning but a call for tin shed thinking in curriculum planning that allows matter to take center stage that counters dull, disciplinary silo thought that eschews learnt ignorance and insensibility to actual places-as-happenings. Even students on the third floor of a brutalist school building can do tin shed thinking as permeable learning, alert to the fluorescent light co-composing their blood counts (Landesberg & Quatrale, 1996) and the xylene marker fumes in their airways, perceived through the teacher's tidy but permeable lesson-script.

Tin Shed Thinking: Reconvening Science Club as Poetry

In this chapter I have moved from a surprising material-discursive account of science club as earth, through a more traditional narrative account (although I acknowledge the leaky borders of these contrasting stories) and an overview of relevant theory informing new curricular orientations. I turn now, again as if burrowing through earth, to a reimagining of science club as:

- Becoming iron
- Becoming concrete
- Becoming polymer
- Becoming stem
- Becoming bird
- Becoming soil

In doing this, I take one of the science club experiment plans (acknowledging that these weekly experiments were permeable to each other) and diffract it with the writing of poetry, treating both these texts as permeable overlays of each other. I treat both my original science club plan, reproduced below, and also this further diffractive writing as sieves through which things pass and are made. This juxtaposition allows the reader to think about what these texts try to retain and what they allow through. In this way, we can read the science club plan through the poem, and vice versa, so neither serves as a fixed form of reference, and we perceive what and how differences are made (Barad, 2007, p. 30). We can also sense what moves through, and what is made in assemblage with the previous vignettes, of science club as earth, of researcher narrative and theoretical explication.

Science Club Week 7: Birds' Nests

Aim: to study how birds make their nests and make our own.

Materials: dirt, water, sticks, leaves, twigs and dried grass, and ice cream container to make mud in.

Method:

1. Collect your materials.
2. Mix some water into dirt in your ice cream container to make mud.
3. Experiment with making a nest, using the mud to stick things together. You can shred or tear the materials, twine, and bind them.
4. Practice using two fingers like a beak, so see how skilled birds are at nest building.
5. Leave your nest to dry before trying to move it.

Findings:

Science Club Week 7: Birds' Nests

Woiwurrung word, and still
the ground is thickly shaded
here where iron wave
casts ripples laid
over acrylic skin.
Bird flit from ivy dark,
Pre-Raphaelite, polycarbon-night.
Swift, lark, I do not know
your name.
Thermoplastic pants elastic
makes us pluck and weave.
The female builds
allometric-wise, the nest
thick-twig-sticks will
hold her mass.
Saliva binds, inside
the humans shriek.
[Sweetie, don't get your dress dirty!]

Checked cotton, all be-smock'n
limbs, claws, digits do
that women's work,
BlueScope branded, zinc strippin'
party trippin'.
Here is mud. Here is moss.
All these raw lovelies make
a pretty child at play
in rosy glass, paint,
and rust-sucked muck,
in foot-pestled powder
on dried bird-dribble
splashed cement.
[Honey, you don't want to mess with that!]

I must feed my young
bird's egg banana cake and,
for God's sake
polypropylene vanilla sludge
polyethylene dust and stuff
that clogs Bangladesh,
strangles seals.
The very same that makes
transvaginal mesh if
you mix it – quick girls–
with cows' or pigs'
tissue. So one fine day
we'll know our melt-flow rate, or
become degraded, oxidised,

crackled, brittle. . . *but,*
but – we're only little.
[Samantha, this project has gotten out of hand.]

Fifty five million
tons of us will feed
a global goblin market.
We will leach BPA,
we latex angels of the home,
when we go to landfill.
In one bird's nest
is a fine petroleum line, a
bread bag tie.
Give us this day
voracious fungi, larvae, pupae
plastic-munching, ladies lunching, hope.
In science we trust,
in chemistry's base mettle,
not in alchemy,
mystery, artistry.
[Careful! Why don't you hand that to your brother?]

Writing Poetry as Diffractive Research

Poetry is more porous than prose, with strikingly more void (white) space around the textual material on each line when compared to prose and a grammatical, syntactical looseness that leaves room for interpretation and imagination. Poetry created as and through associative, intuitive, sensuous, affective energy is ideal for challenging humanist and positivist reason. It also has particular affordances for exploring new materialist themes (McKnight, 2016; McKnight, Bullock, & Todd, 2016) and the Anthropocene (Bristow, 2015). This is to move beyond understandings of poetic research as attention to solely human experience as heightened state (Leavy, 2009) but to awareness of a more diverse universe. I've argued elsewhere that:

> this is poetry as experiment, not literature, poetry put to work empirically to engage the medium, the water or air in which we (both human and non-human) live, breathe, move, and learn. This is poetry as realization of some of the ambitions of new materialism, as a concrete example of what this more diffuse, fragmented, naturally attuned, and multiple thinking might look, sound, and feel like. I offer new ways to be with emerging theory in education. (McKnight 2016, p. 198)

As an intervention here, it serves to break down silo thinking that separates curriculum, literature, and the writing of an academic book chapter. If we squint through these textual layers, and blur their boundaries, we fall into a tumble of Indigenous memory, animal husbandry, and subversive wordplay, as girls and readers delight in vividly and aesthetically realized dirt play and then get pulled up

short by the square brackets of parental discourse. Words, images, ideas, and things can move between different spaces-as-happenings. The poem itself includes multiple intratextual references to sections of this chapter and intertextual references to sources such as Christina Rossetti's poem *Goblin Market* (1862/2017) and other Victorian literary and artistic texts setting up enduring relationships between women, children, nature, and domesticity; these emerge through the arts-based practice of writing poetry as research, as materially rich creative and cultural resonances that may elude other forms of inquiry.

References to Pre-Raphaelite paintings and poetry suggest an urge for the naturalism and close attention to detail of their lush gardens and also highlight the risks of their romanticism and sentimentality. Such works were produced in the context of rigidly sexist moral and professional mores, by an artistic "brotherhood." While new materialist theory and research practice have been critiqued for its absence of politics (Snaza et al., 2016, p. xviii), this poem brings gender politics to the fore, with a simmering resentment of the materially abject, dirt, and feces-smeared feminine work of the home that is ironically echoed by the girls' testing of nappies as polymer samples and the wearing of pseudoscientific latex gloves in the domestic setting of science club.

What further insights come into being when reading these texts diffractively to try to answer the open questions posed above of any curricular project and awake Bennett's "new regimes of perception" (2010, p. 108)? There is a greater sense of the complexity of the choreography of the encounter in the poem and of learning in the club. We become aware of affect, with a bulge of urgency rather than the flat complacency of the plan with its matter-of-factness. This dry tone of science as procedural text is immune to the unexpected entanglements of process, even though it gives a patronizing nod to the wisdom of creatures. The plan reads as insensible to the aesthetic dimensions of the project described or to the possibilities of humanbird or humanplastic assemblage that the creative affordances of the poem enable.

The poem does not pretend that the experiment is discrete from the material-discursive world of broader communications, whereas the plan forms an ostensibly less permeable bubble. For example, the poem gives reference to the media, via recent reports of scientific advances in the waste management of plastics via consumption by wax moth larvae (Sample, 2017). The lines in square brackets are quoted from telecommunication giant Verizon's (2014) advertisement promoting the participation of girls in science, *Inspire her mind*, that went viral online around the time science club launched. This advertisement shows a young girl interacting with (or, rather, intra-acting to co-create) the environment yet being thwarted by her parents' gendered concern and reminded to conform to being "a pretty girl" who does not play with yukky nature. In the final frames, the grown-up teenaged girl approaches a glass-covered noticeboard advertising a science fair; she does not read the notice but touches up her lipstick while admiring her reflection in the glass.

Steel industry multinational BlueScope owns Lysaght, the company which galvanized the iron of the shed; we work and play with ironic, feminine Lysaght logos (Fig. 6) on the wall that neither the girls, nor I, think to investigate until I come to take the photographs forming this research assemblage.

Fig. 6 Corrugated iron company logo

These logos represent the masculine-dominated professions that this STEAM-fired club imagines the girls may one day permeate. Surgery, another of these fields, contributes to the becoming machine (Braidotti, 2013) of posthumanism; one surgical procedure has resulted in multimillion dollar claims for compensation by women whose sexual and reproductive organs have been repaired with faulty plastic mesh, after damage sustained in childbirth (Campbell & Fishwick, 2017). What is the gender politics of this plastic manufactured by global corporations, the same plastic we mix mud in, absorbed from my daily media reading and filtering though into poetry? The poem collapses girl and woman, child and mother, and all into matter that complicates interiorities and exteriorities.

The Absence of Curiosity

The absence of curiosity about our surroundings is curious and might be offered as a key finding of this study, even at this early stage. Despite its romantic, feminized garden shed location and girl power posters, the original science club presents as a list of topics, not questions. It offers a single procedure to follow to reify human understanding of the world, despite the proclivities of science to disprove what has been believed before. The dirt writing, narrative, and poem of this chapter conspire to expose how our rote activities, like Prévert's multiplication tables in his *Page d'écriture* poem (1972), demote and conceal the matter in which we are immersed and part of, so that our connections to the wider world are lost. We focus on the human-arranged set piece demonstrations at hand.

I forget to write "plastic bags" on the materials list for the birds' nest experiment. I call the girls in when they are spending too much time looking at the birds in the ivy nest. I hurry them on when they are examining how the helices of snow pea tendrils secure the plants to their support. Science club learning, despite pretensions to breaking down binaries of home and school, girl and scientist, and child and nature, is predicated on a particular understanding of what matter matters. It is all too easy to elide my deployment of a dire global pollutant (plastic bags) as common-sense science club equipment and to steamroller the wonder of the materiality of existence in favor of my planned imperatives.

We know the shed floods when it rains, due to drainage issues with the new development at the rear, but do not think to experiment with engineering a solution together in science club, even when the girls' mud nests are at risk. We could be mixing cement ourselves, filling sandbags, running hoses, using spirit levels, and examining Google Earth to check building and permeable soil ratios on surrounding blocks, even as we talk about satellites, security, privacy, monopolies, and topographies, not to mention earth art and the agencies of water.

Instead of perpetrating learnt ignorance, we could be finding out what humans call the bird in the ivy shed nest and how these birds call to each other and how they build their nests. How do their lives compare with those of the birds whose yolks we have just ingested, in our banana cake, the nutrients from which will enter and become our cells? Would birds ever use a human-made nest? We could consider how these garden birds fit into broader biodiversity, especially considering the removal of the tree canopy due to recent migration patterns. Along with the sound of traffic, the roar of chippers provides a forgotten backdrop to science club; this is the roar of the universe Braidotti urges us to hear (2013). We could spend a whole club slot watching and listening to the bird, learning from the bird, and wondering what the bird learns from and about us.

What of my impervious and imperious attitude to the waste matter created through science club? What of the elephant in the shed, the pile of acrylic and latex paint tins (Fig. 7), that my partner and I are not sure how to dispose of? Science club completely ignores this matter. As an ever-ready consumer, I purchased new matter (water beads and nappies) to explain polymers, when the shed was already full of them. We could have explored the chemistry of paint, opened the tins, tested the paint, found out how to reuse and recycle it, and discussed the history and properties of lead (inevitably present on our house, given its age). The periodic table is not in a book or a chart. We are breathing it, at 0.1 micrograms per cubic liter of air, and storing it in our bones. This is science infusing, or permeating through everything, not presented as if by a magician, with a precise beginning and end to the show. What would a science club be, in which children designed the experiments? What would a science club be, led by birds, paint, water, and soil? What about a science club in which art proved the basis of each event, rather than demurring as handmaiden to the explication of superior scientific concepts or as an add-on to use up free time at the end?

Fig. 7 Paint tin collection

In the early 1990s, Joseph Dunne was already lamenting the instrumentalist turn in education and the backlash against progressive movements. He dreamt of an alternative derived from "the nature and texture of a practical engagement" (1993, p. 8) but before the bodily, new materialist and ontological turns in philosophy. Science club sought to provide such a practical engagement yet still falls short, in that it was conceptualized prior to my own engagement with these turns. It is discursive-material theory-diffracted science club, however, that acts as a kind of hinge (Ellsworth, 2005) for different thinking and acting, as explored in this chapter.

I have tried to avoid romanticizing or sentimentalizing nature, or children, here, and falling into the trap of positing nature as salve, or panacea for human ills, or as vehicle for presenting humans as saviors, as a well-known passage from E. Nesbit's classic *The Railway Children* (1906/2008), in which the children attempt to make mud nests, does:

> I've often thought people don't do nearly enough for dumb animals," said Peter with an air of virtue. "I do think people might have thought of making nests for poor little swallows before this.

The human as benign savior has little purchase in the Anthropocene, in which we have become aware that human influence on the planet has been anything but benign, or solicitous to the welfare of "dumb animals," species of which are becoming extinct at an ever-increasing rate.

Conclusion: Sliding into Permeable Learning

Along with ongoing poetry writing in relation to each experiment, the proposed next stage of this study is to reconvene science club, with all its myriad nonhuman and human bodies in attendance, for an arts-based workshop construed as science club as

art. This will be concurrent with ongoing poetry, narrative and exploratory writings as sampled here, enacting tin shed thinking and permeable learning, as the assemblage that is science club continues to form and dissolve, and I attempt to use aspects of it to address the research questions. This humanist overlay of researcher and researched persists and is part of any posthumanist project. Ethical approval for this next stage is currently being negotiated, although this writing highlights the absurdity of ethics being confined to research with/on humans and foreshadows future Faculty Planetary Ethics Research Committees (FPERCs), which would pull me up on my use of plastic bags in science club and demand that matter be made to matter.

Prévert chooses the verb *s'écrouler* to change the walls of the classroom in his poem, as they open to the imagination*: les murs s'écroulent.* This word means to collapse like a house of cards, to lose value, to relinquish resistance, and, in the vernacular, to become weak with laughter (Larousse, 2017). The membranes of walls and stationery weaken, and multiple flows of agency fashion them into other things. *Ecroulement* is a French geological term describing the *désolidarisation* of an edifice, such as a chalk cliff. This chapter has attempted a similarly dramatic shift of concepts, using the arts of literary and academic writing to slide them together like moraine, as childhoodnature, girl-bird, and art-science merge in ongoing becoming. The reference list of this chapter, too, although dense with academic theory, is shot through with newspaper articles, social media video, poetry, children's picture books, and other aesthetic literature. What is as solid as rock or curriculum or academic writing becomes understood as permeable. There is much further to go, however, in imagining an art-science learning event that is not human sanctioned and controlled and truly engages distributed agencies. This is learning that does not succumb to humanist hierarchies that place male above female, science above art, and culture above nature.

a unique approach to research and scholarship, one that is an emergent decolonizing methodology though it has long been used by Indigenous cultures: A conversation. In Indigenous cultures, oral language and storytelling are one of the oldest traditions. In keeping with the topic that is explored, Tewa scholar, educator, and artist Gregory Cajete and eco-educator Dilafruz Williams raised in India have come together to share through conversation the nature of eco-aesthetics, metaphor, story, and symbolism in Indigenous thought presented in Cajete's writings of three decades. Our conversation method aligns with Indigenous worldview and upholds its relational significance. We discuss aspects of the Indigenous mythopoetic tradition as part of the traditional education practices of Indigenous cultures. We draw upon our lived cultural experiences and professional practices to elaborate upon the rich use of metaphor, story, symbols, and art to convey notions of eco-aesthetics in the teaching and learning process and the education of children. Our goal is to produce new levels of insight as we engage in this dialogue. Exploring the environmental, mythic, visionary, artistic, affective, communal, and spiritual dimensions of Indigenous education, we conclude the chapter with a discussion of how Indigenous ecological thoughts may be eco-aesthetically symbolized through contemporary art forms to show possibilities for childhood and nature interconnected.

Introduction

> Who can tell stories, and, more particularly, who can tell stories that embody Indigenous knowledge and experiences? (Davis, 2004, p. 2)

In Indigenous cultures, oral language and storytelling are one of the oldest traditions (Archibald, 2008; Cajete, 2005; Denizen, Lincoln, & Smith, 2017; Kovach, 2017; Smith, 2013). In this chapter, we use a conversation format to discuss insights into eco-aesthetics from an Indigenous perspective, drawing upon three decades of writings, personal stories, and professional practices shared by co-author Gregory Cajete, a Tewa Indian from Santa Clara Pueblo, New Mexico. The stories are interlaced with co-author Dilafruz Williams' East Indian cultural lived experiences and practices related to ecological education and garden-based education. Since conversation and storytelling have traditionally been accepted as form of scholarly methodology for decolonizing research (Kovach, 2010a), we foreground the chapter with an explanation of this process. Next, we explore the use of the term *Indigenous*. We highlight the significance of *metaphor, myth, storytelling, and symbolism* as holistic and integral to life from an Indigenous perspective (Cajete 1993, 1994, 1999, 2001, 2005a, 2015, 2017). Although discrete sections are enlisted to discuss these concepts, there is much overlap among them. While we touch on critiques of modernity and modern decontextualized education (Williams & Brown,

2012), in this chapter, we share our aspirations for insights that can be gained from a relational ontology (Cajete, 1994; Feldman, 1999; Porsanger, 2004; Smith, 2013), to guide eco-aesthetic education. Although the academic trend is to accept the term "Anthropocene," we wish to move away from its colonial underpinnings and acknowledge that Indigenous Peoples of the world have had cosmologies that shaped alternative ways of being and living sustainably for millennia. The stance taken is one that elaborates upon and explains Cajete's depth of experience as an artist, writer, and educator, to show the interconnectedness of childhood and nature. (We have chosen to not heavily self-reference Cajete's work in the text and encourage the readers to review his original works listed in the References.)

In *Conversational Method in Indigenous Research*, Kovach (2010b) explains the use of conversation and story as legitimate forms of research that honors and upholds this process as a means of sharing Indigenous knowledge. She explains:

> Indigenous knowledges comprise a specific way of knowing based upon oral tradition of sharing knowledge. It is akin to what different Indigenous researchers, the world over, identify as storytelling, yarning, talk story, re-storying, re-membering (Thomas, 2005; Bishop, 1999; Absolon & Willett, 2004)... I refer to this same approach as the conversational method...[which] is a means of gathering knowledge found within Indigenous research. The conversational method is of significance to Indigenous methodologies because it is a method of gathering knowledge based on oral story telling tradition congruent with an Indigenous paradigm. It involves a dialogic participation that holds a deep purpose of sharing story as a means to assist others. It is relational at its core. (Kovach, p. 40)

Antoine (2017) furthers the cause for decolonizing research: "The complex, dynamic, and multifaceted aspects of research mean there are many opportunities to raise one's hand when research strays too far from including Indigenous voices and knowledges," she writes (p. 114). She calls for "an activism beyond a simple nudging to encourage our colleagues to put an Indigenous agenda front and centre when it comes to researching Indigenous peoples, nations, and communities," (Antoine, 2017, p. 118). Similarly, Denizen and Lincoln (2014), Kovach (2009, 2017), Kovach, Carriere, Montgomery, Barrett, and Gilles (2015), Smith (2013), and others have argued that conventional research and academic scholarship have ignored and discounted the customs, knowledge, and perspectives of Indigenous communities resulting not only in marginalization but also omission of Indigenous relational methodologies. Smith (2013) challenges the perceived observational neutrality of Western research that is the norm of the academy. In making a case for storytelling as legitimate research methodology, Kovach (2010a) counters the often inadmissible methods of oral histories and storytelling, and the ignoring of authentic voices of the Indigenous peoples. She reminds us that production of knowledge and academic inquiry are political. For Smith (2013), "stories are not entertainment, they are power," (p. 92). If research were undertaken through decolonizing eyes, then Indigenous cultures would be honored and Indigenous agenda and voices would be at the front and center of scholarship. To decolonize research, we need to "push the academy," urges Antoine (2017), by confronting the norms and conventional research practices:

> Researchers rely on epistemologies and ideologies that legitimize particular ways of understanding the world and what counts as knowledge. What is perceived to be legitimate knowledge is determined largely by a small and relatively homogenous group of people who form the academy. (p. 116)

However, Indigenous experience and knowledge, "emerge from centuries of survival strategies and cultural systems that have sustained Indigenous communities, whether in pre-contact societies negotiating survival with each other, with the land, and with ancestors," she claims (Antoine, 2017, p. 116). Our attempt in this chapter is to provide an Indigenous approach to sharing knowledge where the relational dynamic between the authors is central to the content that emerges. As Kovach (2009) writes, while "a decolonizing perspective may provide a critically analytical framework with which to identify the power dynamics of a research problem, an Indigenous perspective supports a relational conceptual model that moves beyond problem identification to action" (p. 16). The nuances of our own place-based lived experiences are deliberately interwoven into the text, since "without the grounding of place, knowledge becomes trivialized and fragmented into bits and pieces of memorizable waste," (Kincheloe & Pinar, 1991, p. 5). In taking an unusual approach for this *Handbook*, we are taking a risk. We agree with Kovach (2009) that "current scholarly writing on Indigenous Knowledges takes place with academic sites that are not yet free of colonial narrative" (p. 79). Having a conversation with each other, we hope to produce "new levels of insight" (Feldman, 1999). In exploring together and sharing stories, our intent is to come to an understanding of ecological aesthetics. However, following the proposition of Kincheloe and Steinberg (2008), we are engaging in dialogue, not seeing ourselves as saviors. We begin our conversation with situating what we mean by the Indigenous.

Situating the Indigenous

Dilafruz Williams: You have written extensively about Indigenous education and ecology for the past 30 years. As a Tewa Indian artist and educator from Santa Clara Pueblo, New Mexico, in your writings, you honor the foundations of Indigenous knowledge in education. You do so by speaking specifically to your lived experience. I particularly admire your acknowledgment upfront in your writings that your narratives do not presume to be an "objective" treatise, but rather, a culturally contexted and "subjective" perspective of Indigenous ecological relationship (Cajete, 1994, p. 17). As a Pueblo Indian, and specifically as an educator and an artist dedicated to environmental issues, could you first explain what you mean by "Indigenous?" Why do you capitalize the term in your writings, as do several Indigenous scholars including Margaret Kovach (2009, 2010a)? Also, could you elaborate on its relationship with various other terminologies such as Native, Native American, and Indian American and why you choose to use the term "Indigenous"?

Gregory Cajete: Here, it would help to situate myself. I am Tewa from Santa Clara Pueblo in New Mexico. My ancestors have lived in this region of the

Southwest for over 10,000 years, cultivating ways of life through interacting with this landscape. Relationship to land is predicated on history and interaction with place. By being rooted in this place, we developed a sense of being. We were immersed in growing food, collecting seeds, nurturing plants, all the while tied to the natural landscape. Growing up in that context, you are influenced by the soils, the elders, the communities. As a Tewa Indian, I grew up directly involved with and nurtured by my extended family and land that gave me a sense of generational, communal ties to place. I had authentic, intergenerational experiences and a sacred orientation to place (Cajete, 1994, 2000).

While these terms have been debated by Native scholars, I use the more inclusive, generic, and capitalized term *Indigenous* as an honorific terminology for the many traditional groups of peoples who have been identified with a specific place or region for millennia and whose cultural traditions continue to reflect an inherent environmental orientation and sense of sacred ecology derived from the long-term relationship with place (Cajete, 1994, p. 83). I use the general term *Indigenous education* to refer to the most inclusive description of culturally based forms of education that are not primarily rooted in modern Western educational philosophy and methodology (Cajete, 1994, p. 14). Another term such as *American Indian* is used when referring to the Native Indian people in the Americas with their specific histories and cultural traditions. The term *Native American* refers to the precolonial Indian inhabitants of the Americas. I use the term *Native* to refer to those who identify themselves with an Indigenous heritage. All the terms mentioned are capitalized to honor the peoples. The United Nations Declaration on the Right of Indigenous Peoples (United Nations, 2007) recognizes Indigenous peoples across the globe as inheritors and practitioners of unique cultures distinct from the dominant societies in which they live at present. For me, *Indigenous* is a preferred, more inclusive, term though I do refer to my own stories also as a Native American.

Dilafruz Williams: Exploring the interconnectedness of nature, culture, and aesthetics and initiation/education of children, from an Indigenous perspective, is our main task. First, let us discuss how being, reality, and knowing are conceived and interrelated? Using a decolonized framework, how do we know the world (Kovach, 2009)? As Caxaj (2015) reminds us, "The most familiar storied approaches to research in the academic world are based in a Western school of thought that may be at odds with, negate or minimize local Indigenous epistemologies and ontologies" (p. 1). Perhaps you could clarify what Western philosophers would call "epistemologies"?

Gregory Cajete: There is no word for *epistemology* in our language. As I have said elsewhere, there are bodies of understandings that can be said to include what this branch of Western philosophy would explore as the origins, nature, and methods of coming to know that give rise to a way of life (Cajete, 2000). Thus, for instance, there are as many Native epistemologies as there are Native Peoples. To understand how we come to know, it is useful to explore the realm of cultural ideals from which learning, teaching, and systems of education evolved (Cajete, 2000). I will use my own Native American context. Traditional Native education occurs in a holistic social milieu that upholds the importance of each individual as a contributing

member of the community; this form of education is a cultural and life-sustaining process. The learning unfolds through mutual, reciprocal relationships between oneself and one's community and the natural world. As learners participate in the life of the community, these relationships involve all dimensions of one's being. The mirroring between knowing and educating is a two-way process. Indigenous epistemologies are nature-centered and education is not separate from how one lives in community. Participating in all aspects of life is key to this education.

Dilafruz Williams: Related to this, we know that Indigenous vision for life and education is informed by *relational* ontology in contrast to modern atomistic and individualistic ontologies. For Wilson (2008), "It is not the realities in and of themselves that are important, it is the relationship I share with reality. It is not necessarily an object that is important, it is my relationship with that object that becomes important" (p. 177). These relationships are often expressed through metaphors, along with stories, myths, and symbolisms that personify this relational sensibility, as you have elaborated in your writings. In the next section, providing examples would help clarify their embodied connections.

Metaphor, Story and Symbolism

We devote this section to the themes of metaphor, story, and symbolism elaborated by Cajete in his writings. First, we examine the relationship between metaphor and symbolism and then the connections between myth and story. Indigenous storytelling engaged all levels of higher order creative thinking and imaging capacities, developing a fluency of metaphoric thinking and mythic sensibility which served Indigenous people in their understanding of their own inner psychology and maintenance of their spiritual ecology.

Metaphor and Symbolism

Consider the Southwestern Indian symbol of the humpbacked flute player, sometimes called "Kokopeli" or ant man, which is a mythological symbol that represents the bringer of seeds, fertility, sexuality, abundance, the spreading of art and culture. The Kokopeli is a natural process symbol which is "pregnant" with meaning. As such, the symbol of Kokopeli is surrounded by many myths; these myths in turn abound with metaphors representing various dimensions of the procreative processes of nature. Each of these processes is encircled by a body of psychological, aesthetic, and cultural expressions. These expressions in turn are tied to realities which are observable and which form a basis for Indigenous teaching through myth (Cajete, 2017, p. 121). Our conversation turns toward an inquiry into symbols and examples of metaphors that guide learning and living.

Gregory Cajete: The use of metaphor as a teaching tool is an ancient strategy that has been adopted by virtually all the great teachers of human history. That it is an integral part of storytelling and mythology reflects the great capacity of metaphor as

a means for conveying highly abstract concepts. Allegories, parables, riddles, visualizations, symbols, poems, rituals, and myths all provide specific expressions of metaphorical thinking. Metaphors are also highly flexible in their uses and can be adapted to virtually all cognitive levels, from child to adult. Our metaphors show the depth of relationships humans have with nature and how all beings participate in life. The most well-known phrase is: *Mitakuye Oyasin*, i.e., "all my relations" or "we are all related." I come back to this again and again as do many others. It is a Lakota phrase that captures the essence of Indigenous knowing and educating because it reflects the understanding that our lives are truly and profoundly connected to other people and the natural and physical world. Pueblo elders often remind young people to live their myths by saying, "These stories, this language, these ways, and this land are the only valuable we can give you—but life is in them for those who know how to ask and how to learn." The metaphor for this seeking is coded in the Tewa phrase: *Pin Peye Obe*, i.e., "look to the mountain!" Reconnecting contemporary Indigenous education to its mythic roots may metaphorically be viewed as looking to the cardinal mountains of thought from which our stories come and to which they return. This nature-centered understanding is reflected in how we educate. In traditional Indigenous education, knowledge is gained from first-hand experiences in the natural world and then transmitted and elaborated through ritual, ceremony, art, and appropriate technology. Education, in this sense, becomes education for "life's sake." Indigenous education is learning about life by participating and developing relationships with community – a community that includes not only people but also plants, animals, and the whole of nature (Cajete, 1994, pp. 116–119).

Hah oh is a Tewa word sometimes used to connote the process of learning. Its closest English translation is to "breathe in." *Hah oh* is a shared metaphor describing the perception of traditional Native teachings – process of breathing in – that was creatively and ingenuously applied by all tribes. While we do not have a word such as eco-aesthetics, as a whole, our traditional education revolved round experiential learning (learning by doing and seeing), storytelling (learning by listening and imagining), ritual/ceremony (learning through initiation), dreaming (learning through unconscious imagery), tutoring (learning through apprenticeship), and artistic creation (learning through creative synthesis). The legacy of traditional Native American education is significant because it embodies a quest for self, individual, and community survival and wholeness in the context of community and natural environment.

The understanding and application of the metaphoric thought process is invaluable both as a teaching strategy and as a thinking skill which can enable students to dramatically increase their creative thinking abilities. The intimate use of metaphor is especially evident in Native American mythologies. In these mythologies, metaphor provides the key vehicle for the presentation and elaboration of cultural truths, relationships, behavior, and personality traits deemed important in particular Native American contexts. This is especially the case in myths which relate concepts and ideal relationships to the forces of the natural environment and all the living things therein. Metaphoric thinking is closely involved with the process of imagining in creativity.

Dilafruz Williams: I can link your point about the importance of metaphors to my own writing about "living soil" as a metaphor to engage children on school grounds and in school gardens in meaningful ways for learning. This requires a shift from paving with asphalt and/or manicuring with grass the vast land mass surrounding school buildings. It is in the actual process of conversion of these lots by first exposing soil that its life-giving qualities can be appreciated and from which learning gardens grow (Williams, 2012). "In sight, in mind," living soil surfaces as the frontier where nature, culture, and biology are intertwined, where humus teaches gratitude, where knowledge of de-composition becomes as significant as learning composition. As you state, Indigenous learning unfolds through mutual, reciprocal relationships formed in community and with Nature. Soil is home to plant, animal, and microbial life and is vibrant life itself, thus making it an exquisite entry point into teaching about relationships by breaking down ontological barriers that divide nature from culture, humans from nonhumans, and food from soil (Williams & Brown, 2012). A dynamic food web, living soil, I believe, exposes the fallacy of mechanistic understandings of life and calls upon us to re-member ourselves as part of the biotic community (Williams, 2012, 2018). Human cultures have had historical, spiritual, and sensual relationships with soils (Kumar, 2002; Shiva, 2008). Thus, paving over soil alters the human experience and psyche in deep ways. Terms such as *earth* and *ground* – while some of the oldest in human language – are etymologically related to *soil*. In addition, words such as *humus, humility,* and *humanity* are associated linguistically. Soil is intimately connected with human culture and history (Hyams, 1976; Montgomery, 2007). Through soil, we learn about the sacredness of life, as taught by diverse revered texts such as the Gita or the Bible. As a living entity, soil invites us into kinship and serves as more than a mere growing medium. Soils are a web of relationships, heaving with life.

Gregory Cajete: Indigenous people, in every place they lived, found ways to address these questions of survival and sustainability in profoundly elegant ways. They thought of their environments "richly" and in each environment they thought of themselves as truly alive and related. As I mentioned earlier, "All My Relations" (*Mitakuye Oyasin*) is the metaphor used by the Lakota in their prayers. It is a metaphor whose meaning is shared by all other Indian people. Its shared meaning stems from the fact that it is a guiding principle of American Indian "spiritual ecology" reflected by every tribe in their perception of Nature. For it is at once a deeply spiritual, ecological, and epistemological principle of profound significance. Guided by this metaphysical principle, American Indian people understood all living and nonliving entities of Nature as having inherent meanings which were important to honor. Based on this understanding, they symbolized their relationship to plants, animals, stones, trees, mountains, rivers, lakes, streams, and a host of other living entities. And through the seeking, making, sharing, and celebrating of these natural relationships, they came to perceive themselves as living in "a sea of relationships." In each of the "places," they lived they learned the subtle, but all important, language of relationship. It was through such a mindset, tempered by intimate relationships with various environments over a thousand or more generations, that Indigenous people accumulated and applied their ecological knowledge (Cajete, 1994, pp. 74–77).

Dilafruz Williams: I am reminded here of the significance of the "metaphoric mind" in your work.

Gregory Cajete: The metaphoric mind is the facilitator of the creative process; it invents, integrates, and applies the deep levels of human perception and intuition to the task of living. Connected to the creative center of nature, the metaphoric mind has none of the limiting conditioning of the cultural order. Its processing is natural and instinctive. It perceives itself as part of the natural order, a part of the Earth mind. It is inclusive and expansive in its processing of experience and knowledge. It invented the rational mind, and the rational mind in turn invented language, the written word, abstraction, and eventually the disposition to control nature rather than to be of nature. But this propensity of the rational mind also leads to the development of anthropocentric philosophy and of a science that would legitimize the oppression of nature, its elder relative, the metaphoric mind.

Dilafruz Williams: Indigenous knowledge is couched in the intangible quality of being in relationships, as you explain. Indigenous scholars Caxaj (2015), Kovach (2009, 2010a, 2017), and Smith (2013) are particularly critical of research and narratives that are based in Western schools of thought whose assumptions about the nature of knowledge are often different and devoid of context that you, too, have pointed out. Caxaj (2015) states that when the assumptions about knowledge "originate in settler/colonial practices," that knowledge is incommensurable with several Indigenous standpoints" (p. 1). Similar to your viewpoint, she explains, "a focus on human agency on the world may construct a dichotomy of human and nature that is contrary to Indigenous knowledges that champion the interconnectedness and the relational aspect of the universe" (Caxaj 2015, p. 2). Congruent with your position and my own upbringing in India, Indigenous ontology of humans is manifested in a sacred relationship with the natural environment, one that is intimate and place-based, with knowledge and understandings passed from generation to generation. Taking this thought further in the next section, you can elaborate on your writings regarding the power of myth and story in the educational legacy of Indigenous peoples.

Story and Myth

Story is a primary structure through which humans think, relate, and communicate. We make stories, tell stories, and live stories because it is an integral part of the way of being human. Myths, legends, and folk tales have been a cornerstone of teaching in every culture. These forms of "story" teach us about the nature of human life in all its dimensions and manifestations. They teach us how to live fully through reflection on, or participation in, the uniquely human cultural expressions of community, art, religion, and adaptation to a natural environment. The stories we live by actively shape and integrate our life experience. They inform us, as well as form us, through our interaction with their symbols and images. Stories are "congruent with the relational dynamic of an Indigenous paradigm" (Kovach, 2010b, p. 43). In this section, we dialogue about this significant aspect of education and learning.

Dilafruz Williams: I was born and raised in India, where my parents and community practiced and lived the oral tradition. As children, my siblings and I were not read to at home; instead, we were told stories orally, often passed on intergenerationally. Stories had tremendous evocative power. This reliance on oral storytelling fascinates me as I look back, since I also had formal schooling influenced by the British colonial legacy with English as the medium of instruction and text books that were British adoptions. Yet, my fundamental beliefs and values were carved through the daily rituals of Indigenous myths that encouraged imagination. Sacred rituals, myths, and stories were at the core of how one form of learning took place, even as I was torn between two cultures: one sort of emergent with its "forward" Western pull, another deeply embedded in knowing the inner self through place and a sense of sanctity for all life. I was taught to seek meaning from nature as she was considered to be a wise teacher. We "operated" under a different cosmology in traditional culture, where spirit and materiality were inseparable; humility rather than human arrogance was the norm. There was clearly a different ontology guiding how we lived and learned even as we were ensnared by the modern monoculture of decontextualized and homogenized education that formal schooling offered. Analogous to my experience growing up, in much of your writing on Indigenous education, you discuss the role of ritual, mythology, and the art of storytelling as a means for cultivation of relationship to one's inner self. In what practical ways do these encourage children and youth to "trust their natural instincts, to listen, to look, to create, to reflect and see things deeply, to understand and apply their intuitive intelligence, and to recognize and honor the spirit within themselves and the natural world" which, as you state, are critical to Indigenous understandings?

Gregory Cajete: As an integral part of the teaching/learning process, serious consideration for myth and story is rarely given in most modern educational contexts. Yet children thrive on the mythical perspective, and there is evidence that the expression of childhood creativity is primarily facilitated by a mythological perspective. Myths mirror truths through a unique and creative play on untruths and imagination. Within traditional Native American contexts, myth and storytelling are regarded as tools toward true understanding. They are a primal way of presenting realities and truths. Models of behavior, the significance of ritual, the basic realities of human existence, and natural creative processes are presented in this form of coded communication. Storytelling and experience form the foundation for much traditional Native American learning and teaching. Stories give focus to and clarify those things which are deemed important. Experiencing through watching, listening, feeling, and doing gives reality and meaning to important Native American cultural knowledge. Combining story with experience, Native Americans are able to achieve a highly effective approach to education, basic to life (Cajete, 1994, pp. 116–118).

Myths perform four basic functions. The first is to kindle and represent a sense of awe combined with the realization of relatedness of human beings to the natural world and the universe. The second is to represent or relate a mythical history of creation, how things came to be, and how a pattern of relationship or a perspective of the natural world was first established. The third function lies in the structuring and

representation of symbolically coded cultural knowledge. The fourth function revolves around the development of imagination and representational thinking as it involves living a myth through its reenactment and application of its precepts (Eliade, 1963, pp. 18–19). Through the process of telling stories, skills in listening, thinking, and imaging are creatively molded. Through experiencing, the skills of knowledge application, observation, and experimentation are enhanced. Myths offer a great diversity of expression among different Native American groups. Myths that have survived the test of time are often those whose message is both immediate and timeless, eternal realities as true in the present as they were at the creation of the myth. Myths can express their meanings through a rich and creative use of language in an oral tradition through the art of a storyteller.

Because many Native American myths relate the learner to paradigms of proper relationship to plants, animals, and all of nature, as well as to the consequences of a poor relationship to nature, they provide a place to begin a greatly humanized discussion of the general areas and underlying assumptions of modern science. Myths are themselves a holistic form of communication. They appeal not only to the intellect and imagination but also, through their enactment in song, dance, theater, oral recitation or art, to the entire human capacity for experience. Through myth, the Native American cultural relationship to the natural world is made to live in both mind and heart. In addition, myths provide a vehicle for explaining metaphysical realities and mindsets encountered that are extremely difficult to discuss or explain through any other means.

The importance of the mythological perspective is multidimensional. For instance, at one level myth, through the oral traditions of Native Americans, provides a way of communicating about nature that has seldom been surpassed by other modes of communication. Myths are used to transmit generations of "understandings" concerning the natural environment. Myth provides a way to explain and think about natural phenomena which goes beyond the mere physical description of the phenomena, a way to describe nature that combines actual observable physical characteristics with affective, psychological, and cultural perceptions. Northwest Indian cultural myths relate how a mythological being first taught them how to fish, the nature of the first fishery, and the way the people must relate to fish in order that they might perpetuate themselves and the fish upon which they are so closely dependent. Inherent in all Native American myths concerning the natural environment is a philosophy and the ethics guiding Native American behavior toward nature. The understanding, respect, and conservation of natural resources, the land and all of life, is reflected throughout Native American myth (Hughes, 1984, p. 5). For instance, there are Native American myths relating to the Earth Mother concept: These myths are universal among Native American cultures and include "Changing Woman" (Navajo), "Spider Woman" (Hopi), "Thinking Woman" (Keresan), "Sedna" (Inuit), and a host of other representations. Myths also provide a way to compare, contrast, or integrate two ways of perceiving natural realities, and in doing so stimulate real appreciation of the aesthetics of life. In the telling of stories, the content of myth and everyday reality are integrated within the content of the learner (Cajete, 1994, p. 196).

Dilafruz Williams: Oral traditions, such as mine and yours, have used stories for millennia to evoke a sense of place and a deep understanding of interconnectedness of all life. This also means connecting past with the present and encouraging imagination. Writing about orality, Kovach (2010a) explains that the conversational method and storytelling are used as a means for transmitting knowledge by upholding the relational and collectivist Indigenous traditions (p. 42). In India, too, Indigenous communities similarly pass on rituals, myths, stories, songs, dances, and drama, from generation to generation, orally. Knowledge of sacred groves, mangroves, or medicinal plants that were endemic was shared with a view to preserve health of place and people. There really was no universal formula on how to live unlike the present consumerist messages for conformity that pervade our lives. Diverse contexts required diverse responses and attentiveness. Interestingly, as Luisa Maffi (2001, 2005, 2007) and others have argued and shown, biological diversity and cultural and linguistic diversity are interlinked. We need to recognize and value the importance of biocultural diversity, to life. The cries of ecosystem fragility also call for a recognition of the harm of homogenization to cultural resilience. The problems of loss of diversity in language and perpetuation of monoculture emanate from dominant Western stories influencing our personal mind-sets and lives. We need to bring life to the center of the educational enterprise at an early age.

Gregory Cajete: Yes, the homogenized and sanitized stories of western monoculture are becoming pervasive throughout the world. In contrast, Indigenous storytelling engaged all levels of higher-order creative thinking and imagining capacities. Stories helped with developing fluency of metaphoric thinking and mythic sensibilities. Stories kept listeners aware of the interrelatedness of all things, the nature of plants and animals, the earth, history, and people's responsibilities to each other and the world around them. Storytelling, like myth, always presented a holistic perspective, for the ultimate purpose is to show the connection between things. Through the cultivation of hearing, understanding and insight were enhanced by the stimulation of the imaging capacity of the mind. Storytellers fulfilled a vital role in the continuity of not only the tribal culture, but of the mindset concerning people's relationship to the natural world. In this respect, the storyteller was the philosopher-teacher of tribal America. That the storyteller earned widespread distinction in Native American cultures is no accident. Traditional Native American storytellers were masters of the art of making stories real through a variety of rhetorical techniques, creative dramatization, and the skillful use of metaphor. The use of artistic symbolization, song, and dance were commonly employed by traditional Native American storytellers to add flavor and emphasis to their stories (Cajete, 1994, pp. 138–141).

In many respects, the role played by the storyteller is the forerunner of the more formalized and eclectic role played by the modern teacher today. Whether teachers realize it or not, every time they teach they are echoing an aspect of the storyteller's art. Storytelling, whether about science, history, social science, language, literature, or art, is an essential dimension of the teaching process. Teachers must continue to learn about and express their innate potential in this area. All stories have multiple

levels of meaning ranging from the very basic and straight forward to the complex and the metaphoric. Stories, especially those of the mythic variety, present philosophical, psychological, and ecological truths simultaneously. Such stories provide opportunities to analyze, explore, and develop new perspectives about Native American cultural knowledge of the natural world. There is an art to both the telling of a story and the facilitation of an experience. Both take practice. *Dilafruz Williams:* Our challenge is to give legitimacy to traditional stories. Margaret Kovach explains: "The nuances and complexities of an Indigenous paradigm may not be fully understood (or viewed as legitimate) by all members of the academy, but few would openly contest, at least in public spaces, that an Indigenous paradigm exists" (Kovach, 2010a, p. 42). In the context of contemporary education, we have to ask what metaphors are being used as a basis to shape and reform policies and drive educational practices? Often, market place analogies and business models are favored for their greater efficiency; these models are themselves predicated upon lifeless *mechanistic* metaphors that guide schooling as complex machines. Modernist educational orientations are grounded in: de-contextualization of learning, loss of curiosity for nature and its wonders, acceptance of mechanical and industrial scale, homogenization of curriculum and learning, privileging of abstract ideas, stimulation of only certain senses such as eyes and ears, and perpetuation of individualism and autonomy; these are incongruent with living systems. Founded upon mechanistic metaphors, contemporary educational reforms imagine schools as no more than complex machines and overlook the value of life itself. What is sorely missing is an understanding of the power of life-enhancing guiding metaphors, myths, and stories, as you have shared. How might their significance for connecting with nature and life be acknowledged?

Gregory Cajete: Creating a classroom environment in which the Indigenous foundation of storytelling and story-making might once again flourish is a creative challenge whose potential benefit far outweighs the effort required to bring it into being. Storying is a natural part of all learning and what is required is learning how to facilitate and guide its development in students. Indigenous education has always been characterized by a process of "co-creation" between teachers and students. The enablement of storytelling within the classroom is indeed a "co-creation" in which teachers and students learn the discipline of storytelling through constantly finding, or making, stories and telling them. Empowering the creative process of storying in both teacher and students requires nothing more than once again becoming conditioned for it. Just as a distance runner conditions themselves for running by increasing their distance a bit each month and maintaining a proper diet and a balanced schedule of work and recreation, teachers and students can condition themselves for ever-greater capacities for storying. The following groups of activities are some of the possible ways to bring the creative conditioning for Indigenous storying back into being. First, creating opportunities to be in Nature and partake directly from the natural sources of life and creativity; gaining a perspective of past, present, and future through selected stories of one's tribe and place; and recognizing and honoring our "teachers" that are with ourselves, in our relationships with others and the natural world. This triad represents the development of orientations and mindsets

which facilitate the deeper and more creative exploration of story. Second, cleansing our vision through letting go of preconceived notions and other personal or social attitudes that we identify as being obstacles in our creative process of storying; exercising our creative imagination through creating and discussing all kinds of stories; and learning to envision a story from all sides to gain an understanding of it in all its dimensions and practice the skill of thinking "comprehensively." This triad represents the basic kind of preparations needed to enhance the ability to comprehend a story with greater levels of clarity. Third, learning how to apply the lessons and understandings which come from storying to other learning and life experiences; learning the techniques of Indigenous storying making, story giving, and story getting all of which are centered in the social and interpersonal realm of community; and learning the communicative art of performing story in a variety of forms and settings which is the foundation of the participatory and celebratory experience of story. This triad forms the foundation for applying stories in an integrated experience of learning and teaching which is inclusive of other forms of art and educational content (Cajete, 1994, pp. 140–141).

Dilafruz Williams: In India, too, myths are grounded in symbolic images that have profound meanings. The lotus flower, for instance, symbolizes purity. One can think of similar symbols in the west, the most common being a dove symbolizing peace. The concept of "performing story" you mentioned earlier is a culturally specific ritual that can be linked with teaching and learning about culture. Among the Hindus, there are devotional dances, for instance. The celebratory aspect of stories connects well with our topic on eco-aesthetics. We can elaborate on this further in the next section on rituals and especially highlight what you mean by mythopoetics.

Mythopoetics and Ritual

Thinking and communicating "poetically" through the structures of myth is a natural expression of human learning. The tremendous influence of mythopoetic traditions becomes apparent when one tracks the rich array of oral forms used by traditional societies to their ancient sources. These traditions depended upon the spoken word for communication. Indigenous peoples through their use of various mythopoetic forms of communication applied strategies and orientations to learning that are important to revive and nourish in today's education. Mythic poems were ritualized, performed, sung, or recited using a particular system of rhythmic structure which in turn required the application of creative and imaginative thinking processes and learning capacities. In this section, our conversation turns mythopoetics and rituals.

Dilafruz Williams: In the opening ceremony at the *Carleton University Institute on the Ethics of Research with Indigenous Peoples*, John Medicine Horse Kelly (2016) reminded all that "(f)or a long time society has asked us to learn their way. Now the time has come for you to learn our way." Rituals have been a significant aspect of my upbringing in India where we were raised to become conscious about the more-than-human world, in fact a cosmocentric world. Could you elaborate on rituals and symbolisms with some examples of how they encourage learning the

Indigenous way and developing a sense of eco-aesthetics? Given the disembedded and disembodied modern sensibility, we need to reconceptualize a new ontology, one where children and adults are seen as relationally constituted. Indigenous ontology provides insights here. The hierarchical and dominant role played by modern humans, as we have stated, arises from the fact that they are disconnected from nature. We need an alternative language, a different ontology. We need to understand the links among cultural diversity, linguistic diversity, and biological diversity as these are intricately intertwined. The challenge is that Indigenous perspective and knowledge systems cannot simply be imported into Western ontologies; they are highly contextual with integration of learning and living.

Gregory Cajete: The complex rituals associated with the growing of corn and the coming of rain in Southwestern Pueblo groups illustrate not only an ecological ethic, but also an understanding of the Pueblo relationship to the natural entities and the land itself. Every tribal group evolved their knowledge of nature around the central theme of humans as part of their environment, not its master. The so-called totems and spirits with which all Native Americans symbolized their relationship to their world have often been misunderstood. In reality the ecological relationships, the sacredness of nature, and the constant "seeking of life" are underlying mindsets focused upon in Native American ritual. Fetishes and other paraphernalia which are present in many Native American rituals were highly respected because they were symbols that represented the sacredness of the various forces of nature (Cajete, 1994, pp. 153–160). In general, Native American concepts of nature were not meant as explicit explanations of natural processes as are concepts in Western science. Rather, concepts such as animal or plant spirits, benevolent or malevolent forces of nature, and the mythological or ritualistic symbolic representations of nature were symbolic representations of essences and relationships which Native American groups have come to understand through generations of experiences within a given natural environment. These concepts and symbolic representations reflected a highly evolved resonance, a feeling for the natural environment which Native Americans shared so intimately that it was commonly accepted that it was possible for humans and other living and natural forces to communicate with and affect each other through their interdependencies and reciprocal relationships (Hughes, 1984, p. 28). As Hughes (1984) explains: "The Indian view of nature comes from deeper inside the human psyche than mere rational thought or intellectual curiosity, although Indians certainly have these too. But Indians regarded things in nature as spiritual beings, not because they were seeking some explanation for natural phenomena, but because human beings experience a spiritual resonance in nature" (p. 16).

Because of this resonant relationship with nature, Native American tribes developed ritualistic expressions around the recognition, celebration, and evocation of mutualism with the natural environment. Whether it was a Pueblo "Rain Dance," the hunting of game, the planting of corn, or the healing of the sick, Native American rituals sought to maintain the harmony of these relationships and through this "seeking of life" gained a glimpse of the sacred whole of which they were a part. Native American ethics concerning the natural environment were geared toward the preservation and perpetuation of all life. Everything in nature was imbued with a

spirit which was a part of the "Great Mystery" and, therefore, was also a part of oneself which had to be respected (Hughes, 1984, pp. 2–3). The "Great Mystery" breathed life into everything; therefore, all natural phenomena had the power to affect everything else. This was especially true for such elements as wind, water, fire, lightning, the sun, moon, stars, and certain birds, animals, and plants. In addition, everything in nature was viewed as having intrinsic value and therefore could not be exploited simply for the sake of exploitation without dire consequences. Traditionally, this understanding of mutual interrelationships was not merely a philosophical concept. Native Americans lived this interrelationship in their adaptation and interaction with the natural environment. In short, Native American cultural sciences were sciences based on experience and a high level of sensitivity and intuitive insight which is only now being explored in modern Western scientific philosophy.

Dilafruz Williams: In the context of eco-aesthetics, how do indigenous mythopoetic traditions provide guidance for our modern times?

Gregory Cajete: The tremendous influence of mythopoetic traditions on the development of global childhood education becomes apparent when one tracks the rich array of oral forms used by traditional societies to their ancient sources. These traditions depended upon the spoken word for communication rather than the visual word which dominates modern education today. Globally, Indigenous Peoples, through their use of various mythopoetic forms of communication, applied strategies and orientations to learning that are important to revive and nourish in today's global education (Rothenburg, 1985). Modern people, for the most part, have become "mythically blind" and suffer all the consequences stemming from such a "handicap" because their natural poetic sensibility has been "schooled" out of them.

Thinking and communicating "poetically" through the structures of myth is a natural expression of human learning which has been evolving for the last 40,000 years. Mythopoetic orientations are apparent in most children before they learn how to read. Indeed, children at this "illiterate" stage of their life show amazing metaphoric thinking and storying skills reflecting their natural poetic nature. In modern education's mad dash to make children (and for that matter Indigenous people) literate, it fails to recognize or honor a powerful dimension of a natural human way of knowing and understanding. The hidden message is "stop being children and stop being Indigenous." It is ironic that today so many modern people lament the loss of this primal human sensibility and strive in so many ways to recapture it through participation in some "thing" creative, Indigenous, or mythological (Cajete, 1994, p. 131).

Print, literacy, and the *written* story are very recent developments in human history – even in the history of Western societies. They, never-the-less, evolved from "illiterate" mythopoetic roots which cannot be denied in spite of the negative connotation that Western "civilized" cultures have promoted with regard to "illiteracy" as a sign of being uneducated, uncivilized, and primitive. The study and honoring of oral traditions and "orality" in children offers essential insights into the nature of natural learning. The human "oral" orientation to education offers techniques as well as windows into the world of Indigenous education. A better understanding of oral-based learning revitalizes old yet highly effective techniques

for learning while opening up new dimensions which have been forgotten or have become dormant with the development of the *printed* word, *literacy*, and modern education's focus on making everyone *literate* (Egan, 1987).

Dilafruz Williams: What then was the nature of the mythopoetic tradition and why must it again become an important element of childhood education?

Gregory Cajete: Mythic poems were performed, sung, or recited using a particular system of rhythmic structure which in turn required the application of a different set of thinking processes and developed a different kinds of learning capacities than today's modern schooling. The Aztec tradition of "flower and song" is one Indigenous example of a mythopoetic tradition of education in which teaching, learning, and reflection were founded upon chanted stories, poems, or prayers. The Aztec poet, philosopher/priest, would compose poetic storied chants or teach the divine songs, the mythic tales, and poetic verse which embodied the essential thoughts and content of Nahuatl religion and philosophy. He would then chant these stories and poems to students who would reflect on or internalize the essential messages which they contained. Later, as they became experienced in this oral system, students would compose poetic chants of their own to present to each other and their "tlamatinime," their poet-teacher. In essence, the "flower" was the thought, the feeling, the insight, the wisdom, and knowledge that was considered of importance as a teaching. The "song" was the vehicle which transported and transformed the "flower" of knowledge and made it live through the breath of the chanter and in the hearts of the listeners (Portilla, 1963, p. 140).

Indigenous mythopoetic traditions are essentially educational. Indigenous mythopoetic perspectives were founded upon an awe for the "*Great Mystery*" (that unknown spirit that permeates and animates everything, everywhere); the development of a strong, wise, and pure heart; an abiding respect for one's tribe, traditions, and law; and deep sense for the relationships and connections between all things. Tribal myths transferred these basic teachings through enlivened images and metaphors which embodied an expansive view of people in relationship with each other and a multiverse full of potential and possibility. Tribal myths encompassed every "thing" within a context which was spiritual yet irreverent, serious yet humorous, logical yet illogical. The messages conveyed through these stories had the power to heal and bring resolution to conflicts because, at its core, *poetry* illuminates, transforms, and mirrors the heart and soul of both the individual and the People. The presentation of these messages went beyond just words to include sounds, dance, music, games, gesture, symbol, and dream. In this way, thoughts, teachings, and emotions were amplified. Every word, every act, had meaning and energy. This allowed specific Tribal myth and poetry to become part of a larger context of situation and human expression, thereby making the presentation of myth and poetry a true expression of the "sacred" breath within humans and all living things. The mythopoetic realm of teaching and learning is not a relic of the past as might be construed from the designation of the arts and theater in the curricula of so many American schools. Rather, it is an educational necessity for enabling the kind of "new" imagination so desperately needed in today's sterilized and homogenized approach of modern education. Modern educators must admit to the fact that

non-European, traditional cultures around the world exhibit a level of complexity and sophistication of thought which equals and many times surpasses modern perceptions of what it means to educate. Many ingrained modern biases and preconceptions of the "primitive" which have been conveyed and conditioned through the hidden curriculum of modern education must be examined. This is especially true of the mythopoetic traditions of Indigenous America. The negative connotations associated with the word "primitive" must give way to a more enlightened understanding of the complexity and richness of "primal" traditions of myth, poetry, and storytelling.

In contrast to the usual conditioned modern perceptions of "*the primitive*," oral traditions and Tribal art forms are as individually oriented as they are collectively determined and contexted. It is a fallacy that traditional cultures and their oral traditions do not change, or that creative self- reflection is not a part of the traditional formula. I am not naive to think that orality alone defines Indigenous thinking. Indigenous oral traditions have always been integrated with drawing, arts, and practical education. It is the perpetuation of injustice to think that Indigenous people have not reflected equally as hard about the nature of language, myth, art, culture, aesthetics, ethics, and philosophy as Western scholars. If anything, the mythopoetic traditions of Indigenous people reflect that in reality there is no such thing as "primitive" in the way in which Western education has traditionally conditioned people to perceive it. The tendency of Western education to divide myth and poetry from music, dance, and relationship to nature, community, spirituality, history, and even politics reflects an illusion of Western thinking (Cajete, 1994, p. 133).

Dilafruz Williams: In the following section, we can highlight how art serves to advance creative expression.

Art and Expression

The human "need" to express through art has its roots in the deep reaches of hunter/gatherer origins. Art, as a human thinking and expressing process, is intimately connected to human consciousness. As a facet of such a "consciousness," Indigenous art presents a reality that is at once specifically unique, yet humanly universal. In addition, the process and product of Indigenous educational philosophy is intimately expressed through the various Indigenous art forms, a unique way of perceiving the world. Expression of Indigenous art presents what is inherently real about the Indigenous experience and understanding of the world – past, present, and future. Indigenous arts show the possibility, the many different "windows" from which to view the world, and each window, and the doorway which accompanies it, opens upon another possibility of human experience which has an equal level of validity. In this section, we explore these connections.

Dilafruz Williams: In your writings, you have shown how Native art is not done for mere individual expression. Rather, art such as pottery, sculpture, carving, clay painting must have context and are cultural expressions. For instance, sand-painting

is a ceremonial art tradition among many cultures, where meaning emanates from its ritualistic and performative context. In India, I grew up learning to make colorful patterns, known as "rangoli," on the earthen floor especially in courtyards. This art was not done alone; it was a collective undertaking mostly made by girls and women as a form of celebratory art, with motifs and patterns passed on from generation to generation. Rangoli is still a vibrant floor art (Tadvalkar, 2015, p. 173). If you were to visit India during certain festivals such as Diwali or Pongal, you would find the decorations widespread. It comprises often of geometric designs, floral and animal designs, agricultural motifs, or impressions of deities. Colored sand, red brick powder, vermillion, turmeric, and other natural colors and dyes are used along with the foundational white powder which is often pounded rice or wheat flour. Flower petals are also used. Usually rangoli as art captures the flora and fauna of the local region; thus, the artistic renditions are often place-specific. The art is impermanent. The materials used are compostable. But more importantly, the art of rangoli is ceremonial and ritualistic (Tadvalkar, 2015, p. 180). Art evokes deeper meanings, as you have eloquently captured over the years. Totem poles are packed with meaning. How does Native art emerge from and develop relational sensibility? In what ways does this art represent lived experiences along with "holistic view of life and cosmology through symbols that convey a deeper meaning of culture, honors traditions," as you write. And how does this relate to Indigenous peoples viewing themselves as part of nature, not apart from it?

Gregory Cajete: Traditionally, there was no specific word for "art" in Native American languages. Native American cultures viewed the creation of art as a natural way to communicate their perceptions of nature and their feelings and interrelationships with different natural entities within their environment. Familiar images within nature were incorporated into designs of Native American art. Nature provided the Native American artists with inexhaustible content for creative expression. All Native American art forms – from pottery, jewelry, and weaving, to stone sculpture and architecture – provided mediums for expressing their maker's perception of natural phenomena. Clouds, birds, animals, fish, wind, water, sun, moon, insects, plants, and spirits represented mutual relationships among all things. Each traditional art form required the learning and mastery of particular types of technology. For instance, certain forms of pottery such as that of the Rio Grande Pueblos of New Mexico require great skill and a substantial knowledge of the nature of various kinds of clays, slip and pigmentation characteristics, preparation and firing techniques. Weaving, basket-making, and architecture all required great skill and a high level of knowledge of the nature of the materials used. Expressions of "resonance" with the natural world required the application of material technology, creativity, and problem-solving skills, with the same kind of processes used to calculate, for instance, the movements of the sun and moon, the development of healing techniques, and successful hunting practices, all of which required the application of a basic understanding of natural entities.

Dilafruz Williams: We have been discussing Indigenous perspective in its own rights, not to champion it to fit into other ontologies. Given that we are addressing learning and eco-aesthetics what would you say to posthumanists? To those who

might want to indigenize the Anthropocene? How would your perspective/ontology fit with contemporary science, technologies, arts, theory?

Gregory Cajete: From my perspective, posthumanists can learn a great deal from Indigenous thought which focuses on the imperative of human relationship with and participation in the life processes of the natural world. Indigenous education must be seriously studied. Educating and enlivening the inner self in participation and resonance with the natural world is the primary imperative of Indigenous education embodied in the metaphor, "seeking life." Inherent in this metaphor is the realization that ritual, art, myth, vision, and learning the art of relationship in a particular environment is what ultimately facilitates the health and wellbeing of individual, families, and communities. Education for wholeness, by educating for a level of harmony between individuals and the natural world, is an ancient foundation of educational processes for all cultures (Cajete, 1994, p. 209).

Dilafruz Williams: You have developed a detailed foundational perspective of Indigenous education and learning, in *Look to the Mountain: An Ecology of Indigenous Education* (Cajete, 1994). Within the context of our discussions, it would be fitting next to elaborate on this perspective and how a sensibility for an interconnected view of childhood and nature might emerge.

Indigenous Education

In this section, we describe the cultural and life-sustaining process of Indigenous education as we develop insights into the community of shared metaphors and understandings specific to Indigenous cultures yet, reflective of the nature of human learning as a whole. In essence, an exploration of traditional Indigenous education is an exploration of nature-centered philosophy. Traditional Indigenous education is an expression of environmental education par excellence. It is an environmental education process which can have a profound meaning for the kind of modern education required to face the challenges of living in the world of the twenty-first century. It has the potential to create deeper understanding of the collective role as "caretakers" of a world which we as modern humans have been largely responsible for throwing out of balance.

Gregory Cajete: The legacy of the traditional forms of American Indian education, for instance, is significant because it embodies a "quest" for self, individual, and community survival and wholeness in the context of a community and natural environment. Indigenous education is really "endogenous" education, that is, it is an educating of the inner self through enlivenment and illumination from one's own being and the learning of key relationships. Therefore, the foundations for Indigenous education naturally rest upon increasing awareness and development of innate human potentials through time. Based on this orientation, American Indians and other Indigenous groups used ritual, myth, customs, and life experience to integrate both the process and content of learning into the very fabric of their social organizations thereby promoting wholeness in the individual, family, and community.

Dilafruz Williams: In your writings on traditional forms of Indigenous education, you have made a case for seven foundations of education that are intimately interrelated. You write that they relate to each other in such a way that exploration of any one foundation can guide you into the very heart of the Indigenous education experience.

Gregory Cajete: Extending the metaphor of environmental orientation and process inherent in the sacred directions to education, we may speak of seven elemental yet highly integrated kinds of thought that form the foundations on which the vehicles and contexts of Indigenous education rest (Cajete, 1994). These orienting foundations may include the Environmental, the Mythic, the Artistic, the Visionary, the Affective, the Communal, and the Spiritual. In traditional life, these foundations are so intimately interrelated that they act relativistically at all levels of their expression. In every sense, they contain each other in such a way that exploration of any one foundation can take you into the very heart of the tribal education experience. However, a complementary balance occurs in the interplay of these foundations. This balance can be illustrated by the interaction and interpretation of foundations that play within the environmental and spiritual fields of experience. An ebb and flow of interactive realities characterizes the play among these foundations of education. Dilafruz Williams: Providing an in-depth description of each of the seven elements will show how aesthetics also comes into play in Indigenous education. You have written that these elements are like the living stones, the *Inyan* (a Lakota term), that animate the expressions of Indigenous education. Here, you could highlight your observations about the sacred view of nature, and how, in your view, interrelatedness and reciprocity are essential to framing education.

Environmental Foundation

The Environmental foundation forms a context through which the tribe observed and integrated those understandings, bodies of knowledge, and practices resulting from direct interaction with the natural world. This foundation connects a tribe to its place, establishing the meaning of tribe members' relationships to their land and the earth in their minds and hearts (Cajete, 1994). To say that American Indians were America's first practical ecologists is a gross simplification of their deep sense of ecological awareness and state of being. The environmental foundation of tribal education reflects a deeper level of teaching and learning than simply making a living from the natural world. For American Indians, as with other nature-centered Indigenous cultures around the world, the natural environment was the essential reality, the place of being. Nature was taught about and understood in and on its own terms. Relationship and its expressions in all aspects of life formed the basis for a profound process of education. Based on the environmental foundation of tribal education, tribal people and their environment established and perpetuated a mutual and reciprocal relationship. Nature was used for sustenance; however, the use of material technology was elegant, sophisticated, and appropriate within the context of traditional society (Cajete, 1994).

Mythic Foundation

The Mythic foundation rests on the archetypal stories that describe the cosmology in the language and cultural metaphors of a tribe. This foundation explores the guiding thoughts, dreams, explanations, and orientations to the world. In short, this foundation represents the tribe's worldview and, through the process and structure of storytelling, presents the script for teaching, learning, and participating in the stories that guide a people. Ultimately, all education is the expression of some sort of storytelling, as we discussed earlier.

Visionary Foundation

The Visionary foundation rests on the deep psychological and spiritual experiences at the individual level that lead to or result from a tribe's practices, rituals, and ceremonies. Such practices and contexts provide a framework for individuals and groups to teach and learn through exploring their inner psychology and their collective unconscious. American Indians applied the visionary foundation to directly access knowledge and understanding from primary sources deep within themselves and in the natural world.

Artistic Foundation

The Artistic foundation contains the practices, mediums, and forms through which we usually express the meanings and understandings we have come to see. Art allows us to symbolize knowledge, understanding, and feelings through image, thus making it possible to transcend a finite time and cultural wrapping. Art itself becomes a primary source of teaching because it both integrates and documents a profound process of learning. Art was such an integral part of American Indian life that the various Indian languages have no words that translate exactly to mean Art. The closest direct translation to English refers to making or completing. The Artistic foundation also acts as a bridging and translating foundation for the Mythic and Visionary foundations. That is, the Artistic mediates the other two.

The Mythic, Visionary, and Artistic foundations form a natural triad of tools, practices, and ways of teaching and learning that, through their inter- action and play, form a fourth dimension for deep understanding of our inner being. Remembering the metaphor of the Sacred Twins, we may say that this triad of foundations springs forth from the twin that represents the teaching, learning, and innate knowledge of our inner self. It might be called the Winter Twin or the deeply inward aspect of Indigenous education.

Affective Foundation

The Affective foundation of tribal education forms a second context that contains the emotional response to learning, living, growing, and understanding in relationship to

the world, ourselves, and each other. This is the foundation in which we establish rapport with what we are learning and why we are learning it. It reflects the whole gamut of our emotion as it relates to the educational process. It is the seat of our primary motivation and the way we establish personal or group meaning for our learning. It is the foundation through which we cultivate our intention, choice, trust, responsibility, and heart for learning. And like the Artistic foundation, the Affective foundation acts as a bridge between the environmental and communal foundations. It mediates our feelings for our place and our community. For American Indians love for one's land and people have always been a primary motivation for learning and service to one's tribe.

Communal Foundation

The Communal foundation forms a third context containing the responses and experiences that reflect the social and communal dimension of tribal education. The life of the community, as well as the individuals of that community, is the primary focus of tribal education. The community is also the primary context – through the family, clan, or other tribal social structures – in which the first dimensions of education unfold for all human beings. All humans after all are social animals who depend on each other directly not only for their mutual survival but their identity. The Communal experience is the seat of human cultures; as such, there is not one thing in human life that it does not influence. The Communal experience and the inherent process for teaching and learning in tribal cultures are tied through history and tradition to some of the oldest and most instinctually human-contexted mediums of education. The structure, process, and content of teaching and learning resulting from traditional American Indian tribal and communal experience were and continue to be inherently human, highly contexted, situational, highly flexible, and informal. Learning and teaching are going on at all times, at all levels, and in a variety of situations. For American Indian tribal education, the community was and continues to be the schoolhouse.

Spiritual Foundation

The Spiritual orientation of tribal education may be considered as both a foundational process and field through which traditional American Indian education occurs. For Indigenous peoples, Nature and all that it contains formed the parameters of the school. Each of the other foundations of tribal education is exquisitely complex and dynamic contexts through which a kind of thought develops from a unique yet creative process of teaching and learning. The Affective, Communal, and Environmental foundations form the other triad of tools, practices, and way of teaching and learning that complements the understanding of the first triad. This might be called the Summer Twin or the highly interactive and external dimension of Indigenous education. In traditional American Indian life, the context in which these foundations interact is the Spiritual-Ecological, the seventh orienting foundation of knowledge

and process. It is the Spiritual that forms not only the foundation for religious expression but the ecological psychology that underpins the other foundations. A value many American Indian people share is that they must preserve their stories, languages, customs, songs, dances, and ways of thinking and learning because they sustain the life of the individual, family, and community. The stories in particular integrate the life experience and reflect the essence of the people's sense of spiritual being through time and space. For the mythic stories of a people form the script for cultural processes and experience. Culture is the face; myth is the heart; and traditional education is the foundation for Indigenous life. And all cultures have Indigenous roots that are bedded in the rich soil of myth from which the most elemental stories of human life spring.

Conclusion: Look to the Mountain

Dilafruz Williams: To conclude, our conversation leads me to my cultural reminder that myths, stories, performances, and the art are all about engaging relationally whereby we learn more about ourselves in the process. It would be appropriate to conclude this conversation with one of your art creations. Perhaps you could shed light on how this art weaves the concepts you have elaborated upon here. As well, do you have some final thoughts that can summarize the topic related to eco-aesthetics and learning?

Gregory Cajete: Environmental relationship, myth, visionary traditions, traditional arts, tribal community, and Nature-centered spirituality have traditionally formed the foundations of American Indian life. These elements formed a context for discovering one's true face (character, potential, identity), one's heart (soul, creative self, true passion), and one's foundation (true work, vocation), all of which lead to the expression of a complete life. A primary orientation of Indigenous education was that each person was in reality his or her own teacher and that learning was connected to each individual's life process. One looked for meaning in everything, especially in the workings of the natural world. All things of Nature were teachers of humankind; what was required was a cultivated and practiced openness to the lessons that the world had to teach. Ritual, mythology, and the art of storytelling combined with the cultivation of relationship to one's inner self; individuals used the family, the community, and the natural environment to help realize their potential for learning and a complete life. Individuals were enabled to reach completeness by being encouraged to learn how to trust their natural instincts, to listen, to look, to create, to reflect and see things deeply, to understand and apply their intuitive intelligence, and to recognize and honor the spirit within themselves and the natural world. This is the educational legacy of Indigenous peoples. It is imperative that we revitalize its message and its way of educating for life's sake at this time of ecological crisis (Fig. 1).

To bring a metaphoric kind of closure to our conversation, I would like to offer an image (Fig. 1) that I believe conveys the spirit of our dialogue about eco-aesthetics, learning, and the hopes for the education of all future children. As an artist, I like to

Fig. 1 *Asking*. (Painting by Gregory A. Cajete)

explore my concepts and ideas about Indigenous education through artistic images and constructions that convey the essence of an insight that I think is important. One such image is the painting that I used on the cover of my first book, *Look to the Mountain: An Ecology of Indigenous Education.* This acrylic painting is inspired by the tradition of Huichol Indian yarn painting and represents the first act in the journey toward understanding, that of *Asking*. Looking to the "inner" form of an archetypal mountain, the human form *asks for and receives understanding,* with the trickster, in the form of a spider monkey, and four *kokopeli* witnessing the vision of understanding. As the *flower and song* of the human touches the face of the Great Mystery, the human connects to a great *Rainbow of Thought and Relationship* which brings illumination and true understanding of *the ecology of relationship* and the inherent truth that *We Are All Related!*

Abstract

CineMusicking, a portmanteau of Cinéma vérité and *Musicking*, is an ecological approach to digital ethnographic filmmaking for music research and teaching in critical youth studies. The methods of CineMusicking were developed as a way of undertaking research about ecologically embedded lived personal experience. This method makes use of Gregory Bateson's work on ecology as it was developed in ethnomusicology by Christopher Small and, in a separate development, biosemiotics. The goal of this method is to explore the coupling and subsequent formation of individual consciousness and culture within a semiosphere-biosphere matrix, what I call *the matrix that embeds*.

I will show through discussion of the production of three of my original ethnographic films *Megamorphesis*, *Letters to Attawapiskat*, and *Pimachihowan*, that ecological ethnographic films made with youth can co-create an ecological aesthetic education with the potential to be deeply transformative for themselves, their schools, community, and environment.

CineMusicking · Cinéma vérité · Musicking · Biosemiotics · Critical pedagogy

Introduction

CineMusicking, a portmanteau of Cinéma vérité and *Musicking* (Small, 1998), is an approach to ethnographic film production as a form of ecological critical pedagogy. Cinéma vérité was developed by ethnographic filmmaker Jean Rouch and made possible by portable sync-sound film cameras and by "deliberate intrusion" (Heider, 2006, p. 31) into a social world by filmmakers. Musicking was formulated by ethnomusicologist Christopher Small, building on Gregory Bateson's *Steps to an Ecology of Mind* (1972). Small recognized in Bateson a new way of thinking about the study of music, one that is based in an ecological orientation. Small argued that music is not a noun, but a verb – a system – and the notion that music is a noun has gotten in the way of a proper understanding of musicking as an ecological system *within* systems. This reorientation follows Bateson's definition of ecology as the study of an organism in its environment and provides a new way of studying the role of music in youth culture. For a relational ontology of consciousness, I turn to Jean-Paul Sartre's *existentialism*, for a relational ecological ontology of the body and community I turn to biosemiotics, and for community-based method that help make explicit these implicit processes, I use Paulo Freire's *critical pedagogy*. By doing this I am able to provide a systematic framework for the filmic study of music in ecology that does not exclude either the prepersonal or the biosphere. CineMusicking forwards an ecological existentialist ontology and ethic for the production of educational ethnographic film about music cultures, and "Rouch's technique of showing people reacting to their own images has rarely been followed up in any systematic way" (Heider 2006, p. 32).). CineMusicking utilizes biosemiotics as a way of getting above the culture/nature binary, where endo- and exosemiotics joins science and social science together in a joint program with the potential to contribute a rich interdisciplinary starting point for the study of *the matrix that embeds*.

CineMusicking

The methods of CineMusicking began when trying to communicate my hip-hop research with the inner-city youth with whom I was working. After 5 years of close contact at an inner-city drop-in program, the youth no longer wondered why a professor sat among them. But I was also aware that despite my explanations, I could not communicate the uniqueness occurring in this particular hip-hop cypher. In my book, *Remix and Life Hack in Hip Hop* (2016), I explored the production of an aesthetic system that produced hip hop as well as hiphoppas. I worked with youth to write histories, interview long-time hiphoppas, to document the operation of the hip-hop cypher, and finally to theorize the production of subjectivity within this

system. The youth, however, were not going to read my book, nor was it written for them. I decided to bring in a video camera and to make a film about the work I was doing with them so that I could show them what I saw, that the hip-hop cipher is an existential situation, and that it shared with Paulo Freire's culture circle, a pedagogical goal. On the first instance of filming, I set the camera and posed a question: "Who is more powerful, your civilian self or your hiphop self?" The youth required no further explanation; they had all developed a hip-hop self; Daniel was DNA, David was ViceVerser, Andre was Dre Pharoh, and Mike was Eflow. In each instance, they articulated the moment or moments where another self was brought into being. They did not require a master class on existentialism to know that "existence comes before essence" (Sartre, 2007) and that the existential situation is "self-making-in-a-situation" (Fackenheim, 1961, p. 37). Nor did they need to be told that "freedom is acquired by conquest, not by gift" (Freire, 2000, p. 47), nor that they are living in a time that treats youth as "disposable" (Giroux, 2011, pp. 89–107). They had already learned that "concrete thought must be borne from praxis" (Sartre, 1963, p. 22) and had been learning to live hip hop – learning to write and spit rhymes – in ways that would help them critically understand and play a role in shaping the ecology of the city in which they live. Hip-hop practice contributes a pedagogy of freedom located in the knowledge of the "unfinishedness of the human condition" (Freire, 2001, p. 66) and their capacity to self-create (Fig. 1).

On the second filming day, I arrived with two cameras and recorded the culture circle and cypher described in my article "Cipher5 As Method" (MacDonald, 2016b). With Diana Pearson operating the second camera on a tripod, I moved around the circle with a handheld camera (Fig. 2). I edited both of these days of filming into one film called *Megamorphesis*; the title comes from the song written by

Fig. 1 Megamorphesis. (Michael B MacDonald Films)

Fig. 2 Megamorphesis. (Michael B MacDonald Films)

the young hiphoppas during the filming. My co-facilitator Dre Pharoh (Andre Hamilton) rapped the chorus:

> From my mind to my mouth
> From the mic, to the mixer
> From the amp and the speaker
> It's in the air and it hits ya
> Ya, Megamorphesis gets ya
> Open your mind and let me paint a mental picture

Upon completing the film, I showed it first to only the young hiphoppas along with friends and family they invited. Given that they had previously showed little interest in my scholarly work, I was surprised that so many arrived at the university theater that night for the screening. The lights went down and the opening thump of the title song cut through the speakers. The youth began cheering, hollering back and forth, laughing and loving each other. There they were, larger than life on the screen. After the film ended and the lights came back on, we were all changed. They saw the point of my research for the first time and understood why we had created the circle. They also witnessed the power of ethnographic film as a pedagogical force. They were able to engage in a recursive conversation about themselves. They could see themselves both in the particular, the general, and in an ecology: as individuals telling their own stories, as hiphoppas who are members of the global hip-hop culture, and as bodies interacting in a space. Ethnographic film provided a way to create what Paulo Freire called *Situations* (Freire, 1974/2013, pp. 58–80). The Freirean method of critical pedagogy:

> Links together our existential situations in life with conditions of consciousness, and provides a possible explanation for how both become what they are. In other words, Freire helps

> think through that many of our existential situations are in part the result of a consciousness that has been shaped by a particular process – education. All three – existential situations, consciousness, and education – are inextricably bound. (Shudak & Avoseh, 2015, p. 464)

After this initial screening, I began to take the film to a wide variety of places including university classrooms, community centers, research centers, and film series. Each time I screened the film, the conversation that followed was rich and penetrating. Discussion always began with the feeling of proximity that the film created for the viewer, the feeling of being there. And then moved outward to think about the social situation of the youth, the environments in which they live, and the potency of their struggle. In the depths of each conversation, I saw more and more clearly how powerful, and ecological, the film situation can be.

A few months passed and in the news, alarming stories of youth suicide at the Attawapiskat First Nation in Northern Ontario, Canada, began to circulate. The members of Cipher5 decided to organize a letter writing initiative, to send personal letters to Attawapiskat youth. Dre reached out to me to return with my camera. This time the youth themselves decided what the film needed to be. Together we made *Letters to Attawapiskat*, a film that explores the ongoing hurt of colonization, intergenerational trauma, and the role of the hiphoppas and of hip hop in creating a new civilization (Fig. 3).

I began screening *Megamorphesis* and *Letters to Attawapiskat* together. The films feature inner-city youth speaking about their understandings of the world and the role of hip-hop music in their lives and in the lives of those they know, and they also speak about the ways that they see themselves nested in a complex and sometimes predatory ecology. This new civilization is not a small matter. In many ways Cipher5's new civilization is an ecological critique that locates aesthetics and

Fig. 3 Letters to Attawapiskat. (Michael B MacDonald Films)

healing, not reason and conscious purpose, at its center. While Bateson was among the first to talk about the transformative healing power of an ecologically embedded ethico-aesthetics, he did so as an antidote to the ecological degradation caused by conscious purpose, a consequence we are now calling Anthropocene.

Predatory Anthropocene

The negative consequences of conscious purpose can be seen in the emergence of the concept Anthropocene which has come to describe the Earth's current geological epoch (Steffen et al., 2015) (This has been dealt with in more detail in my 2016 book *Playing for Change: Music Festivals as Arts-based Community Learning and Development*.). And while it seems that what we thought we knew about the environment has all been thrown into doubt, I want to illustrate that the narrative that is emerging about the Anthropocene is problematic or at least not fully formed. If we undertake a political economy of the Anthropocene, it becomes evident that the so-called Great Acceleration that began in the late nineteenth century has introduced an epistemic-ecological illness that is ecologically predatory. It is essential to begin our discussion of environmental aesthetic education on this very shaky ground in order to first face up to the impact of conscious purpose, before we can introduce a biosemiotic aesthetic education capable of challenging the aesthetic subjectification that continues to contribute to predatory Anthropocene.

Anthropocene is defined by human action that is, for the first time in the history of the planet, having a direct impact on climate and the environment. This impact marks the conclusion of the geological epoch called Holocene that lasted 11,700 years and included the entire evolutionary history of human civilization. Particularly striking evidence was forwarded in Steffen et al.'s (2015) "The Trajectory of the Anthropocene: The Great Acceleration." They showed that rising rates of 12 human systems mapped directly onto 12 earth systems, and these increasing rates of impact began after the Second World War (Source: International Geosphere-Biosphere Programme http://www.igbp.net/globalchange/greatacceleration.4.1b8ae20512db692f2a680001630.html).

The Great Acceleration was the expansion of socioeconomic activity turbo charged by increasing resource use that created new technologies that further expanded rates of consumption. This was a celebrated new socioeconomic phase that was supposed to lead to full employment and a bright future for all. It was also the beginning of a next phase of the capitalist world-system accelerated by increasing urbanization. By 2008, humanity officially entered a new urban phase where 50% of the earth's population lives in urban spaces. John Bellamy Foster, York, and Clark (2011) argued that capitalism has produced an ecological rift caused by a core of the capitalist world-system out of step with ecological resources and its system thresholds (Particularly concerning is of course the carbon dioxide limits, and this is much discussed. But more concerning are some of the other earth systems like nitrous oxide, methane, ocean acidification, and coastal nitrogen. We are not having

a public discussion about the correlation of these systems nor the possible impacts that may arise from breaching their limits.).

The Great Acceleration produced a staggering amount of wealth that benefitted a very small percentage of people. In 2010, OECD countries had 18% of the earth's population but accounted for 74% of GDP. But it is reported that only 0.1% controlled this vast wealth. This is illustrated in the 2015 Oxfam-released Working for the Few (https://www.oxfam.org/en/research/working-few), a terrifying document that shows "almost half of the world's wealth is now owned by just one percent of the population," that "the bottom half of the world's population owns the same as the richest 85 people in the world," (2) and that this already extreme economic disparity is getting worse. So, while it is clear that everyone will be impacted by the implications of Anthropocene, its causes and the economic value that emerges from these impacts are not equally shared. A new form of ecological inequality has developed (As I have discussed elsewhere (MacDonald, 2016a, b), social scientists already know that human impacts on the earth are not equally disseminated across the globe and locations of resistance often located in capitalism's periphery are beginning to emerge. While environmental scientists study environment impacts, and environmental studies and environmental activists politicize governments and society to these impacts, social scientists from within a critical theory or cultural studies tradition have an opportunity to talk about what Niklas Luhmann calls "ecological communication" (1989). Social scientists in many disciplines are beginning to develop new approaches informed by this emerging data. Ecomusicology is one example.).

Predatory Anthropocene (PA) is the consequence of an epistemic illness. It is manifest as a crisis of the environment, the economy, and the human organization, occurring within communication. The source of predatory Anthropocene is the radical revolution in the semiosphere, the new languages, new discourses, new knowledges, and new politics of capitalism (Lazzarato, 2014, p. 16). Gregory Bateson provided a foundation for a way of studying these impacts on the semiosphere. His work has been expanded into biosemiotics and approach that I see as foundational to CineMusicking. This expanded notion of ecology that locates the semiosphere within the envelope of the biosphere, in an interactive way, helps explain the operation of predatory Anthropocene and its maintenance in popular culture. It also provides a way to explain how youth hiphoppas in Cipher5 are able to recognize that their self-work is able to build a new civilization. Moving out from *Megamorphesis* to *Letters to Attawapiskat* sketches out two levels of semiosphere. I followed these films with *Pimachihowan* that explores the role of Cree traditional ecological knowledge (TEK) and learned about the ecological aspects of *the matrix that embeds*. Previously, I had been sketching out a semiosphere without thinking very clearly about the recursive relationship between semiosphere and biosphere. I could see the impact of semiosphere on the biosphere, but I had not yet seen that the biosphere may also shape the semiosphere which would also be shaped by individual choices. The study of Cree traditional ecological knowledge taught me this, and trying to find a path that walks in parallel with Cree TEK brought me to biosemiotics.

Biosemiotics

Biosemiotics "is the name of an interdisciplinary scientific project that is based on the recognition that life is fundamentally grounded in semiotic processes" (Hoffmeyer, 2008, p. 3). Built upon the work of Charles Sanders Peirce, Jakob von Uexkull, and Gregory Bateson, it offers "path-breaking new ways of understanding both culture and nature" (Ibid.). Central to the biosemiotic approach is the position that "living nature is understood as essentially driven by, or actually consisting of, semiosis, that is to say, process of sign relations and their signification – or function – in the biological processes of life" (Hoffmeyer, 2008, p. 4). This provides a radically new platform for ecological aesthetic education (There is, however, a significant distance between music education and ecological music research on the one side and systems science, like biosemiotics, on the other. In Canada, praxialism is the dominant music education philosophy, and it denies a place for aesthetics. Ethnomusicologist Christopher Small brushed up against second-order cybernetics in *Musicking*. And while the concept has become widely used, its relationship to cybernetics is unknown. Ethnomusicologists have generally agreed that music "is a key resource for realizing personal and collective identities which, in turn, are crucial for social, political, and economic participation" (Turino 1999). While some ethnomusicologists utilize Peircean semiotics in their methods research in this orientation has tended toward identifying formation, and while this is undeniably important, it is only one part of communication. Ecological (ethno) musicology, in the form of the new subdiscipline ecomusicology, while the most likely candidate for systems science has utilized ecocriticism as its dominant framework. In this essay I seek to forward one response to these three threads. First, that music education might expand its practice beyond its rigid allegiance to studio practice and performance-based pedagogy. Second, that Peircean ethnomusicology might find resonance in biosemiotics and contribute ethnographic research to studies of human signification and, third, that ethnomusicology might benefit from rethinking "nature," by reorienting toward biosemiotics.). The goal is to get above the humanist binary of nature/culture in the recognition that semiotics is not exclusive to humans but is in the biological environment, a semiosphere, within which humans have evolved unique complex practices of symbolic learning in "cultural sign processes [that] must be regarded as special instances of a more general and extensive biosemiosis that continuously unfolds and acts in the biosphere" (Hoffmeyer, 2008, p. 4). Instead of thinking about "nature," biosemiotics allows us to inquire after the recursive impacts of semiotics phenomenology (art in this case) in the shaping of the semiosphere and how the semiosphere is functionally coupled (Luhmann, 1989, 1996, 2000, 2009) and embedded inside the envelope of the biosphere. The semiosphere is not undifferentiated; different semiospheres are produced recursively through the engagement of ways of acting within the biosphere. We call the collection of these thoughts, dreams, symbols, and actions *culture.*

The cybersemiotic perspective (Brier, 2008) builds upon biosemiotics by including Niklas Luhmann's *Social Systems Theory* (1996) which allows us to pose evolutionary questions about the role of art in the semiosphere without resorting to

reductive biological questions of evolution, i.e., sexual selection. Instead, a cybersemiotic question would ask about the recursive role of expressive practices in meaning creation about the environment; how it contributes to, and about the semiosphere, how changes in the semiosphere require the semiotic organism to respond as we attempt to shape the semiosphere to successfully integrate into the biosphere; and whether we are able to even tell what is successful. The evolutionary role of language signification and of its expansion across textual, aural, visual, and gestural modes, as we currently engage with them in popular culture, requires significant transdisciplinary research. One of the most pressing cybersemiotic questions regarding aesthetics is the impact of capitalism on signification and the semiosphere-biosphere matrix (It has been long acknowledged that aesthetics has been incorporated into integrated world capitalism (Adorno 1984, 1991; Adorno, Benjamin, Bloch, Brecht, & Lukacs, 1977; Benjamin 1968; Guattari & Rolnik, 2008). It has recently been argued that new forms of information workers, that some call the cognitive proletariat or the cognitariat (Lazzarato 2011, 2014, 2015; Marazzi 2008, 2011a, b), are being trapped in decentralized creative/semiotic factories working for capital accumulation, profit that benefits "creative" industries' executives. What began with the rise of neoliberalism has become the information economy, the gig economy, built upon precarious creative labor within a growing sector of the global economy extending into self-driving vehicles and expanding automation.).

Gregory Bateson (1972; Bateson, Jackson, Haley, & Weakland, 1978) has shown that the definition of the living organism is provided by the organism itself and that although the organism is self-aware, it does not follow that its actions and its environment are evident to the self. Further, because the organism is a self-reflexive (second-order) system, its environment can be known, and its history known, only through the resources available to it within its system (Von Foerster, 2003, 2014). Further, what the organism uses to know its environment (resources it has made for itself) contributes to autopoiesis (self-creation) (Maturana, & Varela, 1987). But as Bateson warns, self-awareness does not provide a privileged claim to ontology, and the community does not get access to its ecology. The maps are only what they think they know and are always in a virtual relationship to the territory.

Accepting Bateson's observations about the problems of self-awareness, it is necessary to clarify the capacity of critical theory, which provides the critical theorist a privileged critical vision that has remained largely unquestioned. Further, some strong forms of critical theory have turned everything into discourse. While it is necessary to talk about the construction of discourse, when taken to an extreme, it makes the mistaken claim that the biosphere, and all of the science dedicated to its clarification, is a construct of discourse. The result of this strong approach to discourse is the incorrect and dangerous belief that changing the discourse alone is enough.

Unreflective science that has claimed a monopoly on the real also has a strong form that does not see the place of human semiosis in knowledge production. As semiotics has shown, our biological engagement with the world is based upon humanly produced maps of territories that we can never have access to with our

analysis. All of our knowledge is a map of a territory. The tension between the strong humanities and strong science position is a continuation of C.P. Snow's *Two Cultures problem* (1998), where science believes that its analysis of nature and the universe is comprised of information and that there is no meaning. Social science and humanities believe alternatively that they are studying culture and society and that meaning systems are only located in discourse.

The problem of the two cultures is not a problem of personalities but is a problem with the entire framework of knowledge production. If ecological aesthetics is going to deal with both ecology and aesthetics, a framework that includes both science and semiosis is necessary. Cybernetics was developed as an interdisciplinary initiative to bridge the two-culture problem. The major theoretical contributions were cybernetics and systems theory which were expanded upon by second-order cybernetics, a system where self-aware observers of the system include themselves in the system, as with Maturana and Varela's (1987) theory of autopoiesis (self-creation). Niklas Luhmann (1989, 2000, 2009) built systems theory and autopoiesis into social systems theory. In a parallel development, biosemiotics was developed. Soren Brier brought Luhmann's work together with biosemiotics to develop cybersemiotics, a portmanteau of cybernetics and biosemiotics. This approach articulates levels of semiosis that joins science and social science and humanities together. Biological autopoiesis occurs through endosemiotics seen in DNA, for instance, psychological autopoiesis uses neurosemiosis, the communication of the nervous system and organs of the body. These endosemiotics are related to the exosemiotics of the social system and the relation of the social system made up of members of the same and different species (zoosemiotics and anthroposemiotics) and its semiotics coupling with the biosphere. Von Uexkull remarked that "Organisms are wrapped in semiotic networks in which specific circulating signs are accessible on to complementary systems of interpretation. The exosemiotic sign processes, which transform the objective environment into subjective universes, are intrinsically related to the endosemiotic sign processes in a continuous basis" (Barbieri, 2008, p. 366).

And if this was not complex enough, we are now facing a three-culture problem with the awareness that traditional ecological knowledge (TEK) has been maintained through songs, stories, foodways, and Indigenous epistemologies as a body of evolutionary ecological knowledge. This is knowledge about a biosphere in which Indigenous people are embedded and have been for as much as 15,000 years in Western Canada. The development of ecological aesthetic education within predatory Anthropocene needs to have the three-culture problem on its horizon. I propose cybersemiotic ethnographic film as a research methodology capable of addressing the three-culture problem. In the final part of this essay, I will discuss the journey of making my film Pimachihowan and the ways that ethnographic film (In an interest to finally get to the main subject of the paper, I will spare the reader a survey and discussion of the work written about ethnographic film though important is a methodological discussion that will have to await a follow-up paper.) can provide a valuable method for researching as well as practicing cybersemiotics.

Pimachihowan and the Matrix that Embeds

Pimachihowan began as an ethnographic film contribution to a web-based petroleum education learning tool (PELT). PELT was a federally funded research project headed by business ethics professor Dr. David Lertzman and partnered with Cree elder Conroy Sewepagaham, to explain to business students, destined to work in the Alberta energy sector, the complex sociocultural-economic environment they are about to enter. David, Conroy, and I began working through potential ideas for the film, but after a few failed attempts, it became clear that the traditional documentary approach was not going to work. A central complexity was that the film's goal was to explain Cree traditional ecological knowledge to people who do not have the framework for understanding it. Canadian energy sector professionals come to Indigenous communities understanding that they have a responsibility for consultation and accommodation. But these two words are not translatable in the Cree language. So, these students came to learn expectations that are often difficult to meet in the field. Over the process of David and Conroy's work, it was agreed that Cree words would have to form the center of the film. We began to work toward developing a film method that would have the capacity of being ecological in the same way that the hip-hop films would be. In the process of developing the method, I began to see that once again it was necessary to utilize the CineMusicking method. That I was not exploring music explicitly was made unnecessary by Conroy's observation that in Cree TEK, all education is ecological aesthetic education, not of nature but of our relationship with *the matrix that embeds* (Fig. 4).

In the short educational film *The Matrix that Embeds*, Humberto Maturana and Heinz von Foerster explain that the form of the described universe is shaped by the tools used to do the describing ("The Matrix that Embeds" Humberto Maturana and

Fig. 4 Pimachihowan. (Michael B MacDonald Films)

Heinz von Foerster, American Society for Cybernetics and Change Management Systems. Directed by Pile Bunnell 1998. https://www.youtube.com/watch?v=acx-GiTyoNk (accessed March 19, 2017)). In other words the method taken to describe the universe is therefore not just one method among many that will lead to the same end, but is a choice, made often with little foreknowledge of the consequences the method will have for the model. In particular, von Foerster explained that the root word of science (skei) means to take things apart as in schism and schizophrenia. While taking apart in the act of naming produces a universe of parts useful to its itemization, this method does not necessarily lead to understanding of the ecological productiveness. There is sometimes a confusion between mechanical science and living science. For instance, if you take a car apart in your driveway and take very close notes, you can reassemble it based on your very close notes, and it will restart. Attempting this on your cat will not produce the same result. Another method is necessary.

The opposite of skei is the root syn, to unify, to put together, as in the root of system. In *Steps to an Ecology of Mind* (1972) and *Mind in Nature* (1979), Gregory Bateson presented systems of interconnected "minds" established upon *the pattern that connects*. In his later work *Where Angels Fear* (1987), he and his anthropologist daughter Mary Catherine Bateson explore aesthetics and sacredness as the experience of being embedded in human-animal-planet matrix (Charlton, 2008). Bateson's ecological view was of the whole and had to "accommodate aesthetics to the question of consciousness" (Harries-Jones, 1995, p. 212). He argued aesthetics and consciousness were two parts of a necessary triad with the sacred. Harries-Jones, summing up Bateson, wrote: "The sacred (whatever that means) is surely related (somehow) to the beautiful (whatever that means) in that the sacred is a sort of surface, or topology, on which both terms, beauty and consciousness could be mapped" (212). Following Bateson, it is possible to inquire after questions of aesthetics through the sacred, as the pattern that connects.

The pattern that connects allows for a view of parts and wholes; it is the study of the connections between things. Heinz von Foerster, however, did not feel that the paternal association of pattern, from the root *pater* meaning father, was the correct metaphor. Pattern presupposes a master form, a maker (Platonic forms?) capable of cutting out parts. Instead of father (pater/pattern), Foerster suggested mother, mater or matris, from which a system emerges as wholes, built of relations-of-difference that embed. Instead of a pattern (pater), von Foerster suggests matrix (mater) and substitutes *the pattern that connects* for *the matrix that embeds*. The change of metaphor from father science to mother matrix introduces a new approach to ecological aesthetics that works in parallel with traditional ecological knowledge of Indigenous peoples in Canada and maybe more broadly (Because of the colonial history of Western rationality, in both science and the humanities, meta-questions for researchers in post-Truth and Reconciliation Canada are of great ethical, epistemological, and methodological importance. Indigenous writers have long recognized the negative impacts of skei, the tearing apart of "things" in Western rationality. In "Custer Died for your Sins" Vine Deloria Jr. (1969) critiqued colonial scholarship when he wrote: "Into each life, it is said, some rain must fall, some people have bad horoscopes, others take tips on the stock market, but Indians have been

cursed above all other people in history. Indians have anthropologists" (78). Although Treaties 6 and 8 were signed between Indigenous peoples and the Canadian government as an agreement to share the land and to provide Western education, these treaties were systematically ignored. The promised education was delivered in the form of a system of residential schools dedicated to "kill the Indian in the child;" European aesthetic education was used as an epistemological weapon. The federal government apologized in 2008. Soon after, the Truth and Reconciliation Commission of Canada traveled across the country to hear and record testimony of the impact of residential schools. Concluding in 2015, it is now public record that Indigenous people were physically, psychologically, and sexually abused in a government-supported system of cultural genocide. However, while the government says "we are sorry," treaty obligations as of 2017 are still rarely lived up to. What's more, the epistemological operation of colonization remains opaque. It is this field that I am seeking to theorize aesthetic education not in the hopes of explaining traditional ecological knowledge but instead of contributing to an allied ecological aesthetic education.). For instance, when Sewepagaham talks about *Kimaamanow* (This is not a Cree word but instead is *Michif*, a complex language comprised of Cree and French. It is not a patois that mixes and reduces the complexity of two languages into one hybrid but is instead a language that was built by expert speakers of both Cree and French and therefore has very complex grammar structures.), there is some hesitancy with the often-used translation *mother earth*. I believe the hesitancy comes from the fact that the English words do not quite capture what is being expressed. Matrix with its root in *matris* brings us closer than the English word mother. The process of engaging with the *matrix that embeds* is part of the practice of life called *Pimachihowan*, experienced as sacredness.

I began to realize during the making of Pimachihowan that it was *the matrix that embeds* that I described in the film *Megamorphesis*, and it was the larger context of the hip-hop semiosphere that *Letters to Attawapiskat* attempts to describe. *Pimachihowan* attempts to describe Cree traditional ecological knowledge, which needs to be understood in order to more fully understand the semiosphere of Cree youth in Edmonton. It is worth noting as well that many youth involved in hip hop in Edmonton are Indigenous (Fig. 5). The role that Cree TEK plays in the lives of young hiphoppas, or youth in Edmonton more generally, is not well understood. But as Cree elder Sewepagaham explained, predatory Anthropocene is impacting TEK:

> With our teachings, it is subtle. If it's walking down through a boreal forest or tracking down a game animal it's soothing. It's totally opposite to what youth are now being engaged on. It's not 'bam' right in your face, here's a frag grenade, 'boom' you have instant reaction. With our teachings it's calm, it's soothing, it's *pah'pe'ya'ht'ik*, slow, it's like steeping your tea. You don't rush it because it doesn't taste good. It's like that, our teaching needs to steep nice and slow. It takes time. So when you ask how can we teach that to non-indigenous folks or even with our people who are not able to be granted that kind of teaching, how do we do that, at the end of the day we have to teach them patience. You don't get an instant reaction, you're not going to get instant gratification. When you go out and walk on the land and say 'here it is', you're not going to go out there and say 'wow I'm changed'. You have to do it repetitively, you have to do it over the years. It's slow healing and without the slow healing it's not true healing.

Fig. 5 Pimachihowan. (Michael B MacDonald Films)

Showing this distinction in the film was complex and relied upon the Cinéma vérité method. In one scene, we followed Conroy walking through the deep snowy woods of the northern boreal forest, breaking large branches as we moved. Eventually, and without warning, Conroy stopped and began making a fire. He made a space in the snow and started to stack pieces of wood; he added some cotton synthetic fur from his gloves and lit it with a lighter. David asks, "can you tell us about *Pimachihowan?*", and Conroy responds: "We're doing it right now" (Fig. 6).

Conroy explained that nothing starts on its own, that we are all just like the fire, and that we are all in relation to each other. He goes on to explain that a key teaching of Pimachihowan is that if we respect the environment then we learn to respect ourselves, and if we respect ourselves we learn to respect the environment. We realized that Conroy is teaching us Cree TEK. As a filmmaker, I realized at that moment what Conroy had decided to do; he had chosen to "perform" TEK for the camera. In the process of filming and editing the film, we learned that slowness provides an opportunity to interpret your ecology using all of your capacities. Your senses, feelings, dreams, memories, and knowledge. I edited the rest of the film with this in mind. Everything was edited for slowness, to allow time for new ideas, observations, and feelings to emerge. I learned in the process that slowness was not just tempo, but a space of productivity. Long takes were utilized throughout. It is with great satisfaction that the feedback I regularly receive from audiences is focused on the tempo of the film, the feeling of being there, of sitting next to Conroy. In the second half of the film, titled *Kawitapmatoa* (sitting down with people), the approach to the film direction explicated the central notion. David and Conroy were joined by Willard Tallcree, and they sat down together at Conroy's family's hunting cabin deep in the boreal forest. We learn more about the continuity between

Fig. 6 Pimachihowan. (Michael B MacDonald Films)

how we live and the wellness of the environment. That colonization and the impacts of Indian Residential Schools have emotional as well as ecological ramifications for all people and that the impacts of colonization are not over until we are both healed, settler and Indigenous alike. These observations map on completely with the observations made by the hip-hop youth in both *Megamorphesis* and *Letters to Attawapiskat* (Fig. 7).

When I screen *Megamorphesis* with *Pimachihowan*, questions emerge about youth migration, rural to urban, and youth living in Indigenous community and then moving to metropolitan multicultural community. Youth tend to respond in either two ways. Non-Indigenous youth tend to be amazed that there is a hip-hop culture that is influenced by Cree TEK. For youth who understand hip hop exclusively as a product of American popular culture industries, it is quite a surprise to recognize that hip hop is formed by the ecology within which it is embedded. They are surprised because they are used to not thinking about the environment, because they do not yet have the capacity of thinking about semiosphere-biosphere coupling. Indigenous youth are often very happy to see this connection made and often explain authoritatively to non-Indigenous members of the audience details about their lived experience. In such a way, at-risk youth who are often the least empowered find a central place in a public educational environment. Following Paulo Freire's methods, the oppressed are able to find voice in their lived realities and in doing so dissolved the bonds that holds oppressor and oppressed in their places. The films help Indigenous inner-city hiphoppas talk back to power, to help make explicit the implicit epistemologies of hip-hop culture and traditional ecological knowledge. And we are able to do this together because we have set out to make ethnographic films together. To understand ourselves more deeply as we put ourselves on screen and then share our journeys with audiences.

Fig. 7 Pimachihowan. (Michael B MacDonald Films)

Conclusion

I began making ethnographic films during my graduate work as a way of doing aesthetic research that could communicate outcomes that print publications, no matter how literary, could not communicate as effectively or as ecologically. When I began incorporating my ethnographic films into my teaching, it was with great effect. My students not only began to see what I was researching but began to report that they "felt" as if they were entering into someone else's lifeworld. I have found that the affective impact of film can be molded through editing into a variety of phenomenological forms that are sometime intersubjective and sometimes ecological. I am increasingly convinced that CineMusicking is not only an excellent vehicle for communicating cultural research in aesthetics, but it provides a two-sided opportunity for aesthetic education. First, because of the immediacy and multimodality of film, it is an excellent technology for ecological and intersubjective aesthetic education. The second side is that through ecological ethnographic filmmaking, young people can gain an aesthetic education that has the potential of being deeply transformative for schools, young people, their community, and environment. CineMusicking is an inherently interdisciplinary practice for aesthetic education. It draws together all of the traditional forms of aesthetic education: visual art, theater, theater production, music, composition (screenwriting), and new forms of aesthetic education like audio recording, video editing, coding, design, and communications. Through CineMusicking young people can produce films about their environments and communities, and by doing so, they engage in the research of the semiosphere that may help their communities and themselves understand their world in ways not currently accessible.

Finally, we live in a time when digital film production equipment costs much less than even maintaining a traditional music program (and dissemination by Vimeo is almost free), but most schools do not make film production a priority. Perhaps it is because Hollywood so controls the stories we tell ourselves about ourselves that we are unable to imagine what aesthetic education could look like after we take control of our own narratives. Perhaps it is a lack of ecological aesthetic education philosophy. This chapter takes one small step toward this emerging film-based ecological education.

Abstract

This chapter explores patterning as a transdisciplinary approach to conceptualize childhoodnature through the ways patterns of self and environment interconnect, relate, and resonate. In doing so, we aim to critique the compartmentalization of education through discipline foci, space and time limitations, and separations from nature. We argue that despite trends toward integrated and holistic approaches in education, such as STEAM (science, technology, engineering, arts, and mathematics), and inquiry-based learning, a deeper, more aesthetic and ecological approach that encompasses childhoodnature is needed. Analyzing research on patterning in the early years of education and development, it has

been noted that patterning is mostly conceptualized and understood through discipline-focused lenses, such as in mathematics, science, and the arts. Putting forward the argument that innate knowledge of patterning has been eroded from our everyday lifeworlds, a holistic concept of childhoodnature is required. We contend that knowledge and learning about patterning could enable children to make complex connections with their selves and environment, as ecological and aesthetically engaged learners. Based on eco-critical perspectives and incorporating Indigenous cultural arts, this chapter reconsiders and reconceptualizes ways pedagogies and curricula in education to encompass a more transdisciplinary approach with a biophilic focus.

Introduction

The three authors of this chapter are teacher educators who work in different discipline areas – art education, early childhood education, and STEM (science, technology, engineering, and mathematics) education. In our attempt to challenge the anthropocentric view and paradigm, we consider humans' connections with other living organisms and the natural environment as an integral part of a conceptual framework for understanding the foundations of childhoodnature. These connections enable us to focus on natural, embodied, and holistic approaches to education, some of which are shared in this chapter. In particular, we discuss the notion of patterning, defined as identifying and creating regularities and/or repetitions in space, time, and behavior. The chapter focuses on the usefulness of this notion of patterns and patterning in thinking eco-critically about childhoodnature and taking into consideration ecological aesthetics and the learning environment.

Drawing on Crutzen and Stoermer (2000) and others, our definition of the anthropocene is "[the] earth's most recent geologic time period as being human-influenced, or anthropogenic, based on overwhelming global evidence that atmospheric, geologic, hydrologic, biospheric and other earth system processes [that have been] altered by humans" (Encyclopedia of Earth, 2017). We share a concern about the compartmentalization of disciplines in education and research within an anthropocentric era, a compartmentalization that has limited space and time for children to be creative, to be able to explore, contemplate, experiment, experience, and deeply connect with nature. Along with discipline knowledge traditionally being compartmentalized, education has been affected by accountability and performativity discourses and the culture of efficiency (Kilderry, 2015; Wilkins, 2011). Moreover, Rolling (2013) explains how the dominant contemporary education system stemmed from American inventor and engineer Frederick Winslow Taylor's ideas about being efficient in the workplace:

> . . ..the stopwatch became emblematic of Taylor's system, often likened to "management by measurement". As Taylor's approach was applied in schools, the completion of homework assignments, sequenced workbooks, and timed tests became the order of the school day. (p. 30)

Typically patterning in early childhood education and in the early years of school has been taught in traditional discipline areas, such as mathematics, science, the arts, and music (see Fig. 1).

There are many reasons for the compartmentalization of discipline areas and for predictable systems with defined and categorized information and knowledge. For example, critiquing the traditional structure of schools and how it lingers today, Rolling (2013, p. 42) observes that:

> Schools do what they are intended to do – schools underdevelop creativity in favour of the development of citizens who are easy to categorise, easy to sort into cubicles or assembly lines, and easy to manage. Twentieth century behavioural psychology and the principles of 'scientific management' converge across the nation to shape a system of education that penalizes unpredictability and a lack of adherence to prescribed metrics.

While we do agree with the importance of students gaining in-depth disciplinary knowledge in mathematics, science, or design, we argue that disciplinary knowledge could be taught in more holistic and integrated ways. For example, patterns and patterning could be explored in sensory and embodied ways along with a focus on transdisciplinary learning experiences in and through nature across the arts, sciences, and mathematics. Over the past few years, we have been exploring patterning as part of children's learning and investigating how children are exposed to patterns in educational contexts, local communities, and homes. In particular, we are interested

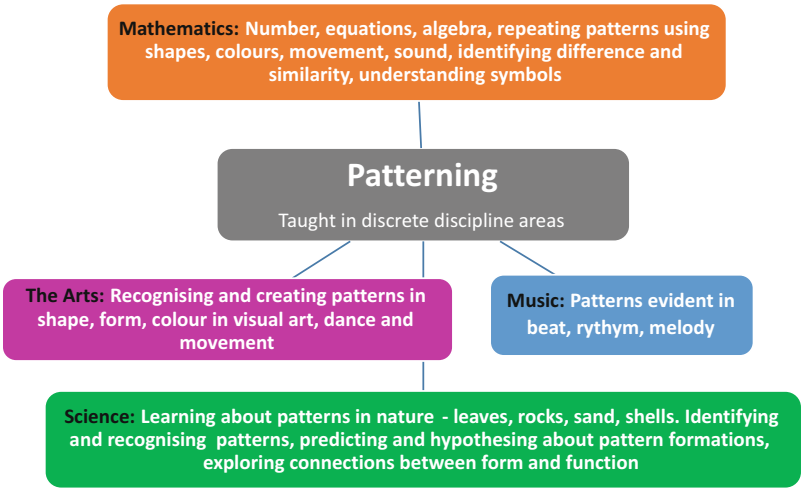

Fig. 1 Patterning: taught in traditional discipline areas

in how different contexts enable children to learn about patterns and patterning through their own sensory and embodied experiences with the natural and built environments and how their engagement with these spaces can be fostered in ecological and aesthetical ways.

In this chapter, we draw on research literature and practical applications to suggest some potential roles that patterning might play in nurturing children's curiosity and interest in nature and how patterning can enable an understanding of childhoodnature in a holistic and integrated way. The first section of the chapter theorizes the *ontology of patterns* and includes an overview of the central place of patterning in art, education, Indigenous cultural arts, ancient knowledge, and lived experiences (Warren & Miller, 2010). In this section we explore what constitutes a pattern and how we might distinguish between patterns of difference. We maintain that patterns of difference can open up new potentials for experience, rather than patterns of sameness that simply reinforce habituated thought and behavior (Barad, 2003; Deleuze, 1994; Shostak, 1999). Drawing on eco-aesthetics, we discuss ways of learning from contemporary art movements embracing an interconnection of self and place. Drawing on reflections on our own experiences of learning concepts in silos and space/time limitations within education, we discuss pedagogical and curricula possibilities for childhoodnature education. This is where pattern and patterning can be both an integrating and engaging platform for environmental and eco-aesthetic learning.

Theorizing the Ontology of Patterns

The growing interest in STEAM (science, technology, engineering, art, and mathematics) indicates a need for more interdisciplinary and transdisciplinary approaches in education (Ghanbari, 2015; Henriksen, 2014). Researching in a transdisciplinary space illuminates the limitations of thinking, teaching, and learning within one single discipline and a myriad of shared conceptual interconnections and possibilities. Gregory Bateson's work (1972, 2017, np) provokes us to question "things, labels, categories, diagnoses." He urges us to "think about living and relationships, communication and set ourselves free (or at least be aware) of what these lenses are that we see through" (Bateson, 2017, np). Likewise, Bowers (2001) advises us to be aware of the metaphoric meaning that a categorized subject like science or art might conjure up as we engage in teaching or learning within a particular discipline. He urges us to disrupt such conditioned ways of categorizing and labeling at the deep metaphorical level. Wheeler (2016) notes the metaphorical similarities between how organisms change and how art and poetry are structured. She explains that, "nature is made of the stuff – the patterns, repetitions, figures and movements – that make song and poetry in humans" (p. 40). Furthermore, she argues that change for organisms "is neither mechanical nor law-like; it is metaphor driven and subject to chance and the making of meanings. In this sense, organic life bears the structure of art rather than the machine" (p. 39). It is these more relational aspects including metaphors of animals, nature, and environment that we explore through a focus on patterning in education in this chapter.

The Ontology of Patterns

Our definition of pattern includes regularities and repetitions of actions, units, or shapes in space, time, and/or behavior. Pattern can be understood in many ways within and across school curricula. For example, patterning can be viewed in mathematical terms (Bjorklund & Pramling, 2014; Papic, 2007), perceived as fundamental to the arts (Geist, Geist & Kuznik, 2012), and regarded as an important concept in science (Ampartzaki & Kalogiannakis, 2015; Murray & Winteringham, 2015). We recognize patterns as useful and important ways to explore disciplinary concepts such as number sequences in math, patterns in art, and biological patterns in animals and plants but propose that patterns can be understood as a transdisciplinary concept for disciplinary integration.

Patterns are the most basic and pervasive building blocks of organisms and environment. Patterns can be found in relation to the biologic and genetic makeups of living organisms (including humans) and identified in both natural and sociocultural environments that we live in. One example of such pervasive patterns is the *Fibonacci sequence,* which was first written down in 1202 by the Italian mathematician Leonardo of Pisa, known as Fibonacci. The Fibonacci pattern of numbers is where each number is based on the sum of the two numbers before but also equals the difference of every two numbers that follow it (e.g., $34-21 = 13$). An example of a Fibonacci sequence of numbers is 0, 1, 1, 2, 3, 5, 8, 13, 21, 34, and so on. Fibonacci patterns can be identified in the arrangement of the leaves around the stem of a plant, the arrangement of flower petals, or the patterning of an artichoke or spiral shell (Ball, 2016). The ratio of two successive Fibonacci numbers approximates the golden ratio Phi 1.618 (where the ratio of two numbers is the same as the ratio of their sum to the larger number). The golden ratio can be found in the structure and form of plants, animals, and planetary systems. The golden ratio is also used in the arts and architecture in many cultures. The impressionist painter Seurat was one of the many artists who have used Fibonacci patterning to develop his compositions (Meisner, 2014).

Patterns and patterning can be explored in sensory and embodied ways across the arts, sciences, and mathematics and can be translated across different senses such as sound, touch, and vision. Visual patterns in art, design, architecture, and mathematics are often repeated shapes, lines, motifs, symbols, numbers, or images. In science, patterns are often represented visually, for example, in the form of cell structures, DNA, atomic, and subatomic arrangements. Patterns are understood both structurally and through audiovisual and spatial awareness in mathematics, science, and music. Furthermore, patterns can be internalized, conceptual, imaginative, invisible, and thus non-sensuous. Patterns and spaces need not necessarily be seen visually (Wertheim, 2015). Christine Wertheim reminds us that pattern and space in art, such as poetry, may be imagined. She refers to this kind of inner structure (invisible in the optic sense) as "inner sight" rather than "external sight" (np). Such internalized pattern occurs in music, writing, and theatre, where a linear structure enables rhythms and repetition of elements across time to be imagined, whereas writing or arranging music sequencing on computer screens or music manuscripts is arguably "visible" musical patterning.

Murray and Winteringham (2015) reveal how humans design, create, and live with patterns. Just as spiders weave their webs or bees create honeycomb, so do humans create patterned things that are both functional and important for survival. Examples of the way people live with patterns can be seen in the design of cultural artefacts, utensils, homes, and clothing. Indigenous cultures have meaningful patterns illustrated in clothing, mats, artwork, and ceremonial artefacts. Australian aboriginal and Torres Strait Islander "rarrk" patterning is a particular kind of cross-hatched patterning found in the Northern Territory or central desert paintings. Other Indigenous patterns include Scottish and Irish tartans, woven tapa cloth from the Pacific Islands, and Islamic patterns found in ceramics, artwork, and tiles. These patterns have emerged over place and time, representing particular cultures, spiritual beliefs, ancestral story and heritage.

Patterns can be found in thinking and behavior, such as rituals that are repeatedly practiced by particular groups of people or habits and movements that we engage in everyday life. Examples of patterns in thinking and behavior include breathing, walking to and from work each day, the action of jogging, dancing, slicing bread, or work activities such as hammering a nail or folding a napkin. Patterns can also be found in the way we think and communicate, for instance, the way we are taught to learn to say words, learning by rote, poetry, times tables, mantras, and prayers – even the format of debating. Patterns require a unit (speech, action, image, shape, sound) to be repeated or arranged in a sequence or structure. When such units are randomly placed or do not exist (are plain), then it is not a pattern. This leads us onto the topic of patterns of sameness and patterns of difference.

Patterns of Sameness and Patterns of Difference

Patterning is an integral part of who we are and our environments. The architects Alexander, Ishikawa, and Silverstein (1977) suggested that "every single part of the environment is governed by some portion of a pattern language" (p. 88). When considering patterning as an integrating and holistic approach to educating in childhoodnature, we need to be aware of the difference between patterns of sameness and patterns of difference. Patterns of sameness potentially reinforce habituated thought and behavior (whether these are good or bad), and patterns of difference offer possibilities of opening up new potentials for educational experiences. These concepts are explained in some more detail in the next sections.

Patterns of Sameness

Patterns found in Indigenous cultural artefacts are an example of how integrated people are to their place, culture, and identity. For example, Scottish clan tartans depict ancestry, region, and clan. The Australian Indigenous desert painters create dreamtime stories through patterns of dots that are important records of place, identity, and ancestral knowledge. The process of being in one's place and nurturing one's identity in that place can be habitual and developed out of a need to survive as a

species over time. Epigenetic research suggests that these patterns are imprinted on markers that affect the expression of genetic code for generations (Barros & Offenbacher, 2009; Kanherkar, Bhatia-Dey, & Csoka, 2014).

Patterns found in artefacts or clothing of some cultures represent information about food sources and harvesting. In Maori culture in New Zealand, for instance:

> Men involved in the ceremonial planting of kūmara plots on the East Coast were required to be clothed in garments such as the aronui, māhiti, paepaeroa, puhoro or pātea – all finely woven garments of dressed flax, differing from one another in their ornamentation. This was part of creating the most auspicious conditions to ensure a successful harvest. (Tamarapa & Wallace, 2013, p. 1)

Haddon (1914) reports that in what was British New Guinea, artefacts of the Orang Belnda people feature patterns that are symbolic of survival processes, such as farming and building shelters. As an example, the decoration of a bamboo stick "is a formula to enable a man (sic) who wishes to build a house to easily find the necessary materials" (p. 246). The stick is decorated with various patterns, which represent aspects of house building, including cross-hatching, symbolic of trellis for a wall of a house, and "diagrammatic representations of burnt trees which have remained after the firing of the jungle" (p. 247). Haddon reports:

> The rest of the bamboo is divided into longitudinal bands, most of which look like attempts at decorative patterns, but they really signify a liana with many leaves, the frame-work of the roof of the house, a ladder, split leaves interlaced for thatching rattans, while a zigzag line means the long path which goes from side to side, and thus indicates the obstacles which befall the leaves for the thatch whilst they are being carried through the jungle. (p. 91)

While these patterns on the bamboo are decorative, they are also forms that record and communicate ways of building ideal habitat. They offer patterns of sameness that are useful records of how to successfully build these shelters again. More recently, Alexander, Ishikawa, and Silverstein (1977) delineated patterns of habitable environments so as to assist people in the design of their ideal habitats. They call this a pattern language as it provides a model to understand and apply the complexities of the habits of creativity, such as building shelter and tools for survival, to create functional communities. This pattern language is, like the bamboo designs described above, a "practical" language, distilled from Alexander et al. (1977) own building and planning practice of 8 years. This model emphasizes the importance of patterns in human-made environments. They explain:

> The elements of this language are entities called patterns. Each pattern describes a problem which occurs over and over again in our environment, and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over, without ever doing it the same way twice. (1977, p. x)

This notion of doing then recording a patterned way of creating, doing or being, or aesthetic design, is reinforced by Wheeler (2016) who explains the human

creative need and habit to tinker and create things. She notes that when we create things, we tend to "look for a solution which will repeat the success of (our) earlier triumph by making use of similar structures" (p. 32).

In addition to doing and recording things, living beings have developed patterned ways of living for survival around seasons, food, hunting, and work. Finkel (2017) tells the story of the 20-year-old man, Christopher Knight, who was drawn to live in the forests around Maine, USA, as a recluse for 25 years. In order to survive, he learnt to observe the habits of people who lived at the edge of the forest. He noticed their daily habits and patterns of activities around seasonal breaks, when he could take the opportunity to break into their homes or gardens to steal food and resources. From his own survival habits across so many years, Knight observed that everyone has predictable patterns.

Furman and Gallo (2000) posit that pattern information links the environment that is a person (e.g., cells, DNA, nutrients, waste) to the environment that is his/her place. They state that:

> As a subterranean cave is dynamically shaped by the passage of water, the human brain and its resulting mind and behaviours are shaped by the passage and presence of information, the universal measure of order within a system. In a sense, the human being becomes a living fossil, a dynamic informational bioarchitecture formed from the interaction of information within the agglomeration of matter and energy. (Furman & Gallo, 2000, p. 123)

This eco-critical perspective acknowledges the interconnection of things, and it recognizes the potential for sameness and difference. Barad (2003) observes that "'we' are not outside observers of the world. Nor are we simply located at particular places in the world; rather, we are part of the world in its ongoing intra-activity" (p. 28). This view suggests that even if we do engage in repetitive behaviors like getting a certain type of coffee from the same café each morning, there is such constant variability within structures (i.e., changing cafe staff, changing customers, changing weather, and so on). It has been argued that repetition will produce difference through the reconfiguration of these variables (Deleuze, 1994).

The focus on pattern and patterning acknowledges the importance of interconnections between self, place, and dimensions of environment that could be of sameness or difference. Through patterns and patterning in early childhood education, we propose that educational experiences can offer holistic perspectives that link our biological selves, actions, and lived experience with an appreciation for the patterns of our environment. At the same time, this focus on patterns and patterning along with taking into consideration the learning within natural environments can teach students about how selves and places are dynamically interconnected (Malpas, 1999), rather than separate limited spaces that we enter and exit.

We maintain that education should provide positive experiences to assist young people to develop positive patterns of life and healthy habits that benefit both themselves and the environment. This could be done early in life through childhoodnature pedagogy, as knowledge about patterns commences from a very young age such as in the form of schemas.

Repeated Actions or Schemas

Children learn and make sense of their surroundings through repeated behaviors and actions, and this begins their patterning learning journey. Repeated actions, or "schemas" (Arnold, 2010; Athey, 1990; Meade, 1999; Whalley, 2007), are concepts used in early childhood education drawing on Jean Piaget's work. Schemas are considered as crucial information required in order for people to make sense of the world. *In his analysis of culture and cognition,* DiMaggio (1997) explains how a schema is a basic unit of analysis for studying culture and for "focus[ing] on social patterns of schema acquisition, diffusion, and modification" (p. 269). Schemas in early childhood comprise patterns of behavior and include actions such as "transporting" where children repeatedly carry objects from one place to another, "enveloping" where children wrap themselves up in a blanket or cover themselves with sand, and "enclosing" where children fill up empty containers and put objects down plug holes (Athey, 1990, Meade, 1999, Whalley, 2007). It has been argued that these schemas later develop into concepts (Athey, 1990) and mark the beginning of a child's patterning journey of sameness and difference. Routines, such as feeding, bath, sleep, and waking times, set babies up into patterned behaviors. Childhood-specific patterning emerges through repeating behaviors and actions based on what they are taught, what they observe others do, and/or their own experiential and experimental play.

Development in cognitive science in the last two decades suggests the everyday embodied experience gained in the early years is the foundation for later abstract and high-level thinking (Lakoff & Johnson, 2008). An important concept in cognitive linguistic studies is "image schemes" (Hampe & Grady, 2005; Johnson, 2013; Lakoff, 2008). Image schemas describe recurring patterns of our sensory-motor experience by which we can make sense of that experience and reason about abstract concepts and make inferences about abstract domains of thought. According to Johnson (2005), image schemas arising from recurring patterns of organism-environment sensory-motor interactions in conjunction with the capacity for conceptual metaphor. This process provides the basis for abstract human reasoning. For example, an image scheme *collection*, involving the pattern of adding or taking away objects from a group, can be mapped conceptually to arithmetic through the concept metaphor *arithmetic is object collection*. As a result, image schemas operating within conceptual metaphors make it possible for us to use the logic of our sensory-motor experience to perform high-level reasoning with abstract entities.

Patterns of sameness are regular, seen, experienced, known patterns that we associate with things and processes. Habitual behaviors can be considered as patterns including sleep patterns, eating patterns, and exercise patterns, for example, eating cereal with a sliced banana each morning, an evening walk, or a morning meditation sitting on a cushion, facing the same way in the same room. Children might prefer to eat out of their preferred bowl and go to sleep with their comfort toy snuggled up in the same way each evening. Behavioral patterns of sameness can be observed in many situations.

Patterns of Difference

Recurring patterns are usually associated with habitual ways of thinking and behaving, which are reinforced through day-to-day living experience of the child. Patterns of difference, however, are as important as patterns of sameness because they are key mechanisms for learning (Marton, 2016; Marton & Booth, 1997). Marton and Booth (1997) discuss the structure of human awareness and indicate that to experience something as "something," we must differentiate it from other aspects and relate it to a context and be able to discern parts and relate them to the whole. According to Pang and Marton (2013), new meanings are acquired from "experiencing differences against a background of sameness, rather than experiencing sameness against a background of difference" (p. 1066). The pattern of difference inherent in a learning situation is fundamental to the development of certain capabilities and for experiencing a certain aspect of a phenomenon (Marton, 2016; Marton & Tsui, 2003).

Conventional education taught in disciplines focuses on patterns within mathematics, science, art, and music, and the pedagogical approach can isolate and disconnect patterns from our innate and ecological understandings. The Irish artist Dominic Fee explores patterns and subverting patterns in his artistic practice, influenced by patterns from human-made, urban environments, and geometry. Fee has spent time living in the United Arab Emirates where he has become influenced by Islamic patterning. Fee (2013) also puts his interest in pattern art down to his fascination "with the early modernists, especially Kazimir Malevich's Suprematist works" (np). However, when creating his artworks, Fee repeats motifs to create and play with pattern and then creates possibilities to change the pattern formations by asking others to construct the works or even creating possibilities for the work to fall over. With reference to Fig. 2, Fee explains:

> When you set up the expectation of regularity in a work, it becomes interesting to subvert that expectation to see what effect it has. For example, the physical structure of a work might

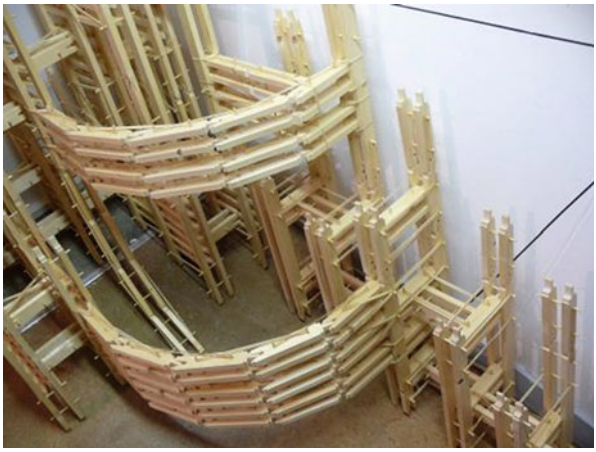

Fig. 2 Dominic Fee's *dimensions, location variable (DLV)*. Medium: wood, elastic bands. Dimensions: variable

> be very regular, but there may be some sort of organic or random element in the surface texture, or in the environment in which it's installed, for that to kick against. It's also fun to introduce elements of messiness into say, a regular, modular artwork, by getting someone else to assemble it, or maybe pushing the construction of it to the point where it falls over. (Fee, 2013)

Fee's artistic practice offers an insight into how we might value patterns that are "correct," but sometimes we might need to play with disrupting patterns to see things differently and to understand balance or just because it feels interesting and is fun.

A childhoodnature perspective enables us to look beyond the disciplinary patterns of the classroom with the aim to understand, "know," and make connections with nature in embodied ways, so that links can be made between music, art, nature, visual images, texture, imagination, memory, and so on. Learning patterns and patterning as part of disciplinary content is still important, but we argue that the conceptualization of patterning can be broadened to include a deeper, holistic, and more aesthetic, ecological, and playful approach to pedagogies. We suggest this allows for possibilities to alter people's habits, patterned ways of thinking, moving (dance), creating, and understanding how we and our environments are connected and patterned in different and exciting ways.

Art, Aesthetics, Nature, and Patterning

Our discussion of patterning in childhoodnature considers young people's potential to be ecologically and aesthetically engaged learners. We therefore consider ecologies across the arts and environments of self and place and the role of patterning in this process. Nora Bateson (2015) is one of many who have noted the similarities between art and nature because they both are layered and complex. When we walk in nature, we are among infinite patterns such as birds flying, swarms, patterns in leaves, petals, and seeds. We may notice how patterns form on rivers, lakes, and oceans or footprints in the sand.

Crafts are important as they offer young people ways to learn technical skills to create useful or aesthetic artefacts. In so doing they exercise their brains, engage in creative processes, use their hands, and engage in sensory experiences of touching, feeling, imagining, and making visual aesthetic judgments. Knitting and crocheting offer young people ways of learning how the repetition of creating a series of knots can create a plane form (square, one side of a mitten, and so on.). Haraway (2016) picks up on this importance as she notes the ancient patterning habits when creating string figures in different cultures and territorial mappings of pigeons' flight paths. Her work examines deep meaning and reasoning, stating ". . .it matters what knots knot knots, what thoughts think thoughts, what stories make worlds. . ." (p. 12). She writes about these string figure/flight path lines as both literal and metaphorical ways of communicating and connecting across in and with places, environments, and cultures and devises a "fictional equation" called Terrapolis which is "at once a story, a speculative fabulation, and a string figure for multispecies worlding" (p. 10).

With a similar embodied and transdisciplinary sensibility to Haraway, Margaret Wertheim explains the process of crocheting hyperbolic geometric structures with her artist sister Christine Wertheim. Margaret Wertheim (2009) recalls how, as a scientist, she was adhering to the "rules" of how to create such structures, but her sister began experimenting and creating irregular hyperbolic structures using different colored and textured yarns. They realized from this aesthetic experience that their crochet forms started to resemble coral reefs, which in turn made them realize how irregular coral reef hyperbolic structures are. This experience led to their international collaborative arts projects where up to 10,000 people contributed to crocheting coral reef structures for exhibitions in many countries including Germany, Australia, and the USA (Wertheim, 2009). This is an example of the creative process of creating through the repetition of making knots as crochet, which then became an interdisciplinary project that considers deeply, environmental and art aesthetics in representing and appreciating the interconnections between selves and nature through patterning processes of crocheting.

Knitting with plastic bags and providing knitted garments for trees (yarn bombing) are alternatives to traditional wool knitting. The alternatives that artisans and crafts people offer today provide students with opportunities to think creatively about other possibilities such as patterns of difference. A recent trend has been to knit with your arms instead of knitting needles, and such alternatives offer students embodied and bodily felt ways to learn about how knots create other forms and, after Haraway, what knots have knotted these knots.

Artists such as John Wolseley challenge conventional ways of painting and creating art by allowing nature into the process. For example, he lays paper at the edge of a lake so that the muddy Australian water, sediment, and live creatures imprint the work. He takes a dead bird, inks it, and presses this onto paper as an unconventional way of printing. Wolseley (2017) provides further insight about his work:

> My work over the last thirty years has been a search to discover how we dwell and move within landscape. I have lived and worked all over the continent [Australia] from the mountains of Tasmania to the floodplains of Arnhem Land. I see myself as a hybrid mix of artist and scientist; one who tries to relate the minutiae of the natural world – leaf, feather and beetle wing – to the abstract dimensions of the earth's dynamic systems.

Taking another perspective, Carmel Wallace, an Australian artist, has a different relationship to her patterns in her environment. She lives near Portland in Victoria, where large amounts of plastic debris wash up on a local beach. Wallace collects this debris then arranges it into art installations based on her particular ways of binding, weaving, and arranging this material (see Wallace, 2011). The artist and coauthor of this paper, Hannigan, knows the painting process as a constant problem-solving endeavor: "As soon as you put a mark on a canvas you have a problem to solve." Hannigan deliberately includes patterns into her paintings to complicate the "problem-solving" dynamic of her painting process and also always paints to music because the embodied patterning of music and the way music is mood-altering and informs her work (Fig. 3).

Fig. 3 Shelley Hannigan's *Dress at Bundanon*

The Japanese artist Mako Sasaki photographs the regularly lit nighttime scenes of cities such as Singapore, Shanghai, or Tokyo. His photographic technique is to use long exposure to capture the movement of lit elevators and other city lights, so that their patterns are caught and exaggerated in motion. See Figs. 4 and 5.

The patterns of lit shapes and colors become blurred in Sasaki's photographs as a way of capturing the movement of place and capturing our knowledge of this movement and both his and our interaction with this movement. Within the frame of the photograph, we see a snapshot of a patterned place made up of city lights, but it is deliberately blurred to emphasize the movement of patterns. Sasaki (2015) loses some of the detail and original shapes of his patterned subject matter (night lights of the city) because of the way the photographs are stretched and blurred during the process of capturing movement with still photography.

These alternative ways of engaging with, viewing, imagining, and creating patterns of environments are ideal ways to show people how they are interconnected with their environments. In addition to arts and crafts, music is an aesthetic and holistic approach to teaching and learning childhoodnature through patterns and patterning. Music is a patterned language that plays with our feelings – thereby potentially changing moods, inspiring the body to move, and activating the brain and imagination or even memory. Music can conjure up images of places or remind the listener of places where they may have heard similar music. Therefore, music can be an interesting way to connect people to sound-scape art.

The musician John Luther Adams (2012) describes how fundamental concepts of ecology are important to his practice, describing his music as "not the specific patterns of harmony, melody, rhythm and timbre" but "the totality of the sound" (n.p.) – that is, the way all these different patterns come together to create the complex and layered patterning of the piece of music. It is this holistic notion of patterns that we think should be explored in nature. Educators need to consider how children learn and identify pattern information for growth, development, and well-being through and across all the disciplines taught at school. Therefore, our pattern-

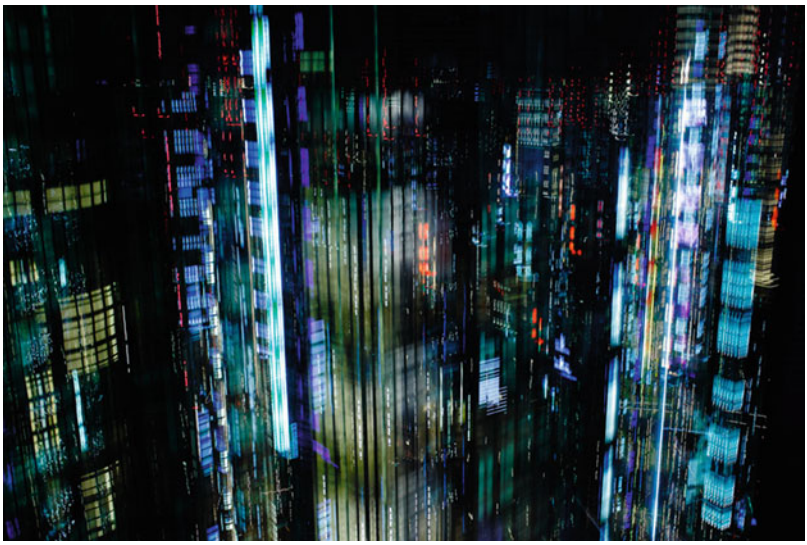

Fig. 4 Mako Sasaki's *Tokyo Layers*

Fig. 5 Mako Sasaki's *Shanghai Layers*

inspired pedagogy and curricula for childhoodnature foregrounds the arts and aesthetics as a transdisciplinary focus for children to learn in sensory and embodied ways. As Graham (2014) suggests, "when extended to the beholding of Nature's patterns, the 'artist' is Nature itself" (n.p.).

Being Ecologically and Aesthetically Engaged Learners

Having explained our theoretical stance, which is transdisciplinary, and introduced theories that support our view of childhoodnature with a focus on patterns and patterning, this section discusses the development of environmental aesthetics toward ecological aesthetics. In a similar way that discipline foci are remnants of the past, such as the factory model for education, remnants of modernism exist where art was that created by "the" genius, to be appreciated from afar. That is, portrait paintings, still life, sculpture, and other traditions in western art have tended to focus on the object d'art as an object that we admire from a distance. One way of aesthetically knowing and appreciating environments has been through the art of landscape painting – where people captured a view of landscape as something "out there." This compartmentalisation and hierarchical view of art, people, and environments shares the tradition of discipline foci and limited time, scope, and space in schooling – where everything is defined, contained, and bordered with a place and/or space.

This traditional kind of people/place relationship views nature as landscape places which are separate from us (Carlson, 2012). In contrast, ecological aesthetics challenge an anthropocentric view of humans to nature where, particularly through the tradition of landscape painting, landscapes were selected, bordered, and viewed – often depicting control or ownership. Both eco-aesthetic and eco-critical approaches to art and nature have critiqued this human-centered depiction of nature (Banerjee, 2016). These approaches have inspired art that enables the viewer to engage in and with landscapes or places through community art, site-specific art such as those exemplified by Wolesley (2017) and Wallace above, or socially engaged art projects.

Aesthetics is not limited to art and Carlson (2012) explains that an ecological aesthetics can engage people in more embodied connected ways than traditional object-based aesthetics. One model is the *natural environmental model.* This aesthetic suits our proposition of patterning in childhoodnature as it "bases aesthetic appreciation on a scientific view of nature and its qualities. It thereby endows the aesthetic appreciation of nature with a degree of objectivity that helps to dispel environmental and moral criticisms, such as that of anthropocentricism" (Carlson, 2012, p. 12).

Another model that Carlson (2012) proposes is called *aesthetics of engagement.* This model considers the way artists have in the past few decades engaged more with nature, communities, and environments. It is a model for appreciating art and nature that encompasses aesthetic dimensions of natural and human-made environments as well as the social aesthetics of human relationships. This fits with our understanding of childhoodnature explored through patterns and patterning as teacher educators as we teach conceptual knowledge about nature and environments. In addition, we support and encourage embodied experiences of being in and with and how we interact with others as part of the environmental-self/environmental-place happenings.

The aesthetics of engagement is a relational way of learning and teaching about patterns in and with place. This may include finding patterns (in context), noticing

patterns, understanding how and why patterns are organized from scientific or mathematic perspectives, creating patterns, and discussing and experiencing patterns in various spaces and places. Thus, one can start to gain understanding about how and why patterns exist in holistic ways. This approach requires teaching young children to see and understand patterns within themselves such as their skin and within their environments such as insects, leaves, shells, sand, and waterways and not only to appreciate the artistic possibilities of patterns but also to appreciate the science of how and why they emerged and the mathematics of their forms. This holistic and transdisciplinary approach enables people to see and understand things, beings, and their place and their interconnections with each other.

Gregory Bateson's daughter, Mary Katherine Bateson, reminds us of the importance of understanding and perceiving these kinds of ecological interconnections. She states, "what is there about our way of perceiving that makes us not see the delicate interdependencies in ecological systems that give them integrity. We don't see them therefore we break them" (Bateson, 2015). It is through learning to see, by noticing, feeling, and focusing on things such as pattern that are all around us and interconnect us as natural beings to our environment, that we can foster children's connections to their environment in complex ways, as ecologically and aesthetically engaged beings.

Patterning and the Possibility of Biophilic Pedagogies

In this chapter, we take the perspective that humankind's connection to nature is innate. Wilson (1984, p. 1) describes this process as *biophilia* or the "the innate tendency to focus on life and lifelike processes." He argues that as part of our humanity, we are deeply embedded within our biology to "explore and affiliate with life" and that "it is a deep and complicated process in mental development" (p. 1). Considering humankind's biophillic tendencies, we maintain that compartmentalized understandings about complex concepts such as patterns and patterning are limited when viewed from stand-alone disciplines, whether from mathematics, music, or science perspectives. New ways of thinking about how we can connect children to complex knowledge and insights through biophilic explorations and engagement with nature are needed.

Of utmost importance to our survival within the anthropocene is the situation where children, as part of childhoodnature, are not only encouraged to become environmentally aware but are able to recognize and maintain their innate connections to nature. In recent years there has been a surge in interest in eco-aesthetic and nature pedagogies in early childhood education. Nature pedagogies are effective ways to foster children's learning and curiosity in nature and to support them to be environmentally aware and comfortable as ecological beings (International Association of Nature Pedagogy, 2017). For example, the forest school movement, originating in Denmark after the Second World War, is now popular across Scandinavia, the UK and Europe, and in other countries (Knight, 2013; Williams-Siegfredsen, 2012). In Australia the "bush kinder" approach, where children learn in, through, and

about nature is gathering momentum (Campbell & Cutter-Mackenzie, 2015). Other examples of connecting children's learning to and within nature are from the artist and educator Peter London (2003) who invited his students to lie down on a forest floor to learn about nature in a sensory way. Tim Ingold (2013), an anthropologist and educator, encourages his architecture students to develop their awareness of designing in and with place by spending time on a beach to learn in embodied and sensory ways with nature.

Integrating Patterns of Sameness and Difference into Children's Learning

Children's biophilic engagement with nature along with environmental play and aesthetic engagement is often missing from discipline-centered teaching of patterning. Thus, the question that needs asking is what would eco-aesthetic pattern-based education for children look like?

First, for children to have opportunities to engage in activities, teachers need to understand the big picture of the difference between discipline foci presented in Fig. 1 and more fluid and holistic ways of exploring patterns and patterning across different cultures and disciplines (see Fig. 6, *A pedagogy for patterning in childhoodnature*). In Fig. 6, we have conceptualized a complex pedagogy that shows the different elements of our pedagogy in black circles, all interconnected with the blue lines and with opportunities for play and experimentation across all areas.

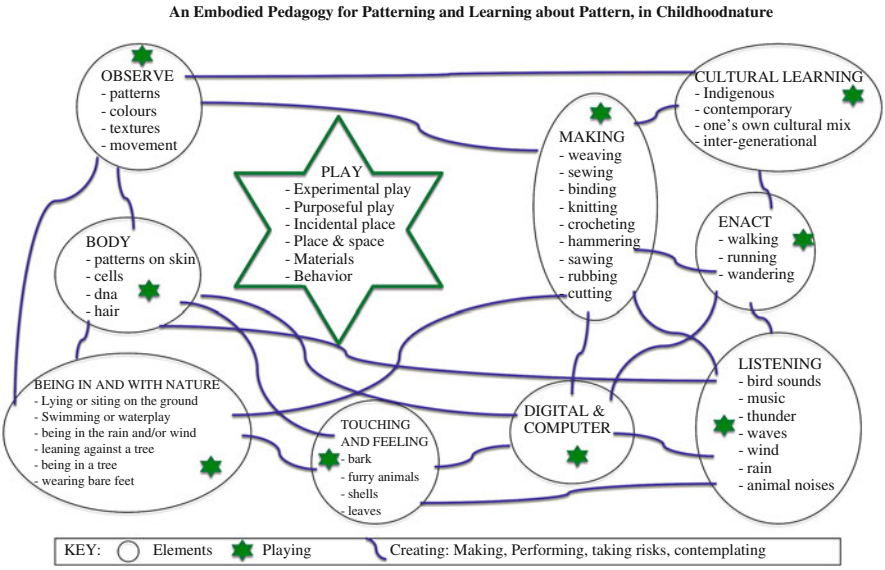

Fig. 6 The authors' diagram of *a pedagogy for patterning in childhoodnature*

There are many patterning experiences children can have in and with nature, such as building shelters with driftwood, lying down in a forest, and allowing nature to leave imprints and marks on paper as part of developing artworks. However, a way that students could take responsibility for "connecting the dots" of their learning is to record drawings of science experiments, nature observations, street scenes, samples, notes, writing, photographs, and so on, in their own handmade journal that they take with them to document their different experiences. A "patterning journey" journal could look different for different individuals and contexts. For younger children, for example, educators might scaffold children's learning experiences through asking questions and pointing out different patterning features along with documenting the process and initiating group reflection.

As an extension of Haraway's thinking about string figures, teachers could more consciously include children's string games in the teaching and learning process to explore the following: where string games originated from, different cultural approaches and materials used, and learning about pattern, line, complex structures, symmetry, and knots. Similarly, the "jumping elastics" children's game has different names and derivatives in Germany, France, and China. As part of their patterning learning, children could explore the variations to the game and learn about the materials used in the past and where this game might have originated. Jumping elastics to a rhyme in itself provides children opportunities to learn patterning through repetitive jumping, musical understanding with riddles, and mathematics learning as they achieve the different heights, jumping combinations, and levels of competence. It offers visual, spatial, and embodied ways of learning patterning with others through the engagement of the properties of the elastic.

Weaving with natural fibers, including dried grasses, reeds, hand-spun paper (shifu), felted fibers, or handmade rope, provide children with opportunities to understand how different string fibers are made then how they are woven. Weaving provides links to cultural practices of patterning across the world and links back to ancient times. Author one, Hannigan, recently worked with an Indigenous elder and an art class to create dried grass animals. The students used straw for convenience, but she noted how this activity involved patterning through binding with wool while shoving dried grass into an animal form. Once children have engaged this activity themselves, they are able to then appreciate the material, technological, and cultural information one generates when creating toys with binding more traditional materials such as dried grasses among Indigenous artists.

As Fig. 6 shows, to think differently we believe patterning learning should cross boundaries. Rather than preschool children learning about patterning in mathematics by rearranging colored blocks, playing with dress-ups as part of dramatic play, and then on another day learning about beehives as part of science, we suggest combining the patterning learning across disciplines. An example of a transdisciplinary approach to patterning learning might be where children construct a beehive, with hexagonal units made with cardboard or cut plastic milk containers, with opportunities to understand the patterning. Next, children could design and dress-up in homemade bee costumes, with opportunities for children to study the different patterns on the bee's abdomen and, like bees, inhabit the beehive wearing their

homemade costumes learning about insect behavior. They could enact the process of bees making honey and fanning the hive when temperatures rise. This transdisciplinary learning experience would provide knowledge and insights about architecture, art, textiles, biology, insect behavior, nature, and culture.

One common way of learning patterning in preschool is where children line up their shoes to learn beginning mathematical concepts such as identifying attributes, matching, sorting, and patterning. Our childhoodnature pedagogy could expand this to provide children with opportunities to explore cultural practices of storing shoes outside in patterned and ordered rows (e.g., as practiced in Japan). This could extend to histories of making shoes out of natural materials and fibers and how this links to nature. To extend the patterning learning further, other cultural practices about shoes could be explored, such as shoe shops with shoes in size order across the store expanding to different size footprints and animal footprints on different surfaces, i.e., sand mud, snow, and so on.

Patterns and exploring the process of patterning are ways of overcoming discipline boundaries and connecting children's biophilic engagement with learning. For example, children observing patterns in water ripples in a river or a creek, or tracking snail trails on a path, or watching ducks fly in a "V" formation, exposes them to nature's patterns and in turn supports children's ecological learning. Further engagement with the ways patterns begin, end, and take a different turn allows children to explore with patterns of sameness and difference within nature. Environmental play is crucial for children to be able to become ecologically and aesthetically engaged learners, in order to inquire about the 'why,' 'why not,' and 'how' of patterning. This in turn fosters interest and insights and helps to develop biophilic dispositions. Through reconceptualizing teaching of patterning in education and by crossing the discipline divides as Fig. 6 illustrates, embracing biophilic pedagogies allows for information and phenomena to be learnt about within all its complexity. We know that young children learn through play, but as argued by Cutter-Mackenzie, Edwards, Moore, and Boyd (2014), children's environmental education needs to be supported by adults because play alone "does not help children to develop pro-environmental dispositions and understandings" (p. 34). Furthermore, adults who have biophilic attitudes can support children to access learning and knowledge about nature, extending their understanding about the environment (Cutter-Mackenzie et al., 2014). Thus, we argue that to teach, learn, and know patterns and patterning require a rethink about what constitutes discipline and non-discipline content, pedagogy, innate knowledge, and connections to nature. Engaging with biophilic pedagogies might just be one way to do this.

Conclusion

This chapter has explored patterning as a transdisciplinary approach to (re)conceptualize childhoodnature. By transgressing established barriers and boundaries found in mainstream education, we have highlighted the potential of patterns and patterning for reconsidering and reconceptualizing pedagogies and curricula. This reconceptualization offers a way of teaching that engages children through finding,

noticing, understanding, and creating patterns. Our reconceptualization of childhoodnature education has maintained that knowledge about patterns and patterning can bring children closer to understanding themselves as ecological beings connected to the natural environment. It provides opportunities for alternative inquiries that allow for deep understanding of the self and its connections to nature.

As the introduction to Section 9 of this handbook states, our patterning and patterned proposition offers a way to attend "to the sensuous and affective qualities of childhoodnature encounters" and that "multiple sites are opened up as vital spaces for children" ("Introduction to Section 9: Childhoodnature Ecological Aesthetics and the Learning Environment" by Rousell and Williams, 2018, this volume). Possible spaces are opened up for children's exploration and wondering, inspired by contemporary artists who practice aesthetics of engagement (Carson, 2012) and promote eco-aesthetic ways of doing and being. The eco-aesthetic, patterned possibilities discussed in this chapter illustrate ways of thinking about transdisciplinary practices with a wide reach into natural and cultural environments and within holistic ways. On a final note, as twenty-first-century citizens, we need to be aware of and respond to creative, transdisciplinary approaches in education, to further the conceptualization and embodiment of childhoodnature.

Abstract

This paper is based upon the inspiration that I find, as an artist and educator, among areas of nanotechnology, art, and pedagogy in response to the Anthropocene. The notion of scale is paramount to this research: through a shift in scale to include the very large and the very small, dichotomous thought is eschewed for a concept of life understood as continual, material process. This awareness affords a pedagogy of creative imagination about the world that can confront current anthropocentric habits and attitudes. The nanoscale space between the atomic force microscope and a single atom is related to the vast geological time of the Anthropocene so that these extreme scales can function as catalysts for artistic imagining. Furthermore, I consider these extreme, inhuman scales with respect to the child in/of nature. Specifically, I examine the Western, educational norms of nature understood as a benevolent backdrop to human rejuvenation. In doing so, I look to a Deleuze-Guattarian concept of intensity within a rhizomatic concept of measurement as an artistic strategy. Current life

requires a shift in ontological understanding to first identify established assumptions about planetary relationships and, second, to experiment with novel views offered by emergent conditions and technologies. This can begin with a reconsideration of ideas about the child and nature. Educators are poised to influence how this version of human/non/inhuman relationality will develop. Changes in the ways we live among other species and with the inhuman Earth must take into account a more geologically and ecologically sensitive perspective, and cultural connections between the sciences and the arts can help promote this necessity.

Introduction

This chapter critiques the educational trend that considers the child and nature as a narrowly constructed dichotomy whereby the typical urban child is imbued with the loss due to a lack of exposure to nature (Louv, 2012). In considering alternative configurations of childhood in education, I expand to connect education to the larger society, something that is necessary to understand how change can be relevant within and beyond educational institutions. I theorize how the nanoscale can expand the imagination of what our human relationship with the planet might become. Given that ecological destruction is evident in this age of the Anthropocene, ways to educate children and the larger public with an ontological shift toward a greater sensitivity about the planet are desirable and necessary. I posit that through art making and viewing, the deeply tacit values with respect to human-non/inhuman relations can be examined and better understood.

Furthermore, the aesthetic approach can help to unpack the constructed duality of nature and culture with specific focus on the child. The expanding understanding of the world to include the tiny nanoscale affords a pedagogical moment to help formulate how humans are part of a material process of natural/cultural emergence. With this in mind, I probe what significance this might have for creative, cultural, and educational work. This fosters another avenue of investigation: what does it mean to be human within relationships fostered through imaginative considerations of materiality? Put differently, when anything can be created by manipulating atoms through nanotechnology, what might be made of ourselves in the face of this power? Specifically, I ask how nano-culture is explored so that an understanding of this scale develops with respect to social and environmental implications and so that students and teachers are able to take full advantage of the imaginative potential and the social implications of nanotechnology in the continued development of an entangled world.

As a form of education, meaningful aesthetic experiences that open up ideas about life occur when notions of self are linked to ways that social values are cultivated, communicated, and/or questioned (Emme, 2001; Pente, 2008, 2010).

By considering a shift of scale, the ways that we, as educators, take the human scale regarding Earth for granted can be highlighted through imagining the world at the very small level of the nanoscale. By including consideration of this scale, I call into question the pervasive underlying assumptions of human exceptionalism, including an assumption of fixed identity that purports a superior self as contained within the world, yet separate from it. Variations of this position play out within education in the correlation of notions of the child with an idealized form of nature (Louv, 2012). This is the Anthropos-centered perspective of human experience. Obviously, different species perceive different ranges within scale, but the problem in which I engage is the implication of perceiving multiple scales of life at this contemporary Anthropocentric moment. When nanotechnology stretches scales of perception, the artist can catalyze movement into uncertain, new territories, and this has the possibility to change notions of what life might become and what the world might become.

Nanotechnology is about the study and manipulation of materials at the scale of billions of a meter: beyond what the eye can see without the prosthetic of electron microscopy. Such a specific size positions the nano-world between the physical properties and behaviors of quantum mechanics and those of the macro-world. In other words, unique events occur among and within materials at this range. In a sense, it is a hidden world within our everyday lives. Nano-science is a relatively recent influence within the public imaginary and will continue to have an accelerated, exponential impact on the world (Drexler, 2010). Given that visualization of phenomena is key in education and given that there exists a creative confluence of science and art within many contemporary art and educational circles, we have what philosopher, Gilles Deleuze, might appreciate as a perfect storm of generative possibility with regard to nanotechnology, art, and education. The eye of this storm is the ethical and social imperative to consider our relationship with the Earth and each other in these Anthropocentric conditions. As Jami Weinstein and Claire Colebrook observe, "what we know as 'life' and 'nature' is always given in multiple, fleeting, partial, haunting, and disturbing encounters" (2017, p. 13). I inquire into ways that aesthetic encounters with measurement and expanded scales might open up and "disturb" the multiple relationships among concepts of the child, nature, and education. Significantly, this kind of ontological thinking can support renewed educational practices in the classroom with respect to our ecological selves.

Accuracy of measurement is desired tremendously within all scientific and educational areas that use scales to seek exacting representations of the world. There is an unspoken quest for *the* empirical truth in such activities of measurement. As sophisticated instruments measure at the nanoscale, the data expands knowledge beyond the human, thereby extending thresholds of the known/unknowable regarding our material world. By rethinking the act of measurement as a process of differentiation, disruption, or interruption, rather than as a form of representation, the potential for the aesthetic and imagination to open possibilities for considering the human as integrated with the world is possible. The significance is the influence of difference, in a Romanticism (1994) sense, rather than the influence of identity: with such a focus, the world becomes strange and thus renewed in moments of perception. This parallels aesthetic experience and/or artistic acts of exploration.

In delving deeply into generative questions and answers to these probes, I organize the chapter with a critique of nature and child in education, followed by a discussion about nanotechnology. Next, I expand with comments about the Anthropocene. Finally, I will link the previous sections to opportunities within art, anticipating the future educational world that will continue to mix technical, physical, and virtual relationships as part of the material world.

Nature and the Child in Education

There is a customary division between nature and the child within educational circles that reflects a form of human exceptionalism: it underlies a perpetuation of "man" as manipulator of the land, as evidenced with his environmentally destructive planetary use of resources. This perspective underlies environmental and outdoor education in North America (Clarke, 2017; Malone, 2017). Specifically, these fields are based upon understanding of the child as a separate being who acts within a rural environment that is called "nature." This has the unintended result of sustaining larger social, humanist assumptions that William Connolly (2017) identifies as "ghosts of mastery, sociocentrism, and human exceptionalism" (p. 13). Connolly warns that none of these social realities can be sustained over years if we are to adjust to and change our current, Anthropocentric realities of this planetary, climactic situation. With our continued mix of capitalism and planetary overuse, our educational systems in the West are complicit with these tacit values that continue to gird an understanding of childhood as a time of individual development where this separation of human and planet is maintained. For example, there are typical lessons surrounding sustainability where the phrase, "recycle, reuse, and reduce," is common in North American schools. On the surface, this is, of course, a good attitude to introduce to children, yet this also maintains a division between human and the planet in terms of agency. The child is the agent in this scenario and is encouraged to act upon the planet through consideration of her environmental footprint. What is often missing in these practical assignments, however, is a consideration of our human and non/inhuman relationships. Alternatively, introducing a posthuman perspective situates children, along with adults, as ontologically invested with a relational world among other living and nonliving agents. This aligns with Weinstein and Colebrook (2017) who purport a renewed examination of life in a philosophical sense, and now that life in a biological sense has moved so far beyond the human into – for example – nanoscaled entities. In recent posthuman studies and philosophies of new materialism, this perspective is championed as a potential way of considering life. With respect to moving into a different relationship with the Earth, educator, David Clarke, draws upon a Deleuzian focus to envision an ontological middle in order to eschew the familiar, linear story of beginnings and endings. As he suggests, a middle "... may be one way to help engender new materialist and animistic ways of seeing with learners, demonstrating the intra-relational becoming of the world with students in any way we can" (2017, p. 317). Taking his lead, I consider the threshold between notions of child and nature as active and mobile,

so that the relationship between these two can move toward a new understanding of our planet and our human selves in education. I build on work that has already begun in this area.

On the topic of the usual shaping of human/planetary or child/nature relations, educator, Karen Malone (2016), identifies and debunks three assumptions within current discourse regarding the *child in nature* as a movement that has developed within Western educational circles. Firstly, she observes the assumption that the child is separate from nature; secondly, that nature is romanticized as a backdrop, like an "inanimate object" for human use; and thirdly, that the ways the child is theorized hide a white, middle-class, male bias. All three points are key to analyzing a Western residue of Cartesianism (referenced as a mind/body division) that is maintained through the narrow perspective that there is a "thing" called nature that is benevolent, rejuvenating, and kind. This cultural depiction is reflected in popular forms of entertainment when notions of wilderness and untouched green spaces are presented as idyllic. The person is made whole through physical experiences within this utopian idea of wilderness. Identified as ecocriticism or green Romanticism, this view of nature is found in much Western English literature. As Vince Carducci (2009, p. 633) explains, "the 'problem' of ecocriticism is its putting nature on a pedestal, casting it as the pristine other of modern civilization and of the autonomous individual self..." This version of untouched nature as healer is also found in ubiquitous advertisements for various products, in movies and television, and in other forms of visual culture. It is so prevalent that the population tends to accept this perspective without question. However, in actuality, all of the land, air, and sea are worked, used, marked, and/or occupied by the human footprint in some way. The Anthropocene adds geological evidence of this fact (Crutzen, 2002).

I return to the idea of a benevolent nature as a Western male bias (Malone, 2016). What is missing in this normative assumption is the important fact that humans, male, female, or otherwise identified, are also part of nature, along with nonhuman and inhuman entities. It is more productive to think about all life anew through a Deleuze-Guattarian (1987) notion of mobile intensities and processual change within and of the world. The child understood as an emergent, material agent along with the rest of the living and nonliving agents reflects this perspective. Significantly, in reference to her research with children in La Paz, Bolivia, Malone describes how "these approaches allowed me to imagine a view of agency not tied exclusively to humans. Nonhuman entities became more than simply objects being directed by humans, but as subjects in their own right, they were shaping an exchange and co-merging with children" (2016, p. 48). Alas, this perspective is not yet as pervasive as the romantic idea of the child in need of benevolent nature to become whole and to have agency, which continues to perpetuate the notion of human domination over "nature" and at the same time limits the multiple ways that materiality presents as the world. The relationships among entities in/of the world are much more complicated than a simplified duality can accommodate. This becomes evident in various areas of knowledge. For example, in the development of nanotechnology, the division of life/nonlife at this very small scale becomes moot. These nanoscaled workings have repercussions for thinking about the reshaping of the

terms human/child and nature in this time of the Anthropocene because they provide material force of the particle without the familiar macro-sized divisions (e.g., human and other).

Nanotechnology

Nanotechnology refers to the study and use of materials at the small range of 1–100 nm, where 1 nm is equal to 1 billionth of a meter. To put this into perspective, one human hair has a diameter of 80,000 nm. It is at this size that materials exhibit unique properties and behaviors. For example, melting points, magnetism, color, tensile strength, reactions to other materials, etc. are different at the nanoscale, and this allows for novel applications (Ramsden, & Freeman, 2009). Organic and inorganic take on new meaning. Although still experimental, scientists can manipulate and move individual atoms with the use of electron microscopy. Future applications continue to expand (Drexler, 2010). Industry and academia are very active and efficient in self-regulation (Rip & van Lente, 2013), but there is much that is unknown because discovery moves to application relatively quickly (Dorbeck-Jung & Shelley-Egan, 2013; Hunt, 2006). The drive for economic profit has produced items as variable as cosmetics, paint, and drug delivery systems (Khan, 2012). Importantly, nanotechnology may hold keys for stronger environmental sustainability: a goal that is increasingly becoming urgently needed (Newberry, 2012; Smith & Granqvist, 2011). Many scholars agree that nanotechnology is the most influential change of our times (Bowman, Stokes, & Bennett, 2013; Corner & Pidgeon, 2012; Feyman, 1960; Goldenberg, 2006; Hayles, 2004; Lively, Conroy, Weaver, & Bimber, 2012; Mehta & Hunt, 2006; Ratner & Ratner, 2003; Wolfe & Medikonda, 2012; UNESCO, 2006). With this in mind, I question how nanotechnology is taken up in the consideration of our ecological relationships regarding the child and nature in education. Greater discussion about the concepts of nanotechnology in the public realm and in K-university education systems is necessary (Duncan et al. 2010; Light Feather, 2012). Firstly, with greater discussion about the natural/human world filtered through the nanoscale, students may make connections that take them beyond the conceptual separation of their physicality and their world. At the level of the nanoscale, commonalities and traits between living/nonliving take on new meaning. While careful not to fall into yet another romanticized version of life whereby all living and nonliving entities are viewed simply as various compilations of small atomic particles, as an initial perspective, the nanoscale is useful in opening conversations regarding the established dualities within child/nature. Importantly, these multiple ways of understanding the world differently emphasize the idea that nature is cultural: that a person's point of view, bias, and upbringing all contribute to how nature is understood. As Congdon (2006, p. 50) notes, "we must ask questions about who has the power to make new knowledge, represent new ways of seeing the world, and participate in the construction of new cultures and a rapidly changing world." In this regard, questions about the nature and reception of that knowledge are important. Consequently, scholars have cautioned against demonizing or

deifying this emergent nanotechnology, where fantastic scenarios about products and effects of nanotechnology have instilled fear or hope in unrealistic ways (Gimzewski & Vesna, 2004; Rogers-Brown, Shearer, Herr Harthorn, & Martin, 2012; Siegrist, 2012). Ultimately, the ethical compass of policy is in the hands of individual governments, and so it is imperative to have an informed public who can guide and provide input for future direction (McGinn, 2012; Newfield, 2012; Peterson, 2004). This is not an easy task, however, if information about nanotechnology is minimal, distorted, or incomprehensible to the average person. Scientist, Ahmed Khan, notes, "as we design systems on a nanoscale, we develop the capability to redesign the structure of all materials – natural and synthetic – along with rethinking the new possibilities of the reconstruction of any and all materials. Such a change in our design power presents tremendous social and ethical questions" (2012, p. 25). Khan's point brings to the forefront the urgency to examine the ways that education continues to support human exceptionalism in either covert or overt ways. Rather than considering nanotechnology as a tool that humans use to control the world, it can be employed in a philosophical sense to create linkages among entities along with the human: a distinctly posthuman (Braidotti, 2013) interpretation of nanotechnology.

Measurement as an Artistic Methodology

One interesting challenge for educators considering nanotechnology is the relationship of the "invisible" materials at the small nanoscale with the visible character of the human scale. This becomes an ontological question about the human in relation to other entities due to the fact that the electron becomes key in understanding "nature" at this level. The assemblage of electron scanning microscope – human eye – electron acts to dissolve barriers between nature and the human, opening thought to relationships among human/nonhuman/inhuman/posthuman. All of these prefixes indicate the expanded conversation within new materialism to reposition the human in relation with the Earth. One move toward this goal might be found through creative explorations of nanotechnology concepts of self-assembly, volume-to-surface ratios, electromagnetic forces, and electron spin: all of which focus attention on actions at the level of the electron – within and beyond the human.

Historically, we have always instinctively measured our positionality in the world through corporeal comparisons which are automatic responses to our bodies in/of place. However, as Nordmann (2006, p. 56) notes, the "inconceivability" of the complexity of nanotechnology results in a "decoupling of the technical control with causal representation." This occurs, in part, when we attempt to understand the ramifications of nanotechnology capabilities that are so distant from our physical perceptions. The very small size and inherent complexities baffle human perception. A useful approach to this "lost sensibility" is found in the work of new materialism. In this body of literature, the mixtures of culture, nature, and technology can shift the hierarchy among entities in the world so that humans are no long at the ontological pinnacle (Bennett, 2010). Scholars highlight our embeddedness in the world through

shared, material connections (Ahmed, 2010; Barad, 2007; Connolly, 2010; Coole, 2010; Grosz, 2010). This perspective aligns with Malone's (2017) understanding of the complexities of the child enmeshed in daily encounters and historical experiences with other entities.

Within nano-measurement, divisions are shaken as the logic of dichotomy is re-tasked. Dualities at the nanoscale are physically softened as borders and membranes become permeable at the size of the particle. While this is an unnerving possibility for many, it also loosens thought toward a metaphorically thinner skin. Thus, subject/object, child/nature, or culture/nature is eschewed for a Deleuze-Guattarian (1987) middle of emergent subjectivity (Braidotti, 2011) that focuses on notions of surface (Deleuze, 2003) and manifests in opportunities for wonder. By thinking the act of measurement differently, not as a quest for truth and/or confirmation of existence as it currently plays out within a stationary, corporeal positionality, but rather, as a creative act of continual emergence as the surface of the Earth, measurement shifts from a scientific act toward one of philosophical and artistic inquiry. Such a renewed consideration of measurement can be pedagogical, suggesting a deterritorializing of attitudes, identities, and possibilities. By rethinking the act of measurement as art praxis, the artist pushes out from within the norms of the human scale. Thus, in aesthetic exploration, measurement becomes a line of flight, as the artist "becomes" surface through a shift in scale (Deleuze & Guattari, 1987). This focus on the surface of the Earth, and on the skin of the body, sets up a commonality that functions to think other than the separation of the body and world. Both are surface, albeit with different textural qualities. The "ontological gap" of dualities, Karen Barad (2003, p. 802) suggests, is sometimes better addressed without language. Thus, artistic moments influenced by the nanoscale provide opportunity to think about one's place in the world metonymically as part of the surface of the Earth. This is significant because surface areas, so key in nanotechnology, become the "between" or middle when two surfaces touch through electron force.

This way of thinking about one's "place" as a continuation of the surface of the Earth not only erodes the separation of self and others but also works as a form of smooth space. Deleuze and Guattari (1987) describe the smooth and striated as ever changing, always connected, and open to possible ruptures within normative behaviors. In this case, normative considerations of the body are fixed in a particular place as striated space remains within dichotomous forms of representation. Like the nano-surface, however, the psychological, aesthetic middle space is active and continually changing in unpredictable ways so that to consider surface as smooth space can be an inroad toward thinking anew. The human/nonhuman duality is reconsidered. The advantage might be a more responsible attitude or outlook toward the Earth and to children with whom we, as educators, teach/share/connect as part of this convoluted surface. It is in creative thought such as this that the child/nature machinic assemblage can emerge and be transformative for education.

Deleuze (1994) thinks through the significance of repetitions that are found, not in representation (identification of one thing as being different from another) but in the activity that is repeated through, in this case, creative linkage of nanotechnology to

concepts of the self in relation to the world. Following Deleuze, rhizomatic linkages among extremes of scale offer a very different approach to measurement than what is normally assumed as the metaphor of linear sizes that move from larger to smaller, or the reverse. Instead of this nesting metaphor, so ingrained in approaches to measuring natural phenomenon, the rhizomatic metaphor allows for divergent sizes to affect each other and to work randomly. This is nearer to the function of materials at the nanoscale and to their influence on the macro-world.

This is not to suggest that educators become familiar with and use the materials and/or processes of nanotechnology in depth, for this suggestion would negatively feed into the illusion of human exceptionalism with respect to affordances within new technologies. As a heuristic strategy, however, educators can look to phenomena highlighted by nanotechnology with its focus on the unique activities at this size, and consider what it means to be a child who is emergently living in/with/as the Anthropocene.

Anthropocene

Much has been discussed and written regarding the Anthropocene. As the term suggests, it refers to the levels of human activity that are evidenced in the geological layers of the Earth. For example, rising ocean levels, high carbon dioxide levels, extensive overuse of fossil fuels, species extinction, ozone depletion, and many more destructive changes – some irreversible – are the result of human activity: typically, activity that maintains or drives a lifestyle of affluence (Colebrook, 2016). Atmospheric chemist, Paul Crutzen, along with colleague, Eugene Stoermer, used the term, Anthropocene, to denote these permanent signs of human activity that stand out as a layer of geological strata upon the Earth (Crutzen, 2002; Crutzen & Stoermer, 2000). Currently, the Anthropocene is entrenched within popular culture through disaster cinema, TV, and other forms of culture (Colebrook, 2016; Jagodzinski, 2015). There are many ways that the Anthropocene presents to the public: websites that focus on it as a form of public education, artists who consider the Anthropocene (Anderson, 2015), scholarly journals about the Anthropocene, and advertisements that exploit the term to promote "greener" consumerism. The ways that this term and its connotations are taken up within education are of concern here.

The dualism of human and planet, or as discussed earlier, child/nature, exists in assumptions concerning the Anthropocene. Discussion often results in urgent calls for the human to fix the planetary woes that are the result of continued human consumption. While stopping such glut is necessary, care must be taken that the call does not lump all of humanity together in a way that reinforces a form of humanism whereby "man" is in control of the planet: as Colebrook and Weinstein note, "what has now been referred to as the Anthropocene seems to chasten humanity by noting a destructive impact that reaches geological intensity, but the Anthropocene also invites projects of geoengineering and uncritical uses of a once multiple but now reunified humanity" (2017, p. 22). Such a complicated reaction to this current state of planetary stress reflects an all-too-human desire to fix and stabilize the

environment. However, this may only exacerbate the separation of the human from the world. The relationships among entities on/of the planet are much more complex. The threat of extinction of the human as a species has further united the human, which has had the unfortunate result in strengthening this divide in some instances (Colebrook, 2016).

Politically, such an urgency to act toward a more sustainable relationship with the Earth, while necessary, also entertains a negative side. Colebrook (2016) warns that this perspective opens the door to institutional action that impedes the voicing of multiple, contradictory positions. This dissention and discussion are necessary for healthy democratic process. She notes that the fear of species destruction and other dire consequences surrounding the degradation of the planet can give governments a tool by which they act unilaterally, with the populous in fearful acquiescence. In this scenario, the Anthropocene flattens out all possible differences into the narrative of privileged humanity with respect to the rest of the planet. It erodes theoretical efforts to build new, more symbiotic relations with living and nonliving entities (Colebrook, 2016).

The very large scale of geological time that is brought to attention with discussion of the Anthropocene leaves most of us humanly incapable of deeply internalizing its significance. While opposite in size, the nanoscale suggests a similar incomprehension. There are unique affordances and limitations in every scale, but it is noteworthy that both the inhuman geological time scale and nanoscale emphasize our all-too-human limitations with respect to understanding the complexities of the planet. Within nano-measurement and within geological time, the norms that orient the human on the Earth are shaken. As Weinstein and Colebrook propose, the "…*inhuman* orients us to all that is not human, not just that which comes after the human. It also pushes us to scales beyond the human-temporalities and spatialities both deep and astronomical" (2017, p. 5, italics in original). As scale moves from kilometric to nanometric spaces and as time moves from the hour or year to the eon, it raises questions regarding the very notion of what it means to perceive: a very human activity that begins a child's entry into her world.

Art and Education for the Anthropocene

Imagination and perception of the observable world are two poles upon which an art curriculum often is built. Children are encouraged to tap into both of these methods of understanding their lives through various activities with art materials. Typically, in education, concepts quickly turn to application in the practical school setting. Thus, it can be difficult to maintain a force of inquiry that reveals new ways of considering life and the world. However, through the creative force of art, alternative approaches to the creation of new problems to be investigated are encouraged. It is important to open avenues for children to think about life in new ways such that success in dealing with the complexities within the term "nature" can be broached. As Weinstein and Colebrook advise about approaching the current climate crisis, "this approach must be creative and experimental, expansive and self -overcoming,

insofar as an analysis of life that utilizes traditional methods and concepts risks an unwitting return to the predictable, universal, habitual, and hegemonic" (2017, p. 12). Art within the child's life can be such an avenue, and there is, with its potential for affect, opportunity to reach deeply into ontological thinking about life.

The failure to fully recognize the value of creating and viewing art for the pleasure of exploring the imagination and for making connections between art and the world leaves the child missing important understandings about her place in/of the world and about her abilities to act in public situations that demand her voice. This reality is particularly troubling at the level of the young child, whose imagination is at its most formative, expansive, and vulnerable phase. Part of the responsibility of educators is to help students make connections between their creative efforts and their relationships with the world and with others. Art education can be a form of affective, continual interruption in normative assumptions about the multiple, concurrent aspects of our planetary systems. Art can generate the education that is needed to participate in conversations regarding events, activities, and objects hitherto unknown – like the advent of nanotechnology and the Anthropocene. Influenced by the artistic encounter (O'Sullivan, 2006), there is a powerful opportunity for learning within emergence from familiar, artistic forms to unfamiliar, uncertain ones. Consideration of the nanoscale offers artists, teachers, and children avenues that deviate from the norms of skill-based art education trajectories that often lack thoughtful discussion and learning about our contemporary relationships with/as nature. As art educator Jan Jagodzinski notes, "Nature will continue to enjoy in its own "meaningless" way. It is perhaps part and parcel of the *fetishistic disavowal* of an ecological crisis that is already here. We need an ecology *without* Nature" (2013, p. 279, italics in original). For art educators who might be stuck in a representational cycle of defining art as self-expression that primarily romanticizes nature as beautiful, the discovery of concepts that move beyond these traditional forms can be daunting. However, it is this unique aspect of art that can generate new thinking about social responses to the human/non/inhuman (Garoian, 2014). The magnitude of the problems of the Anthropocene requires this kind of consideration.

Thinking of art and the nanoscale not only suggests alternative ways to investigate this realm of art and science, but more importantly, it opens the possibility that there may be deeply ontological shifts in the child's understanding of her world through these kinds of activities. Importantly, art educator, Thomas Barone, links art and agency when he states, "Art is connected to a political act – to think otherwise is doing a disservice to society, to students, to artists – there is no private aesthetic imagination" (Barone, 2001, p. 147). Art that lays bare, resists, or intervenes in social norms to draw attention to the peculiarities and paradoxes of contemporary life is glimpsed through cultural moments of affect. As a method of inquiry, affect can be a powerful moment for teachers and children to consider their lives in new ways (Hickey-Moody, 2013). Educators can reach for this kind of ontological surprise through experimentation in creative activities along with their students and communities (Pente & Beaton, 2015).

Consideration of nanotechnology can stand as one example of this process. Witness, for example, the work of artist, Les Bicknell, who explores the thinking

processes of scientists working with nanotechnology. The unique interdisciplinarity of these technologies lends themselves to creative thinking so that the borders between art and science tend to meld and blur. In his project, *Unfolding the Thinking*, Bicknell captures, through image and film, the ways scientists move. Their physical gestures are the focus of this work. His artistic investigation is also inspired by the specific capacities of the machinery used in nanotechnology. Much of this work is being completed in a residency at the University of Cambridge (Bicknell, 2017). Furthermore, in work that I am currently exploring, after spending time in a similar residency at the Canadian Institute for Nanotechnology (The Canadian National Institute for Nanotechnology can be found using this link http://www.nint-innt.ca/), the behaviors such as molecular self-assembly are the inspiration for a series of GPS drawings that are underway. This type of artistic work offers insight into the ways that interdisciplinary projects can uproot traditional dualities (such as child and nature) that stifle new approaches to life. Art projects that are informed by the nanoscale can be incorporated into education through an interdisciplinary approach.

Conclusion

In this research, consideration of what might become of education if the child's world is expanded through an aesthetic exposure to the discoveries and processes of nanotechnology is pursued. Based upon the affordances of electron microscopy, rethinking notions of nature/culture (Haraway, 2016) and the child raises questions about what humans might create with their bodies in space and time if the perceptions of the world stretch to the nanoscale and geological time. Teaching and learning with the invisible force of electron activity informing perceptions of bodies on the surface of the Earth can extend a sense of materiality: an ecology that moves toward a greater aesthetic connection with the entities of the Earth – living and nonliving. As Clarke describes such consequences for education, "in this way the student is not urged to 'connect with nature,' as there is no 'nature.' Rather, they are urged to consider how they are materially manifested of the world" (2017, pp. 313–314). Influenced by qualities and behaviors of particles within nanotechnology, a shift to an idea of the body as part of the surface of the Earth is helpful in disturbing social and educational norms that situate the child as detached from a "backdrop" of nature. Furthermore, if children are offered artistic opportunities to imagine materials and locations with/in the surface of the Earth – to imagine that which they cannot see – the scales of nanotechnology and geological time may suggest to them alternate ways of becoming in the world. This expansion of measurement and scale may afford a different kind of perception and an increased awareness of ways that the Earth is linked to/as life in all its shifting permutations.

In closing, the realities of the Anthropocene will instigate a renewed exploration of life that can bring children and their education closer to a more intimate connection with/among entities of the world. Unfortunately, fear and urgency may channel individual agency too far onto the State through a misguided interpretation of the

human acting to correct past ecological wrongs. Current life requires a shift in understanding to first identify established educational assumptions about planetary relationships and, second, to experiment with new concepts offered by new conditions and technologies. This can begin with a reconsideration of the concepts of the child and nature. Educators are poised to influence how this version of human/non/inhuman relationality will develop. Changes in the ways humans live among other species and with the inhuman Earth must take into account a more geologically and ecologically sensitive perspective, and cultural connections between the sciences and the arts can help promote this necessity. With this in mind, I continue to explore the ways that philosophy inspires at the edges of materiality and science pushes at the edges of art to generate educational change.

Abstract

This chapter aims to establish embodied movement as both the physical and metaphysical ground for learning, including aesthetic learning in an ecological context. We advocate the moving body as critical to celebrating and deepening childhoodnature. The disconnections from embodiment that have occurred within western cultures and the implications of educational settings that lack an acceptance of natural movement expression and experiential "whole body" learning methodologies are discussed.

A *double bind* arises from the split between mind and body, humanity and nature, and scientific materialism and broader holistic views of science (Moradian, Double Bind: Finding our way back home (manuscript in preparation), 2017). Examples of problems, solutions, and research suggestions are provided through a series of vignettes that offer an analysis of bodily disassociation, or disembodiment, and propose a revitalization of thinking, feeling, and living childhoodnature through the body *in* and *as* movement. We suggest that developing a lifelong somatic relationship with our bodies in motion, a relationship in which we bring our attention to our lived (psychosensory-motor) experience, is a powerful way to reclaim that wholeness which allows us to care and connect for self and others, to feel a sense of place and belonging, and to self-regulate our behavior for optimal interaction with our world.

Introduction

> The body itself holds many of the lessons we need to live sustainably in the world. (Moradian, 2017, p. 9)

Dance has been called forth in recent years as a powerful metaphor, reminding us that time, space, and matter are intimately interwoven through movement (Manning, 2013). Somatic practice, the study of "the living body" or *soma* (Eddy, 2016a, p. 5) "not as an objective 'body,' but an embodied process of internal awareness and communication" (Fraleigh, 2015; Green, 2002), can offer a way of remembering our place in the living world, a way of *dancing* which engages us consciously in the movement of life in its fullest sense, rendering each life a *work of art* (see also Rousell & Fell, in press).

This chapter aims to set embodied concepts of childhood and nature in motion by establishing an aesthetic of embodied movement as both the physical and metaphysical ground for learning. We advocate the moving body as critical to celebrating and deepening childhoodnature. We begin by outlining the disconnections from embodiment that have occurred within western cultures. We discuss the implications of educational settings that lack an acceptance of natural movement expression and experiential "whole body" learning methodologies. A *double bind* arises from the split between mind and body, humanity and nature, and scientific materialism and broader holistic views of science (Moradian, 2017). These are hurdles we must overcome to return to wholeness. We provide examples of problems, solutions, and research suggestions through a series of vignettes that offer an analysis of disembodiment and propose a revitalization of thinking, feeling, and living childhoodnature through the body *in* and *as* movement. We share views that work through the concept of childhoodnature as a moving experience and the embodiment of movement itself as a

living creative process of learning and transformation. Rather than proceeding in a linear fashion, we have preferred a visceral, intuitive, and creative interplay of words, ideas, movements, metaphors, images, and interrelations, which can be envisioned as a *dance*.

A key thesis of this chapter is that including bodily movement in education is important and that, in order to specifically foster concepts of childhoodnature, selectivity about the types of movement education engaged in matters. We propose the use of activities that meet the goals of whole-bodied engagement merged with teaching somatic awareness that supports compassionate, kinesthetic empathy. We purport that learning both personally and experientially includes the ways that nature interacts within ecologies, providing strategies for self-regulation, sustainable relationships, and coexistence that are necessary for species survival. Somatic movement education, especially within a "social somatic" context, meets these objectives even within the adverse conditions of disruption, displacement, fear, bullying, harassment (Eddy, 1998, 2016a), violence, and torture (Eddy, 2010a). For the purposes of this chapter, the term "somatic movement" is being used in its fullest sense to include not only contemporary practices of mind-body integration but also all practices that engage whole body-mind-being in life-affirming relationships, including the antecedents of somatic practices within indigenous cultures in the East and Global South.

Thomas Hanna, who coined the term *somatics*, defined it as "the body as perceived from within" (Hanna, 2015). We appreciate the expansion of this definition to:

> . . .a holistic change theory that understands both personal and collective transformation from a radically different paradigm. Somatics understands both the personal and collective as a combination of biological, evolutionary, emotional and psychological aspects, shaped by social and historical norms and adaptive to a wide array of both resilient and oppressive forces. (Generative Somatics, 2017, p. 3)

The body itself is an important landscape for learning, a complex system within other complex systems, including not only natural and physical ecologies but also ecologies of thought, feeling, community and culture. Dwelling in the moving body opens directly to the experience of childhoodnature – to the vast field of relational interplay that is life. This state of awareness establishes direct and interactive relationship with nature, teaching us to recognize what is sustainable and what is destructive. Our long experience as movement practitioners indicates that these patterns of movement spill over into a myriad of relationships.

The Double Bind

> Ecological health continues to elude us – and perhaps indeed depends upon the reconstruction of patterns of thought. (Bateson, 2000, p. xii)

The attempt to set humanity apart from nature predated the Cartesian split of mind and body (in the early seventeenth century) by at least a couple of millennia, both in the west and in the east. A dualism between "that which endures and that

which changes" was introduced during the late Bronze and early Iron Age (1550 BCE to 600 BCE), preparing the way "for the distinction between energy and form, later to become that between 'nature' and 'spirit'" (Baring & Cashford, 1993), and followed by a rejection of both body and nature.

Economist John Maynard Keynes "believed that it was fear of the unknown which played the predominant part in shaping the religions, rituals, rules, networks, and conventions of society. The function of belief systems and institutions was to give humans courage to act in face of the unknown and unknowable" (Skidelsky, 2010, p. xix). At least since Archimedes (287–212 BCE), if not well before, enormous effort has been invested in the attempt to systematically understand, predict, manipulate, and control the natural world. Great strides have been made in this direction since that time. Hannah Arendt, however, presciently predicted that in discovering the *Archimedean Point* (that point outside the earth from which we might control and manipulate it), we would find ourselves stranded, outside and apart from our world, unable to find our way back in (1998).

The alarming increase in dysfunctional human behavior (Brown, 2010) and the destruction of planetary equilibrium (Brown, 2009) point to a "self-correcting system which has lost its governor" and has begun a "spiral into never-ending, but always systemic distortions" (Bateson, 2000, p. 212). Despite the advancements of science and technology, persistent behaviors, dominant belief systems, and their constructs (Berger & Luckman, 1966) have brought us to a point that places life on the planet and the *web of life* that sustains us in peril (Capra, 1996). To survive within the human world that we have created, we have learned to shut off our feedback systems of embodied awareness, pretending that we neither affect nor are affected by one another or our world (Brown, 2010; Eddy, 2016a; Stromsted, 2017). This deeply entrenched idea of humanity apart from nature, and the separation of body from mind, has created a double bind (Moradian, 2017). Gregory Bateson identified a double bind as "a situation in which no matter what a person does, he can't win" and suggests that living in a double bind contributes to schizophrenia (2000, p. 201). While our deepest human need is intimacy, connection, and belonging (Brown, 2010; Stromsted, 2017), we have systematically *dis*connected in order to "succeed" in our rational, competitive, consumeristic world. When we disconnect from the body, we lose our sense of place and self, along with our capacity to feel, self-regulate, care, and belong. When we disconnect from nature, we deny the processes and structures of relationship that sustain life. When we disconnect from each other, we render our actions toward each other less and less humane.

In our desperation to fill the vast emptiness engendered by severing ourselves from the experience of our lives, we race ever-faster away from our unbearable discomfort or toward the acquisition of something we hope will relieve it. Western civilization, we find, has developed into a culture of detachment, objectification, competition, and exploitation, with an economy based on relentless acquisition, consumption, and waste of limited resources. In the USA, Johann Hari points out astutely that "We have created a society where a significant number of our fellow citizens cannot bear to be present in their lives" (2015). We suggest that the violence we see outwardly expressed against each other and our natural world reflects this less

visible violence of disengagement that many of us commit against ourselves on a daily basis and that this condition is perpetuated in our schools.

In writing this chapter on the role of movement in re-establishing life-affirming interrelationship – which we see as fundamental to childhoodnature – we recognize that we speak primarily from a western, northern-hemisphere perspective. While accounting for only a minority of the world's population, the western exploitative and hegemonistic perspective has been disturbingly successful in spreading, bringing the world today to the threshold of disaster. Understanding and addressing the issues that lay at the roots of this malaise may help prevent or even inoculate against it, as well as find ways to engage in new patterns of dynamic equilibrium (Capra, 1996; Capra & Luisi, 2014). Furthermore, awakening to knowledge from and rooted in non-western and indigenous cultures is vital to restore balance through holistic self-regulation and health, as well as in giving voice to disparities (Low, 2013).

Vignette 1: Dancing our Lives

> We enter the world through the body, embraced and cradled in the ceaseless motion that is the hallmark of life itself. The body is, simultaneously, a landscape in and through which we discover, explore, and express our being; a vehicle through which we navigate, learn about, and act with/in the world; and our primary dwelling place. All matter is an expression and a part of nature and is in a constant process of change.

An ongoing state of dynamic balance is foundational to all living systems (Capra & Luisi, 2014; Margulis, 2011). This includes the human body and human being. Every child born into this dimension of time-space enters and experiences the moving world through a moving body. Neither movement nor the body can be separated from nature. We suggest that "mindful movement" and the relatively new field of somatic education offer a way, like "Ariadne's string," to remain conscious as we delve deep within our moving bodies, immersing in and merging with our living wholeness (Eddy, 2016a).

In the context of childhoodnature, aesthetics, and sustainability education, we propose that repairing the mind-body split is necessary not only for personal health and wholeness but also for healing our relationship with each other and with nature. Helping children embrace, maintain, and retrain healthy patterns of being in their bodies is critical to transforming the violence both in and against our world into healthy, sustainable, and life-affirming relation with it. Allowing children space and time to move through, in, and with their universe, to feel, sense, ponder, play, and explore what it is to be alive and a part of the world – to *dance with life* – is essential to embracing this sense of wholeness and belonging and to accessing the resilience and creativity needed as we face the unknown future. We purport a dire need to establish patterns of consciously inhabiting the body, caring for and tending to it *before* children shut down access to their senses, emotions, intuitions, and their capacity "to move and be moved" (Moradian, 2017, p. 8). We also advocate for all children being equally important and deserving of healthy conditions for growth.

There are numerous opportunities available through the body to affirm wholeness and explore the complexity, contradiction, and challenge of existence – which is inherently the challenge of *co*existence. As children play, run, roll, and spin through their full-bodied experience of being, we suggest encouraging presence of both mind and body, inhabiting our bodies, and embracing them consciously from the inside out or *somatically*. We emphasize the process of responding to the feedback from both inner and outer worlds, communicating between them, and making choices consciously. As this happens, we as "educators" must prepare to be challenged and to change in response to what we meet, to learn to inhabit our own bodies through moments of both ease and discomfort. Sylvia Miller, well ahead of her time in 1933 when she wrote her *Rhythms Notebook*, said:

> We cannot start with a regimented curriculum and hope to work backwards to spontaneous invention… The child's job is to initiate the activity, attach his media, and develop his techniques as he proceeds, and the teacher's job is to preserve that atmosphere of detached absorption within which creative effort flourishes and becomes operative. (cited in Eddy, 2016a, p. 188)

We suggest that developing a lifelong somatic relationship with our bodies in motion, a relationship in which we bring our attention to our lived (psychosensory-motor) experience, is a powerful way to reclaim that wholeness which allows us to care and connect, to feel a sense of place and belonging, and to self-regulate our behavior for optimal interaction with our world.

Vignette 2: The Importance of Movement for Children

> Children burst forth into the world clamoring with thirst, hungry to be loved, and driven to move, discover, and grow. Each conception and birth comes from movement and is a call for relationship. We enter life engaged with our universe in an ongoing process of motion.

Movement is an elemental part of being alive and functional in the world. We attend the environment with our eyes, ears, nose, and skin and, more, respond with our muscles, joints, and vocal apparati, our full bodies in motion. These movements form the basis for learning and transformation. In this sense, education cannot be separated or abstracted from the environment or the body, nor can it be demarcated to the confines of *a* body, *a* school, *a* program, *a* family, or *a* community. The use of abstraction, logic, language, and linear and mechanistic thinking have been highly successful in comprehending, managing, and controlling our world. These are powerful and important tools, but not our only tools, and not appropriate to every situation (Abram, 1997a; Capra & Luisi, 2014; Williams & Brown, 2012). Indeed they could not work without the primary tools of learning through *listening, touching, doing, and being*.

Our first movements are unconscious, beginning in the womb, and gradually become more conscious as we explore our environment. Maxine Sheets-Johnstone (2009) correlates the beginning of consciousness with the choices made by cells for

survival, to go toward or away from stimuli (see also Capra, 1996; Capra & Luisi, 2014). Successful physical development requires healthy and efficient access to and use of all available body parts and, through exploration with any body parts that are able to move, links to metacognitive processes. Movement provides this critical connection of brain and body that expresses choice; strengthens autonomic functioning, balance, and motor activity; and promotes psychophysical intelligence (Eddy, 2016a; ISMETA, 2003).

Movement stimulates biofeedback. One somatic premise is that "the body itself holds many of the lessons we need to live sustainably in the world" (Moradian, 2017, p. 9). We suggest that it is particularly important to help children establish and maintain healthy patterns of "mindful movement" and "embodied being" *before* the natural skills of full-bodied self-awareness are dismantled. Keeping the body's feedback systems turned on and engaged allows us to sense self and our agency. In the same way that we affect our environment, the environments we interact with can support this process of self-making (Eddy, 2009, 2016a) and communities-in-the-making (Dewey, 1927). We assert that "staying awake" and engaged through movement is a reciprocal relationship, an interactive and collaborative creative process. We further propose a somatic approach to movement as a creative lens through which to experience our lives as a living *work of art* (Roussell & Fell, in press). And when life is the work of art we attend to throughout the duration of our lives, then there is no doubt that art can and does change the world.

Vignette 3: Movement, Creativity, and Play

> Attending to the play of our senses brings us into the present moment, "which is the only place and time in which we can effectively act, feel, communicate, teach, or learn" (Williams & Brown, 2012, p.147)

Movement is a vast domain, from simply breathing to full out dancing, and the scope for study of its impact in different settings is enormous. Learning can be evidenced through successful motor planning, effective nonverbal communication, establishing positive climates through socio-emotionally astute games, play, embodied learning activities, role-plays, assessing the quantity and quality of psychophysical reflection, and the products of art-making.

Each facet of whole body-engaged learning awakens related interneural connections of internal and external perception. Dance is a key resource. Dance education is at the forefront of actively engaging learners in diverse STEM and STEAM subjects – science, technology, engineering, arts, and math. Virtually every imaginable subject has been danced and many have been chronicled. Somatic educators seek to keep the dancing spirit alive whether indoors or outside by creating environments that are sensorially rich and provide freedom for diverse, peaceable responses.

Movement is also inherent in school day transitions (e.g., from classroom to lunch, from hallway to school bus). Indeed, it is these moments that cause many teachers angst and certainly when bullying and other sorts of conflicts arise (Eddy,

1998, 2016a). Embedding movement games, body awareness, and physical activities during these periods are reported to instigate an enjoyable shift in a school's climate. Movement has begun to be built into the day to make time for recuperation as well. Yoga, in particular, has become a familiar component in many school days, largely because it is taught as a series of relatively still, formal postures that promote breath, flexibility, and mental concentration, while helping to manage emotions and stress. Its relative stillness is often easier for teachers to manage than freer forms of movement. However more open-ended movement is a support to higher-order learning.

Education can be evoked through play, sports, dance, and outdoor recreation among other modes. Learning through movement and motor responses may be revealed in numerous more subtle ways, including gesture, whole body "everyday" movement, or the action of the voice in words or song. The full cycle of sensory stimulus and motor response brings us into the cycle of sensory-motor action, also known as perceptual-motor activity. When educators are creative in introducing diverse sensations that allow for full-bodied and "free-to-have-one's-own-truth" responses, we become more sensate and alive. When awareness of both the environment outside of ourselves and our presence within ourselves awakens, we are embodied (Eddy, 2016a).

Play has its roots in nature and seems closest in maintaining childhoodnature. It demands presence, inviting participation and engagement in the moment. It calls upon all of our human capacities, and all of the senses, serving as a form of both exploration and recreation. Play immerses us in a universe of complexity and possibility, demands attention to surrounding stimuli, develops strength and agility, and helps us explore and build relationships. Play allows us to try something new or test out a variety of hypotheses, including those about physical potential, environmental awareness, and social skills. It provides a space in which to take risks and to fail, fostering imagination, creativity, resilience, and responsiveness. Even play fighting has value. While any type of fight is perhaps not a typically desirable goal, it is one of the few socially acceptable outlets in many western cultures for boys to touch one another (Beardall, Bergman & Surrey, 2007; Eddy, 1998, 2016b).

At its best, play is a bodily immersion in experience, fully cultivated in an aesthetically rich multisensory and safe environment. Inviting children to share their experience and stories in movement, rhythm, and sound can awaken awareness to the rich layers of nonverbal communication that make up 60–93% of our communication patterns, tapping into layers of self-expression and creativity (Eastman, 2011; Thompson, 2011).

What environments foster the richness of play and play that enhances childhoodnature? Learning gardens and soil are an excellent example of multisensorial environments that integrate learning about science, aesthetics, life, and interrelation (Williams & Brown, 2012). Like learning gardens, movement activities based in somatic awareness, no matter what the physical environment is, "take us beyond intellectual understanding, opening a door that connects the living world inside to the living world outside" (pp. 147–148).

Play is an active doing, necessary for being more cognizant of our world, especially as an antidote to the overriding experience of being "talking heads." When subsumed by intellectual and technological tasks, we need to reawaken sensorial alertness to the natural world. It is interesting to note how much sensory input is no longer "real" but rather is only available through virtual stimuli and interaction. Play in nature is a dying art form in urban areas and in education. This is unfortunate. Outdoor play allows for a myriad of responses including self-awareness and growth.

Nonetheless, where play in nature is not possible for logistical or conditional reasons, there are many forms of movement through which proprioception (knowledge of self) and kinesthesia (self-awareness of movement) can be taught. Dance improvisation is a form of play that can happen in simple open and even fairly confined spaces. Dance/movement education out of doors brings us closer to the dances and ritual derived from ancient tribal and indigenous practices. Somatic dance allows for this sense of ritual and interconnection, whether indoors or outdoors. Educational policy is supported by research that demonstrates that these methods help us to keep our humanity and our animal wholeness intact, along with our ability and willingness to respond, connect, communicate, interact, and tend to our world in healthy, constructive, and sustainable ways. Musical Seeds is one such curriculum that brings classes outdoors to meet educators devoted to preserving the cultural heritage of planting and harvesting. In the process of learning about plant life, students are exposed to the music and dance that accompanies the agricultural process in diverse continents.

Vignette 4: Neurodevelopmental Movement Inroads

Important to movement research is finding more information about what and how physical activities enhance all aspects of development (Lovatt, 2011; Ratey, 2008). Several schools of somatic education hypothesize that the progression of movement development corresponds to neurological development (Bainbridge Cohen, 1993; Dart, 1950; Dimon, 2003; Feldenkrais 1989, 1997; Hannaford, 1995; Miller, 1933; Murray, 2005). A powerful choice is to focus on those movements that accompany brain development. Embryonic movements through the first year after birth performed in sequence include skill-building, beginning with control of the head and senses; learning to lift and strengthen the upper back; rolling over (which also helps shift attention); waggling and then crawling to get somewhere using core muscles necessary for becoming upright; sitting (a crucial social skill); creeping on hands and knees; cruising along a table or with other upper body support; standing independently; and taking first steps, critical to individuation. These accomplishments are relatively uniform for all human beings with variation due to disability and across cultures (e.g., as in Bali where children in traditional environments are not placed on the floor). Somatic movement educators often have students follow this developmental movement sequence (or adaptations of it) as a way of working toward more efficient overall function (Bainbridge Cohen, 1993; Dart, 1950; Dimon, 2003;

Eddy, 2012; Feldenkrais, 1989, 1997; Thelen & Smith, 1994), but there is little empirical research substantiating it (Eddy, 2002, 2012). While Thelen and Smith found physical coordination could be gained, and Arnold Gesell hypothesized brain development in response to movement, research is needed on specific potential cognitive changes.

Research on mindfulness and meditation has been underway for some time now, and research into the effects of conscientious movement practices has begun (Kabat-Zinn, 2003; *Psychology Today*, 2015). For example, results from studies in neuroscience begin to distinguish between the effects of breathing practices, meditation, and physical yoga postures; between mindful practices like yoga or tai chi and walking; or between formal sequenced dance movements and improvised ones (Lovatt, 2011; Telles, Sharma, Yadav, Singh, & Balkrishna, 2014; Villameure, Ceko, Cotton, & Bushnell, 2015).

More subtle instrumentation is needed to answer how the brain-body, neuromotor experience impacts cognition and communication. Readings by fMRIs that penetrate to the wavelengths of deep brain structures such as the basal ganglia, the pons, and the midbrain would answer many questions (Ironically, it may be the study of how computer exposure is damaging our brains that may help us study our brains more fully.). In the meantime, research can progress with correlational studies of brain development, motor coordination, and quality of life. Just how specific movements stimulate the brain could eventually reveal how *embodied cognition* works. Embodied cognition is the idea, pioneered by cognitive neuroscientist Antonio Damasio, that consciousness is not isolated in the cerebral cortex, but that the brainstem plays an important role in our awareness as it passes afferent information from the body and viscera to the brain (Craig, 2013). Further understanding is that correlated emotions within the cerebellum and limbic system impact memory, thought, and learning (Röhricht, Gallagher, Geuter, & Hutto, 2017), that we need to "move to think."

What is more easily studied than the response of deep brain structures to movement is how the brain responds to thoughts about movement – also known as imagination, ideation, or ideokinesis (Bernard, Steinmuller, & Stricker, 2006). Ideokinesis, a somatic movement system developed by Lulu Sweigard and based on the work of Mabel Todd, works with images of movement – ideation of kinesis, movement, primarily to improve performance (Matt, 1993) and reduce injury. It asks participants to track their proprioceptive cues before, during, and after their practice. Current research on goal-oriented movement, like dance virtuosity, shows that thinking about movement is best timed in advance of an action and results in heightened movement performance.

Vignette 5: Sensory Awareness Includes Awareness of Self

> Our bodies are not only our access to nature; they are nature. Awakening to the senses is a necessary and important part of reclaiming relationship with ourselves and orienting in our world – knowing who we are, how we are, and where we are. Our bodies are the sensory

lived experiences of nature that are ever present in our lives. Movement teaches responsiveness. It is the active, creative, and life-sustaining response to paying attention to our world. It includes ease as well as challenge, falling, and balance.

Somatic movement highlights the simultaneous experience of sensory awareness and carefully interlaced responses, providing an interface between our inner and outer worlds. It is this type of perceptual-motor interaction that the authors advocate as a perfect way to affirm the importance and value of childhoodnature. Its strategies can aid in repairing the fractures that have led us to unhealthy patterns of relationship at all levels. *Perhaps it is here that the potential to transform unconscious (and often negative) life patterns into "conscious positive habits" resides.*

Somatic movement happens when the mover is aware of his or her psychophysical experience. Proprioception, the ability to know one's own body position via information from the joint and muscle receptors within the nervous system, and kinesthesia, being aware of how one is moving through space – as perceived by proprioception combined with information from the vestibular system and eyes – assist awareness of more than bodily experience (Eddy, 2016a). They awaken a sense of self, including our emotional self (see Fig. 1).

Environmental stimuli are also known to trigger emotions. Emotion within decision-making is embedded in the concept of embodied cognition, as discussed earlier. Somatic movement practices recognize that emotions and thought correlate with body movement and bring awareness to this. Hence through somatic awareness of bodily experience, researchers and practitioners often describe a capacity to sensitize more fully to self, other, and surroundings (Bales & Nettl-Fiol 2008; Williamson, Batson, Whatley, & Weber, 2015).

Karen Olness proposes that every child "have an opportunity to be hooked up to a biofeedback system, maybe some sort of computer game that was cued to a physiologic response" so they might understand "Aha! I change my thinking, and my body changes" (cited in Moyers, 1993, p. 78). Access to simple biofeedback instrumentation is a great goal. Given budget limitations in many education settings, it is also important to consider avenues to self-awareness that involve minimal costs. Somatic education and mindful movement practices offer a type of personal biofeedback enhancement (Eddy, 2016a). Giving children the sense that they can have control over their behavior is a critical strategy for self-regulation. Within the somatic paradigm, rather than receiving feedback from technology, the feedback comes from a refined ability within oneself to register changes in the body-mind through the other five senses our body provides – proprioception of (1) muscle tension; (2) joint angle and kinesthetic; (3) awareness of posture; (4) self-perception of stopping, starting, and velocity; as well as experiences of (5) tilting, falling, or turning.

In the domain of biofeedback, we undervalue the importance of having permission to "fail," particularly in learning environments. Falling is a case in point. We learn about our place in the world by striving to become upright and stay upright. The process of finding balance includes working with a combined experience of gravity, surfaces, natural and man-made objects, and atmospheric pressures. Learning includes both finding balance and sometimes falling and learning how to get back up. Learning is, after all, an encounter with the unknown. In her work with teenagers, Moradian finds it particularly important to help students become comfortable with imperfection and meeting the unknown. Once students understand that "perfection is a moving target" (2016) rather than an achievable goal, their entire body language changes: eyes brighten, spines lengthen, and they breathe more freely. It is easy to impose our own fears and limitations onto others' honest and sincere process of growth and learning. As educators, we need to know when to step back and give our students the time and space to explore *their* questions (like *How does this relate to the world I know and care about?*) and not just answer ours. This "validate(s) their own experience and give (s) them the courage and clarity they need to live their lives with authenticity, confidence and creativity." It also "invite(s) them to *participate* in and take ownership of their lives" (Moradian, 2016) and their learning.

Vignette 6: The Rhythms of Nature: Racing with Time

> From our first entry into the material world, we are immersed in an ocean of not only space but also time and rhythm. Each body has its own natural rhythms of breath and blood; work, rest, and play; and birth, regeneration, and decay. These cannot be separated from the body or from our world. Natural rhythms surround, embrace, and weave their way throughout our lives.

Trying to bypass nature's rhythms, like pushing children to reach developmental markers ahead of their body's natural development, is actually counterproductive. The documentary film *The Moving Child* interviews experts in motor development,

occupational therapy, dance therapy, and psychology who espouse the necessity of allowing babies the time to discover their natural movements. There are dozens of articles on the deleterious impact of baby walkers and other products used to accelerate a child's development (Lamont, 2015). Toddlers shown the "solution" for how to traverse a jungle-gym bridge, for example, miss out on the exploration of their own embodied and lived "questions." Parents and educators can, instead, take a moment to scaffold experiences with verbal and nonverbal prompts, like: *What is this thing? How does it feel? What part of your body is touching it? How might your body and this object interact? What can you do with it?*

Time is an invisible, inseparable, and often forgotten aspect of space (Abram, 1997a). It critically influences how we relate with ourselves and our world. Pushing ourselves to do more in less time – this adds a layer of stress. Taking time to "do nothing" or immerse in a soothing natural environment seems to wash stress away and often helps us function better. Having the perfect environment serves little purpose if we do not also make the time to experience it. When we allow ourselves to pause, "suspending" the moment between experience and action or inquiry and response, we open a fertile space of not knowing (Bigé, 2017; Fiadeiro, 2017) which can provoke fear but can also expand into a state of listening, imagining, questioning, searching, experimenting, and discovering. Like play, this time for listening is a powerful place where creativity, new possibility, and transformation reside.

The compression and expansion of time-space becomes evident when observing the difference between the martial arts of Aikido and Kinomichi. Developed by Masamichi Noro (a disciple of Aikido's founder Morihei Ueshiba), Kinomichi uses many of the same forms, techniques, and principles of Aikido but encourages encounters to slow down in time and expand in space. Much like somatic inquiry, this slowing down opens up more internal space for a deeper, more conscious, and nuanced exchange of information through the bodies' contact. At faster rhythms, the time to process and become conscious of information diminishes, increasing the risk of injury for inexperienced practitioners. This extension of time and space in Kinomichi reveals how the same movement slowed down can unblock tension and heal, without losing its capacity to guide and direct. This expansion of "embodied time" is the basis of somatic movement therapy and somatic psychology.

Speed and efficiency can be useful in competition (like running a race) or in an emergency (like dousing a fire), but when misplaced they "compress time" and abbreviate our experience. In many countries, our business, social, and economic systems propel us forward ever faster. This trend, evident since the beginning of the industrial revolution, is exacerbated intensely today by the speed of information exchange through the internet and digital technologies (Fleurot, 2017). Always on "high speed," we often set our adrenal systems on high alert, affecting our mental and physical health (Eddy & Zak, 2011). By habitually moving too fast, we shut down receptivity to our own feelings and to those of others, effectively numbing our senses and in turn our sense of self. The pressure to accelerate the rhythm of our lives toward relentless efficiency not only diminishes our capacity to inquire, engage, and assimilate but can also be seen as a form of violence (Moradian, 2017). Alan Block (1997) views the lack of contemplative, Thoreauvian space and movement within

the school day as a form of violence as well. All rhythms have their value, but in high-speed, high-stress, reactive cultures, the somatic maxim of "slowing down to feel" (Eddy, 2016a, p. 140) is called for. Racing with time leaves no space to wander, wonder, ponder, respond, or integrate, the very experiences that connect us with our naturalness.

Vignette 7: Cultivating Space for Embodied Learning through Movement

> Ergonomics is concerned with mechanics and parts of the body. I'm more concerned with total systems, the role of culture and psychology, and making cultural change. We're not just dealing with a mechanical problem about how we're going to be more comfortable. It's a cultural problem. Galen Cranz (in Dalton, 2008)

Though typically situated in studios, gymnasiums, out-of-doors, or other open spaces, learning through the body can occur in any environment. Schools with an ecological focus often structure their programs in naturalistic environments like parks and learning gardens or other nature-rich settings, which are all ideal. Many educational institutions, however, have limited access to nature and open spaces and minimal funding for field trips, special equipment, or events. Ideally all school administrators would have data on what types of natural and man-made environments, beyond gymnasiums and natural spaces, best foster childhoodnature and different types of learning and design curricula accordingly. The goals of embodied learning in educational environments can range widely and may include all subject areas, as well as environmental empathy, socio-emotional development, aesthetic development, and somatic awareness.

Curricula that encourage bodily play or creative interactions can also be supported by shifts in school environments – introducing a new suite of sensory learning and responsive possibilities. This engagement can happen indoors or out. Indoor spaces *can* foster movement and body awareness. One school in Cambridge, Massachusetts, brought physio-balls (large gymnastic balls) into the classrooms to be used as chairs, others are using standing desks, or, in the case of Adaptive Design Associates lead by MacArthur winner Alex Truesdell, schools work with local artisans to create cardboard seats and desks that suit the varied bodies of children, including those with disabilities (Lomot, 2013; www.AdaptiveDesignAssociates.org). As another example, the Pono Learning Center in New York City (www.PonoLearningCenter.org) is a school that has explicitly chosen to use a limited amount of low-to-the-ground furniture, with open wooden floors, low platforms and tables, and well-sanded tree stumps. These are moved around, and children are found sitting, standing, lying, or balancing on them throughout the day. They are thinking, drawing, writing, reading, and discussing with the "furniture" available to support any of these activities. Learning groups happen here in circles or clusters of children, with occasional lines.

Varying spatial formations among people foster different ways of relating – horizontal, vertical, and sagittal. These relationships with each other and within

the space allow a person to bodily self-adjust for the sake of comfort, focus, and health but also promote new perspectives within relationships. Varying spatial formations in the classroom is like being invited to change your seat during a performance. This flexibility of place allows for multiple perspectives, inbuilt recuperation, and ever-changing contact within the group process of relationship building.

Another example is EcoMoves for Kids, a curriculum from the Center for Kinesthetic Education (www.WellnessCKE.net) that engages students in physical activities (e.g., dance, hikes, cleanups, etc.) outdoors, reflects on these experiences indoors using movement and dance, and then strives to bring awareness to the needs of local flora and fauna around the school, teaching advocacy for students' suggestions for adaptations to their school environments (e.g., use of water fountains and bottles, roof gardens, etc.). Providing ergonomic furniture (including adjustable standing desks and varied seating options, like balls and kneeling chairs, Lomot, 2013) and outdoor exploration are emerging exploratory trends. Including more movement within these indoor and outdoor environments is critical to completing the sensory-motor cycle and to overall well-being that comes from being present and aware of the body and the environment.

Vignette 8: The Lure of Detachment: Overcoming Violence

> The powerful drives and emotions the body contains can be, like nature itself, exhilarating and joyous but also confusing, uncomfortable, and disturbing. Ultimately, the body decays and we come face-to-face with death. Like nature, the body is a wild space where life brushes up against us and challenges and defies our control (Abram, 1997b). The body may be our home for the duration of this experience called life, yet cultural practices alternate between celebrating our embodiment and escaping it. The body is our birthright, yet many of us reject it.

A *sense of place* is not only about the surrounding physical environment. From a somatic vantage point, place begins with the body. Disregarding the need to listen and to give voice to human movement or to learn movement skills is a way in which we reject not only the body but life and our very place in the world. When life is tough, or as Hari (2016) suggests, "unbearable," people take flight from their bodies, disconnecting from embodied experience in numerous ways (van der Kolk, 2014). These disconnections may be expressed as numbing (which, according to Brené Brown, "cannot be done selectively"), imposing certainty on uncertainty, imposing or insisting on perfection, pretending that we do not have an effect on other people or our world, perpetuating systemic racism and classism, intellectualization, addictions (including workaholism, overstimulation, and technology use), post-traumatic stress disorder (PTSD), and "spiritual bypassing" whereby people use spirituality as a way of avoiding their embodied emotions (Brown, 2010; Masters, 2010; Stromsted, 2017). When we disassociate from the body, experience and learning remain only partial. Partial, disembodied existence makes wholeness, healthy functioning, and, according to Antonio Damasio, even full consciousness impossible (Pontin, 2014).

Movement not only helps us to be present, but it makes us visible. In safe environments this can be a cause for joy and pride. However in hostile environments (whether socio-emotional/psychological or physical), people often prefer to cut off from their physical selves in order to become "invisible." For instance, in the film *Invitation to Dance* (Linton, 2014), people with disabilities struggle to find private venues for parties to avoid being blatantly visible while dancing. In a "safe space," they overcome their fears and open up to the joy of dancing. In many western cultures, people dim the lights or imbibe mind-altering substances to lessen self-consciousness that comes from "showing our bodies in movement." Another example is the courage it takes for female students with hijab to play soccer – one of the only semi-acceptable ways to engage in physical movement as teenagers in Muslim countries (Sheerazi, 2017).

Harsh judgment and strictures about the body, body image, and body action may make for caustic learning environments. What causes judgment may be rooted within cultures or the minds of individuals. Economics may play a role as well. Instead of striving for nonjudgment, awareness of interdependence, and creative interaction, a commercialized, objectified, competitive world fosters indifference to others. This can lead to negative judgment of one's self and others, repressive power dynamics, bullying, and violence. These types of interactions can be seen in corporations and governments, as well as among individuals, and within schools (Katz, 2013). The effects of bullying and self-consciousness are enormously deleterious – from shame to suicide among children, teens, and adults.

When working with the body and movement in school, awareness of the continuum from stress to trauma and how these conditions are impacting youth can be important. In an ethnographic analysis of six violence prevention programs across the USA, Martha Eddy (1998) gathered information about embodied movement practices in conflict resolution and peace education. The study found that all educators benefit from skills for dealing with abuse and trauma, given how rampant physical, psychological, and sexual abuse and cultural dislocation are (one-quarter of the world's population lives in nonpermanent housing). Teaching in nature is often a wonderful way to calm the nervous systems of students and teachers alike. Any teaching community can strive to provide, or devise democratically as a group, guidelines that contribute further to calm, by ensuring emotional and physical safety. Another set of findings from Eddy's research revealed that excellent educators of conflict resolution selected topics for exploration such as self-control, increasing awareness of potential violence (with the goal to detect and avoid it), developing the strength to stand up to injustice and violence, and/or pointedly engaging in peacemaking. Eddy has created a matrix using these features to ensure that programs meet their own objectives (1998, 2016a) across the continuum of violence prevention and peace education. For instance, when teaching peace education, it can be deemed insufficient to simply teach self-control; adding self-defense, self-assertion of one's own strength and power, and compassionate work with others for peace makes for a fuller experience of diminishing conflict within the context of societal injustice (Eddy 1998, 2010b).

Within the conditions of discomfort including, but not limited to, fear, overwhelm, hopelessness, confusion, callousness, indifference, pain, negative judgment,

poverty, bullying, abuse, and violence, people of any age may disconnect from the body, becoming numb to one's own sensations (Eddy, 2016a). Some people might stay physically connected with their bodies, building up irritability that may result in bouts of aggression or even violence (Eddy, 2016b), which can be further amplified by interaction with violent media, television, and games (Carlsson-Paige, 2008). More education is needed.

Vignette 9: Combining Indigenous and Somatic Approaches for Well-Being

> In Chinese medicine, the movements of tai chi and chi gong teach people "where their center is, what is a balanced form, where the right and left are. . . In the Chinese culture that defines health. If you can figure out where your center is and how to concentrate your mind, you're healthy, and once you lose that, you get sick" (Eisenberg cited in Moyers, 1993, p. 282).

While teaching at Columbia University, a native of mainland China reported to Eddy (2002) that "finding center somatically" was new and not part of her traditional Chinese experience. The somatic work transformed an abstract idea into a powerful and visceral experience. Eisenberg explains that it is the combination of mindful attention and conscious movement that is essential to the Chinese idea of well-being in the world. "One without the other is not enough." The Chinese consider the universe to be made up of both the physical and spiritual, "and the struggle is in maintaining the balance between the two forces." In addition, movement is experienced within an ethical framework that includes how you treat others and yourself (cited in Moyers, 1993, p. 283).

This idea of *holistic* experience, a relationship of "systems" within systems (Capra & Luisi, 2014), is central to wholeness and health from an ecological perspective. It is also foundational to somatic approaches such as Laban-based Bartenieff, Body-Mind Centering, or Dynamic Embodiment and in the Feldenkrais method, as well as many eastern and indigenous approaches (Eddy, 2016a). In these embodied practices, "We can touch this place of wholeness where body and mind, emotions and thought, matter and energy are given to us as one" (Ford cited in Eddy, 2016a, p. 255). The challenge in this state of complex and interrelated wholeness is to be awake fully to the internal *and* external – *self* and *more-than-other* (Abram, 1997a) – which "lies at the heart of the challenge of co-existence" (Moradian, 2017, p. 11). Helping children become conscious of the body's experience, affirming its wisdom, and learning to moderate its impulses are important steps to dwelling, at home and at ease, in the body. Only then can we really begin to experience what it is to dwell on the planet. This harkens back to Gregory Bateson's "ecology of mind" (2000).

Somatic education is built on European, Eastern, and Afro-Caribbean constructs (Eddy, 2002, 2016a) that unify the physical and the mental, action and contemplation. Mind-body movement techniques use the mind to "control the body" (Eddy, 2016a). As is hopefully clear by now, the "body-mind" approach of somatic

education (with various forms shaped by cultural framework and/or historic settings) offers the particular vantage point of listening to the body to learn from *it, mining psychophysical wisdom*.

Educational approaches akin to somatic education are understood in the psychological and sociological domains as well. Bessel van der Kolk finds that "mindfulness" helps emotional regulation, physical health, and stress-, psychiatric-, and psychosomatic-related symptoms including depression and chronic pain (2014, pp. 211–212). He highlights yoga, tai chi, qigong, African drumming, and the martial arts which "focus on the cultivation of purposeful movement, and being centered in the present" and points out that they all combine ". . .physical movement, breathing, and meditation" (p. 210). Cognitive linguist George Lakoff also acknowledges the importance of embodiment (2004). Celebrated educator Nel Noddings asserts that education should expand its focus from linguistic and logical intelligence to include also spatial, bodily kinesthetic, musical, interpersonal, and intrapersonal intelligences (based on Howard Gardner's theory of multiple intelligences) with a focus on *caring* (cited in Williams & Brown, 2012). Somatic education builds upon all of these, and particularly upon caring and empathy, by building the capacity to feel, to integrate, and to respond creatively and appropriately to life circumstances, linking directly to agency (Shafir, 2015). Noddings focuses on developing students who are healthy, competent, and moral people even if this is at odds with a national agenda of education, which in many cases may be "disconnected from life." In the same way that Williams and Brown argue for the living soil as "a dynamic metaphorical guide" that affirms life and "brings attention to relationship as a central feature of education" (2012, p. 139), we suggest the living body is a learning landscape that both affirms and teaches us about life, complexity, responsivity, and relationship.

Vignette 10: Movement: The Ground for Learning in Educational Settings

> The body in motion is the foundation for experiential learning. Ironically, some experiential learning does not highlight, or even recognize, the knowledge gleaned from the vehicle of our very experience – the body itself. As we embrace an awareness of self in relation to the ongoing movement of life, in all its complexity – as we begin to dance with that ongoing interrelated process of transformation that is our life – we can readily extend this understanding to the classroom, community, culture, ecosystem, and biosphere.

Movement can be used to teach, exemplify and improve content learning, smooth out school-day transitions, provide brain and body recuperation, and be a powerful source for aesthetic experience and development (Selver-Kassell, 2008). When any of these movement activities are done in nature or with nature in mind, one is entering into the domain of eco-somatics. An eco-somatic approach can be central or adjunctive in curricula. It is a reflection on bodily experience, sensation, and response to sensation as experienced in whatever nature is available that completes

the childhoodnature cycle. By learning with the whole body and bringing awareness to what is learned *through* the body, we experience the very essence of being interdependent with and part of nature.

Lessons on breath are the quintessential example. A somatic approach to learning could focus on oxygenation, the human cardiovascular system, chemical processes, and our interdependence with plant life, all while actually breathing, smelling, and tasting the quality of the air. Experiences, like feeling the pulse and the pumping sensation of the heart, the rhythm, textures, length and depth of the breath, and visualizing the five lobes of the lungs and their three-dimensional, balloon-like expansion and contraction, are best followed by reflection and discussion about the sensations, discoveries, and curiosities that emerge. Moradian invites her students to "release the resistance to the breath" by incrementally letting go of contractions in the throat, chest, and heart region that restrict the lungs' capacity to breathe fully. She encourages them, both viscerally and through the imagination, to slow the breath and become aware of the "nourishment and support, cleansing and release that come with each and every cycle of breath" (Moradian, 2015). Breathing immerses us experientially in our deep interconnectedness with the living planet and can tangibly remind us of the dynamic processes and balance inherent to all living systems. In addition to deep inner awareness and awakening to our interdependence with the world around us, breathing practices like these prepare the learner to be more comfortable "at school" by massaging the abdominal organs, oxygenating the body's cells, and calming the nervous system (Eddy & Zak, 2011; Iyengar, 2010).

Similar teachable moments can be infused in numerous situations, including eco-aesthetic and ecological contexts. For example:

- Bringing attention to the sensations of the feet while walking on different surfaces, to the living nature of the soil beneath the feet, to the relationship of bodies and plants to gravity and their movement and growth, to the vestibular system with eyes open and closed, and to how occluding different senses alters sensory awareness.
- Discussing what happens when living organisms become dehydrated, malnourished, or poisoned and then paying attention to the sensations that arise in the process of drinking water or eating a snack, followed by imagining how a plant "drinks" or "eats." These could be followed by reflection on metabolism or the liquidity of our bodies and the planet.

To shift beyond sensation into motoric, creative expression, it is critical to allow for more options. Free movement is the most explicit choice. Allowing a student to choose three postures and move between them teaches the making of a "movement statement." The postures or movements selected can be related to a discussion theme – like representing three states of water, three moods, three types of stress, three different trees, and three animals. Three is a key number because it represents a sentence – a beginning, a middle, and an end. Group discussion can go in a myriad of directions.

In her doctoral research, Eddy found that the process of co-choreography enhances problem-solving and builds peer leadership (1998). Peter Lovatt's research in dance psychology shows that improvisational movement opens up a world of "divergent thinking" (2011), including experimentation, invention, and creativity. Dance education research is adding to the canon of how to enhance information retrieval including the potency of movement memory, and discussion among dance education professionals supports the hypothesis that experienced improvisers are not only more comfortable encountering the unknown but also often even relish meeting change and challenge.

Conclusion

> Sensory perception is the glue that binds our separate nervous systems into the larger, encompassing ecosystem. (Abram, 1997b, p. 9)

In reclaiming our bodies and our place in the larger world, dwelling within the living system of our bodies and nested within the living systems of the earth, we shift from what might be a parasitic or exploitative relationship with our world to a symbiotic interaction with nature. Biologist Lynn Margulis defines symbiosis as "the living together of more than one species." She asserts, "all organisms that you can see with the naked eye are living in symbiosis with others," and cooperation between species is more common than competition for evolutionary survival (2011). In a videotaped presentation to NASA in 1984, Margulis explained how life on earth (including humans) can actually make the world greener and more alive, as long as it is in *dynamic balance*. For adults and children alike, equilibrium depends upon the ability to respond appropriately to the feedback we receive, through and also from our bodies (which includes, but is not limited by, what we think of as our "minds"). We cannot disconnect from our bodies and still hope to respond optimally. In welcoming movement and the ongoing process of change it stimulates, we can move from stationary dis-ease into ease, presence, and a natural state of flow; we move toward health and wholeness, not simply as individuals but as ecologies of community and place. This takes time and attention, along with a willingness and ability to respond to the intricate, subtle, complex messages coming from the myriad of relationships that we, in the west, have tried to ignore or deny. Neglecting our bodies in education teaches us to disconnect from nature. To embrace our interdependence demands humility and requires a willingness to recognize both our power and our vulnerability – that we affect and are affected by all that we encounter.

In conclusion, we suggest that changing conditions in both our human and more-than-human worlds demand better communication and optimal responsivity at all possible levels. The ongoing state of dynamic balance that *is* life demands our willingness to *dwell* here and now, consciously in our bodies, face-to-face with complexity, contradiction, and the unknown. This expanded consciousness, or "reconstruction of patterns of thought" (Bateson, 2000, p. xii), moves us to recognize

our interdependence with our world, helping us to treat the earth not as our possession but as our home and as our symbiotic partner. Embodiment processes like somatic movement can help us to reconnect with the multilayered worlds of our living body in place. The goal is to reclaim the natural, any-shape, any-person's, nonobjectified, non-commercialized body and to live in healthy relationship with it. As we do this, we engage and participate in our learning processes and nourish our ability to respond to challenges with creativity and agility. Life-affirming, movement-friendly environments need to be cultivated. Caring for ourselves, each other, and the earth is called for, not simply as a "good" thing to do, but as a necessary part of thriving in and with our world. This is more than just a dance. It is the dance of our lives and life.

The history of progressive, constructivist, and existential schools of education has hypothesized that enactive education that includes sensitivity to the needs of planetary and community sustainability produces learners who are aware of and care for the environment (Eddy, 2016a). By promoting awareness and self-management of the feelings and sensations that come up in the process of learning, we can encourage children to experience and shape the world in life-affirming ways. Our contention is that aligning education and conscious embodied movement intensifies not just self-awareness, self-knowing, self-care, and self-regulation but also moves us to act and interact with greater awareness and care for others and our world, including the places we inhabit and share (Eddy, 2016a). "The body (is) the portal through which we can re-enter the world – even after we have locked ourselves out. . . Consciously attended, the body offers a living landscape for *deep ecological experience*" (Moradian, 2017, p. 8).

Abstract

This chapter works through a series of methodological experimentations with movement and materiality in order to explore the potentials of environmental arts pedagogies. We address the question of what environmental arts pedagogies might come to look like in the ever-changing contexts of children's social and environmental worlds. This leads us to engage with the movements and materialities of learning environments as they come to co-compose pedagogical encounters. In doing so, we draw on new materialist accounts of matter as agentic, fluid, and dynamic; movement as a choreographic architecting of experience; and a/r/tographic approaches to pedagogical engagement and embodied practice. Taking up the use of concepts as methods, we develop a series of artistic and pedagogical experimentations with concepts of "corridors," "flight," "viscosity," and "construction." In teasing out the implications of these concepts for an environmental arts pedagogy, we combine imagery and text to both render and diagram the movement of bodies, materials, and environments in passage through each of these four conceptual enactments. This leads us to develop a series of propositions for an environmental arts pedagogy based on our creative research process. In doing so, we aim to sketch the contours of an environmental arts pedagogy that combines the speculative imagination with embodied, sensorial, and empirical experiences.

Keywords

Environmental arts pedagogy · Movement · New materialism · A/r/tography · Speculative empiricism

Introduction

In this chapter we address the need for environmental arts pedagogies that are responsive to the rapidly changing material conditions of children's social and environmental worlds. Children are growing up in increasingly precarious times, as rates of anthropogenic climate change, loss of biodiversity, human overpopulation, ubiquitous computation, and biotechnological innovation continue to advance and proliferate with alarming frequency (Malone, 2016; Rousell, 2016). How might environmental arts pedagogies become more attuned and responsive to the material conditions of contemporary life? What role might environmental arts pedagogies come to play in the lives of children in these times of accelerating change? This chapter responds to these questions through a series of a/r/tographic experimentations that explore the relationship between movement and materiality through new materialist theory and artistic practice. As a methodology that operates through relational practices of artmaking, researching, and teaching/learning (Irwin, 2008), we take up a/r/tography as an ecology of practices in which human and nonhuman agencies are always entangled in processes of co-composition, negotiation, and constructive functioning (Stengers, 2005). This chapter thus contributes to an

emerging body of scholarship that uses new materialist theories to explore the relational spaces between art, environment, and pedagogy (see, for instance, Garoian, 2012; Knight, 2016; Rousell & Fell, 2018).

Our focus on the environmentality of art as a pedagogical encounter urges us to think and work outside the limitations of human(ist) discourse and identity. We seek to explore the ways that "art also does its work without human intervention, activating fields of relation that are environmental or ecological in scales of intermixings that may include the human but don't depend on it" (Manning, 2015, p. 72). We define environmental arts pedagogies as transdisciplinary processes that merge, transmute, and cut across environmental and arts fields in their doings, knowings, and tellings (Cutcher, 2015; Cutcher, Rousell, & Cutter-Makenzie, 2015; Irwin & O'Donoghue, 2012). Environmental arts pedagogies are artful and open-ended processes that both condition and modulate learning experiences through environmental engagement and creative experimentation. As McKnight et al. (2017, p. 10) suggest, this reorientates the concept of pedagogy toward forces of affect, movement, materiality, and sensation as they are "actualised through the bodily experience of teaching and learning." We therefore propose a shift in the emphasis and enactment of pedagogy toward more-than-human processes that cut across bodies, environments, materials, concepts, surfaces, feeling, sensations, and ideas. This is necessarily an ethical as much as an aesthetic shift, as it brings an ethico-aesthetic paradigm to bear on the embodied and emplaced practices of environmental arts pedagogy (Guattari, 1995).

In the sections that follow, we begin by contextualizing our approach to environmental arts pedagogy within new materialist theorizations of materiality and movement as forces that exceed human intentionality, knowledge, and control. We then introduce the a/r/tographic fieldwork that we used to develop a series of creative experimentations with concepts of "corridor," "flight," "viscosity," and "construction," each of which explores the entanglement of matter and movement in different ways. This is followed by a series of visual and semiotic renderings that work through each of these concepts in turn, drawing on the images, field notes, and theorizations that emerged in and through our a/r/tographic fieldwork. These renderings are followed by a diagrammatic analysis of the four conceptual practices. This analytic process leads us to develop a series of propositions for an environmental arts pedagogy that integrates empirical movement and materiality with the flight of the speculative imagination.

Matter, Movement, and Art

Our approach to developing an environmental arts pedagogy builds on new materialist theorizations that position movement and materiality as agentic forces in the production of works of art and associated learning experiences (Bolt, 2013; Rousell & Fell, 2018). New materialism is a strand of speculative philosophy and theory that has emerged over the last decade. While new materialisms encompass a wide variety of theoretical positions, approaches, and investments, their ontological orientations

generally hold that all of existence is embedded in some manner of material substrate, including not only material objects and bodies but also conceptual, discursive, semiotic, and incorporeal constructs, ideations, and projections (Coole & Froste, 2010). As Coole and Froste (p. 10) note, new materialist philosophies outline a political ecology in which "matter is no longer imagined. . . as a massive, opaque plenitude but is recognised instead as indeterminate, constantly forming and reforming in unexpected ways." In positioning matter as a force that both materializes and expresses the potentials of nature's dynamic indeterminacy, new materialism ultimately "sees its task as creating new concepts and images of nature that affirm matter's immanent vitality" (p. 8). This also confirms new materialism's compatibility with Indigenous ontologies (e.g., Hunt, 2014) that acknowledge the vitality and agency of animals, plants, metals, minerals, and elemental forces such as wind, rain, and electricity (Ingold, 2011).

While new materialism has its roots in feminist-materialist thought associated with poststructuralism (Alaimo & Heckman, 2008) and ecofeminism (Mies & Shiva, 1993), it explicitly breaks with dialectical, Marxist traditions predicated on social constructivism, deconstruction, relativism, and "critical theory" more broadly (Braidotti, 2013). Instead, new materialisms tend to draw on fields such as quantum physics, the life sciences, and posthumanist philosophy to propose visionary and creative "alternatives to critique" (Dolphijn and van der Tuin, (2012), p. 14). In challenging the ongoing dominance of humanist and anthropocentric ontologies and practices, these emerging materialisms seek to develop new conceptual tools that are responsive to the changing social, technological, and environmental conditions of the contemporary world. While new materialist theory is having a timely impact in the arts, humanities, and sciences, the movement has also impacted significantly on the field of education, including the areas of environmental education (Malone, 2015), arts education (Rousell & Fell, 2018), and post-qualitative methodologies for educational research (St. Pierre, 2016).

In developing a new materialist approach to environmental arts pedagogy, we build on recent scholarship that has theorized the materiality of creative practice beyond the limitations of representational and anthropocentric thought (Bolt, 2013; Tiainen et al., 2015; Triggs & Irwin, in press). Drawing on the work of theorist and physicist Karen Barad (2007), this involves a movement away from *reflection* as the core practice of teaching and learning through the arts (e.g., Schön, 1983). In lieu of reflexivity (an "iterative mimesis" that produces reflections of reflections ad infinitum), Barad (2007, p. 88) proposes a turn toward *diffraction* as a creative practice that is orientated toward patterns of difference. Rather than the "self-referential glance back at oneself" associated with reflection and identity, diffraction attends to the interference patterns that are generated through the "specific material entanglements" of heterogeneous agencies (p. 88). The work of art, in this sense, is produced not *by* the agency of the individual artist but *through* multiple agencies which disrupt and interfere with one another within an "ontologically heterogeneous field" of environmental relations (Bennett, 2010, p. 23). To learn through the arts, then, is to become entangled with "the shared materiality of all things... of which we are all composed" (pp. 12–13). The work of art becomes a "co-collaboration" in

which "matter as much as the human has responsibility for the emergence of art" (Bolt, 2013, p. 6). The question is to what extent the artist become "attentive to, and responsive/responsible to, the specificity of material entanglements in their agential becoming" (Barad, 2007, p. 91).

Studies of movement have also been central to new materialist scholarship in the arts, in which choreographic processes are seen to operate outside of human intentionality and knowledge (see Knight, 2016; Manning, 2013; Massumi, 2011; Manning & Massumi, 2014. Movement is understood to be as ubiquitous and all-encompassing as matter, as Manning (2013, pp. 13–14) writes:

> Movement is everywhere, always, at all scales, speeds, and slownesses. There is never stability. And there can never be non-movement – even in what appears to be complete stillness there is a quality of movement-moving, force of form.

This makes choreography a more-than-human phenomenon that "attends to the immanent field of relation that is part and parcel of an environment in-forming ... a self-generating practice of difference" (Manning, 2013, p. 76). In linking such distributed and ecological conceptions of movement with pedagogy, Knight (2016, p. 19) further describes how "choreographic movement emerges as rhythmic through the effect of energy as it flows between diverse sensory, temporal, and material agents." Choreographic movement thus becomes pedagogical in its capacity to "initiate reactions and responses between agents that change course of direction, prompt reconsiderations, and adjust trajectories" (p. 25). We therefore see a profound connection between movement and materiality as primordial elements of the environmental arts, with pedagogy emerging as a choreographic force that brings movement and materiality together in ways that generate novel assemblages, environments, events, experiences, and ecologies of learning and participation.

A/r/tographic Fieldwork

Drawing on this genealogy of thinking in new materialist theory and artistic practice, we set out to design a series of experimentations that would unfold through collaborative a/r/tographic fieldwork. For the last two decades, a/r/tography has developed as an international methodology that operates in the dynamic interstices between the relational practices of artmaking, researching, and teaching/learning (Irwin, 2013). In taking up a/r/tographic fieldwork as an ecology of practices, we aimed to discard the all too human identities of artist/researcher/teacher in favor of a more distributed and environmental process of becoming (Stengers, 2005). We also sought to negotiate a consonant shift away from the calcified identities of the adult/teacher and child/learner, as captured within a closed system of dyadic stimulus and response. In foregrounding the immanent ethics of the event of encounter as the basis for environmental learning and art, we chose to pursue a tentative movement toward the learning environment itself as productive of new forms and manners of life-living (Rousell, 2017). The result was that a/r/tography began to operate as a loose

assemblage of framing practices that modulated the relations between elements of life/nature/environment/movement/matter and worked to put theoretical concepts into play through creative experimentations with materials and media (Tiainen et al., 2015).

Our starting point for this a/r/tographic fieldwork was the question: **How does movement come to matter in environmental arts pedagogies?** This question was initially formulated through a series of research dialogues, in which we discussed the methodological, conceptual, and practical issues facing the field of arts education at the contemporary moment. In order to investigate this problem through creative, philosophical, and empirical experimentation, we firstly worked collaboratively to establish a series of enabling constraints. This allowed the research to emerge through a series of negotiations within a problematic field of entanglement. After a series of intensive dialogues, we settled on the following six protocols as the basis for our a/r/tographic fieldwork:

1. Each of us would draw on a concept from our own arts/educational/research practices in addressing the research question.
2. Each of us would design a creative research activity for experimenting with our chosen concept.
3. We would not disclose the concepts and their associated activity designs prior to their enactments on the day.
4. We would use Southern Cross University Gold Coast campus and surrounds (airport and beach) as the context for these experimentations over the course of a single day.
5. Each of us would select a site for experimentation within this geographical location, thus forming the itinerary for our collective movements over the course of a single day.
6. The four activities would be followed by a period of discussion and artmaking that explores the conceptual and material yields, provocations, and movements instigated by the fieldwork.

In foregrounding the process of "concept as method" (Lenz Taguchi, 2016), we aimed to explore how the actual movement of thought occurs in/through/as matter and how the nondiscursive and affective capacities of art enable concepts to proliferate outside the limitations of human language and cognitive interpretation. By restricting prior knowledge of each other's concepts and activities, we sought to avoid the trap of a consensual framework that would have simultaneously delimited and "answered" our research problem preemptively. Rather, our conceptual designs were formulated discretely as nodes of experimental knowledge practices within a problematic field that remained virtual/unknowable (Deleuze, 1994). This allowed for a continuous tension between the structures of our individual "setups," and the ruptures, immediations, resonances, and dissonances that emerged spontaneously between them. Each of the conceptual designs also operated as a machinic "suspension" of concrete procedures/constraints and abstract indeterminacies with regard to the qualitative enactments they

engendered internally. We could say that each of the individual activities exhibited *intensive* properties particular to its design (both concrete and abstract) and *extensive* properties particular to its emergent relationships with the other three activities (both virtual and actual). It was in this sense that the conceptual framing of the research problem took shape through a series of pedagogical experimentations, in which semi-structured conceptual designs mobilized an emergent theoretical framework that only became perceptible in and through its enactment and subsequent articulation. We thus allowed each concept to materialize through the enactment of the research design as an emergent a/r/tographic process. In doing so, we aimed to "strengthen the concept's abilities to reach beyond the generalising classificatory tendencies of language toward affecting how the world's specificities are felt, perceived and lived with" (Tiainen et al., 2015, p. 16). The following four sections of the chapter provide a visual and textual rendering of each of the four concepts as they were set into motion through the a/r/tographic fieldwork process.

Corridors

We begin our investigation into movement and matter along a strip of Kirra Beach that stretches for miles along Queensland's Gold Coast. The beach provides a relational playspace to explore the extended site as well as the theoretical implications of beyond human relationships or what Barad describes as the "interconnectedness of all things" (in Cahill, Coffey, & Smith, 2016, p. 80). Movement, and its expression through the art of dance, "is an embodied practice that engages bodies as matter" (Ulmer, 2015, p. 39). The body has limitations within itself and inspires both matter and movement to play within the imaginary boundaries. A body enables and disables depending on the constraints of relation, and the creativity happens in the spaces between, stretching the material availability to explore and investigate the potentialities of the body as a conduit for relationships of matter to itself. As a composition of choreographic movement and materiality, it is plausible that the "body becomes an ontological site of being" (Ulmer, 2015, p. 38). The aim of the excursion is to employ and deploy choreographic practices to account, analyze, and create movement and appreciate the embodiment of matter's capacity for self-relation.

The provocation is simple. Movers are invited to develop a spatial limitation in the sand, to draw the outline of an identified space or "corridor" using only their feet. The design needs to be drawn within 10 s and reflect some thought about the beach on which they create. The movers are also asked to configure a movement pattern, which needs to be repeated twice in order to commit the movement to bodily memory while deepening and intensifying the markings more with each iteration. Ironically, it is the subduction of thought that is an indicator that body memory is being enacted. A reliance emerges on the body itself to provide knowledge, to build awareness of capacities and dispositions, and to structure and guide through movement (Koch, Caldwell, & Fuchs, 2013).

The Movement Is Fleeting and the Capture Elusive

The beach as a site emerges from fluidity with boundless limitations. There is a proliferation of lines, imposed, imagined, observed, and disregarded. The purpose of controlling flow seems at odds to the reality being explored a/r/tographically, and yet the constraint of the task is the very impetus for movement.

The Movers Play

Movement is the central focus and as movers we imagine and create. The beach provides an open surface for gesture and inscription, while also activating a geographic spatialization of education outside of institutional boundaries. As a kind of autonomous zone or deterritorialized space, the coastal landscape becomes the cloth from which a choreographic body-space-time can be cut. This becomes our task to craft a block of body-space-time as the corridor for a choreographic experience.

What emerges from the process of diagramming, this enactment of corridors is the relationship between a choreographic impetus (or the will to move), the enabling constraints of the spatiotemporal proposition, and the emergence of a series of structured improvisations that produce difference through bodily repetition.

The movers immerse themselves in the sand. For moments the sand and their skin become one, and it seems difficult to know where one started and the other ended. The movement has a linear legacy, a suggestion of a corridor embodying inside and outside of the constructed perimeters. The design is made obvious through the indent in the sand, yet the movement suggests that the lines extend upward into the air creating corridors. The base of the space is evident and implied as it permeates the air with suggestion. The movers' respect their imaginary walls, deliberately working

within or without the corridor, suspending (dis)belief, reminiscent of days when a childhood thought allowed for potentialities only barely grasped.

The product of the practice was artifact/relationship/teaching moment. The contributions of the audience, the dancer, the sand, the imaginary corridors, and the potentials of pedagogy for all make for a fertile investment of affect

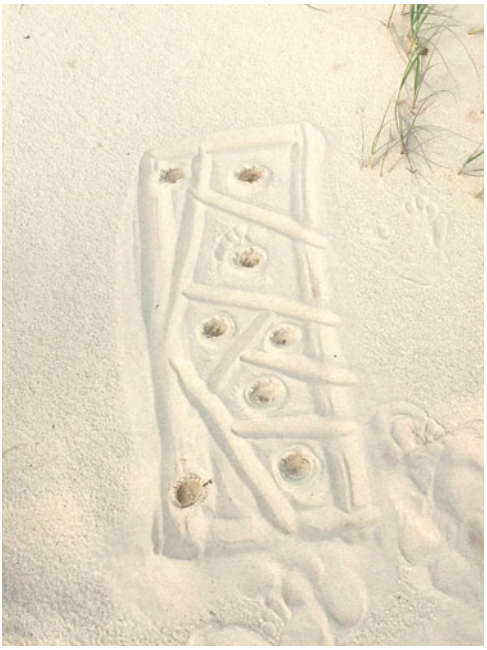
In the dance world, "corridor" is a choreographic term used to describe spatial constraints that are designed to enable "structured improvisation." Corridors are commonly used to break up the studio or stage space into blocks within a larger floor pattern, allowing choreographers and dancers to enact improvisational movement designs within a complex spatiotemporal structure. The corridor on the sand gave a start to an a/r/tographic field day; with limited instructions the bodies drew or perhaps just moved. In creating the corridor, the responses varied in size and shape and in directions against the backdrop of the foreshore. One forward, one sideways, and one on the diagonal: the experience becoming the borders, and the borders becoming the canvas. The corridors were complex, simple, and yet multidimensional, stretching the possibilities of what a corridor could be and what it could house. The movers performed with rhythm and dynamics and manipulated the sand for effect, and the sand pushed back. The movers' focus became intensive and intimate and entwined: with the activity, with the lines, with the sand, and with their imagination.

These relationships, as elements of movement, are concerned with the interactions between the body and itself, the body and other bodies, the body and the objects it can grasp, and the body and the environment it coinhabits with myriad

others. While this event was stimulated by spatial exploration, the trace elements of the activity were the residue and accretion of these material relationships. We can see evidence that the body behaves differently when objects and environments are introduced and considered as part of movement, and bodily responses are altered and augmented in response to the surrounds (Davies, 2003). Trying to capture what a/r/tographic fieldwork looks like gave way to what it *feels* like. As Ulmer (2015) states:

> What new materialism offers to dance-based practice-as-research, therefore, is an emphasis upon dancers as knowing beings within dynamic systems of movement. By sharpening the focus on dancers as embodied beings, new materialism offers an additional approach for embodied methodologies. (p. 39)

As a/r/tographic fieldwork would encourage, the opportunity arises to creatively document understandings of movement and matter as process. The movers were asked to find unexplored spaces away from their canvas and visualize themselves creating the lines. They recreate smaller memories of the drawing on the sand. The accessibility of the sand both geographic and material afforded ample opportunities and could be adapted and adopted into any learning site irrespective of age. The invitation of new materialism to reconfigure movement foregrounds the materiality of thought, imagination, and poetics as the concrescence of bodily experience. The dance of drawing also moves with rhythm, space, dimensionality, and the sharing of meaning as a public intimacy.



We are invested in movement,
And that it is matter.
And it matters.
And the matter is movement,
And that matter moves
is moved
and is moving.

Flight

As we step off the beach and back onto the esplanade running parallel to the ocean, we transition into the next experiment with how movement comes to matter as we consider lines of flight as advanced by Deleuze and Guattari (1987). We stand in a circle and utter single words associated with the concept of flight: the emphasis being on the materiality of the words rather than their syntactic properties. It's a simple algorithmic design in which each word spoken provokes the next, each word taking on some liminal, subconscious relation to the previous. There is a speed involved, a movement circling at the speed of thought – the very notion of words as transcorporeal entities (Alaimo, 2010), passing through the bodies that make up a pack or collective, weaving thoughts together. This is indeed flight, a way of putting the concept to flight in ways that change the consistency of the concept itself: how flight can be thought.

A six-word memoir: In-between invisible lines of flight

We break the huddle and drive to an area of the airport that is lined by security fences and signs to keep out, a strange kind of borderlands in between the university and the actual runway. Curiously, the campus borders intersect two side-by-side federal states, and amidst these visible/invisible borders, an international airport stretches across large swatches of land. Two time zones playfully engage with habits of mind, and while no signs dedicated the land to Indigenous peoples, we remain aware of the contested ownership and colonization of the land. As we take all of this into account, we walk

the terrain considering a proposition inviting us to experience borders in relation to flight. As Deleuze and Guattari (1987) state:

> Lodge yourself on a stratum, experiment with the opportunities it offers, find an advantageous place on it, find potential movements of deterritorialization, possible lines of flight, experience them, produce flow conjunctions here and there, try out continuums of intensities segment by segment, have a small plot of new land at all times. (...) Connect, conjugate, continue: a whole "diagram" as opposed to still signifying and subjective programs. (p. 161)

Together we walk though these disjunctive borders and time zones, peering into and beyond the secured borders and the invisible borders. We write six-word memoirs, take photos, and linger within interpenetrating territories of conflicting agency. Our bodies constantly navigate the open and closed spaces as we move, experimenting with our own lines of flight as flights soared above and beyond. We feel an entanglement of experiences emerging. Using Karen Barad's (2007) concept of intra-action, we come to appreciate how each person's study within the space influences our own. Rather than doing this work on our own and experimenting with self-initiated ideas, working together in relation to one another, in a co-emergent space, brings forward multiple lines of flight that pursue diverse directions, points of view, and purposes, creating an assemblage of diagrams. Indeed more potential emerged together than if we were apart.

Six-word memoir: Origins are coming, move away now

It is here that our "work" of art exists – in the spaces where nothing yet everything exists. We accepted the ascribed borders and escaped them to imagine the places and spaces as open to potential. Deleuze (1994) would say: 'The work of art leaves the domain of representation in order to become "experience"' (p. 56). As our collaborative a/r/tographic fieldwork experience focused on the potential of flight, we encountered movement as a choreographic architecting of experience (Manning, 2013). It was through our diversity that we experienced the potential of how environmental arts pedagogies might respond to a changing world. By creating an assemblage of lines of flight intersecting, eclipsing, falling into, rising from, and entangling one another, we glimpse how movement comes to matter.

Six-word memoir: Borders collapsing remain intimidating, nature reigns

Deleuze's project of immanent ethics asks us to consider how we should live in the world. In this sense, ethics is always about becoming: that endless state of change that moves us into unexpected encounters. After all, becoming is always in the middle. A middle space is in constant movement as all entities vibrate in connection to all other entities. Becoming is therefore not about moving toward transcendent values; instead, we embrace life's immanent ethics (Deleuze, 1988) and pursue our desires through experimentation with ideas. Environmental arts pedagogies that embrace these middle spaces are moving us toward an experimental, personal, societal, and ecological emergence where movement matters in our immanent becoming.

Six-word memoir: Pulled to the limit we expand

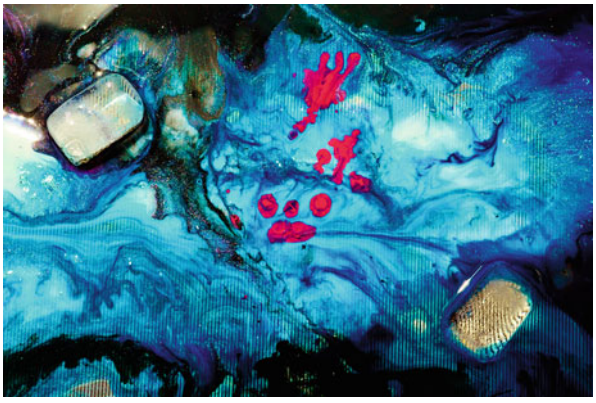
Viscosity

We reassemble from our forays into the borderlands between territories, walking together into the university campus proper and taking the elevator up to the tenth floor. Suspended in the glass-paneled staircase that flanks the building's northeast corner, we find a peculiar assemblage of found objects and media for exploring the concept of *viscosity* through material experimentation. There are two upended wooden boxes, between which is suspended a ribbed sheet of toughened glass taken from the front of an old oven. A range of found art materials are arranged on either side, including variously colored inks, solvents, binders, varnishes, and fluxes, along with a bucket of ice cubes. A high-resolution camera is placed in the space underneath the sheet of glass, allowing the movements of bodies and materials to be captured from the lower surface. It's a cross between an interactive artwork and a science experiment: what Barad (2007) might call an apparatus of material production.

Viscosity

1. The quality or state of being viscous
2. The property of resistance to flow in a fluid or semifluid
3. The ratio of the tangential frictional force per unit area to the velocity gradient perpendicular to the direction of flow of a liquid – called also *coefficient of viscosity* (Merriam-Webster, 2016)

Viscosity is not only a property of fluid materials but is theoretically a property of matter in all possible states, whether liquid, solid, or gas. There is even scientific evidence of viscous movement observed over long periods of time in concrete formations such as granite (e.g., Kumagai, Sasajima, & Ito, 1978). Attending to viscosity reveals that everything that exists materially is also in movement but that these matter flows have varying speeds, consistencies, and coefficients of resistance and mutability. Even the elemental material flows of air, light, and water vapor exhibit viscous resistance in relation to other materials and fluctuations in temperature. For instance, flight only becomes possible through the dynamic resistance between air and water vapor ratios and higher viscosity materials that make up the wings of birds or airplanes.



Situated in the corner of the 9th floor stairwell overlooking the university parking lot and the Gold Coast's highways and beaches, we begin to realize that the glass structures joined with steel and granite continue to move at ever so slight and miniscule speeds. We begin to squeeze, flick, squirt, and layer the materials onto the surface of the glass, probing and guiding mixtures of varying viscosities into differential patterns of color, light, movement, texture, and form. As we drop the ice cubes into the mix, they immediately begin to change from solid to liquid, gliding on their own volition across the surface while releasing water molecules into the concentration gradient of the materials. Never does the paint become muddy – it upholds its consistency, discerned as a mixing of colors that somehow retain their origins. The surface is dappled with moving patterns of colored sunlight and shadow:

> Viscosity is a feature of the way in which time emanates from objects, rather than being a continuum in which they float. (Morton, 2013, p. 35)

The surrounding social and ecological environment becomes part of this molecular experiment: the stairway surrounded by glass in every direction, light flooding in from multiple sources, and the panoramic tableaux of ocean, roadways, airport, and parklands. We begin to notice the numerous viscosities operating within this vista. The viscosity of a flock of birds in flight, the viscous flows of human and nonhuman capital across the surfaces of the landscape, the burning of fossil fuels with each car that drives by, or plane that takes off. The concept of viscosity takes on a new consistency, as we raise questions regarding the viscosity of thought and bodies in movement, the flows of desire, engagement, and creativity in classrooms, as well as the distributed viscosities of social networks, economic capital, and political ecologies.

> Viscosity wants to emphasise this mobile spatiality of togetherness, of coordinated flowing and relative stability . . . Human flows become viscous in crowds, in large airports and in traffic jams . . . packs, cities, nation-states, social classes and racial formations are also examples of human viscosity. (Saldhana, 2008, p. 329)

As a concept for environmental arts pedagogy, viscosity enables us to account for the primacy of movement in materiality itself, the way that movement puts bodies into

motion and thoughts into flight. We can begin to consider learning itself as a viscous material flow of transcorporeal movements that pass through, activate, and rearrange the capacities of bodies (Alaimo, 2010; Tuana, 2008). The viscosities of light passing through a classroom window; the increased metabolisms of children when they go outside to play; the shifts in temperature, air pressure, and humidity that alter the capacities of bodies; the viscosities of affect in the compositions of porous social assemblages: the inclusions and exclusions, engagements and disengagements, mixtures, dilutions, diffusions, permeations, precipitants, and calcifications of experience within a classroom, or playground, or museum.

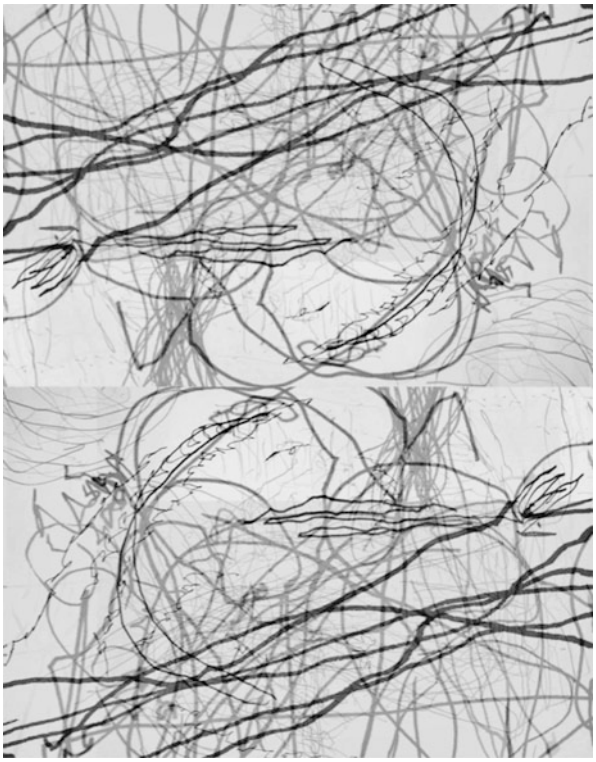
Construction

In returning to the office level, we regroup, astonished to near-silence by the aesthetic positionings of our actions and our thoughts and our documents of these movements and these matters. All at once we begin to speak eagerly as our thoughts follow our actions, jumbling and tumbling in excited dialogue. Reluctantly we restrain and constrain; we have yet another concept to interrogate and further work to explore. We drift into the next episode and bring ourselves back to the quiet, back to the flow (Csikszentmihalyi, 1997).

The hushed space of intensive artmaking is contrasted with the noisy space of construction next door. The campus we inhabit is growing, expanding, and developing around our very bodies, as another building is added to our footprint. Once a lovely

green space of swamplands, small animals, and native flora, it has been excavated and repurposed in order to accommodate a further wave of student occupation and learnings, growings, and doings. We have watched, from the end of our corridor, as the space beyond us is transformed: once a place to rest our eyes, now a place to avert and anticipate. The ground has been cleared, and a machinic assemblage (Deleuze & Guattari, 1987) of human and nonhuman agents is working vigorously to construct our next building. Its monstrous presence in our working day is one of immanent capture. The place of construction today is not the same, as yesterday and tomorrow again it will be altered further. Issues of encounter, emplacement and displacement, synergies, and discords are present and in constant flux in this space, and it is those movements that we now seek to map, somewhat inadequately, as each collides and interrupts and glides with and against the other (Knight, 2016).

The material process of construction has been a daily reality for those of us who inhabit this campus. It has interrupted, inconvenienced, and intruded in our lives. In positioning this last experimentation, we call forth Ingold's (2007) work on lines and surfaces, specifically those that track and document movement, such as the passage of feet on the ground, or the movements of tank treads across the landscape. In short, the passages and lines and movements through time and in place, this place, become ecologies of entanglement, a meshwork.



> Indeed nothing can escape the tentacles of the meshwork of habitation as ever-extending lines probe every crack or crevice that might potentially afford growth and movement. . .for inhabitants, however, the environment does not consist of the surroundings of a bounded place but of a zone in which their several pathways are thoroughly entangled. In this zone of entanglement – this meshwork of interwoven lines – there are no insides or outsides, only openings and ways through. An ecology of life, in short, must be one of threads and traces, not of nodes and connectors . . . Ecology, in short, is the study of the life of lines. (Ingold, 2007, p. 103)

In this experimentation, we seek to create traces, entanglements, meshworks, as we follow the lines of movement over time and in place, even as that place is itself in constant motion and in mutability. In this instant, and for a comparatively fleeting moment, we follow those lines by engaging the technologies of drawing, of making marks, in this case abstract lines, on a recording surface. We find our way through this meshwork of construction, as drawings.

The language form of drawing has been a sensemaking device in all of human existence. It precedes written language through history but also through life, as children engage with mark making prior to the development of a coherent writing schema. Drawing also requires a different type of cognition to writing, or speaking, although it is indeed a language form. As we draw, our chatter ceases, and we continue in silence through this engagement with seeing, with following, and with way-finding (Lasczik Cutcher & Irwin, 2017).

The drawings have been further troubled and extended through the use of layered digital media, so that the images created by the four individual artists have become enmeshed, further entangled, and curated as a single artwork that enables the viewer to see in and with. All four drawings have been layered together to robustly portray the suite of marks: the energies of the construction site, the movement of feet, tires, tank treads, trucks, and cranes that were followed and mapped. The drawings become a layered document that constructs construction, a network of aesthetic engagements, and a c/a/r/tography (Lasczik Cutcher & Irwin, 2017; Rousell & Cutcher, 2014). Thus, the artwork both describes and embodies these situated c/a/r/tographic events, becoming itself a curated display of sensory encounters with construction and its evidentiary passages.

Diagramming Pedagogical Propositions

In taking a new materialist approach to a/r/tographic fieldwork, the four renderings above have put concepts of movement to work through artistic and pedagogical experimentations with bodies, places, times, events, and materials. In order to further analyze the potentials for these renderings to inform an environmental arts pedagogy, we now undertake a process of diagramming the pedagogical forces and movements at play in each of the experimental situations described above. Diagramming has previously been used as an analytic process in new materialist educational research, including the diagramming of classrooms as topological assemblages (de Freitas, 2012) and the diagramming of concepts through arts-based research (Rousell, 2017).

As Deleuze and Guattari (1987) write, such diagrammatic processes "do not function to represent, even something real, but rather [construct] a real that is yet to come, a new type of reality" (p. 142). Accordingly, the diagrammatic processes we undertake differ from conventional understandings of diagrams as visual or textual representations or mimetic descriptions of pre-existing processes. The diagram is instead associated with mapping the pedagogical potentials of each rendering as an abstract machine that produces new movements of thought. In this way, diagramming necessarily involves analytic techniques that operate at the very limits of thought, as a speculative process of analysis that is always opening onto the next threshold of thinking and practical action. As Watson (2009, p. 12, emphasis in original) writes, such "diagrams do not *represent* thought; rather, they *generate* thought." As heuristic devices for generating pedagogical thinking and action, the diagrams below aim to mobilize the forces at play in the concepts of corridors, flight, viscosity, and construction as they emerged through a/r/tographic fieldwork. In this way, we diagram the concepts themselves as *methods* for generating pedagogical designs that implicate matter in movement and movement in matter.

Diagram 1 shows how the concept of the "corridor" operates as an enabling constraint for the production of improvisational movement within a series of open structures. The choreographic impetus for movement is seen to come from a source external to the corridor, and this could be attributed to the ideas, techniques, affects, and propositions for movement that are embedded in the formulation of a pedagogical design. In this case, the design is based on applying the constraints of repetition in order to produce difference, such that each corridor renders a unique configuration of gestures and patterns in response to a proposition for movement held in common. Rather than functioning as a container or backdrop for human experience, each corridor is actively constructed through embodied practices that mutually implicate space, time, and materiality. Crucial to this formulation is the embodied activation of

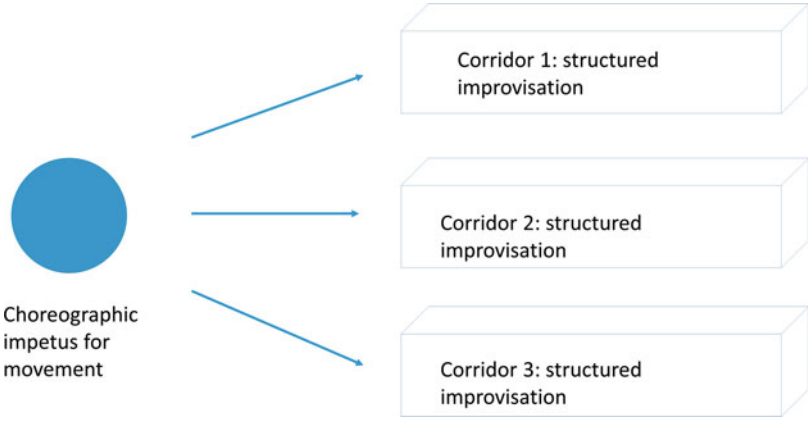


Diagram 1 In which the concept of **corridors** produces the enabling constraints for the structured improvisation of movement

the corridor as a space for intensive, experimental processes of individuation. From there, the question is how this concept of "corridor" might come to matter in educational contexts, particularly in terms of how we think about and construct learning environments across a wide range of disciplines and learning areas. We might, for instance, rethink the design of a primary or early childhood classroom in terms of experiential corridors for structured improvisation and movement, rather than prefabricated "spaces" for sedentary forms of reading, art, science, and mathematics instruction.

Diagram 2 follows the formations and distribution of bodies as the concept of **flight** shifts from a semiotic to a visual register. The two-stage nature of the pedagogical design reveals the differences produced between different arrangements of bodies in relation to patterns of movement. In the first instance, there is a circular arrangement of bodies that facilitates the rhythmic movement of wordplay and symbolic associations with "flight" within a collective huddle or pack formation. This generated a feeling of togetherness among the a/r/tographers, while at the same time generating a semiotic movement of thought across bodies in a unified group. In the second instance, there is a dispersal of individual bodies moving separately and yet together through the environment, with the shared aim of capturing photographs. The distributed movement of the group then contracts once again, back to the circular formation of discussion and consolidation of the collective experience. What becomes palpable through this diagram is the way that the collective assemblage of bodies holds together while passing from one state and configuration of movement into the next. Each stage of the process appears to resonate through the next, modulating the learning process without direct intervention or didactic instruction. In applying this pedagogical diagram to the classroom, we can conceive of similar processes that could modulate the degrees of collectivity and autonomy in children's "flight" through different activities and arrangements of bodies. The setting of circular patterns of movement, thought, and association could be used as the starting point for more dispersed and distributed explorations of ideas and environments, which then lead back to group discussion and the collective consolidation of diverse experiences.

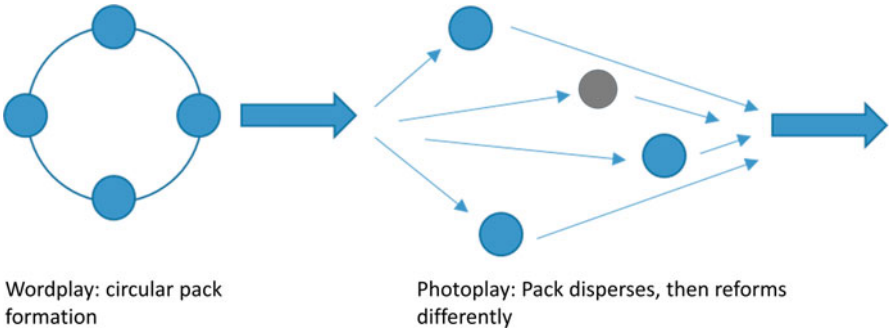

Diagram 2 In which the concept of **flight** moves from a cyclical to a distributed formation as bodies shift from wordplay into photoplay

In Diagram 3, we see the pedagogical design of a material apparatus for experimenting with different viscosities of movement and flux. Differential forces are seen to intervene in the apparatus from the outside, including the forces of human bodies that engage with the apparatus as well as elemental forces, such as light and temperature, that affect the states and consistencies of different materials. The machinic apparatus of the setup becomes the locus for the bodily activation of potentials for organic and molecular movement within the learning environment. This experimental confluence of forces is captured by a camera as a sensing "body" or "device" that registers the patterns of light, shadow, color, movement, and form as materials with different viscosities come into contact with one another. By bringing participatory art and science together through aesthetic and material experimentation, this pedagogical diagram foregrounds the ways that heterogeneous elements of the learning environment congeal into dynamic, spatiotemporal events. If we extend the applications of this diagram into the classroom, we can imagine learning environments that are designed for children to enter and experiment freely with a wide range of viscous materials that mix, meld, and change state depending on environmental conditions. Capturing these interactions through oblique cameras or other ubiquitous sensing technologies would allow both teachers and learners to view the event from the perspective of the apparatus itself, introducing further opportunities for understanding the material and aesthetic processes at play within the environmental arts classroom.

In Diagram 4, we grasp the material processes that enable movement to be translated or "transduced" through practices of empirical observation and inscription. Drawing is seen to offer a technique for converting movement from one medium to another, feeding the ongoing construction of the external environment through the intensive processes of attunement and creative expression. The observer, in this sense, becomes a conduit for aesthetic expression through movement as it is

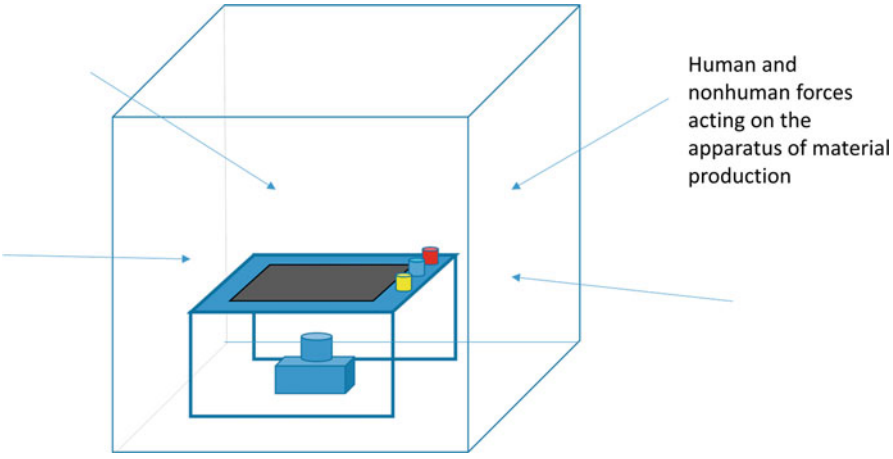

Diagram 3 In which the concept of **viscosity** follows the movement of matter across different forms, states, and consistencies

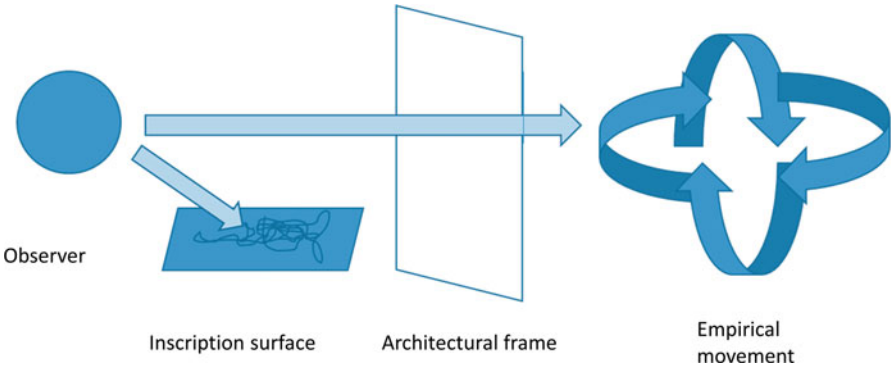

Diagram 4 In which the concept of **construction** connects the observer, the surface of inscription, the architectural frame, and sources of empirical movement in the external environment

mediated by architectural framings of the sensible world and the substrates and inscription materials at hand. In converting this diagram into a pedagogical design for the classroom, we can envision children learning to observe and translate environmental movement through various practices of transduction, such as drawing, painting, dance, music, or creative writing. By focusing on the transduction of movement through environmental attunement and responsive observation, children's artistic learning experiences could move from a representational to an enactive, embodied, layered, and embedded mode of aesthetic engagement.

In Diagram 5, we consolidate the previous diagrams within a pedagogical sequence of conceptual experimentations that are linked to Whitehead's (1978) methodology for speculative empiricism. This configuration shows the relationships between the free play of the creative imagination and the embodied materiality of sense experience and rational thought. As Whitehead writes:

> The true method of discovery is like the flight of an airplane. It starts from the ground of particular observation; it makes a flight in the thin air of imaginative generalisation; and it again lands for renewed observation rendered acute by rational interpretation . . . the success of the imaginative experiment is always to be tested by the applicability of its results beyond the restricted locus from which it originated. (p. 5)

Diagram 5 shows how the concept of the corridor can provide a spatiotemporal architecture for the flight of the imagination; the viscous flows and mixtures of ideas, sensations, bodies, and materials; and the return to constructive observation and interpretation of empirical phenomena. Rather than positioning this sequence as a blueprint or template for environmental arts pedagogies, we see it as a heuristic diagram for how teachers and children might collectively configure and produce their own learning activities and experiences. In other words, Diagram 5 offers an operative modeling of environmental arts pedagogy as an open-ended and participatory process of learning through artistic and environmental experimentation. Any number of concepts could be substituted for the ones that we have selectively chosen based on our interests in movement and materiality. What is crucial to our

Diagram 5 In which the concepts of **corridor**, **flight**, **viscosity**, and **construction** are arranged into an assemblage that produces new concepts, practices, and knowledge applications

pedagogical formulation, however, is the use of *the concept itself as a method* for empirical experimentations with environmental and aesthetic phenomena (Lenz Taguchi & St. Pierre, 2017). By following the movement of concepts as they modulate and condition material processes, we were able to open up a whole domain of potential learning experiences connecting movement with matter, body with environment, and imagination with empirically observable phenomena.

Conclusion: Propositions for an Environmental Arts Pedagogy

In this chapter, we have shown how a new materialist approach to a/r/tography can be used to investigate the relations between matter and movement, thus contributing to novel configurations of environmental arts pedagogy. We see the entire process of designing, enacting, analyzing, and theorizing this project as an exploration of what environmental arts pedagogy might come to look like and how it might come to work. Drawing together the aesthetic, material, and conceptual yields that have been rendered through this emergent process, we conclude with a series of propositions for those who might adopt a resonant approach to environmental arts pedagogy in other places and times. As we employ the term here, a proposition is a theoretical lure or provocation that combines virtual potentials of the speculative imagination with the empirical dimensions of embodied experience in the actual world. We activate the term "proposition" proactively in the Whiteheadian (1978, p. 22) sense, as a "matter of fact in potential" and also as the source of enabling constraints. "Thus propositions grow with the creative advance of the world" (p. 188). Much like the diagrams in the previous section, the propositions below should be taken as heuristic provocations, vehicles, and catalysts for learning activities and experiences that exceed our capacities to foresee.

First Proposition: Use Concepts as Methods

We began with new materialist theories of movement and materiality as the points of departure for this project. From there we each selected a concept as the vehicle

for practical experimentation with specific locations, environments, activities, dialogues, materials, media, techniques, and technologies. On the one hand, this approach situates, expresses, and materializes the concept through concrete practices and artful experimentations. On the other hand, the concept retains a consistency throughout the experiment that contributes to the pedagogical yield of the process. This lets us learn *through* concepts as we put them to work creatively within an architecture of engagement, rather than trying to learn *about* concepts in ways that are detached from worldly experiences and emplaced encounters.

Second Proposition: Modulate the Thresholds Between Individual and Collective Learning Processes

Our experiments were designed individually, and yet they were enacted, documented, analyzed, and theorized collectively and collaboratively. This allowed us to see how the thresholds between individual and collective learning processes could be warped, stretched, conditioned, and modulated in relation to different concepts and practices. We therefore propose that the individual become just another element in the pedagogical machine, a learner among learners, a mover among movers, an organism among organisms, and a flow among flows.

Third Proposition: Foreground the Environmentality of Art and Pedagogy

Rather than making art *about* the environment or environmental issues, we tried to create spaces for thinking and working artfully across environmental scales, durations, and life processes: quantum, molecular, genetic, cellular, organismic, social, ecological, planetary, and cosmic. Ultimately we found that waves crashing on the beach, an airplane taking flight, an ice cube moving across a sheet of glass, or machines moving tons of earth and steel all became active and agentic elements of an environmental arts pedagogy – with or without the intentionality of the artist, researcher, or teacher as masterful human identities. This makes the environment itself the medium and milieu through which artful learning process occur, rather than being the background, object, or container for learning that is primarily determined by human design and interpretation.

Fourth Proposition: Set Protocols for Experimenting Wildly

Our project began with a relatively tight series of protocols for selecting a single concept and a specific location and set of activities for experimenting with matter and movement. Nonetheless, the actual learning processes that emerged from these protocols turned out to be wildly experimental, experiential, and productive for creative thinking and dialogue. The rigidity of the initial protocols also allowed us

to analyze and assemble the four concepts and associated practices into a diagrammatic sequence, which gave the project more consistency as a modeling of environmental arts pedagogy. What is crucial in this proposition is the design of constraints that support open-ended learning processes and novel forms of participation.

Fifth Proposition: Fold Cartographic Practices into the Learning Process

In each of the conceptual experimentations that we engaged in this project, we can see that cartographic practices of mapping and documentation were embedded into the actual process of learning. We mapped **corridors** by drawing in the sand with a stick and photographing them; we mapped **flight** with six-word memoirs and digital cameras; our experimentations with **viscosity** were mapped by cameras placed above and below the surface; and our engagement with **construction** was mapped through the drawings that were created and then layered digitally. Each of these cases demonstrates how the mapping and documentation of the learning process was folded into the process itself. This reveals ways that cartographic processes can increase the aesthetic, material, and conceptual yields of a given learning activity, allowing the experience to be translated through aesthetic renderings, conceptual diagrams, and material transductions of the learning process.

We hope that these five propositions are both provocative and useful for those seeking to develop an environmental arts pedagogy for engaging children with movement and materiality or with any number of other concepts, issues, questions, or concerns about the changing environmental conditions of our times. As we continue to experiment with the relations between concepts, environments, pedagogies, artworks, bodies, spaces, technologies, and times, we note the urgency of finding ways to coinhabit the world more artfully, more relationally, more sensitively, and more experimentally.
