Piaget also theorized that there are times when too much disequilibrium can hinder future adaptability, in a sense causing a person to forgo attempts at adaptive learning and action. When educators implement a Kaleidoscope of Places pedagogy, teaching children about their many interconnected places, they will need to scaffold the exploration and learning so that it does not create too much dissonance. Scaffolding exploration, feeling, and place meaning requires careful, individualized differentiated instruction. Beginning with the child's current conception of place, whether it is a single sense of place rooted in one locale or a mosaic of places that results from mobility, will help the sociological educator differentiate instruction, thereby modeling adaptability.

Feeling, examining, and sharing emotional responses: an essential skill set for developing a sense of kaleidoscope of places and future visioning. We cannot genuinely explore and inhabit a Kaleidoscope of Places without sharpening our ability to *feel in response to experience.* In order to learn about, develop an identity in relationship to, form attachment bonds with, and make meaning of our Kaleidoscope of Places, we first need to access the compassion, despair, and hope precipitated within us by the conditions of our planetary nexus. At the same time, our bonds with our Kaleidoscope of Places inform our ability to "feel with" others, enriching our understanding and helping us to better envision change.

The realization of suffering, coupled with a sense that we lack the agency to change it, often leads to despair. For instance, when we experience meeting homeless people or learning that our water supply is so polluted as to be undrinkable, we may feel a combination of sorrow or grief (in response to our own or others' distress), fear (that nothing can be done or that harm will be done), and anger (that harm has been done, that our society let this happen, that the government let this happen, that God let this happen, that we feel powerless to change the situation). Many of us have been conditioned to squelch, hide, or deny "negative" emotions. However, when we deny despair, we lose opportunities for informed connection, adaptability, co-creation, and mutual survival:

> It is a fallacy, inextricably linked to the myth of ever-upward progress, that 'doom and gloom' thinking is held to be disabling and disempowering for the learner. . .working through despair can be a powerful progenitor of new vision and commitment. (Selby, 2015, p. 31)

Our feelings serve as signposts. The more fine-tuned they are and the more genuinely we feel them, the more we gain the understanding required to use our power in the world responsibly. Inhabiting our full range of emotional responses provides us with a more nuanced understanding of the world. Feeling despair honors our connection to the painful conditions around us, thus challenging the idea that we are powerless to create change – for a point of connection is also a point with latent power, if we can learn to access it. Feeling is part of the constructivist process of developing a sense of our Kaleidoscopes of Places, contributing to our capacity to recognize, explore, and inhabit the entirety of our socioecological contexts, not only the places that "make sense" or "feel good" but the entire spectrum of places: the good, the bad, and the messy. Feeling despair which contains a kernel of dissonance is often the initial step toward a critical evaluation of our experiences, which then facilitates the creation of new schemas to guide future transformative adaptations. Despair may spur a range of agentic responses, such as interrogating the systemic values that helped to create these conditions and probing the ways our Kaleidoscope of Places is linked to this system. It may help us connect more authentically to those most intimately affected by "the bad" – who, by virtue of their own Kaleidoscope of Places, have information, ideas, and power that differ from and can complement our own. Understanding the mutuality of our becoming means that when we witness the plights of others, we are witnessing a plight with which we are intraconnected.

As we enter a new epoch or boundary event, the likelihood that we will be forced to relinquish "what once was" is high. Such letting go will often be emotionally, cognitively, and physically uncomfortable. Our choices will be to suffer, to stagnate, or to engage in transformative learning:

> Transformative learning involves conscious, deep and sustained processes of engaging with pain, despair, and grief over what we are losing, moving towards acceptance while searching for radically new meaning and values, and equipping ourselves for personal and collective empowerment and action: what has been called despair, accept, act. (Selby, 2015, pp. 31–32)

In workshops initially called "despair and empowerment workshops" and later known as "Deep Ecology" workshops, Joanna Macy (2012) developed a series of exercises for people to work through despair and avoid denial of the ecological crisis. Macy's exercises also teach future envisioning strategies that emerge from one's emotional journey. The envisioning process helps produce hope and empowerment if – and only if – we acknowledge and move through the emotional disorder of despair. The only way out is through, and to be effective, education must take up the spiritual and emotional mantle of feeling. Our "pain for the world" is important because ". . .these responses manifest our interconnectedness. Our feelings of social and planetary distress serve as a doorway to systemic social consciousness" (Macy, 1995, pp. 262–263). Environmental educators who foster students' ability to allow and share their feeling responses to socioecological contexts wrought with complex

problems can help them to develop their "capacities for nurturance and empathy." Empathy and an awareness of mutuality change how we conceive of agency, not as "power over" but as "power with" or "synergistic power," a prime component of co-creation. *Feeling with* the planet inspires fresh perspectives and novel solutions. "Through the systemic currents of knowing that interweave our world, each of us can be the catalyst or "tipping point" by which new forms of behavior can spread" (Macy, 1995, pp. 262–263).

Agency, decision-making, and social participation, locale out to planet and back to locale. The UN Convention on the Rights of the Child (CRC) (1989) delineates children's civil, cultural, economic, health, political, and social rights. These include children's right to participate, which is ". . .an essential part of 'agency in action'" (Brown, Jeanes, & Cutter-Mackenzie, 2014, p. 40). Agency in action is civic engagement or engagement in community decision-making, the enduring goal of place-based education. Mapped onto this foundational goal, the Kaleidoscope of Places pedagogy aims to facilitate children's agency in both local and global action. While researchers call for increased focus on local civic engagement and participation (Hart, 1997) and KoP pedagogy acknowledges the critical importance of the local, it equally esteems conscious global participation, since children's consumption, waste/pollution, and mobility affect both local and global spheres.

How can educators help increase children's global and local agency? Paulo Freire (1972) asserts that critical pedagogy, the convergence of critical theory and education, can awaken critical consciousness and thus empower individuals to take action that creates changes they would like to see in their world. Many educators are already well versed in culturally responsive teaching (CRT), a critical pedagogy which relates the learner's cultural context to specific content (Gay, 2010; Ladson-Billings, 1994). CRT is geared to create meaningful learning environments that encourage children's agency (White, Cooper, & Mackey, 2014). Similarly, KoP is a critical pedagogy that relates the learner's socioecological contexts of his or her Kaleidoscope of Places to specific content. However, while CRT and KoP pedagogies are both critical pedagogies, their objectives differ slightly: the critical pedagogy of CRT aims to empower children to make changes *that better their social and cultural contexts*, whereas the critical pedagogy of KoP aims to empower children to make changes *necessary for the survival of their socioecological contexts*. In the Anthropocene, it is critical that educators who are interested in facilitating children's agency expand the culturally responsive critical pedagogy to include individuals' socioecological contexts. Without our socioecological contexts, humans and their culture would be meaningless. As Greenwood (2014) writes:

> . . .in an era of perpetual war, mass extinction, unprecedented inequality, food, water, and energy insecurity, a warming planet, all manner of environmental degradation, and the social stress associated with global development and sustained population increase, cultural study can no longer be divorced from the larger socioecological contexts in which culture now unfolds. (p. 20)

To increase children's agency concerning their sociological contexts, we need forums and contexts that cultivate children's participation. In the decades since the CRC laid the groundwork for considering children's rights, researchers in the

environmental education field have begun to theorize about and research children's agency. Building from Hart's 1997 theories of children's participation, Barrett-Hacking, Cutter-Mackenzie and Barrett (2013) examined the potential for undertaking environmental education research with children serving as active researchers, rather than as objects of research. Several contemporary studies, such as Green's (2016) study of children as active researchers and Malone's (2016) examination of children's agency through nature-child encounters, suggest that making space for lived experiences and opportunities to explore the socioecological contexts of their Kaleidoscope of Places fosters children's agency and social participation in these contexts, which can lead to inventive solutions that promote survival.

The process of lived experience and exploration contributes to children's experienced confidence as they negotiate their places, make authentic decisions that impact their lives and those around them, and achieve social participation: agency in action (Cutter-Mackenzie, Edwards, & Widdop Quinton, 2015; Green, Kalvaitis, & Worster, 2016; Hart, 1997; Lim & Barton, 2010).

> Being an active place explorer is not simply about how much children know or how long they have lived in a place. It is about their attitude and intentions to engage in a place that drives them to become active participants in their place. Children's sense of place is neither a passive response to the environment they are positioned in nor a mere product of long-term residency. Rather, they are actively and purposefully exploring their urban environment and nurturing their sense of place. Children critically read into their place and create layered significance and meanings of a place with critical awareness and assessment. (Lim & Barton, 2010, p. 336)

The layered experience speaks to both the intrinsic layering of the Kaleidoscope of Places, expanding and contracting from local to global and back, and the transfer of skills from one socioecological context to another, to achieve agency in action. Brown et al. (2014) suggest that educators must explicitly resolve to provide "agency in action" experiences in a multitude of contexts:

> The challenge therefore is to provide individuals with experiences of agency but recognise that this alone is insufficient to develop capacity to make change. We must also recognise how the various layers of the socioecological framework may support empowerment – or create disempowerment – and subsequently equip individuals with the necessary tools to gain agentive capacity within wider contexts/environments that currently disempower them. (p. 40)

Critical pedagogy aims to empower children and students in disempowering contexts. A Kaleidoscope of Places pedagogy supports empowerment by encouraging children to explore and learn with a transdisciplinary mind-set, broadly and deeply considering the shifting layers of their sociological contexts while building the skills to adapt, feel, and civically engage in a multitude of local and global ways.

Conclusion

The Kaleidoscope of Places theory posits that each individual is comprised of and contains innumerable socioecological contexts. Freedom of exploration in socioecological contexts and a transdisciplinary approach to decision-making

about complex problems emerge as teaching strategies that support children's transformative learning in the areas of adaptability, feelings, and agency. By developing and achieving these three overarching skills, a Kaleidoscope of Places pedagogy teaches children not only how to inhabit their expanding and contracting Kaleidoscope of Places but how to adapt to sudden changes, move through their feelings in order to accept all aspects of their socioecological contexts, make decisions, and act for the survival of all beings and places, in the great unknown of the Anthropocene.

KoP and the Freedom to Explore

Brown et al. (2014) advance the belief that socioecological educators should support lived experience and exploration, "...acknowledging the personal and embodied experiences... in sociological and ecological descriptions and theories in education" (p. 38). A KoP pedagogy is inherently exploratory, and the teaching strategies utilized to implement it should provide avenues for a child's exploration of his or her local place of residence and also the globally situated, unseen places he or she inhabits as a result of consumerism and mobility. Recent research examining the exploration of nature-human in varied place types such as urban, suburban, rural, and wilderness (Duhn et al., 2017; Wattchow & Brown, 2011) supports the notion that the exploration of nature-human can take place in multiple socioecological contexts. Because some of our places are not physically accessible to us, it is important to use all available tools, learning methods, and entry points into these contexts if we are to comprehensively explore and embody our KoP. Based on the explorer's abilities and the accessibility of the place, the exploration of places can take multiple forms, ranging from physical, experiential exploration of places to differentiated learning through books, film, visual art, and other transmissions of experience.

KoP and Transdisciplinary Learning

When children explore freely, they will discover complex issues or problems in their socioecological contexts. Teachers can aid them in honoring their feelings and expanding their thinking about these issues, by modeling a transdisciplinary mindset and drawing on multiple disciplines in discussions, examples, and learning exercises. Fiercely adaptive, full of opportunities to feel, and innately agentic, transdisciplinary learning "... necessitates that people find ways to cope with the resistance of shifting perspective...Transdisciplinarity presumes that consciousness and information can flow, meet and shape, creating a moment of breakthrough, an 'aha' moment, when new knowledge emerges" (McGregor, 2015, p. 95). It is in transdisciplinarity, when people think outside of and in the interstices between content area silos, that they are most able to generate creative and innovative decision-making. Transdisciplinary learning asks teachers and problem-solvers to leave their silos, bring to one shared table the divergent, reciprocal, and independent academic skills from diverse disciplines, pool knowledge and perspectives and –

blurring disciplinary boundaries – work together to produce new knowledge for a common cause.

What better approach to the Anthropocene? For the places in our Kaleidoscopes are so varied today, linked through scientific and social means to so many disciplines, that it is impossible to comprehend or address their complex relations through any one field of study. Transdisciplinarity is, itself, an interrelated web. It is the natural home for a Kaleidoscope of Places pedagogy that says: *multitudes as one, the individual within a larger web and a part of it,* an ongoing figure and ground exercise filled with illumination and transformation. An educational pedagogy that explores our Kaleidoscopes of Places via transdisciplinary modalities offers children an adaptive, empowered, agentic approach to meeting the exponential challenges of mutual survival in the Anthropocene age.

Abstract

This "Companion" to the Childhoodnature Handbook is a co-creation between children, young people, and adults, curated by four academics and five graduate students to bring children and young people's voices to the foreground. The Companion disrupts conventional academic publishing to present an exceptional aesthetic work of children and young people's creative, sensory, and imaginative musings that reflect their chosen modes of engagement with their childhoodnature. The compositions of childhoodnature experiences within this section enable the reader to become "companions" with the children and young people in sensing, feeling, and thinking of the world a little bit differently.

Keywords

Children and young people's voices · Stories · Imaginative · Sensory

Introduction

What does it mean to create a Companion? How might the voices of children and young people become "companions" with the other chapters that make up this Handbook? We began the process of compiling and editing this section with these open questions in mind. We wanted to explore how a notion of companionship could grow and develop organically and perhaps become something more than what we'd expected. Maybe a Companion could disrupt as much as connect, deviate as much as collect, entangle as much as (re)present?

In early 2017, we extended an international call for contributions from children and young people all over the world. The call asked for children and young people (from early childhood to 25) to submit essays, photographs, poetry, drawings, creative writing, or personal narratives that expressed their experiences and understandings of childhoodnature. We asked for "*anything and everything that you, as children, teenagers, and young people (ages 0–25), might contribute that draws on your ideas about nature, your experiences with animals, or your thoughts about environmental issues*." As we received a dazzling array of submissions over a period of 8 months, we began to realize that something new was happening. A Companion was beginning to emerge that did not follow the conventions of academic research, publishing, and authorial prestige. Children and young people were submitting their own work, their own ideas, and their own creations that were unfiltered and unfettered by the tacit rules and expectations of academic research and publishing. They were collectively re-inventing what a Companion could be.

As we began to work through the submissions, we discovered a rich tapestry of voices emerging from a wide range of geographical locations. We were taken on a sensory journey through experiences of childhoodnature all over the world: swamps, cities, mountains, oceans, schools, rainforests, deserts, suburbs, shanties, remote villages, lakeside retreats and more. All of these experiences had found their way to us, and into the Companion, through the openness, generosity, and sensitivity of children and young people. We would like to acknowledge our deep appreciation for

children and young people who chose to respond. In the very act of creating and submitting these works, you have demonstrated a powerful sense of care and togetherness that resonates through each page of this Companion.

In the work here, it was important to us to honor the UN Convention on the Rights of the Child and the voices of these youth as important contributors in the work around childhoodnature in and of themselves. The Handbook Editors regard The Companion as an essential section of the Handbook, to bring children and young people's voices to the foreground and be represented alongside academics and other adults. Positioning The Companion in the middle of the Handbook is indicative of the status of this section. It was our intention as section editors to respect and honor the agency of children and young people in assembling The Companion, to avoid treating these contributors in a tokenistic manner and instead, learn from their important perceptions and conceptions. Indeed, contemplating their work as editors has already helped us to shift into new and generative modes of knowing and being in this world.

Our editorial approach to constructing the Companion has attempted to preserve the quality and diversity of the submissions that we received. We also worked with youth reviewers who helped to shape our approach and understanding of the material. Helen worked with two students (Tayla and Ricco) in Melbourne, while Joshua worked with three students (Chanel, Mary, and Allison) in Buffalo to review and discuss the submissions according to various iterative criteria. We started with simple questions regarding appropriateness of the submission, asking whether children's voices were central and whether they addressed their own ideas about nature, experiences with nonhuman animals, or thoughts about environmental issues and futures. We also encouraged the youth reviewers to identify what they thought were consistent and relevant themes across the submissions and how various submissions might be woven together. From those conversations, we began to think about ways to organize the submissions and even opportunities to send back questions or suggestions to authors in order to make drawings, poetry, stories, or other writing clearer for a wide audience. Writing alongside the youth reviewers focused and shaped our editorial thinking and included the youth "voice" in the process of assembling The Companion. We are grateful for the amount of work that these youth reviewers put into this process.

The Companion is a something new in academic publishing – there were no models or templates to guide us. In response to the overwhelming number of creative, aesthetic, sensory, and imaginative pieces that were submitted by children and young people, as well as our feedback from youth reviewers, we decided to foreground the children and young people's voices in an open and aesthetic way, reflecting the manner they chose to express their experiences of childhoodnature. Rather than attempting to represent, interpret, or categorize the experiences of children and young people, we created four distinct *compositions* of interwoven feelings, places, sensations, and ideas:

Composition 1: stories of human and nonhuman relation
Composition 2: practices of sense and sensation
Composition 3: eco-poetics of childhoodnature encounter
Composition 4: the childhoodnature imaginary

In putting these compositions together, we have endeavored to give each submission space to breathe, inhabit, and saturate the page, while also weaving together different voices and geographical locations to produce a range of feelings and sensations for the reader. We hope that these compositions give you a sense not only of what children and young people think and feel about childhoodnature, but also how they actively choose to grow and develop these connections through sensory and creative practices. We are reminded that the qualities of care and togetherness that these compositions portray are not simply given but must be actively imagined, sensed, crafted, practiced, and sustained with each passing moment.

The children and young people's submissions have opened up a new and intimate space of engagement that is more harmonious with the emergent and storytelling spaces of Indigenous ways of being than with the rigidity of academic publishing. Following the children, young people and youth reviewers' lead, the compositions deliberately resist the interruptions of academic interpretation and analysis in order to foster the reader's subtle engagement with the children and young people's artifacts, ideas, and expressions. This required some careful maneuvering of submissions from academics reporting on behalf of young people in order to free the children and young people's expressions from the interpretive conventions of academic writing. Some of the more traditional background information about projects and methodologies is included at the end of The Companion as biographical notes on the authors and contributing research projects. We are grateful to these authors for graciously allowing us to de- and recompose their submissions in order to disrupt traditional academic writing formats. We also encourage the reader to refer to the notes on the contributors at the end of this Companion section to add richness and context to the compositional assemblages.

Our framing of The Companion as gentle, aesthetic compositions of children and young people's practices was not without problems. We often encountered aspects of submissions that did not seem to "fit" into the various compositions, and which challenged us to think differently about the aesthetic relationships between form, content, and expression. Frequently our youth editors took a different view and this casts some of the more unconventional submissions as authentic, honest expressions of children and young people's thinking and meaning-making that needed to be included in The Companion. Eventually however, the section editors were the orchestrators of the final editorial movements and interweavings of submissions. For Companion author Liticia Gardner this raised some valid concerns about lack of opportunity for the young authors to control and contribute to interpretative and theorizing dimensions of the discourse:

> When I first heard about this project it felt very empowering to be a young person welcomed into something that might really have the power to shift conversations and perhaps even actions of people in places of power and prestige. . ..The idea that the younger people were merely submitting "personal narratives" on the topic of nature is quite misleading, as anything "personal" is always social (and deeply political). My work, while trying to take up this probe of a "personal narrative" was actually theorizing our world much further than simply my own subjective experience. What I'm trying to get at is that it seems that the

> adults are granted access to theorize the world in less subjective (and more privileged terms) through block text and the ability to draw out their argument, while the younger people are being made to be highly subjective.

Liticia troubles our approach taken in this Companion to the Childhoodnature Handbook. She questions the focus on children and young people's sensory and subjective practices of engaging with/in/as nature and our decision to take an aesthetic and compositional approach that leaves spaces for further interpretation and theorization. We acknowledge the insights embedded in these concerns, while also suggesting that the compositions that populate this companion are "more than" personal and that they do engage a wider social, political, ethical and aesthetic domain of childhoodnature experiences and sensibilities. By taking a compositional approach, we have aimed to highlight the relational connections between children and young people's sensory practices, concepts, and theorizations from many different cultures, histories, and geographies. By leaving spaces for the reader's aesthetic engagement and critical interpretation, we hope to invite others into this relational space and thus resist the normative conventions of the adult interpretative "voice of reason" which too often overwhelms the voices of children.

Although the compositions presented here draw from a range of author ages and locations, they do not thoroughly express the diversity of childhoods and natures across the world. Where the call-for submissions landed, who was receptive and responded to this call: this is its own story. The editors' networks were strongly represented among the submissions, while serendipitous connections and the generosity of practitioners and researchers in the field enriched the compositions significantly. While we have global expressions of childhoodnature practice included in The Companion, there are a smaller percentage of low socioeconomic, indigenous, and peripheral (nonwestern) context contributions, and no submissions from children or young people with disability. This Companion to the Childhoodnature Handbook captures a tantalizing glimpse into children and young people's experiences of their childhoodnatures. We therefore see this Companion as both a touchstone and a point of departure for future projects that might assemble a more comprehensive collection of children and young people's experiences, practices, concepts, and expressions of childhoodnature.

For now, we invite you into the following compositions of childhoodnature experiences. We invite you to become "companions" with us and our contributors, as we learn to sense, feel, and think the world a little bit differently.

Composition 1: Stories of human and nonhuman relation

I started to know to keep pigeons from a friend, then I became interested in buying 4 pigeons through him. At that time I decided to keep my pigeons when I was at age 10 at Sekolah Bisa school. My parents gave me a full support for keeping pigeons. Each day my pigeons multiply, the number of pigeons has increased to 16. Every day I feed the birds with corn. The advantage for me to keep pigeons is that I become consoled and my family too.

Because I was still in school, the money that I used to buy bird feed was from my mother and sometimes I had to use my pocket money to buy bird feed. The pigeon coop is located 3 m behind my house. Once a week I cleaned the cage with water. The obstacle I face was when the bird likes to lose itself and does not return. Sometimes when I did not have a pocket money I sell some of my pigeons. I sell it RP 20,000/each, at the pigeon shop.

The benefit I am raising pigeons is that I like to play with it as before that I always hang out and play with my friends. Sometime I feel, it feels better to play near my house so that I would have time to study at home. In time, I have lost my pigeons one by one, and I have only two left, however I am still happy to keep 2 pigeons.

> – Ikki, age 10, Jakarta, Indonesia (translated by Mr. Adimas Grahito, *Sekolah Bisa!*)

On a particularly sopping wet day in Vancouver, I watched as an elderly woman dropped a pile of decaying food on the ground while a sea of feathers encircle her and the unassuming passers-by. Watching this encounter I wondered what causes certain people to be indebted to the creatures that tend so regularly to fall outside of being worthy of acknowledgment.

Pigeons, starlings and mice all fall under the category of "synanthrope," most easily described as animals who benefit by living near humans. Unfortunately synanthropes tend only to receive attention in the moments where the eradication is in hot pursuit. Synanthropes are deemed pests due to their ability to impede the flow of labor, or their ability to destroy property. Pigeons are capable of destroying a business with merely their existence and feces that follow, meanwhile mice have the power to bring fire to the homes of any nuclear family who misses the memo about steel wool as a preventative measure. Synanthropes are furthermore devalued due to their perceived association with filth and disease and their ability to reproduce rapidly putting human forms of flourishing at risk. Having an orientation towards beings who are deemed to be of no value to human production is a radical orientation, and one which is surprisingly symbiotic in the case of aging people. This orientation towards things that have no value in capitalism is radical because it is actively practicing life through a shared material existence that also happens to be in contradiction to profit, the acquisition of private property, and engagement in waged labor. I'd like to argue that having a shared material existence means that they have a vested interest in the liberation of one another. Those who are pushed out of social life tend to find themselves sharing the material conditions of existence.

I remembered my great grandmother, and that when she immigrated to Canada it was her first experience living in a post-industrial capitalist society. This was her first encounter with waged labor after living in a small farming village in Slovenia that was entirely self-sustaining, before their violent displacement at the end of the Second World War. I remembered her dedication to her garden. No matter how scant it was in contrast to her old ways of relating to land, plants, and other nonhumans, she continued to hold onto the little semblance of relations that could remain in her new home. This made me wonder if these aging women had experienced this same kind of loss, and chose to hang on to the little autonomy they had left in the face of such crushing alienation in the city.

– Liticia, Gardner 22, Vancouver, BC, Canada

I was happy when I saw the black swan in Australia.
It was first time I saw them and I found they were so beautiful!
I like meeting different kinds of animals in different places.

– Kasumi Furukawa, 7, Christiansburg, Virginia, USA

It appears that we humans have lodged an idea into our minds that we must fulfil every need of ours; every craving, desire, anything that could help to increase our over-enlarged egos. This is the main reason as to why climate change has been worsening. Our species has developed a sophisticated society, where each new generation paints many new ideas and lifts the rate of environmental destruction. This continually reduces the natural world, a world which we cannot live without, a world that's far away from today's high-tech gadgets and devices.

Sadly, we are virtually blind to our destructive habits, actions that are the center to the expense of our own wellbeing and flora and fauna that inhabit the Earth. We appear to be so self-serving and lacking of self-awareness that we've become selfish and short sighted to the bigger picture. Always wishing for bigger. . . better. . . more; so much so that we never appear to be satisfied or pleased. We find ourselves currently facing a global climatic crisis due to each and every one of us, where each new thing is only admired for a short period of time before we establish a new desire, a cycle which repeats continually. We must change our values and what we believe is important to us- this change mustn't only occur in a small minority of the population, but almost all seven billion of the humans whom inhabit Earth.

Our lifestyles directly contribute to not only us humans, but to the lives of many diverse species of animals, plants, and bacteria too. Life as we know it must change for health and the wellbeing of our future. Everything has a life center and needs fresh air and water to remain alive. As humans, we may think of ourselves as being superior and better than all other life forms due to our advances in the creation of "technology." Yet we've missed the crucial part of the "big" plan. By stepping forward and learning how to make our lives better and outliving many, we've been progressively destroying the habitats of many, causing species' extinction rates to rise to unprecedented levels in history.

The health of the planet is directly correlated with our own health. We are so wrapped up in what's happening in our focus upon sports, fashion, and the media that we have just evolved to disregard/not care for what really does matter. We are in a routine of selfishness and consuming more, and more. We have missed out on the basics of nature, our connection to it, and its role in our wellbeing and how it's essential for our survival. We've been destroying animals' lives and their habitats daily without even realizing the downfall to our selfishness. We as humans have created and succeeded in numerous positive and improving feats, yet while doing this, we've also succeeded in destroying much of the physical world. And yet we have failed to notice this when it's completely obvious.

The only possible solution is if humankind realizes that we must evolve to become more realistic with our lifestyles, opinions, focuses, and choices; we must take action towards saving our tainted planet, before your thoughtless destruction of environmental resources has gone so far that there can be no reversal. This issue must become the top priority within every single nation. We must band together to reverse the effects of climate change to which we ourselves have caused. The difference must begin with us. We must make drastic changes to how we think and make choices about our everyday activities and focuses. We were not placed on this Earth to make an acquisitive and ideal life that supports the human race only; we were placed on this planet to foresee a life for all things, whether they are living, or nonliving, plant or animal. Not to destroy the climate by means of our own self-centered needs.

– Nikki Whitehead, 12, NSW, Australia (*Climate Change and Me*)

The Little House is a one-room shingled structure on the seven-mile peninsula called Sandy Neck, in Barnstable, Massachusetts. Barnstable is a small village on the bicep of the Cape. This place's simplicity and dishevel have served me well and provided a wonderful environment for me to grow up in. Inside the Little House are straw floor mats, a fireplace, some chairs and a table, and a small rusty grill. The simplicity of the Little House is part of its beauty, but the real spectacle is surrounding the small shingled box, displayed in the sprawling dunes and golden marsh of Sandy Neck. Upon arrival, chairs are quickly dragged out onto the porch, so that one can lounge in comfort while lazily gazing upon the constantly shifting shades of blue and green that paint the vista with a delicacy that Monet would envy. The Little House has no running water, no power, no toilet, no Wi-Fi. It is simple, and it is enough. In his book titled *The Little House at Sandy Neck*, my grandfather writes: "It doesn't sound like much: and it isn't. But come evening, looking down from a dune after dinner, the lighted window speaks eloquently to some fundamental need we all share for enough warmth and light to fend off cold and darkness."

The second I hop off my grandparents' tiny Boston Whaler and dip a pointed toe into the cold water, I feel waves of electricity shoot through my bloodstream, and I am *alive*. Nothing brings a person to the present as quickly and effectively as slipping on the slimy marsh-bank, where the ocean and marsh meet to form the perfect opportunity for a sudden and unplanned swim. As I make the slow trek up the well-beaten path, I welcome the feeling of pointy sea grass itching my feet as I sink lower and lower into the sulfury muck. My flipflops splash brown mud onto the back of my legs, and I smile and look back at the marks like the excited dots of exclamation points sprinkling my calves. When I'm there, each intake of breath brings a flood of salty air and each exhale releases pent up tension. I let go of my worries – overdue homework assignments, looming deadlines, whether or not a certain person has texted me back – I embrace my surroundings. I really *look*. I observe. I reflect. My Aunt words it well: "It's an escape from, and it's an escape *to*. You're getting away from things, but you're also getting *to* that place that's so beautiful." Looking around, the beauty of the surrounding nature seems to flow through me, tinting all my thoughts and feelings with the same sunny warmth that polishes everything in my sight.

One of the many things that are special about the Little House is that its environment continues to function without human presence. The ospreys will go about their day the same way as when they are being watched from afar through binoculars. In the winter, when the marsh grass turns rusty brown, the tides continue to rise and fall under the weathered porch, with or without spectators. Cloudless nights on Sandy Neck allow the stars to shine triumphantly, reminding us of their power when not contaminated by the light pollution of a city. Out there, I have learned how to identify animal tracks in the sand and examined the carefully whittled perfection of an ancient Native American arrowhead. I have been exposed to the delicacy that is a sea cucumber, picked fresh from the salt marsh on the way back to the boat. I have been on long walks through the pine-needle coated forest, gotten lost, and had to find my way back using my own intuition and the help of a tall sand dune that served as a look-out point. I have explored, grown, rested, and lived.

– Lucy Handy, 17, Providence, RI, USA

In summer vacation, my grandparent come and camp at sleeping giant. They usually let me stay and camp with them for about a week and we go hiking or biking. My grandparents started taking me on small and easy hikes. But then when I was 6, my dad had to start losing weight for surgry so he started hiking. When I was about 9, me and my mom started hiking. Our first hike was about 8km of the casque Isles trail. But then we started doing bigger and longe ones.

The hikes that I do are usually between 12 and 20km. I go hiking more frequently with my mom then my dad. (mind you I go mountain biking with my dad) My most frequent hikies are Tee harbour, Eagles Ridge, Ruby Lake, Palisades, The hikes that I've done are sawyer bay, Lehtinens Bay and top of the giant. The hikes average 5-7 hours long. We mostly go to parks like Sleeping Giant and Ruby Lake. Then I've done hikes in Nipigon and North Dakota. And finally my favourite hike is probably the Palisades.

– Gabriel Lemelin-Wiersma, 10, Thunder Bay, Ontario, Canada
Image: Ruby Lake Provincial Park, Elaine Wiersma

One of my better friends that I had from middle school through high school owned a dairy farm that had over 200 dairy cows on it, as well as their own manure pond to convert cow poop into reusable energy. He studies agricultural science now and plans to take over his dairy farm when he can but now I know how the dairy industry works most of the time. I think back to all the times I walked through the aisles of dairy heifers and now I regret just walking by and petting their wet noses. Was their welfare actually better than the dairy factory farms? I think so, at least a little bit better, but it's still awful. Was the dairy farm really such a cruel practice if they were using the cows to be green about their energy source? I believe that helps me see them as persons who aren't blind to the fact that there is important causes to fight for, like reusable energy. However, I didn't learn about factory farming until I left rural Ohio completely and found myself surrounded by grey, dank, city with hardly any natural spaces around.

Crazy to think that I learned the most about wildlife, nature, and practices that concern the natural world and those nonhumans within it in the grungy city. I assumed that I had learned a lot while I walked through state park trails or tore through corn fields on my mountain bike growing up, but I really hadn't learned that much at all. My eyes were opened to all the ins and outs of the natural room while in a college classroom, the furthest thing from nature.

What this deprivation from natural spaces did do is make me seek out chances to go forth into nature more. I actively sought out urban green spaces to explore, and this made me appreciate that time outdoor and the chance to learn about those small ecosystems. Although I have come face-to-face with chimpanzees in Gombe National Park, listened to humpback whales sing in Hawaiian water, quietly watched exotic birds and sloths in Costa Rica, and even got to experience the jaw-dropping brilliance of the Antarctic Peninsula I would say that those are the times I will never ever forget. However, I also won't forget being five feet away from a red-tailed hawk that landed on a grave stone in a local cemetery when I was sitting and taking a break from a run, I won't forget looking at all the hundreds of slugs on the sideway of the college street I lived on after a good rain, and I certainly won't forget the breath of crispy fresh air in a local park in the late evening when I needed to de-stress from everything. Those experiences close to home, in the city, I remember and think back on just as much as the epic travel adventures I had.

What the move from rural to urban taught me was all experiences are worth it. Any experiences with nature were the experiences I yearned for. They did not have to be insanely expensive trips in faraway lands, they could be in a puddle in the street or in a local garden. Any time in nature was a learning experience and impacted me in some way. I remember all of it because I remembered to take the time to look for these experiences, stop, and appreciate them for what they were, little blissful moments. If anything my relationship with nature has been strengthened ten times over now that I live in an active city environment. Not only have I learned more, but I appreciate nature more and truly take the time I get to spend in any natural space to heart. Nature is everywhere not just where you assume it will be. That is what I have learned.

– Allison Maynard, 21, Circleville, OH, USA

"What would you do when you meet a frog under your bed?"
"I would take care them." The girls group answered it.
"I would make it my pet, because I like frogs"
"I would put him in the aquarium, in a huge aquarium"
"I would throw them on the river," "I would throw them on the river again," "I would expel him from home" "me too." Some children answered.
"I would catch him, to save, to leave it there in his lake" "I'd leave him also at the lake"
"I would put some food on the floor so he could follow it until he left," a boy said.
"Kill them," few children, most of them boys, answered.
Later, discussing if it was right to kill the frog, the boys said "not" to killing the frog.
"Because he is from nature"
"It is because if kill them, after, we do not have frog"
"Because we have to let them here, because they are good to us."
"Because they are made of nature, and he is . . . Jesus takes care of animals, and if they die, they will not live, and all animals of nature will die."
"I'm going to get a frog to protect my house from the dengue mosquito."
"I love frogs" "I love too, but I am afraid" "Why are you afraid of frogs?" "Because there was a giant spider wanting to eat a stone frog" "because they bite" "because they pees in our eyes" "I like cat, and I am afraid of frog spit in my face."

Being part of the DIAN (Debates and Investigations on Animals and Nature) team was an amazing experience! My graduate course is Environmental Management, it broadens the ecological view and inducts respect for all life. I entered in the DIAN team because I like working with children. Thus, the proposal to Debate and Investigate about Animals and Nature was a nexus to connect the theoretical inquiries of my course with practical activities of the group, as well as to contribute with creative ideas to do activities to children. In addition, approaching animal rights with 5-years-old children was, besides a novelty for me, a challenge, since there is a cultural heritage present in our society which causes our utilitarian point of view. The greatest stimulus and challenge for me, during my participation in this project, was the introduction of a systemic perspective, in an ethical way, in the kindergarten.

– Leticia Sanfilippo Rojas, 20, São Paulo, Brazil (*DIAN project*)

Nature has always felt like a comfort for my anxious thoughts. I have lived with Generalized Anxiety Disorder throughout my life, and in the times when my anxious feelings are mild or unyielding, the thought of the natural world is calming. Transporting myself into the depths of the wilderness, whether that may be through my own imagination, or physically visiting an unpopulated beach, a local forestry reserve, or even simply walking around the local parklands, I find comfort. I believe it is the feeling of being surrounded by pure and uncritical life forms, plants and animals that allow me to withdraw my focus away from the superficial things in life such as school, work, societal norms, and indirect, unrealistic expectations. The animals that fluster around, going about their day, seem strong, persistent, and resilient to the numerous daily challenges. They are all inspiring. It is these forms of natural flora and fauna that I believe can be used as a source of comfort, care, and love, particularly in times of stress, and psychological hardship.

I have been lucky to travel to various countries throughout my life, where I have been able to see and experience some of the wonders of the natural world. I guess I can say that I have also witnessed some of the worst aspects such as the heavily polluted cities of Beijing and Shanghai in China, and the uncovered landfill hills in Thailand. I have also hiked through some of the most majestic forests and mountainous lands of North East India, and I have explored protected islands in South East Asia that possess some of the most amazing tropical plants and animals. It is deeply saddening to see the potential human beings have in causing destruction to the natural world. However, I do remind myself that with the unity of others, we have the power to create change and this change can be achieved by simply altering minor behaviors in our daily lives. I have recently made the decision to become a Vegetarian, and I consider myself to be an environmentalist and an advocate for the sustainability of the natural world. The impact my direct actions have on the natural environment is a continuous, daily consideration in my mind.

Other living beings share this precious world with us, they do not live in our own creation. I have many vivid memories of experiences with animals, some that I have found quite confronting and disturbing. These memories take me back as far as my early childhood, and after some deep analysis, I have realized that these have undoubtedly contributed to my strong personal sense of empathy for other living species. One day at a rock pool in the Port Phillip Bay, myself and my cousins were exploring what seemed like the untouched beauty of the rock pools. An array of crustaceans emerged from beneath the water, and I remember 100's of small black crabs. It was fascinating to watch them scrambling along trying to find a hiding place, however my cousin thought that it would be a great idea to collect them as bait for fishing. I remember pleading with her to leave them, however, she refused. I felt as though I had lost the battle for the lives of the crabs, a deep feeling of sorrow, and grief come over me as I knew now of their doomed fate. This was a feeling I would continue to encounter whenever I would witness a confronting situation with other animals. The screaming of crammed hogs in the back of trucks destined for slaughter will never be erased from my memory as I remember the drivers speeding voraciously over the border between Shenzhen and Hong Kong on a blistering hot day. The pigs were clearly in distress, overheated, and banging and clashing into each

other and the steel bars that imprison them. Even the numerous fish I've seen over the years gasping for air as they lay to die on the sandbank after being reeled in as worth catch by my keen fisherman family members.

Through adolescence and as a young adult, I become more aware of the confronting aspects of the interaction between humans and the natural environment. One vivid memory I have as a child is when my Father explained to me how disappointing it was that some human beings have such little regard for the environment that they would leisure within, and exploit for their own gain. He explained this to me after asking me to help him collect fishing wire, discarded plastic buckets, empty water bottles, and plastic food wrapping on the beachfront as we exited one of our favorite holiday beaches in Gippsland. Seeing the carelessness struck me, I remember a distinct feeling of sadness and emptiness, however my Father did reassure me that it was the minority who were careless, for most people look to preserve and protect beautiful places such as the beaches. I never lost my sense of hope in humanity to protect and see ourselves and nature as one, and up until this present day, I haven't yet.

– Ricco Dezan, 24, Melbourne, VIC, Australia

Composition 2: Practices of sense and sensation

I hope that when readers see my photos that they can look at them and live the experience of a swamp – for anyone who has not had the chance to see one in real life. I feel that photography is the best form of art to capture nature in its element. I live in Buffalo, NY but travelled to New Orleans for a family vacation. We had been to Honey Island Swamp before and I knew it would be a good opportunity to take photos there. I wanted to capture more exotic wildlife and scenery than I normally see every day. For me, getting good shots is a reward in the end but I most enjoyed being able to experience the swamp first-hand. I felt very connected to the animals I captured on camera – more so than the ones I just viewed, because I got to study them more by trying to capture the right moment. I chose these six photos because I really liked the composition. All of them consist of water, which I think makes a picture more interesting because you get light and reflection. I also really like the way the trees made pathways or a trail in the water.

– Claudia Critoph, 16, Buffalo, NY, USA

There will always be some life if there is oxygen and water. Nature rises from the ashes. It will push on past the impossible.

– Grace O'Shannessey and Chiara Wenban, 11, NSW, Australia (*Climate Change and Me*)

Sensory station in a therapeutic garden:

- *Balance beam (Bricks underneath the ends of a wood plank to be balanced on)*
- *Wood blocks (Wood blocks placed on the ground to be stepped on)*
- *See saw (Log held by bricks underneath the middle of a wood plank to be traversed)*
- *Rocks (Rocks placed on the ground to be stepped on)*
- *Log (Log placed on the ground to be balanced on)*

Venturing at the edge of the property that borders some woods, unassuming piles of rocks and logs can be found. The locally sourced materials furnish some basic stations.

We considered the rocks based on their "personality," such as a temperamental rock with light colors and sharp edges or a round dark colored calm rock. We were looking for diversity and considering the rocks as a group that should display different personalities. We were beginning to feel like landscape architects and finding ourselves awakening to Japanese aesthetic sensibilities (*wabi-sabi*) as we noticed the depth and complexity in the simple rocks. There was something fulfilling as we were making choices, or rather listening to the rocks telling us where and how they were to be placed.

We encountered a log that became the most challenging and interesting station. The log had a slight bent and an unpredictable wobble when stepped on.

Luna: "I like the wood [logs], because you get to balance and fall." Stella: "We need to make it harder."

– Tomoaki Imamichi with Stella, 5, and Luna,7, Chestnut Ridge, NY, USA (*A Therapeutic Garden*)

It is a battle between the environment and the humans trying to cut things down. The humans will win.

– Riley Ball and Blake Wilkin (both 9), NSW, Australia, (*Climate Change and Me*)

Summer

In August,

path itself back to being a path,

moss dried,
branches broken,

Easier to get to my site…
with it being less blocked,
more people could be interested in going

down that path,

I wasn't sure how I felt about that.

Fall

The weather was getting

darker and wetter,

and I felt confused about
what I wanted to do with my life.

One of the cottonwood trees
that had surrounded my site
had fallen…

For the first time, I really felt that

the site wasn't welcoming me in.

Winter

There were no footprints in the snow

aside from mine

and everything was quiet….

Unlike in the human world where

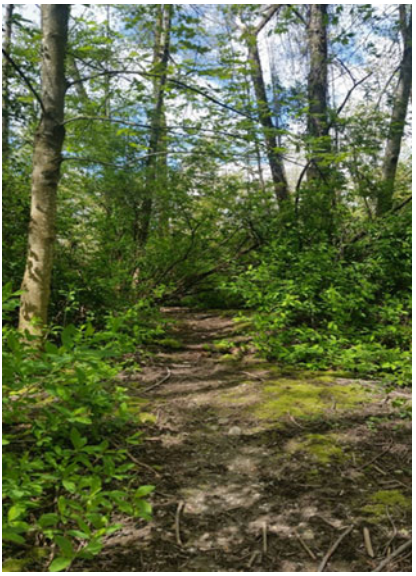
everything still keeps moving

despite how cold it is,

in nature things take

a pause.

Spring



A pleasant surprise to come back and see

a mass of green,

and life…

I could hear different birds again.

The wind rustled the leaves

and the sun was

shining through the branches.

– Jenna Masuhara, 21, Burnaby, BC, Canada

I am going to draw air.

I'll fill the whole page with blue …

And stars.

This is where an owl was flying back to its home in the morning.

– Teya McAdam-Chase, 5, Vancouver, BC, Canada

The wise old tree

The owl lives in the tree

I call it wise because it's old

– Kai McAdam-Chase, 5, Vancouver, BC, Canada

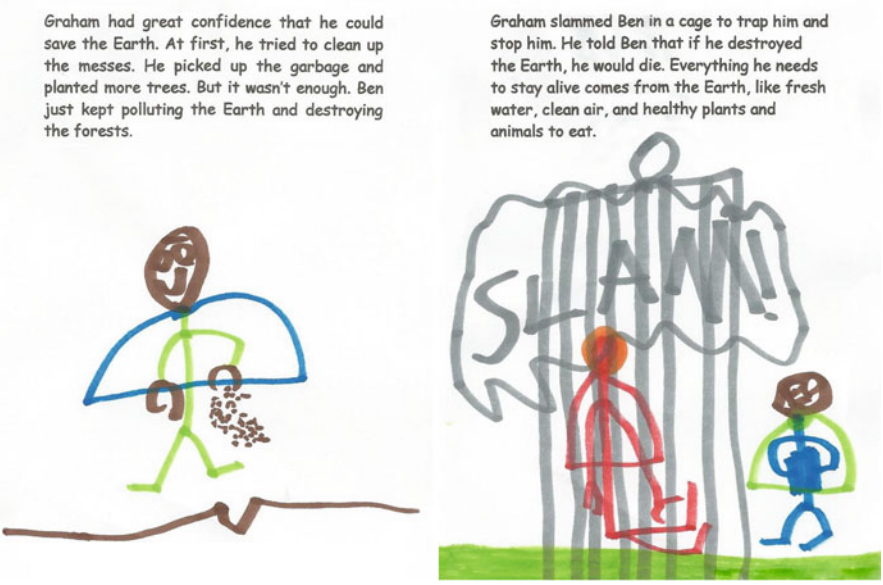
Holes like this in the glacier would appear every so often, though they would not last long. It was predicted to melt and fall apart within a few days.

– Sam, 13, NSW, Australia (*Climate Change and Me*)

I like this mountain very much. I feel good (about the mountain).

There, on the top of the hill … The prayers are written on the flags and then the wind blow the prayers through the village… When it flows (the prayers) I like much.

– Srijal, 14, Ghoom, India (*Places that Matter*)



– Jack Whitehouse, 5, Orchard Park, NY, USA

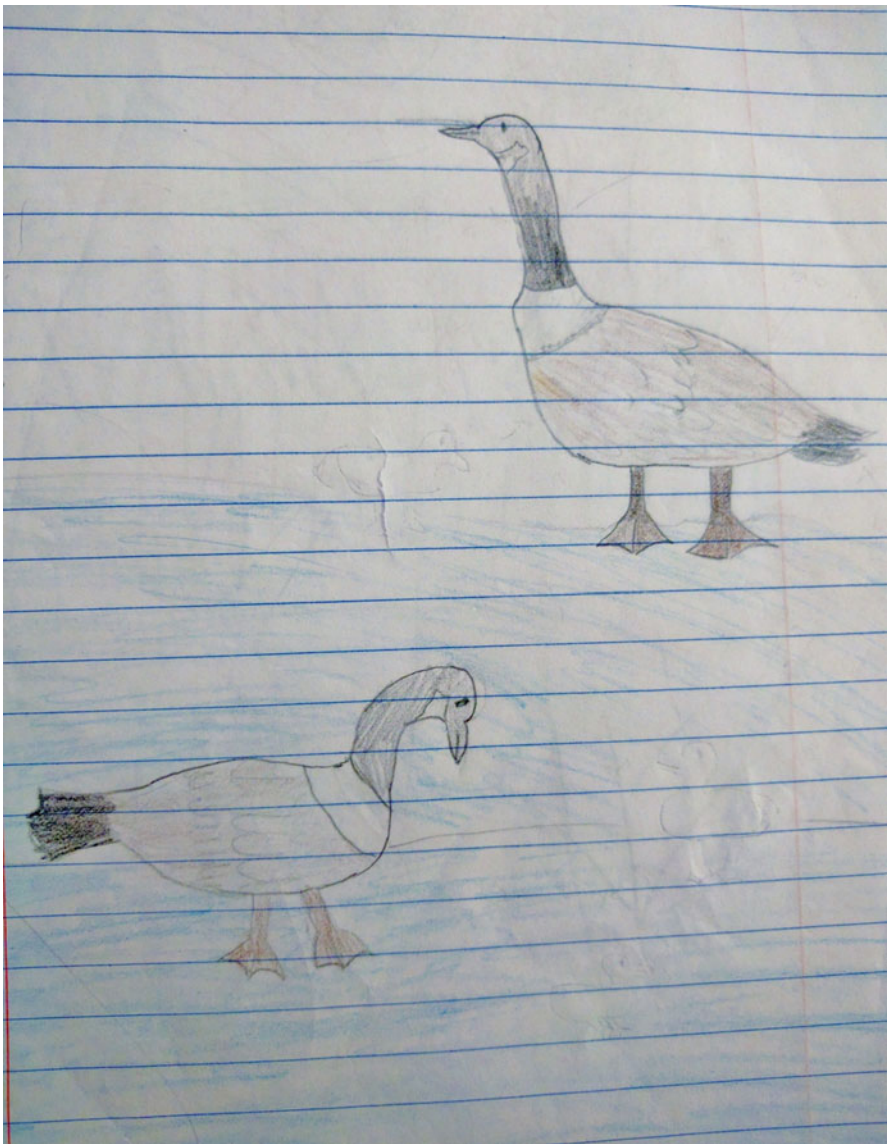
The story of Tica and Mao

- Mary Woodruff, 21, Ringoes, New Jersey, USA

The everyday lives of bugs and their food sources- the little worlds that exist around us.

With more CO2 in the air, these natural processes will be interrupted and eventually lost.

– Grace O'Shannessey and Chiara Wenban, both 11, NSW Australia (*Climate Change and Me*)



What I liked to sketch geese was that I felt calm watching them, sitting the lake side. The geese are calm even though they are sometimes noisy.

– Minami Furukawa, 8, Christiansburg, Virginia, USA

– Arpan, 16, Chuikhim, West Bengal, India (*Places that Matter*)

It is dark on the HORIZON… but through this project it is becoming clearer.

Clearer of the way out of the dark, to the age of natural information.

The heat, the cold; they cannot become extreme… or we will die.

– Kairo Byrne, 12, NSW Australia (Climate Change and Me)

Composition 3: The Eco-Poetics of Childhoodnature encounters

Nature

I step into a world,

Of silence and serenity.

Of soaring birds,
That sing at sunrise,

And leaves of trees,
That whisper softly,

All the joys and sorrows,
And secrets of the world.

– Liv Evans, 11, Brisbane, Queensland, Australia

Photo by Claudia Critoph, 16, Buffalo, NY, USA

Chirp and Fly

A dog came stumbling down the path
A fern he crumpled didn't last
A hole he dug beneath his paw
I don't believe he knew I saw

Until his eyes reached mine at last
I gave a look that looked aghast
The dog ran off to explore anew
To that dog, I bid adieu

The owner next came wondering through
I don't know why she looked quite blue
She walked on by without a word
I said to her, have you heard the bird?

What bird?
She looked up to spy
Just listen
as the birds chirp and fly

– Acacia Cresswell, 22, Vancouver, BC, Canada

Who Comes in My Dreams?

You come in my dreams
While I sleep and nap
You have the perfect smile and,
Laughing eyes, beautiful hair and,
Naturally Varnished lips,
That figure is simple, yet attractive,
That figure has no well,
Still spends the thought,
That figure has no spring,
Still I can swing and have fun,
You have come in my dreams,
You spoke the lovely words,
As the new snow in the old world,
We can drench, once the snowflakes melt,
You are too lovely and smart to secure my heart
Who comes in my dreams?
Climate change does

– Kiara, 10, NSW, Australia (*Climate Change and Me*)

Circle of Life, Circle of Love

For thirty years, my home
is the foamy sea.

Then it is time
to make a journey,
to bring life to the unborn,
who will soon come alive.

Trudging through thick sand
they will soon reach the foamy sea as well.

Thirty years later
they will make the journey.

It is a circle of life,
a circle of love,
that is what creates us.

– Sarah Margulis, 22, Chicago, IL, USA

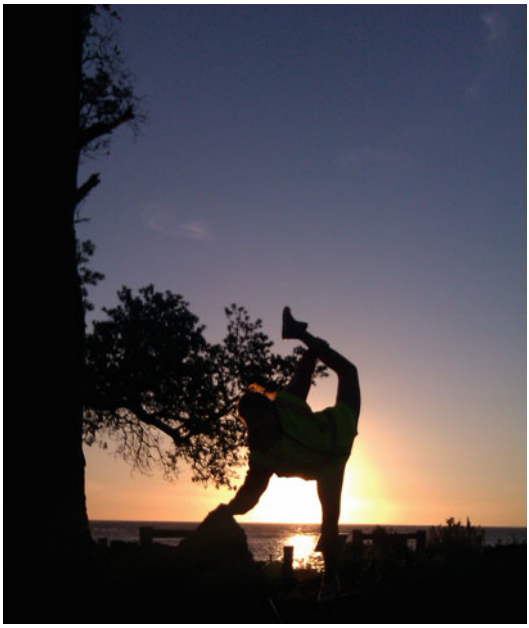


Photo by Anya, 14, Melbourne, VIC, Australia (*Places that Matter*)

A Lending Hand

A forgotten land
A heap of garbage
A lending hand
A smidgeon of soil
A touch of rain
A flicker of sunlight
A family of trees
A few chirps of a bird
A new land
A shared land

– Acacia Cresswell, 22, Vancouver, BC, Canada

New World

Devotion to technology,
Ill environmental care,
Food sources dropping
Fail to stabilize,
Everyone changes…
Regrow the planet,
Environmental reboot,
New world.
Can be saved,
Everyone should care.

– Blake, 10, NSW, Australia (*Climate Change and Me*)

How Much?

You hear the sound of the wind

And the sway of a tree

The flowers are bright

Even at night

As the clouds dance in the day

But will it be the same?

How much will climate change affect the earth…?

– Jade, 11, NSW, Australia (*Climate Change and Me*)

EC Stroll

Left, right, left, right
Breathe

Crunch, snap

Wooshh …

Chirp, chirp

Left, right, left, right

Breathe

Snap

Wooshhh …

Left, right, left, right

Breathe

Woosshh …

Breathe

Breathe

Breathe

– Acacia Cresswell, 22, Vancouver, BC, Canada

The Steps

Before the world was ending,
The beauty was incomparable,
But now the perishing heart of the world decays bit by bit.

A slowly rotting tree stump,
Filling and overflowing with rainbow hued life,
A sadness is not complete without a joy.

The better things in life stay if you treat them well,
But the fact is that we can't live in a rotten world,
It's just a fact.

Watching the wind whistling and the leaves fluttering you realise,
To save ourselves is selfish, to save but ourselves is selfless,
We must help save everyone.

That is the first thing you must realise,
The second is what I've said is almost true,
Our world is not completely ending, we can still help it survive.

To survive in our world, we shall help the trees and oceans first,
All animals need them to breathe so that is the obvious choice,
If our oxygen flow stopped so will our life.

Humans need to separate good and bad in their minds,
Then accentuate the good,
For if we do this we can better ourselves.

Before the world was ending,
The beauty was incomparable,
But now the perishing heart of the world decays bit by bit.

– Eva, age 10, NSW, Australia (*Climate Change and Me*)

All We Cannot See

I wonder about the trees at night
The dark, the bats, the park that sleeps

I wonder about the things that crawl
The path, the ants, the ground unseen

I wonder about the birds that chirp
The flight, the nest, the words unknown

I wonder about the hidden gems
The ferns, the berries, the dwellers that speak

– Acacia Cresswell, 22, Vancouver, BC, CA

Real Life

Real life haunts us
Real life will change us,
Real life will always be here,
But…
Climate change is our real problem.
Can we put climate change at a halt?
No!
Can we slow down climate change?
Yes!
But how?
By leaving nature how it is,
By not constructing useless buildings.
Please just leave our earth as it is.
Please don't touch our nature.
Please just stop.

– Hayley, 10, NSW, Australia (*Climate Change and Me*)

The Simple Site

The land is changing

the days are breaking

the simple site of the beautiful land is a gift above

the world is breaking

the light is fading

we have no clue to stop

the change is raging

why is it changing

as our gift is fading

we need to stop the land from breaking.

– Mekisha, age 10, NSW, Australia (*Climate Change and Me*)

Photo by Sam, NSW, Australia (*Climate Change and Me*)

I am the Earth

I am the earth
I am a cloud
I am the children
Noisy and loud
I am a tree standing tall
I am winter
Spring
Summer and fall
I am the grass
Thick and deep
I am the meadows
Luscious and sweet
I am the landscape
That meets my eye
I am the desert
Sandy and dry
I am the ocean
Endless and blue
I am the animals
I am me and you
I am the earth
I am a tree
I am the earth
And the earth is me

– Sarah Margulis, 22, Chicago, IL, USA

Composition 4: The Childhoodnature Imaginary

Selected works from the *ArtScapers* project

By children from Cambridge Curiosity and Imagination (CCI), Cambridge, UK

– A Hot Air Palace, Katharina, Cambridge, UK (ArtScapers)

A hot air palace

A shiny silver hot air balloon palace
fashioned from pure silver.
Giant garden.
Free hot air balloon.
Fly high with a hot air balloon of your own
and land in a giant garden full of breathtaking flowers.

Dream Flower

The dream flower is
a strong and powerful
flower. It catches all your
dreams. The bits on the side
are a bit like ears.
The circle means it is a dream flower
and it produces its own special water
which is poisonous to humans.

Tectonic Nature Island

Trees and berries,
Tree from the future,
Snails grow on trees,
and only maybe
one berry,
one leaf

– Kirsty, Hannah and Bea, Cambridge, UK (*ArtScapers*)

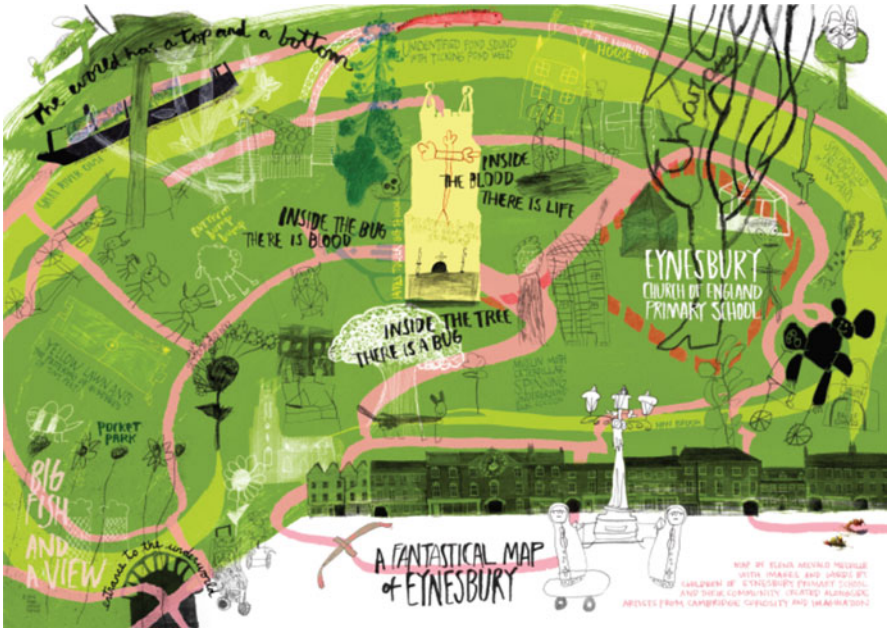
Each minute is a symbol.
Each heartbeat is a second.
One minute is a cheetah step.
When we are happy the days are longer.
How the ball rolls will tell the time.

If you take a leaf off every day
when you get to the middle you know it's been a year.

Selected works from the *Fantastical Cambridgeshire* project

By children and artists from Cambridge Curiosity and Imagination (CCI) Cambridge, UK

FANTASTICAL
CAMBRIDGESHIRE



Use your imagination…

Let your mind go free…

Be really focused and look at a LOT of different things…

Let everyone join in…

Use different materials…

Look at lots of different maps…

Use 3-D objects…

Measure, be inventive, think about shapes and how things stick and go together…

Do what you want. It could be a map of anything…

It's up to you. It doesn't matter…

Think carefully about the real and the fantastical. Like the real river running through and all the connections to this…

Think differently, think in different ways …

Thickest black

ink black, dark willow at midnight

midnight black, ashen black, rabbit-hole black, night tree black, diamond black

black mantle, midnight sky, sunset black, dark night, disappearing black

black oak, luna black, willow at night

beneath the trees, mud black, the dark lake….

A Fantastical Map for Roundhouse Primary School ©Elena Arévalo Melville 2017

If you learn to explore like a mouse you can learn to explore like anything.

They find a little hole and sleep in it for a night, then another hole

then they keep going.

I explored being my Nan, and I was called Nanny Mags.

I had a walking stick and I walked slow and I sat down lots.

I had to hold my back all the time.

I explored like a fox and a toddler.

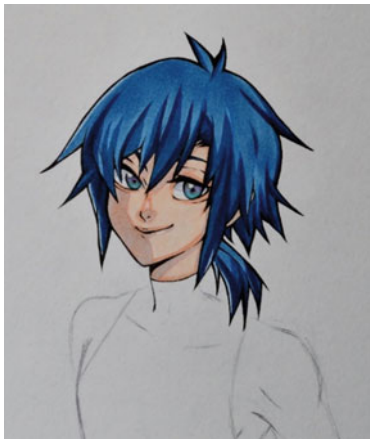
When I was a fox and I had four legs it was amazing.

When I was a toddler everything looked so high up.

Selected entries from *The Beginning of the Changes*

By Jasmyne Foster, 12, with collaborators from
the *Climate Change and Me* project, NSW, Australia

Entry I. November 17th 2014



NAME: AOI

AGE: 14

GENDER: BOY

HAIR: AN ALMOST NEON BLUE, SHORT, MESSY

CLOTHING: CASUAL, MOSTLY JEANS, BAGGY SHIRTS AND LARGE HOODIE JUMPERS AND LARGE SNEAKERS

ACCESSORIES: ONE SILVER EARRING AND A GOLD FAMILY RING

A room that looked like a bomb hit it, clothes scattered messily on the floor. A bed that didn't look much like a bed, more like a table with sketchbooks scattered on the end. A bag crumbled in the corner with a clatter of key chains and bulging with the shape of a lunch box. This was Aoi's room.

Aoi was interested in the workings of the universe and was a full blown realist. He had always cared about the earth's geological problems and biological workings. But when he thought about it, helping scientists in the lab might be difficult for someone who just loved to draw so much. But just when he thought of giving up on science and becoming some generic worker for a large company, he found out about climate change. He decided to search for some information and he was so strongly taken by the topic that he began to post about it on social media. Aoi was so interested in climate change and he wanted people to become more aware, but how could he make a difference?

He was only a child in the eyes of the public, not likely to be taken seriously.

Entry II. November 18th 2047

NAME: ELBERETH

AGE: 47

GENDER: WOMAN

HAIR: WHITE WITH SLIGHT STREAKS OF BLUE

CLOTHING: OLD CLOTHES WITH HOLES THAT HAVE BEEN EATEN BY MOTHS

ACCESSORIES: TWO PEARL EARRINGS AND A FOX MASK THAT SHE KEEPS IN A BOX UNDER HER BED

COMPANIONS: A WISE AND TIRED OLD DOG NAMED TURIN

The wind blows in the door again and I can hear the rush of the water breaking on the cliffs below. Turin barely moves at all, he just opens one eye and looks at me as if I've created the disturbance. The air is full of frozen salt crystals, they bite my cheek as I brace the door closed with the last of my heavy books. Soon I'll have used up all my esoteric books for fire-starters and everything in them will probably be forgotten. It's been too long since I've felt the power of the earth in my fingertips, the electric current that turns the waves away from the valley below. Now I lack the strength, and the memories flow back like the tides that nobody can stop from washing in.

But what's that? Turin is up, stretching and starting to growl at the same time. I hope it's not those raiders again, last time they cleared me out of rice and oats faster than I could get out of my rocking chair. Something is scratching at the wooden door. I grab the knife from next to the cutting board where I'd been chopping kale from the garden. It's only a bread knife, but it's better than nothing.

"Who's there!" I say in my deepest, scariest voice. I open the door just a crack and can just make out the shadow of a person against the pelting wind and rain. It's a child, no a man, with a face that looks so familiar and yet cloaked in shadow. I open the door all the way and he falls into my cabin, drenched and exhausted on the floor.

"Who are you?" I say sternly with the kale knife gripped steadily in my hand.

"Aoi," the voice faintly replies.

Entry III. December 5th, 2014

All the kids at high school had been invited to the research workshop about climate change. Aoi found himself doing a practice interview with a talkative girl named Elbereth. "I think the Earth has already transitioned into a new geological era," she was saying. "Humans have become like this viral force that's affecting every ecosystem on the planet."

That afternoon after school they went for a walk in the old forest behind the school, Elbereth with her notebook writing stories and Aoi with his sketchbook drawing the creatures that sprang into his mind. They came to a rushing stream that had swollen with water after the recent flood. Aoi started to make his way across the stream on the wet log. Suddenly, he slipped on a patch of moss and fell into the rushing water. His head hit a rock and his body was swept downstream.

Elbereth ran along the bank as fast as she could, but when she finally caught up to him his body was cold and lifeless. Desperate, she placed her hands on his heart and summoned all the power in her body to put warmth into him. She felt a vital energy enter her body from the forest floor, pulsing through her arteries like blood, producing heat that made her skin burn as if touching flames. Suddenly Aoi sputtered and sat up, looking at her with wild eyes.

Later they found Aoi's sketchbook soaked and lying upside down alongside the rushing stream. It was moving slightly. Aoi picked up the sketchbook and jumped back in surprise – underneath it was a frog-like creature with pale translucent wings. It jumped onto the nearest rock, then flapped its wings and flew away.

With trembling hands, Aoi turned over his notebook to the page he had been working on before he fell into the stream. There on the page was the very creature

they had just seen fly away- an amphibian with the wings of a dragonfly. Aoi looked at his drawing hand in amazement.

The flesh had changed to a strange blue color, and the nails had become like black claws.

Entry IV. March 23, 2021

The staff stood silently in the center of the task force building. Nerves were high. It was rare that the entire task force would be asked to meet unscheduled. Everyone was tense, even senior detective Shinohara looked tense. The eerie silence continued for another few seconds until Shinohara broke it. "Task force, we are gathered here today to see the latest technology from Astral Labs to combat the ever-growing aberrant infestation. I will now hand the floor over to Professor Arima."

A small man emerged from the other side of the room. He wore a white coat and carried a brief case with him. He stood next to Shinohara in the center. "This," Arima said pointing to the brief case, "is the future of aberrant hunting. It will allow you to find aberrants and neutralize them faster than ever before. Here, allow me to demonstrate."

Professor Arima pushed down on the handle of the brief case. The case split into two revealing a block of metal slowly taking on humanoid form. "This is Shudon, the latest in aberrant hunting technology. This is military funded weaponry with a built in psycho-pass able to scan aberrants to a 50 m radius; all that is required is a sample of blood. With on-board facial recognition system and a fully equipped medical kit, Shudon is by far the most powerful weapon for aberrant extermination ever invented."

Entry V. April 15th 2021

Elbereth buried herself into her coat. She walked steadily, looking at the graffiti scribbled across the side of the buildings. Many were political slogans so she paid no attention to the messages. She soon came across the task force headquarters where wanted posters of criminals were pasted along the side of the discolored brick walls. But criminals weren't the only ones with wanted posters.

The wall had a section for "aberrants." This was the dim name that the humans had classified those with powers under. She walked over to the wall and looked for her wanted poster. It didn't take long to find a poster of her with her mask on. It was labelled "Firefox." Elbereth could feel heat emanating from her hands. *Dangerous, volatile, and will kill without remorse?* They were all lies!

She grasped a corner of the poster and tore it down from the wall, using the heat emanating from her palm to set the poster ablaze with fire.

Entry VI. November 20th 2047

I wake in my rocking chair to the smell of oatmeal cooking over the fire. No, it wasn't all a dream. My oldest friend Aoi is crouching over the flames, stirring the pot with a long wooden spoon. He turns and looks at me, the piercing clarity returning to his eyes by the second.

"Aoi," I say. "I can't believe you're here. How did you find me after all those years?"

"There was just this map, Elbereth, a map in my mind. And I followed it to your door. But tell me, please. I think I've lost my memory for thirty years. Are we the only ones left in the world? Did my visions actually come true?"

"Many came true, and we are deep in the Changes as they have spread across the Earth," I explain. "The power grid shut down five years ago, and the Netscape was destroyed not long after. Wireless mesh networks still communicated for a while- I have a node here that kept me updated with the latest information until it rusted out from the saltspray last year. Transmissions were coming through from communities up and down the coast that had formed their own collectives, rebuilding their towns and villages to adapt to the Changes. The cities are apparently lawless and mostly deserted. People like us have been helping- using our earth powers to protect and heal the communities- and fighting off the raiders when we need to."

Entry VII. December 1st 2047

"Aoi, the food's ready."

"I'll be out as soon I can. Just have to finish this," I say softly, trying not to show Elbereth how desperate I am to finish the drawing. Drawing is the cure to my illness. When I have a sketch book near me I feel my power and memories rushing back. Drawing makes me feel invincible. It's like I draw power from the image, and the better the image the better I feel.

Then we hear a ghostly rapping on the door. I freeze, while Turin barks furiously at the door. "Who's that?" Elbereth calls from the kitchen. I can hear her kale knife coming down with force onto the chopping board.

"Come out meat," a voice calls tonelessly. I feel my heart skip a beat. I've heard that voice before. Then the door breaks open and an arm of steel emerges through the hole in the wood. The hand draws back and a pulsing robotic eye peers through. "I found you Anthropos!" the toneless, mechanical voice calls out.

I bolt up, sweat pouring down my face. "We have to leave," I mutter nervously, my voice cracking like glass as I speak.

Elbereth just stares. "Who is that Aoi?" The metal hand is scraping furiously at the wood like a caged animal.

"It's Shudon. He's finally found us." I start flipping through my sketchbook, desperately searching for the right page.

Notes on The Companion Contributing Authors and Projects

The Young Authors

Acacia Cresswell, 22, Vancouver, BC, Canada

I learned a lot about the possibilities of studying relationships with nature and outdoor learning having taken SFU's Semester in Dialogue – "Semester Outside in the City." We spent weeks learning outdoors, rain or shine, while developing our

facilitation skills and thinking of ways to get others interested/excited about outdoor learning. For an individual project, I presented some poems inspired by the park we were studying in. I spent much time in a small area of the park, trying to forget everything and focus on what was around me, and how I felt in the spot. I would write down whatever came to mind and later would look back and refine my ideas into cohesive poems. I had always written poems for myself for as long as I can remember, but until then, I had never really shared my poetry with anyone else. My poems are from that time, as well as new ones, inspired by my connection with different environments or "nature." I hope my poems inspire others to get out there and have new experiences with nature – to take part, research and encourage relationships with/in nature. Sharing my experience and my work would mean the world to me if it means inspiring others to take part, research and encourage relationships with/in nature.

Claudia Critoph, 16, Buffalo, NY, USA
I love all animals especially dogs. I hope some day to have a career that helps rescue dogs in some way. I shadowed our family veterinarian from Ellicott Small Animal Hospital, for a day. It was very interesting. I also was a Junior Teen Naturalist at the Buffalo Zoo last summer. I attend The Buffalo Academy for Visual and Performing Arts. My major is visual arts and photography. My images are of nature and animals. I like to photograph in Delaware Park and the Buffalo Zoo.

Ricco Dezan, 24, Melbourne, VIC, Australia
I am a newly graduated teacher after completing a Business undergraduate degree and my Master of Teaching. Preserving nature is something I am quite passionate about. In my submission, I am reflecting on some of my most vivid memories and encounters with nature.

Liv Evans, 11, Brisbane, Queensland, Australia
I just love writing and I also love the outdoors. I think this would be a great opportunity to share my ideas and be published! My submission is what I love about nature and what is worrying me about the future of it.

Kasumi and Minami Furukawa, 7 and 9, Christiansburg, Virginia, USA
Minami and Kasumi are sisters. After Minami submitted her sketch of geese, Kasumi also wanted to share her sketch and thoughts.

Liticia Gardner, 22, Vancouver, BC, Canada
I'm an avid window-looker-outer. I sit in my house a lot watching my surroundings, and I love listening to birds. I'm an undergraduate student at Simon Fraser University studying Women's Studies. I come from a low income household, with a 16 year old mother, and I feel that my relationship to nature has been most directly impacted by my class position, particularly the places I lived and schools I went to. I'm interested in this book because I very much still relate to being a kid. I feel like I'm in a world that's too big for me and I'm excited to have the opportunity to focus my

energy and writing on the topic of "nature" and my relationship to it. I worked with the Semester Outside program, through City Studio, and the program has had a lasting effect on my life.

My submission to the Companion covers my current thoughts on the nonhuman world. It will most directly relate to my experiences with the nonhuman world, but it will draw on a number of ideas that have impacted me and my relationship to the world lately. An excerpt from Liticia's full essay is included in the Companion.

Lucy Handy, 17, Providence, RI, USA

My submission is about simplicity, and the importance of nature as a retreat from modern day stresses of technology and social media.

Gabriel Lemelin-Wiersma, 10, Thunder Bay, Ontario, Canada

I enjoy hiking and seeing nature and wildlife like salamanders, frogs, dragonflies, birds, bats, and insects. I am glad that there is still forest left in the world, and hiking makes me feel happy, relaxed, and a sense of accomplishment. I want to tell people of my experience with nature, and that I love all types of nature. I want people to realize that there is still nature left and they should stop polluting and destroying it. We go hiking almost every week.

Sarah Margulis, 22, Chicago, IL, USA

I wrote these poems when I was 11 years old for a 6th grade writing project where I produced a book of poetry entitled "I Am the Earth." As a young kid, the landscapes around me intrigued me because they were something I could not fully conceptualize. That is why I chose poetry to write about nature; because poetry leaves room for imagination. The first poem "I am the Earth" I wrote based on a view I had of the sky and the sun while swinging on a swing set at the park. The second poem "Circle of Life, Circle of Love" was inspired by Sea Turtles I saw on a family vacation to Costa Rica. Poetry allowed me to imagine and create the inner workings of the natural world which I couldn't experience through my senses. Since I wrote these poems (over 10 years ago), I have continued with my love of writing. I have experienced all types of writing, research papers, essays, analytical papers (which I wrote many of as a philosophy major in college); and grants (which I currently write through my job as a grant writer). My favorite type of writing is writing that stretches my imagination to the limits. To me, writing is an exercise in creativity. That is why I am so interested in the Childhoodnature book; because nature is the perfect subject for creative expression. When I am not writing, I enjoy movies and TV, baseball, walks and hikes, exploring new places, cooking and baking, and hanging out with my 14 year old cat DD.

Jenna Masuhara, 21, Burnaby, BC, Canada

I am a university student at SFU, taking a Communications Major, and Business, Dialogue, and Publishing Minor. While growing up my family and I went on a lot of camping trips and hikes, and taking part in nature education programs. Nature was an important part of my life and I believe that children should be encouraged to

explore nature in any way possible. Last summer I was part of the SFU program Semester in Dialogue, Semester Outside the City, where we had lessons at Everett Crowley Park, learning about dialogue and ways to learn with nature as well as how to connect with it. It was a really eye-opening experience and I have kept those teachings with me as I continued my education. I thought that submitting something to the Childhoodnature book would be a good way to share some of the lessons I learned during the program as well as continue practicing them. My submission is a reflection piece of my experiences visiting my micro-site – a little spot of nature in Everett Crowley Park – over the past year, accompanied by photos to mark the changes the site went through as the year progressed. An extract of Jenna's year of photos and observations is included in the Companion.

Allison Maynard, 21, Circleville, OH, United States

As of 2017 I will be a graduate of Canisius College with a bachelor's degree of Animal Behavior, Ecology, and Conservation, as well as a degree in Digital Media Arts. My minor is in Anthrozoology and I have been passionate about animals and nature since I can remember. I hope to continue my education with a Masters and a PhD in child-animal-nature studies, or a related field. I am very intrigued by, attached to, and involved with the topic of childhoodnature. My narrative is about my changing experiences with nature and wildlife as I moved from rural Ohio to urban Buffalo. I focus on how I manage to get my fix of nature in such an urban setting; focusing on specific stories, relationships, or people/places that helped me to do so as my passion for nature and all of its inhabitants grew as I continued my college education.

Kai and Teya McAdam-Chase, 5, Vancouver, BC, Canada

Our experiences related to the trees and other plants and animals in our neighborhood.

Jack Whitehouse, 5, Orchard Park, NY, USA

Jack is homeschooled. A schooling choice made, in large part because Jack's family feel that it is crucial for children to have more time in outdoor, active, self-directed play. They have noticed a wonderful and unexpected benefit of this hands-on immersion approach is Jack's feeling of belonging to and personal responsibility for protecting the Earth. Jack loves to draw and write comics. He has created a short story about evil doers trying to destroy the forests and the heroes trying to stop them. All the language is Jack's. The family follow a homeschooling writing curriculum which encourages the child to dictate writing so their immature handwriting does not interfere with language and creativity. He dictated his story to his mother who typed it, and then helped him edit it down to a reasonable length. An excerpt of Jack's story is included in the Companion.

Mary Woodruff, 21, Ringoes, New Jersey, USA

I am an undergraduate student majoring in Animal Behavior, Ecology, and Conservation and Psychology. I am extremely interested in the study of anthrozoology,

particularly in regards children's relationships with nonhuman animals. I have experience working with children for over 5 years and most recently as a nature trail guide and ecology education for elementary to middle school age children. My story for children, Tica and Mao, follows the lives of two nonhuman animal friends. Tica, a Magnolia Warbler, and Moa, a Hoffamn's two-toed sloth, are both natives to the Costa Rican rainforest. Magnolia Warblers are Nearctic – Neotropical migrants that fly back and forth from the tropics to North America each year. In the story, Mao and Tica keep in contact with each other during Tica's migration through letters Tica sends Mao via "air mail." Tica tells Mao of her journey and the challenges she faces along the way. The story is 13 pages and incorporates an interactive component as readers open attached envelopes to read Tica's letters. An excerpt of Mary's story for children is included in the Companion.

The Projects

Climate Change and Me Project

David Rousell (Manchester Metropolitan University) and Amy Cutter-Mackenzie (Southern Cross University)

Between August 2014 and July 2015, 135 children and young people from across Northern New South Wales (NSW) Australia participated in the Climate Change and Me project as researchers. The children and young people attended research methodology training workshops with experienced educational researchers from Southern Cross University. They learned to engage with theory and methodology and use a variety of ethnographic and art-based research methods for producing data about climate change in their communities, including interviews, video, photography, field notes, drawings, poetry, and fiction. They were not given predetermined definitions or perspectives on climate change but were encouraged to investigate the diversity of children and young people's awareness, attitudes and actions towards the issue. The Climate Change and Me website was developed as a social media space for the researchers to post and comment on their research findings and creative works. Researchers also worked together to analyze and curate the data for the Past Now Future exhibition, which travelled to nine public libraries across Northern NSW. Researchers were actively involved with all aspects of the exhibition, including the titling, selection of works, locations, and artist/researcher statements.

Over the course of the project, certain researchers developed their own creative and scholarly research practices in response to climate change in their communities. A wide range of works were generated, including speculative fictions, short stories, essays, poems, artistic photographs, drawings and illustrations.

Cambridge Curiosity and Imagination (CCI)

CCI is a UK based arts and well-being charity that has been working creatively alongside children to play with ideas and make them grow since 2002. *ArtScapers* and *Fantastical Cambridgeshire* are both CCI projects that are briefly outlined

below. The artists' practices with children working at the intersection of nature and creativity are further explored in the Handbook Chapter: *Artists as Emplaced Pedagogues*. The CCI website is www.cambridgecandi.org.uk

ArtScapers

ArtScapers is developed and delivered by CCI and art education consultant Esther Sayers and is part of the Art program at the North West Cambridge Development. The ArtScapers workshops have been planned and led by CCI artist Susanne Jasilek to provide creative ways for children to connect with the changes happening in their local area, changes which effect both the natural and built environments in which they live. The project provides a space for imagination where extraordinary possibilities for living are explored and in which children's voices and ideas can be heard and recorded through creative outputs. "ArtScapers makes you think differently. . .. you're free to open your mind" (Jasmin, aged 8).

Through working with local schools, ArtScapers has focused on the overarching themes of community, place, sustainability, ecology, and archaeology. Pedagogic approaches have been designed to enable children to connect with their environment by slowing down and noticing the minutiae and the seemingly inconsequential aspects of place that are often overlooked. Time is taken for example to playfully record ways of walking along the chestnut tree lined lane into the site, to carefully place new work in the fields around the site and to joyfully be together whilst eating lunch or having a snack.

ArtScapers is commissioned by University of Cambridge as part of the North West Cambridge Development in partnership with Contemporary Art Society and InSite Arts.

Fantastical Cambridgeshire

Fantastical Cambridgeshire is an ambitious long-term project that connects people of all ages, their local area, adventuring and culture. A series of beautiful maps is being co-created through this work. These multilayered images are made of words and images from the children and their community, created alongside artists from CCI. They are fantastical because they combine real and imaginary places and stories. Each project starts with a primary school but reaches out to the wider community. People of all ages are invited to join in with creative adventures to discover the spaces in and around the school and develop a sense of wonder about the possibilities these offer. Together these communities have explored woods, orchards, new planting, ponds, rivers and wild spaces as well as more familiar parks and playgrounds. Discoveries are shared in the form of drawings, words, collections and even animations. Every single contribution is valuable and shapes the projects in exciting ways. Many of the wonderful ideas are incorporated into the final fantastical maps. The maps by illustrator Elena Arévalo Melville carefully weave together the fantastical drawings, words and ideas of the children, their friends and families. The creative invitations were designed by CCI artists Filipa Pereira-Stubbs, Helen Stratford, Sally Todd and Deb Wilenski.

DIAN: Debates and Investigations on Animals and Nature

Tânia Regina Vizachri, Letícia Sanfilippo Rojas, Luís Paulo de Carvalho Piassi, and Adriana Regina Braga, São Paulo University, Brazil.

In São Paulo, Brazil, we create and apply activities to discuss Interspecies Ethics with children through the D.I.A.N. – Debates and Investigations on Animals and Nature. This is a science outreach project oriented to socioscientific activism. DIAN aims to design outreach activities to discuss human-animal relationship from an ethical, cultural and scientific viewpoint. Through playful resources as theatre, music, plays, we investigate the process of rising conscience about animal ethics in children, checking how they construct their reflection about the cultural way to deal with animals. The DIAN team is driven by graduate and undergraduate students. The undergraduate students are responsible to create and conduct the activities and ludic resources to apply in the schools, as well as they conduct these activities. They are advised by the graduate students with theoretical frameworks to help them think which resources are suitable for the children.

Places that Matter

Helen Widdop Quinton (Victoria University, Melbourne)

In connected research studies in 2012–2016, adolescents (aged 13–17) explored the places that mattered to them, including the role of nature in their lives and how they perceive the natural environment as part of the places and spaces they inhabit. The framing of place created a generative, flexible focus for the adolescents to explore their everyday experiences of nature through photography, maps, Facebook posts, and conversations. The adolescents "narrating" these stories of nature in their lives are drawn from contexts of difference – different geographic locations, socio-cultural settings, and times – from urban Melbourne, Australia, and remote villages in the Himalayan foothills in north east India. An extensive range of photographs were generated through the research. The *Places that Matter* images shared in the Companion were taken by young researchers who particularly characterized their lives as connected with/in nature.

Sekolah Bisa!

Mr. Adrian Thirkell (founder Sekolah BIsa!)

Sekolah Bisa! is a tiny school of 25 students, originally conceived by IB students at The British School Jakarta as part of the IB "CAS" program, in partnership with The Body Shop Indonesia. It's now 8 years old and continues to offer shanty-dwelling children extraordinary opportunities to develop a capacity to rejoin society as educated, fully fledged citizens. Its commitment is to the organic life of the whole child: it does not placate poverty with charity but, by bespoke educational programs, seeks to ensure the worth of every child is valued and provision made to affirm their collective presence in the world as capable, healthy, and aspirational citizens. The literal translation from Indonesian of the school's name is, "I Can School." Sekolah Bisa! provides the opportunity for shanty children such as Ikki to attend school he'd otherwise have forfeited, and also functions as an environmentally friendly

sanctuary. The school's garden-like design, and profuse greenery, compensates for the conditions at home, where toxicities released into the air from burning rubbish have a negative impact on children's health and wellbeing. Any child subjected to toxicity, where the family's livelihood is partly dependent on recyclables, has a remarkable story to tell about nature, particularly how he or she remains aware of its value, and how it functions to compensate for the materially degraded circumstances of the shanty.

A Therapeutic Garden

Tomoaki Imamichi and daughters Stella (age 5) and Luna (age 7), Chestnut Ridge, NY, USA

The Therapeutic Garden account is about some of the experiences of a joint project of a parent and two children building a therapeutic garden. Therapeutic delight in a backyard came in unexpected ways. It started out with a plan by a parent and two children (ages 5 and 7), something to entertain them, something to support their development and their "sensory integration" – the buzzword at our beloved alternative school. In order to create varied surfaces that foster vestibular (spatial and balance) and proprioceptive (bodily and coordination) senses, inspiration was found in everyday objects lying dormant under the porch, such as wood planks and bricks leftovers from past projects, to be awakened for their newfound purpose. The real therapeutic effects were achieved, not so much through the sensory-integration, but via the creative design process. These experiences of seemingly simple childhood pleasure link to deeper philosophical concepts, Japanese aesthetics, Zen and the existing literature on children and environments.

Abstract

By foregrounding childhoodnature experience and its ongoing influence, significant life experience (SLE) offers a formative field of research for consideration

by childhoodnature researchers. The first part of this Chapter summarizes key findings and insights from previous SLE research and, as a contested field, aspects that have been challenged. In the second part, we introduce the nine chapters; here, a collection of contemporary studies interweaves the fields of SLE and childhoodnature through time and space. Together the studies in this section supports previous findings and affords new understandings of how childhoodnature is experienced and how this influences environmental behavior.

In the third part we group the Chapter findings into five childhoodnature insights: embodied experience, nature as family, cultural participation, childhoodnature loss, and developing methodologies. The studies reaffirm that SLE in childhoodnature can be a combination of continuous or single experiences, but that self-awareness within experience is significant. Further, SLE are often sociocultural in character involving cultural participation. Authors have also demonstrated the value of exploring the notions of SLE and childhoodnature with educational professionals.

In the final part, we raise issues for future consideration, not least the need for longitudinal research and the advancement of child-framed approaches in these fields. We contend that there is an urgent need for more research in disadvantaged and culturally diverse contexts as a response to the contemporary realities of, and changes to, childhoodnature in the Anthropocene. Importantly, we appeal for a paradigm shift to bring childhoodnature experience into the heart of all education systems.

Introduction

Childhoodnature rejects the anthropocentric view of childhood and nature. It argues that children are nature and, as such, are interconnected with and part of the natural world. As children are nature, we can therefore assume that the social and cultural worlds of children are a subset of the natural world. Bringing together the natural and, within that, the sociocultural worlds of children enables us to understand more about the significant influences on children's learning and development as natural beings. This section explores how significant life experiences (SLE) research both informs and challenges our thinking around childhoodnature. We argue that understanding the importance of SLE in childhood is a fundamental prerequisite for the exploration of our developing notion of childhoodnature. SLE research provides a methodological approach that explicates insights and intentions within childhoodnature, both of which create our reality. Together, these two fields of inquiry, childhoodnature and SLE, challenge researchers to reexamine their beliefs, values, notions, and understandings of how children see themselves within and as part of nature, and further, how we think about research methodologies and design.

SLE are important phenomenological events considered critical in determining or influencing concerns, beliefs, and actions in later life. This body of research suggests that SLE in and with nature may directly influence environmental activism or opportunities to care for the environment in some way. We argue that the SLE field represents an important formative body of research that is inextricably connected to the concept of childhoodnature. This is because it foregrounds the importance of childhood experience in, with, and as nature, investigates the multiple-complexities of children's lived experiences in nature, and predicts their influence on environmental choices in adulthood. This section of the Handbook invited contributions from researchers in the field of SLE who were interested in exploring the relationship between childhoodnature and SLE.

SLE is a term introduced by Tom Tanner who developed a basic methodology and inspired an avid interest in this area of research (Tanner, 1980; Tanner, 1998b; Chawla, 1998a). Tanner's ground-breaking study, first reported in 1979 and then again in 1980 (Tanner, 1998a), identified affective experiences in nature that had an impact upon people's respect and appreciation for the environment. Building on Tanner's work, research by Chawla in the USA (Chawla 1998a, b, 2001, 2007) and Palmer in the UK and other countries (Palmer, 1998, 1999) also endorsed and confirmed the influence of SLE in nature (Tanner, 1980).

However, what is it about SLE that have such an impact upon people's lives? The quality of SLE have been shown to influence learning, not just in early childhood but throughout life. Chawla (1998a) noted that factors such as positive experiences in natural areas; environmental awareness and concern modeled by family members, teachers, books, and media; environmental organizations; as well as negative experiences that include habitat destruction have all been attributed to forming these SLE. In addition, research supports the premise that formative experiences in relatively pristine natural settings that include time with adult mentors, time alone at certain ages, family time, and time with peer adventurers are important (Corcoran, 1999). Further, personal attributes related to pro-environmental attitudes and behavior include having knowledge, competence, and an empathic perception of nature (Chawla, 1998b; Hungerford and Volk, 1990).

Building on the foundations of this field of research, the first part of this Chapter provides an overview of SLE research and associated understandings of SLE in childhoodnature. We discuss some insights into SLE, including research that also questions the impact of SLE. As an area of controversy, critical perspectives and antithetical research is important to consider in order to develop a balanced view of SLE. Yet, regardless of this controversy, Chawla (2001) reminds us that the personal stories highlighting sources of environmental interest and motivation can have a powerful impact on our understanding of significant moments and have generated this important field of study.

In the second part of this Chapter, we introduce the nine chapters included in this section, highlighting the common threads that connect examples of contemporary SLE research from around the world. The included authors provide in-depth exploration of SLE and extend the range of methodologies and tools used in childhoodnature research. Through this, the authors contextualize the influence

of society and culture on childhoodnature relationships. It is proposed that by developing a deeper understanding of significant childhoodnature experiences, this section will offer new perspectives on authentic practice in childhoodnature, and subsequent environmental action.

Finally, we present our insights from these chapters, reflect on what is missing from SLE research, and suggest foci, contexts, methodologies, and theories for future consideration by SLE and childhoodnature researchers.

Insights into Significant Life Experience Research

Pro-environmental behavior is often a goal of environmental education for children, and commonly relies on the assumption that engaging with nature, and, in particular, more than human nature, will foster a desire to protect the environment. The affective connections that people develop with the natural world are thought to foster this desire and may be the result of immersive experiences. For example, a study evaluating immersive field-based environmental education in contrast to classroom-based education found that only the field-based participants expressed sentiments toward conservation, a desire to return to the environment visited, feeling happy about themselves, and feeling safe (Cachelin et al. 2009). In addition, the field-based group more frequently discussed sensory experiences, while classroom-based participants were the only ones to express negative opinions of the wetland that was visited. The importance of sensory connections with the natural environment was also discussed by van den Born et al. (2001). Their findings support the idea that immersive, concrete experiences with nature, and those involving the senses, as opposed to theoretical learning, are associated with nature-friendly behavior in adulthood.

While children are often not able to recall these experiences, they act to shape lifelong learning, which develops into personal adult characteristics, as is demonstrated by adults' reflections upon their experiences. Eilam and Trop's (2014) study of formative experiences in environmental schools found that it can be easier to influence adults' behavior than their attitude toward the environment. Further, they found that media and formal education may be more effective at influencing behavior change since they can provide relatively quick, preplanned experiences. Whereas, influences on attitude require experiences over time.

Although wilderness programs may not provide a long-term experience, they provide an immersive experience in nature. A study with eight teenage participants of a 12-day wilderness program found that although the trip was a powerful experience for the youth, they did not anticipate that it would translate into changes in action toward the environment at home because they were too busy with their daily routines (Haluza-Delay, 2001). Based on the findings, Haluza-Delay recommended careful development of immersive environmental programs within pristine wilderness areas in order to more clearly help participants understand the connections between humans, more than human nature, and the local environment. In addition, programs

should be offered in environments at home where they are more familiar, rather than far away from children's daily lives (see also Barratt et al., 2014).

Overcoming fear of nature, especially wildlife, may be an important consideration for environmental education experiences. Investigating SLE through narrative interviews with alumni of three different environmental education programs, Williams and Chawla (2016) noted the importance of overcoming fear of nature or wildlife in natural settings, and the importance of mementos as objects that hold program memories. Fagerstam's (2012) study with high school teachers and Environmental Education Centre officers also found that students experienced fear of Australian nature and animals as a response to environmental education programs.

Providing children with opportunities to explore the natural world is important to their psychological and physical well-being. Through research at the Child Development Lab at the University of Nebraska, Benson and Miller (2008) describe opportunities for young children, aged 20 months to 5 years, to develop important skills that can lead to later learning and academic success. The natural environment provides opportunities for: social interaction through collaborative exploration and negotiation, physical development and fine motor skills as they examine natural materials and unfamiliar spaces, and language skills as they learn to express ideas and feelings about what they encounter. Although SLE research is commonly conducted with adults, asking them to reflect on their earlier experiences, Chawla (2001) supports and promotes the idea that we need to understand and consider the experiences that young people themselves consider important. Stating that environmental education and activism are "intergenerational affairs," she urges researchers to understand multiple sides that include generational differences (p. 457).

Significant Life Experiences Research as an Evolving Field

SLE research has faced varying levels of critique, with questions about the methodologies, methods, and theoretical frameworks commonly proposed. For more than 20 years, critics of SLE research have questioned the epistemological grounding of the research in relation to the use of autobiographical methods, and the apparent focus on validity, reliability, and generalizability (Gough, 1999). Further, Dillon et al. (1999) challenged the lack of theoretical frameworks for SLE research. Specifically, they suggested the use of identity theory as a way to explain how people develop their pro-environmental beliefs and enhance SLE research.

More recently, Williams and Chawla (2016) suggest the use of social practice theory to frame SLE research which implies that it should not be approached as a simple problem of identifying three or four most influential experiences. But instead, it is important to view the significant experiences within a broader context of practices in particular places and social settings, and how the various factors together shape the environmental identities that people form. There have also been challenges to the use of the term "significant" in SLE since research participants may not see childhood experiences as significant. Payne (1999), like Williams and Chawla (2016), argues that a series of experiences, or "continuity of experiences," may be

more important than one specific or significant moment or event (Payne, 1999, p. 366). Similarly, Ji's (2011) study with 14 Chinese environmental educators found that for almost all of them, it was the totality of their experiences, rather than one significant experience that led them to develop their environmental awareness and sensitivity. Russell (2006) encourages researchers to be open to learning from social movements and other theoretical positions, and that her own SLE work has been informed by women's studies, science studies and environmental thought.

In terms of methodology, SLE research has typically drawn on those methodologies that are sensitive to the research context and foreground the intricacies and richness of meaningful experiences, as participants view them. SLE research originated using qualitative and autobiographical approaches, including open-ended interviews, to enable people to provide a narrative of their experience in detail. Chawla (1998b) discusses this emphasis on qualitative research as a positive aspect, noting that the broader field of environmental education research traditionally relied on quantitative approaches. Similarly, Cachelin et al. (2009) highlight the fact that much evaluation of environmental education programs still applies quantitative methods, yet could benefit from supplementing this with qualitative approaches that add rich, nuanced descriptions of sensory experiences in the field. Further, Russell (2006) highlights the challenges of working with different methodologies, but also recognizes the importance of being open to other methodological, ontological, and epistemological approaches in order to bring richness and diversity to the SLE field.

Yet, the emphasis on qualitative, retrospective, reflective research is not without critique, including the challenge posed by the effect of the experience weakening over time and the limited accuracy of memory (see, for example, Stevenson et al., 2014). Although this is a characteristic of any interview and survey research that is based on personal views or behaviors, SLE research often requires adults to recall events from the distant past in childhood. In her article exploring SLE research methods, Chawla (1998b) highlighted this and other weaknesses of SLE research, including the lack of built-in comparator groups.

While the autobiographical tradition is still evident in SLE research, there has been some diversification of approach together with findings that do not necessarily align with previously accepted ideas. For example, Stevenson et al. (2014) conducted a quantitative study with a random sample of middle school students. They found that watching nature-related TV was actually a negative predictor of environmental knowledge. Students who had a teacher with a master's degree was the strongest positive predictor of pro-environmental behavior, but time spent outdoors and having an adult role model for environmental sensitivity were weak predictors of pro-environmental behavior. In addition, they found that minority students (American Indian, Hispanic, and African American) exhibited significantly lower levels of environmental knowledge than Caucasian students. Leppanen et al.'s (2012) study on gender and generational environmental attitudes was also quantitative, using questionnaires with sample of 237 young people and 212 parents in Finland. The findings showed that boys display more negative environmental attitudes than girls or adults, and in general, the Finnish children in the study held more

negative attitudes toward the environment than their parents. As this is contrary to other studies, Leppanen et al. postulate that the cultural context and life-stage barriers could have been influential.

Further, some critics noted the inclusion of predominantly white privileged participants in SLE studies. Yet, the diversity of participants has grown from predominantly white males, dedicated to environmental education or wildlife and wilderness preservation, to include more gender and ethnically diverse participants (Chawla, 1998b). For example, Corcoran's (1999) study with US members of the North American Association of Environmental Educators included 54% female respondents. Additionally, one study found that environmental justice activists often use their social position of disadvantage to embrace their negative social and environmental experiences and ground their work in empowerment and social justice (Ceaser, 2015).

Turning to findings, some research, albeit limited, has challenged the extent to which outdoor experiences during childhood, such as camping, playing in natural areas, and observing wildlife, are seen as influential (Howell and Allen, 2016). Howell and Allen's study found that involving 85 people connected with climate change education, found that those childhood experiences were not mentioned as a major formative influence for the sample as a whole. Although these outdoor experiences were important, and formative for some participants, they did not have the impact on climate change mitigation efforts that previous research findings would have suggested. In addition, the authors compared the matched age groups, and determined that this finding was not simply because children have fewer opportunities for nature experiences than in the past (Howell and Allen, 2016). Similarly, Ji's (2011) study with 14 Chinese environmental educators found that it was not their environmental consciousness that led them to work in environmental education, but rather a job opportunity or requirement. And unlike other studies, childhood experiences in natural areas were not seen as significant to developing their environmental consciousness.

These research findings raise questions about the influence of childhood SLE on future environmental behavior; nontheless, SLE research has overwhelmingly connected experiences, sensitivity, and activism in relation to the natural environment. One important area that has had less attention is the synergies between theory and practice. While SLE research has identified particular experiences as influential, and recommended appropriate practice (for example, see Chawla and Flanders Cushing, 2007), the extent to which this knowledge has informed practice in environmental education is less clear. Payne (1999) described this as "the biggest gap in the SLE literature… (that is) how these SLE research findings might 'translate' into culturally sensitive and contextually specific curriculum and pedagogical practices" (p. 366).

The rich and varied research on SLE, in addition to the many critiques of its traditions, suggests that it is an important of area of research that is still evolving. Much of the recent research raises additional questions that need to be explored. The next part of the Chapter introduces the research presented in this section and how it is responding to earlier critiques while progressing this field of research.

Significant Life Experiences and Childhoodnature: Introducing New Research

As discussed above, there have been a number of criticisms of SLE research in relation to its retrospective methods, less represented groups and under theorizing. In many ways, the chapters in this section start to address these concerns. Using novel and creative methodologies, which are sensitive to focus and context, and working with theory, the authors explore new and underresearched areas in the field of SLE. In doing so, they provide in-depth discussion about childhoodnature, specifically, how children encounter, interact with, and think about more than human nature, what influences this, and how nature experience in childhood may influence future thinking and behavior. This section discusses how the Chapter authors are reaching out to new contexts and groups, developing novel methodologies and portrayals of SLE and childhoodnature and concludes by exploring how the authors work within new theoretical frames.

Reaching Out to New Contexts and Groups

The contexts for the research reported in the following chapters are varied and reach out to lesser researched groups. This includes working with young children in early years settings in Alaska (Green), a deciduous forest environment in the USA (Porto and Kroeger) and forest schools in England (McCree); preservice educators in Australia (Black) and England (McCree) focusing on how educators think about SLE and their future careers; how global mobility and attendance at international schools across the world impacts on SLE (Van Zalinge), informal learning through parenting relationships in Australia (Blom) and through Family Nature Clubs around the world (D'Amore and Chawla); and children's TV in Sweden (Pettersson).

New Methodologies and Portrayals of Significant Life Experiences

The authors of this section provide in-depth analyses of children's experience in and with more than human nature, in some cases connecting this to childhoodnature practice. In beautifully crafted narratives, many of the authors provide rich portrayals of SLE in childhoodnature. So, how can researchers explore SLE in the present rather than reflecting on the past? This is addressed imaginatively by Green and by Porto and Kroeger who report research with children in real time using phenomenological approaches. These authors develop novel research tools for capturing early childhoodnature experiences and behaviors both at a prereflective and a reflective stage.

Green analyzes findings from two research projects with young children in Alaska, focusing on somesthetic experience, which Green describes as the "felt bodily experiences of childhoodnature." Children's use of wearable cameras followed by video-stimulated recall discussions gives agency to the child and enables the researcher to experience what the child sees, hears, and does during their sensory tours in the Tundra in order to discuss it with the child. Green finds childhoodnature embodied and storied entanglements as the children play and tour freely and develop a sense of being within this natural environment. Similar to

Green, Porto and Kroeger's participatory research is designed to give agency to the child; acting as co-researchers, children aged 4–5 years explore their prereflective and reflective experiences of a deciduous forest environment on a weekly basis for 9 months. A mosaic of tools (adapted from the mosaic approach, Clark and Moss, 2008) is employed to address the question, "what does it mean to be in this place?" The tools, for example, taking (and discussing) still and moving images, tours, bookmaking, and child interviews, enable children to choose how and when to share their meanings of experience. Porto and Kroeger argue that regular time to play freely in natural environments and time to talk about nature with each other may lead to pro-environmental behavior later in life. There is evidence in this study that weekly visits to the same natural environment supported children in discovering nature's needs and realizing that nature is family and, like other family members, requires care. Both of these chapters illustrate how research with children can give the child agency and how this fundamentally enriches the research. Here, both approaches invite children to gather data about their childhoodnature experience as it happens and then share their reflections using the data as a stimulus. This avoids the researcher interpreting and making assumptions about the child's experience, a tendency typical of research with children (Barratt Hacking et al., 2013), thus enabling rich and insightful findings.

D'Amore and Chawla similarly report research in real time, in this case with children and parents/carers attending Family Nature Clubs (FNCs) in the United States and Canada, as well as New Zealand, Peru, Germany, and England. FNCs are a relatively unique environmental organization as they bring parents/carers and children together with more than human nature on a regular basis. Thus, the study of FNCs represents a new area of research in SLE with opportunities to apply findings from previous SLE studies through a "triad of experiences . . . (for) children and their parents: time in nature, role models of nature appreciation, and membership in a nature-based organization." In this multimethod study, D'Amore and Chawla combine quantitative surveys with ethnographic observations and interviews. While SLE research has typically identified spending time in nature alone or with friends as important, this study identifies the significance of a collective, social experience in which leaders, parents/carers, and children learn and act together. The notion of permissive (childhoodnature) parenting is an example of how FNC leaders influence families by providing role models of parenting childhoodnature; similarly there is evidence that parents/carers learn from observing different childhoodnature parenting norms from other FNC members. While this study, like Porto and Kroeger's, and Green's real-time research, would require a longitudinal approach to demonstrate influence into adulthood, each of these studies enabled children (or parents/carers) to convey what is significant about the childhoodnature experience as it happens and consider how it is influencing their thinking or behavior.

Building on the tradition of retrospective SLE research, four authors in this section adopt novel approaches to reviewing childhood experience; Van Zalinge and Blom use an autoethnographic approach, while Black and McCree study their participants' memories of childhoodnature experiences in order to explore the links between SLE and their current professional concerns as educators. In a moving

account, Van Zalinge reflects on her experience of global mobility as a child and how this influenced her childhoodnature. This includes her experience of attending numerous international schools around the world as a "third culture kid," "by the age of 20, I had lived in 11 different countries and moved more than 18 times." She frames personal memories and critical moments through poetry and photographs to develop an autobiographical commentary. Her analysis suggests that a sense of belonging and security is a precursor to SLE without which the child may be detached from potential SLE. This is the case for all children, but especially relevant to children who experience disruption and loss in childhood through, for example, relocation. In a world where global mobility is growing, this area of research is especially pertinent and no more so than in the case of refugees. UNICEF (2016) report that child refugees increased by 75% in the previous 5 years and, at the time of writing, accounted for one in 200 children across the world.

In the second autoethnography, Blom reflects on her own experience as a child and as a mother in Australia to explore another new area of SLE research: childhoodnature parenting relationships. Her approach "draws on past memory data and artefacts to reflectively analyse visual research journal entries about my current perceptions of childhoodnature as a parent." Through this, Blom negotiates her own childhoodnature journey showing her experience with more than human nature changing "from a place of being, to a place of refuge and escape to now, nature as a parent." From this, Blom suggests that childhoodnature parenting should be a reflective process; this recognizes that parents are also role models for their children and thus can provide a "living inspiration" for how to be with and as nature, taking time to be present with nature.

In other retrospective research, Black's Chapter reports on research with two groups of 27 preservice early childhood educators studying a sustainability-focused undergraduate degree in Australia. The participants use narrative and arts-based methods to explore their personal childhoodnature experiences and then consider how this might support their current professional aspirations for working with young children. Black provides beautiful examples of her students' art and insightful narratives to reveal the wonder and importance of childhoodnature SLE and, similar to Green's findings, embodied ideas about nature relationships. In turn, this reignites the educators' commitment to working with young children and promoting experiences with natural environments. This recognized the way in which the educators themselves experienced more than human nature and natural environments "as places of being, belonging and becoming for children and families."

McCree similarly connects SLE to professional commitments by studying eight forest school trainees in England and their reasons to train. She asks "Why do Forest School practitioners choose their vocations? What role do significant life experiences play in their choices?" and responds through an ethnography of Forest School trainees using interviews and observation. Interestingly, McCree finds evidence of the impact not just of childhood SLE on reasons to train, but also views of the future environment using the concept "future shock" (Toffler, 1970). While SLE in childhood are a key driver for most of the trainees, a few disagree. Also influential are a passion for pedagogy, changes in the natural world, and a consequent

sense of loss, together with "a sense of responsibility, anger, fear and future shock." The role of negative experiences, including habitat loss and social justice concerns, aligns with findings from other SLE studies (Chawla, 1998a; Ceaser, 2015).

In a departure from previous SLE research, Pettersson's analysis of TV for children in Sweden draws on childhood sociology and visual studies; adopting a posthumanist stance, it employs discourse analysis to identify the child-nature relationship in TV, accounting for anthropocentric, and "adult-centric" views on childhoodnature. Pettersson justifies this focus by showing how public service TV is influential in the lives of Swedish children and that nature dominates TV content; hence watching TV could be seen as a potential SLE. The study samples TV content from 1980, 1992, and 2007 with additional discussion of content in 2017. Pettersson finds content represented in three ways: children outdoors, animals, and environmental issues. A detailed analysis shows overall that "the child-nature relationship represented here is more of a burden, because it positions children as becoming adults, rather than as being children in the present. And the responsibility for nature is thereby assigned to children." This study reinforces the view that SLE are socially, culturally, and historically influenced; Pettersson argues that, in the case of Sweden, "it is difficult to even imagine a childhood that is not lived in a close relationship with nature and that is not ready to save it."

Working with Theory

As discussed earlier, SLE research has been challenged for a lack of theoretical framing. While there has been some development in this respect (see, for example, Williams and Chawla, 2016), the authors in this section address this theoretical gap by working with a number of theoretical frames, as Pettersson's study, discussed above, illustrates. Some of the authors take productive forays into learning and child development theory as a lens for exploring and interpreting childhoodnature SLE. For example, Blom uses and develops Bronfenbrenner's socioecological systems theory of child development in exploring parenting relationships for childhoodnature. Like Davis and Elliot (this Handbook), Blom critiques Bronfenbrenner's model for its absence of nature and, as such, develops an adapted model to redress this. A number of authors reference social learning theories (Blom, Van Zalinge and D'Amore and Chawla) and this would seem to be a productive theoretical lens for SLE researchers; in part, this is due to the importance of children learning from more experienced others in groups and communities by observing and participating in (environmental) activity (Rogoff, 1990). More broadly, D'Amore and Chawla discuss learning and child development theories relevant to SLE research, arguing that "key experiences identified in past (SLE) studies are not surprising: they represent basic processes of learning agency in the world, learning what to notice and value, and developing a self-identity related to the environment." Theories considered include those associated with learning, agency, motivation, and a sense of competence; social modeling and apprenticeship; sympathy and stewardship; and environmental identity.

In response to the underuse of identity theory to inform SLE research, D'Amore and Chawla, McCree and Van Zalinge draw on environmental identity theory

(Clayton, 2003) and ecological identity theory (Thomashow, 1996). Both McCree and D'Amore and Chawla develop these ideas by arguing that ecological or environmental identity cannot be severed from social identity. McCree offers ecosocial identity theory, the ongoing construction of self as part of nature and society, postulating that "we do not have an authentic self that pre-dates our social self, or a relationship with nature that excludes society; we are social beings. Similarly, we do not have an exclusively social self without our biological nature; we are natural beings." D'Amore and Chawla argue that social environmental identity needs to be considered alongside ecological identity as manifested in childhood experience around environmental and nature-based organization in many SLE studies. In her autoethnography, Van Zalinge considers the influence of childhoodnature experience as a globally mobile child on her own environmental identity. In so doing, she, like the authors above, acknowledges the significance of the social and cultural contexts in the development of her personal environmental identity.

Insights into Childhoodnature

The research discussed in this section of the Handbook illustrates the ways in which SLE research can contribute to the concept of childhoodnature. As such, the following discussion elicits a number of insights from the chapters which may serve to support and challenge our childhoodnature work.

Embodied Childhoodnature

Childhoodnature experience is not just conceptual, it is embodied and cannot necessarily be put into words (see, for example, Green, Black). The idea of embodied experience in childhoodnature is sympathetic to Ingold's (2000, 2007) "dwelling perspective" in which it is argued that humans instinctively "dwell" in the world so that environmental experience represents an emergent intertwining of perception and world. This also reflects Cele's notions of embodied knowledge, "the kind of knowledge our bodies collect for us when we interact with a place frequently or intensely" (Cele, 2006 p. 9). Therefore, when developing methodologies, researchers interested in childhoodnature and SLE should be cognizant of embodied knowledge in developing tools that enable access to it. For example, a number of the authors in this section employ sensory encounters and art work. Two of the studies in this section adopt a phenomenological view (Green; Porto and Kroeger) in exploring children's prereflective experience in childhoodnature as it occurs; in early childhood, the more natural embodied dimension of experience perhaps predates the more complex cognitive elements that require language. This section has illustrated that the consideration, with children and adults, of SLE in childhoodnature can elucidate embodied knowledge and help us to understand more about childhoodnature.

The Family of Childhoodnature

Authors in this section have reminded us that children interact with non-human nature in ways that might be different to that of adults and that the child's developing physiology is stimulated when in natural environments, for example, through movement, exploration, and imaginary play (Green, Blom). This supports previous research findings that "children have different experiences of the (natural) environment to adults and value different aspects of it" (Barratt Hacking et al., 2013, p. 456). Authors also show how young children want to belong and be cared for (Van Zalinge) and that they seem to have a natural affinity with the rest of nature (Porto and Kroeger). Given sustained time and experience in natural environments, for example, visiting the same place repeatedly (see also Barratt et al., 2014), children recognize themselves as a part of the wider family of nature. The metaphor of family seems helpful in this respect; when the rest of nature is viewed as family children recognize the importance of caring, just as they want to be cared for, have friends and family, and belong. Blom and Porto and Kroeger remind us that in this way, we can think of non-human nature as family, parent and teacher. So, childhoodnature is not just in the individual realm, it is being part of nature, human and non-human, and recognizing oneself as nature within the wider family of nature.

Cultural Participation and Childhoodnature

A number of authors in this section have shown that childhoodnature SLE are culturally influenced. Thus, depending on the child's cultural traditions and norms, children may think about nature and interact with non-human nature in differing ways. Blom and D'Amore and Chawla found cultures of parenting and parenting style influential in childhoodnature, for example, permissive and reflective parenting. Pettersson shows how culturally Swedish attitudes to nature and the outdoors influences the type and quantity of nature TV that children grow up with in this context.

Ideas about cultural impacts on childhoodnature reflect sociocultural historical perspectives on learning. This theoretical lens suggests that children's learning and development is influenced through observing and participating in sociocultural activity within families and the wider community and environment (Rogoff, 1990) as D'Amore and Chawla point out. Rogoff's more recent research with indigenous communities in the Americas, "Learning by Observing and Pitching In (LOPI)" (2014), advances a model for understanding children's learning through experience. This model would seem to speak to SLE research in its explanation of the efficacy of participatory and apprenticeship learning in families and communities including environmental organizations. D'Amore and Chawla's research with Family Nature Clubs suggests that children find participating in collective environmental action stimulating and memorable. Others have suggested that skills around environmental action represent "empowerment variables," that is, variables that contribute to pro-environmental behavior (Hungerford and Volk, 1990). Children aspire to do what the more knowledgeable others or role models do (peers, older children and

adults/leaders) by participating or leading and by contributing to democratic decision making and change. A caveat is in relation to the political and cultural setting where opportunities to engage in political debate and activism of any kind may be constrained. Further, Pettersson suggests some caution is required in asking children to "shoulder the burden" of problems to do with the natural environment; children need to work alongside role models and see that others are contributing.

Childhoodnature Loss

The loss of nature and even some of the words used to describe nature (Macfarlane and Morris, 2017) is of significant concern in the Anthropocene. Emerging research on the new concept of ecological grief (Cunsolo and Ellis, 2018) identifies a "legitimate form of grief felt in response to experienced or anticipated losses in the natural world" (p. 279). This may provide new insights into the significance of ecological loss in childhoodnature. Cunsolo and Ellis argue that "ecological grief will become an increasingly common human response to the losses encountered in the Anthropocene" (p. 279). A response to this form of grief is evident in McCree's study of Forest School practitioners' SLE in which negative experiences of habitat change, environmental loss, concerns, and future fears became key motivations for the practitioners' childhoodnature practice. McCree, citing Toffler (1970), helpfully relates this to the concept of "future shock" where humans become disoriented and distressed when there is rapid and ambiguous change to deal with. McCree argues that, with the onset of the Anthropocene, "we all share a future shock upgraded for the twenty-first century and writ large into the geological record." Other section authors found that adult desires to go back to nature, as it was in their own childhoodnature, accelerates the desire to provide children with SLE and counteract potential loss (Porto and Kroeger; Blom). So, the loss these authors refer to is not solely about the loss of the natural world, but also the loss of experience. This reflects Pyle's notion of the "extinction of experience" where "the loss of neighbourhood species endangers our experience of nature. If a species becomes extinct within our own radius of reach (smaller for the very old, very young, disabled and poor) it might as well be gone altogether, in one important sense. To those whose access suffers by it, local extinction has much the same result as global eradication" (2002 p. 261). Previous studies in SLE have found that positive *and* negative forms of environmental experience can provide SLE; studies in this section support this and show further how ecological grief and concerns for the future hold significance as prompts for childhoodnature practice.

Developing Childhoodnature and Significant Life Experiences Methodologies

The authors in this section have demonstrated how novel directions and approaches in SLE research can further our understanding of childhoodnature in theory and

practice. While some of the authors in this section draw on the more established autobiographical methodologies of SLE research (Black; Blom; McCree; Van Zalinge; and D'Amore and Chawla), they adapt this approach by combining it with methodologies that access childhoodnature experience in the present. In this way, the research represents a sort of time shifting; by revisiting and connecting past and present, these authors are able to explore the relationships between past and present childhoodnature SLE. The authors focus on how practitioners' or parents'/carers' personal SLE in childhood influence the way they now think about and practice (or parent) with childhoodnature. Importantly, reflecting on past SLE appears to rekindle motivations for supporting childhoodnature in the present, for the future. Other authors focus more on SLE and childhoodnature in real time using child-framed approaches (Barratt et al., 2014; Barratt Hacking et al., 2013; Cutter-Mackenzie, 2009). These approaches recognize that "children are experts in their everyday experience, have a particular knowledge set in relation to the (local) environment and act as agents within it" (Barratt Hacking et al., 2013, p. 454) and that "children can develop and use innovative child-friendly research methods" (p. 456). Adopting a phenomenological lens, Green and Porto and Kroeger invite children, as co-researchers, to share prereflective and self-conscious awareness of childhoodnature experience as it happens in forms of their choice. This illustrates how children, including the very young, can have agency within childhoodnature research. Involving the children as co-researchers enables in-depth insights into childhoodnature experience, together with children's personal perspectives on its significance.

Overall

Research in this section has shown that SLE in childhoodnature would appear to be a combination of single momentous events and continuous or regular experience over time. Furthermore, SLE are often intergenerational and sociocultural in character and enable children to observe, participate, and/or lead in environmental action. The research also suggests that, for childhoodnature experience to be significant, children need to be self aware in the experience. And, in considering how to apply SLE to childhoodnature in practice, authors have demonstrated the value of exploring the notions of SLE and childhoodnature with educational professionals.

Looking Forward

Nevertheless, further work remains in seeking new avenues to pursue around contexts, methodologies, and theories for SLE in childhoodnature research. Child-framed SLE research in real time represents a worthwhile avenue for developing methodologies in the fields of SLE and childhoodnature. But what might such studies tell us in the longer term? What remains is a need for longitudinal studies that explore long-term impact of SLE in childhoodnature across the lifespan. Importantly, there is

a pressing need for further SLE research in contexts of disadvantage, to do with childhoodnature experience in the majority world, urban poverty or forced migration and refugees. For example, how does experience of disadvantage in such contexts influence childhoodnature? We would ague that SLE needs to better represent the contemporary realities of childhoodnature and natural environments worldwide.

In the context of unprecented change to (and loss of) our natural habitat in the Anthropocene, a key challenge is to reconcile the current trajectory with the impact on children's physical and psychological well-being. Children are having to accommodate accelerating change; this impacts on childhoodnature and more than human nature now and for the future. Together, the research represented in this section affords new understandings of how childhoodnature is experienced and what might influence children's current and future environmental behavior. Future work in SLE and childhoodnature needs to promote synergies between research and practice so that educational systems can be responsive to ongoing changes in childhoodnature. Experience within the natural world should not be a marginal activity in education; childhoodnature should be at the heart of any education system. This section, with its focus on what is significant about childhoodnature experience, invites us to rethink education and consider a paradigm shift in relation to the sociocultural implications of childhoodnature for education systems.

Abstract

Early childhood educators are uniquely placed to support children's ways of knowing and being and to share in and respond to children's wonder and understandings about childhoodnature encounters and relationships. The context of this Chapter is a sustainability-focused course in an Australian undergraduate early childhood education teaching degree. As part of this course, two groups of 27 pre-service teachers used narrative and arts-based methods to explore personal childhoodnature experiences and memories. Supported by their stories and creative and historical artifacts, pre-service teachers remembered their childhood wonder of belonging to a universe – a universe they are part of and shape – but

https://doi.org/10.1007/978-3-319-67286-1_48

that extends beyond them (Bennett. *Thoreau's nature: Ethics, politics, and the wild*. London: Sage, 1994). This Chapter highlights how pre-service teachers' reflection and representation of their significant childhood experiences supported their subsequent communication of personal and professional commitments to working with young children in relational ways toward sustainable worlds (Rautio. *Children's Geographies*, *11*:4, 394–408, 2013b).

Remembering significant childhoodnature encounters assisted pre-service teachers' articulation of conceptualized and embodied ideas about relationships, including their sense of belonging, wellbeing, and connectedness to other people and the more than human world around them and their physical, mental, and spiritual health. Remembering the wonder has connected them afresh to their values and work as educators who recognize the significance of childhood experiences, the interconnectedness of human and more than human worlds, and early environments as places of being, belonging, and becoming for children and families.

Pre-service teacher reflection and representation · Early childhood education · Narrative and arts-based methods · Childhoodnature encounters

Introduction

Remembering significant relational experiences and encounters can support children's and adults' ways of *being*, knowing, and becoming *with* and *within* human and more than human worlds. In his oft cited paper "Significant Life Experiences," Thomas Tanner discusses both the importance of educators and early significant experiences with nature and the environment (Tanner, 1980). Responding to Tanner's ideas, this Chapter looks to early childhood educators and the significance of their formative experiences. It explores how pre-service teachers come to understand early childhood education for sustainability, how their own childhoods and childhood experiences shape their ideas of sustainability practices, and how ideas are formed, enacted, and understood in the context of their lived experiences – including their senses, perceptions, and feelings. Additionally, through the sharing of pre-service teachers' stories about their "ecological homecomings," this Chapter offers ideas about how we might tend to our/children's awareness, delight, and absorption "in *being*" – attending to and remembering experiences that move us, experiences "when we resonate with the world that surrounds us" and are drawn "into relation" and "interbeing" (Bai, Elza, Kovacs, & Romanycia, 2010, pp. 362, 359, 360).

The context of this chapter is a sustainability-focused course in an Australian undergraduate early childhood education teaching degree. As part of this course, two groups of 27 pre-service teachers used arts-based methods to explore their childhoodnature experiences and memories. The arts-based methods chosen and used by the participants included narrative accounts, photo-stories and film, collage, painting, and sculpture and often incorporated historical artifacts such as childhood

photographs, drawings, and film footage. These storied representations supported pre-service teachers' recollections of their childhood wonder, of their belonging to a universe – a universe they are part of and shape – but that extends beyond them (Bennett, 1994).

Pre-service teachers described the experiences in their lives that connected them to their relationships with/in/as/to nature. Their remembering and representation connected them to their hopes for children and their educator role in bringing these hopes to life. This provided a platform from which they communicated their personal and professional commitments to working with young children in relational and everyday ways toward sustainable human and more than human worlds (Rautio, 2013b).

Education for Sustainability

Within the early childhood education sector, there has been growing recognition of the value of quality learning experiences and interactions in environments where the natural world has a central place and where a love of and relationship with nature is fostered (Davis, 2009). Sustainability is a strong feature of early childhood education discourse, through which young children are positioned as citizens and acknowledged as having ideas about and capacities to contribute to sustainability and environmental issues (Barratt Hacking, Barratt, & Scott, 2007). Learning in this context is often sensory-focused and embodied. Children are active beings in their everyday life environments. They/we act as one part of a complex mesh of relations, relating, and relationships (Rautio, 2013b).

Childhood is considered a crucial time for establishing commitments to environmental issues and cultivating lifelong dispositions of care for the environment (Davis, 2008). Childhood is a critical period in life when the foundations of thinking are established and relationships are shaped (Samuelsson & Kaga, 2008). Research shows that environmental and sustainability education is important and effective during the early childhood years (Madden & Liang, 2016).

Chawla and Hart (1995) concur that our concern for the environment has its origins in our childhoods, during which our early feelings and sensations of the world have opened our awareness and attachment to the world as a living being. Further, Bai et al.'s (2010) commentary suggests that love of life and nature takes root in a consciousness that *attends*. Attending. Attending to the senses. Attending to relationship. Attending to connection. Attending to *being*, not just to knowing or learning or doing. When we attend, our focus is on consciously indwelling our experiences. When we attend we become "unselfed" and experience "a dynamic presence that confronts us and draws us into relation" (Abram, 1996, p. 56). Abram (1996, p. 68) describes it like this: "To touch the coarse skin of a tree is thus, at the same time, to experience one's own tactility, to feel oneself touched by the tree."

In terms of intellectual knowledge, there have been shifts in the discourse. The dialogue around children and nature is changing as are ways of viewing nature encounters and relationships. Where once we worried about "nature deficit" (Louv,

2005), now we worry about the dangers of "anthropocentricity" and "human-nature binaries" (Malone, 2016). Whatever our preferred terms and emphases, may we not forget to *attend*, and to our embodied ways of knowing, may we not forget about the *wonder*.

Young Children's Sense of Wonder

Pelo (2014) asserts that children's ecological identities are developed through a sense of wonder and delight toward the earth – by a connection to place, a love of the environment, and a concern for its wellbeing, by relationship. Chawla's (2015) research builds on this to describe how natural areas provide opportunities for wonder – for children to engage in creative play alone and with friends, set self-paced challenges, find quiet retreats, learn about the environment from direct experience, and form emotional bonds with places and the natural world. When we watch children closely with openness and respect, we can see that childhood is filled with curiosity, creativity, and unlimited possibility. As Bateman (2000, p. 31) says, "Children are naturally enchanted by the world of trees, birds, plants, and rivers. . .."

Yet, learning and teaching in schools, and increasingly in early childhood settings too, is "far more into the explicative than into the evocative, and this imbalance, as reflected in our education system, is problematic in terms of the openness and connection we seek with/in nature" (Bai et al., 2010). Rachel Carson also described this problem (1987, p. 42) writing "A child's world is fresh and new and beautiful, full of wonder and excitement. It is our misfortune that for most of us that clear-eyed vision, that true instinct for what is beautiful and awe-inspiring, is dimmed and even lost before we reach adulthood." And she reminds those of us who work with children that:

> Exploring nature with children is largely a matter of becoming receptive to what lies all around you. It is learning again to use your eyes, ears, nostrils, and fingertips, opening up the disused channels of sensory impression. For most of us knowledge comes largely through sight, yet we look about with such unseeing eyes that we are partially blind. One way to open our eyes to unnoticed beauty is to ask yourself, "What if I had never seen this before? What if I knew I would never see it again? (Carson, 1987, p. 52)

A love of nature is unlikely to take root in a consciousness that is focused on "learning information," "explicating facts," or "doing educational activities" (Bai et al., 2010). It *can be* nurtured when children and pre-service teachers return their attention and energy and absorption in their *being* and to their sense of wonder and delight.

The Role of Teachers in Supporting Children and Supporting Change

How might we support the awakening of pre-service teachers' sensory impressions and fuel their desire to engage children in practices that cultivate and sustain "aesthetic-affective openness" to their surroundings, practices that sustain "sensory

attentiveness, openness and imaginative interests towards the material world" (Rautio, 2013b, p. 400)? How might we support teachers to create beautiful learning invitations and offer formative experiences that resonate with children and that move children to wonder, exclaim, and share what excites and intrigues them? And, perhaps pick up a shell or a stone to put in their pocket (Rautio, 2013b)?

Engaging pre-service teachers in the art of awareness is critical given teachers play a lead role in shaping children's experiences and understandings and can mediate children's learning toward sustainability (Wals, 2006). Early childhood educators are uniquely placed to support children's ways of knowing and being and to share in and respond to children's wonder, appreciation, and understandings about childhoodnature encounters and interdependent, interconnected relationships.

This Chapter invokes the idea that recollecting and storytelling significant life experiences returns us to our bodies and senses and offers a place to produce people who will actively work to maintain "a varied, beautiful, and resource-rich planet for future generations" (Tanner, 1980, p.20). Remembering and cultivating the wonder supports care for the earth (Thomashow, 2002). Gathering and sharing stories offers an opportunity to understand how significant life experiences occur and how pre-service teachers can use their own childhood memories to support their work with children. Storytelling is an aesthetic-affective process that supports pre-service teachers in perceiving again their relationships with people and place. Storytelling is a way of connecting again with felt and embodied relationships, of remembering past experiences, and of recognizing the relevance then and now (Bai et al., 2010).

Accompanying Children

Rachel Carson reminds us of the importance of "the significant adult": "If a child is to keep alive his inborn sense of wonder. . .he needs the companionship of at least one adult who can share it, rediscovering with him the joy, excitement and mystery of the word we live in" (Carson 1987, p. 55). While moving away from methods where *adults* define and determine how nature matters to children and away from situations where children become passive recipients of treatments and activities that adults are providing to them (Chawla, 2015), parents, educators, and adults still have a role to play. We have important roles to play as "awestruck pedagogues" working *alongside* children to nurture intrinsic ecological understandings, relationships, and identities. How we listen *with* and attend *with* children matters, ". . .how we sunbathe them, let the wind play on their faces and hair, how we bring them to flowers and trees, to look at and touch, how we call their attention to the birds in the sky and on tree tops. How we attend with them. . ." (Bai et al., 2010, p. 353).

Remembering our own childhoods can reestablish our inborn sense of wonder and can help us rediscover our own relationships and interconnectedness with more than human worlds. This can help us move from indifference to care, reverence, deference, compassion, and respect. Sharing *our* love and appreciation, our awe and wonder of the magnificence of nature, *with* children can foster *theirs* (Bai et al., 2010).

Attending to our shared stories of childhoodnature encounters supports our intentions as educators and researchers who promote issues of sustainability and builds our/children's love of nature. Our stories can support understanding of personal, practical, and implicit philosophies, values, and ideas, including the influence of our own experiences, understandings, and hopes, as key determinants of how and why and what we bring into children's learning (Noddings, 2006; Green & Somerville, 2015).

Teacher Education as a Site for Remembering

The University of the Sunshine Coast is one of many universities including courses on early childhood education for sustainability in their teacher education programs. As a result, pre-service teachers often recognize that they, with children, have an important contribution to make to the world and have an important role in shaping it and being shaped by it. Their educator role requires them to keep in touch with their sense of wonder and awe.

For the last 2 years, pre-service teachers in their second year of their early childhood degree have engaged in a course I developed focused on early childhood education for sustainability. "Young Children and the Environment" (Davis, 2015) is a core text. Developing and teaching this course, I designed the assessment to encourage connection. In 2016 and 2017, two cohorts (of 27 pre-service teachers each) engaged in reflection, writing, and art-making about childhoodnature encounters. The course encouraged us to look to our own childhoods; remembering our own tender relationships with people and place can be an important starting point for education for sustainability.

Exploring Significant Life Experiences Using Arts-Based Methods

Scientific discourse and research, the predominant and dominant discourse, does not – and cannot – adequately capture the richness and complexity of human experience, yet it vigorously asserts itself in many fields (Bullough, 2006; Leavy, 2009). There are many ways in which our world can and should be known. Ways of comprehending the human experience occur along a continuum between scientific and artistic knowledge, and so research cannot belong to science alone (Eisner, 1998; Rolling Jr, 2010). For those working in social and educational disciplines, understanding human experience is critical. Arts-based research is a knowledge-building paradigm offering spaces to explore alternatives (Rolling Jr, 2010). It offers extensive approaches and possibilities for addressing research questions and problems, for investigating issues that matter, and for opening research to diverse and larger audiences. Arts-based research offers a place to explore ways of *being* and ways of knowing. It is grounded in the idea that the materials and encounters of our lives are essential to our meaning-making and to our understanding of relationships, their interconnectedness and interrelatedness (Eisner & Powell, 2002). Arts-based

research values processes that have the capacity to promote connections to ways of knowing, to embodied knowledge, to affect, to aesthetics, and to internal and external experiences. Importantly, the process and products of creative approaches can offer catalysts for deep thinking, reflection, and problem-solving/posing (Black & O'Dea, 2015).

For all these reasons, arts-based methods were valued exploration tools for engaging pre-service teachers in meaning-making about significant life experiences and for supporting their "attending" and *being.* Arts-based and creative methodologies supported pre-service teachers' reflective inquiry and the telling and sharing of stories.

This Chapter focuses on one of the assessment pieces in the early childhood course which involves the creation of a sustainability-focused narrative or creative work. The goal of this task is for pre-service teachers to consider their own experiences with nature and how these have influenced them and will influence their educator roles. Pre-service teachers are encouraged to use images and visual components to support their storytelling and remembering. The course outline offers the following advice:

> Create a narrative or creative work to capture the connections, interconnections, and disconnections of your personal experiences with nature and the natural world, as well as your holistic thinking in relation to values, commitments, learning, living and wellbeing. You might consider how your experiences and relationships with nature and the natural world have supported your experiences of belonging, wellbeing and connectedness. You could consider the effects, positive or negative, your experiences of the natural environment have had on your sense of self, your connectedness to other people and the world around you; or on your physical, mental and spiritual health. In your reflection, you will consider how these experiences might influence and enhance your role as a professional working with young children. You will identify how you will support children's relationships with nature and articulate some guiding principles for your work as an educator who advocates for relationships with nature, early education for sustainability, and early environments as places of belonging for children and families.

Pre-service teachers chose a range of formats and methods to share their stories and histories, including written narrative accounts, paintings with artist statements, films and digital storytelling, visual collages, photography, poetry, story/photo books, installations of various kinds, and narrated PowerPoints incorporating image, effects, and music.

By encouraging pre-service teachers to engage in arts-based methods that value narrative and autoethnographic components, I am seeking to create spaces for authentic conversations and opportunities for ongoing conversations. Sharing educational meanings and stories is a way of reaching and exploring real places that we each have been (Clandinin & Huber, 2002). This type of experience offers reflection that enhances personal and professional meanings and deepens and advances open-ended conversations about research, about experiences, about learning, and about *being*. Engaging in this kind of "assessable" meaning-making can feel uncomfortable and a bit risky, especially when our experiences and memories are characterized by layers and traces, partial reflections and forgetting, complexity and ambiguity, or

deep feelings. But, as Hart (2003, p. 9) suggests "at its best, narrative inquiry has the power to bring together stories and in so doing transform the story and the participants in the process" with our narratives inviting us "to rethink what we thought we knew."

Bringing the personal realm and inner lives into educational and university settings challenges conventional understandings about what education, research, and academic work are, and are not, about (Golden & Elbaz-Luwisch, 2007). However, there are a growing number of us who recognize the importance of valuing our experiences and the value of caring about what it means to be human and part of something bigger. There is a growing recognition of the need to attend to our lived and relational lives and the significance of experiences and encounters if life and learning is to be meaningful. When we share our experiences, there is a greater chance we will recognize deeper understandings of what is shared and remember our belonging to a universe that articulates through us and extends beyond us (Bennett, 1994).

Telling Stories and Histories

The next section illuminates the ways in which the pre-service teachers described how their childhood experiences have influenced them and their visions for their work with children. My interest and focus here is not the *analysis* of pre-service teacher's childhood experiences and assessment work. Rather it is to encourage contemplation of pre-service teachers' stories about the experiences which have led them into their environmental commitments and to employ "a listening approach" where attention is paid to what *they* are saying about their formative experiences and what *they* are describing as significant.

When they commence this assessment task, many pre-service teachers begin their reflections by gathering photographs from their childhood and by talking with family about their childhoods, local place connections, and significant connections and relationships with the more than human world. Many say they cannot remember the child version of themselves pictured in the photograph, the child splashing in the waves during a family holiday at the beach or laughing under the hose in the backyard. But somehow connections are made and (re)activated by this going back in time, by this being in the moment, and by this engaging again in an embodied remembering of feelings and relationships with human and more than human worlds. Looking back and looking forward, pre-service teachers describe appreciating their childhood experiences more; they describe recognizing the significance of these early experiences, and they connect with new insights and awareness. As they share their stories and memories with other pre-service teachers, they also recognize the uniqueness of their own meaning-making and their own experiences. Story snippets and vignettes follow to illustrate these various aspects.

Invariably pre-service teachers focus their storytelling on the natural features of their favorite places and holiday experiences and the feelings these places and

experiences cultivated. There is an emphasis on relationships with friends, family, and animals and many descriptions of play and activity and adventure.

> **Laura** – *As a child, my memories are not centred on the places I visited, but rather to my connection to the animals and people I shared the experiences of the natural world with. As an adult, venturing to natural environments provides me with a sense of tranquility enabling me to relax. This gives me a sense of responsibility to look after my own health and wellbeing as well as to look after the natural spaces I am engaging with.*

Relationships with animals, both wild and pets, are described in many accounts, with sometimes an exclusive focus. And, when describing relationships with the local environment, the influence of grandparents and early gardening experiences feature in multiple stories. The role of the significant adult is clearly important. Many pre-service teachers describe understandings and imaginings about their connections to the universe, sharing encounters that have stayed with them with regard to the mysteries of the universe and their lifelong sense of wonder.

> **Aimee**—*One great childhood memory that I will never forget is star gazing with my dad and sister. On a bright starry night after dinner we would go outside, lie on the grass and stare at the stars—and occasionally we would see a shooting star! Dad would always say "quick make a wish!" This is a magical moment and a calming moment for me still to this day. It makes me feel small, in a wonderful way. It makes me appreciate how small we all are as humans in the vastness of the universe.*
>
> *I've realized that my best experiences with nature have come when looking at her from a distance but ever so closely. That makes me feel a sensation of awe for the world that surrounds me. But what does this mean for me as a teacher? And how has this influenced me as a person? During writing this assignment I have been thinking deeply about my own experiences with nature. Even though I can't remember all the moments I've had as a young child, I know I was definitely involved with and enriched by nature. I know this by looking back at photos, having conversations with my parents, reading, swimming and acknowledging the love I have for animals which all have roots in my relationship with nature.*

> **Matilda—***My art piece (*Fig. 1*) symbolises my connection with nature. It visually expresses the way I see people and earth—as one. It captures my own connection with nature as well as the deeper connection existing within us all. My experiences and connections have been shaped by my early experiences, in particular with the Mary Valley. This artwork says 'the land is terra mother'. And 'we are nature'.*

In constructing "significance," a spectrum of thoughts, feelings, and beliefs about nature are revealed in pre-service teacher's accounts. As Chawla (1998, p. 19) reminds, "the ultimate target of research about significant life experiences is not merely to know the experiences that people have had, but how their significance becomes constructed." In many stories, there is an innate recognition that "we are nature," such as is seen explicitly in Matilda's reflections and creative work (Fig. 1).

Also apparent in pre-service teacher's stories is their relating to the widely held belief that it is possible to feel disconnected from nature (Louv, 2005), especially when there is limited interaction with natural environments. Many pre-service

Fig. 1 Matilda's creative work illustrating "we are nature"

teachers communicate that contact with natural areas and spending time outdoors is what connection "looks like" or "feels like" – that "being in nature" supports their sense of connection. Their accounts communicate that people interact with, connect with, conceive, and think about nature in many different ways. Just because we *are* nature doesn't necessarily mean that we all believe or understand that reality.

Pre-service teachers describe that "contact with natural areas" is a significant influence. When Tom introduces his story (below), he describes that before moving to life on a farm, his only "real" connections with nature were "exploring the backyard" or "the trips to the park to feed the ducks." Similarly, Savannah's exposure to the ocean over her life-span is at the heart of her relationship experience.

"Direct experience *with*," rather than just "learning *about*," is a key theme permeating pre-service teachers' stories and revelations (and this is clear in Terry's story). Pre-service teachers describe their sensory and emotional responses and their "inner experience" during their connections with natural surroundings and elements. Stories highlight that *being* matters – engaging with senses, bodies, perceptions, feelings, and lived and embodied experiences. Having knowledge, or some kind of external awareness, is *not* what pre-service teachers are describing as influential. In terms of what *is* influential, the role of "the significant adult" (often a family member) as an "accompanier *with*," rather than solely as an imparter *of* knowledge, is emphasized. As educators, we can typically assume that if we "impart knowledge" to students, responsible action will follow (Hungerford and Volk, 1990), yet pre-service teachers recognize that this is not enough. This takes us back to Bai et al.'s (2010) ideas about *attending,* listening, and dwelling *with* children and ensuring that children have sensory, embodied, and evocative (rather than just explicative) experiences with more than human worlds.

Stories of Relationship

Larger excerpts from the storying of three pre-service teachers are provided below to animate some of these ideas and to demonstrate the depth, quality, and impact of pre-service teachers' recollections and meaning-making. Given that narrated PowerPoints and films are not easily transferable in a printed book, the examples presented here come from artifacts that students submitted as part of written narratives and photographable creative works.

Rather than engage in further commentary of or between the stories, the following passages are offered with little analysis. You are invited to make sense of them in your own ways using whatever perspective or lens or philosophical thoughts you bring – perhaps even letting those perspectives and lenses and thoughts fall away so that you can just sit and *be* with another's experience and storytelling.

Tom: Living and learning with the land

Tom—*As a young kid I lived in central Toowoomba. My only real connections with nature at that time was exploring our back yard, or the trips to the park to feed the ducks. The year I turned seven my family sold everything, bought a grain and cattle farm, and moved over an hour away, out into the country. Our farm was a long way out of town, and was so different to my previous suburban environment. I now had an entire farm to explore as my back yard. The stark change of environment meant that I didn't recognise the various dangers that came with that change. Rather than worrying about traffic or getting lost on an unfamiliar street while riding my BMX, I now had to learn about living in the country.*

My parents and grandparents purchased the farm together, so now my grandma was around a lot more and she was a significant part of my life and my younger sisters' lives. Grandma grew up in outback Quilpie during World War Two. The intense war rationing and outback lifestyle during her childhood had given my Grandmother her perspectives on nature and survival (Fig. 2).

Some of her first lessons to my sisters and I was to stomp your feet in tall grass; always be on the lookout for brown and black snakes; don't startle a horse while standing behind it; and check if a fence is electrified with a piece of grass 'before' trying to climb over it. Just a few little tips for a new country kid connecting with his new landscape. As I reflect, I can see

Fig. 2 Tom's photo of his grandma

how these experiences might be applied in my own work as a teacher. I can envision myself as a teacher asking children to think about the different aspects of living in different places, like the city or the country.

I gained a new perspective on the importance of the weather too. Like most suburban kids, it is a bad day at school if it is raining and you can't play outside. However out west, rain makes everyone very happy. I came to understand the importance of rain for a drought stricken community that relies on the climate so heavily for its industry. Rain equals money out there. The other new environmental experience was living through 'too much' rain. Flooding happened many times through my childhood, and our family farm has a section of the Myall Creek running through it, so it never missed us. I saw our farm get carved and changed by flood waters, and I learned very early about land and soil erosion, land and soil salinity, and about subsoil moisture tables. The creek on our farm is bone dry most of the time, save for a few deep waterholes dotted along it (Fig. 3).

Rain has to happen on the Bunya Mountains (upstream) for our part of the creek to run, but when it does, all of the water holes get refreshed with new clean water. This means that the water holes are now clean enough to swim in for a while. Swimming in a dirty creek is great for getting familiar with different types of soil. I would feel the slimy-smooth-silky silt, or dig down and pull up thick clay which was great for building mud slides with. These connections are what I draw on to realise the value of mud, sand, water, and rocks for young children, and the importance of childhood opportunities to handle, explore, and create with natural materials.

Being a 'farm kid' meant I had many connections and experiences with animals. While we kept animals such as horses, cows, dogs, and chickens, we also had a large property, which made it possible for many encounters with wild and native animals as well. Exploring nature and animals from horseback was a great way for me to enjoy connections with animals and to learn respect for, and bond with another animal. Riding a horse and mustering cattle involved working as a team and having trust in the horse I was riding. I would have to walk out into the field and find the horses first, then bribe them with carrots so that I could catch them for a ride. I had to learn how to keep the horse comfortable with a saddle on, and how to not lose control of a beast that weighed seven times my weight.

*My experiences helped me gain understandings and respect for natural places and the animals that lived amongst those places. I was getting fresh milk by milking our own dairy cow by hand (*Fig. 4*), and collecting eggs from the chickens we kept. They didn't just come packaged from the store. The milk was still warm from the cow some mornings. I believe in*

Fig. 3 Tom's photo of the drought-affected land

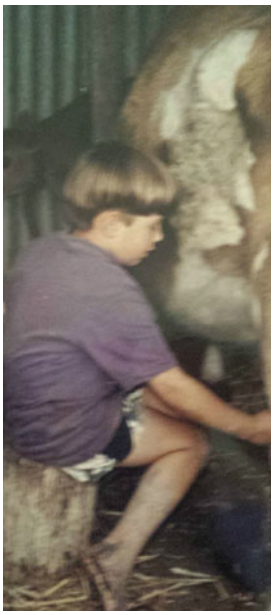

Fig. 4 Tom's photo of him milking the cows

showing children real examples of where their food comes from and how it is produced. Milk and eggs don't just come from the shop.

I think it's important to give children real connections with the common things that they all use and consume from nature, and to know where those things come from originally.

The unfortunate side to having constant close engagement with nature and animals is that I also encountered death and dying. Our dogs got bitten by snakes, we had to euthanize old or sick livestock and occasionally even horses, and shooting wild pigs and culling kangaroos were experiences I had to grapple with as a kid. This was perhaps balanced by helping birth calves in a paddock, raising baby chickens, and growing food. Therefore, life and death were concepts I had an understanding of as young child. The interactions with nature in rural areas are often quite harsh. It isn't very nice to jam a young steer in a calf crush, hold it down while it snorts and kicks, grab the red-hot irons out of the fire, and brand the calf on the rump while it bellows in pain. But a quick splash of tick treatment, maybe a quick castration, and then it seems they're all happily back out to pasture. That brutal type of experience is something that was accepted as part of the work that had to be done. But, as a young kid, witnessing the process showed me the harshness that non-household animals endure. If I find myself teaching in a rural area, I may have children in my classroom who live around livestock and who will have similar encounters.

I was lucky to have such a rich natural environment to explore as a child.

I have many memories of experiences, places, and connections that were formed while I was empowered to be, become, and belong through engagement with my natural surroundings. These experiences have helped form my own reflections and perspectives on nature and how I fit into it. As a teacher, I can draw on these experiences, and other resources, to inform my role as an educator. I hope to empower my learners to explore their own connections and experiences with nature.

The significance of "direct experience *with*" nature, and the influential role of the "responsive and accompanying adult," is captured in both Tom's story (above) and

Terry's story (below). For Tom, his experiences connected him to feelings of respect, care, and reverence for the more than human world. Far from being simplistic recounts of time in nature, Tom's stories also highlight moments of conflict, hardship, and deep feeling. And, he engages in reflection about how he will integrate his experiences and his stories with those of his learners.

Like Tom, Terry's grandmother played a key role in teaching her to appreciate the more than human world. Terry's account shows how her childhood experiences inform her love of nature and her educator commitments. She describes how she shares her *own* love and appreciation of nature with the children in her care and the particular approaches she takes to foster *their* love and appreciation of nature.

Terry: Being accompanied and loving the earth

Terry—*Since I was young my Nanna has been a massive influence. Her place always invoked a sense of excitement, of exploring the unknown and engaging in new adventures. Looking back at my experiences, I can see she was the perfect example of an ideal educator. Rather than 'filling a child with knowledge' I see the value of 'having children experience it themselves'. I see the relevance of this statement in the Early Years Learning Framework: "Children's understandings are constructed as they interact with and make meaning of their experiences in their complex natural and constructed (physical and social) worlds". Children learn better by experiencing than by being told.*

I remember when we would visit Nanna's and Poppa's place we would drive down their driveway and I would spot Nanna in her 'vege patch'. It became a game between me and my brother of 'who would find her first'.

*Once we arrived we would bolt for the garden (*Fig. 5*) and be given a snack—fresh from the garden. It would change with the season: sometimes strawberries, carrots, bananas, apples, mangos, or our favourite: 'the liquorice plant'.*

After our snack, we would be given simple jobs like watering the plants, mulching, feeding and watering the animals, putting the weeds in the compost heap.

Then the fun time of harvesting our lunch began. It was always a pizza which Poppa made—but the vegetables were always picked fresh from the garden by us, which seemed to always make the pizza taste extra amazing (and I can't seem to recreate that flavour again).

Fig. 5 Terry's Nanna's vegetable garden

With these experiences in my early years I naturally came to respect nature and wanted to look after my own 'patch'. This respect emerged not only in my home life, but my workplace as well. It took the form of me creating and looking after gardens in both my home yard and the childcare centres that I worked. In many centres, there was not enough room for me to create an elaborate garden so I have had to improvise and create 'mini-gardens'.

By experiencing living off the land from Nanna & Poppa I have found that wherever I live I seem to naturally have a vegetable garden and grow my own food to eat. I also conserve water, and have a 'scrap bucket' that I use for either animals or composting, depending on what I have at that point in time. These eco-friendly resource-management teaching strategies have naturally become a part of my everyday routine, and of course I impart my knowledge to the children through our daily routines.

Nanna's compost heap was a huge tank that had been cut to a quarter of its height. My brother and I used hunt for things to throw into it while Nanna pitched out forks of compost for her gardens. I remember watching the worms wiggling around in the compost heap each time she took out some compost.

Remembering my own childhood gardening with Nanna, and the knowledge I gained, influences how I interact with the children around me. While at work, I impart my own knowledge to the children while we garden, talking about nature, seasons, life cycles, companion planting, harvesting and so many other topics. And sometimes we just rest and watch the environment around us in the garden.

Children connecting with nature: the feel of the dirt, the smell of the natural environment, the taste of the fresh produce, the colours that beam in front of them, wildlife, and chattering companions—each of the senses processing information about their surroundings and optimising engagement in the natural environment.

I remember how as a child Nanna's garden had so many little nooks and crannies that I could hide in and just relax. I would listen to the wind and animals and just 'be a part of nature'. As an educator, I understand how important it is for children's and adults' wellbeing, to have that time to just let the wide world pass you by and to relax, and communicate with the natural environment around you. It could be as simple as looking at a flower beside you, sitting under the shade of a tree, feeding the fish and watching them fight over the food, or watching the sunrise or sunset. Beautiful moments to relax and let go of stress that has piled up.

Another way to instil a sense of wonder in the children is as simple as having them experience a storm or rain. Whenever it rains at the centre I work, the children rush to grab the cushions and sit on the veranda to listen to the rain and watch it make puddles. I like to use this beautiful teachable moment to my advantage and together the children and I move our plants out into the rain.

Terry's formative experiences have provided a basis for her interest in the environment, her feelings of concern for it, and her receptivity and responding. She is now passing this on to children and providing opportunities for children to respond receptively to the more than human world. Terry's practice of gathering children to sit and watch the rain, and moving the plants out in the rain, engages children in environmental sensitivity and environmental concern. Chawla and Hart (1995) consider that this fusion of feelings and sensations of the world can form the basis for children's awareness of the world as a living being to which they are attached. Similarly, Savannah's art-making (below) represents her fusion of feelings and her diverse emotional responses and communion with the ocean over her life-span. Savannah connects with her early feelings as a young child and to her current feelings, understandings, and appreciation of this interdependent relationship.

Through their storying, like many of the pre-service teachers, Terry and Savannah identify the sense of belonging, wellbeing, and centeredness they have experienced during "here and now" moments of "communicating with the environment" and "immersing" themselves in experiences with the more than human world.

Savannah: Sensing and feeling relationship

Savannah—*Innocence: This art piece* (Fig. 6) *represents the first stage of my personal connection to the ocean, being one of innocence, enjoyment, and fond family memories. Growing up in the coastal town of Busselton, in the South West of Western Australia, I spent many hours at the beach as a child. Looking back on these early years of my life, I feel my connection to the ocean was one of naive innocence and pure enjoyment, unclouded by the reality of any threat the ocean could cause me or by any current environmental issues. I associated the ocean with sand castles, fish and chips, ice-cream, sun-cream, and family time. I attempt to communicate this innocent childhood perception through an almost stereotypical depiction of the ocean, using light colours and 3D art mediums.*

*Antipathy: This second piece (*Fig. 7*) represents the second stage of my relationship with the ocean, when as an older child and young teenager, I developed a level of fear, due to some traumatic events I experienced. I attempt to depict a dark and formidable wave in the second frame, communicating the sheer power and uncontrollable force of the surf. It was at this point in my life when I experienced what it was to be dumped by one of these waves and my reaction at the time was to retreat from the ocean, due to the loss of control I experienced in that moment. For a long period of time I would walk a tightrope of emotions: on one side holding a true fear connected with the strength of the waves, on the other side still craving that innocent childhood enjoyment.*

*Harmony: The final art piece (*Fig. 8*) is a 3D layered effect I have created using multiple prints of a photograph. The original image is one that is very dear to me. It was taken of myself and my husband, by a close family friend, in the lead up to our wedding day. The location is one of my husband's favourite coast lines in the South West of Western Australia and coincidentally, not far from where my previously mentioned trauma occurred. I feel this image is an appropriate representation of my adult relationship with the ocean, which has*

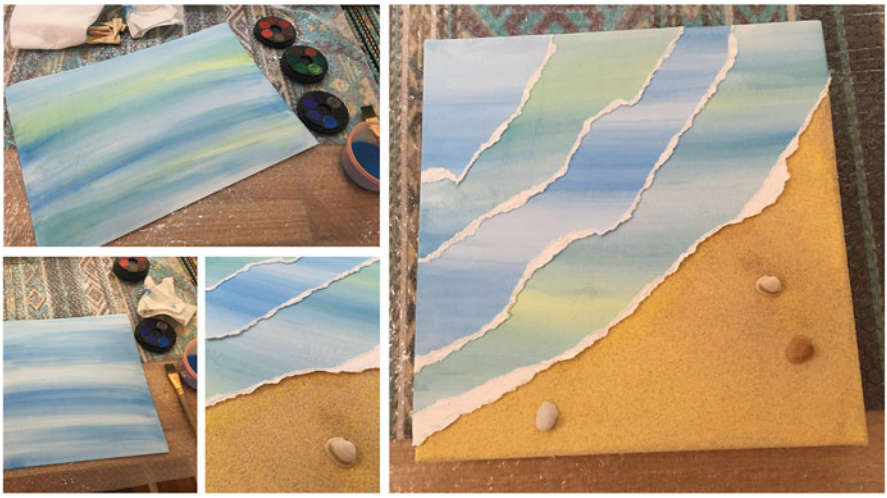

Fig. 6 Savannah's collage illustrating early innocence and connection with the ocean

Fig. 7 Savannah's collage illustrating her changing relationship with the ocean and her sense of antipathy and fear

Fig. 8 Savannah's collage representing her adult relationship with the ocean, characterized by respect, connection, and harmony

become one of deep respect, connection, and harmony. During my later teen years and adult life up until this point, I have grown to love the ocean at a deeper level. My once limiting fear has now become healthy caution, respect, and understanding of the strength the ocean holds. As an adult, I have also learnt of the vulnerability of the worlds' oceans and sea creatures. I realise how fragile this aspect of our environment currently is and that it is my responsibility to contribute to sustainability efforts. On a spiritual level, I now experience a cleansing and grounding effect when I visit the coastline of Australia. Stress will melt away from my body and I feel much more centred after immersing myself in the healing salty

waters. This photograph communicates a stunning coastline, powerful currents, the connection between two people, and most importantly, their deep respect of the amazing environment they have the privilege to have grown up in. The strong connection I have developed with the environment will enable me to adopt a holistic approach to my future vocation. "We are all visitors in this time, this place. We are just passing through. Our purpose here is to observe, to learn, to grow, to love... and then we return home"—Australian Aboriginal Proverb

These story excerpts and creative and historical artifacts are visual and "textual representations of different experiences" (Denzin, 2003, p. 5). They highlight how the materials and experiences of one's life influence understandings and educational commitments (Golden & Elbaz-Luwisch, 2007).

Creating narrative accounts and creative artifacts supported pre-service teachers to remember, revisit, and renew their appreciation of early experiences in the natural world. Through writing and creating, pre-service teachers became sensitive to embodied emotions and those significant times in their histories that moved them and which move and resonate with them still.

This kind of approach was meaningful to these university students. Pre-service teachers' evaluation (63% response rate) of this sustainability-focused early childhood course both statistically (4.9 out of 5) and qualitatively reflects their appreciation of opportunities to make personal/professional connections:

I loved this course. It helped me articulate ways that I can implement sustainable practices into an early childhood setting as well as how I can pass on this passion to the next generation of children.

I loved our creative piece for assessment, and the hands-on learning experiences we were provided with. I was able to show my own personal view and understanding.I have loved this course and I will take it with me forever.

I have reconnected with my appreciation for our environment and the need to live a sustainable life.

For these pre-service teachers, engaging in reflection about their own childhoodnature experiences, their *being*, and their sensory, embodied, cognitive knowing has supported articulation of commitments and desires to contribute to social change. Reflection has supported deeper understandings and appreciation of their relationships and encounters with nature, which have now become integrated into identified educator commitments.

Educator Commitments

Our perspectives and priorities shift over the course of our lives. But, remembering and revisiting experiences can (re)connect us with what we value and support the transformation of priorities. Remembering the wonder cultivates the wonder, supporting our receptivity and priorities for the world around us.

The teacher education course has provided pre-service teachers with a place to tend to their relationships and understandings. They have had an opportunity, as Rautio (2013a, pp. 452, 453) describes, to tend to their "self-environment

relationships" and engage in "the articulating – finding, inventing, and rearranging – of connections" and "conceptualizations" with and about human and more than human worlds. And through this articulating, they are recognizing their commitments and hopes for children and the important role they play in facilitating significant life experiences for the children they will teach.

Adam—*After writing my narrative, I feel grateful for the opportunities I was afforded as a child. My experiences have had a huge influence on my personal connection to nature and my wellbeing. In my adult life, I use the natural world and the connections I have made to it, to assist my health and wellbeing, both physically and mentally. Whether it is going for a run or walk outside or going and lying in the park or the beach and reading a book, being in the natural world, has a calming effect on me. The physical feeling of the wind, sunshine and the noises of leaves rustling in the breeze or birds singing is to me a soothing feeling.*

These personal experiences are something I intend on using in my approach as an early childhood teacher—and with mental health issues in young people on the rise, the natural world and its benefits have never been more important. As an educator, I understand that not all children in my care will have had a rich and nurturing experience to the natural world. Children come from diverse backgrounds and situations.

Deb—*The environment has always been a valuable part of my life. I hold a great respect and appreciation for the outside world. I would like to do everything that I can to support children in learning and valuing the same principles that I have. I realise that many children do not have many opportunities at home to engage and explore nature. Everywhere I have ever lived I have always developed a deep sense of belonging and sense of place. This is because of my strong connection with that natural world. I feel safe, secure and supported in nature and I wish to ensure that I support children in doing the same. Growing up in an aboriginal community has also supported and developed my understanding of the importance of developing a sense of place and cultural appreciation. I want to envision a better future for myself and for children; to think critically and reflect; to question current beliefs; and acknowledge links and synergies; to build effective partnerships with families, children and the wider community; and participate with children in decision making about issues that affect us.*

Louise—*Reflecting on my own experiences with nature and the natural world, as a future educator I want to create learning environments that are authentic, engaging, supportive and safe for the children, families and the community. I believe that wellbeing, along with wonder, curiosity, respect, belonging and connectedness are crucial for a young child's healthy development. Making time to be in natural environments, and providing opportunities for children to freely and independently explore, discover, imagine and investigate, will contribute to children's sense of place, connectedness, belonging and wellbeing. Children need to engage in unstructured time to play within nature and follow the wisdom within their own bodies and hearts—as this is when we learn our most expressive and important lessons.*

Conclusion

This Chapter offers a space for reflective exploration. Recognizing that early childhood educators are uniquely placed to support children's childhoodnature encounters and relationships, it focuses on pre-service teachers and provides an assemblage of significant life experiences from their childhoods. It provides points for

philosophical rumination, on topics such as *attending, being,* and *remembering the wonder.*

Knowing that the early years are an important and foundational time, and recognizing how critical it is that pre-service teachers understand their professional roles and responsibilities, we can feel concerned about how we can support teachers in establishing personal direction and guiding principles for early education for sustainability. Although we might worry about how they will learn the information they will need, this chapter redirects us away from information transmission and toward *being*, toward *embodied ways of knowing*, and toward *story.* Pre-service teachers' *own* experiences and stories are important resources for connecting and contextualizing what matters. Using the resources of their own significant life experiences invokes a desire to attend to such experiences and relationships *with children*.

The methodologies used in this project, including storytelling and arts-based approaches, have supported "consciousness transformation" and provoked "pre-sencing" (Bai et al., 2010, p. 361). They provided ways for pre-service teachers (and others) to bring their attention to their experiencing and being in relationship. The power of narratives as invitations to rethink and reflect and to support our navigation of the changing landscapes of environmental education and sustainable worlds is immense (Hart, 2003).

Opening spaces for embodied remembering and consciousness transformation – rather than information transmission – is important. We need to offer spaces (in teacher education and in early childhood education) for *being* – for remembering senses and feelings and perceptions and dwelling (again) in significant experiences and relationships. Stories support these ecological homecomings; they return our attention to meaningful and resonant experiences. As Bai et al. assert (2010, p. 362) "Yet we may forget who we are, and have lost our way—not in the forest but in discursive languages that take us away from our senses and presence.. . [s]torytelling can return us to our bodies and senses, and to our indwelling presence.. . storytelling is really the heart of environmental education."

Abstract

In past research on significant life experiences (SLE) that influence environmental values and behaviors, a triad of experiences frequently emerge: free play and exploration in nature in childhood or youth, influential role models who communicate nature's value, and opportunities to learn how to take action on nature's behalf. This Chapter opens with a review of past SLE research and theories of child development that predict these repeated findings. It also reports on an

evaluation of family nature clubs (FNCs) – community-based organizations that regularly bring families together to enjoy nature together, creating conditions for families to share all three of these experiences that have been associated with care for the natural world. This study of more than 330 FNC leaders and participants found both quantitative and qualitative support for the effects of these formative experiences. Statistically significant survey results are complemented by ethnographic observations and interviews that offer insight into what happens during these experiences that makes them important and lasting in memory. The consistency between this study's results, previous SLE research, and relevant concepts in the psychology of child development is discussed.

Significant life experiences research · Childhood time in nature · Family nature clubs

Introduction

What childhood experiences lead some people to feel a bond of connection with the natural world and understand that they are part of the interdependent web of life? What early experiences encourage lifelong expressions of care for other parts of the natural world? Efforts to answer these questions have come to be called "significant life experience" (SLE) research: the study of experiences that promote the development of values and behaviors consistent with awareness of and appreciation for nature (Tanner, 1980). The first part of this Chapter reviews studies that have sought to answer these questions. The second part of this Chapter adds new content to this literature from a study of family nature club leaders and participants from six countries.

Family nature clubs (FNCs) bring families with growing children together at regularly scheduled times to explore natural areas in their local surroundings. The design of FNCs can vary widely, but they all offer events that occur outdoors, are geared toward full family participation, and are intended to develop positive connections with nature through direct experience. The majority of the FNCs included in this research were registered with the Children and Nature Network, an international organization that promotes FNCs (www.childrenandnature.org). This research was able to relate parents' perceptions of significant experiences, as captured through surveys and interviews, to researcher observations of what actually occurred during experiences in nature via the case study of a new family nature club created specifically for this purpose. This Chapter is the first to connect FNCs to research about SLEs.

This Chapter also seeks to connect SLE research to well-studied aspects of child development that may help explain recurring results. Significant experiences in nature appear to embody basic processes of development, including the development of agency and a sense of competence, social modeling when children look to role models to determine how they should act, joint attention when two or more people knowingly focus their attention on the same object or event, empathy, sympathy, and

an environmental identity when people's relationship with their environment becomes an important part of their sense of self. This Chapter considers how its findings about FNCs correspond to these developmental processes. The conclusion discusses parallels between past SLE research and the new study presented here.

Review of Significant Life Experiences Research

Defining a New Field of Research

Engagement with nature through direct experience has many immediate positive benefits for children (Chawla, 2007, 2015); and from a life span perspective, it is the most frequent experience associated with later action on nature's behalf. It is only one of a sequence of experiences, however, that motivate later interests in nature and caring environmental behaviors, whether they are expressed through environmental career choices or volunteer activities (James, Bixler, & Vadala, 2010). Efforts to identify key events in this process, or significant life experiences (SLE), began in 1980 with a seminal paper by an environmental studies professor, Tom Tanner, who noted the need to understand the kinds of learning experiences that produce "an active and informed citizenry" who will work to maintain "a varied, beautiful, and resource-rich planet" (Tanner, 1980, p. 20).

The investigation of formative childhood experiences that encourage people to feel connection and care for the natural world began with retrospective studies. Through interviews (Chawla, 1999; Peterson, 1982; Peterson & Hungerford, 1981) and written narratives (Palmer, 1993; Tanner, 1980), people were asked what motivated them to choose careers in conservation work or environmental education or why they became engaged in actions to preserve or protect the natural environment. Findings from Peterson's (1982) qualitative study were integrated into quantitative surveys that examined statistical associations between childhood experiences and environmental values and behaviors in adulthood (Marcinkowski, 1988; Sia, Hungerford, & Tomera, 1985/86; Sivek & Hungerford, 1989/1990).

The second SLE study, by Peterson (1982; Peterson & Hungerford, 1981), had the goal of identifying life experiences associated with "environmental sensitivity." According to the Tbilisi Declaration drafted by international leaders in environmental education in 1977, one of five major objectives of environmental education is "to help social groups and individuals acquire an awareness and sensitivity to the total environment and its allied problems" (UNESCO, 1980). In an often cited paper, Hungerford and Volk (1990) listed environmental sensitivity as the major "entry-level" variable in their model of life pathways in the development of responsible environmental citizenship. Whether SLE research should focus on the outcome of action for the environment, or antecedents of action like environmental awareness and sensitivity, was an early controversy (Chawla, 2001; Payne, 1999; Tanner, 1998). In practice, studies have investigated diverse outcomes that include environmental sensitivity, awareness, attitudes, values, interest, concern, and career choices as well as committed activism. Environmentally active subjects have included

volunteers at marine centers, natural history enthusiasts, farmers who maintain wildlife habitat, teachers of environmental education and geography, members of environmental organizations, political activists, and people in the general population who take relatively simple steps like recycling and voting for green candidates (Chawla & Derr, 2012).

Previous Literature Reviews

A series of reviews of SLE research have traced the field's methods, measures, and findings over the years. In a review of early studies and a subsequent investigation of life paths into environmentalism, Chawla (1998a, 1999) noted that people mentioned multiple experiences that included both direct engagement with nature and learning how to interpret nature in positive ways. In seven qualitative studies based on interviews and open-ended narratives, she found that people referred most often to time outdoors in natural areas, often through childhood play and exploration, but other common responses were witnessing habitat destruction, teachers or education, youth groups, and books. She also made recommendations for strengthening future research, including working with more diverse social and ethnic groups and a broader range of environmental issues, and including less environmentally active comparison groups (Chawla, 1998b, 1999). Since she wrote, the field has moved in these directions. Beyond its origins in the United States, studies now include samples from Canada, El Salvador, the United Kingdom, Ireland, Norway, Germany, Switzerland, Lithuania, Slovenia, Greece, South Africa, Uganda, China, Sri Lanka, Taiwan, Hong Kong, Japan, and Australia (see studies reviewed in Chawla and Derr (2012) and, more recently, studies by Catling, Greenwood, Martin, and Owens (2010) and Li and Chen (2015)).

Marcinkowski (2001) reviewed applications of a survey created by Sia (1984) to distinguish the life experiences of more versus less environmentally active people. Sia's index of "environmental sensitivity," based on Peterson's (1982) study, asked people whether they were involved in hunting, fishing, and hiking as children or adults and whether they were influenced by parents, teachers, or books. (Hunting and fishing are often a way of life in rural areas, and many rural people learn outdoor skills and the ecology of natural habitats through these practices.) When Sia (1984) collected surveys from members of Sierra Club chapters and participants in an elder hostel, people who reported many responsible environmental behaviors versus few scored significantly higher for environmental sensitivity as well as knowledge of environmental action strategies and self-perceived action skills. When Sivek and Hungerford (1989/1990) used the same survey with members of fishing, hunting, and trapping associations in Wisconsin, these three variables, again, were most strongly associated with behavior scores. When Marcinkowski (1988) used an extended version of the survey with members of the US Sierra Club and Audubon Society, behavior scores were most strongly explained by knowledge of environmental action strategies. Together, these studies indicate that significant childhood experiences may increase the likelihood that people will take action for the

environment as adults, but action is also influenced by whether people know what they can do and believe they can act effectively.

Sward and Marcinkowski (2001) reviewed research on SLEs associated with measures of environmental sensitivity, concern, and action, with an emphasis on studies published from 1980 to 1998, but with attention to relevant studies prior to 1980. They covered many of the same studies as Chawla (1998a) and found similar results: people often identified direct experiences of nature, role models such as family members and teachers, and involvement in outdoor-oriented youth organizations or camping. When they examined studies of people who chose careers in natural science or environmental education, they found the consistent importance of outdoor experiences. Like Chawla (1998a), they noted the need for future studies to include comparison groups who are not environmentally sensitive or active.

Two more recent reviews have covered both the SLE literature and evaluations of environmental education programs. Wells and Lekies (2012) found that the results of Tanner's (1980) initial study have been repeatedly confirmed by subsequent descriptive studies, including the importance of time in nature, influential individuals, books, and seeing the loss of valued natural places. They noted that the greatest commonality across all studies is "the importance of time spent outdoors in natural habitats during youth" (p. 206). They observed that studies in this field typically focus on people in environmental careers or activism, so results may not be generalizable to other groups or the population at large. Relatedly, because descriptive studies like Tanner's rely on self-report, they are limited by the potential inaccuracy of memory. "Is it the case," Wells and Lekies (2012, p. 207) asked, "that certain childhood experiences lead people to be dedicated to the environment? Or, rather, do individuals construct coherent stories of their life experiences leading up to their ultimate environmental careers or activism?" An autobiographical approach may generate hypotheses, but it cannot establish causal connections.

Turning to quantitative surveys, Wells and Lekies (2012) observed that these studies support a connection between childhoodnature experiences and later pro-environmental attitudes and behaviors. Reviewing seven studies that involved large, general population samples from the United States, Germany, and Scotland, they found that people who reported spending time in nature in childhood were more likely to express favorable attitudes to trees and natural areas, perform actions like recycling and environmental cleanups, support nature protection, prefer natural areas for recreation, understand biodiversity, and express ecocentric beliefs. Although these studies lend validity to descriptive studies, they also rely on memory. To make causal claims possible, Wells and Lekies recommended longitudinal designs.

In a review that covered 39 publications related to significant life experiences, Chawla and Derr (2012) noted that whether studies involved interviews, questionnaires with open-ended narratives, or surveys of large samples, the most common antecedent of valuing and caring for nature was time in nature in childhood and youth. Other frequent results were participation in environmental or nature-based organizations, influential people or books, and the loss of valued natural areas. In two studies, one in Japan and one in the United States, that compared people who demonstrated interest and care for nature with others who did not, positive contact

with nature in childhood was the distinguishing factor (Furihata, Ishizaka, Hatakeyama, Hitsumoto, & Ito, 2007; James et al., 2010). A unique study observed elementary school children in upstate New York as they engaged in intense creative play and fort building in a natural area that adjoined their school and then, unexpectedly, as they witnessed it being bulldozed and coped with its loss (Blizard & Schuster, 2004). The children expressed strong emotions of attachment to their natural play area and sadness and anger over its loss. This longitudinal case study illuminated the importance of both nature play and the loss of valued habitat.

As another means of insight into experiences that shape children's environmental values, attitudes, and actions, Wells and Lekies (2012) and Chawla and Derr (2012) also reviewed studies that evaluated outcomes from environmental education programs. They drew similar conclusions. Programs are most likely to increase concern for nature and pro-environmental behaviors when students are actively engaged in hands-on activities that include direct experiences of nature, they address meaningful local issues, they do their own investigation and information gathering, and they have extended or repeated exposure to a program. These characteristics of impactful programs may help explain why nature-based programs often emerge as a significant life experience.

New Directions for Significant Life Experiences Research

SLE studies that have been published since 2010 and not included in previous reviews confirm preceding results but also explore this subject with new groups and new methods. A paper by Place (2016) brings the field full circle to its beginnings. Tanner (1980) was motivated to initiate the study of SLEs after reading biographies and autobiographies of prominent conservationists. When Place (2016) examined histories and personal writings of five prominent conservationists in the United States, the three strong strands that ran through their early lives were childhood exploration of nature, a parent or grandparent who taught them to notice and appreciate nature, and books about natural history and outdoor adventure.

Extending the study of formative experiences that motivate environmental career choices to a new career area, Catling et al. (2010) found that geography teachers identified time in nature, influential parents and teachers, an enjoyment of maps in childhood, and, later in life, fieldwork as the main experiences that excited them to pursue geography. Extending SLE research to China, Li and Chen (2015) found that environmentally active citizens were most likely to write about time in nature – primarily in childhood, organizations, environmental destruction, education, and role models. In a follow-up survey, a large sample of Chinese college students identified participation in environmental organizations, nature experiences, and their college education as most important.

A new subject of study is the background of people who are taking action against climate change. Pearse, Goodman, and Rosewarne (2010) investigated the lives of adult climate activists in Australia, Fisher (2015) interviewed international youth

climate activists, and Howell and Allen (2016) surveyed people involved in climate change writing, education, and mitigation. Although positive engagement with nature was an important influence for some respondents, other experiences were more common: direct contact with environmental problems and their social consequences, learning at work or in organizations, education, influential people, and media. Howell and Allen (2016) observed that for climate activists, social justice themes are more important than nature connection.

Fisher (2015) noted that the international growth of environmental youth groups has provided new opportunities for significant experiences, as several young activists talked about the sense of inclusion and empowerment that they gained from being part of the climate movement. In previous studies by Sivek (2002) and Arnold, Cohen, and Warner (2009), youth found the identity and relationship that they felt at environmental gatherings to be significantly motivating and sustaining. Empowerment from working with others was also important in Ceaser's (2015) study of environmental justice activists. When Colvin Williams and Chawla (2015) interviewed adults who had participated in nature center or wilderness programs as children or teens, salient memories included direct encounters with nature, inspiring guides, and their sense of pride in belonging to their group. Colvin Williams and Chawla related free exploration and guided learning in nature to the development of an ecological identity formed through a personal history of connection with nature (Clayton, 2003; Thomashow, 1995), and the sense of group belonging to an emerging social environmental identity, as people came to identify themselves with others who actively work on the environment's behalf (Kempton & Holland, 2003). The work by Ceaser (2015) and Fisher (2015) suggests that the second type of identity may be primary for climate justice and environmental justice activists.

Two recent studies open promising new paths for longitudinal designs. In a small qualitative study, a preschool class was observed as the children visited a river in a state park in the United States each week over the course of a year (McClain & Vandermaas-Peeler, 2016). The children's understanding of the natural world developed through a combination of their own direct exploration and inquiry along with teachers' questioning, and teachers promoted children's appreciation for nature and stewardship behaviors. A larger longitudinal study measured the environmental attitudes and behaviors of 118 young people at ages 6 and 18 and surveyed their mothers when their children were 6 about their children's outdoor play habits in their upstate New York towns and their own environmental attitudes and behaviors, political values, and level of education (Evans, Otto, & Kaiser, 2018). They found that 18-year-olds reported more pro-environmental behaviors and attitudes when they spent more time outdoors at 6, and their mothers expressed more pro-environmental attitudes and behaviors and more liberal political values. Future longitudinal studies can build on the strengths of these two approaches by combining children's and parents' responses to standardized survey measures with observations of children's interactions with the natural world at repeated points in time.

Pivotal Processes in Child Development

Although SLE research identifies experiences associated with appreciation and care for nature in later life, it sheds limited light on why these experiences have lasting influence. It has not yet predicted outcomes based on well-established processes of child development and child-environment relationships and then observed whether the predicted results occur. This Chapter seeks to build a foundation for research of this kind by proposing that key experiences identified in past studies are not surprising: they represent basic processes of learning agency in the world, learning what to notice and value, and developing a self-identity related to the environment. This section proposes processes of child development that may underlie existing findings.

Agency and a Sense of Competence

Theories of agency suggest why people frequently remember childhood play in nature as a meaningful experience, as the natural world is rich in opportunities for children to develop agency and a sense of competence. In a classic paper, White (1959) identified a strong intrinsic motivation in humans and other animals to exercise autonomous agency and experience competence in engaging with the environment. Intrinsic motivation and agency are also core parts of the self-determination theory of Ryan and Deci (2000). Defining intrinsic motivation as "the inherent tendency to seek out novelty and challenges, to extend and exercise one's capacities, to explore, and to learn," they noted that relating to the environment in this way fosters feelings of vitality, competence, and self-esteem, which contribute to a general sense of well-being (Ryan & Deci, 2000, p. 70). They observed that intrinsic motivation and agency are facilitated by environments that offer optimal challenges: not only repetition of what a child can already do but opportunities to take the next attainable step. Other important elements of supportive environments are feedback that offers clear evidence of achievement and people who give positive evaluations and encouragement.

Synthesizing a large body of research regarding the development of a sense of self-efficacy, or people's belief in their ability to achieve personally valued goals, Bandura (1997) came to similar conclusions. Above all, people experience this healthy sense of efficacy or competence when they enjoy mastery experiences and demonstrate to themselves and others that they can be successful. When they achieve significant goals by working with others, then a sense of self-efficacy combines with a sense of collective efficacy, with feelings that we did this together and I contributed my part. Other supports for self-efficacy are coaching and encouragement from others, reassurance that feeling stressed or anxious in undertaking daunting challenges is normal rather than a sign of inadequacy, and seeing others with whom one identifies achieve desired aims (Bandura, 1997).

The ecological approach to perception and action of James Gibson (1979) also emphasizes the importance of agency, with close attention to relationships between

an organism and its environment. According to Gibson's theory of affordances, the opportunities for experience and action that an environment offers depend equally upon the physical features of a place and the capabilities of an organism. A tree affords climbing for a child, for example, only if its lowest branches are within her reach and she has the strength to pull herself up. Therefore, as children explore the environment, they simultaneously learn about the characteristics of the world and their own capabilities.

Viewed through the lens of these perspectives, the natural world is filled with opportunities for engrossing and exhilarating experiences of agency that sustain intrinsic motivation (Chawla, 2007). In Ryan and Deci's (2000, p. 70) words, it is full of "novelty and challenges, to extend one's capacities, to explore, and to learn." As children play in nature, they can select optimal challenges for themselves – and each success is a mastery experience. As they dam a stream or build a fort, the environment provides clear feedback about their abilities, and when they accomplish goals together, they experience a sense of collective as well as personal efficacy. Given the centrality of intrinsic motivation and autonomous agency for healthy functioning, vitality, and wellbeing, it is not surprising that childhood play in nature emerges as a significant experience.

Social Modeling and Apprenticeship

When people in SLE studies identify influential adults in their childhood, they commonly describe them as role models of appreciation and care for nature, who notice and talk about plants, animals, and places and introduce the child to stewardship practices. These stories suggest processes of social modeling, joint attention, perspective taking, direct instruction, and practice in helping skills that have been associated with the development of prosocial and, by extension, pro-environmental behaviors. By watching what others do, engaging with others in joint attention to things and events in the world, and acquiring skills through apprenticeships, children learn what others around them consider important in the natural world, how to respond, and how to engage with nature with competence and care.

According to the social learning theory of Bandura (1986), people learn by observing others as much as through their own exploration, and this extends to learning emotional responses and socially approved ways of interacting with people, animals, and objects. A child is more likely to pay close attention and reproduce what another person does if this person has pleasing characteristics and she is doing something functionally important that gains benefits and if the child finds imitation rewarding. Rewards can be intrinsic, through the pleasure of the action itself and the sense of competence and achievement it engenders, or they can be material gain or social approval. The role models identified in SLE research have influential characteristics. As family members, teachers, or mentors, they spent extended time with the child or youth, who had many opportunities to observe them, and they commonly engaged in rewarding actions and expressed emotional warmth and approval.

In the body of SLE research, people often describe episodes of joint attention with role models. Joint attention happens when two or more people notice the same thing with a mutual understanding that they are sharing this experience, and it is central to

learning what other people consider worth noticing and how to respond (Carpenter & Liebal, 2011). It is not only one-directional, with a child learning from others. At its best, it happens when an adult or friend directs a child's attention to an object in nature as something worth stopping to watch and appreciate, *and* when others enjoy something that a child points out, affirming the value of the child's interests.

Joint attention and social modeling combine when children participate in apprenticeships and learn a set of skills through shared activities under the guidance of someone more experienced (Rogoff, 1990). Through this involvement, children gradually develop competence to take responsibility for this activity themselves, at the same time as they learn the activity's meaning and value in their culture. Many significant experiences that people remember involve apprenticeships in the environment under the guidance of family, teachers, or other adults, such as farming, gardening, camping, fishing, and bird watching (Bixler, James, & Vadala, 2011; Chawla, 1999). Through these activities, young people develop competence in the natural world.

Sympathy and Stewardship

Empathy is an innate tendency to apprehend the feelings of another creature by experiencing similar feelings, such as when a baby exhibits distress when someone nearby cries (Hoffman, 2000). As young children begin to distinguish the feelings of another from their own, adults need to help them extend their innate capacity for empathy to sympathy, which combines awareness of others' feelings with concern for their situation, and to encourage the disposition to help (Eisenberg, 1992). Adults do this by demonstrating caring behaviors themselves, showing that they value expressions of kindness, giving their child instruction and practice in helping skills, and encouraging social perspective taking when they ask their child to imagine standing in another's place (Eisenberg, 1992). Without this guidance, children may act detached or seek to escape the scene when they witness another's suffering or need (Eisenberg & Eggum, 2008).

Similar processes appear to foster the development of empathy, sympathy, and care for non-human animals and elements of the natural world (Chawla, 2009). When young children imitate animals' gestures, facial expressions, and vocalization with similar body movements and emotions of their own, Myers and Saunders (Myers Jr. & Saunders, 2002) hesitate to use the term "empathy" for children's responses – given the difficulty of interpreting animal behavior accurately – but they propose the related concept of "cofeeling." Gebhard, Nevers, and Billmann-Mahecha (2003) found that young children also tend to attribute emotions to trees. Several researchers have proposed that when adults encourage children's perceptions of similarity between themselves and other living things, they create a basis for active care for nature and a belief that the natural world has moral standing (Chawla, 2009; Gebhard et al., 2003; Kahn, 1999; Melson, 2001; Myers 2007; Myers & Saunders, 2002).

Environmental Identity

Whether a person develops an identity as someone who is part of nature, deeply connected to it, and committed to conserving and protecting it, is another important

environmental orientation. One facet of this orientation is what Thomashow (1995) and Clayton (2003) call an ecological or environmental identity. As they define it, an ecological identity involves people's feelings, values, and understanding regarding their relationship to the Earth and all living things, and it reflects their personal history of engagement with nature and often their emotional attachment to a particular place. They note that people who report feeling connected to nature typically have an extensive history of nature experiences.

Although people who express an ecological identity tend to report taking personal actions for the environment (Clayton, 2003), Kempton and Holland (2003) claim that sustained and organized action for the environment requires a social environmental identity, when people integrate membership in an environmental group into their self-identity. This may be a general self-definition, such as "environmentalist," "naturalist," or "animal lover," or identification with a specific group such as Friends of the Earth or the Sierra Club. Through group activities, the cultural world of environmental action becomes more salient, people identify themselves as actors in this world, and they gain practical knowledge about how to act effectively. Kempton and Holland's (2003) emphasis on a social environmental identity for sustained environmental action is consistent with the importance of environmental and nature-based organizations in many SLE studies (Chawla, 1999; Ceaser, 2015; Colvin Williams & Chawla, 2015; Fisher, 2015; James et al., 2010), including studies with adolescents and youth (Arnold et al., 2009; Sivek, 2002). These studies indicate that a social environmental identity, as well as an ecological identity associated with direct engagement and connection with nature, can begin to develop in childhood.

Significant Life Experience Research in the Context of Family Nature Clubs

The second part of this Chapter shares an evaluation of FNCs that apply SLE results by making three formative experiences available to children and their parents: time in nature, role models of nature appreciation, and membership in a nature-based organization (referred to as the youth nature triad for ease of reference moving forward). Taking many forms depending on their context, FNCs are community-based organizations that regularly bring families together to enjoy the benefits of time spent in nature (D'Amore, 2016). Some FNCs are small, while others are quite large; some meet at the same place each week, while others make a point of going to a new place for each gathering; some are focused on education, while others are focused on free play; some are run by a parent volunteer, while others are part of a larger organization's mission (D'Amore, 2015). FNCs can be adapted to diverse community interests and conditions.

FNCs are part of a growing movement to reconnect people with the natural world (D'Amore, 2015). The Children & Nature Network (C&NN) is a leader in this international movement and promotes FNCs as a form of self-replicating social change that can help to scale up family and community engagement with the natural

environment. At this time, there are over 275 FNCs registered with C&NN, the majority of which are in the United States.

A long-term longitudinal study would be required to assess how participation in an FNC as a child impacts environmental behavior as an adult. However, FNC participation has the potential for a number of near-term effects, including changes in time spent in nature and household environmental behavior as well as a sense of connection to nature, individual and family wellbeing, sense of community, and social engagement. From 2014 to 2015, one of this chapter's authors conducted a study to understand FNCs and the near-term effects of participation in these organizations (D'Amore, 2015). Her sample drew from FNC leaders and adult participants in six countries, primarily in the United States and Canada. Other countries included New Zealand, Peru, Germany, and England. All study participants were asked to complete an in-depth survey, and the FNC leaders were invited to also complete an interview based on the most significant change (MSC) technique (Dart & Davies, 2003). In her community of Columbia, Maryland, she created the FNC named Columbia Families in Nature (CFIN) as a case study for this research. After each family's first CFIN event, they were invited to take an initial survey. The researcher also recorded direct observations of family participation in each event. After attending six events, CFIN parents were sent a post-survey that included questions about their club experiences. The parents that complete the post-survey were invited to participate in an in-depth interview based on the MSC technique. As a comparison group, parents who expressed interest in CFIN but never attended were sent a shorter version of the pre-survey given to other parents after attending their first event. This combination of quantitative and qualitative methods, shown in Table 1, facilitated the exploration of FNCs from multiple triangulated perspectives. For the surveys and full descriptions of the samples and methods, see D'Amore (2015).

Quantitative survey analysis was done using Excel for descriptive statistics and t-tests and Python for regression analysis. The significance threshold was set at .05. Qualitative data from interviews and open-ended survey questions were analyzed using an open coding process to identify common themes (Patton, 2002). This Chapter reports on portions of this study relevant to SLE research. The data and analyses that this section presents cover participants' experiences in nature in childhood and youth, family time spent in nature, sense of connection with nature, and pro-environmental behavior.

Youth Nature Experience Triad

The surveys administered to FNC leaders and adult participants included three statements drawn from the "youth nature experience triad" found in past SLE research: (1) playing outside in nature was an important part of my childhood; (2) as a child, there was at least one adult (parent, grandparent, etc.) that spent time with me outside and helped teach me an appreciation for nature; and (3) during my youth, I participated in an organization that had a nature and/or environmental

Table 1 Study methods and samples

	Participants	Methods
Overview of FNCs	FNC adult participants $N = 170$	28-item survey
	FNC leaders $N = 52$	28-item survey
	FNC leaders $N = 20/52$	Most significant change interview
	FNC leaders and adult participants $N = 190$	Effects validation survey
Case study of CFIN	Club parents $N = 81$	24-item pre-survey
	Club parents $N = 29/81$	18-item post-survey
	Club parents $N = 28/29$	Most significant change interview
	Parents in comparison group $N = 45$	20-item comparison group survey
	Participant observer of 133 club families at 31 outings	Informal conversations, field notes, reflexive journal, photographs, archive of club history

focus. Participants were asked to score each statement along a five-point scale from strongly agree to strongly disagree. A total of 337 study participants completed this section of their surveys (Table 2).

FNC leaders were most likely to state that playing outside was an important part of their childhood (95%) and that they had a role model for nature appreciation (68%). FNC participants also indicated that playing outside was an important part of their childhood (83% for the FNC sample, 80% for CFIN pre-survey respondents); and slightly more than half stated that they had a role model for nature appreciation (56% for the FNC sample and 59% for CFIN pre-survey respondents.) The response rate for involvement in a nature-focused organization was similar for FNC leaders (46%), FNC participants overall (46%), and CFIN pre-survey respondents (41%).

Group responses were compared using a two-tailed, type-three t-test (Maxim, 1999). FNC leaders ($n = 52$) were significantly more likely to agree with the statement that "playing outside in nature was an important part of my childhood" than FNC participants including CFIN pre-survey respondents ($n = 242$, $p = 0.001$) or the control group of parents ($n = 43$) who expressed an interest in CFIN but never attended ($p = 0.0035$). There was no significant difference between the participant and control groups ($p = 0.307$). There were no statistically significant differences between these groups' responses with regard to having an adult who spent time outdoors and taught appreciation for nature when they were young. For the prompt "during my youth, I participated in an organization that had a nature and/or environmental focus," FNC leaders were significantly more likely to agree than FNC participants (the FNC overview sample as well as those in CFIN ($p = 0.0226$).

Table 2 Youth nature experience triad response comparisons ($n = 337$)

	FNC leaders	FNC participants	CFIN post-participants	CFIN pre-participants	CFIN comparison
Respondents	52	162	28	80	43
Playing outside	[a]**95%** [b]**3.73**	[a]83% [b]3.36	[a]68% [b]2.96	[a]80% [b]3.26	[a]82% [b]3.14
Adult role model	[a]68% [b]2.83	[a]56% [b]2.48	[a]50% [b]2.25	[a]59% [b]2.55	[a]58% [b]2.49
Nature organization	[a]46% [b]2.27	[a]46% [b]2.19	[a]64% [b]2.46	[a]41% [b]2.24	[a]56% [b]2.40

[a]Percentage is derived from adding "generally agree" and "strongly agree" responses
[b]The average weight is a zero-to-four scale with four indicating a stronger agreement response

The youth nature experiences of the entire study population were analyzed as an independent variable that may influence other response variables. Linear regression was used to test the relationship between the responding parent's youth nature experience triad and current family time spent in nature, sense of connection to nature, and environmental behaviors. For this analysis, all survey respondents (FNC leaders, FNC participants, CFIN pre-survey respondents, and CFIN nonparticipants) were aggregated. For current family time spent in nature, there was a positive, but not statistically significant, relationship with youth nature experiences ($n = 318$; $p = 0.077$). There were statistically significant relationships between youth nature experiences and an individual's sense of connection to nature ($n = 306$; $p < 0.001$) and level of environmental action ($n = 314$; $p = 0.03$). Mayer and Frantz's (2004) five-item connectedness to nature scale was used to measure sense of connection, and Canada's household and environmental green index (Statistics Canada, 2009) was used, in part, to measure household actions, such as recycling, turning off lights, and buying organic or local foods. Although current family time in nature did not have a statistically significant positive relationship with club leaders' and parents' nature experiences in youth, it trended this way ($n = 318$; $p = 0.077$).

Family Time in Nature

A total of 353 people completed survey questions about how frequently, and for how long, their families spent time in nature together (FNC leaders and participants, respondents to the CFIN pre- and post-surveys, and the CFIN comparison group). FNC leaders went out in nature with their families most frequently, with 33% saying they went out daily and 31% saying they went out two to three times per week. For the other groups, their most common frequency was two to three times per week (32–38%). CFIN nonparticipants reported the lowest frequency of family time in nature, with 47% saying they went out once a week or less. The study group that spent the greatest quantity of time in nature was also FNC leaders, with 28% spending more than 8 h of family time in nature per week and another 46% spending between 3 and 7 h. Other participants were most likely to say they spent 3–7 h in

nature in a week (38% of FNC participants, 53% of CFIN pre-survey respondents, and 50% of post-survey respondents). CFIN nonparticipants had the lowest quantity of family time in nature of all the groups, with 63% indicating that they spent 2 h or less in nature each week. The quantity of time spent in nature by club leaders and participants is remarkable when it is compared to estimates that the average child in the United States engages in 7 min or less of unstructured outdoor play each day, which equates to less than an hour a week (Juster & Thomas, 2004; Rideout, 2010).

Ordinary linear regression was used to determine relationships between current family time spent in nature, connection to nature, and environmental action. For this purpose, respondents consisted of FNC leaders and participants, CFIN post-survey respondents in order to reflect the effects of club participation, and the comparison group. There was a statistically significant positive relationship between family time in nature and sense of connection to nature ($n = 249$; $p = 0.007$) as well as environmental action ($n = 256$; $p = 0.021$).

Taken together, the quantitative survey data show that people who lead, join, or even express an interest in joining an FNC frequently report that playing outside in nature was important to them as a child – and this is especially true of club leaders. More than half of the survey respondents also stated that they had adult role models in nature – with this, again, most characteristic of club leaders; and 41% to 56% reported that they participated in an environmental or nature-based organization in youth. People who were more likely to report these experiences in childhood and youth were also more likely to report a sense of connection to nature and pro-environmental household behaviors in adulthood. Although the relationship between these experiences and current family time in nature was not statistically significant, it was positive and approached significance. Club leaders spent the most weekly time in nature with their families and parents in the comparison group the least amount of time. The more family time in nature that respondents reported, the more they were also likely to report feeling a sense of connection to nature and performing pro-environmental behaviors.

Qualitative Survey and Interview Data

In addition to quantitative questions, all the surveys included narrative prompts designed to solicit descriptions of club experiences and their personal meaning and effects. 145 people responded to the question, "What has been particularly meaningful for you and your family with regards to your participation in a family nature club?" Each response was reviewed and coded for emerging categories of effects, with most responses indicating multiple effects. Table 3 presents the 13 most common effects in their order of frequency. Although the question allowed people to share negative as well as positive effects, all reported effects were positive.

It is striking that many of the effects that parents identified related to the experience that SLE research most commonly associates with environmental interest and action in adulthood: free play and exploration in nature. The value of time in

Table 3 Analysis of narrative responses regarding effects of FNC participation. ($n = 145$, with some people giving multiple responses)

Description of effect	Responses per effect
1. Sense of community (shared values, like-minded people, friendships)	31
2. Spending time outdoors and learning about new places	28
3. Fun/interest/friendships (variety, novelty, adventure, other kids/ parents)	27
4. The opportunity to learn something new	27
5. The opportunity to get to know new people	22
6. An enhanced sense of connection with/comfort in nature	20
7. Opportunities for free play (independence, creativity, exploration)	16
8. A greater sense of connection with family	15
9. The passion, knowledge, guidance of the leaders	12
10. Norming/increased confidence/improved child behavior	10
11. Sense of accomplishment/wonder/break from the norm	9
12. Taking care of environment/nature	5
13. Sense of safety/presence of other adults	4

nature is suggested by themes shared by study participants such as "spending time outdoors and learning about new places"; "fun, interest, and friendships"; "the opportunity to learn something new"; "an enhanced sense of connection with/ comfort in nature"; "opportunities for free play"; and "sense of accomplishment/ wonder/break from the norm." Together, these responses account for 127 out of the 226 responses listed in Table 3 or 56%. Parents did not specify whether they were referring to effects that they observed in their children or themselves. Based on direct observations of the researcher, most likely, their responses reflect both.

Parents did not specifically write about opportunities to serve as role models of appreciation for their children – another part of the youth nature experience triad, but by registering their family in the club and enjoying experiences in nature along with their children, they stepped into this role. When Chawla (2007) analyzed what environmentalists remembered influential family members in their childhood doing, parents and other family members were most commonly remembered as giving attention to elements of nature, with evident fascination and appreciation, or simply sharing pleasure at getting out into nature. These are the types of behaviors that the FNCs encourage in parents. For many parents, being in nature together also brought "a greater sense of connection with family."

It is also striking that what parents wrote about most often was the "sense of community" that they developed in their club. This benefit is also implicit in "the opportunity to get to know new people," the friendships in "fun/interest/friendships," and the "sense of safety/presence of other adults." Whereas time in nature on club outings was intended to provide the history of personal engagement with nature and relationship to the earth that are associated with the development of an environmental identity, for many parents, their club also provided the group identity that is important to an emerging social environmental identity (Kempton & Holland,

2003). This came as part of joining a nature-based organization with their children, the third part of the "triad." Comments about "the passion, knowledge, and guidance of the leaders" and "taking care of nature" showed appreciation for the clubs' leadership and structured stewardship activities.

In the narratives that Table 3 summarizes, many parents described processes of development that have been implicit in past SLE research: experiences of agency and competence, social modeling and apprenticeships, stewardship, and a sense of environmental identity. For example, parents shared that significant effects of their FNC participation included:

- "My children and I are gaining so much by being so involved in our natural world. We have grown emotionally, socially, spiritually, intellectually and I have watched my children's self-confidence and focus increase and anxiety and stress decrease." (P#130)
- "My daughter has an innate interest for the flora and fauna present in nature. Participating in nature club activities reinforces her strong bond with nature." (P#22)
- "Not being a particularly 'outdoorsy' person myself, doing activities with the nature club really helped me to observe other parents interactions and setting limits in nature and it helped me 'loosen up' a bit! Also, it helped me gain confidence to do more with my kids on my own outside of the club." (P#41)
- "We have all learned incredible amounts of information about our local ecology and have made many connections within the community who share our same conservation goals. It is empowering and inspiring for everyone in our family but especially for our children. It gives them hope and incentives to change the world instead of the hopelessness that comes with watching news and nature shows reporting only doomsday predictions." (P#156)
- "Having the opportunities to go out as a family (vs being split up as would happen in scouts, say) and enjoy the company of other like-minded families and to learn about nature. The boys learn so much from other children and engage in activities that they wouldn't if it was just our family." (P#158)

CFIN parents also described these processes in their interviews about the most significant changes that they and their children experienced during club outings, and D'Amore was able to observe these processes as the CFIN leader and participant observer and record them in her field notes. The following section shares some of this material from the CFIN case study. It illustrates each developmental process through quotations from the survey narratives written by CFIN parents, their comments during outings, and their significant change interviews.

Columbia Families in Nature Case Study

For the purposes of her research, in March of 2014, D'Amore began offering Columbia Families in Nature (CFIN) outings to her community in central Maryland, along with her husband and two young children. On at least two Sunday afternoons, a month of CFIN outings were offered at nearby natural areas. By connecting

families with nature, the primary goals of CFIN were to foster greater connection with nature and the community, increase environmental awareness and action, support the wellbeing of participants, and help strengthen family relationships.

31 CFIN outings were held in 2014 at a variety of natural areas, including public parks, farms, gardens, wildlife sanctuaries, and community open space trails, with few repeat visits. The foci of each 2-h outing were also diverse, ranging from free exploration and play to active hikes to structured, conservation-focused events, such as tree planting and garden creation. A total of 133 distinct families participated in these 31 CFIN outings, with an average of 15 families attending at one time. (Another 52 families registered to participate in CFIN, but never attended an event, forming this study's control group.) As the leader for CFIN, co-author D'Amore was able to make close observations of participants' experiences during these events and compare these observations, as well as participants' feedback via narrative surveys and interviews, with the pivotal processes in child development suggested by existing SLE findings.

Agency and a Sense of Competence

For many families, CFIN offered their first experience walking through a meadow, wading in a stream or river, foraging for wild edible plants, exerting themselves on a hike, planting native species, or camping. On the other end of the spectrum, some families were seasoned explorers, with parents who had taught in Outward Bound and had already brought their young children backpacking. Observations during outings as well as parents' written and verbal feedback indicated that club participation provided children, parents, and families as a whole many opportunities to feel agency and competence. General feedback such as "our family has developed new confidence in exploring nature," "we have learned that we can do more outside than I thought we were capable of," and "we have gone to great places that we would not have ventured to on our own" were common themes.

According to the self-determination theory of Ryan and Deci (2000, p. 70), a person experiences feelings of vitality, competence, and self-esteem when he or she has autonomy "to seek out novelty and challenges, to extend and exercise one's capacities, to explore, and to learn." According to Bandura (1997), the most potent way to develop a sense of efficacy is to undertake a meaningful challenge and experience success. Parents observed that children enthusiastically enjoyed the novelty and challenges that nature play afforded. For example, one CFIN mother shared:

> I have never let my son play in a creek or river or anything like that before. I wouldn't have known if it was allowed, or safe, or what to do. So, for us this outing was a big deal, and he LOVED it! He seemed so happy and content and excited and interested and didn't want to leave. We've been talking about where else we can go to play in natural water this summer, it is his new favorite thing, so much more interesting than a pool, with all the rocks and sticks and critters to look for.

Another mother observed about her daughter: "I can see the things she enjoys doing, not just walking but stopping and looking, throwing sticks and climbing on rocks. She likes to do it with other kids and now she gets that going out in nature can be fun."

As parents witnessed their children's achievements, they felt more comfortable with allowing the autonomy that self-determination and mastery experiences require: "It is kind of awesome to see what he can do when he is outside. I think that it has done a lot for his confidence in new situations and to a certain extent mine as well. Certainly, he has shown me he can do stuff that I didn't know guys his age could do." A mother said about her daughter, "She definitely wants to be outside more, and I feel more comfortable with letting her be outside more by herself because now I know she knows how to handle herself outside." Some CFIN parents had significant nature-based experiences prior to having children, whereas others had few. Based on the researcher's observations, the opportunity for intergenerational outdoor exploration and learning helped parents across this spectrum witness and encourage their children's independent relationship with nature.

Nature outings engaged parents as well as their children in new experiences of agency and competence:

> You can see on some of the more ambitious hikes people feel like they have never quite done something like this before. I think that is an amazing thing because you find out that the journey isn't just going out there, it is also the internal journey. You are moving the map of your own self at the same time as you are moving on the map. And I have seen folks definitely finding that. When you can see them get to the top of that thing and they are kind of glowing a bit. They have dug a little deeper, both in terms of their comfort zone of where they are willing to go outside and what they are willing to subject themselves to. Those are great lessons.

As another parent said, "The way back was tough, but we worked together as a family and are proud that we were able to do it!" As parents observed their children's abilities and had mastery experiences of their own, they began to take their children into nature more often outside of the club: "Getting out to CFIN outings helps me be able to go out to more places with [my son] more often and for longer because now I have more knowledge of where to go and what to do."

Social Modeling and Apprenticeships

Opportunities for shared attention, social modeling, and learning were built into all the CFIN events (D'Amore & Chawla, 2017). Parents were encouraged to slow down and explore with their children. The leaders and occasional guest guides modeled desired behaviors, such as being respectful of plants and animals, being curious, having fun, helping one another, and picking up trash. Most events included educational opportunities such as a scavenger hunt of things to look for during exploration, taking out a field guide to identify a plant or animal, or a guest speaker who shared wisdom about a topic like animals or edible plants.

Parents expressed appreciation for both the attention to details of nature that the club leader and guest guides encouraged as well as the sense of safety that they provided:

> I spend a lot of time out in nature with my kids, getting exercise and letting them play. But there is something about going out on these CFIN outings where we see nature with deeper eyes than we do when we are just out by ourselves. Maybe it is because I am not alone with my kids and solely responsible for them, maybe it is because the leader makes a point of drawing our attention to neat things, like the praying mantis egg cases today. Either way, we all come away feeling more grounded and connected to nature than we do during a lot of other outdoor time.

Many parents made similar remarks. One parent noted that instead of just going outside for exercise and fresh air, her family learned about "really engaging with the environment and learning about different things and different seasons of the year." She explained, "Because you can kind of just bypass everything in nature when you are just going for a walk and you're like, 'Oh, it's pretty out,' but you don't really see the details. Now we do more." Another parent noted: "We used to walk down to the river, look at it and walk back up. Now we actually take the time to look at the different plants and pick up these little shells. Now we are actually involved."

As families learned to notice and understand elements of nature from the club leader or guide, they began to share what they learned with each other and from child to child. This was some of the richest organic learning that took place during CFIN events. "It was great to learn a bit more about some of the native plants today. We learned about wineberry, raspberry, and blackberry and can tell the stems apart now. My daughter watched the trout lily for ages and can point out May apple now." Children also began to teach each other. A mother said about her daughter, I "enjoyed watching her explain to a friend the difference between a thorny plant and another plant that could be touched without getting pricked."

In addition to directing participants to notice details of nature, the club leader served as a role model for more confident and permissive parenting in nature:

> Going out on different outings with you has helped us to get out and explore things differently than we necessarily would have and we have also explored different areas that we haven't ever been to before. She also likes being outside and dirty more than she used to before. I have to catch myself sometimes because I will start to say, "Oh, be careful you're going to get dirty," but then I remind myself it is okay for her to get dirty.

Parents also learned new parenting norms by observing other families: "It is just nice to be out with other families and see people interact with their kids and how they encourage them in different activities. Now I give her more leeway."

On some outings, the club leader and invited guides involved families in apprenticeship activities that combined joint attention, social modeling, and instruction to demonstrate how to care for places they visited. Activities included learning to distinguish native and nonnative plants, pulling invasive weeds, planting trees, and

planting butterfly habitat. Because these activities were deliberately intended to cultivate stewardship skills, they are covered in the following section.

Sympathy and Stewardship

One of the primary goals of CFIN was to increase the environmental awareness and action of participants. This included fostering a sense of sympathy and stewardship toward nature. All CFIN events sought to impart sympathy for other living things. Participants were taught to consider when it was appropriate to leave the trail and explore and when fragile plants would be damaged by such wanderings. The appropriateness of picking plants was discussed: "If you can count more than 100 of something it is ok to pick one, but do not pick things that are not as plentiful," and when participants did pick something, "do not rip plants out by the roots, it hurts them like it would hurt to pull your hair out." Any animals found during exploration were noticed with care and protected from harm. When environmental damage was evident, the potential cause and remedy were discussed.

Many CFIN outings involved families in stewardship actions that were designed to teach skills such as tree planting, planting native plants, and removing invasive weeds. These activities had the elements of apprenticeships, as they involved the club leader or an invited expert who explained the importance of the project and how to perform it effectively and then guided families in their work. In most families, parents as well as children were learning new skills, and this work appeared to increase their connection to the places where they labored: "Planting trees was a totally new experience for the kids as well as us and it was hard work. We enjoyed working together on this positive project. I took a few before and after pictures and think we will come back each year and follow the tree's growth."

These activities were intended to help families feel empowered rather than helpless when they learned about environmental problems. For example, after a visit to a nature center where a guide explained the life cycle of monarch butterflies and monarch caterpillars' dependence on milkweed plants, families engaged in planting milkweed and other native plants. A parent explained that this changed what she and her child noticed in their surroundings at the same time as it showed them the positive role that they could play:

> To have an awareness now of native versus invasive plants and animals is also amazing, because before we started doing the hikes with you I had no idea about that stuff. Now I am so aware of it. When I walk around and I see the plants that we have and the ones the neighbours have, so many are not native and we are going to set up a garden that is good for butterflies soon. The kids are really excited about the milkweed and the monarch butterfly and helping them.

Another parent noted her family's growing sense of confidence it their action capabilities: "The being outside part is important and good, but we are also really appreciating the knowledge that we are gaining. But at the same time we are appreciating a bit more that we don't have to be experts to get our hands dirty and

do something – we are feeling braver." On one outing, families shared what they had learned by gathering at a member's house to prepare a butterfly garden together.

Several families talked about integrating what they learned into their household life: "Participating in CFIN has stimulated us to do more around our own home, to take care of our yard and the piece of land that we can care for. Especially since we went to the native planting event at the lake we are really aware of this. Instead of just picking plants that are pretty we want to think about what is local, and what is beneficial for animals and the planet." Another parent noted: "In the spring we were talking about trying to get some weeds up and our daughter is so aware of stuff now she said, 'We can't use pesticides because of the earth worms in the ground.'" A mother shared that she and her husband deliberately tried to make connections between the beautiful woods and water bodies that they visited and daily actions: "Then we can tell them this is why we turn our faucets off when we are brushing our teeth, this is why we recycle our mail once they can start to make that connection."

Environmental Identity

CFIN strove to cultivate families' environmental identity by offering opportunities for them to develop a personal history of engagement with nature and an emotional attachment to natural areas in their region. Parents' remarks suggested that emotional attachments were forming through stewardship activities: "It was interesting to see how excited our daughter was to get involved in planting the native species. Then when we went to throw the seed bursts into the fields, she was going on and on about how people don't notice how beautiful nature is and how much of a gift it is!" At the same time, emerging social environmental identities as members of the club appeared to be meaningful for many. Just as FNC parents overall identified a sense of community as a major effect of club participation, many CFIN parents believed that doing stewardship activities together contributed to their sense of community. A parent noted, "My son likes being a volunteer with the group, being outside and enjoying nature while helping the community." Parents expressed this sense of belonging for themselves as well: "I appreciate belonging to a solid group of people with like interests regarding nature, people who are definitely interested in preserving and caring for nature."

One parent connected an environmental identity as a sense of connection with nature to this social environmental identity with particular eloquence:

> I feel like I am starting to notice how much we benefit from feeling part of something bigger. That this is our planet, this is our community, we coexist with all of these species. It teaches you a lot about life, about yourself, and about the life cycle. There are so many lessons you can teach the kids with nature. The more we are outside the more we realize this importance of taking care of the environment. You can learn so much from just being outside and seeing that we are coexisting and we all need to take care of each other. One thing I have really found is that I need that community connection and that environment connection. I need to feel like we are a part of something bigger.

Her statement showed that she understood CFIN's linked goals of fostering greater connection with nature and with the Columbia community.

Conclusion

Since Tanner (1980) initiated the field of SLE research, generally consistent findings have emerged. People who express connection with and concern for nature and who act to protect it, across a broad range of actions, commonly have childhood experiences of play and exploration in nature, influential role models and books, and participation in nature-based or environmental organizations, and they often witness the destruction of a valued natural area. The salience of different experiences varies study to study, with the exception that time in nature in childhood is a consistent thread across almost all studies. These findings reflect what basic research in child development would predict.

Connecting with the natural world affords children opportunities to fulfill their intrinsic motivation to explore and master challenges, with abundant attractions for all senses. Given the centrality of experiences of autonomous agency for human vitality and well-being and a sense of competence and self-esteem (Bandura, 1997; Ryan & Deci, 2000), it is not surprising that play in nature leaves vivid memories and lasting effects. Research on joint attention, social modeling, and apprenticeships suggests how adults may influence children in lasting ways as they demonstrate appreciation and care for nature, encourage sympathy for other living things, and teach conservation skills. Together, personal engagement with nature and identification with other people who take action to care for nature, often through membership in organizations, contribute to the formation of an environmental identity. The results of SLE research are generally consistent across studies and consistent with child development theory.

FNCs are designed to embody results of SLE research in the form of a "triad" of childhoodnature experiences: regular time in natural areas, role models, and participation in a nature-based organization. The research on FNCs summarized in this Chapter demonstrates yet another way in which this "triad" of early experiences influences environmental action. Nature club leaders almost universally reported that play in nature was important to them in childhood, and this experience was shared by most parents who participated in clubs or even expressed an interest in enrolling. The majority of leaders and parent members also had an adult who taught them appreciation for nature in childhood, and about half or more belonged to an organization with an environmental focus in their youth. This evaluation of FNCs also shows that people with these experiences in childhood and youth were more likely to feel a sense of connection with nature and engage in pro-environmental behaviors as adults. This chapter extends SLE research into a new area of environmental action: in this case, leading and joining FNCs.

Many environmental organizations bring children out in nature under the guidance of adult role models and engage in conservation activities, but few involve whole families. Park interpreters see families, but they typically see any individual family only once. FNCs are unique in encouraging parents to join with their children in nature, serve as role models of appreciation for what they find together, and feel comfortable in their skills to explore nature and demonstrate stewardship. This study suggests that nature clubs often attract people who have already had positive

experiences in nature in their own childhood; but once they are together, club leaders and parents build a foundation for the next generation to form its own connection with nature and know how to act to protect the natural world.

In the past, SLE studies identified childhood play in nature as a solitary activity or something enjoyed with a few playmates. In FNCs, it becomes a collective social experience: potentially a foundation for a social environmental identity (Kempton & Holland, 2003) as well as an ecological identity (Thomashow, 1995). A new direction for SLE research in the future can be longitudinal studies to track the influence of FNC participation on children's developing environmental identities and behaviors. This Chapter also suggests that SLE research will be strengthened if it draws on basic theory and findings in the psychology of child development to understand why recurring experiences that it documents have a formative influence.

Abstract

How do globally mobile children, especially *Third Culture Kids* (TCKs), with their mobile lifestyles, form their environmental identities? Through their many relocations, they are constantly in a state of flux in their ever-changing lives. Therefore, as these expatriate children move in and out of various countries,

cultures and schools, they may experience significant life experiences (SLEs) and learn who they are within their prevailing/temporary culture.

The nature of challenges faced by TCKs, the role international schools play in environmental identity formation and the creation of childhoodnature experiences in TCKs will be explored through my own lived experiences as a TCK. By framing an autoethnographical exploration of SLEs as a globally mobile child through photographs and poems, I will illustrate my own lived childhoodnature experiences growing up as a TCK in international schools in eight different countries before the age of 18.

Myers (1997) and Chawla (1998) identified the importance of both the *outer environment* of the physical and social world, and the *inner environment* of people's own interests and feelings. Consequently, they recommended that additional research was needed exploring the influence of the *inner environment* in shaping an individual's SLEs.

For TCKs, this *inner* environment is critically important in shaping their SLEs but sadly, within international schools, this is often overlooked. To support TCKs in achieving much needed harmony, support, stability, understanding, and attain a sense of belonging, strategies will be identified to assist staff and students of international schools.

Introduction

> When we are no longer able to change a situation, we are challenged to change ourselves.
> – Viktor Frankl (2006, p. 112)

As Frankl (2006) so eloquently stated, if you cannot change your situation, then try to change yourself. In an ever-increasingly globalized world, this represents an important theme in this Chapter as creating an identity and a sense of belonging, are major challenges for Third Culture Kids (TCKs). TCKs are globally mobile children who neither grow up in their passport country nor are citizens of their host country and are therefore part of a *third culture*.

In 2015, the number of people living outside their country of origin had reached 224 million (United Nations Sustainable Development Goals, 2016), highlighting that international mobility is becoming a distinctive feature of today's society with people/families moving voluntarily or involuntarily across the globe. Due to their mobility (refer to ▶ Chap. 70, "Third Culture Kids and Experiences of Places" by Picton and Urquhart elsewhere in this Handbook), globally mobile children such as TCKs find that some of the greatest challenges they face is in creating a sense of

identity and a feeling of belonging (Bennett, 1993; Hoersting & Jenkins, 2011; Picton & Urquhart, 2018; Pollock & Van Reken, 2009).

The focus in this Chapter is on the frequent mobility of globally mobile children (TCKs) from expatriate families. For instance, this includes children of international organizations and companies, foreign embassies, NGOs, the armed forces, and charities or missionary programs. In many cases, the children of expatriate families that move frequently for work or careers are often forced to move and it is their voice that needs to be heard. It is through my own experiences growing up as a TCK in an expatriate family, attending international schools and describing my own childhoodnature experiences that I will reflect upon.

International schools represent an ideal option for expatriate families in that they cater to students who are not nationals of the host country (Wechsler, 2017). These schools provide a comprehensive cross-cultural education that immerses students in multiple languages and gives them access to a global, mobile community that is defined by its internationalism and provides a unique cultural identity. Furthermore, international schools are generally more focused upon cultural identity than on a student's birthplace (Buchanan, 2014). Globally, there are 8,600 international schools, serving 4.5 million students and employing more than 420,000 teachers. According to the International School Consultancy (ISC), demand for international schooling is rising rapidly. Thus, in the next 10 years, the number of international schools will double to more than 16,000 schools to cater for 8.75 million students worldwide (Wechsler, 2017).

For those TCKs, who relocate often with their parents, mobility is simply a part of life. These children encounter multiple cultural settings due to their frequent mobility and thus experience a cross-cultural lifestyle (Downie, Koestner, El Geledi, & Cree, 2004). By cross-cultural, I mean that they experience their host country's culture, their parents' culture, and their own *third culture*.

Most studies dealing with environmental identity has centered on traditional schools and schooling. Consequently, there is a relative dearth in research dealing with the role of international schools in the creation of a sense of belonging in TCKs (Ota, 2014), and even less about their role in promoting a TCKs' childhoodnature and significant life experiences (SLE). Thus, for TCKs, creating a sense of belonging is more complicated than for children who have lived in one place all their lives because TCKs move between cultures and countries often and therefore identity formation is a complex issue for them. Yet, both their families and the international schools that these TCKs attend can play a key role in whether a child successfully creates a sense of belonging within their new community (Ota, 2014).

Consequently, questions arise about the opportunities for expatriate children to develop an environmental identity in a foreign context, especially when frequent moves occur? In the following sections, I will discuss the context of international schools and the nature of TCKs and then apply an autoethnographical lens to reveal my life as a TCK and reflect upon how my own SLE were shaped to create the person I am today.

International Schooling and Environmental Initiatives

An international school can be loosely categorized as one that promotes international education in an international environment (Nagrath, 2011; Wechsler, 2017). This is usually achieved by following an international curriculum, such as the International Baccalaureate (IB) or Cambridge International Examinations.

One of the many great advantages of an international school is that students are more open to people from all walks of life. In the very fabric of their education, students are exposed to a multitude of cultures, languages, religions, and values. They learn how to adapt quickly to change and how to form and nourish fast friendships. This promotes a broad-minded spirit and a multicultural attitude of acceptance. Indeed, with multiculturalism and International Baccalaureate (IB) qualifications, international schools might not be traditional, but they certainly reflect the future of education in a truly globalized world (Wechsler, 2017).

The rapid growth has corresponded with the proliferation of the title *international* placed on many schools that may possibly have the veneer of being international in name only. For instance, Nagrath (2011) reports that of the 345 new schools opened in 2010, 80 (or 23%) are offering one or more of the IB programs. Yet, what about the more than 75% of international schools those are not offering that program? What international program or curriculum are these new schools offering? Do they truly represent international schools? In 2009, the International Association of School Librarianship (IASL) developed a list of criteria to describe an international school. Although not all international schools would meet all of the criteria, most would meet the majority of the following eight specified criteria:

1. Transferability of students' education across international schools
2. A moving population (higher than in national public schools)
3. Multinational and multilingual student body
4. An international curriculum
5. International accreditation
6. A transient and multinational teacher population
7. Nonselective student enrolment
8. Usually English or bilingual as the language of instruction (Nagrath, 2011)

In 2015, the International School Consultancy (ISC) estimated that four million students attend international schools in more than 8000 English-medium international schools in 127 countries worldwide, including children of all nationalities aged 6–18 years (Relocate Global, 2015). International schools and teachers follow a largely western educational curriculum, with the dominant cultural identity being American or British. In fact, many TCKs grow up speaking English with an American or British accent (Ota, 2014). In any given year, international schools can have 40+ nationalities attending their school, with yearly student turnover rates of 25% (Ota, 2014). Due to the high turnover of students, the sense of belonging and community is much more transient than in a local school. Consequently, both teachers and students live in an ever-changing and dynamic environment. With these frequent (re)adjustments to new locations, differing cultural norms and values,

Table 1 My TCK journey from birth to 18 years (Father's career sponsored by the UN)

Town	Country	Duration	School
Mazatlan	Mexico	6 months	Not applicable
Jakarta	Indonesia	4 years	International nursery
Kuwait City	Kuwait	2 years	Kuwait American
Kuwait City	Kuwait	2 years	Kuwait British
Karachi	Pakistan	4 years	Karachi American
Haarlem	The Netherlands	6 months	Marnix Lyceum
Mussoorie	India	1½ years	Woodstock International
Blantryre	Malawi	1½ years	St. Andrews International
Calgary	Canada	1 year	Winston Churchill
Amsterdam	The Netherlands	1 year	Hogere Hotelschool

and various languages and schools, TCKs often struggle to create both a sense of identity and a sense of belonging (Moore & Barker, 2012).

Furthermore, the number of environmental initiatives evident in international school's pales by comparison to local state and national schools. Some examples of national approaches: whole-school initiatives include programs such as the UK's *Learning through Landscapes (LtL)*, Canada's *Evergreen*, USA's *Green Schools Initiative*, New Zealand's *Enviroschools*, Sweden's *Green School Awards*, and ENSI's *Learnscapes* focusing on greening school grounds and maximizing the potential of these spaces for quality educational and environmental experiences (Henderson & Tilbury, 2004). Environmental action and awareness initiatives do exist in the international school community; however, they are very sporadic. One example is the Eco-schools initiative (Eco-schools, 2014) which is one of a number of environmental education programs developed by the Foundation for Environmental Education. Eco-schools encourage and engage active young people to act for the environment in preserving and sustaining it. It starts from the ground up as it begins in a class and builds through the school and aims to ultimately foster change in the community. If achieved, schools can achieve certification and be awarded a Green Flag. Eco-Schools have been running for over two decades and now reach more than 15 million students in 59 countries worldwide. However, to date, only 31 international schools in 18 countries are registered.

Consequently, in all my experiences as a TCK and during my time in international schools (Table 1), the role of the international schools in developing any SLEs in me was negligible. In fact, the main source for the development of my environmental ethos was largely driven by my parents rather than my experiences in international schools. Despite there being times, such as at the 163 year old Woodstock School (an international school which was located at the base of the Himalayas) that the significance and its location, and the surrounding majesty of the natural environment was totally lost on me, despite being the perfect setting for the development of my SLE. Mind you, as a young female at the age of 14, I was not only grappling with adolescence but struggling to make sense of my own world and where I belonged especially as a TCK in an international school in India. Furthermore, my younger brother who was about 11 years old at the time also attended the same school and

loved being in nature and has since become a staunch environmental scientist. Thus, both our experiences differed at the same school, largely because, in my opinion, I felt that issues of adolescence and feeling very lonely clouded my judgment and my view of the world. I will reflect on these issues later in this Chapter through my autoethnographic journey.

Third Culture Kids . . . *Who Are They?*

> No generation before now has had so many of its members simultaneously living in, between, and among countless cultural worlds as is happening today.
> Lois Bushong (2013)

Who and what are these TCKs? To fully appreciate the circumstances and issues faced by TCKs, it is important that the reader understands *who they are*. Based on the increasing scale of global movements of families and children, greater attention in the future will be needed to more fully appreciate and cater for the many issues faced by these globally mobile children and TCKs, to ensure a smoother transition for children into schools and also into the general community.

The concept of Third Culture Kids (TCKs) was first introduced in the 1960s by Ruth and John Useem. They:

> . . . defined the home culture from which the adults came as the first culture. They called the host culture where the family lived the second culture. The shared lifestyles of the expatriate community they defined as an interstitial culture or culture between cultures and named it the third culture. Children who have grown up in this culture are called third culture kids. (Pollock & Van Reken, 1999, p. 20)

Pollock and Van Reken (1999) defined a TCK as:

> A person who has spent a significant part of his or her developmental years living in one or more countries outside their passport country because of their parent's occupation. The TCK builds relationships to all of the cultures, while not having full ownership in any. Elements from each culture are incorporated into the life experience, but the sense of belonging is in relationship to others of similar experience. (p. 19)

However, the concept of culture is a contested concept and notoriously difficult to define. Apte (1994) (p. 2001) summarized the problem as follows: *"Despite a century of efforts to define culture adequately, there was in the early 1990s no agreement among anthropologists regarding its nature"* (Spencer-Oatey, 2012).

A typical notion of culture is that it is formed by the ideas, customs, and social behavior of a particular people or society. It is the shared patterns of behaviors and interactions, cognitive constructs, and understanding that are learned by socialization (Zimmerman, 2017). Thus, TCKs are formed by many cultural aspects: firstly, by their parents' culture; secondly, their host country's culture; and thirdly, by their peers, international school, and mobile lifestyle that all contribute and strengthen their TCK identity.

Despite the first (parents) and second (host country) cultures being tangible, social constructions, the third culture is temporary and intangible, and constantly changing as TCKs move and connect with other TCKs going through the same transcultural experiences. This third culture, more than the first or second cultures, gives TCKs both a sense of belonging and being understood (Lijadi & Van Schalkwijk, 2014). In the third culture, the sense of belonging comes from the shared expatriates' internationally mobile experiences despite the differences in nationality, cultural background, or ethnicity.

First a Sense of Belonging, *then* an Environmental Identity

SLE research, initiated by Tanner (1980) and continued by numerous others (e.g., Chawla, 1999; Myers, 1997; Palmer, 1993) suggests that several factors occurring during childhood strongly influence one's environmental interest and can lead to an active role being played in environmentalism during their life. These factors include: positive outdoor experiences as a child with respect to nature; positive (adult) role models that create these outdoor experiences; and reading nature books (Stevenson et al. 2014).

However, Chawla (1998) states that more attention should be paid to your inner (physiological, personal) environment rather than just the outer (physical) environment. Furthermore, my position is that only once your inner state is at peace and feels safe, can you start bonding with others, which is when learning and identifying with someone/something can occur. This is best illustrated using Maslow's "*hierarchy of needs*" (2006), a motivational theory within psychology, that provides a five-tier model of human needs. It contends that people are motivated to achieve certain basic safety and physiological needs which take priority over others (Fig. 1). For instance, our most basic need is for physical survival, which is the first thing that motivates our behavior. Once that level is fulfilled the next level above it motivates us, and so on (McLeod, 2017).

Jose, Ryan, and Pryor (2012) state that *"there is general theoretical consensus among the diverse array of researchers that a perceived sense of belonging or connectedness is a basic psychological need, and that when this need is satisfied it brings about positive outcomes."* (p. 236). If children's basic needs are met, both physiological and safety needs (Fig. 1), then they start creating friendships and a sense of belonging to their environment. A sense of belonging is needed *before* you can identify with an environmental ideology to be integrated into their identity.

It is therefore important to understand how an environmental identity is created. Clayton (2003) argues that environmental identity is part of your self-concept, namely, that it is a part of you; making you feel at one with nature, based on memories of past activities, or an emotional bond, that ultimately affects how you see and behave in the world. Furthermore, he highlights the importance of positive outdoor experiences in helping to form an emotional attachment with your environment. Stapleton (2015) identified, in relation to environmental education, that in early childhood, children start to learn what their society expects them to be and to do and to develop personal responses to this. Thus, merging one's

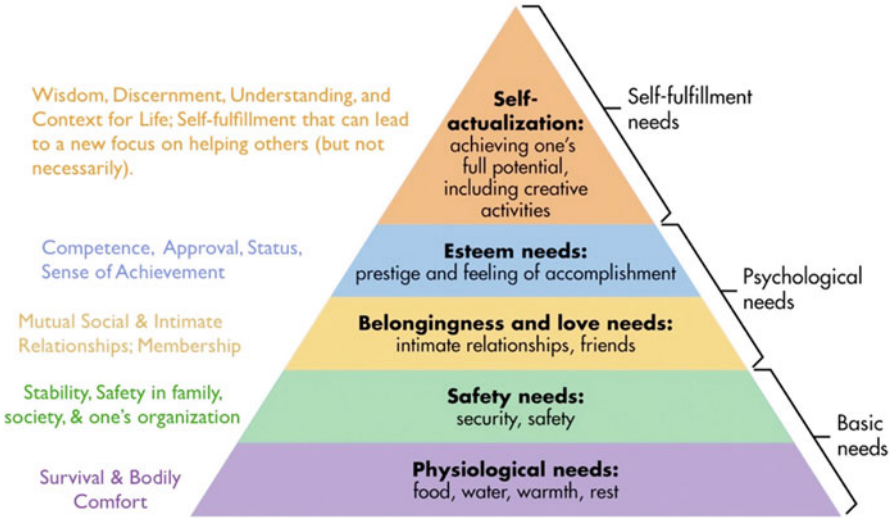

Fig. 1 Maslow's hierarchy of needs. (Source: Finkelstein (2006) https://commons.wikimedia.org/wiki/File%3AMaslow's_hierarchy_of_needs.svg [CC-BY-SA-3.0 (http://creativecommons.org/licenses/by-sa/3.0/)].)

personal identity (goals, values, and beliefs) with one's cultural identity (sense of belonging to a group).

The examination of environmental sensitivity, the openness to environmentally friendly behavior, and the development of environmental commitment through life events came into focus in the 1980s, with experiences in nature (or outdoors) being the most significant factor in the development of an environmental identity (Chawla, 1998, 1999; Palmer, 1993; Tanner, 1980). Furthermore, the role of childhoodnature experiences, which can be family holidays, summer camps, or outdoor activities were also significant. Palmer (1993) concluded that *"outdoor childhood experiences led to their concern for the environment"* (p. 29) and SLEs. They have less importance in domestic research (Hofmeister-Tóth, Kelemen, & Piskóti, 2012), but their role is important in the study of life events. Also, negative experiences as influencing factors appeared in research studies (Chawla, 1999; Palmer, 1993; Palmer & Suggate, 1996), which refer to perceived environmental issues. Chawla (1999) examined which life stage the given life experiences have the biggest influence. Outdoor experiences, family members, and education clearly have the biggest role in childhood. These results are confirmed by Hofmeister-Tóth et al. (2012), adding the possible positive effects of belief and religion. During the university years, friends and education have the most intensive influence. In adulthood, the influence of organizations and communities become an encouraging factor.

Stevenson et al. (2014) suggested that SLE research highlights that role models, time outdoors, and nature-related media can help to promote pro-environmental behavior; however, most of this research is qualitative. Furthermore, it is evident that among middle year students in the USA, life experiences appear less important

than promoting small class sizes and addressing challenges associated with lower incomes in schools (Stevenson et al. 2014).

In addition, there is support for the importance of childhoodnature experiences and experiences obtained in nature (Chawla, 1999; Palmer, 1993; Tanner, 1980), with 36% of positive experiences coming from one's childhood and another 24% being based on high school experiences. The importance of role models also appears to be significant, while activities learnt from parents and grandparents were the most salient among family memories (Piskóti, 2015).

Autoethnography

Chawla (1998) stated that *". . .research into SLEs is only as valid as the autobiographical memory on which it is based"* (p. 363). Therefore, autoethnography can thus be a risky means for researching SLE as the subject's memory can be faulty, especially if it describes details of vague memories produced a long time ago. (Simone Blom provides some additional ethnographic research elsewhere in this Handbook.) However, in my case, I feel my memories are a very relevant source of information because they encompass *significant* moments in my life. *"Events of high personal importance produce more vivid and accurate memories than events of low importance"* (ibid., p. 363).

The methodological approach that I took in this Chapter was rather straight forward. I chose an autoethnographical approach largely because it allowed me to use self-reflection to explore my personal experiences and the development of my environmental identity within the social context at the time and to also connect my autobiographical narrative to wider cultural and social meanings. I also wanted to explore and reflect upon my own lived childhoodnature experiences as an expatriate child in international schools.

I was inspired by the approach that Hopkins (2015) used of framing personal memories and critical points in my TCK journey through poetry. The focus of the poems was guided by Hanauer (2010) where I was directed to select provocative points to generate stimulus material upon which to shape my commentary for scrutiny.

Furthermore, poems and images were combined to generate richness in my ethnographic journey. Provocative prompts were used in combination with photographs that characterized the five critical stages of my cultural transition (Pollock & Van Reken, 2009), which include: involvement, leaving, transition, entering, and re-involvement.

The issue of identity formation interests me because of my own globally mobile upbringing as a TCK. As a dual Dutch/Mexican citizen, I struggled with my identity upon returning to my passport country, the Netherlands. This was supposed to be my home, and yet, it did not feel that way at all. By the age of 20, I had lived in 11 different countries and moved more than 18 times; plus, I attended five different schools in five different countries during my 6 years of high school, all of which classifies me as an Adult Third Culture Kid (ATCK) (Tarique & Weisbord, 2013).

The Early Years

Let's start at the beginning. My name is Rianne Carolina van Zalinge. Just looking at my name alone you would say that I am Dutch. My name sounds Dutch, I look typically Dutch (blond, blue eyed), however, I also have Mexican citizenship, and I only lived in The Netherlands a few months until I turned 18. Internally, I am as Dutch as most expatriates living in the Netherlands!

I was born during my parents' first posting abroad in Mexico. My father worked as a fisheries biologist for the United Nations, which meant that we travelled extensively around the globe. I was born in Mexico and at the age of 3 months, we moved to Indonesia (Fig. 2) where my brother Robert was born a few years later. I am told that I spoke Dutch, English, and Indonesian before the age of four. Many memories must have been unconsciously imprinted with lifelong effect, because in Indonesia our garden (and many others) were covered with bougainvillea's, frangipani's, bananas, and palm trees. To this day, I have a weakness for many of these. My everlasting love for the tropics and ginger-red cats stems from those first 4 years of my life in Indonesia.

When I was almost 5 years old, we moved to Kuwait (Fig. 3) where I started kindergarten at the American International School. How I loved my school! But after 2 years we were told there was a new posting for us, so we packed up and sold everything only to be told at the last minute that the project had been extended for another 2 years, so we were not leaving. Unfortunately, my brother and I could not go back to our beloved school and to our school friends and classmates (as our places had been filled), so we had to go to another school. I hated wearing school uniforms at this (new) British International School and having to make new friends when my old friends were at a school so close by! We also had to move to a new house, but that made less of an impression on me than having to change schools.

My other memories of Kuwait were of our family trips into the desert and sealing the windows and doors very tightly to stop sand from getting into our house during one of the many sandstorms we had. If you did not get to the windows in time, you would end up scooping sand out of the house for the rest of the day!

A vivid memory I have is of always being looked at and touched by the local people. They had often never seen a young blond-haired girl before. This feeling of being *different* typified much of my upbringing in Asia and Africa. As it turns out, many TCKs experience this, as it contributes to one identifying with what one is *not*, rather than what one *is* (Easthope, 2004, 2009). It was now that my sense of cultural marginality (Schaetti, 1996) was formed. I did not feel part of my host country, nor my home country, so I did not really belong anywhere except with other TCKs in our own third culture world.

During the first Gulf war, I remember going to school hearing the jet planes fly over-head and dropping bombs in Iraq just a few kilometres away. This was a very scary time for us all. Especially because my family and I had visited the lovely Marsh people in southern Iraq on several occasions (Fig. 4) and my heart ached to think about what they must be going through amid all this war. When we went back

Fig. 2 My life in Indonesia (Ages 0–4). From top left clockwise: My (visiting) grandfather and I, the only blond blue eyed girl, surrounded by locals; Tira the daughter of our housekeeper, who was my best friend; lots of outdoor activities like horse riding; preparing for a picnic with my friends; Tira and I playing with interesting things found in the garden

to that area after the Gulf war was over, we found the marshes had been drained and all the marsh people had been killed by Saddam Hussein's army. I felt terribly saddened to think of those lovely families all having been wiped out.

Fig. 3 Life in Kuwait (Ages 4–8). From top to bottom: Checking the safety checklist before setting off into the desert; visiting a local family; going for a camel ride

After Kuwait, our family moved to Pakistan (Fig. 5), where my brother and I had the most wonderful time at the Karachi American School (K.A.S.). I attended this school from age 8–12, when my identity was being shaped. It was all rose-colored unfortunately, because after my first year there (I was 8 years old), my best friend Monique moved away, and I felt very lost and lonely for many months after that. I remember thinking, *"OK, I need to find other friends, but I will never again become such good friends with someone, because I don't ever want to feel this bad again."* This was my first (conscious) step that I took to keep people at an (emotional) distance to protect myself from getting hurt. Many TCKs describe finding it hard to bond with people out of fear of losing them again.

At the age of 12, in the first year of high school, I also began to see things differently, as it was the first time that I sensed the importance of an international school, TCK identity, and my sense of belonging. All my friends attended the school and my after-school activities also took place there. Basically, everyone and everything I loved happened there – except my parents. The school gave me a sense of

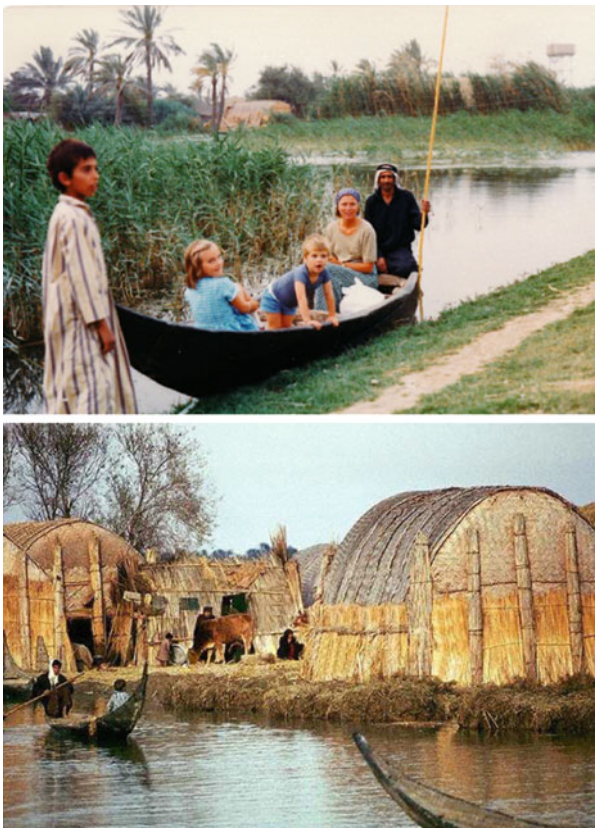

Fig. 4 Visiting the Marsh people in Iraq by gondola (top); The houses of the Marsh people built from dried grasses and reeds (bottom)

belonging as I belonged to the K.A.S. family. It was my community, my family when I was away from my parents.

The Dutch Stopover

At 13, I arrived in the Netherlands for a very temporary stay. My mother, brother, and I moved in with my grandparents while my dad worked at the UN headquarters in Rome, Italy, for a few months. I went to the Marnix Lyceum School in Haarlem but never really tried to fit in because I knew we would be leaving again soon. I did make friends, but I was very aware of the fact that they were transient relationships. In fact, I was very excited when we heard we would be moving abroad again.

Off to the Himalayas I Go

After leaving Pakistan, and spending 9 months in the Netherlands, my brother and I were sent to a boarding school in the Himalayas, India. I was 14 then and it broke

Fig. 5 Life in Pakistan (Ages 8–12). Walking in the hills of northern Pakistan (top); Activities at K.A.S. (Olympics and Nationality Day) (bottom)

my heart. This was the first time in my life that I felt utterly, truly alone. The reason was that for the first time ever, I was separated from my parents. For many TCKs, myself included, family provided the most important relationship, representing the only stable factor in an ever-changing life (Lijadi & Van Schalkwijk 2014; Gilbert, 2008). Being separated from them felt like I had lost my one rock, and I felt completely lost. This was all during my teenage years, which did not help.

Imagine the magnificent Himalayan mountain range. The snow capped mountains, winding rivers, lush forests, more stunning nature than you can imagine. Beautiful, isn't it? … But at 14 years of age it was anything but wonderful. I remember looking out over the Himalayas one morning on my way to boarding school thinking, *"This is beautiful, but I feel so alone. I don't belong here."*

I recently discovered the 2011 Academy Award nominated short film called *"The Road Home"* by film-maker Rahul Gandotra, which is based on the exact boarding school that I went to in the Himalayas in India, called Woodstock (Fig. 6). It tells the story of a boy who is Indian, looks Indian, but doesn't feel Indian (because he grew up in Britain), and tells how he gets bullied and misunderstood because his looks do not match his inner identity. He, like me when I returned to the Netherlands, was a hidden immigrant (McCaig, 1996). He wants to run away, to escape back home, only to find out he is not British either. This is a classic example of when one's inner and

Fig. 6 My years in India (Ages 14–15). From left to right: Woodstock school in Mussoorie, India; The foothills of the Himalayas, where the school was located

outer environment (Chawla, 1998) are not synchronized, one is not at peace. I did not have a sense of belonging at all, therefore I felt very lost and lonely, resulting in a feeling of alienation with my community, surroundings, and my environment. Any outdoor activities (hikes and camping trips) my teachers organized were lost on me because I did not want to be there. I did not feel safe, secure, loved, or a sense of community. Feeling so much negativity toward my surroundings made any attempts to develop an environmental identity fall on deaf ears. Here, again, is an example of how well Maslow's hierarchy of needs' triangle (Fig. 1) portrays reality: because my basic needs had not been met (i.e., feeling safe, secure, and loved), and thus I could not enjoy the environment I was in.

I was also strongly influenced by both my father, grandfather, and the schools and places where we lived. My father is a keen bird watcher and, like his father, an avid environmentalist. Many of my childhood memories were of us as a family being rounded up to have a weekly *bird-watching day.* Even when I was 12, I often battled with my parents because I felt I was being forced to do something I didn't want. The fact that it was a forced activity worked counter-productively as I resented these outings more and more. I was not a fan of bird watching, and consequently, I started building my identity by what I wasn't, rather than what I was (Easthope, 2009).

If my outdoor experiences (bird watching and my boarding school period in the Himalayas) had been under more positive circumstances, they could have been valuable and critical steps towards building a lifelong environmental identity (*c.f.,* Chawla, 1998; Palmer, 1993; Stevenson et al. 2014). However, because they were shrouded by my negative state of mind – symbolizing a period in my life when I felt lost and lonely – this valuable learning and identity building process was lost.

Having said that, I cannot negate the fact that my father and grandfather's ethos as biologists and environmentalists strongly formed my love and respect for nature. I agree with Erikson (1980) that role models (in my case my father and grandfather) strongly influenced my moral compass. Despite the experiences I went through

being lost on me, during my angry teenage years, the seeds planted as a child were not in vain, because a few years later, when we lived in Africa, my love for the environment came rushing back.

Interesting to note is that my brother (who is younger than me and is not as emotional as I am), quite enjoyed the solitude of the Himalayas with its rugged nature. He has gone on to work as an environmentalist for his whole career and engages in bird watching as his main hobby in his spare time.

The African Sojourn

At the age of 15, after a short intermezzo in the Netherlands, we moved to Malawi (Africa) (Fig. 7). This country opened my heart to environmentalism, as our house was on beautiful Lake Malawi and we had our own private stretch of beach. Every weekend, when my brother and I were home from boarding school, we would invite friends over and go surfing, canoeing, diving, or just chilling by the water. SLE were generated during these few positive years of living by the beach in Malawi which opened my heart again, and all the positive seeds about nature and the environment which were growing inside me.

Creating My Sense of Belonging

My identity was constantly (re)molded throughout my various moves, yet after a while, I always created a new home and sense of belonging wherever I went. Even if I knew I would not be staying very long, it was important that I feel attached to a place, school, or people to feel safe, and thus at home.

I get restless, if I live in a place too long and yearn for the feeling of adventure that a new move will provide. I love exploring this beautiful world we live in, but as a typical TCK, I feel a sense of belonging everywhere a bit, but nowhere totally. I always thought, *when will I truly be home?* However, I have found that home is where my family is. When I have my loved ones around me, this is when I am truly home.

The Stages in My Life through Poetry

These five poems that I have written each symbolize a stage in Pollock and Van Reken's (2009) five stages of transition that I experienced when moving: Involvement, Leaving, Transition, Entering, and Re-involvement.

Stage 1: Involvement
Sand crunching under my feet as I walk along the beach sipping my coconut
Having good friends to laugh and hang out with, in the thatched beach hut
Feeling relaxed while taking the canoe out, back home as the light is dimming
Having naughty monkeys steal my sunglasses while I had gone swimming

Fig. 7 My years in Malawi (Ages 15–16). Clockwise from top left: Our lovely private garden/beach in Monkey Bay, Malawi; Inviting friends over to spend the weekends in Monkey Bay with them; Swimming in Lake Malawi (together with crocs and hippos) with my beloved dog, Candy

Experiencing the paradox of seeing such poverty everywhere
Yet when listening to the people singing, I feel their happiness and joy in the air
Tagging fish for an important fisheries project in Monkey Bay
Banana and palm trees swaying in the wind during another warm, sunny day
Petrified when noticing a hippo coming up next to me while I stand motionless on a surfboard
Feeling the relief when my friends save me and my heart rate is restored
Swimming alongside beautiful fish as I learn to do deep sea diving
Feeling that I'm not just surviving, but I'm thriving!

Summary: Truly my happiest state of being. Feeling connected with my environment on all levels (social, personal and physical, inner and outer) is when I am most content.

Stage 2: Leaving
Saying goodbyes
Sadness hangs heavy in the air
Weighing heavy
Knotted stomachs
Farewell all that is known

Fig. 8 Saying Goodbye (. . .all too often)

All that is loved, all that is cherished
Grieving at what will soon be lost
But somewhere, deep inside
Feeling the fluttering of anticipation
Of what is to come (Fig. 8)

Summary: Grieving for the loss of friendships, home, school, climate, and all that is familiar. Stepping into the great unknown.

Stage 3: Transition
Airports are my second home
Watching people come and go
Symbolic of my life
I come and go too
Arriving, staying and leaving again
Always in transit
Mobile, fluid, global citizen
Always on the move
It's what I am used to, what I have always known, what I have become (Fig. 9)

Summary: Living in limbo. I have neither the home I just left, nor the one I am moving towards. I am in no-man's land.

Stage 4: Entering
Anticipation
Excitement
New life

Fig. 9 Endless waiting at airports during my many travels

New chances
Bit scared
Bit tired
Putting on a brave smile
Here we go again
But this time will be different because I am home

Summary: Mixed feelings. Exhilaration one moment and loneliness the next. Excited and sad. Happiness and loss. Starting to get to know the unknown.

Stage 5: Re-involvement

I am torn – if I am not Dutch, then what am I?
Where do I belong now?
Breaking down and rebuilding my identity
I become a chameleon, fitting in when and where I want to
Doing it so well I lose sight of who I truly am
Trying to create new friendships, a new home
Connecting with other expatriates

I am not Dutch, I am a global citizen
My home is everywhere yet nowhere (Fig. 10)

Summary: Trying to fit in. Where do I belong? Where is my home? Can I make this my new home?

Final Reflection

Hoersting and Jenkins (2011) observed that when TCKs returned to their home country, they may grieve and feel a sense of loss over the relationships and environments they left behind in their previous home. In addition, TCKs (myself included) often identify with their nationality more strongly when abroad than when they are in their home country. This is because when abroad, their nationality becomes a way of setting themselves apart from their peers, because their peers come from all over the world. Once they return home, they find out that the identity they had built up for themselves abroad, in my case the fact that I was Dutch, is false.

This leads to the complication of being a *hidden immigrant*. As McCaig (1996) so eloquently explains:

> The children's culture is basically an international one with an overlay of the passport culture. They therefore often feel like hidden immigrants when they reach "home." Because they look and talk as if they should belong, their outlook, actions and lack of knowledge of local and cultural trivia are often bewildering to those around them who do not know (or care) that they have lived abroad. (p. 111)

Being a hidden immigrant was an added and unexpected pressure, both from the locals and the pressure I put on myself. When I arrived back in the Netherlands, both the locals and I expected me to be Dutch. However, when my outer environment (my nationality and physical looks) did not match my inner environment (my lack of feeling at home, my English accent, and my distinct feeling that I was not Dutch), I felt more torn than ever before. Consequently, at the age of 18, I was in a full-blown identity crisis. The identity I had built up all my life abroad turned out to be false. I might be Dutch, but I did not feel Dutch. That is when I knew I had to rebuild my identity from scratch.

I fled the country to travel to Australia, New Zealand, and Cambodia, only to return 4 years later. I came back to study Cultural Anthropology and Sociology at the University of Amsterdam and I have lived in the Netherlands ever since. The reason the second return to the Netherlands was more successful than the first was because of my lowered expectations. I knew this time I was not coming home, I was simply moving to the Netherlands, similar to any other country, which was my way of coping.

Fig. 10 Reconnecting and rebuilding my Dutch identity playfully with my work colleagues (top and middle); and with my family near the tulip fields (bottom)

What Can International Schools Do to Promote a Sense of Belonging and SLE in Third Culture Kids?

Feeling accepted and comfortable somewhere is, of course, very important for all teenagers, but for TCKs even more so because in addition to the usual teenage identity crises and hormonal surges, they must cope with adjusting and readjusting to a new home every time their parents move. A new school which is familiar and welcoming helps them cope with the new living environment faster.

The children's expatriate world is mostly revolving around their school. International schools are a hub of TCK activity and take up a large part of a child's social life. There are large amounts of after-school activities organized, which sometimes even take place on weekends. Inter-school activities are frequent, with all kinds of sporting competitions taking place. This strongly enhances the school feeling like "*we are one big family*."

Since international schools form such an important part of a TCK's life, it is bound to be an integral part of their identity. Identification can sometimes take place in the form of idealizing the dominant culture of the school that the children are attending.

> If the majority of life is spent in activities connected with the school, the child will tend to become more American than their own nationality. Once again the school plays a key role in the cultural development of the young person. (Smith, 1996, p. 209)

Schooling and after-school programs are a major route to the development of an environmental identity (Colvin, 2013; Stevenson et al. 2014; Colvin Williams & Chawla, 2016). These programs can create a sense of belonging to a community and to the environment, which will lead to a respect for the environment and link it to a child's identity. Since international schools are such an integral part of a TCKs identity, this is a very important route to take when installing a sense of belonging and identity with nature in children. My environmental identity was shaped by the international schools that I attended, as discussed in my autoethnography earlier in this chapter.

Combined with living in a host country, international schools help to strengthen a child's perception of the world being a multicultural place. For many TCKs, living abroad is synonymous to attending international schools. The schools are often seen as a safe haven, a constant factor in a frequently changing world. What creates a bond between TCKs and their school, is their perception of being different from the locals (and thus creating a *we* vs. *them* identity) and sharing a transient lifestyle. All TCKs experience having to survive in a strange country and that creates mutual understanding. This TCK identification and affirmation seems to replace the importance of nationality for these children. Thus, as I experienced during my time abroad, TCK children appear to identify with expatriates firstly, and their nationality secondly (McCaig, 1996).

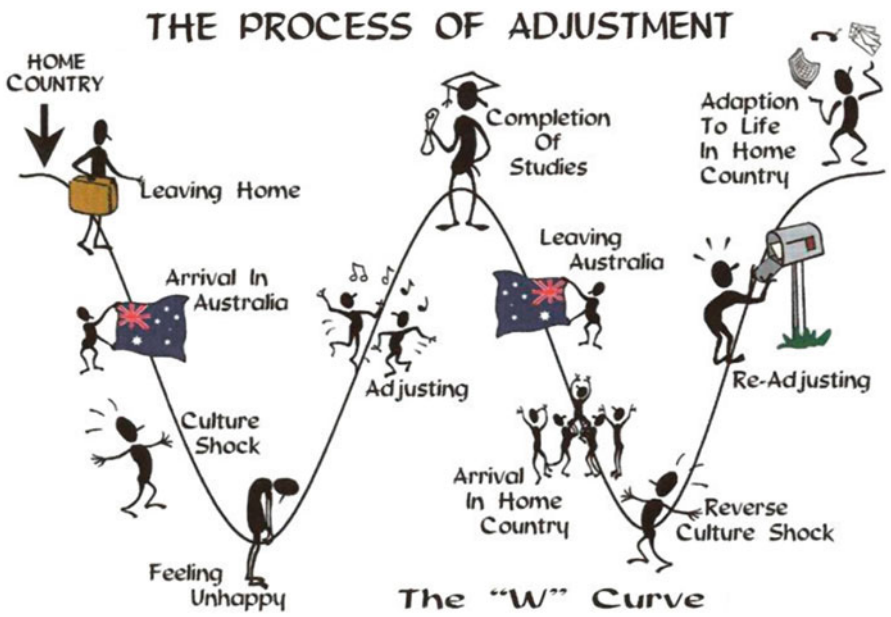

Fig. 11 The process of adjustment when moving to another country (Source: Oh My God, 2014: https://ohmygodd.com/side-effects-of-moving-to-a-new-country; Barker 1990)

Steps for International Schools in Managing Third Culture Kids in Transition

How can international schools and teachers optimally facilitate TCKs in their transitional process of arriving, staying, and leaving (see Fig. 11)? Transition programs need to be established to help these TCKs cope with the constant emotional flux of entering, staying, and leaving that encompasses and characterizes their lives: to help TCKs cope with the frequent moves and in handling the constant coming and going of friendships. The program should also help families to maintain and strengthen their family attachment bonds in all the five transitional stages of the move (Ota, 2014; Pollock & Van Reken, 2009).

International school staff needs to help TCKs actively manage their "grief" to help them settle into their new life at the school (Ota, 2014). When leaving, grieving can also take place, and goodbyes need to be handled effectively for there to be some closure for the child, so they can successfully move on to their next location. International schools need to collaborate with other international schools so that the transition from one international school to another goes as smoothly as possible.

School counselors should not underestimate the unique difficulties experienced by TCKs when adapting to a new culture, with their continuous personal struggles to build and maintain relationships in their ever-changing lives (Lijadi & Van Schalkwijk, 2014). Ota (2014) highlights the importance of creating a *safe harbour* (he was referring to an international school) for children. Once children feel safe,

they will start to absorb information and the learning, healing and sense of belonging process will start. Until they feel safe and secure, very little learning, healing, or feeling at home will take place. This is where Maslow's hierarchy of needs (refer to Fig. 12) becomes relevant, as it highlights that one's basic needs need to be fulfilled before progressing to the next level. If the lower, base levels (physiological, safety) are not met, the higher levels (feelings of belonging, community, school, education, etc.) cannot be addressed.

With respect to teaching environmental education and nurturing environmentalism to children in international schools, one needs to make sure TCKs are in the right frame of mind (feeling safe and happy) so that they can best absorb and assimilate the information and experiences made available for them. Furthermore, the action component in environmental education is important in doing something positive *for* the environment, but at the same time, it is also helping in molding/creating their identity: the more they do it, the more their identity thickens (Holland & Lave, 2001).

Having positive and environmentally conscious role models and outdoor experiences are indeed important to children, but for any of that to make a difference and have a lasting effect on TCKs, they first need to be in the right frame of mind. This was clearly not the case for me as my mind set was not ready to embrace environmentalism, especially to the same degree as my TCK younger brother, who largely went to the same international schools as me. Furthermore, supporting and embracing the environmentalism messages provided by environmental role models such as my father and grandfather did not have any impact on my mind set at this time.

According to social practice theory (Hargreaves, 2011), for people to become lifelong environmental activists, their love for nature and the environment needs to become a part of their identity, which can only be achieved if they feel a sense of belonging to the environmental cause and to the natural environment itself. Therefore, greater focus is needed upon identity and culture in the interpretation of SLE research (Dillon, Kelsey, & Duque-Aristizabal, 1999). This would be especially significant in my experiences and also for TCKs within international schools.

Coping Mechanisms

TCKs may use coping mechanisms to interact with the host culture and social groups, mostly when they find that behaviors considered socially appropriate in one context, are not accepted in a new country or culture. Pollock and Van Reken (1999) mention that one of the major areas that expatriate children need to cope with is their unresolved grief. They need to identify and mourn the losses they have felt during their lives. It remains as an unresolved part of my experiences. I also felt that I really did not get a chance to grieve.

Children might appear to adjust quickly in the sense that they get used to their new life, but when adjustment refers to feeling at home somewhere, the process could take a lot longer, and many never feel a sense of belonging to the places where they are living (Bennett, 1993; Fail, Thompson, & Walker, 2004). As Pollock and

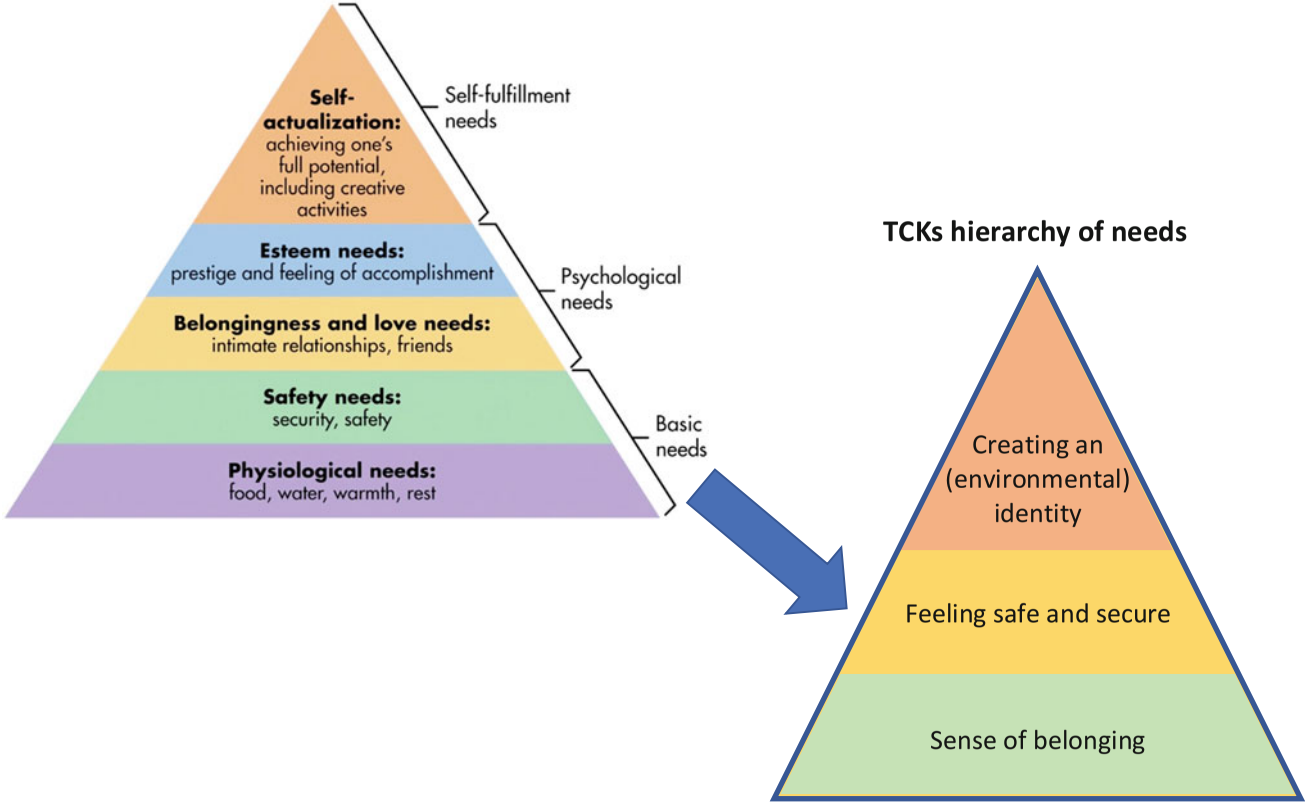

Fig. 12 Adapting Maslow's Hierarchy of Needs (Fig. 1) based upon my own experiences as a TCK. (Source of Maslow's top left diagram: Finkelstein (2006) https://commons.wikimedia.org/wiki/File%3AMaslow's_hierarchy_of_needs.svg [CC-BY-SA-3.0 (http://creativecommons.org/licenses/by-sa/3.0/)])

Van Reken (1999) point out, these children mourn the loss of *"status, lifestyle, … relationships, identity, role models and a past that wasn't and a past that was"* (Nette & Hayden, 2007, p. 436).

Conclusion

American-born Hopkins' (2015) experiences as a TCK growing up in West Africa as a child of missionary linguists were summed as follows:

> I never considered my African childhood Paradise, and when I returned after not quite a dozen years away, I felt comfortable, but not at home. I've moved on, or moved forward, or moved away, or something. (p. 819)

His account resonates in so many ways with my own autoethnographic journey. Of course, my journey represents just one voice and journey as a TCK; however, there are some key messages reported from the literature in the chapter that also arise. For instance, TCKs feel at home everywhere a bit, yet nowhere totally. Each move shapes them and changes them, therefore when revisiting their *last home,* they find out that they have changed and their previous home is not their home anymore. Thus, for many TCKs, the search for belonging/home is a life-long one. In my case, I feel that I still have unfinished business in my quest to find *my home*.

I have also explored some of the SLE research and its potential relevance to TCKs and addressed the many challenges arising from frequent relocation that many TCKs experience, including the impacts of/on international schools, through my own lived childhoodnature experiences growing up as a globally mobile child. It is clear from my dialogue that children need to feel safe and have a secure and nurturing learning and social environment where they feel a sense of belonging, before schools can try to develop an environmental ethos and SLE through environmental studies and environmental/outdoor experiences, as all these opportunities may well be lost on the students. This is true for both local/national and international school students; however, international school students have the added issues to contend with associated with being TCKs. Thus, it is vitally important that TCKs feel a sense of belonging to their international school/community, and that they feel safe and secure so that the next level of learning and identity forming in Maslow's hierarchy of needs (Fig. 1) can take place to help integrate childhoodnature experiences into their identity and thus be able to have SLEs as part of their lifelong calling and engagement with and for the environment.

After-school programs are a major route in the development of an environmental identity (Stevenson et al. 2014). These programs can create a sense of belonging to a community by linking environmentalism to a child's identity. International schools need to utilize this chance at cultivating a child's environmental identity when given the chance. By introducing TCKs to positive outdoor and SLE, they are paving the way for them to create personal attachments and identify with the environment and

thus learn to respect and take care of it. Not because they are told to, but out of love for the environment. Ultimately, what is instilled in children, manifests when they are adults (Chawla, 1999).

Approaches have been identified to assist TCKs in providing much needed harmony, support, stability, and understanding for both staff and students of international schools. This can be achieved by looking at how one's inner and outer world influences the construction and significance of one's SLE as articulated through my own TCK journey. However, there is clearly a need for additional childhoodnature research in many aspects of environmental educational research in international schools, especially further exploring the role of identity formation and its impact on SLE for TCKs.

Abstract

The purpose of this research was to investigate young children's perspectives of nature while exploring a deciduous forest as an extension of their early childhood classroom in a University Lab School. This work was framed theoretically on the premise of ethical listening and doing curriculum and research *with* children in efforts to gain a phenomenological understanding of children's prereflective and reflective experiences of nature. Children's prereflective and reflective experiences were captured through methods adapted from the Mosaic Approach and video methodology as part of a dissertation research project. Children spent a minimum of 2 h per week in a natural environment with their teachers over the course of a school year. Key findings highlight how children's extended nature experiences led them to conceptualize how they can be (in) nature, that they can manipulate nature, resources in a natural space, and how they are nature themselves. Significant life experience (SLE) literature is drawn upon to show implications for early childhood practice and research with children.

Phenomenology with Children: My Salamander Brother

Doing Phenomenology with Children

Phenomenology as defined by Max van Manen, "is the study of the lifeworld – the world as we immediately experience it rather than as we conceptualize, categorize, or theorize about it. Phenomenology aims to come to a deeper understanding of the nature or meaning of our everyday experiences" (van Manen, 1984, p. 37). Phenomenology as a research approach was adopted for this study to reach the goal of understanding children's everyday experiences with(in) nature with little to no interruption of adults. Video methodology, adapted from The Mosaic Approach method of magic carpet, became a primary method as children's immediate experiences were captured (pre-reflective) and could be reflected upon as often as desired (reflective experiences). van Manen (2014) emphasizes the study of reflective experiences but by also collecting pre-reflective experiences, a dual understanding is revealed. The authors use the terms "we" and "I" in this Chapter to share different viewpoints. "We/our" refers to our joint understanding of meaning derived from the study, while "I/my" refers to Adonia's primary position in gathering data and children's reflections of their time with(in) nature. We use the terms with(in) and (re)know as a rhetorical move to show the complexities of how children interact with and within nature while constructing knowledge with or without adults, simultaneously, and/or in different rhythms that are not easily discussed as linear experiences. Be(in)nature is a term I use to consider two possible conceptions of nature: that as humans we can be in nature and manipulate its resources and/or we can be nature. We are alive, breathing, and moving, because we are nature. We are a part of Earth.

SLE literature contributes to our understanding of how direct childhood experiences with(in) nature often influence our future attitudes and behaviors towards the environment (Chawla, 1998, 2007; Chawla & Cushing, 2007; Laird, McFarland-Piazza, & Allen, 2014). When I was a child, I remember using fallen fir tree limbs to sweep the dirt ground and pretend to be Mom. I can remember the smell of the sap and how dirty my hands would get as the dirt stuck to my palms. My connection with (in) nature throughout my life has led me to believe the more time we spend in nature, the more we begin to know and understand the Earth. We can be(in) nature. I assumed that children could also be(in)nature. After reflecting on my own childhood and reminiscing about my joys in nature, I knew I wanted this opportunity for children. This assumption, about children understanding themselves as nature, led me to develop a phenomenological study to investigate preschool children's pre-reflective and reflective experiences of nature because what I did not know is

what experiences would lead children to be(in)nature. Twelve preschoolers, ages 4 and 5 years, experienced nature in a forest environment near their school with myself and an outdoor educator over the course of nine months. Interpreted Phenomenological Analysis (IPA) (Smith, Flowers, & Larkin, 2009) was utilized to portray children's experiences in anecdotes of a greater phenomenological text. Three of the 14 final anecdotes featured in my research are shared in this Chapter to emphasize how children's construction of nature changes over time, along with what children consider significant about nature. Furthermore, I considered how these SLE in childhood may lay the foundation for pro-environmental behaviors if children carry a pro-environmental consciousness into adulthood, meaning their "knowledge, values, and attitudes are part of their emotional involvement" with(in) nature (Kollmus & Agyeman, 2002, p. 256).

Children's Perspectives of the Outdoors

The key to studying nature as a phenomenon with children is providing them with uninterrupted time and many opportunities to revisit direct experiences (Kellert, 2002). Children can move freely, explore nature's elements, and decide what nature is for themselves and as phenomenologists, "grasp of the very nature of the thing" (van Manen, 1990, p. 177). Then when needed, teachers are nearby for support. Moss and Petrie (2002) suggest that children's spaces such as outside environments "allow children to exercise agency, to participate in their own decisions, actions and meaning making, which may or may not involve them engaging with adults" (p. 93). Revisiting natural spaces over time allows children to (re)know, discovering something different than the visit prior (Tovey, 2007). The more time children spend in nature, the more they find meaning in places they consider significant. Kernan and Devine (2010) confirmed "the most prevalent value attributed to the outdoors by adults was freedom" and moving freely was considered natural and "a necessary part of being a child" (p. 377). There are limited studies capturing children's perspectives of the outdoor experiences while employing The Mosaic Approach (Clark, 2008) as ways to understand. However, one influential study (Waller, 2006) suggests that learning from children without a formalized research agenda gives us the opportunity to know children differently. While the focus of the study (Waller, 2006) was to examine children's participatory methods, children's perspectives of the outdoors were generated through drawings and camera use. Additionally, another study (Mawson, 2014) implied that children approach the wild woods similarly as other outdoor spaces, but in our study children approached the woods with a completely different demeanor and concentration. Without interruption, children addressed their own inquiries and questions about nature.

Ethical Listening in Curriculum and Research with Children

The teacher-child hierarchy begins to dissolve when children are in conditions of (be)coming curriculum with their teachers (Sellers, 2013). Sellers (2013) describes (be)coming as both being and becoming curriculum with children in ways that are not traditionally straightforward and product oriented. Being in the moment and

empowering children as agents of their own learning and (be)coming curriculum while children and teachers are in a constant state of learning from one another However, moving beyond traditional curriculum and doing research with children sets the pace for additional tensions, involving decisions about, for example, how research is enacted, when and for how long, how roles in the study are decided. (Farrell, 2005). The Convention on the Rights of the Child (United Nations, 1989, 2005) has set a guide for recognizing children's rights to participate in decisions about their own lives and circumstances. However, Pramling Sammelsson and Johansson (2009) argue that supporting children's right to decision-making depends on how adults receive children and their knowledge, learning, and experience (p. 79). If we consider (be)coming curriculum with children, perhaps we can know children differently.

Furthermore, Dockett, Einardottir, and Perry (2009) suggest that "efforts to engage children not only in the generation of data, but also in the interpretation of data can ensure that the voice of the researcher is not the only one considered" (p. 290). Adults should try to recognize when they are listening to some children more than others (Einarsdóttir, 2007). The phrase *ethical listening* describes the practices that I used, derived from others (Dockett et al., 2009; Farrell, 2005; Samuelsson & Johansson, 2009) in efforts to try and support each child as a co-researcher throughout this study. I acknowledge that the teacher-child power dynamic cannot be denied, but the following practices assisted in discovering a true representation of children's meaning-making:

1. Build strong relationships with children.
2. Children decide when and how to participate.
3. Support children's initiation of reflection invitations.
4. Read children's reflections aloud for editing and confirmation.
5. Share adult interpretation and seek child feedback or edits/additions.

Upholding these values and practices meant that sometimes the children would share what I valued as a great implication for research but then would ask me not to show anybody else. I respected their request because I valued ethically listening and their right to decide how our work was portrayed for others. All of the work was vetted through the appropriate channels of human subjects review boards at our institution, but working with children is far more complex than these institutional procedural steps. The practices described above supported my intentions to carry out a research project while involving children as active researchers (Barratt Hacking, Cutter-McKenzie, & Barratt, 2013).

Doing Curriculum and Research with Children

Doing curriculum and research with children is paired in this section to extend on the notion of children as active agents and researchers in our study. Inspired by Reggio Emilia approaches, curriculum at the research site is developed based on inquiry led by children and teachers both indoors and outdoors. The data generated in this study acted as both curriculum and research as the children were not asked to participate in

ways any different from their regular expected school day. Sellers (2013) suggested a lived understanding curriculum where children and teachers inquire together about what and how learning will take place. In this study, research questions were broad enough to ensure that children could lead how data were generated without an adult agenda. The questions leading to children's understanding of be(in) nature were: (1) How do young children, ages 3–5, experience, interact, and respond to the direct physical elements, an outdoor forest environment near their school? (2) How do young children create meanings about nature in a group setting? and (3) How do young children's meanings of nature emerge and change over a school year?

The Mosaic Approach Adapted

Methods adapted from The Mosaic Approach (Clark, 2008) were employed to capture children's pre-reflective and reflective experiences while considering their right to choose when and how to participate as well as how much to "say" about their experiences in a natural environment. The Mosaic Approach is a meaningful way of conducting research with young children (Clark, 2008; MacNaughton, 2003; Rinaldi, 2006) and asks the question "What does it mean to be in this place?" which may be interpreted as, "What does it mean *to be you* in this place now in this present moment, in the past and in the future? (Clark, 2008, p. 17). A goal of using The Mosaic Approach is to provide research methods that promote children's confidence in answering a question with no "wrong" answer (Clark, 2008). Each element of The Mosaic Approach encourages a different level of engagement, from talking or watching videos to creating books or drawings about their experience. The Mosaic Approach "combines the traditional adult-directed research tools of observation and interviews of family members, practitioners, and children, with participatory tools for children, including the use of cameras, bookmaking, tours, and mapmaking" (Clark, 2007, p. 2).

The methods that were adapted from The Mosaic Approach were Magic Carpet and Child-interviewing. Magic Carpet (Clark, 2008), a method where children typically view a slideshow of photographs from the experience, was revised to offer videos captured by the children or myself. This adaptation of the magic carpet offered a less product-oriented level of engagement that was welcomed by children who did not feel as comfortable drawing or writing or had less experience taking photographs. Child-interviewing, a method of short semi-structured interviews, was also revised to be an open invitation for reflection that could occur at any moment initiated by the children or myself. The methods (Table 1) provided an avenue for participants to choose how and when to share their meanings of experience.

Role of a Phenomenologist and Teacher

My role in this phenomenological study involved my participation as both a teacher and a researcher. During the data generation phase of the study, I invited another teacher, Tess, to help facilitate children's everyday needs in the forest so that I could take on a stronger researcher role to collect participant observations and children's pre-reflective and reflective experiences with video and photographic documentation. Everyday needs involved assisting children who needed a Band-Aid, a shoe

Table 1 Ways of reflecting: The Mosaic Approach

Ways of reflecting	Data generated
Observations	Qualitative accounts of how children respond and experience nature
Child-interviewing	Reflection invitation conducted one-on-one or in a group (adapted)
Photography/ bookmaking	Children's photographs of "important things" and books created with photos, words, and drawings
Tours	Tours of spaces led and documented by children
Map making	Children create 2D representations (drawings/photos) of space
Magic carpet	Children view videos of experience (adapted)

Note: Adapted from Clark and Moss (2008)

tied, a bathroom break or other specific care from an adult. Even with assistance, I acknowledged that my roles of teacher and researcher could not be fully separated especially when some of the participants were members of my own classroom during the study. My intention was that by inviting participants from another classroom, less biased accounts could also be incorporated. Continuous video recording allowed me to capture most experiences while being open to child-initiated reflections or use of the video camera. Then children could request to see a video of their experiences to support their reflections. Phenomenology, not often done with children, allows adults to *listen* and capture children's in-the-moment experiences so that they can be invited to reflect later. While in the act of experiencing, we do not always notice the possibility for reflection and meaning-making.

Phenomenological Writing and Interpretive Phenomenological Analysis

Three anecdotes of the dissertation study are shared in this chapter to portray how children came to recognize themselves as nature. The use of anecdotes in early childhood education is not a new method of observation (Carr, 2000; Clark, 2004, 2007; Clark & Moss, 2001, 2005). Partnered with methods of phenomenology, "anecdotes recreate experiences, but now already in a transcended (focused, condensed, intensified, oriented, and narrative) form" (van Manen, 2014, p. 250). Additionally, van Manen (2014) described meticulously the complexity of writing a phenomenological text and the challenges of writing about the living now while knowing philosophically, it is already too late (see pp. 43–44). Further he advised:

> The problem of writing is that one must bring into presence a phenomenon that cannot be represented in plain words—it would escape all representation. So, we may distinguish between the presentative (immediate) and the representative (mediated) modes. The presentative mode is immediate or direct— the representative mode is mediate or indirect. The writer who aims to bring the object of his or her gaze into presence is always involved in a tensional relation between presentation (immediate "seeing" and understanding) and representation (understanding mediated by words). (p. 370)

The challenges of writing the text, in my opinion, were attempting to write about the essence of the present in past tense to put the reader in the forest, experiencing nature with children. While avoiding the phrase "You had to be there," I was forced

to consider what anecdotes of children's conversations were pertinent to phenomenological understanding. Capturing the essence meant watching and re-watching videos to transcribe the conversations while bracketing my own ideas and reflections, just long enough to know the children's meanings before reflecting and incorporating my own. Additionally, punctum was used to leave a lasting impression in the reader (van Manen, 2014). For the purposes of punctum in this study, photographs were used to capture snapshots of pre-reflective experience and reflective drawings with children's one line statement about their experience.

Epoché-Reduction

The act of capturing the pre-reflective and reflective experiences of preschoolers calls for careful consideration when selecting methodology. The Epoché-Reduction method (van Manen, 2014), when writing a phenomenological text, begins with the understanding that the researcher cannot deny their own preunderstandings of the phenomenon itself and must practice radical openness to the phenomenon while bracketing interpretations and assumptions (van Manen, 2014, p. 224). The radical openness in phenomenology is being aware that our preassumptions, interests, and ideas cannot fully be separated. Bracketing refers to acknowledging one's own interpretations and assumptions separately from the generated data. However, when working in conditions of (be)coming (Sellers, 2013) with children in this study, my own preunderstandings and assumptions were revealed before, simultaneously and afterwards rather than separate. Bracketing all interpretation and assumptions was not possible in this study as my initiative was to instead research with children, listening and understanding together. Practicing with radical openness (van Manen, 2014) allowed me to video record children's direct experiences with (in) nature while journaling about my own thoughts or assumptions. In doing so, the data generation encompassed it all, children's meanings and my narrative interpretation.

Finlay (2008) suggests that an alternative to separating one's preassumptions is to practice with a phenomenological attitude. This means working in a back and forth process of acknowledging personal assumptions and returning to look at participants' experiences in a fresh way. As stated before, because everything we do can have a reflective phenomenological interpretation attached to it, critical decisions are made about what experiences to "bring to life" while maintaining a phenomenological attitude. Videos, photographs, and reflection invitations, as adaptations of The Mosaic Approach, were used as potential ways to understand children's reflections. We should remember that all children are unique and reflect in a variety of ways. These methods, and often those in phenomenological research, do not intend to expose the explicit meanings of one specific person but rather to suggest that these meanings are possible human experiences that are usually constructed as a group. Furthermore, the intent of writing the collection of anecdotes was to "make intelligible the kinds of meanings that we seem to recognize in life as we live it" (van Manen, 2014, p. 221).

A double hermeneutic interpretation was used to analyze preschooler's social constructions (meanings) of nature. Smith et al. (2009) in *Interpretive*

Phenomenological Analysis (IPA) suggest that double hermeneutic interpretation refers to "the researcher trying to make sense of the participant trying to make sense of what is happening to them" (p. 3). IPA seeks to understand the phenomena for what it is and not within the confines of predefined analysis. Smith et al. (2009) explicitly describe six steps to data analysis and uncovered how they might be helpful but are not meant to be prescriptive and can be used in any order. The six steps are as follows:

Steps of data analysis	Process
1. Reading and re-reading	Read and re-read to eliminate feeling overwhelmed connection possibilities
2. Initial noting	Write exploratory notes to comprehend data without rules and pinpoint a phenomenological focus
3. Develop emerging themes	From comprehension comments, participant guides understanding but researcher interpretation is interweaved
4. Find connections across themes	Charts or maps are used to consider how themes might fit together. Some emerging themes may be discarded
5. Moving to the next case	Researcher brackets the ideas from the first case to view the next with new openness. Steps one through four begin again.
6. Look for patterns across	These lend to theoretical understanding cases

Note: Adapted from Smith et al. (2009)

Each of the data analysis steps (above table) was considered for interpretation. Each way of reflecting using The Mosaic Approach (see Table 1) was transcribed employing these steps. Through these steps of interpretation and analysis, each data excerpt was interpreted to capture the essence of a preschooler's experience in nature.

Anecdotes, Photographs, and Drawings of our Significant Life Experiences

Three anecdotes, "The Earth is Right Here," "The Butterfly Visit," and "Salamander Brother," are shared in this Chapter to demonstrate phenomenology with children and carefully asking questions in the moment to effectively elicit meaning-making. Additionally, these anecdotes were selected to highlight how practicing in conditions of (be)coming with children, in both curriculum and research, led to child-initiated reflection and data generation. As children reflected on their experiences, they found deeper meanings and understood nature as needing compassion and understanding. The experiences that led to child-initiated reflections are the moments that I found mostly likely to attribute to pro-environmental behavior and attitudes.

Tanner (1980) described experiences in childhood, prior to age fourteen, to be the most influential to pro-environmental behavior later in life and most influential to their love for Earth. Additionally, Chawla (1998) found that the adults modeling care and environmental action also credited their direct childhood experiences as influence.

However, Sobel (2012) argued that the "don't touch" mentality of many environmental educators is limiting children's access to similar experiences of older generations and (Laird et al., 2014) confirm that many educators recall catching bugs as part of their own childhood but are limiting the same opportunities for children. The experiences in our anecdotes empowered children to make their own decisions about what experiences were valuable and how nature was treated. Beginning with "The Earth is Right Here," we invite you into our journey in discovering how children came to know nature.

The Earth Is Right Here

Lee, Midas, and Carmen began to walk down by the water so I followed. Lee climbed to lounge on a tree and Midas, Carmen stood nearby.

I asked, "Do you want to talk about what nature is while we wait to see another animal?"
Carmen asks, "Do you mean nature items?"
I nod with my camera recording.
She pauses before saying, "Hmm. Nature can be all on different planets."
Lee states quickly, "I don't want to talk about this."
Midas repeats Carmen's question, "Nature items?"
Lee interrupts, "Carmen, climb this log."
So I ask, "Are logs nature?"
Lee says, "Yep. And leaves."
Carmen bursts out, "Trees are nature! Leaves are nature! Poison Ivy's nature!"
Lee adds, "Branches are not."
"Houses are nature, trucks are nature." Midas suggests.
Lee says, "No they're not."
Carmen adds, "Children and people are nature because they live on nature."
I ask, "Lee, why do you say houses are not nature?"
"Because they don't walk or something?"
Midas says, "Well, they kind of walk but they don't."
Then I say, "So Lee, trees don't walk but Carmen said they are nature."
"Yep they are," nods Lee.
So I say to all of them, "How do you know then when things are nature or not nature?"
Lee confirms, "Because they're in the wild. Sometimes they move."
"I'm going to try to wiggle this tree" as he bear hugs the tree and tries to wiggle it. Agitated Carmen shouts, "I CANNOT get up here" referring to the log.
"Trees move when you cut them open" she adds.
"But that hurts the trees" remarked Lee.

Silence breaks our conversation about nature and Midas announces, "We don't really care about nature, right guys?" and I say, "Well I really do care about nature a lot" and Carmen immediately joins in, "Me too. Everybody in the world is nice to nature." I then ask, "Why do you think?" and Carmen says, "Because Earth likes the nature and it likes its beauty." Midas then changes his mind and reconsiders, "I do like nature and the Earth is right here." When Midas changed his mind, I knew that together we could help him understand care for nature.

When Carmen said, "Everyone in the world is nice to nature," I knew she had already formed a connection with nature because she moved carefully and quietly and described the forest as "the animal's home. I could tell her words were important to the

children as they listened to her intently. Midas was quick to show her that while her theory was ideal, it was not true. However, her influence led Midas to reconsider, if only for a moment, that there is importance in caring for the Earth. Right in front of us. Taking time to talk about nature, to study it as a phenomenon creates opportunities for understanding. Together, we participated in a conversation about nature that led me to understand the children's perspectives as I sparked their interest with one provocative question so the children could lead how the conversation was carried out. The open-endedness of our conversation taught me that talking about nature as a thing, a space and a part of us is essential for children's sustained connection.

Rosie's drawing as reflective response: Our hands are on the ground because we're looking for worms

The Butterfly Visit

Right next to our school, Carmen yelled, "Whoa! Our butterfly came back to visit us!" Lillian was being dropped off at school and she met us by the parking lot. Nikki, Midas, and Fitz yelled, "Li-ll-ian! Our butterfly came back to visit us! Come see!" She yelled, "Okay guys!" as she carried her lunchbox next to her mom. We had just started towards the Log Playground when we discovered the butterfly. Nikki carefully touched the monarch's wings and Nadia and Zeke both pushed into Nikki to see it too. She whined, "Ugh! Stop pushing me. It's fragile." Zeke asked, "Can I just see it, please?" Nikki backed up and I called to Tess who had kept walking with the rest of the group, "Tess! There's a butterfly!" She walked the group back to meet us and Midas told her, "It's our butterfly. It came back to visit us!" Tess said, "Oh the one you had in your classroom? That's great." The whole group crowded around the butterfly and Carmen said, "Remember it's wings are so fragile. It bled out of its rolled-up chrysalis. Please don't hurt it." Luis added, "We watched it so long. The poor little buddy. It missed us." I said, "It's great that we get to see it again. Its wings

seem larger." Lee said, "It might not be our butterfly, guys." Fitz added, "It probably grew up and came back to see us."

The Return of the Monarch

Carmen's drawing as reflective response: The butterfly came back to see us because we watered its leaves.

Zeke and Nadia were ready to move on and started to walk towards the path. When we entered the Log Playground it was as though everyone knew their plan. Zeke immediately climbed onto the Monkey Bar of the Log Playground Tree. He shouted in a teasing way as he swung, "You can't catch me up here! Oh, no you can't!" At the same time Nikki asked, "How do I get up there again?" I said, "Remember at the bottom and then you can climb up to where Zeke is." Nikki carefully climbed up the Slide of the Log Playground Tree and said, "I can totally do this now. My mom would be so happy." I agreed, "We can show her this part of the movie if you'd like." "I am the movie star, duh!" she spits out. I laughed and could hear Luis ask, "Remember when we were looking to see inside the tree?" Yoshi heard him, nodded, and said, "Milly and Nikki, do you want to play with me? Follow me if you want to play with me." Luis followed him and Yoshi began to pound on the stump of the tree and Luis found a stick to join in.

That butterfly missed us. In this journey, I have come to understand that each experience leads us to know something new or remember something old. This is especially true for children. For adults, we often fly through the busyness of life and skip moments to speed ahead to the next. That was the task at hand, to get to The Log Playground. Tess may have seen the butterfly, but we were on a mission to get to The Log Playground. When given a task, it is easy to forget your surroundings. To notice life around us in the moment. Seeing the Monarch butterfly reminded the children of the one we raised together. Our experiences lead us to make connections and process what is happening. Seeing the Monarch sparked a memory and led the children to think about the one we raised and the possibility of it coming back to see us because "it missed us." The lifespan of Monarchs is typically 2–6 weeks, except for the ones that migrate to Mexico. In that moment, I realized that my factual knowledge as an adult led me to immediately assume it was not the same butterfly. Reflecting on it more, I had hoped that it was a Monarch that would migrate to Mexico and I considered how it was more pleasing to perceive that the butterfly missed us. Furthermore, Carmen reminded us of the butterfly's journey, "it bled out of it's rolled-up chrysalis," as if reminding us of the complexity of its journey since birth.

Considering the feelings of a butterfly made us feel as though we had modeled a pro-environmental attitude by encouraging their conversation about the butterfly particularly following the hatching experience (Chawla & Cushing, 2007). Recognizing nature has feelings allows us to see immediately that our actions impact life. The butterfly "missed us." The children were careful not to hurt the butterfly and considered how fragile it was, especially the wings because "they had bled." They cared for a caterpillar in the classroom for weeks before it became a butterfly. It felt rewarding to all of us that it came back to visit us. The children's work and care paid off.

Salamander Brother

Tired of our conversation, Zeke ran and shimmied up The Monkey Bar and hopped down, "Tess, did you see that? I hopped right down from that monkey bar. I couldn't

do that before." "Let me see," she replied, before he did it again. Fitz, Carmen and Rosie were now at the highest point of the Log Playground Tree when Carmen hopped down and said,

"I'll let you know if I find any bugs, Rosie." And you dropped your mitten."
"Oh! I always do that," laughed Rosie.
Fitz asked, "Hey guys? Do you think all the worms are sleeping because it's cold?" "Well it's a little warmer actually," Carmen remarked.
"Yeah. No mittens," adds Rosie.
"Maybe they're in their cozy beds and we got to find them," considered Fitz.
"They probably are in a group hug so they can stay warm," smiled Carmen.
"Do you think they know to use their leaf beds we made them?" asks Rosie.
"Yeah," replied Fitz.
Rosie looked for a while and then shouts louder than normal,
"I found something! It's a bug! It's a beetle, it's hard!"
"Let me look!" said Carmen, "Oh yeah. It is a beetle."
"Let's make a bed for it," added Milly.

She picked up a large leaf near the Log Playground tree and laid it on the trunk. "This can be its trampoline," she announced. When Milly places the leaf, the beetle falls a few inches down the side of the tree and Carmen catches it. She whispers, "Got it!"

Rosie, irritated, says, "No! No trampoline! A bed! We're making a bed!"
I ask, "Hey. What's all this about? What's wrong?"
"I want to have it. I want to make it a bed, no one else."
"I want to be lucky and find a beetle too," sighed Carmen.
Rosie grumbled, "Ugh," and says, "Yeah. I am lucky."

Moments pass by before Carmen yelled, "P! We found something!" I walked over to see and the girls had just turned over a log. Two wet salamanders laid in the log's print. Carmen was holding a worm in one hand while touching the salamanders with the other. Rosie whispered,

"Aww. Look at it! Can I hold it?"
"Just pet it lightly first" whispered Carmen.
Nikki comes over, "Is it a worm?"
Carmen whispers, "No they are salamanders."
Rosie goes to pick it up and says, "Whoa. It's so wiggly. How can I pick it up?"
"Soooo carefully," remarks Carmen.
Carmen tries to pick one up with just one hand and whispers, "Yeah. Wow. Very wiggly." She placed her worm on a nearby log and says, "You rest here a minute." Carmen gets a salamander in both hands and shrieks as it falls to the ground." I ask, "What made you scream?" She says, "Because it wiggled way too fast." Rosie giggled at the wiggling as she loses it in the soil. She moves some of the ground around and instantly jumps up and takes two steps back. "Ahhh! A tiny spider," she yelled. Then she pauses and says, "Oh well. It's just tiny" and begins looking again. As she looks she says, "Ugh. I can't find my salamander." I say, "Just keep looking under those leaves." She moves some leaves and I say, "Oh! I see its head." She picks it up and closes her hands loosely. She opens them to look and moves it from one hand to another whispering, "Whoa. I got it."

She throws her head back laughing and says through giggles, “Ha! He’s tickling me.” She puts her mouth close to her closed hands and whispered, “That tickled me. . .you tickled me.”

Midas is nearby and Carmen says, “Show that salamander to Midas.”
Rosie nods, “Midas! I found a salamander over here.”
“Can I hold him?” He asks as he peeks in her hands.
“Yeah, sure” as she circles back around and checks back to see if she can quickly find him his own to hold.
He asks, “Can you help me find one?”
“Oh-kay,” Rosie says, “Thanks for not taking it from me. We found it by this log.” “They’re just so very cute!” she continues as she scanned the ground.

Carmen placed her salamander on the log for just a moment and Midas says, “Found it!” and went to pick up Carmen’s.

“No! I was just resting my hands for a minute,” she snapped.
Picking it back up she demanded, “Ahh-ah! Stop tickling me you little salamander!”
Sighing, she continued, “When they wiggle really fast, it tickles too much!”

Rosie peered closer at Carmen’s and Carmen said,

“Rosie when they wiggle, they tickle. Like tickle-wiggle, tickle-wiggle.”
“Pah-lease. . .help me find one. Please!” Midas pleads.
Carmen says, “Okay. They’re very squirmy.”

Milly joins them showing her hands. She is holding a well-formed ball of mud. Carmen says,

“Oh! I bet my salamander would love that mud ball, Milly.”
“Yep. He likes it!” as Carmen put the salamander’s face by the mud ball.
“Rosie, can we see if yours likes my mud ball?” asked Milly.

Rosie lets go of it in her hands and Fitz watches. She says, “This little guy is quite a handful. I can’t even take it.” Midas talks Carmen into holding her salamander and Milly passed the one she was holding to Fitz. Fitz giggles loudly and spins in a circle as the salamander moves in his hand.

“I can’t believe how cute he is. He’s crawling up my sleeve because he’s cold. I know it!” squeals Midas.

Midas holds it between his fingers and flips it over to see the belly. He remarks,

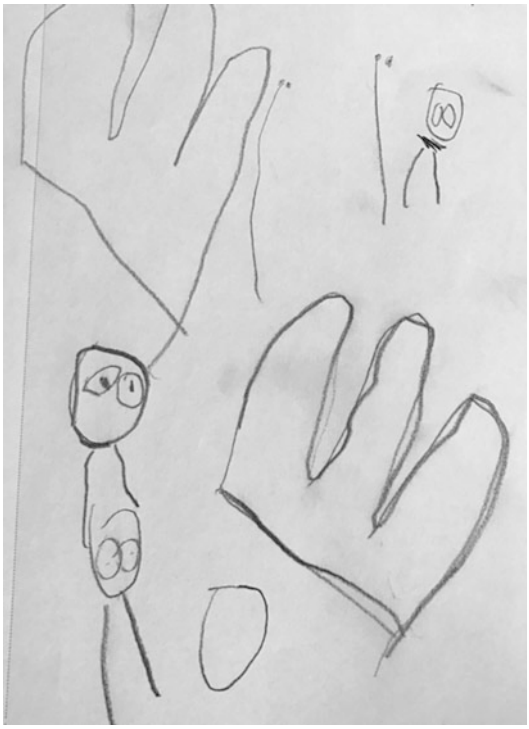
“Oh, my goodness! He’s so spotty. He’s like a Dalmatian.”
“Why are you tickling me so much, brother?” Fitz yells to the salamander in his hand.
“Yep. Mines my brother too,” confirms Midas.

Tess told us it was time to head back to school and so Midas puts the salamander on the log and says, “I’ll miss you Salamander Brother.” Right then, Carmen wrapped her arm around Midas and says, “Pssst. You’ll always be my brother.”

Midas carefully holding a salamander

Midas noticing the salamander’s spots

Midas' drawing as reflective response: Here's my little brother, Mikey!



Lillian's drawing as reflective response: We always hold the worms. They love us.

Nikki's drawing as reflective response: To find worms you must look really hard and then bam! You see them!

I assumed that the conversations about group hugs and cozy beds were the children's way of embracing the chill in the air that day. After we walked for a while, our bodies were warm and we could shed our mittens. The children also empathized with the worms or insects that could not escape into the warm school like they could. When thinking about a group hug, I thought about the warmth it brings. The physical warmth of being close but also the emotional warmth of being held and cared for by people you like. It makes you think of love and family. The salamanders became our brothers. As Rosie was searching for her salamander she was forced to address her fear of spiders again. She jumped and shrieked at first but remembered she had overcome it before and could again. When I think about what it means to have a brother, I envy people with older brothers who probably tickled them and picked on them when they were young just like the salamanders were tickling the children. I wondered if some of the children longed for an older brother too. When Midas said sadly, "I'll miss you my salamander brother," Carmen comforted him by wrapping him in her arms and telling him that he is her brother. In the end, we found that if we care for nature, nature will care for us.

The part of be(in)nature that I find most important is "be nature." That children can connect with nature to learn they are nature themselves. The children learned that anything once alive, particularly things that could breathe were nature. They learned later that plants and logs, dead or alive are nature too. This realization allowed their relationship and connection with nature to grow. For example, the butterfly "missed us." Although it could not express feelings, it missed us because it was alive. The children knew that living things had feelings like humans. Ending our experience with salamander tickles was powerful for us. Fitz accepted the salamander as his brother which told me he accepted that he is nature or that nature deserves the same respect. Midas joined in his compassion and his caring side shined through. Carmen accepted his need for care and embraced him allowing me to see the children bond over a special moment that felt like family.

Discussion and Implications

Uninterrupted Time in Nature

Studying how children interacted and came to know nature was simple and challenging at the same time. It was simple to support children's uninterrupted time and just be. To be with children with(in) nature while videoing their conversations and interactions with the ground, trees, insects, and life without an agenda. For 2 h, we escaped the real world back at school. We escaped the schedule, logistics, and structure. Doing phenomenology was challenging because children pulled me in every direction to experience nature with them. One child found a worm for the first time and touched it while another climbed higher on The Log Playground Tree than before and they both needed me to experience it with them at the same time. The excitement and passion was real. Without an agenda or adult leading their study, children moved freely and excitement filled the forest. The discovery of a monarch led to the reflection of our care in the classroom to the sadness of the blood it shed. Its return led us to believe it missed us. Discovering a salamander meant realizing nature is like us, and when it has arms and legs, it becomes clearer nature is family. Nature is our brother. Additionally, it was challenging because while doing phenomenology a phenomenologist knows that every second has the potential for a reflection and being open to any experience and any reflection meant the data was abundant but a project was to unfold in the end. Uninterrupted time in nature meant the children discovered nature for themselves and realized over time that you can be(in)nature and nature needs our care.

Children's Curriculum, Research, and Voice

Children guided this study of nature and we discovered how nature leads us to understand that we can be(in)nature. Listening to children and allowing them to guide the research is a priority for phenomenologically understanding children's

experiences. Each time the children approached me for a reflection invitation, where they would talk about their experience, request to watch a certain video, or draw about their experience; we knew they found meaning or significance in their interaction with(in) nature. Stepping back while being present meant that the children felt competent in their reflections with no right or wrong answer. More importantly, they did not look for approval or praise to know that their research and voice were valued. The role of a significant adult in children's experiences links directly to Chawla's (1998) point of adult modeling of pro-environmental behavior and attitude. By empowering the children to experience with(in) nature, consider themselves nature, and listen to one another while supporting their needs gave them agency over what they learned about nature and what led them understand that they are nature and nature needs our care.

Significant Life Experiences of Preschoolers

van Manen (2014) reminds us that every experience can be reflected upon and stays with us until the next experience takes precedent. While we know children's nature connections as important, how do we inspire children to sustain connections into adulthood? SLE literature suggests direct experiences in nature (Chawla, 1998, 2007; Chawla & Cushing, 2007; Laird et al., 2014). The most influential direct experiences from our research that may lead to pro-environmental behavior later in life include:

1. Defining Nature Aloud: The children could talk about nature often, uninterrupted by adults to discuss, negotiate, argue, and contemplate the elements of nature leading to the discovery of what it is and group meaning-making.
2. Discovering Nature's Needs: Over time children used their knowledge of their own needs to suggest that nature needs the same: group hugs, cozy beds, trampolines.
3. Realizing Nature is Family: Being in a group with the consensus that nature should be cared for, let's children realize that nature is family.

Based on these experiences, there is a potential for children to reflect on these experiences as memories later in life and recall what nature is, its needs and the discovery that as humans we are nature and/or we can be(in)nature. While SLE suggests strong connections to nature in childhood with adult models, encouraging children to conceptualize themselves as nature provides a new avenue for connection. Phenomenology as a research approach gave us the framework to understand nature as a phenomenon from children's perspectives. We encouraged their lead to help us understand their sense of wonder with(in) nature. Campbell and Jobling (2012) suggest that children need to find a sense of wonder and joy in the natural world. Being tickled by a salamander is just one example of joy we found together. The joy connected Midas to the joy his family brings him, thus leading him to see the salamander as his family and himself as nature. Reflecting as an adult on my own

childhood, my experiences in nature feel less significant than the implications in Salamander Brother. We intended for children to be provided with similar experiences like we had when we were children such as climbing trees, playing in the dirt and catching bugs. However, we discovered that when given the opportunity, children will teach us how they can conceptualize nature on much deeper levels as they make connections to their own lives and the ways their actions impact the environment.

Abstract

This Chapter posits sensory tours as a method for discovering children's embodied "storied entanglements" in, with, and for the natural world (Ritchie, 2014, p. 50). Drawing from existential forms of phenomenology (Merleau-Ponty, Phenomenology of perception (C. Smith, Trans.). Routledge, New York.

(Original work published in 1945), 1945/2002), and recognizing the significance of somesthetic experiences (Iared et al., 2016), sensory tours provide a novel approach for understanding children's experiences of being and becoming and relating with other natural beings. During a sensory tour, a child is invited to wear a small wearable video camera; the camera goes where a child goes, sees what a child sees, hears what a child hears, shows what a child touches, and reveals what a child tastes. Informed by the tradition of walking tours, which have been used for some time in place and environmental education research (Hart, 1979), the sensory tour method is uniquely positioned to unravel embodied temporal-spatial meanings during children's exploratory movements. This method opens up possibilities for bridging the "correspondence" gap between being and thought – by capturing children's pre-reflective movement – their imaginative song and dance, self-talk, and expressive utterances, as they interact with and relate to others in the more than human living world. The Chapter will draw from research findings involving young children in an Alaskan cultural and wilderness context (including trudging through tundra, transforming sticks into weapons, and scaling up tree castles). Through these examples, I will reveal how children's first imaginary and sensory encounters inform their sense of being with the natural world.

Extending Significant Life Experience Research

This Chapter builds upon understanding of children's (SLE), an important line of inquiry that has persisted in environmental education and psychology for over 40 years (Cobb, 1977; Tanner, 1980; Chawla, 1998; Palmer, 1993; Williams & Chawla, 2016). This thread of research has sought to understand the "formative influences" of childhoodnature experiences and the way in which early experiences in nature shape an individual's feelings and attitudes as well as their interactions and actions toward their environment. Research on SLE has, however, primarily been based on autobiographical memories of adults. As Chawla (1998) explained, a "retrospective approach is a necessary preliminary that suggests the type of formative events that . . . research should monitor" (p. 361). While Chawla (1998) argued that memories of SLE offer a "lifespan perspective" on experiences that have influenced a person's feelings and behaviors toward their environment, memory-based research poses several limitations. First, memories are tainted by the past and the present and, thus, are unlikely to render complete and accurate details of specific encounters or events. As Chawla (1998) explained, oftentimes recurring encounters may be "blended together into one 'generic' representation" (p. 363). Furthermore, adult reflections on childhoodnature experiences are subject to adult biases and perspectives on what is meaningful and important. In this way, SLE research, collected by way of

adult memories, lacks the firsthand viewpoint of childhoodnature encounters as perceived through the lens of a child. In other words, retrospective SLE, while informative and useful, should not be relied upon as a representation of children's lived experiences. Thus, other naturalistic observations and methods, particularly those that honor the voices and perspectives of children, should also be pursued to build upon a retrospective line of inquiry (Chawla, 1998).

Embodied Essences of Childhoodnature

> The body is the vehicle of being in the world, and having a body is, for a living creature, to be intervolved in a definite environment. (Merleau-Ponty, 1945/2002, p. 94)

This chapter extends SLE research by considering the somaesthetics of childhoodnature experiences, that is, the "soma" or embodied and "aesthetics" or felt experience of being a part of nature (Iared et al., 2016). Children are nature living and breathing natural entities, intricately connected with everything that exists. While much of the children *and* nature literature has positioned children as nature deficient, disconnected, and somehow separated from what has been designated as nature (Louv, 2008), in this Chapter I maintain that children, and all humans, for that matter, are natural beings *always* immersed in an environment and place (Malone, 2016). Humans are indeed absorbed in the fundamental life-giving exchange of oxygen and carbon dioxide, between flora and fauna. Not only do humans play an integral part of basic biological interchange, interactions with other natural beings are also physically, culturally, and spiritually situated in time and place. This temporal-spatial dimension makes up the essence of *Dasein* or being in the world (Heidegger, 1962; Merleau-Ponty, 1945/2002). In other words, utterances of being are informed by the past, oriented toward the future, and enacted in present time. While SLE research has primarily been concerned with reflective essences of the past (Chawla, 1998; Williams & Chawla, 2016), this Chapter is framed around pre-reflective essences of the present, namely, through the lived bodily experiences of a child.

Phenomenology is concerned with "the nature of what is," in "turning from things to their meaning" (Schwandt, 2015). More specifically, Merleau-Ponty's (1945/2002) philosophy of existential phenomenology centers bodily existence at the core of conscious and subconscious understanding of the world and other living entities. Embodied essences of being, therefore, cannot be separated from a time and a place (Merleau-Ponty, 1945/2002), yet researchers have found it challenging to identify data collection and analysis methods that capture the pre-reflective essences of being (i.e., prior to language and thought) in a specific moment and in a particular time (Iared et al., 2016; Thrift, 2008). In this Chapter, the sensory tour method is presented as a strategy for bridging the correspondence gap between being and thought – by capturing children's pre-reflective movement – their self-talk and expressive utterances, their imaginative songs, and place activity, as they interact with and relate with others in the more than human living world.

But how can children's varied states of being in the more than human living world be authentically represented and described? Indeed, researchers pursuing studies within the new childhoodnature framework might be confronted with the nonrepresentational problem, that is, the challenge of "interpreting and explaining the primordial and, often, pre-conscious and pre-rational/linguistic experiences of selves and ecological others" (Iared et al., 2016, p. 191). Additionally, we must also acknowledge the correspondence problem: the gap between being and thought (Iared et al., 2016). In other words, the authentic state of being in nature may be quite distinguished from a reflection on the state of being. Both, therefore, should be considered in researching childhoodnature experiences. So how can childhoodnature scholars capture children's firsthand sensory encounters? Particularly, what methods can be used to explore children's utterances and nonverbal forms of communication expressed during their play and exploratory activities in nature? To answer these questions, and to extend understanding of children's lived SLE, researchers need to consider methods for promoting children's agency in research, specifically those approaches that highlight and honor children's views and perspectives.

Children's Agency

Honoring children's agency in research has been discussed extensively among scholars of the sociology of childhood (James, 2009; Corsaro, 2015) and those interested in environmental and nature-based research with young children (Barratt Hacking et al., 2013; Green, 2015). The United Nations Convention on the Rights of the Child (UNCRC) set precedence for children's citizenship and rights of participation (United Nations 1989, 2005). Specifically, Articles 12, 13, and 14 under the UNCRC established the rights of the child to form and express his or her own views, ideas, and thoughts and have been more broadly interpreted to include all areas of relevance to children's lives, including research (Barratt Hacking et al., 2013). This Chapter advocates for the importance of honoring children's agency in childhoodnature research by proposing a method for capturing the essence of children's being in the world. The method proposed naturally recognizes the unique contributions of children both in the present and in the future (James, 2009).

Additionally, research approaches involving young children must also consider the influence of adults on children's agency during all aspects of the research process. The power imbalance between an adult researcher and child participants can greatly impact *what* data are collected and *how* data are interpreted. To address this issue, some have suggested relational approaches and child-friendly data collection methods, such as book discussions, children's drawings, and interactive photography (Clark, 2005; Einarsdottir et al., 2009; Parkinson, 2001). However, relational approaches still rely on the direct involvement of adults during the research process, and depending on the relationships established, the researcher involvement will inevitably influence what is shared and how children act and behave. Others have suggested the use of video as a means to "pick up different

sorts of voices" along "with a range of images" (Haw, 2008). However, issues regarding adult influences on children's behavior have also been raised regarding the use of video with young children. Namely, Robson (2011) discussed the tension of remaining unobtrusive when filming preschool-aged children through the use of traditional video equipment (a handheld camcorder). Additionally, traditional video data are still framed through the researcher's point of view, that is to say images are never neutral and they are literally and socially constructed (Robson 2011, p. 186). Thus, Robson (2011) experimented with inviting children to hold the camera and film, finding that this strategy was "vitally important" in providing children a "sense of ownership in the process" (p. 183). However, having young children hold video cameras might be logistically problematic in that handheld camcorders can become heavy or difficult for young children to operate. Furthermore, because operating a camera requires the use of children's hands, the use of traditional handheld equipment might prevent children from participating in authentic play or other day-to-day activities. In other words, handheld cameras (held by adults or by children) can be intrusive in the research process. So how can children's authentic experiences of their world be collected in an unobtrusive manner? The sensory tour method was conceived as a novel research approach in using wearable cameras to capture the essence of being in nature through the lens of a child.

Wearable Cameras in Research with Children

Wearable cameras are extending the "ways and means" in which "we see and interpret the social world" (Chaflen, 2014, p. 299). A distinctive feature of the wearable camera is that it records what the user sees and experiences during novel events or situations that would be otherwise difficult to capture (Chaflen, 2014; Green, 2016a). While the use of wearable cameras in research with adults continues to expand (Chaflen, 2014; Dozza & Fernandez, 2014; Fung, 2015; Knight & van Nieuwerburgh, 2012; Leong et al., 2014; Sanchez-García et al., 2015), the incorporation of wearable cameras in research with children has thus far been limited (Kindt, 2011, Ghekiere et al., 2014; Green, 2016b, 2017). Kindt (2011) invited high school students to wear cameras using headstraps in the classroom. The cameras provided the teacher with a "never before" view of "what students see" and experience in the classroom (Kindt, 2011, p. 182–18). Ghekiere et al. (2014) implemented a "bike along" method, inviting 9 to 10 year-old children to wear cameras to record their encounters with environmental features while cycling. The "bike along" method included engaging children in discussions about the features they encountered, suggesting a child-directed approach that emphasized the perspectives of children. Over the last few years, I have investigated the use of wearable cameras in research with young children (3–9 years of age), referred to as the "sensory tour" method (Green 2016a, b, 2017). In this chapter, I will present several examples of children's sensory tours in Alaskan forest and tundra environments in order to consider the somaesthetics of childhoodnature interactions.

Conception of the Sensory Tour

The sensory tour method draws from the tradition of walking tours, which have been successfully used with children in geographical, place, and environmental research for a number of years (Green, 2012, 2014; Hart, 1979; Kjørholt, 2003; Kylin, 2003; Sobel, 2001). Given the tendency of children to "talk while they are doing" (Parkinson, 2001, p. 145), walking tours provide an alternative format to engage children in dialogue as they interact with other living and non-living entities in their environment. Tours provide children with an opportunity to show and tell what is important to them within a particularly setting, be it indoors or outdoors (Hart, 1979; Green, 2012). In other words, "tours allow opportunities for children to show something that cannot be explained" apart from the place (Green, 2012, p. 275). Understanding of children's experiences is thus gleaned through attending to both children's verbal and nonverbal forms of communication. That is, tours reveal children's "pre-linguistic experiences of selves and ecological others" by exploring children's expressions of meaning through their interactions (Iared et al., 2016, p. 191).

Traditionally, adult researchers accompanied children on a tour with a handheld video camera asking questions of children as they pointed out and described different features and experiences of their environment (Green, 2012; Hart, 1979; Sobel, 2001). In this way, child-led tours promote children's agency in the data collection process by providing opportunities for children to direct what they wanted to explore (Green, 2012). A noted limitation, however, is that the course of a tour is dependent on the relationship formed between a child participant and the researcher. Depending on the relationship established, children may or may not feel comfortable sharing certain aspects of their environmental experiences. Furthermore, in tours structured with adults, children may merely show and talk about what they perceive adults might like to hear rather than what they actually do in a particular setting. In other words, it can be difficult to determine if the things children show and talk about actually represent children's authentic day-to-day life encounters of their environment. This limitation relates back to the correspondence gap between being and thought previously discussed, whereas, the state of being in a time and place is distinct from one's thoughts about being in that place (Iared et al., 2016). Therefore, it is important to further explore a "tour" approach that would alleviate the involvement of an adult researcher as well as highlight children's authentic experiences of being in the world.

In two recent research projects, we implemented the sensory tour method, by inviting children to wear small video cameras around their forehead while they "toured" (freely explored and played) in their environment. When viewing footage captured during a sensory tour, one feels as if they are walking in the shoes of the child wearing the camera. The method literally captures a wide range of a child's sensory perceptions, including what he or she sees, hears, says, and touches in their environment (Green, 2016a). In this sense, sensory tours were conceived as a participatory research approach in that findings rendered from the video honor children's voices and perspectives. In addition, when paired with video-stimulated recall discussions and/or other interactive activities, sensory tours can be used as a means for engaging children in developing a research focus and interpreting their own experiences (see Green 2016b, 2017).

In our projects, we simply invited children to put on the wearable camera before going out to play and explore. The children volunteered to wear the cameras and most all appeared eager to do so. Thus, children took turns in wearing the cameras for as long as they were interested. If a child decided they no longer wanted to wear a camera, they simply found an adult (researcher or teacher) and asked to have it removed. In fact, once the cameras were strapped around their foreheads they seemed to forget that they were wearing them. Additionally, an open-ended structure is ideal when utilizing sensory tours. While it is important to provide children with some perimeters (for safety) as to where they can and should not play or explore, to the extent possible sensory tours should be open ended, child initiated, and child led.

The Somaesthetics of Childhoodnature

In this Chapter, we will consider the somaesthetics of childhoodnature, that is, the "felt" bodily experiences captured by way of sensory tours. The term "soma," according to Shusterman (2009), designates the "living, sensing, dynamic, perspective body" (p. 133). "Bodily consciousness. . .is not merely the consciousness that mind may have of the body as an object, but includes the embodied consciousness that a living sentient body directs at the world and also experiences in itself" (Shusterman, 2009, p. 133). Drawing from the phenomenological philosophy of Merleau-Ponty (1945/2002), the body is recognized as a medium in which one establishes a consciousness toward the world: "I am conscious of the world through the medium of my body" (p. 95). Phenomenological meanings are derived from "perception (hearing, seeing, etc.), believing, remembering, deciding, feeling, judging, evaluating and *all experiences of bodily action* [italics added]" (Schwandt, 2015, p. 234). Reality is thus subject to a time and a place, and through the body, which "anchors the subject to a certain 'environment'" (Merleau-Ponty, 1945/2002, p. 90).

In this chapter, the "soma" bodily experiences of childhoodnature will be explored through the presentation of descriptive transcripts of young children's sensory tours. Various aspects of childhoodnature embodiment will be presented to demonstrate the unique approach of using wearable cameras in research with young children. First, we will begin by exploring the physiology of childhood, particularly in considering how the physical body of a child is distinguished from that of an adult. This physical state of being and the assumptions associated with size directly inform the essences of children's experiences. In this way, we will consider the positionality of children within distinct social and cultural contexts. Second, we will consider the imagined essences of childhoodnature experiences. Through the viewpoint of a sensory tour, we will consider how children enact scripts through play and make-believe which shape their state of being. Along this line, we will consider children's sensory perceptions of the more than human living world, that is, those expressed by nonverbal utterances, experienced through movement, exploration, and imaginary play. Finally, we will consider interpretation of childhoodnature experiences; specifically, we will examine the benefit of pairing video-stimulated recall discussions

with sensory tours to consider both reflective and pre-reflective childhoodnature experiences.

The Embodied Child

The embodied experience of a child is distinguished from that of an adult. For one, the period of childhood is marked by progressive, yet at times sporadic, physiological growth and change. James (2000) explained:

> Children themselves have to live with their changing biology, a biology that both shapes what they are and what they can do and one that, at the same time, invites particular perceptions of what, as children, they should be and should do. (p. 26).

Not only does a child's changing physical body shape their self-consciousness, these changes are informed by the "situated agency," of being within a childhood culture in a particular place and time. It is, as James (2000) argued, the "everyday actions and interactions with each other that children develop a consciousness of self" (p. 27).

Size and Perspective

Wearable cameras provide deep insight into how physical stature influences the way in which children perceive and interact with other living beings in the natural world. Size not only influences perceptions but also accounts for what children do. Because of size, certain activities might be more challenging than others. As an adult, I scarcely considered the challenge of wild rosebushes prior to taking preschool children outside for open-ended play and exploration in an Alaskan forest. However, during 4-year-old Kenneth's sensory tour, the camera revealed Kenneth's encounter with the prevalent rosebushes when wandering down a new trail on his own:

> Halfway down the trail Kenneth stopped dead in his tracks when he confronted a large bush. "*A LOT OF BIG STICKER BUSH!*" he exclaimed.
>
> He continued pointing to all of the bushes around him, "*Big sticker bush, there is a sticker bush right there. AWH!*"
>
> Kenneth turned and ran back to his teacher. "*There's big sticker bushes everywhere!*" From the vantage point of a four-year-old, the large bushes were perceived as a threat. After encountering the large bushes on his own, Kenneth sought refuge with his teacher.

Sensory Tours provided a firsthand view of a child's encounter with the rosebushes, some of which towered over the children. Indeed, children exist in an adult world, both physically (James, 2000) and socially (Corsaro, 2015). Beyond mere physical size, children are subordinately positioned in a world primarily driven by

adults. In many instances, children have little, or no control, over the environments in which they are exposed to or the spaces or places in which they grow up (Corsaro, 2015). Access to certain environments is also constrained by adult permissions and restrictions. And depending upon the amount of freedom provided, children's experiences of nature are either largely influenced or scarcely shaped by adults. Natural settings, as opposed to human-built indoor settings, provide a setting for children to exercise a great deal of autonomy in constructing and creating their own sense of place (Green, 2013). Yet size and what is perceived as safe and what is perceived as scary shapes a child's perceptions and interactions with the more than human living world (as indicated in the rosebush example).

Becoming Bigger

Additionally, "children are deeply concerned with physical size," and as a result, they often climb to the top level of any available structure to make themselves bigger (Corsaro, 2015, p. 153). In the following example, Oliver's sensory tour revealed how Oliver and Ryan made themselves "bigger" through their physical actions:

> The two boys successfully cascaded up a fallen tree stump in the forest.
>
> "*Look at us! Look at us! Teacher! Teacher! Teacher! Teacher!*" Oliver called to his teacher who stood nearby in the distance. The video footage showed Oliver's vantage point of being high above his peers and teacher. His feet were positioned on a lower branch and his arms clasped the limbs of an upper branch. Oliver looked down at his and Ryan's feet positioned on a skinny limb above the ground.
>
> "*Whoa!*" Oliver exclaimed, revealing his feeling of unstableness.

Sensory tours allowed for the embodied vantage point of experiencing this heightened view through the lens of a child. While the feat of climbing to the top of a tree might appear simple from an adult's perspective on the ground, Oliver's muttered expressions, his physical movements, and adjustments revealed an inner conflict between apprehension and accomplishment.

Anticipating Growth

In considering a child's embodied physiology, Corsaro (2015) also explained that children "come to value growing up and getting bigger" (p. 153). For example, during a sensory tour, 4 year olds Keenan and Spruce conversed about their desire to "get older" so that they could reach up higher to peel the bark off a large birch tree:

> "*No, I'm gonna get it. I can-I ca-I'm gonna try,*" Keenan persisted.
>
> "*Um after you're done trying if you can't get it then I'll uh re-try it,*" David said.

Keenan stretched up to reach a piece of loose bark with difficulty. David also tried.

"*You can get it. You can get it!*" Keenan encouraged him.

"*See look! There is a little stand up here. Whoa!*" David stated uneasily standing on a small tree stump.

"*Let me try it. I'm super tall. I can reach it,*" Keenan explained.

"*Yeah you can.*" David encouraged.

"*I can climb everything.*" Keenan replied.

"*And I'm even four.*" David said, holding up four fingers.

"*I'm four too.*" Keenan replied

"*We're the same height,*" said David.

"*Can't reach it,*" Keenan said, taking a step back.

"*Well I can't reach it either,*" David agreed, "*So, you get a little older maybe we can reach it.*"

"*Yeah, I need to get a little older,*" Keenan said.

"*Me too!*" David added.

The sensory tour captured Keenan and David's peer-to-peer dialogue. The conversation revealed an inner tension posed by physical size. While the children put forth their best efforts to reach the upper bark of a birch tree, while even encouraging one another, they both acknowledged the limitation of their bodily stature and expressed a desire to "get a little older," anticipating a growth in physical size.

Imagined Essences of Being and Becoming

Proposing an ecophenomenological philosophy, Payne (2013) reminds us of our own "oneness of natures" (p. 425). Natures is referred to in a plural tense, signifying varied interpretations and meanings of nature, "past, present and imagined ecological affordances" (Payne, 2013, p. 426). Presumably, this also relates to what James (2000) described as child embodiment situated and enacted in a time and place. For children, *imagined* ecological affordances are frequently expressed through play and make-believe. Indeed, a child's imagination stretches beyond the boundaries of what might be considered adult-derived temporal and spatial constructs. That is, the sociodramatic and imaginary play of a child reaches beyond possibilities and quite conceivably beyond the realm of adult understanding. To a child, imaginary experiences in nature might be just as rich and meaningful (if not more meaningful) as those that are concrete and realistic. The imagined state of young children fluctuates

between the concrete and the abstract. Physical objects are used to represent the here and now; imagined ecologies represent the possibilities of what one can become. Research expanding the SLE literature would benefit from linking finding on what children *aspire* to become to what adults have come to be.

Play and Make-Believe

While research captured by way of adult observations has widely recognized the role of children's symbolic and make-believe play with inanimate objects in nature (Green, 2013), there is a scarcity of research that has looked at the embodied imaginations of being and becoming. Below, a portrait of an imagined ecology of childhood is presented by way of a sensory tour, keeping in mind that children's imaginary play is both culturally situated and "culture in the making" (Lindqvist, 1996, p. 15). Two 3 year old children played "Christmas" in the forest:

> "*It's Christmas time!*" Jenny shouted and began singing a song in the forest. She twirled around some green foliage.
>
> "*Do you like my Christmas decoration?*" Jenny asked before dropping the foliage on the ground.
>
> "*Christmas time. . ..*" Jenny continued singing.
>
> Jenny's friend Cindy stomped through the forest towards Jenny. She bent down and picked up some foliage, "*Ho, Ho, Ho – Merry Christmas!*"
>
> Cindy appeared to have taken on the role of Santa Claus; she took a few more steps and bent down again, "*Ho, Ho, Ho Merry Christmas!*"
>
> She ran to another strand of trees and bent down, "*Ho, Ho, Merry Christmas!*" Cindy ran and paused, catching her breath in between movements, exclaiming over and over again, "*Ho, Ho, Ho Merry Christmas!*"

The sensory tour method provided a firsthand view of Jenny and Cindy's imagined states of being, revealing the act of how the world is transformed through make-believe. The camera, worn across the brow of Cindy's forehead, revealed Cindy's embodiment of Santa Claus. She deepened her voice in expressing a holiday cheer, moving from place to place through the forest with a purpose. The camera also showed how Cindy's breath quickened with movement, indicating her excitement in bending down to deliver presents as she merrily announced her arrival.

The embodied child is not only influenced by social norms; he or she is also culturally constructed. Perceptions of what children should be and what children should become vary among cultures. As Christensen (2000) explained under Minority western cultural perceptions, "children are constituted as essentially vulnerable beings who can only survive and develop successfully if intensely nurtured and protected by adults" (p. 40). To some extent, the children's make-believe play of

Christmas was informed by Minority western cultural ideals. Santa Claus can be thought to represent a nurturing adult, providing treats and presents to good little boys and girls. Additionally, the children used natural objects to represent symbolically Minority western ideals of the holiday experiences –grass for ornaments and ferns for presents. The schema itself is not necessarily a unique example of children's make-believe play; certainly other children have enacted Christmas. What is unique, however, is the viewpoint revealed through the sensory tour. The tour provided insight into the embodied physiology of imaginary transformation and how the act of role-playing informed the ecology of childhoodnature experiences. In other words, in the role of Santa Claus, Cindy forged her own connection with the more than human world, which seemed to provide her with a sense of confidence and purpose.

Expressive Utterances

"Our initial experience of the world is always sensory, perceptual, and is affective 'emotional' in feeling. All precede language: affect is also and often pre-reflective" (Iared et al., 2016, p. 196). Expressive utterances represent pre-reflective consciousness, preceding language and verbal forms of communication. Expressive utterances, that is, children's nonverbal forms of communication, tell the story of bodily movement in nature and of transformations of an imagined ecology. Peter's sensory tour (illustrated below) revealed a child's transformation of a stick through movement and expressive utterances:

> The camera followed Peter's gaze as he turned upward towards the blue sky, revealing the leaves of the paper birch trees and the pointed tops of the tall evergreen spruce. A brown stick, held by Peter's hand, emerges directly in front of the camera.
>
> "*Do. . .do. . .do. . .do. . .do. . .*" Peter aimed his stick at two peers in front of him on the trail.
>
> "*WOOOW!*" Peter raised the stick high.
>
> *"GRRRRRRRRRRRRRRRRRRR,*" Peter made a rolling R sound, giving the impression that the stick was being energized. Swinging it up, and then to the left, and then to the right, the camera showed Peter hastily turn around in a circle.
>
> "*Bam. . .bam. . .bam..*" Peter moved fast through the forest, empowered and equipped with his magic stick.

Peter's engagement with the stick depicted through his sensory tour brought to life a pre-reflective consciousness of being and becoming (Payne, 2013). Indeed, his bodily movement and utterances of expression tell of an experience inseparable from a particular time and a particular place (Merleau-Ponty, 1945/2002). The wearable camera revealed an essence of being that would be next to impossible to capture through any other method. Perhaps, through a reflective descriptive method (i.e., drawing or an interview), Peter might be able to tell you that his stick was a sword or

another type of weapon. However, Peter would not be likely to put into words *how* the stick became a weapon; in other words, it would be difficult, if not impossible, for Peter to later vividly describe the process in which the transformation occurred. In other words, it would be challenging for a 4-year-old to recall his actions of raising a stick up toward the sky, making a sound and twisting it around to "charge" it. Extending study of children's SLE, sensory tours allow for a distinguished measure for capturing pre-reflective consciousness and the process of being and becoming, as well as the meaning derived behind such actions.

Movement and Exploration

"Our bodies are always interacting relationally via movement in the lifeworld" (Iared et al., 2016). Indeed, movement and exploration play an important role in a child's discovery of being in the world. Movement is intertangled and cannot be separated from knowing and describing, which also entails observation (Ingold, 2011). "Being observant," Ingold (2011) argued, "means being alive to the world" (p. xii). Similarly, Seamon (2014) articulated the synergistic dynamism between humans and their environment, whereas people and their worlds are integrally intertwined. In the following description of Elijah's sensory tour, movement accentuated his bodily relationship with his environment and other living beings:

> Tip toe, back and forth, forward and backward, 5 year old Elijah crept through the forest in pursuit of his teacher. Softly crunching the leaves under his feet, Elijah paused, turned, and looked behind him to ensure that his friend Sally and another adult were still following him. The camera showed when Elijah turned back towards his teacher and the landscape of the forest trees, bushes, and muddy path passed quickly under Elijah's feet. The sound of his breath quickened, and the video footage shook as Elijah moved quickly and quietly to close the gap between him and his teacher. His teacher moved at an even pace ahead of him, unaware of Elijah's sneaky game. Elijah snickered under his breath, and the camera came in close contact with bark of a tree; Elijah hid in the shadow of the tree out of view from his teacher who had turned and looked back. Elijah waited quietly looking at his friend who was also smiling. When his teacher continued forward, Elijah resumed on the trail, closing the distance between him and his teacher, "*AHHH!*" Elijah exclaimed.
>
> His teacher raised his hands in the air, *"AHHH!*"
>
> The children giggled.
>
> "*We've been following you!*" stated Elijah.
>
> "*You are real sneaky!*" his teacher said.

Elijah's propelled his body in attendance to the world around him. Aware of the crunching sound of the leaves, he tiptoed softly, and quietly, as he neared his teacher. Acknowledging the protective cover of the trees, he paused briefly looking away from his teacher, pretending that he was doing something else. His bodily

movement, however, revealed an observation that was keenly fixed and aware of both the teacher in which he followed and the adult and peer who followed him. Sensory tours, once again, revealed the process of being and becoming expressed by way of movement and interactions with other human beings and the more-than-human living world.

Sensational Perceptions

> Once consciousness has been defined as sensation, every mode of consciousness will have to derive its clarity from sensation. (Merleau-Ponty, 1945/2002, p. 17)

Sensational encounters, both those in the present and remembered (consciously or subconsciously), inform how we feel and act toward our environments and the more than human world. An advantage of the sensory tour method (as indicated in its name) is that it is a means for exploring children's sensory perceptions. However, notably the term "sensory" expands beyond the Minority western notion of five separate senses (e.g., vision, smell, taste, sound, and touch) (Pink, 2011). In other words, the body should not be viewed as "a collection of adjacent organs," rather it is recognized as a "synergetic system" (Merleau-Ponty, 1945/2002, p. 297). Sensory perceptions are inevitably linked with one another and overlap in function. "Movement forms the basis for the unity of the senses" and a stream of consciousness with and for the environment (Merleau-Ponty, 1945/2002, p. 272). The following example reveals how movement invokes a sensory experience: 3 year old Spencer discovered a stinkbug on a tree:

> Spencer and Samantha shuffled toward two tall trees positioned close together. Spencer bent down to closely examine one of the trees. As Spencer's head tilted downward, the camera zoomed in on the ruffled bark of the paper birch, "*I found a stinkbug!*" he exclaimed.
>
> "*Did you?*" his teacher asked, standing nearby and moving closer to take a look.
>
> Spencer stepped over a log and pointed to the tree on the left, "*Yes, right there.*"
>
> "*Is it a big one?*" his teacher asked.
>
> "*Where?*" Samantha asked, repositioning herself near Spencer.
>
> "*Right there,*" Spencer answered, pointing to the paper birch tree.
>
> "*Oh, yes,*" Samantha reached up and touched the stinkbug while balancing on a log, *"Ah got it."*
>
> "*I think I'm gonna stand right here,*" the teacher said, taking a step back.
>
> "*Why?*" Spencer asked.

"*Does he smell stinky, Spencer?*" the teacher asked.

"*Yeah,*" said Spencer.

"*Pew!*" said his teacher.

"*He's gonna stink?*" asked Samantha.

"*When you sit on it or you touch it, it'll stink you,*" answered Spencer.

"*Ohhh, well I will not touch it,*" his teacher reiterated.

According to Merleau-Ponty (1945/2002), it is not the external objects in the environment that stimulate our internal organs and activate our senses; on the contrary, it is the body that "rises toward the world," propelling movement and interweaving a system of sensations (p. 87). Sight cannot be separated from touch or smell; rather these are "just different facets of the same activity" (Ingold, 2000, p. 261). Spencer's bodily movement activated an array of interrelated sensory perceptions, which informed his experiences. He stepped nearer toward the tree and leaned in to get a closer view of the tiny creature. Likewise, Samantha stood on top of a log in order to see and touch the stinkbug. His teacher's bodily movement, on the other hand, was directed away from the creature determined to avoid an unpleasant smell from coming close to her body. Indeed bodily knowing and relating informed each person's sensory intake and experiences with others, human and nonhuman creatures in the environment.

Inviting Explanations

In the previous examples, we see how streams of bodily consciousness inform sensory perceptions of childhoodnature. While one's perception is certainly interrelated with the perceptions of others, past experiences provide a strong lens in which to interpret the present. As Merleau-Ponty (1945/2002) argued, "like a picture, a former experience, whereas this past which remains our true present does not leave us but remains constantly hidden behind our gaze" (p. 96). That is, the meaning hidden behind the gaze of one does not necessarily entail the same meaning hidden behind the gaze of another. For instance, in the above example, Spencer's perception was distinct from his teacher's perspective of the stinkbug. Spencer's movement toward the tiny creature revealed a desire for an interrelationship. Spencer's teacher, on the other hand, took a step away, drawing boundaries on such interconnectivity. Such a response was likely informed by her past experiences.

Thus far, we have discussed many of the advantages of the sensory tour method for tapping into the pre-reflective movement of children and addressing the correspondence gap between being and thought. While the sensory tour method is useful for "revealing" the "preconscious and pre-rational/linguistic experiences of selves and ecological others," the method still falls short on interpretation, making up part

of the "nonrepresentation problem" (Iared et al., 2016). Specifically, how can the knower interpret the experiences of the known or how can the interpreter explain the perception of the interpreted? In other words, while the sensory tour invites a child to actively engage in data collection, childhoodnature researchers must also consider a means for engaging children as active agents in reflective interpretation. Sensory tours paired with video-stimulated recall discussions amplify an approach for bridging preconscious states of being with post-conscious reflective thought. In other words, it provides children with opportunities to act without thinking and to think about acting.

In recent years, video-stimulated recall discussions have gained interest among scholars interested in participatory research involving young children (Thomson, 2008). The method "involves video-recording an activity and then replaying the recording back to the participants so that they can comment on matters of interest" (Rowe, 2009, p. 427). Forman (1999) suggests that replaying videos for children can serve as a "tool of the mind," inviting children to interpret the meaning of their actions (p. 1). Additionally, playing sensory tour videos back to children and engaging them in discussion can invoke intersubjectivity and collaborative reflection among children (Dahlberg et al., 2007). By the same means, videos might also invoke esthetic and emotional responses in the interpretation of actions (Thomson, 2008). Furthermore, Rowe (2009) suggests that engaging children in video-stimulated recall discussions can provide an "insider's perspective" on actions, behaviors, and experiences and provide participants with opportunities to raise ideas that have not been previously thought of by a researcher (p. 434).

While I found sensory tours to be an insightful tool for gaining insight on children's pre-reflective behaviors, analysis of such behaviors is subjective to theoretical interpretation and/or the researcher's own epistemological and ontological beliefs. Thus, whenever possible, inviting children to interpret and explain their own behavior is ideal. Particularly, when reviewing the video footage, a researcher might make note of certain movements and expressive utterances that are inexplicable and/or prompt further questions. Rather than guessing and possibly misinterpreting meaning, a researcher might use video-stimulated recall discussions to invoke children's reflective meaning on their own behavior. In doing so, a researcher should also be mindful of the developmental abilities of children, particularly among young children, in engaging in reflective thought. For instance when asking a young child why they like to do something, he or she might provide a simple response of "*because I like to"* (Green, 2012). Nevertheless, video-stimulated recall discussions, when used appropriately, can provide reflective insight on pre-reflective experiences. For example, video footage captured by 9 year old Daisy during her sensory tour revealed sounds of discomfort in traversing the Arctic tundra:

> Daisy, moved slowly while picking tundra berries, sinking with each step. The video picked up her faint whimper, "*Ow, ow, ugh, ow!*" Each step that she took became more pronounced; the camera wobbled: "*Ugh, ah, oh!*"

While reviewing the sensory tour video footage with the third grade children, I wondered what was going on? The challenge of traversing through the tundra was unperceived by myself and other adults whose legs are longer and stronger. I paused the video to engage children in a reflective discussion. Daisy and some of her classmates revealed that it was not only difficult, but it was also somewhat painful to walk on the tundra. Some shared that they got blisters, others spoke that they were not wearing the proper shoes, and still others expressed that it was not a problem. The children also revealed that the task became easier as they got older, with gained height and physical strength. Through a video-stimulated recall discussion of Daisy's sensory tour, the third grade children engaged in a reflective intersubjective classroom discussion on bodily movement on the tundra. Had it not been for the review of the video footage, the children's perspective of the challenge of traversing on the tundra might have remained unbeknown.

Concluding Discussion

This Chapter has explored how sensory tours can be used as a participatory method for discovering the "somaesthetics" or felt bodily experiences of childhoodnature. The examples of children's sensory tours provided in this Chapter extend the viewpoint of the SLE literature from one that has been primarily retrospective (based on reflective memories) (Chawla, 1998, Williams & Chawla, 2016) to one that embraces the agency of young children through the use of wearable cameras and video-stimulated recall discussions (Green, 2016a). While the examples in this Chapter were categorized under pervasive themes related to embodied phenomenology and the somaesthetic literature (Iared et al., 2016; Merleau-Ponty, 1945/2002; Shusterman, 2009), in order to illustrate certain aspects of children's embodied experiences in nature, there is recognizable overlap in all of the various themes in the examples provided. For instance, a child's developing physiology shapes all essences of being and becoming (Christensen, 2000; James, 2000), imaginary expressions, and what a child is able and unable to become. Furthermore, propelled by inquisitive imagination, a child's sense of being and becoming is invigorated in nature through movement, exploration, and make-believe. A child's pre-reflective consciousness is always sensory in interacting with other human beings more than human living world, interweaving taste, tactile, visual, and auditory mechanisms of the body in the discovery of self and the other (Merleau-Ponty, 1945/2002; Pink, 2011).

The sensory tour approach offers a method for addressing the correspondence gap between being and thought through capturing the essences of children's pre-reflective experiences in their environment. Set on the brow of a child, footage captured by way of a wearable camera gives the impression that one is walking in the shoes of a child. In this way, the sensory tour puts size into perspective, revealing aspects of the environment that might go unnoticed by an adult but pose a particular challenge or hold significant meaning to a child. The embodied physiology of a child signifies the challenges of physical size and stature (James, 2000; Corsaro, 2015).

However, with that said children compensate for their physical limitations by making themselves bigger – scaling up trees and other environmental features to obtain a heightened view above their peers and adults. Furthermore, cultural interpretations of what a child should or should not become also informs childhoodnature engagements. Cultural influences on one's embodied sense of being are acted out through children's imagined essences expressed through their imagination and make-believe play. Sensory tours not only tell *what* a child transforms (e.g., a stick into a weapon) but *how* it is transformed through expressive utterances and bodily movements. Bodily movement and exploration lead and guide children's sensory perceptions. Indeed, movement is a prominent feature in childhoodnature experiences; whether consciously or subconsciously, movement enables children to shape and acquire a sensorium of understanding, which informs their perceptions. Finally, while the video footage captured by way of sensory tours taps into children's pre-reflective consciousness, revealing features otherwise unaccounted for by reflective thought, sensory tours are, like any other qualitative method, subjective to the interpretation of the researcher. For this reason, the use of video-stimulated recall discussions, artwork, and other reflective measures are recommended to the extent possible. Pairing pre-reflective sensory tours with strategies for engaging children in metacognition (i.e., reflection on actions and behaviors) further addresses the correspondence gap and nonrepresentation problem of qualitative phenomenology and somaesthetic research.

studying TV programmes for a child audience, nature content spans all genres, leaving few programmes untouched. By analyzing how children and nature are linked together in TV programmes, societal notions of this relationship can be studied. The vast presence of nature content in TV for children reproduces the discursive notion that children are linked to nature in specific ways. Children are supposed to engage in nature, be interested in nature, learn about nature, as well as want to watch TV programmes containing nature in ways adults are not. This portrays both nature and children as somewhat sweet and harmless, at the same time as the heavy responsibility of saving nature from environmental disaster is placed on the shoulders of children. The Chapter concludes that the child-nature relationship, as it is represented for a child audience, must be questioned, because it leaves children with the responsibility for nature and, moreover, portrays adults as unchangeable and unwilling to shoulder the environmental burden that they have created in the first place.

Child-nature relationship · Swedish public service TV · Children · Outdoor life · Environmental issues

Introduction

The present Chapter focuses on the child-nature relationship in televised representations as a way of understanding the consequences of an anthropocentric and an even more "adult-centric" view on children as well as of nature. (The present chapter is a revised and shortened version of chapter 4 in my dissertation Pettersson, 2013.) Why the relationship between children and nature should be studied in TV programmes can naturally be questioned, but I will make a claim for my case: TV has a strong position in society, as both a producer and reproducer of norms, notions, and identities for TV audiences (Ellis, 2006). In a Swedish context, TV is still the medium that children use most, and public service television is the television provider most used by the youngest audience and has been since the very start of television broadcasts (Pettersson, 2013; *Småungar och medier,* 2017). Public service TV can therefore be argued to be a particularly influential institution for the Swedish child audience and hence in the lives of Swedish children. (When studying the Swedish broadcasting arena, one must bear in mind that some aspects are specific to the national context, such as the very long period of a public service broadcasting monopoly (1956–1992 for Swedish television) and the associated strong public service TV tradition for the child audience (cf. Pettersson, 2013; Rydin, 2000)) When studying TV programmes for a child audience, nature as television content turns up essentially everywhere. It spans all genres, leaving few programmes untouched – an aspect that will be presented in more depth below (see also Pettersson, 2013). In Minority western societies, children are understood as being closely linked to nature, and it has been argued that this notion is particularly strong in the Nordic countries (e.g., Halldén, 2009, 2011). This also ties in well with research stressing how important nature

experiences are for human beings (Kahn, 1999; Myers, 2007), as well as with research suggesting that we are replacing our outdoor experiences of nature with mediated indoor experiences of the natural world (Kahn et al., 2008; Kahn et al., 2005, Severson, & Ruckert, 2009). Moreover, the research on significant life experience (SLE) shows that adults who work to fight environmental threats often refer to experiences during childhood that put them on this path (Chawla, 1998). All these strands intersect issues concerning how we, as a society, can ensure that our citizens form valuable relationships with the natural world and understand how our lifestyle affects the planet we live on – and are willing to change this lifestyle. But they also have something more in common, and that is the role that children and childhoods are thought to play in relation to this.

Among these intersecting issues, norms, and notions are entangled. For example, when making claims about nature's importance for humans, research has often focused on children and young people, even when arguing for nature's significance for all of humankind (e.g., Kahn et al., 2008; Kahn, 1999; Myers, 2007). But why is research so focused on children's relationship with nature? And is nature an essential issue for children only? In this Chapter, the argument is that the often-represented and taken-for-granted relationship between children and nature must also be questioned and studied (see also, e.g., Halldén, 2009, 2011; Lindgren, 2013; Taylor, 2011), especially in relation to how the category adults can be understood against the backdrop of the child-nature relationship. By analyzing how children and nature are linked together in TV programmes, societal notions of this relationship can be investigated. It is a fact that the adult world often makes decisions for and controls children as a category (James, Jenks, & Prout, 1998); it also does so in issues regarding nature, and this is considered a normal part of everyday life. It may, therefore, be difficult to question the demands and wishes that the adult world places on people categorized as children and aspects categorized as nature. One way to investigate what children and nature are expected to be like in society is to study how childhoods are portrayed in relation to notions of nature in TV made for children. That is to study notions of the child-nature relationship and, thereby, linking this study to the concept of childhoodnature.

The present analysis draws on childhood sociology, which positions children as beings in society rather than as only developing, becoming adults, thus placing children at the center of research (e.g., James et al., 1998; Lee, 2001; Prout, 2005). It is inspired by visual studies, a research field which stresses that visual aspects must be taken into consideration when researching societal phenomena (e.g., Mitchell, 2005; Rose, 2001). Studies focusing on posthumanism are also a cornerstone of the study, as they highlight the interconnected relations that our everyday life experiences rest on. Such studies also stress that categories such as nature and children must be understood in relation to each other, particularly when mediated representations are under study (e.g., Baker, 2001; Cronon, 1995; Haraway, 1991, 1992; Macnaghten & Urry, 1998). These three research strands form the framework for exploring how the child-nature relationship is produced, represented, visualized, and negotiated in public service television.

In this vein, three questions have guided the analysis:

To start with, what does nature look like in TV for children?
In what ways are children and nature linked together in TV representations for a child audience?
What can the bond between nature TV content and the category children tell us about notions and norms regarding children and nature in society?

Methodology

The present Chapter is based on a study of TV material broadcast for children in Sweden during the years 1980, 1992, and 2007. (The analysis and examples in this chapter is based on chapter four in Pettersson (2013) and can be looked into in further depth there.) These years were chosen specifically as presenting key moments in the evolution of the national broadcasting context. In 1980, the public service monopoly was still strong in the Swedish context. In 1992, the monopoly was abolished, inviting commercial actors onto the terrestrial net. In 2007, the analogue broadcasts where shut down and digital broadcasting took over. All programmes targeting children and young people up to 18 years of age were studied in the main study (Pettersson, 2013). (This covers children's programmes, young people's programmes, family programmes, programmes in ethnic minority languages, and educational programmes that targeted children and/or young people.) Programmes from 14 days for each year were in focus. This amounted to almost 500 programmes and 180 h of TV material in the study. It is in this vast material that the present chapter has its background and from which it borrows its examples, adding some discussion points of public service TV for children in 2017.

This Chapter takes a discursive approach when it sets out to investigate how the child-nature relationship is constructed in the TV material. Discourse analysis is originally a linguistic method (e.g., Wetherell & Potter, 1992). Therefore, studying moving images using discourse analysis has been debated. Visual culture researcher Gillian Rose (2001) nonetheless argues that discourse analysis can be used successfully to analyze visual materials. She maintains that images are so tightly connected with texts and verbal statements that the same method can be used to study all these modes of communication, as long as their specificities are not neglected in the research (Rose, 2001. cf. Lindgren, 2006; Potter & Wetherell, 1994).

In the analysis, I have focused on the discursive practices used in the TV programmes (cf. Potter & Wetherell, 1992). In other words, I have studied the ways in which things are said, re/produced, and visualized in the TV programmes to discover what these practices can tell us about notions and norms in regard to the child-nature relationship. The analytical process was proceeded by "identifying themes" (Rose, 2001:158) that repeated watching and attention to details made visible. One of the themes of specific relevance was the nature content in many programmes.

Nature for and the Nature of Children

When I looked at the issue of televised nature content for a child audience in more depth, this content could be divided into three kinds of representations. The discursive formation of nature in *TV for children* contained children shown outdoors, animals of all sorts, and environmental issues. These three aspects should not be understood as essentially constituting nature. They are discursive representations that form the content of nature in TV for children. In line with prominent gender scholar Donna Haraway's (1991) questioning of binary dichotomies, the representations of children outdoors, animals, and environmental issues are used to discuss and question discourses of represented "nature" in TV programmes for children (see also Baker, 2001; Prout, 2005; Taylor, 2011). Such questioning opens the door to a multiplicity of possible natures and to seeing nature as relational and socially embedded (Macnaghten & Urry, 1998) in TV production for children (James et al., 1998).

As can be seen in the overview (Table 1), nature is a very common content in *TV for children* during all the studied years. It can also be noted that the proportion of this content remains quite stable over the research period. (The proportion of nature content in *TV for children* was about 80% during all the studied years (81% in 1980, 82% in 1992 and 88% in 2007) in the two main public service channels, SVT1 and SVT2.) All programmes containing nature have been counted, even if they do not have nature as their prime content. That means that all programmes showing children outdoors, as well as all animal representations, are present in the overview, regardless of whether the representations portray "real" footage, animated images, or whether animals appear as toys. Moreover, as soon as the environment was an issue in a programme, it was counted. This categorization was made based on the understanding that all these representations perform nature content for children, no matter what representational technique is used and whether or not nature constituted the primary content. Programmes containing these topics are broadcast by both the regular Public Service Television Company, SVT, and by the Educational Public Service Company, UR. They target children of all ages and can be found in almost all programme genres. However, programmes targeting older children and youth do not

Table 1 The number of programmes with nature content in *TV for children*

	1980	1992	2007	Total
Programmes in total	120	141	230	491
Nature in total[a]	97	115	202	414
Children outdoors	71	81	109	261
Animals	76	99	152	327
Environmental issues	12	15	24	51

[a]Many programmes contain more than one of the *nature* categories and therefore the number of programmes containing nature is not the sum of the programmes containing children outdoors, animals and environmental issues

include nature as their primary content as often as do programmes targeting younger children. The selection of programmes is presented in more detail under each heading below, where examples of programmes portraying children outdoors and with environmental issues as their primary content are analyzed. Programmes with animals as their main content is not analyzed here (for in-depth focus of animals in TV for children, see Pettersson, 2013, 2017); however, featuring animals is so omnipresent in TV for children that, as will be shown, the programmes selected for analysis of the other categories also reproduce animals in different ways.

Outdoor Life: Embedding the Child in Nature

Children are often shown outdoors in the TV programmes broadcasted for them. This does not mean that the whole programme takes place outside but that a considerable number of programmes (see Table 1) show children in an outdoor setting at some stage. Many of these programmes simply depict children outdoors in passing as a film narrative practice. This occurs in documentary programmes, as well as in those with a fictional or educational focus. There is outdoor footage of children showing them situated both in towns and in the countryside, in Sweden, as well as in other countries. This says something about where children are supposed to be located. No matter where they live or what their everyday life looks like, in *TV for children* being outdoors is strongly connected to the category children.

For all the studied years, when the outdoor experience is the main content in programmes, they seem to target children more than young people. In 1980, the main focus is often on the value of children being out in the open air. Such programmes are produced both by SVT and UR this year. In 1992, many educational programmes revolve around being outdoors, and the outdoor experiences often take place in institutionalized settings, such as schools and preschools. That is not the case in 2007. When the outdoor experience is the primary content, it is fictionalized in basically all instances. In 2007, instead of placing nature at the center of everyday life, nature is now a special event presented in televised competitions or fictional stories.

Of all the programmes showing children outdoors, three – one from 1980, one from 1992, and one from 2007 – have been chosen for a more thorough analysis. These programmes all have outdoor experiences as their main content. They also have characteristics specific to each year: in 1980 focusing on the valuable outdoor experience for children, in 1992 an educational programme picturing an institutionalized outdoor setting, and in 2007 focusing on an outdoor experience within a fictional frame. Among these are programmes broadcast by both UR and SVT and programmes targeting young children as well as slightly older ones. The issues at stake in this section are how children and outdoor life are re/produced and what kind of child-nature relationship the outdoor nature content constructs.

The Nostalgic Wilderness

The programme *Once upon a time there was a summer* (*Det var. en gång en sommar*) has the outdoor experience as its main topic. The programme was broadcast during the regular children's programmes in the autumn of 1980 (*Once upon a time there was a summer (Det var en gång en sommar)*, aired on SVT2, 3/10/1980, 17.30–17.50. Directed by Tomas and Yeng Löfdahl.). In the TV guide, it is stated that it is part of a series, this being the last of four episodes. The series was produced in 1972 and it was rerun seven times on TV between 1972 and 1987 (The Swedish Film Institute website). The episode is 20 min long and tells the story of three children, Mats, Kickan, and Pia, having a sleepover on an island.

The programme starts by showing traditional Swedish landscape scenery with a lake surrounded by a pine forest in the late summer light. A rowboat on the lake is shown with a small island in the distance. The tempo is rather slow and the viewer gets to see long sequences of the outdoor scenery accompanied by a classical melody and a child voiceover. It is the youngest girl, Pia, who is the voiceover, but occasionally the voices of the three children on screen can also be heard.

On the island, Pia, in her role as voiceover, reports that the children are building a shelter where they will sleep at night. The imagery shows how the children use leaves and branches to build it. When they are finished building, they have a snack. Placed on the table – which is made out of two rocks – are milk, raw carrots, tomatoes, a cucumber, raisins, bread, and cheese. The girls and the boy eat and talk in what sounds like a happy manner before using some of the bread as bait for fishing. It is the older girl, Kickan, who catches the fish, but the boy, Mats, who is the oldest, that kills them.

Altogether only a few of all the programmes included in the study show dead animals (in 1980, there are three other dead animals shown. In 1992, three dead animals are shown altogether. Four dead animals are shown in 2007.), and this programme is the only one that shows explicit images of a child killing fish. Neither the children nor the voiceover express any feelings of sadness when the fish are killed. Instead the constitution of the fish is talked about. Mats and Pia, in her position as voiceover, explain how a fish swims. As a clarification of these scientific facts, the swim bladder from one of the dead fish is shown floating in the water. The fish are cut up in pieces and used as bait in cages for trapping crayfish. That it is Mats who kills the fish could be seen as depicting a traditionally gendered activity (cf. Kalof & Fitzgerald, 2003). However, Kickan is the one doing the fishing and catching them in the first place, and hence this is a team activity. The practice of catching and killing animals is, in this way, naturalized and unquestioned in the programme (cf. Pedersen, 2007).

The three children are portrayed as well accustomed to survival in the wild. As a group, they know what to do when going on an excursion: build a shelter and bring along food and the appropriate equipment for fishing. Their packing is light, as they are wearing ordinary clothes and swimming naked. The only security devices they have are the life vests they wear in the boat. During the island visit, Pia expresses fear on two occasions, first for a bush cricket and the second time for a howling sound.

On both occasions, the two older children assure her that there is no reason to worry. Kickan explains that the howling sound is a dog, and together Kickan and Mats explain that wolves do not live in the area. Their expertise is used to calm Pia. In this way, Kickan and Mats present nature as a safe place to be. There is nothing to be afraid of and this natural environment can be safely enjoyed.

Mats is depicted as the one with the most knowhow, and he answers most of Pia's questions. Kickan also corrects and explains things to Pia, and it is Kickan who manages the boat, while Mats looks after Pia. Here, Pia's young age is a sign of having less competence than the older children. This hierarchy, however, is leveled out by the fact that Pia's voice is used as the voiceover. It is the voiceover that explains the most complicated matters in the programme, allowing Pia as well to hold an expert position. The children work together to perform all the tasks on this outing. Thus, it can be argued that the children are not acting out stereotypical gender roles or age hierarchies but instead cooperating and using their different competences together to manage the excursion on the island. Everyone is needed to tell this story.

When night comes and the children are shown sitting outside the hut looking at the stars, Pia says, from her position as voiceover: "We have been sitting outside the shelter for a long time – just looking." (All examples from the dialogues are originally in Swedish and have been translated by the author.) The outdoor experience is thus overwhelming for all three children. Pia then says directly from her position on the screen: "Never have I seen so many stars – only in fairy tales." Here Pia is experiencing the wonder of nature's beauty first hand. Her awe links well to the title of the programme, *Once upon a time there was a summer*, which draws on the fairy-tale genre. Thus, it is outdoors in the countryside that children can experience stillness and good, sacralized nature. This is the ideal place for children (cf. Jones, 2002).

Another clip shows the children wading around in the water checking the cages for crayfish. The morning light is so strong that it transforms them into glowing silhouettes. This sunlight and the very clear and dark midnight sky are typical for August in Sweden, as is catching crayfish. The August light gives the television programme a dimmed framing, which visually builds an idyllic setting linked to Swedish nature. The beautiful outdoor landscape has been used to create a romanticized view that has been crucial to binding the Swedish national state together during the nineteenth century and afterward (Halldén, 2009; Lindgren, 2009). This programme did not picture a historical event, at least not when it was produced in 1972, and the children fixed the programme in time with their 1970s clothes and haircuts. There is, however, a potential implicit critique in the programme title: *Once upon a time there was a summer*. The question is whether summers like these exist any longer. Is this a fairy-tale view of how it once was to be a child on summer holiday? Is the connection between children, their knowledge and independence, and an undisturbed outdoor life disappearing? The programme can also be interpreted as a nostalgic call to restore the bond between children and outdoor life in the wild, something every child, in Sweden and elsewhere, should experience (cf. Halldén, 2009, 2011).

In this programme, the children are shown on their own in nature. They manage their expedition and tasks without hesitations, and they do not seem to need help from anyone else. However, in the very last sequences, a break in the illusion of the self-sufficient child can be seen. When the children are leaving the island, the camera focuses on Pia and Mats sitting down in the boat. Pia points to something in the distance, presumably close to or behind the camera team's boat. For a second Pia's focus shifts, she smiles, and she looks straight into the camera; Mats smiles also before he hurriedly looks away, a bit embarrassed judging from the look on his face. The illusion of being alone on the island is hereby broken (cf. Allen, 1992; Edin, 2000). The children have after all been looked after on this excursion by the camera eye and the adults behind it. This provides a glimpse at the adults pulling the strings in the narration, the authors behind the storyboard and the speaker text. This glimpse reveals the narration to be an adult's nostalgic views on the connection between nature and children and the children to be acting out these views (cf. Lury, 2005; Outka, 2009; Ågren, 2008). The content of this programme urges the child audience to step out into the wilderness, to experience the outdoors, and to cherish it. However, this is more adult nostalgia talking than producing possible outings for children to try out, as the competence and location for the outing needed seem difficult for almost anyone to realize.

The Urban Everyday Outdoors

Day-care TV for children (*Dagis-TV för barn*) is a preschool programme series broadcast by the Educational Public Service Broadcaster, UR. An autumn morning in 1992, an episode called "We play with things others throw away" is broadcast (*Day-care TV for children (Dagis-TV för barn)*, aired on SVT1, 1/10/1992, 9.30–9.45. Produced by UR.). This programme also focuses on an outing but in a different way than in the previous example. Here outdoor life is located in a populated urban area, and the outings shown take place close to the day-care center. The programme shows preschool children taking care of things that have been thrown away, both to clean up and to refurbish their preschool yard.

The programme starts with a young girl voiceover saying: "Today you will come along on an expedition in *Day-care TV*." Several preschool children and two preschool teachers are seen walking in a line together in an urban area. The voiceover says that they are out looking for treasures. The children look well disciplined, and when they reach a park, the line is abandoned, and, before the teachers even suggest it, the children start picking up litter that has been dropped in the surroundings.

Agneta, one of the teachers, asks the children where litter should be disposed of and why it should not be thrown in nature, etc. The questions are pedagogical more than authentic (Dysthe, 1996), as there is no doubt that Agneta already knows the right answers. However, the children know the right answers too, and several of them answer in quite elaborate ways. For example, everyone knows that litter should be put in garbage cans and not on the ground. One boy knows that "animals can cut

themselves" on garbage lying about and another one declares that people who leave plastic bags on the ground should be called "nature tormenters." The nature referred to here is the park, and the outdoor expedition that these children are part of takes place between buildings. Studies of preschool practices have pointed out that what counts as nature has to be neither wild nor located far away from the preschool (Bergnéhr, 2009; Änggård, 2009). Being outdoors can in fact be synonymous with nature (Bergnéhr, 2009). This is only partly the case in *Day-Care TV*. Here nature is being outdoors, but it is also what is damaged when things are thrown away in the wrong way. Because these children are cleaning up nature, they become part of its cycle.

This expedition takes place on a gray day. There is no sun in sight and not much greenery either. The surroundings are quite muddy and the children as well as the teachers are dressed for these conditions, most of them in wellies and rainwear. The clothing is like a uniform that cuts across age, gender, and hierarchy.

The group walks on to a refuse dump. "You can find good things there," the child voiceover says. They start looking through the containers with help from the station staff. Among other things the teacher, Agneta, asks for an old wooden door and a hammock. The children ask for old vacuum cleaners, two pipes, and some other items. In the dialogue, there is no sign of the adults telling the children to hold back in their treasure hunt. Instead the group leaves the dump with their bits and pieces, and the children are shown carrying their own finds.

As soon as they are back on the yard outside the day-care center, all the children start working with their new things and are assisted by the adults. Agneta brings out tools, and together the children and the teachers start repairing the playground boat. Two young boys are using one of the pipes as a water groove and a few other boys are using the other pipe as a cannon on the roof of their hut. Yet another boy then transforms the water groove into a chimney pot on the boat. The fastening of the pipe on the boat is assisted by one of the teachers, but it is the boy who explains how it should be done and who attaches the pipe with planks and nails. It is mostly the boys who are seen and heard when it comes to the planning and restoration, but girls too are shown doing carpentry work. The fact that the voiceover is done by a young girl also levels out the focus on boys in the programme. Several long sequences are shown of children in deep concentration using tools on their respective tasks, and their conversation is heard without interruption, neither by the adults nor by the voiceover. Even though this programme started off by showing children walking in a line and answering questions, they are allowed to be very agentive both in their treasure decisions and in how the treasures should be used in their outdoor environment. This programme portrays the activities on the yard as being based on cooperation between children and adults. Several children are seen swinging in the hammock at the end of the programme. The last thing the voiceover says is: "A treasure is something that you can play with."

This programme draws on realism. The only encouraged make-believe present is when the children's imaginations are used to see things that others have thrown away in a new light. These children are cleaning up nature and searching the litter for things that they can play with, not standing in awe of nature's beauty.

The children are shown outdoors during the entire programme. The notion of children as benefitting from being outdoors is fully expressed here, even though the nature experienced is urban and institutionalized by the preschool setting (cf. Halldén, 2009; Jones, 2002; Säljö, 2000; Änggård, 2009). This is not exclusive to this programme. Several other educational programmes in 1992 show children leaving their indoor institutional settings, going out. In her study of a magazine for preschool teachers, child researcher Disa Bergnéhr (2009) recognizes that engaging in physical activity, improving one's motor skills, and being healthy are what preschool education should focus on and that these things should preferably take place outdoors (see also Änggård, 2009). Similar notions can be seen in this programme.

The children are not alone in this programme. They are looked after by their caretakers, but this hierarchy is not what the content is built on. Even if these children are portrayed as being in institutionalized care (cf. Säljö, 2000), they have a say in what they do and with what material. The children are performing everyday urban life in an outdoor setting together with adults. This constitutes a form of address built on respect for the children's own actions, for the adults caring for them and for nature. The surrounding city is thus not lacking in nature, but instead the children in the city are taking care of nature close by, living in it, and creating a meaningful everyday life in relation to it. The child audience, thereby, can be inspired and encouraged to play, be creative, and recycle by the way in which this programme portrays outdoor nature as being part of the ordinary. In this programme, there is no nostalgia like that seen in the previous example, just children and outdoor nature, cleaning and recycling in everyday life.

The Grand Wilderness

Yet another programme where the outdoor experience constitutes the primary content is *Expedition Wilderness* (Expedition Vildmark). It is a TV series in which two teams of children compete against each other, performing various tasks and living outdoor life in different parts of Sweden, together with an adult guide. One Sunday morning in October 2007 a 25-min-long episode shows one of the teams and the guide on a mission to transport a reindeer quite a long distance in the Northern alpine landscape (*Expedition Wilderness (Expedition Vildmark)*, aired on SVT1 21/10/2007, 10.35–11.00. Produced by SVT.). The guide and programme host, André, sets the agenda for the programme, while the female voiceover presents background and overview information. The child contestants are quite often interviewed on screen, and they are thereby also part of telling this story.

The episode starts by showing André in a white snowy landscape with mountains and a large cloudy sky in the background. It looks grand, beautiful, and quite inviting. However, André immediately starts to talk about how the bears are waking up after their winter sleep, how wolves and wolverines are close by, and how the approaching spring is causing the ices to melt, making it difficult to move in the area. After setting the scene like this, the friendly looking landscape might not seem so

friendly after all. André declares straight into the camera that: “This is Expedition Wilderness where the adventure is for real.” The scene for this episode’s adventure is also presented: “This is Lapponia, one of our world heritage areas and that means that this place must be protected.” The beautiful surroundings are in this way also put forward as a valuable and rare wilderness.

André and three children are then seen on screen. The children are asked whether they would like to help a friend of André’s with something. The children agree to take on the task before knowing what it is. It turns out that they are to help a reindeer named Bertil back to his heard. The reindeer is in this way humanized by being given a human first name and by his friendship with André. The fact that reindeers are domestic animals belonging to the Saami, a Swedish indigenous people, is not mentioned. Thereby, the fact that Bertil is portrayed as having lost his heard and his mum, and not that it is his owner who has lost him, also builds the anthropomorphic framing of the reindeer.

The team consists of two boys, 13 year old Nils and Brouk, and a 12 year old girl, Fanni, all introduced by the voiceover. The entire group is dressed in wind and waterproof hiking clothes marked with the SVT logo, warm hats, and gloves. They are all also wearing ice prods around their necks. The advanced clothing makes the expedition look professional and not like an everyday type of activity.

Even if the children are supposed to be the main characters of the programme, the fact that they are introduced after André explains the setting for the programme establishes the hierarchy in the group from the start. It is also upheld by the fact that André guides the expedition, asks the children questions, and has the right answers. In addition to this, André reminds the children of the predators living in the area and asks them to keep their eyes open for any signs of bears. Fanni then tells the others to look out for the remains of anthills, because when the hungry bears wake up they eat the ants and destroy the anthills. The children are thus shown to have competences, and they talk to the camera, quite often describing the course of events. Still, André is in charge, so Nils’, Brouk’s, and Fanni’s participation mainly consists of answering Andrés’ questions and reacting to what happens during the expedition.

The programme contains several challenging parts. The group is to cross-country ski to shepherd the reindeer. Bertil is not so easily handled and the group moves quite slowly in the terrain. The animal also manages to get off his leash and the group has to work quite hard to catch him again. To teach the children and point out the seriousness of the weather conditions, André jumps into a hole in the ice to demonstrate how to properly use the security gear designed to deal with weak ice. Shortly afterward, Fanni is shown getting her feet wet and needing assistance to get away from an area of very thin ice. André takes command in rescuing her. André is also seen helping Fanni put dry socks and plastic bags on her feet before putting the wet shoes on again. Here, the 12-year-old is getting assistance in dressing herself, which shows how exceptional and potentially dangerous the incident was. The adult guide is portrayed as responsible for the care of these children, and the hierarchy in the group is confirmed once again.

The group is shown continuing to ski on the frozen lake, and after a while the background music becomes rather dramatic. André has said that the group should

aim for a rock sticking up in the ice, but when the group comes nearer it becomes obvious that it is not a rock. It is a dead reindeer that has had its intestines eaten by some animal.

The group is displayed standing around the cadaver looking at it. They look quite alone in the massive landscape stretching out in the background. Both Brouk and Fanni are expressing disgust at the sight. Nils is heard saying: "I mean I've seen dead animals on TV but not as dead as this one, this guy, he was like stone-dead." He is here experiencing nature first hand, but it is not a beautiful sight, quite the contrary. André and Bertil, however, look unaffected. There is no sign of surprise on Andrés' part. It was he who directed the group toward what turned out to be a cadaver. In this passage, the adult seems to be a puppeteer pulling the strings to make the expedition into a "real" adventure.

André asks the children where they think they should camp that evening. The children express anxiety about sleeping in a tent with a bear possibly close by, and they decide to go back a bit away from the cadaver. A tent is put up and André makes dinner over an open fire before they tie Bertil to a tree and go to bed.

The programme then moves on to show the next morning when the children leave the tent. Fanni exits the tent first. She quickly moves away out of the frame, but before she does one can detect a smile on her face. Then Brouk exits and Fanni is heard saying: "But where is Bertil?" The reindeer is no longer on the spot where he was tied the night before. That the reindeer is gone is portrayed as a surprise for the viewer, but it seems not to be news for the children taking part in this so-called "real" adventure, judging by Fanni's smile. Good shots are needed to make the programme, but it does not feature professional actors (cf. Lury, 2005; Ågren, 2008). Here it becomes clear that the children on screen are experiencing a different adventure than the viewers are. It is also possible that the adventure is only real when watched on TV. The fact that the reindeer is gone is also the perfect TV cliff-hanger to introduce the coming episode, and this is how the programme ends. Fanni, Brouk, and Nils took on the task of delivering Bertil the reindeer and now he is gone, which means that they may lose the *Expedition Wilderness* competition.

In this programme, the outdoors becomes a scene for the competition. Outdoor nature is portrayed as grand, dangerous, and not easily enjoyed without the proper professional gear and adult guidance. The children experiencing the adventure on screen are portrayed as taking part in the competition rather than dealing with the wilderness. The narrative is built up for the child audience and not to the same extent for the children taking part in the adventure. The outdoor nature is, in this respect, portrayed as wild and grand, but this content is perhaps most exciting, safest, and most enjoyable when seen on TV.

The Outdoor Nature and Childhood Notions

The analysis shows that the outdoor content produces different discourses of nature. The nostalgic discourse portrays the outdoors as beautiful, giving, and stable. It is safe and just waiting out there to be explored by children. But a glance at the camera

reveals even the most competent children to be a product of adult nostalgia (cf. Outka, 2009). The everyday discourse portrays outdoor nature as close by, ordinary, and in need of care. It is waiting for urban children to come out and help clean it up. Here, everyday outdoor life is portrayed as documentary and no narrated plot is revealed. The grand discourse pictures the outdoors as breathtaking, far away, and not altogether kind (cf. Cronon, 1995). It has its own conditions and children need expert help in order to make it there. This outdoor representation is said to be real, but a puppeteer is visible as well as the fact that the children are acting out a plot. In this way, how the natural outdoor environment is portrayed also differs across representations and over time.

Outdoor life also re/produces different discourses in relation to the represented children in these programmes. Outdoor nature thus depicts children as belonging to and enjoying outdoor life, but it positions them quite differently. Children in these programmes are shown to be competent users of outdoor nature, as cooperating to handle their everyday outdoor experience and as in need of adult guidance to manage. This is not dependent on age. The children in the programme needing the most assistance were the oldest. Moreover, this competence does not grow with time, as the programme portraying children in most need of assistance was the most recent. (There are, however, also exceptions. For example, in *Ants in the pants (Myror i brallan)* aired on SVT1, 10/4/2007, 18.00–18.30. Produced by SVT, several children, both very young and a bit older, are very knowledgeable about animals and outdoor life.) Something that can also be noted in the representation of children outdoors is that even if outdoor nature is portrayed as distinctly Swedish (cf. Halldén, 2009; Lindgren, 2009) – through the use of a once-upon-a-time approach, everyday Swedish life, and the Swedish world heritage – the children are not portrayed as stereotypical ethnic Swedes. All three programmes feature children with seemingly different ethnic backgrounds, judging by their names and appearance. They are all portrayed as Swedish children, and their respective backgrounds are not pointed out in any way.

These discursive notions of outdoor nature and of the category children also allow for different child-nature relationships. As the audience addressed by the nostalgic view on outdoor nature has little chance of living up to the depicted competence and beautiful location, they are thereby sharing in the adult nostalgia – once there were children and natural environments like these. The target audience for the everyday discourse of outdoor nature has a better chance of living the life portrayed, and what it needs to pick up on is the moral obligation to care about nature in one's surroundings. The audience addressed by the grand discourse of outdoor nature is more likely to be positioned in front of the TV than expected to take part in the adventure (cf. Kahn & Kellert, 2002). Thus, over the years, outdoor nature content has been used to target quite different child audiences, but they are all imagined to take an interest in and have a relationship to outdoor nature.

Environmental Issues: Children Saving Nature and the World

Environmental issues do not constitute a large programme content category, but they are present in the programming to the same extent during all the studied years (about 10%). Three examples of environmental issues, one from each year, have been chosen for in-depth analysis. These examples consist of parts of programmes that focus primarily on environmental issues. They also have characteristics specific to each year: In 1980, the environment and man-made problems are in focus. In 1992, environmental issues are often present in educational programmes. In 2007, children act in regard to the environment. The examples analyzed here target young children as well as youth. The questions in this section are how programmes containing environmental issues construct notions of the child-nature relationship in terms of how environmental issues are re/produced for children.

Adults Destroy: Technology Saves

The children's programme series *Our amazing world* (*Vår fantastiska värld*) contains many different parts. The episode analyzed here was broadcast on the 8th of April, 1980, a Tuesday evening. It contained what has happened on the 8th of April previously in history, the development of the postal service, camouflage in the animal world, the whooping crane, a science fiction series, and an animated series on human history. (*Our amazing world (Vår fantastiska värld)*, aired on SVT1, 8/4/1980, 18.10–19.20. It was produced by SVT. The clip on cranes looks quite old, but no credits for this part are shown so it cannot be dated, nor can the original producer be named.) The male programme host introduces all the different clips and is the voiceover for most parts of this 70-min-long programme. In this section, an 8-min-long clip on the whooping crane will be analyzed. The voiceover informs the viewers about different kinds of cranes but more specifically about the endangered whooping crane. He introduces the clip by saying: "Wouldn't it be a shame if this bird were not allowed to live any longer?"

The storyline focuses on cranes but also raises the issue of endangered animals more generally. "Facts" about them are presented and the reasons for their endangerment are said to be hunting and/or a massive decline in these species' natural habitats. "And this is the fault of humans," says the voiceover and continues by explaining that some humans are making amends for the damage humankind has caused. This brings the story to a nature reserve in the USA. In the reserve, the voiceover reports animals are not only protected, but efforts are also being made to improve their living conditions. The voiceover continues by saying that this improvement is accomplished using modern technology. Images are shown of how tractors and bulldozers shape nature in the reserve to make it more suited to the needs of endangered animals. "The humans are helping nature," says the voiceover.

The nature reserve staff are reported to fly over the reserve once a week to count the cranes and locate precisely where they are. Why that should be important is not mentioned. There is also no estimate of the environmental damage that the bulldozers and the planes could cause or mention that this damage could be a source of disturbance for the precious species. What is reported, though, is that tourists are allowed to visit the reserve only in very restricted ways so as not to disturb the animals. It is hence humans that cause disturbance and are a threat to these animals – machines and technology are not.

However, an oil company in the neighborhood and the US air force have adapted their transport routes in consideration of the animals in the reserve, but more space cannot be set aside for the cranes because the land is being explored for farming, industries, and residential areas, says the voiceover, who continues by stating that about 1000 animal species around the world are threatened. The cranes are reported to have lived for at least two million years, and the programme ends by the voiceover saying: "Now they need all the help they can get to only survive the next 10 years."

This programme draws on a risk discourse according to which the lifestyle of humans is causing other species to become extinct. However, in this programme humans are not expected to change. Still, with the help of technology, some of the endangered animals can be protected in confined areas. Humans are thus the culprits but with the help of technology also the possible saviors. The way the content of this programme is presented places the child audience in a peculiar position. Nothing is said about what children can or should do. It is completely the fault of adults that animals risk extinction, and it is only adults, with their technological knowledge, who can do anything about it. Thus, children should know about the state of nature, and they should be both anxious and slightly hopeful about the future of endangered species.

Adults Destroy: Politics Saves

The TV guide states that *Little News Billboard* (*Lilla löpsedeln*) is an educational news show for middle school and secondary school pupils and for children and young people. (Which means between 10 and 15 years of age. *Little News Billboard (Lilla löpsedeln)*, aired on SVT1, 21/4/1992, 9.15–9.30. Produced by UR.) The first topic on a Tuesday morning in April 1992 is the Baltic Sea and the serious pollution in those waters. One of the news anchors says that the Ministers for the Environment in the countries bordering on the Baltic Sea have had a meeting about the pollution. A female reporter is reading the speaker text as well as interviewing people in a 3.5-min-long reportage about the issue. The damages are reported to have been caused by industry, sewage, agriculture, and traffic. Swedish industry, traffic, and agriculture are mentioned, but the worst polluters are located in the area around St. Petersburg, the Baltic countries, and Poland, says the voiceover. This can also be seen in the graphic image where more smoke is shown coming from bigger industries placed on the eastern side of the Baltic.

The alarming effects of this are said to be reproduction difficulties among seals and death of the seabed due to the concentration of poisonous chemicals and eutrophication. It all sounds rather pessimistic, a notion that is supported by the Swedish Minister for the Environment, Olof Johansson. He says that there is no time to lose when it comes to the Baltic Sea. In his opinion, the current conditions could be considered an environmental disaster, especially on the eastern side. The minister is portrayed in his office, where several shelves of books and reports are seen in the background. This gives his statements seriousness and his conclusions a scientific framing.

A representative for the nongovernmental organization Greenpeace, Rune Eriksen, comments on the action plan for the Baltic Sea that the ministers have sanctioned. In his opinion, the actions suggested are not tough enough. The reporter asks him whether these actions will bring new life to the Baltic Sea's dead seabed. He answers quite firmly: "No." The NGO expert is portrayed outdoors with water in the background. He is thereby portrayed as being in closer contact with the actual water conditions than the politician is. Neither the reporter nor the spokesperson from the NGO questions the Swedish minister's view that the worst problems are on the eastern side of the Baltic.

Images are shown of dead seabed, industrial buildings with smoking chimneys, and foamy waters and of a tractor with a pesticide-spreading device. Where these images are supposed to be located is not altogether clear. But most of them seem to stem from the eastern side of the Baltic Sea, judging by how they are framed by the speaker text.

The reporter says that there is one positive side to the action plan, in that something has been decided about the Baltic Sea. The reporter adds: "In 10–20 years' time, the beaches will be clean and the water will be clean enough to swim in again." She frames the pessimistic story by ending in a prophesy about the effect the action plan will hopefully have. It is not made clear in the programme what the relations are between clean beaches, waters fit for swimming, dead seabed, and reproductive difficulties among seals.

The address put forward in this news clip is multilayered. The state of the Baltic Sea is grave and actions need to be taken now, which is declared by the minister in charge, as well as by the NGO and the reporter. The pollution in the Baltic Sea is presented as a disaster – and one that crosses national borders and requires serious action from politicians in several countries. Whether or not the suggested actions will be sufficient is contested, but the reporter decides to end the clip on an optimistic note. Even though the message draws on a risk discourse, child viewers are not to be left in despair by the newscast (cf. Carter & Davies, 2005). There are, however, no suggestions as to how children themselves can improve the status of the Baltic Sea, and children are not pictured in this clip. The viewers addressed by this newscast are to wait and see (cf. Buckingham, 2000), and hopefully they will have a Baltic Sea that is in better shape when they are grown up, in 10–20 years' time. This produces notions of passive children and passive nature, which both have to rely on adult politicians making things better and can do nothing about the disaster except hope for the best.

Adults Enjoy: Children Fix

The brain office (Hjärnkontoret) is a popular series on natural science that started in 1995 and is still active (The SVT website a). The show has a clearly articulated interest in science. The environment is in focus as regards waste and recycling in a section of the programme called *Junk TV (Skräp-TV*). This particular sequence was broadcast on a Saturday morning in October 2007 (*The brain office (Hjärnkontoret)*, aired on SVT1, 13/10/2007, 10.15–10.40. Produced by SVT.). *Junk TV's* content is inspired by watchdog journalism; it has an intro of its own and it is only 2 min long. In the intro, a pile of TV sets with screens showing the word "Junk TV" is shown, followed by fast clips in black and white, accompanied by music. The images show a young girl confronting people about their garbage. The voiceover introduces the girl as "Nadja, the Waste Detective" and advises the viewer to go to the programme website:

> Where you easily can influence what we throw away as garbage. Go to svt.se/skraptv and you will get lots of good advice on how you can make sure your family throws things away in the right way.

Then Nadja appears on screen in color with what looks like a portable broadcasting device in a backpack, with headphones and an antenna. She addresses the camera when she informs the viewer that she is somewhere in Sweden where she will control what is thrown away. She looks around holding up the antenna as if detecting something and says that she will start with the building closest to her. It is a block of flats. When Nadja enters the building, the scene changes and a living room table surrounded by three ladies is shown. They are having coffee and buns and playing cards. In the next sequence, we see Nadja again. She is exiting the elevator and bursts in on the ladies calling out "Waste control." Nadja declares that she will hold a competition. She then gets the bag of waste from the kitchen and empties it on the table in front of the ladies. The table is still set for coffee and buns.

Nadja informs the ladies that they have 30 s to put the waste into the right recycling containers. Nadja places herself in the corner with a stopwatch and asks: "Are you ready?" The ladies answer: "Yes!" They look quite happy and engage eagerly in sorting the litter into the right containers. Nadja keeps track of time.

Nadja cheers them on and the ladies manage their task within the time limit. "Well done. You did it!" Nadja says and adds: "Now we can celebrate with buns." She reaches for a bun on the ladies' cake stand. "All right, now remember to recycle. We must all help out with the waste experiment!" Nadja says and leaves. The ladies wave goodbye and continue playing their card game and drinking coffee.

In this short clip, it is the child who has the knowledge and the knowhow. Nadja knows how to recycle properly. That recycling is important is implicit in this programme and something that all addressed children should already know. Nadja also knows that not all people handle their waste in this way. She is competent enough to be the judge of whether they are doing it correctly. The fact that Nadja is bossy makes the clip funny. She has the authority to question adults, to interrupt, and also to make adults redo what they have already done in an unsatisfactory way. This is not how

children are usually allowed to treat adults. Coming up with a competition to make people do things is usually something adults impose on children. Thereby this programme manages to set normality aside, and the child serves to blur the norms of the child-adult hierarchy (cf. Baker, 2001; Prout, 2005; Taylor, 2011).

It is the child who not only forces adults to assume responsibility for their environmental footprint but who also assesses them. The voiceover also urges viewers to check out the website to get advice on how to manage their families in regard to recycling. It is the individual child's responsibility to set their families straight in the name of the environment and nature. This content is based on the notion that children should be interested in saving nature, and hence the world, by acting locally and assuming responsibility for the actions of their family members and other adults.

The Environment as Forming a Child-Nature Relationship

The discourse on environmental issues is largely the same one that is visible in all of the above examples. It is a discourse that draws on notions of risk and danger, according to which something must be done about the state of nature. However, how children are viewed in this discourse differs. In all of the programme content on environmental issues in the material, the environment is presented as a matter of importance for children. But in the first two programmes, no possible action is presented that is open to children (See however, *Day-care TV* from 1992, where children should and could pick up litter even if this was not portrayed as an action that would save the entire environment as such.). In these programmes, it is only technology, politics, and money that viewers can set their hopes on, but still the future looks grave. In 2007, on the other hand, the environmental discourse provides children both on screen and at home with a position from which to act on an individual consumer level (cf. Linnér, 2005).

In his study of Swedish educational programming on environmental issues for all target groups during the period 1962–2002, Björn-Ola Linnér (2005) points out that children are portrayed as the hope for solving the environmental crisis in all programmes, not only those targeting them. In *TV for children*, the child viewer is informed but not asked to act in 1980 and in 1992. All blame for environmental problems is thereby put on adult society. In 2007, however, children are asked to step up for nature and set adults straight. But when there are things children can do about nature's problem, this also has consequences. Children are all of a sudden responsible for controlling adults and thereby responsible for saving nature and hence the world. This relieves adults of their responsibility for acting on the crisis they have caused, placing it on children instead.

Conclusion

The analysis in this Chapter has focused how the child-nature relationship is constructed in TV material. Research spotlighting the child-nature relationship has been called for (e.g., Prout, 2005; Rydin, 2000; Taylor, 2011), and, for example,

Taylor (2011) has argued, drawing on Prout (2005) and Haraway (1991), that questioning both nature/culture and child/adult dichotomies allows us to study children and nature in new ways, focusing on how they interact. In the present analysis, these new ways have been shown in several respects. To start with, the vast presence of nature content in *TV for children* reproduces the discursive notion of children as being linked to nature (cf. Halldén, 2009, 2011; Prout, 2005; Taylor, 2011). But focusing on the relation between nature TV content and the category children also allows us to study the nuances of how this bond is upheld.

The nature discourse in *TV for children* does not only present nature as something good and positive in relation to children, as suggested in previous research (e.g., Halldén, 2009, Kahn, 1999; Kahn et al., 2008, 2009; Myers, 2007). The nature representations analyzed here also portray nature as manifold: for example, as magnificent, natural, everyday, nice, intriguing, dangerous, reliable, unreliable, funny, destroyed, and needing to be saved. Representations of a multiplicity of natures thus coexist in *TV for children* (cf. Macnaghten & Urry, 1998). But nature cannot be represented in all possible ways for children in the nature content studied here. It is neither evil nor almighty, and no natural disasters that leave people helpless in the face of the powers of nature are shown.

In these nature representations, children belong in outdoor nature, but they are also struggling to manage outdoor life, recycling to establish a place in nature's cycle, and working to save it. In these televised representations of outdoor nature, the environment and children blur boundaries and question dichotomies, neither of them being possible to label as pure "nature" or pure "culture" (cf. Baker, 2001; Haraway, 1991; Lee, 2001; Prout, 2005; Taylor, 2011). Notions of the child audience are embedded in these nature representations. Children are supposed to engage in nature, be interested in nature as well as want to watch TV programmes containing nature. In this way, televised nature for children also maintains the dichotomy between children and adults (cf. Lee, 2001; deCordova, 1994), as adults are not expected to be particularly interested in nature or to become engaged in environmental issues.

The representations of children and nature draw on primordial notions of children as mysteries of nature and nature as a mystery for children (cf. deCordova, 1994; Halldén, 2009, 2011; Änggård, 2009). These are indeed adult views on these categories, and they uphold discourses that construct the child-nature relationship in the TV content under study. This might seem obvious, as the people pulling the strings behind the scene are by definition adults. However, these adult notions of what children and nature are and should be determine what TV content for children is shown on TV as well as how children and nature are viewed in society at large. They are, thereby, maintaining anthropocentric and "adult-centric" notions and thus preventing children and nature to form other possible relationships based on other views.

A study of TV content reveals, in this way, that programming for children is about norms and notions that concern children as well as nature. The present analysis shows that the child-nature relationship in TV for children is strong during all the years under study, and there is no sign that this relationship is weakening. Tomorrow

(as of this writing June 12, 2017), the yearly summer break morning programme begins. It is a live show being broadcast outdoors with a child audience sitting in the grass around the programme stage. This year the audience will learn, among other things, how to become "planet carers" (The SVT website b). What this highlights is that our societal notions of children and nature are entangled and that it is difficult to even imagine a childhood that is not lived in a close relationship with nature and that is not ready to save it. This view of the child-nature relationship is, as we have seen, something that is also requested in earlier research (cf. Kahn, 1999; Kahn et al., 2008, 2009; Myers, 2007) and something that we, as adults in society, perhaps see little reason to question. But this view on the child-nature relationship might also be what leads us astray when it comes to critical questioning. Naturally, as a society, we need to be very careful about the natural world, which is the very foundation that makes life rich and possible. But as I see it, the important question is: Why should nature be a primary concern for children? The upshot of the matter is that adults have the power, legal possibilities, and the responsibility in society and are thus responsible for environmental damage and for clearing it up. The view of the child-nature relationship represented here is more of a burden, because it positions children as becoming adults, rather than as being children in the present. And the responsibility for nature is thereby assigned to children, who have limited or no possibilities and/or resources to actually do anything about the environmental disaster that is affecting us all. The child-nature relationship as reproduced in the TV programmes also leaves children with the impression that adults are unchangeable and unwilling to shoulder the environmental burden that they created in the first place.

The question that remains after studying all these hours of TV material is whether, after all these years of imposing a special relationship to nature on children, it is not time for adult society to shoulder both the special, caring relationship and the responsibility for the natural environment and set a good example?

Abstract

Why do Forest School (FS) practitioners choose their vocations? What role do significant life experiences (SLE) play in their choices? This chapter investigates some of the reasons behind their choices, as described by an ethnography of FS trainees (2010–12) using qualitative interviews and observation. Arising from the study, a new conceptual model of *eco-social identity* is described, framing the ongoing construction of self as *part of* nature. Environmental and socio-cultural influences are explored, including both negative and positive experiences, drawing on SLE research. Identity formation based upon life experience had an impact upon the trainees' choices and yielded some surprising similarities. Early childhood and adult experience in the wider natural world, role purpose, generational change, environmental loss, future shock, and a passion for pedagogy motivated the practitioners. The study contributes new insights into the impact of FS and similar training, the influence of socialization, environmental loss and degradation, future anticipation, ecological identity, and subjectivity in childhoodnature practice.

Eco-social identity · Early life experience · Generational change · Environmental loss · Futures · Forest School

Introduction

Future Shock: the Significance of Experience Not Yet Lived

What do we anticipate future life on Earth will be like, for all species? What impact might this anticipation have upon us? Critical anticipatory studies attempt to imagine the not-yet possible, for instance, futures based upon socio-environmental justice principles (Amsler & Facer, 2017). In the 1960s, US trend-spotters Alvin and Heidi Toffler coined the phrase "future shock." They presented a convincing argument that we are negatively affected by the speed and uncertainty of change.

> 'Future shock'. . .the shattering stress and disorientation that we induce in individuals by subjecting them to too much change in too short a time (Toffler, 1970, p. 37).

As some global populations experience more precarity than others (Shukaitis, 2013), any sense of future shock will vary. Yet with the advent of the Anthropocene (Crutzen, 2002), we all share a future shock upgraded for the twenty-first century

and writ large into the geological record. Past human actions are demonstrated to reach far into the distant future. Similarly, in our everyday lives, our past actions impact how we think about our future.

What implications might these time-traveling relationships have, specifically upon those engaged in the relational pedagogies of childhoodnature? This Chapter draws upon an ethnographic study of eight Forest School (FS) trainee practitioners in England, UK, undertaken in 2010–2012. The study investigates practitioner experience, including their reasons for training and identity formation as a "situated self" (Goffman, 1961, p. 85). The practitioners reveal relationships to future imaginings and past experiences that inform their present actions.

In the following discussion, identity formation is contextualized within "significant life experiences" (SLE) research from the environmental education canon. Then, a new conceptual model of *eco-social identity* is described, arising from the study, to frame the ongoing construction of a situated self as part of nature. From this frame, themed findings on practitioners' perspectives on their experiences are presented. These include early childhood and adult experience, role purpose, generational change, environmental loss, future shock, and passion for pedagogy. In discussing the findings further, I critique the role SLE played in the practitioners' choices to train and what the implications might be for childhoodnature research and practice.

Relationships Between Significant Life Experiences and Identity Formation

Since its inception in the 1980s, SLE research has been connected to identity formation. The underlying rationale is that there are some life experiences that significantly develop our environmental sensitivity. They may have the potential to change our life paths and lead to pro-environmental choices and behavior, such as environmental activism, conservation, or education work (Chawla, 1999; Chawla & Hart, 1995; Tanner, 1980). The earlier SLE literature cites three main categories that are influential upon choices made later in adult life:

(a) Interacting with wild natural or rural settings, as a child or adult
(b) Interacting with family, close friends or other role models, or related books and ideas
(c) Habitat alteration, including negative changes and environmental loss (Ceaser, 2015; Chawla, 1998, 1999 2001; Chawla & Derr, 2012; Palmer, 1993; Sivek, 2002; Sward, 1999)

However, early SLE research (e.g., Chawla, 1998; Palmer 1993; Tanner, 1980) stirred much debate, to the extent that two special issues of Environmental Education Research explored the subject in 1999 (e.g., S. Gough, 1999; Payne, 1999). Let us consider one or two challenges raised by SLE research that are relevant to the present study. Notwithstanding the immediate question as posed by A. Gough (1999b);

whose lives and experiences are significant? The early research focused on a narrow sample of mostly white, male, educated, privileged populations from the North Americas and Europe (Ceaser, 2015). Further studies have now emerged that consider SLE from other perspectives, attending to individual characteristics, e.g., from women and those under 30 (Gough, A., 1999), those not identifying as activists (Stevenson et al., 2014), more diverse populations, e.g., from Asia (Hsu, 2009; Furihata, Ishizaka, Hatakeyama, Hitsumoto, & Ito, 2007; Li & Chen, 2015), and from a postcolonial, environmental justice position (Ceaser, 2015).

There is a dialectic between two main hypotheses active within current SLE literature, agreeing or disagreeing with the impact of early experience as the primary influence on environmental sensitivity. Beyond the initial SLE studies, further research (Chawla, 2007; Fjørtoft, 2004; Waite, 2007; Ward Thompson, Aspinall, Bell, & Findlay, 2005; Wells & Lekies, 2006) supports the view that a caring disposition towards the wider natural world begins in early childhood experience. We cannot draw from this research that such formative experiences categorically go on to sustain a love and bond with nature throughout life and compel one to ongoing environmental action, more that they inform our choices. As individuals, committed action comes from complex sources in our selves and contexts and our lives are shaped by a multiplicity of choices and chances. Chawla's research (2006, 2007) shows the significance of positive role models, yet later in life we are surrounded by other role models and influences upon our adult lives.

Howell and Allen (2016) suggest that in order to commit to action on climate change, early experience is not necessary. In their study findings, social justice aims and motivations were more influential. Similar findings state the importance of student/teacher ratios and income levels over time outdoors or role models (Stevenson et al., 2014). Caeser (2015) has developed SLE research from the perspective of environmental justice activists and found three different SLEs: recognition of social/environmental marginality, embodied knowledge, and empowerment from environmental justice community work. As described later in the findings, this bears relevance to the present study.

Finally, Dillon, Kelsey, and Duque-Aristizabal (1999) suggest that SLE research lacks a thorough underpinning in identity theories to explain social and personal phenomena. In the following section, I make a contribution towards this through the concept development of eco-social identity.

Eco-Social Identity Integration: an Individual or Ecological Being?

What dynamics are there between identity formation and our relationships with the rest of nature? The study enquired into the identities and subjective experiences of the FS practitioners and their choices for training and practice. To include both relationships with the environmental and social contexts, I assessed critically the construct of an ecological identity and refined the construct to an *eco-social iden* (ESI). Here, I describe the process, to explain how ESI as a construct, and

accompanying theories, relate to the study. I then consider what, in FS practice, reinforces a sense of ESI and to what extent it contributes to becoming a FS practitioner.

An ecological identity (EID) is defined by Thomashow as "all the different ways people construe themselves in relationship to the earth as manifested in personality, values, actions, and sense of self" so "nature becomes an object of identification" (1995, p. 3). EID as a construct was first introduced by Mead (1934) and developed by environmental psychologists, sociologists, and educators, such as Chawla (1999, 2007) and Kaplan and Kaplan (1989). Bronfenbrenner's ecological theory of human development (1979) is perhaps the most widely known and applied model of EID formation, acknowledging the social sphere within an ecological view. Bronfrenbrenner defined ecological as relational rather than purely flora and fauna or more than human nature. He emphasized the interconnected, interdependent nested systems we live in.

An expanded sense of self that includes nature emerged in response to a critique of contemporary life in Minority western society, from ecofeminist and deep ecological positions (Sandilands, 1999). It chimes with evolutionary biologist Wilson's biophilia hypothesis, which posits an evolutionary and innate need for an intimate association with the natural world (Kellert & Wilson, 1993; Wilson, 1984). Various factors are seen to help form EID. Clayton and Opotow (2003) argue that it develops from an individual's "direct, personal, immediate, and emotionally significant experiences with the natural world that change the individual's understanding of self" (p. 14). Further factors in forming an EID can be deep experiences within nature, social interactions in and for nature (Gooch, 2003), beliefs that the environment is important in its own right (Clayton, 2003) and a socially constructed cohesive understanding of self and others, human and non-human (Chawla, 1999; Thomashow, 1995).

This summary of thinking on EID clarifies the area of identity politics and theory with implications for the study. Bragg (1996) argues that an ecological self is innate but stifled by modern life and in this statement a tension between theoretical positions can be found. Theories of ecological selves become inadequate when simply saying that we must become more connected with the natural world, identifying with it, to find our real authentic selves within nature. We live in a sphere of dominant social influence, and therefore, a seemingly purist stance closes itself to other sociological positions regarding the social self. Ecofeminist and deep ecological perspectives can be interpreted as too essentialist in their view of the ecological self, based on "the idea that humans can return to an organic state of grace by transcending the ways in which nature has been constructed in patriarchal development" (Sandilands, 1999, p. 70). Sandilands notes the danger inherent in this quest, for "ecological degradation is a complex social problem" (ibid.). Deep ecology and ecofeminism can be guilty of espousing modern romantic ideas that our *proper* place is as a natural being is distorted by an artificial society. These theories are in danger of reproducing an impossible dualism of nature/culture that they propose to stand against, arguing for a pure *pre-social* state which is impossible, yet a meme that has

been in place since Rousseau's time. Since the Romantic era, the endeavor of social theory has contributed to our understanding of self-formation processes and the complex interweavings of human social life. Therefore, a theory of ecological self can misrepresent sociological theories of social selves, which to a large extent do take into account our biological or embodied self (Goffman, 1961). From an eco-social perspective, we cannot be severed either from the natural or the social realm. We do not have an authentic self that predates our social self, or a relationship with nature that excludes society; we are social beings. Similarly we do not have an exclusively social self without our biological nature; we are natural beings.

Encouraging people to see themselves as part of nature is potentially advantageous in inspiring strategies towards more sustainable societies, but a socially complex view is necessary. Sutton (2004) makes the point that we tend to need to be shaken out of our social self, as the primary reality, to realize our innate biological self. Therefore, we need to accommodate both ecocentric and sociological perspectives to address self-formation that includes an ecological self or identity. With this in mind, I reframe EID and the project of the ecological self as *eco-social identity* (ESI), to overcome the theoretical obstacle of sacrificing the impact of the social self. ESI keeps our relations with the rest of nature in the frame, inviting in an ecocentric perspective, while considering identity from our unavoidably anthropocentric perspective. I return to Mead (1934) who framed identity as derived from the social process, the divide between I and Me, where we partially construct our identities based on the generalized reflections of ourselves from others. When considering the practitioners in the study, despite many of them having a deep affinity with the rest of nature (Kals et al., 1999), their identities are constructed and negotiated largely within social realms. Therefore, ESI has greater fitness for purpose for both the research and the aims of this Handbook.

Using *Eco-Social Identity* as a Conceptual Model

Figure 1 represents *eco-social identity* as a momentary cross-section through a human lifeline. The model reflects the ongoing formation of identity as a series of situated subjectivities across space-time, formed in multidirectional flows of experiential awareness. It is a spatial, phenomenological model that synthesizes the ecological perceptual learning of worldly "inhabitation" (Ingold, 2008, p. 1804) and the social processes more traditionally associated with identity formation (Mead, 1934).

Within the earlier discussion, laying the theoretical foundations for *eco-social identity*, I rejected either/or notions of an innately ecological or social self. With this I also rejected the related dualisms such as nature/culture, in favor of a position that conceptualizes shared processes and blended awareness of our biological nature within our unavoidably anthropocentric perspective. The blended colors in the model represent this position. There is no essential self, only ongoing relational processes. Constantly changing levels of implicit and explicit experiential awareness are present, as a basic constituent of being alive, of the processes of materials and

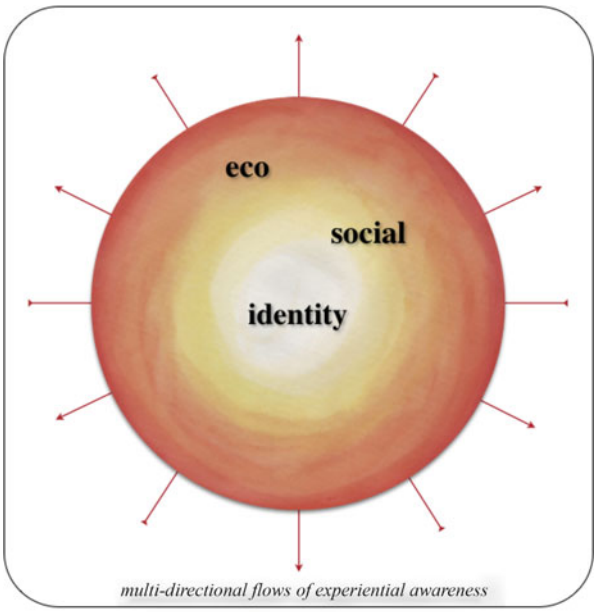

Fig. 1 Eco-social identity

forces shared with others (humans and more-than-human), be they physical, affective, social, or any form. These awarenesses are multidirectional, as represented by the arrows.

The model is in some ways the starter for a metaphysical template of life-itself (Kraftl, 2013) and an experiment in representing the nonrepresentational. It is useful to the study, as the model frames my ontological and epistemological position, and from there I have built the analytic interpretation. Re-conceptualizing *eco-social identity* helps to locate the practitioners' situated selves and subjectivities. However, as a cross-section, it is hard for this model to show movement or change in identity, the temperate nature of affect, or how situated subjectivities are absorbed into the self and continuously adapted. Recognizing the ongoing nature of identity formation, *eco-social identity* can also be shown as a lifeline, or red thread, representing life experiences running along space-time (Fig. 2).

What is Forest School?

Before I go on to introduce the study, first let us introduce the context of FS, as a distinct form of outdoor learning. FS has specific principles that include being in local woodlands regularly, ideally over all seasons, with a play-based, participant-centered pedagogy (Cree & McCree, 2013). Programs are mostly for children via educational and care settings but are provided for all ages (Murray & O'Brien, 2005). The agreed UK FS definition is:

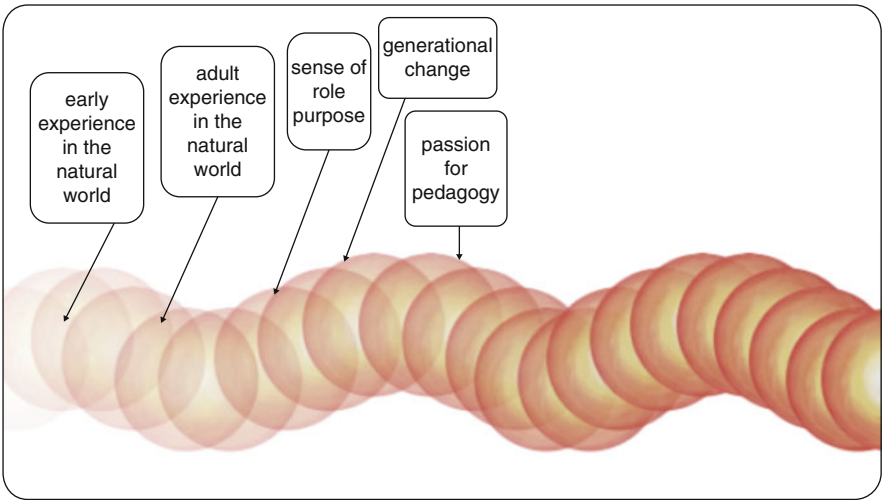

Fig. 2 The lifeline of ongoing eco-social identity

> an inspirational process, that offers all learners regular opportunities to achieve and develop confidence and self-esteem through hands-on learning experiences in a woodland or natural environment with trees. Forest School is a specialised learning approach that sits within and compliments the wider context of outdoor and woodland education. (FS IOL SIG, 2012).

FS builds on a rich tradition of outdoor play and learning in both Scandinavia and the UK, yet not all Scandinavian cultural understandings translate fully to the UK, such as "friluftsliv" (lit. open-air life), Danish Udeskole practice, or the inclusion of animistic nature spirit characters such as Swedish "Skogsmulle" (Cree & McCree, 2013). The UK FS movement emerged from practitioners' needs and interests, countering their context of mainstream education and care. FS can be located within various social or educational movements, including the growing demand for so-called "natural play" and "free range childhoods" (Austin et al., 2015; Gill, 2011), opportunities for outdoor learning, responses to educational pressures, and environmental concerns (ibid.) (Waite et al., 2006). From these grassroots beginnings, UK FS has now incorporated into many mainstream settings and private provision. Hybrid versions have diverged from "full-fat Forest School" meeting all the principles, such as compromised "Forest School Lite" or deeply tokenistic "Forest School Ultra Lite" (McCree, 2014). Hybridity helps a movement to spread and some amount of cross-pollination is inevitable, particularly as the popularity has led to commercial uptake. However, the full implications of tokenization are yet to be seen. For example, the importance of "full fat FS" distinctions and principles remain a key indicator of quality provision (McCree & Cree, 2017).

Method

The design was qualitative involving three stages of interviews and observation. Developmental stages (Miles and Huberman, 1994) reduced predetermined bias and informed further inquiry, hence, the emergence of the concept *eco-social identity* which arose out of the first stage and informed the analysis.

Participant Recruitment and Ethics

Ethical protocols was approved prior by the university committee, in line with guidelines from the British Educational Research Association. The eight FS trainees self-selected with informed consent to participate in the research. I attended four training courses to allow for autonomous voluntary sampling from an emancipatory standpoint. In the spirit of ethnographic research, I valued particularities and favored a depth of narrative and analysis over a large sample number. The participants represent a range of provision, reflective of current diverse UK FS practice for young children. There were two manager-practitioners, three early years practitioners, one teaching assistant, and two volunteers. Four had between 10 and 25 years professional experience and two less than 5 years. Six out of eight were earning below the national average wage. For confidentiality, participants have other species names.

Context

Fieldwork was conducted from 2010 to 2012, firstly at an English environmental education and FS training center, and afterwards in professional settings. The settings ranged from isolated village schools to play sessions in busy urban parks. Six had FS sites on their setting location. The landscapes, species, and affordances varied widely, ranging from 20 meters square of mixed young trees, shrubbery, and concrete, to established woodland set in acres of grounds.

Interviews

The first interview was made during training. The topics were participant background, reasons for training, perspectives on training, and FS ethos (relationship with the wider natural world, child-centered play, and risk taking). A second telephone interview focused on the challenge of taking training into practice, made about 6 months later. In this the participant chose an encounter to reflect upon within a framework of relationships between adults, children, and the wider natural world. A third phenomenological interview was conducted the following year after a session observation, with reflections on lasting impact. The interviews lasted

between 30 and 90 min and were audio-recorded with participant consent and transcribed.

Observations

Factors observed were training and work contexts and social norms; site relationships, type, and use; contextual background and team relationships; evaluation standards, quality, values, and attitudes in the setting towards FS; practitioner's interactions with adults and children; and environment and practical challenges. I witnessed a FS session with each practitioner, talked with team members and surveyed site affordances (multispecies, environmental, and socio-cultural).

Analysis

Using constant comparative method (Glaser & Strauss, 1967) to analyze the data at each stage allowed emergent themes to bear appropriate relevance. The role of the combined, triangulated data served the outcome of multiple instrumental case studies (Stake, 2005), verified by the participants. In synthesizing the case studies, I explored their ongoing construction of their self and professional practice, e.g., in how they approached challenges differently and with whom. I view practice not just as individual skills and knowledge, but as both dialogue and activity combined, "as complex socio-material accomplishments, multi-dimensional, situated, embodied, and fundamentally relational" (Lee & Dunston, 2011, p. 483). Therefore, I located the practitioners within spatial and relational frameworks (Bronfenbrenner, 1979; Ingold, 2011; Kraftl, 2013), including the relationships they held with themselves, others, and the world. Connections were made between common choices, perspectives, and relationships in cross-case comparison and differences highlighted.

Findings: Exploring the Identities of Forest School Leader Trainees

Within the participants, there was a unanimous feeling of passion for practice, with varying interests such as child rights, connection to nature, alternatives to mainstream education, and child-centered practice. The training validated the practitioners' beliefs and encouraged a sense of change agency. For this reason, and for the reason that the training had enabled them to exercise a widening of their professional identity, overall they valued the FS approach and ethos. The practitioners voiced clear concerns for children's wellbeing, in relation to decreasing outdoor play opportunities. A minority of the practitioners reflected on this lack in their own childhood experience. The other practitioners demonstrated varying levels of *eco-social identity*, feeling part of the natural world over their life course. While not everyone identified as an "outdoorsy person" (Maynard, 2007, p. 389), they all

constructed their role with a sense of purpose towards what they perceived children needed, in relation to eco-social justice and generational change. This strong link between their own life experience and their relationships to nature and society contributed to their passion for practice.

How Valuable are Early Experiences in Forming Identity Relations?

Continuing practice requires initial commitment, conviction, and the support to make it happen. Out of a total of eight practitioners in the case studies, five continued their FS practice and qualified: Caterpillar, Monkey, Moose, Rhino, and Salamander. They expressed stronger identity relations with FS and the natural world than the three who did not continue. Interestingly, all five, plus Lion, expressed childhood memories of free range unsupervised play in natural environments and a greater range of independent mobility than they observed in children today.

> We used to go poke fires and we'd be outside all day. My friends had a garden that backed onto an area of parkland and we just used to jump over the fence...they'd call us back in for our lunch or tea and that would be it. But we probably wouldn't do that necessarily with our own children. I tend to be, even though mine are out in the woods and stuff, I'm there, or I wouldn't let them go... even I feel a bit like that and I think that because of all the legislation that there is nowadays, you've just got to be so careful. (Caterpillar 3)
>
> When I grew up, I lived on a big council estate in a town, but the difference was...it's a cul-de-sac... surrounding three sides of it is woodland. As a child, I used to spend all day, every day, in the school holidays and at weekends, out in the woods. That is what my childhood was based on. (Lion)

Caterpillar highlighted how her own attitudes towards her children have changed despite how she used to play herself; I consider this later in terms of generational change. Moose, Caterpillar, and others gave the example of formative experiences of natural play in childhood as a reason why they value similar experiences for children now and why they choose to practice FS. Some practitioners had spent a continuity of time exploring the natural world throughout life. As Moose stated "*I've always spent loads of time outside from a child...I love being outside.*" Caterpillar's environmental knowledge stemmed from a childhood interest she had maintained and pursued into adult life. Caterpillar talked fondly of memories relating with other species in her early childhood play: "*I was always in the garden chasing hoverflies and bees and stuff so... it's a big interest of mine.*" She in particular had a passion for ecology that came through in her FS practice.

Outdoor Play Deprivation in Adults

I asked some FS trainers about how they discussed nature-society relations with FS trainees (McCree, private correspondence, 2012a, b, 2013). Horseman stated that now she does not ask about outdoor play memories, as she has found fewer

younger generation adults have had natural play experiences as children. Play memory sharing is a phenomenological method often used with adults in play or pedagogical training (Sebba, 1991; Waite, 2011a). For example, considering how you played as a child and your responses to different play situations as a responsible adult, e.g., unsupervised, risky, or natural play. In Waite's research (2011a), the values that emerged from preschool practitioners considering their own memories of the outdoors included: freedom and fun; ownership and autonomy; authenticity; and love of a rich sensory environment and physicality. These values were employed as a framework to analyze data from case studies, observations, and interviews in the preschool settings where outdoor play and learning was taking place. The study included open enquiry questions on what the practitioners wanted to share about their own lives in childhood. The topic of our own personal play memories can raise a number of questions such as what each person finds acceptable or not and indicate a wide range of values, attitudes, and differences in childhood experiences within a group of adults (Keichtermans, 2005). Formative childhood experiences can be enablers or disablers in our adult attitudes and perceptions towards nature (Chawla, 1988, 2007; Fjørtoft, 2004; Waite, 2007; Ward Thompson et al., 2005; Wells & Lekies, 2006). It is interesting to see how the sharing of memories in the study draws a parallel with these other studies. In the interviews, I asked the practitioners about their relationship with the natural world in their personal lives, yet I did not prompt them to speak of their early experience, which was instead freely associated and volunteered. Let us now consider those who did not state any significant early experience, but instead felt informed by their experiences as an adult.

Adult Experiences and Sense of Role Purpose

Three practitioners (Ant, Eagle, and Rhino) came to FS training and an exploration of their relationship to the natural world due to influences in their adult lives. They found meaning in a sense of professional purpose, mission, and responsibility. Ant explained that "*it's travel, for me, which reconnected me to the outdoors.*" His perception of reconnection with the rest of nature was important to him both personally and academically, informing his focus as a mature student.

Eagle's motivation for practice was professional and she did not identify with FS on a personal level. Her motivations for FS were because she felt it was "*really important for children*" as a child-centered approach that "*has a lot of positive impact. . .on their development as a person.*" Within her own life, she said she felt "*disconnected*" from the natural world without a strong sense of belonging "*we spend so much more of our time with technology now than we do with the natural world*." She was indoors at work and at home, with no outdoor hobbies apart from camping holidays.

Rhino had formed a clear purpose in her role as a home educator to take the children outdoors. This was very different to the rest of her professional life as a

dance artist and educator, yet she held strong views about the impact of modern life and felt a sense of imperative due to her concerns for the future.

From these first interview findings, I became interested in re-conceptualizing the ongoing formation of identity as a way to understand the practitioners' choices. The findings contributed to the concept of *eco-social identity.* The following sections investigate what helped further *eco-social identity* formation in becoming a FS practitioner. The impacts of generational changes are considered, including multiple senses of environmental loss, then a passion for pedagogy. The findings conclude with a final revisit to the impact of training.

Generational Change

A surprising emergence in the findings was that generational change featured strongly for all the practitioners. The topic emerged from open questioning in the first interviews around reasons for training and perspectives on the FS ethos. Asking the practitioners what they valued and why they were training gave way to many feelings being expressed; including fear, anger, sadness, and passion, with an overwhelming sense of loss. These losses were felt as generational changes and manifested as a form of future shock (Toffler, 1970).

Forerunners of the Future

Theory on generational change is undervalued in research and today, Karl Mannheim's theory of generations from 1923 is still the most systematic and fully developed treatment of generations as a sociological phenomenon. According to Mannheim, generational change designates "a particular kind of identity of location, embracing related 'age groups' embedded in a historical-social process" (1952, p. 367). Mannheim theorized that people are significantly influenced by their socio-historical environment and notable events they are involved in, that predominate their youth and form social generations. The people in that generation in turn can become agents of change and give rise to events that shape future generations. On the subject of forerunners: Mannheim said (ibid.):

> It occurs very frequently that the nucleus of attitudes particular to a new generation is first evolved and practised by older people who are isolated in their own generation (forerunners), just as it is often the case that the forerunners in the development of a particular class ideology belong to a quite alien class.

Mannheim's view of forerunners suits the profile of some of the practitioners in the study. FS practice is an alternative provision and inherently challenges the culture of mainstream schools and settings. In order to identify with a professional role that is rooted in an alternative, the practitioner needs to be resilient to negotiate an

alternative position within prevailing social norms. There are socialization challenges inherent in any setting context, yet the point regarding identifying or acting as a forerunner is worth making here. For the purpose of the study, it is interesting to note which generational changes the practitioners themselves saw as significant and how they expressed this in terms of their identity, or related situated subjectivity. The changes included environmental degradation, nature-society relations, increased urban lifestyles, the experience of childhood, education, risk, and the experience of time outdoors, within an overriding theme of loss. Here follows some of the practitioners' views within a discussion on the different aspects of loss as an overarching theme.

Loss of Relations to the Natural World for Future Generations

Most practitioners perceived that the human relationship with the wider natural world has changed within their generation, lessening in importance. Such losses were tied into a fear of the future and a nostalgia for the past. They expressed fear, uncertainty, and a gloomy outlook on future possibilities, with a continuing sense of loss.

> The relationship with the natural world is about not only this generation but the generations alive now, all of them, reconnecting and learning what's important. And, you know, I think that the transformative process for them is. . . going to be a realisation through something terrible. . .or through an attempt by man like. . .geo- engineering or bio mimicry or that kind of thing? . . . we're going to get to the point now as this battle between technology and the environment. . .they're going to clash. . . and something's going to happen and its going to change the way that everyone's thought about it. (Ant)
>
> We shouldn't be selfish . . .It's a world for us all to share, and I think we should look after it for everyone. And if we destroy forests and woodlands, what will future generations have?. . .. we look at it and we say 'well that's now extinct' but then what impact does that have on other food chains? (Lion)

Moose's beliefs linked to her practice clearly as a sense of mission to bring ecological concepts into education. She located her reasoning in how generations have changed in their perception of the use of natural resources.

> After the 2nd World War everybody thought they'd fought for it and they had the right for it and actually it's this generation now and our future generations that are paying for that. . .And I'm not saying that's the only reason why because obviously its corporations. . .I've a real thing about electricity and energy at the moment. . . and the way that we just use stuff and don't even know where it comes from. Most kids don't even know where electricity is, most adults probably don't even know how electricity is made, or how much they use, how much they waste. (Moose 1)

Rhino was motivated to do the training in part by a sense of past and future loss of natural resources, a modern day eco-survivalist view concerned with the next generation.

> I always liked the idea of knowing how to actually do things in the natural world rather than being just in a completely artificial environment where it's all kind of done for you, cos I think, it's so fragile, our artificial environment. . . it seems an unsafe place to me, to not know how to do certain things out in our world, if we ever had to. I think that our modern world actually sits on a knife edge. I know, perhaps people feel quite secure in it, but I don't, I look at it and I go 'Well, so what if the oil supply wasn't allowed through so then everything like fell apart and nobody knew how to do anything anymore?'It's not actually . . . that far away, you know, it wouldn't take very long . . . the supermarket would be empty pretty fast I think. And, you know, also I think about, there's a whole environmental thing about children being so separate from it that they have no appreciation for it and not take care of the resources and then they will be gone, you know, that kind of connection. (Rhino)
>
> I think it's crucial that children understand how to value their natural spaces, how to look after them and how to be a part of them. Because they're the next generation that has to pass that on to their children and so on. . . if you don't create that sense of amazement and beauty, then it's not going to be valued and we will lose it altogether. (Salamander)

Environmental Generational Amnesia

The problem discussed in the above quotations, where each generation has an increasingly degraded environment to measure as the normal or nondegraded experience, is a psychological phenomenon that Kahn has coined as environmental generational amnesia (Kahn, 1997, 1999), or adapting to the loss of nature. To halt the pace of change in children's experiences is a motivation for these practitioners. Most expressed a wish to help children to realize the value of the environment and our interdependence with natural resources. Ant and Moose shared a motivation to use FS to enlighten participants about current environmental problems. In this way, these practitioners and other environmental educators hoped to counteract the "forest of forgetting" (Hand, 1997, p. 11) that crosses generations and to safeguard what is left. Hand's paper concerns how present day Scottish people, living in one of the most deforested countries in the world, have little conception of how at one time the whole land was covered with forest. There is an interesting crossover with the word "safeguard" here, as again care plays a role; care for both children and the rest of nature enmeshed in the same emotive frame of motivation, for childhoodnature practice. All of the practitioners in the study saw the potential for forging a deep, caring relational identity within the wider natural world, to enhance wellbeing, health, and wholeness, tied to the rubric of biophilia (Kellert & Wilson, 1993).

A romanticized view of the past can be present when people talk about how things were "when I was a child," framing childhood in previous generations as a golden age of freedom and healthy outdoor activity. Yet Kahn (2002, p. 113) believes that a romanticized view of the past is acceptable if it is engaged, showing and investigating with children how the landscape around them has changed over the generations and helping to restore it. This can counteract the effects of environmental generational amnesia and perhaps be beneficial for adults with outdoor play deprivation.

In Rhino's practice, engagement was evident in how the children expressed an urge to want to coppice the woodland, understanding the historical purpose through

learning how to coppice poles for dens and firewood. They witnessed the abandoned coppice stands rotting in the woodland they played in and Rhino followed their interest. However, Rhino did not romanticize or proselytize, simply the children found their own way to this engagement through their direct experience, growing a sense of place and finding their own place within it.

Loss in Professional and Public Life

There were other senses of loss, including the morphing of professional services. Salamander spoke about play service changes and how she identified a gap in the market for outdoor play and FS, transforming practice within an entire borough.

> We have to kind of look at other ways of generating interest and maintaining what we do. . .it's great to be outside and validate. . . what we used to do when we were playing out years and years ago. . . Play work's moved from being. . . very outdoors. . .then it kind of morphed into this kind of centre-led kind of activity, and so [FS training] is allowing me to go back to the root of it and actually why I came into the service and into playwork. So you know, for me, its kind of we've come full circle. (Salamander)

Interestingly, there is an element of history repeating itself, which can be seen theoretically as generational conflict, or a cycle where things move in and out of fashion, in opposition to the previous generation.

Loss of Childhood

"Free-range childhood" is currently in fashion in the UK, challenging social norms about children's independent mobility and outdoor time (Cree & McCree, 2013; Gill, 2011). Losses of childhood were felt keenly by the practitioners.

> We are not very good at allowing children to be children. We create children to be citizens of the future, and we don't think about the here-and-now. And if we lose the here-and-now and they don't have that awe and wonder in their childhood, and are allowed to take risks and play, and be a part of the environment and be a part of the world that they are in, then actually they lose their sense of belonging, and who they are, and so they're never going to be a well rounded adult. (Salamander)

From the child-centered perspective of the practitioners in the study, children have been constructed in different ways by society over time. The effects of their contemporary lifestyles are played out in FS, with the practitioners stating how they need to help children to "*settle in*" to the environment of a wood, as many are unaccustomed to being in such intimate relationship with the wider natural world, in particular with the freedom to choose what to do and only the loose parts afforded by the environment to play with.

> There is this culture of kids being indoors and I was one of those kids you know, I had computers and I spent a lot of time. I'm the kind of cross-over generation you know, where computers were introduced in schools. (Ant)

Loss of Time

Children's free time was perceived as lost also. Practitioners made the contrast between structured time versus natural time to be and the impact that has on wellbeing.

> Children these days. . .have so much pressure on them. (Caterpillar)
> It's all supervised now isn't it? This school, this activity Monday, that activity Tuesday, that activity Wednesday. It's all so structured and regimented, there's no free time. (Lion)
> [Society] is not built for taking the time out to be able to look. Its not built for people to come on this course. . ..very few people have that opportunity to take time to think. . ..kids at school, they don't have that time. (Ant)

Here, Moose extends the loss of free time to the routines of adults, as a psycho-emotional loss, and how this in turn structures children's lives.

> There's so much stuck feelings. . . with adults. People get stuck with stuff but they're unable to shift and they just do the same things, go to work, stay inside, watch telly etc. . .I think its the same with children especially more and more now as we're living in a world where they're doing the same, they're going to work though they call it school, they're going to work, they come home, they put the TV on, they put the computer on, they do more work, they take that work into work and they come home and put the TV on and start to cry. . .I wonder how many people actually go for a walk? But if its been part of you as a child, and you can appreciate those shifts and those moments, then you make it more of a priority in your adult life and if you do that then you're bound to be happier and maybe you don't need as much stuff. (Moose)

Loss of Local, Cultural, and Intergenerational Ways of Knowing and Appreciation

The practitioners reflected on how things have changed from our own childhoods to now, in terms of indoor culture, affluence, and technology.

> In this country we don't see hardship do we?. . . They've got too many, what we class as everyday things, but in other parts of the world they're absolute luxuries and I don't think they appreciate what they actually have. . . But they've got a Wii. . . a Playstation 3. And it's still never enough. But does it really make them happy?I don't think it does. (Lion)

The impacts of consumerism, globalization, and industrialization were keenly felt. Ant felt that "*technology has just transformed things so quickly, that, you know, I*

don't think people have had the time to catch up," stating that an indicator of this process is "*the way our food is produced now.*" He felt that, in the short term, the way society operates has changed very fast and so reconnection and education about the natural world are imperative for the present generations, "*all of them.*" Yet he believed that this will not happen until there is a greater conflict in society, an increase in the "*battle between technology and the environment,*" that will "*change the way that everyone's thought about it.*" There was also a perceived loss of knowledge in the shifts in technology.

> There is this . . . indoor culture and it's been researched and researched and stated and stated but I think it's driven by industry, it's driven by the economy. . .[We need to connect with] people who are older, to be able to pass down their experience, because essentially they're the people that didn't live with this technology and can remember. (Ant)

To summarize the impact of generational change, loss, anger, fear, and future shock featured strongly. In particular, a sense of degraded relationship with the wider natural world invoked feelings of fear, concern, and responsibility for children as the inhabitants of an uncertain future. In contrast, the sense of loss also worked as a motivating force. In the next section I discuss practitioners' passionate responses.

Passion for Pedagogy

Despite the often negative expressions of future shock and losses through generational change, such experiences and perceptions contributed to a passion for relational, child-centered pedagogy. Doing FS involves an everyday deepening of a relationship with wider nature through direct contact, for both practitioners and participants. The focus and goal of FS practice is largely the impact upon the participant, rather than the impact on the environment beyond the immediate FS site. Therefore, a social aspect of our relationship with wider nature is in the foreground. In this section, further *eco-social identity* formations and their embodied values are considered. A sense of belonging within the wider natural world was seen as important by most to share and impart to the participants. Here Caterpillar talks about fostering a deep, respectful relationship with the rest of nature on her sessions.

> I think it's so important. . .we went outside with the children and instantly we all just went 'aahhhhh'. It was peace. It was so quiet and we couldn't hear anything other than the birds up above and them just chattering about things in the wood and that was, for me, what it's all about. They're in tune, they're looking, what plants are coming up, there's buds coming up now, making things with sticks. . .and just them getting in tune with the woodland really. . .there's still that respect for the natural world, and hopefully that's part of what its about isn't it? (Caterpillar)

Caterpillar was especially passionate about biodiversity, based in part upon early experience. Ant had very different early experiences and framed his relationship

with wider nature as a re-connection that grew deeper in adulthood, leading to his choice to train.

> In my past I haven't chosen to build on that kind of connection but I was always aware that it was there. . ...I think that everyone's just got an intrinsic connection with the outdoors, whether they're aware of it and choose to build on it. (Ant)

Ant thought that reconnection was a more accurate term than connection, that we innately belong to the world: "*I think intrinsically people belong there you know, they always were there and we've evolved essentially from that place*." Salamander saw developing our relationship with the rest of nature as part of her professional role.

> I think in a professional capacity, we have a responsibility to support our children and young people to understand how we can maintain our environment, and how we can take it forward and be sustainable, in a way that they can understand it. (Salamander)

Most of the practitioners chose to train in FS based in part on some concern for the future. Moose's motivation was primarily emotional: "*I get really angry that we just use up as many resources as we want to,*" locating her reasoning in how generations have changed in their perception of the use of natural resources. Her passion was self-evident and embedded in how she viewed her place within the world.

> I feel really connected to the natural world and again, always have done. . .It's the feeling of being part of the whole. . . It's understanding how everything is connected and I feel it down my spine. . . I don't feel that there is a border and a boundary between me and an actual world. I don't feel apart from it, I feel part of it. . . which is why I'm so passionate about it. (Moose)

Moose's view was passionate, yet seven out of eight practitioners shared some of this sense of feeling part of nature. Making a choice to train in FS could be seen as an act of passionate defiance in Moose's case or as a conscious choice to improve practice for Eagle, a way of personally redressing an eco-social balance and making an impact upon the future. Connection was a recurring theme for all of the practitioners, expressed variously in terms of a loss, of a disconnection and of finding it again, of reconnection. It was also expressed as a primary motivation for why they are training in FS, in order to facilitate the opportunity for children to connect.

> That's what I think is important about FS and what its doing. . . it can be a fantastic route for people to reconnect, and that in itself is an important thing, for people to go on to understand that you know we're not, that, the outdoors isn't at our disposal, its you know, we are at its. (Ant)

This last sentence highlights the importance ascribed to a holistic view of the self by the practitioners, as in a dialogue with the rest of nature with a priority of care for the world which houses the self. FS was seen as an important agent for reconnecting to the whole, for practical, conservative reasons.

> It's generation on generation of an urban lifestyle. Actually going out to the wood is a treat, or something that you do as a past time, as leisure time, not as something that has any value attached to it. Whereas I see it as part of being, and surviving and being part of it, and the world continuing and going on. (Salamander)

From this perspective, nature-centered practice was a conscious choice as part of working with children and young people. Further reinforcing a sense of ESI was their professional purpose and motivation.

> I think it's strange, we're all very good at talking about it, but actually doing it is another thing. I think if we all made a little bit more of an effort. . .it's about being part of it and taking responsibility for it, but taking responsibility for other people as well. (Salamander)
>
> I think the major contributor factor is, not fear of being sued, but actually apathy. Of not wanting to go the extra mile to allow it to happen. And I'm hoping that we are coming back full circle now, where with things like FS..the Play Strategy, although nationally the coalition government aren't really recognising it. But, it's actually to put that kind of thing out there in the open. . .it's been out there, and people have started to talk about it, and those people that are really passionate about it will continue to take that forward, I think. (Salamander)
>
> If you're the kind of person that has the foresight to look 20 years down the line, 50 years down the line, you know its, its just imperative that people are aware of these kind of systems that are happening around them. (Ant)

Advocacy for children and eco-social justice stemmed from passion in many of the practitioners, expressing strong views on pedagogical theory and policy. A common theme was a sense of socio-emotional values. Some of their previous professional experience had contributed to a building up clear ideas of aims and what is necessary for childhood justice, with enough life experience to form considered views. Salamander emphasized the need for a cohesive partnership approach to childhood.

> . . .a whole range of professionals. . .unless they understand the real importance of that child-centred approach and children have to be free to make choices and decision-make, then we're going to have. . .children who've got no common sense, who can't make decisions. . .can't look after themselves, have no sense of safety or accountability or responsibility. And this child-centred approach enables children to make sense of the world, through their own learning, as opposed to being told how it should be. (Salamander)

Moose's politicized view on child-centered practice extended to her world view.

> And so, my allowing children to be free and child centred is the same as I think it should be for everybody. So, if I think I should be like that for adults then how can I go into a group and tell them that that's the way its supposed to be? They need to discover it for themselves. And I believe that if we give that to children, if they make their own decisions they're going to grow up doing the same thing. And if they can make their own decisions and realise that they're powerful, as powerful as the next person, then maybe they'll make those choices themselves and go 'Actually, you know what? We aren't going to teach our children like that any more'. (Moose)

The affective roots of approaches to pedagogy ran deep for some of the practitioners such as Moose. Before that in this Chapter, some of the practitioners' situated

subjectivities have been explored in the themes of, early experiences in nature, and generational change. These themes all had an influence on the practitioners prior to training, helping to form a sense of *eco-social identity.*

The Impact of Training

How did the experience of Forest School training impact upon the practitioners? The analysis found four themes of *skills and knowledge, experiential process, values*, and *support*. Of these, *support* was the most significant as a meta-theme. Practitioners mentioned support in both positive and negative senses, as present strongly within training and mostly absent within settings. During the course time, support within the group was a positive experience for all the practitioners. The affirmation of shared *values* inspired confidence and purpose as a basis of affective support. Yet many struggled to implement socio-emotional child-centered values in practice, due to social factors and disparities in values in their settings. As they began their initial sessions and coursework, many of them felt that their need for support was not met, from either the trainers or settings, raising an important question of how to best support the realities of establishing practice.

In terms of *skills and knowledge*, practical skills were helpful in terms of resources, responsibility, and autonomy. The fundamentals of tool use, woodland skills, risk assessment, and safety were cited as significant. Practical experience had a knock-on effect, a cumulative learning process that combined with the affective, creating a sense of possibility to experiment and try things out.

The combination of theoretical, affective, and *experiential* was viewed as a powerful, transformative group process (Malone, 2008; Proudman, 1995). Time on the course gave the opportunity to find support by having a chance to reflect critically on both their connection with the world and with their practice. The experience of "*simply being*" in the woods was significant. Some held a politicized perspective on how free time within wider nature affords both emotional and ecological literacy, for both the practitioners and their future participants. Could this be a model for supporting opportunities for positive SLE? Certainly the experiential format bears similarities to many of the programs studied in the SLE literature (e.g., Chawla, 1998; Wells & Lekies, 2006). Therefore, supporting practitioners is of interest as a future SLE research topic.

Using the frame of *eco-social identity*, these themes are summarized in Fig. 3, adding to the themes given as reasons for training. Together, they represent the ongoing formation of *eco-social identity* in becoming a FS practitioner.

Summary

In this Chapter, I explored why these FS practitioners chose to train and what role identity formation and SLE played in their choices. Beginning with future shock and anticipation, I explored identity formation in connection

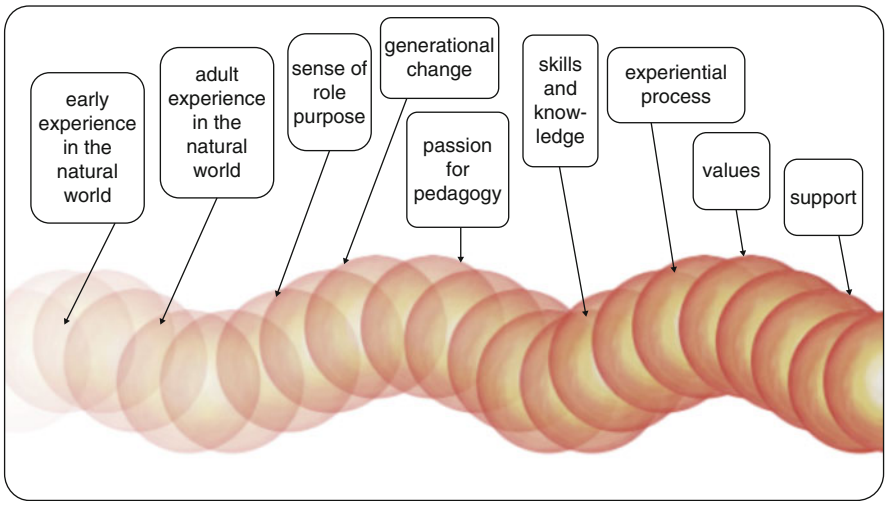

Fig. 3 Eco-social identity lifeline after training

with SLE research. I re-conceptualized *eco-social identity* as a relational framework for the situated self as part of nature. Themes of early childhood and adult experience, role purpose, generational change, environmental loss, future shock, and passion for pedagogy were discussed.

A common SLE perspective was that early experience goes on to influence adult identity. Concern for the future was unanimous, expressed positively in a desire to pass on values and skills to support children to explore their place in the world and care for it. Uncommon differences were that three practitioners stated no significant early experience but chose the training to improve pedagogical practice. *Eco-social identity* was present within their professional role purpose. Generational change preoccupied all of the practitioners, again politicizing the affective domain. Negative changes and experiences were located in a multiple sense of loss felt in themselves, their communities, and wider worlds. A sense of responsibility, anger, fear, and future shock were strong affective drivers. So too was a passion for pedagogy, in part satisfied by the FS training. More experienced practitioners had a sense of conscientization (Freire, 1970) adopting a critically reflective stance and advocating for childhood and eco-social justice. Finally a lack of support for ongoing practice often positioned practitioners at odds to the mainstream educational discourse and knowledge-power relations.

Conclusion

Having got this far, the reader has been through the forest and back again, to encounter a rich panoply of people and other beings situating themselves in the nooks and crannies where children play, telling their life stories. We have felt the

temperate changes of affect and traveled through time to nostalgic memory and dystopic future. Here in the present, I wish us to retain a sense of experimentality.

How might we critique the role SLE played in the practitioners' choices to train and consider the implications might be for childhoodnature research and practice? What authentic achievements can be offered from this study? How do we take action to strengthen the relationship of the human with the more than human? (Taylor, 2017). Can FS practice be construed as valid action? From what position can we act?

Through this study, some observations can be made about SLE research and its contribution to environmental education. Earlier in the Chapter, I explored the view found within SLE research that a caring disposition towards the wider natural world begins in early childhood experience, and those that refute this have found social justice influences later in life to be more influential (Ceaser, 2015; Howell & Allen, 2016; Stevenson et al., 2014). In the ranking of strong influences upon behavior, traditional environmental education ranked much lower down the scales (Hsu, 2009). What is also found is that for an early experience within the wider natural world to be significant in the intended SLE sense, it is necessary for it to be fun, engaging, frequent/regular (Wells & Lekies, 2006), alongside a significant other, with "opportunities to take action" (Chawla, 1999, p.21) as a "fundamental experience" (Furihata et al., 2007, p. 207). The FS approach suits this recommended type of experience.

Implications for research and practice might be to enquire as to how to support full-fat quality provision rather than tokenistic programs, in order for participants to have the chance of SLE impact intended. Connections can be explored between socio-environmental justice and FS, in particular where there are systemic barriers to practice and inequitable access (McCree, forthcoming; McCree et al., 2018). For example, if the school playing field has been turned into houses, as was the case for Lion in the study, where do the children go? If no children go unaccompanied into the woods behind the housing estate to play anymore, as with Caterpillar, what and who will support them to find spaces to play? If an urban multicultural play service closes down due to cuts, as with Salamander, how do we resist and provide alternatives?

More recent research on SLE indicates the importance of positionality, challenging privilege, and working with social justice (Ceaser, 2015; Howell & Allen, 2016). SLE research has been critiqued as prescriptive, for example, in Tanner's outmoded assumptions (1980, 1998) as to the right kind of subject, or that activists capable of saving the earth can be routinely produced via an instrumental SLE program (S. Gough, 1999; Payne, 1999). Bearing that in mind, is there potential for exploring how authentic opportunities might happen for SLE, as part of restorative, socially just FS practice? Therefore, how we support FS practitioners is of interest as a future SLE research topic.

Within the present study, negative experiences of habitat alteration, environmental losses, concerns, and fears were key motivations for the practitioners. Chawla (1998) suggests that there is an increase in negative experiences having an impact, yet Ceaser (2015) notes there remains a gap in SLE research that theorizes on this, particularly from the position of social disadvantage. Negative environmental

experiences are equally significant, or to be specific, and the positions of the people experiencing them are as significant as those having positive or privileged experiences. Can we bring an active sense of *eco-social identity* and justice to bear upon this and strengthen our resolve to act? Let's return to the idea of possible futures, of the not-yet-but-could-be, and reflect finally how the politics of hope and utopian imagination might inform our actions for childhoodnature. If we are to reduce ignorance through research, as Noel Gough suggests (2002), we might start in a small way by supporting FS training and practice with critical reflection and with underserved communities that have not yet given voice.

Ceaser (2015) theorizes on the toxic social/environmental relationships as part of the experience of marginalized power positions. All but one of the participants were women, which raises the specificities of social yet inequitable norms surrounding women's work and how this affects FS practice (Ceaser, 2015). From the position of most early years and similar FS practitioners, low status, low pay, and limited agency within one's role means that any sense of empowered professional identity comes with a challenge. One way to take action is within paid work, where one can afford to act and maintain multiple caring responsibilities and family roles, for example. The practitioners in this study expressed their criticisms of mainstream educational regimes by developing FS in their settings.

However, this very need to act within a professional setting implies a greater risk of losing jobs or challenging work relationships if actions are thwarted. And they often are, as the practitioners are not always supported by leaders and the culture within settings (Waite, 2010, 2013). FS practice that contests the status quo therefore needs further advocacy and collaborative effort to change a culture for effective practice.

This is in part how "FS Lite" happens (McCree & Cree, 2017, p. 224), where a watered-down tokenistic version of FS is landed upon in order to maintain norms within a setting. The dominant discourse has absorbed FS and altered it into "FS Lite" in many mainstream settings, rather than allowing it to change the culture of the school so that learning in natural environments becomes the norm (McCree & Cree, 2017). Yet FS remains a popular training choice and many new hopefuls return to practice with transformative aims and enthusiasm. A similar gap between philosophy and practice in environmental education was highlighted by Stevenson (1987) and in 2007; Barratt Hacking, Scott, and Barratt noted it was still present (Barratt Hacking et al. 2007). I would argue that in 2017, 30 years on, the philosophy-practice gap is even wider, as is the policy-practice gap concerning socio-environmental justice (Coote, 2015).

As Noel Gough argues (2002), research should help to reduce ignorance, and inform purpose to action by investigating our blind spots. What are we blind to already? These are questions that SLE research could ask, and not of the usual suspects. Who is involved in the topic of study but silent, who is least heard and what are their questions? That may help to reduce ignorance. It is clear from the impact of FS practitioners' experiences given in this study that losses are keenly felt, yet so is a passion for practice and this is, on the whole, a force for good. We can support this practice in collective endeavor, in particular with lesser heard voices, challenging

knowledge-power intersections that enclose and divide, to create a positive culture of childhoodnature.

Abstract

This Chapter explores the roles, responsibilities, conceptualizations, and practices of parenting, through the findings of a study into childhoodnature. Childhoodnature is an emerging concept within the field of environmental education that espouses there are no boundaries between childhood and nature and that even separating the words implies a binary exists. Utilizing an autoethnographic approach and founded in posthumanism and socioecological theories, this Chapter seeks to address the paucity of research that exists about parenting in environmental education and offers methodological, theoretical, and practical approaches to parenting in this context. The findings indicate that

through adopting an honest, reflective approach and having a willingness to change, the perceived barriers to parenting childhoodnature can be reconstructed, reimagined, and reconceptualized.

Introduction

A decade ago, UNESCO (2008) released a report that stated:

> Our societies urgently require new kinds of education that can help prevent further degradation of our planet, and that foster caring and responsible citizens genuinely concerned with and capable of contributing to a just and peaceful world. Second, these new kinds of education must be available to all. . .and take place in various settings, including families and communities. (p. 9)

This acknowledgment of the importance of environmental education in ecologically sustainable development has been supported by the current research in the field (see, e.g., Cutter-Mackenzie, Edwards, Moore, & Boyd, 2014) and in practice by many educators. Moreover, this statement from the UNESCO report also acknowledges the significance of the family setting in the educational environment, particularly the early childhood setting. These two aspects, environmental education and parenting within the family setting, are the focus of this Chapter.

In recognition of the role of families on children's learning about the environment, this chapter focuses on the significant life experiences (SLE) field of environmental education to highlight the importance of parenting in this context. The term SLE was coined by Tanner in 1980 who identified childhood experiences in nature as a key factor in determining environmental choices in later life. Since Tanner's seminal article, the SLE field has been the focus of many researchers (see the works of Blanchet-Cohen, 2008; Cachelin, Paisley, & Blanchard, 2009; Ceaser, 2014; Chawla, 1998a, 1999; Chawla & Cushing, 2007; Fägerstam, 2012; Finger, 1994; Gough, 1999a, b; Ji, 2011; Lewis, 2007; Palmer, Suggate, Robottom, & Hart, 1999; Sward, 1999; Wells & Lekies, 2006). The recognition of SLE is important given the current state of decline of the natural environment. Non-human nature is being altered at a rapid rate through the impacts of climate change, habitat loss, invasive species, and pollution among a myriad of other human-induced changes. Due to these changes, it has been suggested that we are now in a new geological epoch, aptly titled the Anthropocene (Crutzen & Stoermer, 2000).

The key findings of the prominent SLE research are discussed throughout this Chapter. Despite this wealth of research, there remains a serious dearth of research about parents' conceptualization of nature and their perceived role in influencing SLE for and with their children through enabling or disabling these experiences. In response to this lack of research, I conducted a study in this domain, focusing on

how SLE shaped my conception of childhoodnature from my perspective as a parent and how my SLE influenced my parenting choices.

To gain a deep understanding of the parent perspective "from the inside," the study utilized an autoethnographic methodology. This methodological approach drew on past memory data and artifacts to reflectively analyze visual research journal entries about my current perceptions of childhoodnature as a parent (Chang, 2008). The visual research journal was constructed as part of the research and is referred to in this Chapter. Through the autoethnographic research process, I gained clarity and insight into my parenting approach, and this changed and evolved during the research journey. This Chapter draws on the findings of this research against a review of the literature and seeks to offer "new kinds of education" by parenting through SLE and childhoodnature.

Conceptualizing Parenting

For the purpose of this chapter, I refer to the term "parenting" purposefully as I am only referring to my perspective as a parent and the responsibilities I see in my role as a parent. I have chosen this approach to ensure that my daughter's perspective is authentically described within this relationship. This is a different approach to that taken by O'Connor and Scott (2007), who use the phrase "parent-child" relationship to define the interaction between parent and child. The phrase "parent-child" denotes that the relationship between parent and child is bidirectional and interactive as they state that the term "parenting" denotes a one-way, top-down interaction. I acknowledge and agree with O'Connor and Scott (2007) that the relationship between parent and child is indeed bidirectional, as also described by Bronfenbrenner (1979) in his ecological systems theory. However, the term parenting more accurately describes the autoethnographic methodology undertaken in this study as I am only considering my perspective. In addition, I do not conceptualize parenting practice as restricted to biological children, although this is generally how it is used in this Chapter. I acknowledge that the parent role also refers to guardians, carers, and or the significant adult/s in a child's life.

In this Chapter I have conceptualized parenting primarily through ecological systems theory (Bronfenbrenner, 1979) that acknowledges the context that the individual, in this case my daughter, exists and lives in. This includes the family situation, the socioeconomic profile, the location, the culture, the religion, etc. The model in Fig. 1 describes the influence of the different factors on one another and is based on the work of Bronfenbrenner (1979); however his original work conceptualized and illustrated each system in a much broader context. The model used in this research (Fig. 1) was designed specifically for the context of this work and includes the influence of nature that was not described in the original model by Bronfenbrenner. The model in Fig. 1 also includes the influence of parent(ing) and education. The center circle denotes the social construct of childhood as the space that children live in and holds the ideas they operate under. The blurred lines

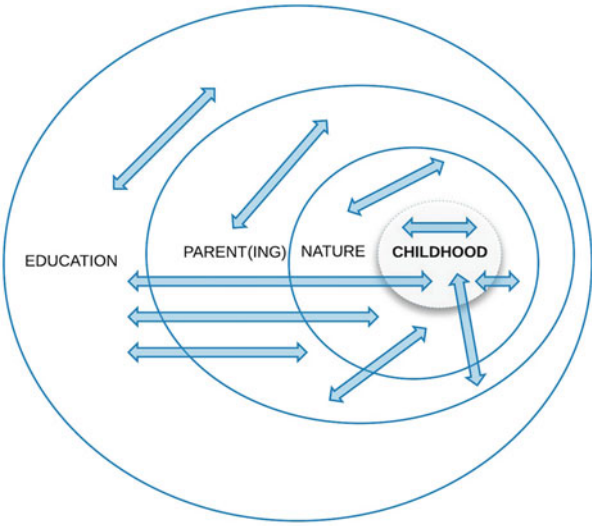

Fig. 1 Conceptualizing childhoodnature through ecological systems theory

between childhood and nature represent the fracturing of the childhoodnature binary to illustrate the boundaryless space that these concepts reside within.

The parent(ing) sphere in Fig. 1 symbolizes the bidirectional influence between the parent and the parenting approach and the childhoodnature concept. The parenting approach that I have adopted has been fluid and responsive. I have attempted not to practice a single style of parenting rigidly, but have been open to changing my approach in response to my daughter's needs. This way of parenting acknowledges and accounts for the developmental changes that occur as children progress into adolescence (O'Connor & Scott, 2007). Along with understanding the developmental changes that my daughter is progressing through, the way I respond to my daughter's behavior also acknowledges the outer influences that my daughter experiences (refer to the conceptual model Fig. 1 and also the original model by Bronfenbrenner). For instance, understanding the impact of how "being spoilt" by a relative or of someone "feeling sorry" for her may change her behavior. This awareness is significant as through understanding the impact of these external influences, it is easier to understand why she acts differently at different times. This way of understanding children and their behaviors is described through social learning theory that states "children's real-life experiences and exposures directly or indirectly shape behaviour" (O'Connor & Scott, 2007, p. 6; see also the work of social-learning theorist Bandura, 1977).

I perceive my responsibility in parenting is to not react to my daughter's behaviors and want them to change but to respond to them in a way that acknowledges that I understand *why* she is behaving in a certain way. Through this action I offer her an understanding of the impact of her behaviors on herself and those around her. I ensure I nominate the behavior as separate from her, so she does not identify with it. As parent and child, we reflect on the experience that caused the behavior. This process encourages, enables, and empowers my daughter to be aware of the

influences of the "outer world" so she can be discerning and know she has a choice about what to engage in. I respond in this way for both positive and negative behaviors and do not profess to being an expert in this practice but see it as a work in progress. This aspect is important as children "learn strategies about managing their emotions, resolving disputes and engaging with others not only from their experiences, but also from the way their own reactions were responded to" (O'Connor & Scott, 2007, p. 6). To practice this way of parenting, I accept the responsibility of modeling this approach through being aware of my own behaviors and discarding those that do not support me, my family, or my community.

I acknowledge that there are two other leading parenting theories: (1) Bowlby's (1969) attachment theory and (2) the theory of child-rearing styles developed through the work of Baumrind (1971); however neither of these theories resonated with my perceived approach to parenting. Bowlby's (1969) theory of attachment draws on the psychoanalytic perspective that attachment quality influences a child's sense of security and trust in people. Baumrind's (1971) theory considers acceptance, involvement, behavioral control, and autonomy granting as key factors that define a child-rearing style and its influence on a child's development. From a critical analysis perspective, I am not clear if my inability to see how my parenting fits neatly into these models is due to subjectivity, that is, that I am too deeply involved in my parenting to gain an outside perspective. An alternative reason is because I find these theories too rigid by definition and do not see my parenting approach as fitting neatly into any of the "boxes."

However, in my parenting practice, I have adopted the approach that my daughter is an all-knowing being. My husband and I often say "you are not 'just a little girl'; you are a person in a little body." This acknowledges and confirms her knowledge as valuable and equal and aligns most closely with the agentic child as described through the sociology of childhood theory by Sorin and Galloway (2006). Surprisingly, given the seeming changing attitudes around the conceptualization of childhood, my daughter is often still seen and treated by adults as innocent, unknowing, and incapable (Sorin & Galloway, 2006). The impact that I have observed on my daughter is that she becomes reduced: as she is treated as a "little girl" and incapable, she begins to behave in this way too.

Significant Life Experience and Parent(ing): A Scoping Review of the Literature

Within the context of SLE and I would argue outside of this field of study also, parents play a significant role in influencing and inspiring their children. This section explores some of the literature in these areas and how they have contributed to or align with my research study.

Generally speaking, SLE is a field of environmental education which seeks to identify the learning experiences that shaped "active and informed citizenry" toward nature in adulthood. Chawla (1998b) listed the major variables which define the adult environmental behaviors and attitudes that SLE is attempting to foster and

recreate as environmental sensitivity, "in-depth knowledge about issues, personal investment, knowledge of and skill in using environmental action strategies, an internal locus of control and the intention to act" (pp. 369–370). Since its conception by Tanner (1980), Chawla has contributed considerably to the SLE field of knowledge. In a study she conducted in 1985, Chawla analyzed 38 autobiographies to discover the type of intense environmental encounters that they recalled, the places that inspired these memories, and the effect that they see these memories had. Chawla (1988) reported that autobiographical authors in her study "attributed an inner sense of calm and connection to nature to profound feelings of communion with the natural world in childhood" (p. 17). The sense of connection felt with non-human nature has been attributed to positive experience in the outdoors (Chawla, 1988).

Palmer has also made substantial contributions to the SLE field through undertaking extensive international studies in association with others (see Palmer et al., 1998a, b, 1999). The findings from these studies led by Palmer, along with those from Chawla, reveal that the most important SLE are (i) having opportunities for positive experiences of, in, and with nature in childhood and (ii) the critical influence of an adult – a parent, teacher, or other family member (see Fig. 2) who inspired "environmental awareness and behaviours" (Palmer et al., 1999, p. 199).

Given these findings, there has been a severe lack of research into the SLE of parents and how they perceive these SLE as shaping their environmental choices and, also, how they view their role in being an inspiring adult for the younger generation. Furthermore, there are limited studies of parental conceptions of nature (see Kahn & Friedman, 1998; Payne, 2005, 2009) and a paucity of research analyzing how, where, and when these conceptions developed.

Parents, however, have been included in many studies in environmental education research, generally in the educational context. One such study that demonstrated some practical and tangible guidance for parents was the research by Chawla and Cushing (2007) who provided a rich analysis of socioecological agency, democracy, and competency in children and youth. Rather than the parental perspective, they looked through the educator lens, which I argue are one and

Fig. 2 The influence of a significant adult: my grandma

the same in many aspects. Their recommendations to educators regarding parental involvement were twofold: "reach out to parents to convey the importance of democratic parenting" and "encourage parents to take an active and supportive role in their child's experiences of nature and participation in community groups" (p. 16). These recommendations provided teachers with a practical way of including parents in the classroom's sociocultural values of agency, democracy, and pro-environmental behavior through personal and collective competence. The recommendations also offered parents a way to support their children to develop a connection with nature through involvement in community participatory activities and encouraging their child's contributions. The premise behind these actions being that these opportunities in nature may provide SLE for that child. Moreover, the underlying theme was to encourage an approach to learning in environmental education which involves the connections between child, teacher, and parent.

The research eliciting the contributing factors to children not having direct experience with non-human nature were found to be spending more time indoors with digital technology, time pressures of families and educators, loss of natural spaces, and parental safety concerns and fear around stranger danger, traffic, crime, pollution, and nature itself (Foster, Villanueva, Wood, Christian, & Giles-Corti, 2014; Louv, 2006; Malone & Tranter, 2003; Neumann, 2015; Palomino, Taylor, Göker, Isaacs, & Warber, 2016; Shaw, Anderson, & Barcelona, 2015; Sobel, 2008; Sweetser, Johnson, Ozdowska, & Wyeth, 2012). Shaw et al. (2015) further developed a model by Crawford and Godbey (1987) to categorize parents' perceived barriers to family participation in nature-based, outdoor experiences into three themes: intrapersonal, interpersonal, and structural constraints. For example, interpersonal barriers include parental time away from work and children's scheduling conflicts. For a more detailed explanation of these categories, see Shaw et al. (2015) or original authors Crawford and Godbey (1987). The model proposed by Shaw et al. (2015) also includes the cultural aspect of outdoor participation which was clarified to mean a system of shared values and beliefs. Without a hierarchical organizational system of constraints to parents' perceived barriers to family participation in nature-based, outdoor experiences, the influence of culture is described as an overarching theme that underpins the conceptual model.

These findings demonstrate that parents' conceptions of nature are influential in providing experiences in nature for children. This view is also shared by Payne (2006) who stated:

> Commonsense tells us that the mundane contexts of everyday home life embedded in family routines and habits, including parenting practices, life histories and functional relationships will significantly shape how the offspring, or children, respond to those educational interventions at school (or in the community) devised to increase environmental knowledge, change attitudes or modify specific behaviours. (p. 82)

In the home in situ, the research around intergenerational influences through the parent-child relationship has also looked at the reverse phenomenon: the influence of

the child on the parent in making behavior changes around the home. A recent study has confirmed that children can be the change agents, as parents of children who participated in an environmental education program were more likely to adopt sustainable practices in the home (Damerell, Howe, & Milner-Gulland, 2013). The results of my study did not draw on specific attitudes or behavior changes that occurred through intergenerational influence, but acknowledged that the entire study would not have been possible without the constant reflection and lessons that were offered by my daughter.

It is noted here that SLE research has not been without contention. Gough (1999b) posed the question which has fuelled academic debate of SLE: "Do the research activities described by SLE researchers actually explore which experiences are likely to produce environmental activists, or rather, what sorts of past experiences are particularly likely to be recalled as significant by those who have, one way or another, become environmental activists?" (p. 353). This idea was considered in my research, and I did question why many of my peers who had experienced similar SLE to me did not hold the same level of care, concern, and interest in ecological sustainability as I did. I acknowledged this critique of the field of SLE, but, given the limited scope of my research, identified that further analysis would be required to comment definitively about these concerns.

Additional to this contention has been the need to discover the most appropriate methodologies for SLE research and determining if past childhood experiences can be used to create influential experiences for children today (Blanchet-Cohen, 2008; Eilam & Trop, 2014; Gough, 1999b). This creates an issue as parents' ideas about what constitutes a SLE in nature may be vastly different to the needs of their children due to the context of the time in intergenerational differences. Criticism has also been given to the "disproportionate focus on privileged groups and positive experiences" (Ceaser, 2014, p. 205). Ceaser (2014) considered SLE and marginalized and disadvantaged groups and found that negative experiences (i.e., emotions such as fear, helplessness, and guilt) play a much greater role than positive experiences in determining environmental activism and justice in adult life, as does the embodied learning of these experiences. Similarly, Hsu (2017) found the negative experience of "losing a beloved natural place" ranked third of the eight most crucial factors for environmental action in the rural areas of Taiwan (p. 51).

This millennium has seen a new wave of SLE research, which has branched out in many ways. These include and investigate the role of personality, schooling, and community and compared the influence on behaviors with attitudes (Eilam & Trop, 2014). Research has also been conducted "on the meaning of both social disadvantages and negative environmental experiences" as motives for practical concern (Ceaser, 2014, p. 205). A study by Ceaser (2014) also highlighted the need for researchers to consider the influence of environment, society, and history on SLE (Ceaser, 2014, p. 215). Moreover, through SLE findings, it has been recognized that environmental education programs need to be assessed not only by cognitive responses but also affective responses (Cachelin, 2009; Pooley & O'Connor, 2000).

Classified separately to SLE, but also related to lived experiences, is the study of the life course path that identifies "interwoven pathways or trajectories" which

together form a life story (Wells & Lekies, 2006). Life course path demonstrates similarities to SLE, such that it builds on previous SLE findings that there is a relationship between childhood experiences and "adult attitudes among environmental professionals" (Wells & Lekies, 2006, p. 13). The findings of Wells and Lekies' (2006) study were concurrent with SLE research that childhood experiences in non-human nature link with both environmental attitudes and behaviors in adulthood (Wells & Lekies, 2006). The study by Wells and Lekies (2006) called for further research from this field specifically identifying the need for longitudinal studies that focus on "exploring people's relationships over time and during various periods of life" (Wells & Evans, 2003, p. 327). Finger (1994) used the phrase "life-world approach" to describe his research, which is fundamentally based on SLE. The findings reflect the similar trend discussed earlier that "the main factors predicting environmental behaviour, or absence thereof, are experiences in and with the environment (e.g., previous environmental activism, experiences with nature, and exposure to environmental catastrophes)" (Finger, 1994).

This section presented a scoping review of the SLE literature, drawing on parenting as a focus. The two major findings from this research named childhood experiences in non-human nature and the influence of a central adult as key determinants of lifelong attitudes and approaches to environmental behavior. The latter finding is significant as it forms the central foundation of my research: exploring the role and influence of the adult. The next section of this Chapter explores these findings through the context of a parent(ing) conceptualization of childhoodnature.

Conceptualizing Nature Through Significant Life Experience

Through my recent autoethnographic study titled Parent(ing) Childhoodnature, the extent to which SLE mediate parent(ing) with/as childhoodnature was explored (for full details of the methodology employed and theoretical framing for the study, see Blom, 2016). The theoretical perspectives of posthumanism, socioecology, and the sociology of childhood were utilized to frame the study (refer to Fig. 3). This angle allowed the distinctions between childhood and nature to be blurred to expose the possibilities that can be enabled through this process; so that there is nothing in between and nothing to separate, it is united: childhoodnature (see Fig. 1).

Prior to conducting research into an approach for parenting childhoodnature, it was necessary to gain a deep understanding of how I, as a parent, conceptualized nature. To do this, I drew on my SLE to explore the impact they had on how I related to and understood nature. What emerged was a complex and varied response to experiences with nature revealing a deeper understanding of myself as being with nature, but also as nature. The autoethnographic approach enabled this deep and reflective response to the research questions. Furthermore, it allowed the parent's perspective to be explored through intimate and in-depth research.

The findings of my research foray were not a neatly laid-out linear map as I had envisaged but a messy assemblage of current memories at times juxtaposed with

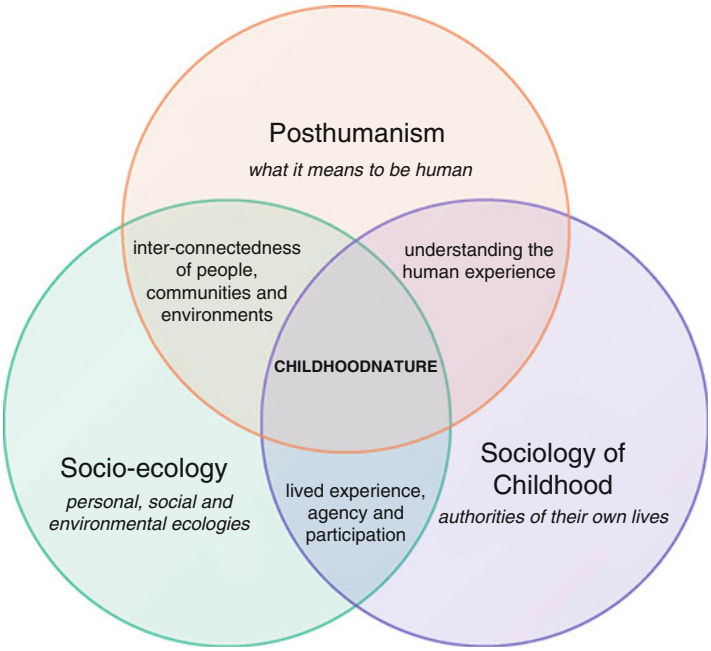

Fig. 3 A theoretical framework for childhoodnature (Blom, 2016)

artifacts from my past. The research found that to conceptualize nature, it was first necessary to develop an understanding of self through honesty, identifying values and an awareness of the images and pictures I operated under which, in effect, governed my movements. Second, the role of nature observations and interactions was identified as a key factor in conceptualizing nature.

Understanding Self

Honesty

My first purposeful foray into non-human nature as part of my research was taking a walk with my daughter in the local park. I came up against the barrier of time: experiencing the difficulty of relaxing into the pace of life on this outing. Through this experience I became aware that I needed to be deeply reflective and develop greater honesty with what I was feeling in each moment. From this walk in the park with my daughter, I was able to discover that non-human nature is much more than the scientific view of an interconnection of living and nonliving things; non-human nature offers space to support growth and development. Through the deep interconnection between human and non-human nature, nature has a knowing. It is there providing a sensory experience which I can choose to connect with and observe the wisdom that it offers. At the same time, non-human nature allows me to simply be and feel.

As a way to illustrate honesty in another context, I reflected on my relationship with tears and crying. This example was particularly relevant as I have always had a strong aversion to crying. To explore the reasons for this required honesty and identifying societal perceptions. Through my research, I drew on a past artifact in the form of a diary entry from my 14-year-old self while I was living on a school-based remote learning program. The program involved spending 8 weeks of the school year in a purpose-built village in the middle of a national park. The diary entry stated:

> After dinner [my teacher] had a chat with me and I began crying again. Why do I cry? I calmed down and walked up to the common room. After being there for five minutes, I began crying again. I kinda [sic] know what [it's] about and it's too hard to explain in the dull light of this torch. I decided to go for a walk to the gate. On the way I saw [my teacher]. He asked if I was alright? I said I was but he didn't believe me. He could tell I was unhappy inside even if I did put on a happy face. At the gate, I looked at the stars and thought about this beautiful place.

In my memory, the actual standout moment was not the tears beforehand but the blanket of stars above my head that reminded me that I was part of something much grander, more awe-inspiring. This reminded me of Carson's (1965) musings about the importance of connecting with the awe and wonder of non-human nature through the "recognition of something beyond the boundaries of human existence" (p. 88).

This reflection contributed to understanding my conceptualization of nature as I began to explore my human body as a continuation and part of non-human nature. I perceived the tears as "clearing the ground" of my body-as-nature allowing the learning moment with the stars to occur. Just as Carson (1965) shared "the Maine woods never seem so fresh and alive as in wet weather" (p. 30), through the crying process my body became "fresh and alive" in a similar way, open to the messages and offerings from non-human nature.

I questioned why I would refuse to allow myself to cry and to experience the lovely lushness in my body akin to the freshness of a rainy day. I concluded that it was due to the façade of two social norms: (1) what it looks like to be "okay" and (2) that as a woman I need to be superwoman i.e., to do everything and come out smiling. As I have grown, I have come to know that I am superwoman regardless of what I do and what it looks like. I don't have to hide behind a mask of pretense. I can be honest about what I am feeling, and this is what being brave and what being a superwoman is *really* about. Through honoring what I am feeling, I am nurturing nature: my body-as-nature.

The idea of the importance of connecting to the "senses and feelings" of the human body-as-nature is argued by Kidner (2007) who asserts that "our current reliance on cognition and our corresponding marginalization of sensing and feeling, in addition to undermining human wellbeing, may be ecologically catastrophic" (p. 123). He further explains this theory through exploring the idea of disembodiment:

> That is, by distancing ourselves from our embodied being and the world it has evolved to inhabit, and by an idealist focus on intellectual and social 'realities', so that thought is used to control and discipline the body and the feelings, intuitions and awarenesses that the body communicates", we can somehow make life bearable. (p. 138)

Furthermore, through this internalization of our individual selves into mental activity, there is danger of becoming disassociated with the physical world such that our society is "increasingly governed by its own internal dynamics and attempts to deny our ultimate dependence on natural processes" (Kidner, 2007, p. 139). These ideas align with my understanding and conceptualization that it is through connecting with our body-as-nature that we can more easily access our biophilia (Wilson, 1984) and feel the deeper sense of connection with non-human nature. Bai, Elza, Kovacs, and Romanycia (2010) support this view in the educational context by stating that education needs to bring children's attention to themselves through "being sense, being bodies, being perceptions, being feelings" (p. 36). They suggest that we are educating children away from their biophilia through a "consciousness that is busily and excessively into 'doing' and 'having', however educational" (Bai et al., 2010, p. 360).

Through adopting a critically reflective process about the social constructs I am a part of and honestly considering the influence these ideas have on my daily practices and movements, I am more easily able to let go of these strongholds of society and live more attuned to the song of nature.

Values

The idea of values emerged frequently through the data from my study, and it drew on many present-day moments and how they were rooted in past SLEs. I identified what I thought I valued in my life and then took stock of what values I live by. Ultimately our values are what we live each day not necessarily what we think they are or would like them to be (Carroll, 2012). This phenomenon has been labeled the value-action gap (see Blake, 1999). While using my values to develop and deepen my understanding of my conceptualization of nature, I resonated with something shared by Carroll (2012) about sustainability. I often feel there is an emptiness in many everyday household sustainable practices, and this was stated through Carroll's (2012) work who stated that sustainability:

> Requires far more from us than the cheap, shallow, and superficial measures commonly taken under the guise of sustainability, measures such as those in agriculture and food systems, in energy and in other ways. True sustainability requires a change in our fundamental values, it requires us to be fundamentally countercultural and revolutionary, at least to the common culture. (p. 2)

I likened this to the work of Latour (2004) who proposed that we no longer accept the value-fact divide if the collective we of nature (both human and non-human) are going to reconceptualize nature and society in a unified perspective. Through this exploration it became evident to me that I needed to let go of what I had accepted as environmentally sustainable and actions "for the environment" and radically open my awareness to the possibilities of what nature was and what a sustainable relationship with nature looked like.

This process allowed me to see how nature has and can be conceptualized such as intellectually thorough science or through a connection from within such as biologically or psychologically (see Kahn, 1997; Perrin & Benassi, 2009; Tam, 2013; Wilson, 1984). Through this analysis, I suggested that it is our biophilia that is our connection: an inner knowing that our body-is-nature and that it connects us innately with all other living and nonliving aspects of the natural world. This idea also correlates with suggestions by Payne (1997) and Kahn and Hasbach (2013) who described the nature within the human being as being the nature "in here."

I further explored my values by reflecting on past behaviors and choices that did not support or nourish me. When life became overwhelming through poor choices that did not care and nurture my body-as-nature, I was able to restore my sense of emotional, mental, and physical equilibrium through time connecting with nature: generally by going for a swim in the ocean or a walk in the forest. By reconnecting with my "biophilia," I felt myself again. I deeply appreciated the gift that nature offered through this process while at the same time the influence of significant adults, such as my grandma (Fig. 2), for sharing the magic of non-human nature with me during childhood.

Over the last decade, my relationship with nature has drastically changed. I no longer seek refuge and escape into nature as I once did. I now understand nature as *my parent* and appreciate the way nature interacts in my everyday life: from the little ant walking across my desk to the flash of a rainbow lorikeet's belly or the seemingly endless sky with clouds that appear painted on in their awe-inspiring perfection. I value and appreciate non-human nature for all of this, more so now than ever before. Nature provides a little reminder to support my biophilic connection when at times I feel like a mind in complete disconnect from the body that houses it. It is through feeling my body and remembering that it belongs to something much grander than merely the individualized self that I can be in harmony within myself and with all other living things.

The choices I make now are aligned with and respect nature more than they ever have been before. I consume less and live more within nature's cycles. Most importantly, I now understand that my body-as-nature is my and only my responsibility, and thus I treat it with the utmost care and love. I now have the intent of treating all others in this same way.

The idea that the human body and non-human nature are conceptually united has been discussed by many researchers, for example, Latour (2004), who states that through the very notion of conceptualizing and conserving nature we are separating ourselves from it. This unification is grounding of the childhoodnature philosophy that proposes that there is no distinction between the concept of childhood and the concept of nature: they have a deeply innate connection to their biophilic source. Developing an awareness of this connection and honoring this internal biophilia is something I value. I now know I no longer need to retreat in the untouched landscape to connect back to this feeling, for it is within me, my body-as-nature.

Images and Pictures

Images and pictures were the third concept presented through my data on conceptualizing nature and are founded on expectations. These expectations generally stem from societal ideals and beliefs that are so ingrained; often it is unclear that I operate under their guise. When I was in my twenties, I became acutely aware of how these images and pictures could be destructive in setting up a framework for disappointment. It was at this time in my life that I renounced many social traditions and norms such as a need for marriage, children, and getting a mortgage on a home, a car loan, and so on. I saw the detrimental effects these images and pictures had on people in my life so decided not to engage in them.

Through identifying the images and pictures I held about what I thought my relationship with non-human nature should look like, I was able to begin a process of letting these go and building a more authentic and natural relationship. Through analyzing the following diary entry from my 14-year-old self, it was clear that in my childhood and adolescence, the role that nature played in my life was simple; it was there to be appreciated, but, mainly, it was just there:

> We woke up to nice but windy morning. I felt like the tent was about to fall down or blow away. After we got up we went and sat around the gas stove. We had breakfast, it was bread and jam. The wind kept blowing sand into the food. Again it was beautiful weather, apart from the wind. The lake water was no longer fresh, it had sand and everything that had blown into it. We had to back-track along the beach. Even though we'd seen it before it was still unreal and beautiful.

The past reflections from my early adolescence are vastly different to my current memories of what that moment was like. The past reflections are devoid of what I remember now about the complexities I was experiencing as a teenager in a remote, highly socialized setting. The past reflections do not describe the depth of beauty that I felt being on that isolated, wild beach nor the impact that being in that place had on my wellbeing. These aspects are highlighted in my current memories of these moments. Through the process of contrasting this writing with my current memory of this SLE, many conclusions can be extrapolated. One is that even though I did not describe everything in detail at the time, it could be that my expression has changed as I have developed from a girl into a woman. As Muncey (2005) stated "although memory is selective and shaped, and is retold in the continuum of one's experience, this does not necessarily constitute lying" (p. 70). The differences in data representation do not deviate from their validity. Memory is an important and unique source of data (Chang, 2008). Chawla (1998a) supported this through her SLE research by advocating that memories are generally accurate around the general course of events, whether a single or repeated experience.

Another reason for the discrepancy between the two descriptions of the same event is that somewhere in the space between adolescence and early adulthood of my late teens and early twenties, I constructed more complex ideas about what non-human nature meant in my life. These were formed through observations of and interactions with non-human nature and are explored in the next section.

Nature Observations and Interactions

So far in this Chapter I have conceptualized nature through the lens of a parent and conceptualized nature *as a parent.* Nature has been shown to be inextricably linked with developing my relationship with self. This exploration is evident throughout my life path and has been a necessary part of resolving the tension I have felt in the current state of the natural environment. As reflected by Orr (2009), we need to answer the question of "who we are and what do we know of ourselves?" to get to this resolution (p.184). Through my reflective approach to understanding my connection with nature, I have observed how this conceptualization of nature has changed significantly along my life path and changed the direction of the path too through SLE. I draw on another example from my 14-year-old self on the school-based remote learning program to illustrate the influence, impact, and meaning-making of SLE from a retrospective viewpoint.

> For today I canoed with the teacher. I patiently sat in the canoe while the teacher took their photos. It was raining so hard and I just remember sitting there while everyone except me paddled off into the distance. We eventually caught up to the others. We had a bit of a yarn about the camp and stuff like that. Even though it was pouring and we were all rugged up, it was absolutely beautiful. I would never have imagined I'd be doing stuff like that. As my teacher said, "It's the time of your life."

The experience was also pertinent as through the SLE field of research it has been identified that the role of an inspiring and influential adult in developing a relationship with non-human nature is integral (see Carson, 1965; Chawla, 1998b; Hyun, 2005; Palmer et al., 1999; Young & Elliott, 2003). I refer to an excerpt from my school-based remote learning program diary (age 14):

> When I first came to this place the environment was everything around me – the forests, the village. It was a special, new place. But to me it didn't mean much – it wasn't my environment to worry about. I didn't know much about the forests – so I didn't care much. Through my time here I've learnt and thought about what's around me all the places and what they mean to me. I've become more aware about everything I do. Because nearly everything I do here will make an impact on the environment – the water I use and the rubbish I make. I'm hoping to use some of the things I've learnt when I return back to the city. Because my environment in the city is as important to me as this place.

Through reflecting on my past experiences of the school-based remote learning program, it is evident that as a collective SLE, it provided a key to my connection with both human and non-human nature. It also gave me the knowledge and skills to enable authentic agency in the practice of caring, advocating, and actioning for the natural environment. Kollmuss and Agyeman (2002) assert that direct experiences (such as seeing the impacts of logging firsthand) provide a stronger influence on environmental behaviors and attitudes than indirect experiences (e.g., learning about an environmental problem in a classroom), which focus on the dissemination of knowledge content of environmental issues. The school-based remote learning

program provided a combination of these strategies which may have contributed to the success of this approach in enabling a SLE.

While the school-based remote learning program was definitely a major shifting point in my life, there were many more SLE that continued to occur as I completed high school and moved into and through my twenties. The learnings from the school-based remote learning program held strong, and I continued to care and advocate for the environment; however, this had become problematic as I had developed a practice of caring more about non-human nature than my body-as-nature. This idea has been attributed to environmental guilt and has been experienced and observed by researchers (see, e.g., Schneider, Zaval, Weber, & Markowitz, 2017).

My next major SLE occurred in my early 30s. I was feeling exhausted by the endless inner conflict between being a citizen in a consumer-based society and being true to my environmental sustainability beliefs. I thought that there must be another way. So I retreated from my seaside residential life into what some may call "the Australian dream": my husband and I purchased a four-wheel drive and a camper trailer and went traveling around Australia with our 18-month-old daughter. After working in some remote areas and being "on the road" for 6 months, we realized that this way of living was not financially nor practically feasible or sustainable long term. We relocated and I began resolving my inner conflicts about being a part of society and living sustainably. The process I adopted to do this was to first accept that "retreating" from society did not work, and second, I let go of everything I thought sustainability was about. From the outside, I would not have looked the picture of someone who cares about the environment. But, on the inside there was resolve. I approached my environmental and sustainability actions through caring for my body-as-nature first. Only through practicing caring for my body-as-nature was I able to begin to understand what it meant to care for non-human nature. This idea was supported by Parker (as cited in Skamp, 1991) who asserted "If I am uncaring of myself, I am careless of my environment and my sister creatures" (p. 82).

I came to realize and understand that my body is made of the particles of the universe, which includes the natural world. My body can work in alignment to the rhythm of this universal order, just as is observed in nature. I am the one who knows and has control over my body, so it is my responsibility and choice to listen to and look after it in a way that respects the universality to which it belongs. Moreover, my body has a way of communicating exactly what is needed. It is my choice to remain open to listening to it, in the same way I "listen to" the nature outside of my body, non-human nature.

Parent(ing) Significant Life Experiences

I grew up in a leafy, city suburb in Australia, with only intermittent opportunities to experience wild nature. Given the profound support non-human nature provided me, I was determined to ensure my daughter had much more exposure and time in non-human nature than I did as she grew up. I was sure that I would be the significant adult in my daughter's life who would provide her with opportunities to be in wild

nature. This picture I held was just another ideal about how I thought things needed to be and what they needed to look like. Trying to live in a way that allowed my daughter to live the idealized childhood spent in non-human nature was not working financially, emotionally, or mentally for our family. I realized that to be a change agent I needed to actively engage in society and be a part of what I had always resisted and retreated from. For me, this was a major turning point in my life that could be described as an unconventional or nontraditional SLE. I started to make changes and critically reflected on some of the sustainability and "green" ways of living that I had adopted. I explored my relationship with food choices; I challenged the concept of time and I reflected deeply on the way I parented my daughter. These concepts are explored in greater depth here.

Food

Food is a sensitive topic for discussion as there are often strong emotional, social, and cultural connections with what and how much we eat. However, despite the discomfort and awkwardness that this topic might arouse, it is a necessary aspect of sustainability, environmental education, and understanding parent(ing) from the childhoodnature perspective. Moreover, food is part of caring for our body-as-nature and is in our direct locus of control. I recall personal SLE that are specifically related to food, which have also formed my beliefs about what it means to be sustainable and nurture childhoodnature.

Looking at food choices through the SLE lens, I can identify two SLE that have strongly influenced my food choices. At age 8, I ate a chicken nugget and was shocked to realize that there was a bone in it. Up until that point I had not considered deeply or acknowledged that a chicken nugget was actually from an animal. As my father was vegetarian, it was a simple transition for me to become a vegetarian in our family landscape and my parents accepted my choice. My second SLE around food choices occurred at age 31. My daughter was 2 months old and I had developed mastitis three times during this period. It was a devastating experience for the pain I experienced, the discomfort for my daughter, and the impact it had on me as a woman. At this point, I decided to stop eating gluten, dairy, and sugar to see what impact it had on my health (as I had dabbled with this way of eating in response to other health issues in the past). After changing my diet, I did not get mastitis again. I actually felt so good from eating this way that I continued, even when I had finished breast-feeding.

I continued to experiment with my diet and became aware that certain foods were causing bloating, raciness, and/or tiredness. Due to the discomfort of these side effects, I was willing to no longer eat these foods. After a few years of eating in this way, I started to hear the voice of my body through craving chicken and lamb. It was a challenging time to let go of the environmental and sustainable belief of vegetarianism that I had held onto for over 25 years, but in line with my decision to explore new ways of being sustainable, I chose to honor my body and renounced my vegetarianism. I thought my body would react to the meat and find it difficult to

digest. But it was the contrary; my body reacted well and had no side effects, except for greater vitality. This was also observed by White (2013) who found that eating meat restored her "healthy body" after a year spent as a vegetarian (p. 129).

Choosing to eat in this way has not been simple, but mainly through the social pressures I have felt and had to confront. It involved a process of letting go of what I had accepted as the social norms of what "healthy and sustainable eating" meant and being brave and trusting enough to accept that the changes I was making were the right choices for me. It gave meaning to the quote by Thoreau, "let your life be a friction against the machine" (as cited in Devall & Sessions, 1985, p. 8). The experience was reminiscent of my choice to become vegetarian at age 8 when it was much less common, especially for a "child," but the intensity at age 32 felt much stronger. Even writing this now I can see how challenging it is to accept that my body does not lie when it speaks. Even when what it says is in direct opposition to what I am being fed by society, such as the recommendations from the government. I problematized the current government nutrition and lifestyle recommendations through a collage in my visual research journal. The collage troubles the Australian healthy food pyramid and physical activity guidelines. These documents are designed to provide parents and educators with support in providing healthy food and lifestyle options for the children in their care. However, during my research process I questioned this advice considering the current "obesity epidemic' (WHO, 2000). It would seem that these promotions are not a sustainable solution for human and non-human nature. I decided to listen to the voice of my body-as-nature and for doing this, I have never felt better.

I would argue that the way I eat now is more sustainable than it has ever been – both for my body-as-nature and for non-human nature. I have become aware how nature is parenting me about how to eat and live through what I observe in animals. Animals don't worry about killing each other for food. They innately listen to their body: what and how much food their body needs without intellectualizing their diet. I propose that this could be a new approach to exploring sustainability in food choices. There is a lot of responsibility as a parent to ensure that my food choices and my relationship with food model that which I would want to see for my daughter. I see this responsibility as another reason to choose my food based on what my body tells me, as this is how I would like my daughter to develop a relationship with food: through discerning and making choices for what works for her body.

Time

Perceived lack of time is a notable barrier for parents in giving their children access to and experiences in nature along with seemingly busier lives of children, families, and society (Louv, 2006; Malone, 2007; Sandry, 2013; see also "interpersonal theme" in Shaw et al., 2015). Given that SLE research suggests that childhood experiences in nature promote future life paths into personal care and concern for the natural environment and careers in the sustainability and environmental education fields (Chawla, 1998b, 1999; Palmer et al., 1998b), it is an area that requires

attention. This concept is explored in this section through a recent SLE from my research data.

Through my research, I challenged societal conceptions of time in a way that could be practically implemented. The SLE that formed part of this process of letting go and reconceptualization of time involved observing my husband with my daughter. Through the data collection period, I observed their relationship and noted their connected, respectful, and loving care with each other in my visual research journal,

> When he is with her, he is with HER! He is not thinking about what he could be, should be, was or will be doing. He is listening to her, celebrating her, offering her his wisdom of lived experience, appreciating her wisdom and makes space in his life to do things together. It is not about what is being done, but understanding the importance of being with each other.

My husband realized that he did not have a lot of time given he was working full-time and studying part-time, so he challenged quantity by offering depth in his quality. The quality spoke volumes. I could see very clearly that connectedness was not about having to spend lots of time doing something, but was about the way that it is done: *it was about the quality and not the quantity.* The same idea applied to my husband's interaction with nature. He deeply appreciates nature in his everyday life, but does not need to retreat into non-human nature or spend a lot of time there. He honors and respects his body and treats it with great care, just as he does with non-human nature.

Through this observation, the concept of time has been fractured in its intensity. While it is obviously still an important aspect of being in society, it should not govern our thoughts and movements. Moreover, it should not be used as a reason not to engage in building relationships with each other or with non-human nature. We can appreciate the time we have without guilt or regret or wishing away life by wanting to be somewhere else. This lesson has been fundamental in reconceptualizing how I parent, particularly with the current wealth of images and ideas about what getting children back into "non-human" nature should look like. Through reconceptualizing time, I am able to practice parenting childhoodnature through the *quality* that I parent with and not on the *quantity* of time I have available. These ideas around parenting are developed in the next section.

Parenting

This section explores some of the reasons that may hinder the seemingly simple twofold actions described through SLE research of (i) providing children with opportunities to connect with non-human nature and (ii) being a role model: inspiring children through living the choices we wish to see in the world (Chawla, 1998b).

It has been suggested that a major reason that children are not given permission to play outside is the "fear factor" – the fear of stranger danger and the fear of judgment about bad parenting practices from others (Louv, 2006; Malone, 2007; Ridgers, Knowles, & Sayers, 2012; Shaw et al., 2015; Sobel, 2008). Through my research, I

explored this by reflecting on an experience in the backyard with my daughter. I was hanging out the washing while she was on the trampoline. When I had finished I went to go back inside to check the dinner. My daughter was clearly enjoying herself but hurried to put her shoes back on to come back inside with me. I asked her why she did not want to stay outside on her own and she said she was scared. The way she rushed to get off the trampoline certainly confirmed this. I pondered on this event to work out why she would have been afraid. As we do not have a television, I knew there would not have been an image or picture constructed about stranger danger from a television program. I had never told her stories about kidnapping or instances of children being lost. I realized it may have come from my movements, in the way I watched her closely. It was my own fear that my daughter felt and took on as her own. By doing this, I had created a need from my daughter. I realized that if my daughter did not need me, then what was my role as a parent and mother? Through the actions of constantly watching my daughter and making sure she was safe, I was in effect saying to her, "you need me to be okay." I know my intentions were to ensure my daughter was safe, to be a good parent, and to spend time together, but at times I know these actions conveyed an underlying message that my daughter is "vulnerable, incapable, and in need of guidance and protection" and thus a "welfare dependent" (Barratt & Barratt Hacking, 2008, p. 287). This view of children is opposed to enabling and empowering children to be the "young citizens" that they are through honoring their "strengths and competencies" and providing them with appropriate "recognition, respect and participation" (Neale as cited in Barratt & Barratt Hacking, 2008, p. 287). This required me to change my parenting perspective: from seeing my daughter as someone in need of protection to empowering her as a young citizen, not as belonging to me but as being her own being.

Part of acknowledging my daughter's independence, agency, and authority of her knowingness was to accept that she is all-knowing and that I am too. Throughout history and in education, children have often been viewed as tabula rasa or empty vessels – empty "mugs" needing to be filled by the "jugs," the wisdom of adults (see The Innocent Child in Sorin, 2005). Sorin (2005) presented an important recommendation for educators, for which I would argue is also a parental role:

> While supporting young children through the sometimes difficult transitions that they experience in early childhood, educators need to make transitions of their own, in their thinking about children and childhood, and to reconstruct their practice accordingly. (p. 19)

I see this as the honesty I bring to my self-reflective practice and my willingness to make adjustments and changes as needed to support my daughter to truly grow and develop and to allow our relationship to deepen. It has been more challenging to draw on and remind my daughter of her inner knowing since she began at school. Through observing this, I can understand why this would occur. Since starting school she has become more heavily involved in the education system than at preschool. She is now working within a system that operates on the foundation that the "students" within it are not all-knowing. The system does not support children to value or share their knowing. In effect, it is a system that is about

achieving outcomes and not about people first, which I argue it should be. This view is shared by Orr who stated that:

> The shortcomings of education reflect a deeper problem having to do with the way we define knowledge. (...) I happen to believe that our prospects depend more on the cultivation of political wisdom, moral virtue, and clear headed self-knowledge than on gadgets. In any event, it is time to ask what we need to know to live humanely, peacefully, and responsibly on the earth. (Orr, 1992, p. xi)

My husband and I continue to remind our daughter to share and act on how and what she feels and to ask questions from her inner knowing. I can see how this approach supports and empowers her in making choices and remaining in connection with her biophilia.

It is quite revelatory to know that I do not actually have to *do* anything: that my role is to inspire. I understand the practicalities of doing the things for my daughter that she is not yet able to do and therefore supporting her development in the practical sense; but I am also acutely aware of her capabilities as she grows. Children are so much more able than I regularly see them being given credit for. Knowing that I do not have do anything is not an excuse or a way out of parenting my child, but a way of reimagining what parenthood looks like. This way of parenting is about making decisions and movements through taking care with myself and connecting to my daughter as a first priority. To transition my parenting from one of need and busyness to one of connection with myself and my daughter first requires honesty and acceptance. I propose that through letting go of any beliefs, pictures, or ideals about what parenting should look like allows endless possibilities to unfold and invites a more open acceptance of the way it actually is. This applies to the childhoodnature lens. When I have held on to pictures or beliefs about what this looks like in practice with my daughter, it creates a deficit where I am always away from where I want it to be. By confirming through appreciation about what childhoodnature looks like as it is, it allows the next learning and lesson to be presented, therefore allowing a deeper understanding and practice of childhoodnature in our lives.

Conclusion

This Chapter has detailed a selection of the SLE that presented through my research that contributed to my everyday conceptions of parenting with/as nature. I view nature as a parent, offering constant guidance about how to live in harmony with human and non-human nature. I understand that my body-is-nature and speaks to me constantly. I can choose to listen and respect the universal order that my body belongs to or not. I have learned that as a human being I have this responsibility of choice, as does everyone. Through the sharing of our narratives and stories, we can learn from each other and, from our learning, discover new ways of experiencing and understanding nature in our lives.

The role of nature in my life has changed and developed over time; my SLE mark these changes. This evolution and changing relationship highlights the possibilities for reconceptualizing the human relationship with/as nature to match the evolving nature of all living things on the planet. I accept that the nature we are living with and experiencing is the result of the collective choices of humanity. Through the autoethnographic process, I have been enabled and empowered to deeply reflect on how my relationship with non-human nature has changed over my lifetime from a place of being to a place of refuge and escape to now, nature as a parent. Autoethnography has allowed my perspective as a parent to be considered from the inside, contributing rich, authentic research to this largely unexplored area of the SLE field. Throughout this inward and outward exploration of both human and non-human nature, I have reconstructed, reimagined, and reconceptualized my approach to parenting with/as nature. This research suggests that to enable and embody an approach to parenting with/as nature that any beliefs, ideals, and pictures about what parenting with/as nature should, would, or could look like needs to be deconstructed. It is then through reconsidering and redefining human relationships with honesty, values, time, food, and perceptions of being in the world that the parenting with/as nature concept can be reconstructed. Practical implementation of these concepts and research findings requires each individual to (a) take responsibility for caring for their body-as-nature and listening to their voice within: their biophilia; (b) be the living inspiration for what they would like to see in the next generation; and (c) utilize each moment with nature by being present at every opportunity and deeply appreciating the messages and wonder that is on offer. Along with the nature of research, this knowledge and understanding is dynamic and will continue to evolve and deepen along with the collective us of human and non-human nature.

Abstract

Ecological systems thinking is an attractive conceptual tool for understanding the complexity of the entanglement of the biological environment (ecological systems including human social systems) with the physical environment. Attention to such interactions in light of Anthropocentric system changes, and the focus of this Handbook urges (re)exploration of ecological systems within childhoodnature. Accordingly, in this introduction to childhoodnature ecological systems and realities, we explore systems thinking and ecological systems, the interaction of humans within the systems and consider a posthuman turn for reconceptualising ecological systems thinking in childhoodnature.

Introduction

Implicit in the childhoodnature theorizing that underpins this Handbook is the framing of children and nature as inseparable concepts (see Childhoodnature: Introduction). Accordingly, explorations of childhoodnature indicate inquiry into childhood and children with/in nature through the lens of an ecological systems conceptual framework. Our interpretation of the Earth's ecological systems is the integrated hydrological, geological, atmospheric, and biological systems that make up the entangled, dynamic, connected ecosystems of the Earth. Consideration of children and childhood as embedded within these complex ecological systems also aligns with global attention on impacts of increasing ecological disasters – environmental catastrophes due to human actions that are changing planetary systems. These widespread changes have prompted many scientists to signal a new period in the Earth's history, the Anthropocene, as a new era of lasting human impacts on a global scale (Crutzen, 2002), recognizing that human activity has changed the Earth "substantially and irreversibly" (Zalasiewicz, Williams, Steffen, & Crutzen, 2010, p. 2231). Framing childhoodnature theorizing, research, and practice through an ecological systems lens in this section of the Handbook is therefore both timely and pragmatic.

Traditionally the domain of the sciences ecological systems conceptualizing applies a systems thinking architecture to scaffold understanding about the complex interrelations between the living and nonliving elements that constitute the dynamic, emplaced, purposeful assemblage of an ecosystem. The ecosystem is the "unit" of natural planetary systems – the bounded, yet porous, collection of physical affordances of a space and the living things that thrive through interactions within this space (Capra & Luisi, 2014). Humans are one element of the many in natural ecological systems, but the view in society is predominantly one of humans as separate from natural ecosystems, highlighted in the English Oxford Living Dictionary's definition of nature: "The phenomena of the physical world collectively, including plants, animals, the landscape, and other features and products of the earth, as opposed to humans or human creations" (Oxford University Press, 2018).

Haraway's quote highlights the absurdity of this notion of the human/nature separation and the masking of our impact on Earth's ecological systems:

> No species, not even our own arrogant one pretending to be good individuals in so-called modern Western scripts, acts alone; assemblages of organic species and of abiotic actors make history, the evolutionary kind and the other kinds too. Just as other biotic and abiotic elements impact us, our actions impact Earth's biological systems (Haraway, 2015, p. 159).

Such posthuman and new materialist theorizing, which problematize human-centered perspectives, uncouples systems ecology framing from the traditional

scientific and often more anthropocentric approaches. Attending to posthuman conceptualizing in combination with ecosystem thinking opens up spaces for new ways of understanding humans with/in nature. An example of this is the transdisciplinary ecohealth theorizing and research by scholars such Parkes (2010) and Panelli (2010).

Ecological systems thinking to identify interconnected elements and influences in complex, active systems provides an attractive conceptual tool, not just in the sciences. Such thinking permeates the social sciences with human social systems as the primary focus in diverse fields such as education, business, health, and human development (e.g., "ecologies of human flourishing," Swearer & McGarry, 2011; "political ecologies," Mauro, 2009). Ecological systems framing is integrative, relational, and generative – a useful guide for theorizing our interconnected social and ecological worlds. The term socioecological has emerged in recent times to highlight this complex entwining of our natural and social worlds (Kyburz-Graber, 2013). Such socioecological systems thinking is essential in our modernity of a complex and rapidly changing world. To be able to understand our human impact on the Earth, it is important to consider the Earth as a global ecosystem but also appreciate the local "biological, physical, and social systems" and how we interrelate with, and impact these systems (Berkowitz, Ford, & Brewer, 2005, p. 236). Thus, taking a holistic "systemicity" (Wadsworth, 2010) viewpoint, where we think in terms of "relationships, connectedness and context" (Capra, 2007), is essential in conceptualizing children and childhood *as* nature.

Systems Thinking and Ecological Systems

The two main fields where system thinking originated were biology and engineering. The biological field goes back to early in the 1920s with Bertalanffy's "general systems theory" and Weiner's work in engineering in the 1940s relating to cybernetics (Sterling, 2003). Since these early works, systems thinking has moved to a holistic approach particularly in living systems which has resulted in a more participatory worldview where human impact on the Earth's ecological systems is debated and addressed (Sterling, 2003). Systems thinking requires a different way of thinking from thinking in parts to a holistic (Capra, 2007) "relational, ….systemic. . ..and. . ...connective way of thinking which is more concerned with process rather than substance, with complex dynamics rather than limited cause-effect, with pattern rather than detail" (Sterling, 2003, p. 102).

A systems architecture in ecology includes all living elements – every animal (including humans) and other organisms interrelating to create a living system. These biological systems interact with the physical systems (atmospheric, geological, and hydrological systems). These living systems are steeped in "renewal, change and transformation" (Capra, 2007, p. 12). Therefore, systems thinking requires us to think "from static state to a dynamic state, from parts to wholes" which brings different ideas, tools, and values (Sterling, 2003, p. 41).

Systems thinking has an influential ancestry in ecological science and environmental education fields. Lovelock's Gaia hypothesis (first introduced in the 1960s) poses the Earth as a living system which is capable of self-maintenance by keeping all systems in balance. Lovelock defines Gaia as:

> a complex entity involving the Earth's biosphere, atmosphere, oceans, and soil; the totality constituting a feedback or cybernetic system which seeks an optimal physical and chemical environment for life on this planet. The maintenance of relatively constant conditions by active control may be conveniently described by the term 'homoeostasis' (Lovelock, 2000).

Lovelock asked questions about how the relationship between Gaia and humans, who are part of the Gaian entity, has led to changes in the balance of this complex planetary system. These Questions are still pertinent decades later in our ecological systems querying of childhoodnature. The deep ecology movement, which also arose in the 1960s, takes a radical form of environmentalism that challenges the predominant anthropocentric paradigm of economic growth at all costs and the subsequent threat to ecological systems (Zimmerman, 2014). Rachel Carson's book, *Silent Spring* (Carson, 1962), was a catalyst for the deep ecology movement, through highlighting the long-lasting effects of human generated toxins added to the environment (e.g., Strontium 90 and DDT) – impacts that spread throughout ecosystems, including human health effects. Decades later, as we move well into the twenty-first century, and despite the identification of the human-impact geological era, the Anthropocene, humans continue to contaminate Earth's systems (Gaffey & Steffen, 2017). The mindset of humans as separated from natural systems prevails, with the Earth predominantly viewed as a resource for the benefit of humans (White, Rudy, & Gareau, 2016).

The value of systems thinking in ecological science and environmental education is not without dissent. Gough describes systems thinking as "reproducing a metaphorical treatment of nature that was initiated in the 17th Century and is reinforced by modern science and industrialisation" (Gough, 1991, p. 36). Gough criticizes systems thinking as an "unsustainable fiction" as it uses terms from mechanical or cybernetic systems such as "positive feedback versus negative feedback" (p. 37) that he warns can result in people thinking that nature can be fixed, just like a machine can be manipulated and fixed. Wolfe reflects on how some environmental researchers see systems thinking as a "post-World War II society's obsession with management, command and control apparatus, informatics reproduction, homeostasis, and the like" (Wolfe, 2010, p. 3). We recognize that there are also inherent concerns with ecological systems theorizing based on a traditional scientific paradigm that is essentially patriarchal and structurally based (Kahn, 2010). More contemporary feminist, posthuman and indigenous ways of theorizing are in tension with traditional scientific thinking that tends to be linear, analytical, measured, quantified (Capra, 2007), and human-centric. By marrying the more fluid and networked posthuman perspectives with traditional ecological systems framing of childhoodnature, our aim is to broaden the scope for exploring childhoodnature and ecological systems realities in this Handbook section. As Sterling (Sterling, 2003) highlights, mechanical systems are very different to complex living systems and so

require a different approach. He advocates that despite the criticism of systems approaches by some environmental educators, systems thinking is still a powerful way of thinking that can lead to greater understanding, particularly with regard to the underlying systemic issues that concern researchers.

In considering ecological systems, it is important to be clear what we mean by "ecological" through a focus on "ecology" and "ecosystem," despite the social sciences adoption of the term ecological to apply to human systems. Capra and Luisi's definition of ecology and ecosystem clarifies the key ideas behind the ecological systems approach that underpins the ecological systems framing of childhoodnature in this section of the Handbook:

> from the Greek *oikos* ("household") is the study of the "Earth household". More precisely it is the scientific study of the relationships between the members of the Earth Household – plants, animals, and microorganisms – and their natural environment, living and nonliving. The basic ecological unit is the ecosystem, defined as a community of different species in a particular area, interacting with its nonliving, or abiotic, environment (air, minerals, water, sunlight, etc.) and with its living, or biotic, environment (i.e., with other members of the community). The ecosystem, then, consists of a biotic community and its physical environment (Capra & Luisi, 2014, pp. 341, 342).

These definitions resonate with both the Gaia hypothesis and deep ecology discussed previously. There are also synergies with the concept of childhoodnature posed through this Handbook as children's everyday way of being and doing as/with/in nature and their "household" experiences of kith and kin. Navigating this "Earth household" necessitates ecological understandings that underpin holistic ecological systems thinking. Orr identifies the essence of this ecological literacy as "driven by the sense of wonder" and the "sheer delight in a beautiful, mysterious bountiful world" (Orr, 1992, p. 84). True ecological literacy is seen by Orr as being "radicalizing" as it makes us look at the causes of the detrimental impacts on the Earth's ecological systems not just focusing on the symptoms (p. 86). To be ecologically literate, humans/children must be aware of the organizational principles behind ecology and use these principles to guide everyday lives (Capra, 2007), in other words, use ecological systems thinking. Therefore, ecological literacy involves being able to interpret and understand the dynamic potential of ecological systems and use this knowledge to take action in our (human) lives to "maintain, restore, or improve" the state of such systems (Scholz, 2011, p. 18) and live in "partnership" with nature (Merchant, 2016). Since the issues central to the Anthropocene are "fundamentally systemic" (Sterling, 2003, p. 40), thinking in terms of systems is essential to gain a deep understanding of ourselves as nature and how the ecological emergencies of the Anthropocene are entangled with our/children's lives.

Humans in the System

The foundation of systems thinking is a holistic perspective, not just considering component parts in isolation without the fundamental interactions and process. Such

thinking is deeply complicated but, as discussed earlier, essential to gain a more realistic perspective of the workings of multifactorial, intricate systems, such as ecosystems. However, such systems conceptualizations are our constructions – conceptual tools for understanding – and as such open to interpretation (Wadsworth, 2010). As we highlighted earlier, an ecological systems lens weaves biological and social systems together. We recognize that there has been much debate about a nature-culture divide in our human mindset (see for example the mapping in White et al., 2016), with increasing interest in shifting worldviews to humans *as* nature *and* social. Taking an ecological systems approach identifies the mutual shaping influences of both natural and social factors. But the very complexity of our socio-ecological systems has meant that ecological systems scholarship can be slanted towards different interests. Ecological systems thinking as we have described earlier is defined by researchers in the full ecological sense as the interrelationship of living things with their physical environment. A popular alternative application of the ecological systems concept is Bronfenbrenner's influential social systems focused model for understanding human ways of being in the world. Originally termed an "ecology of human development" in 1979, later Bronfenbrenner referred to this as an integrated bioecological systems model (Bronfenbrenner, 1994).

Bronfenbrenner's ecological systems model has been used widely since 1979 in the fields of human development and education, particularly in the early childhood fields, and was innovative at the time in terms of encouraging respect for, and valuing children's perspectives. Despite the use of the term "ecological," in this systems model Bronfenbrenner's model does little to reflect children's interaction with, and interdependence on, other living or nonliving elements, which is at the heart of ecological systems. Instead this model relates to human-centered social systems (Davis & Elliott, this Handbook). Bronfenbrenner (1979, p. 3) describes the model as about "the evolving interaction" between the "developing person" and their external influences. Predominantly the social environment is evidenced with interaction between humans and human organizations, and the true "ecological" position of children interacting with the more-than-human world is largely missing. Bronfenbrenner's, 1979 model proposes a series of "nested structures, each inside the next, like a set of Russian dolls" (Bronfenbrenner, 1979, p. 3). The child is at the heart of this model surrounded by the *microsystem* which is the immediate influences on the child of parents, friends, schools, and neighbors. Surrounding the *microsystem* and interconnected to it are the *mesosystem* and *exosystem*. These systems may or may not include first-hand involvement by the child, but they influence the child's social development, such as relationships between friends and family, and the school and home, or the relationship between family members and the work place. Finally the *macrosystem* on the outside of these nested systems is the influence of culture, politics, and public policy. There is much interrelationship between and within these nested structures, and changes in any of these settings in society can result in changes in behavior and development of the child (Bronfenbrenner, 1979). Bronfenbrenner highlighted how comparison and analysis of his model's micro-, meso-, and exo-systems within and between different social, ethnic, or religious groups could allow researchers to systematically describe and identify the

environmental properties "of these larger social contexts" as settings for human development (Bronfenbrenner, 1979, p. 8). It is important to note that these systems were modified frequently by Bronfenbrenner throughout his life and later he added an additional system, the *chronosystem*. The *chronosystem* was to represent "change or consistency" in the life of a person (i.e., over time), which includes change in the "characteristics" of a person or the "environment" where a "person lives" (Bronfenbrenner, 1994, p. 40). An example of this change could be a change in "family structure or socio-economic status" (p. 40).

Now in the context of the Anthropocene and childhoodnature, where we acknowledge the interrelationship with the more-than-human world and how human actions have seriously impacted on all natural systems, Bronfenbrenner's model is problematic in privileging the social of our entangled socioecological systems. The lack of critical epistemologies in Bronfenbrenner's model is also problematic. Power and privilege of humans is implied through Bronfenbrenner's dominance of the social in his ecological model. Experiences of both society and ecology are not the same for all humans however – Minority western privilege influences how our socioecological living systems are experienced; inequities and injustices are evident within the human experiences of the world (White et al., 2016). When extending to experiences of all the entities of our planetary ecosystems, inequalities are very evident for the more-than-human individuals.

A Posthuman Turn for New Thinking

Emergent posthuman theorizing provides a fitting landscape for reconsidering ecological systems thinking in this childhoodnature space (Greedy Bags of Childhoodnature Theories). There are numerous interpretations of posthumanism. Wolfe (2010) suggests that posthumanism can be traced to cybernetics and systems theory from the 1940s to 1950s – the early influencers of contemporary systems thinking as discussed earlier – demonstrating the synergies between posthumanism and systems modeling. Murris (2016) describes a posthuman child as existing in "a complex (always) already entangled network of human and nonhuman forces" (p. 111). The posthuman approach problematizes human dominance over the more-than-human world and reconsiders our relationship with nonhuman others (Malone, 2018). Malone combines posthumanist and vital materialist thinking (including all matter as potential actors in the world), and this has encouraged her in her research to notice "other objects" that may be considered as "aesthetics" such as "animals, plants, buildings, earth and air" that are in fact significant components in a child's life (Malone, 2018, p. 20). The combination of posthumanist and new materialist thinking has led Malone to move away from identifying human and nonhuman bodies "as separate entities with distinct borders" to thinking of these bodies as "assemblages and interdependences" (2017, p. 21). A posthuman position disrupts our perception of humans as an individual dominant species, and it

challenges the dominant paradigm of our bodies being isolated and "fully autonomous" (Neimanis, 2017, p. 33). Neimanis uses the medium of water to illustrate human entanglement with natural ecological systems by reminding us that our bodies are two-thirds water, and this water is constantly being replaced by sweating, breathing, urinating, crying, and drinking. Water condenses, precipitates, and evaporates not only from bodies of water, but from the bodies of multiple organisms. This same water that maintains our bodies and that supports our early beginnings in the uterus connects us to these more-than-human others. Substances we ingest, for example estrogens, are eventually carried into waterways where they can have a detrimental impact on more-than-human others such as fish (Nikoleris, 2016). Just as our bodies interact via watery systems, other ecological system components such as microorganisms, air, metals, plastics, and other toxins flow through our bodies within ecological processes (Malone, 2018; Neimanis, 2017). Our organs, tissues, and cells are composed of elements from nature; essentially we are nature. Therefore, the view of nature as somewhere "out there" that children view from afar, or where, if permitted, attempt to venture into is problematic. A posthuman position opens up thinking to include humans' intimate relation to all nonhuman others (Wolfe, 2010) and complements ecological systems thinking by acknowledging the interdependence of humans with the more-than-human in the Earth's dynamic systems. A posthuman framing of ecological systems thinking is valuable thinking in times of the Anthropocene to position children within the reality of the entangled interactions of human biology, natural, and social systems.

Ecological Systems and Childhoodnature Realities

In this section of the Childhoodnature Handbook, we foreground a posthuman ecological systems lens as a powerful tool for exploring childhoodnature and enhancing children's nature interconnection research and practice. This approach is taken to disrupt the anthropocentric underpinning of socioecological systems perspectives that dominate much of the childhood development and education discourses. Recent popularity of (re)connecting children with the natural world through immersion in nature and nature pedagogies (see for example Louv, 2005, 2011) resonates more with developmental perspectives than weaving children – mind, body, and heart – into ecological systems. Therefore, this ecological systems section of the Handbook explores the realities of childhoodnature embedded within complex planetary ecological systems; problematizes ecological systems thinking in relation to children and nature; and contributes new theoretical perspectives, methodologies, and pedagogies to strengthen childhoodnature and/with/in ecological systems.

Our call for chapter submissions sought to draw from a range of theorizing, research, and practices of childhoodnature framed through ecological systems from different fields, methodologies, contexts, and perspectives (including those of children and young people). We invited authors to advance understanding of the complexity of childhoodnature within an ecological systems framing, in the light

of the magnitude of environmental change as a result of human activity. The Handbook called for inclusion of posthuman, Majority world, and cross-cultural perspectives, focusing on the view that children are nature as an integrating concept. Our hope for this section of the Handbook on childhoodnature and ecological systems was for authors to unpack some of the nuances of childhoodnature in terms of ecological thinking, ecological literacy, and ecological identification of children and young people from a range of contexts; in particular this was to be achieved, through a relational position that troubles the thinking where nature is out there and an object to be tamed rather than embracing the child's relationship with "nonhuman other" (Murris, 2016, p. 51). We anticipated authors problematizing existing ecological systems theorizing and binaries such as nature-culture, mind-body, minority/center/western-majority/periphery/nonwestern and rural-urban dichotomies. Collisions and tensions with other philosophies such as critical theory and ecofeminism, inquiry into methodologies and pedagogies related to science, nature and outdoor education, and inter/cross/transdisciplinary relationships were more possibilities for the section to generate new understandings of childhoodnature and ecological systems.

We recognize that the scope of this section of the Handbook is broad with multiple interpretations, subjectivities, entry points, and pathways in an ecological systems approach, particularly considering that our foundation concepts – childhood, nature, and ecological systems – are all constructs (please see Bryan Wee's ▶ Chap. 45, "The Nature of Childhood in Childhoodnature" in this section for an exploration of childhood and nature constructs). Author contributions to this section apply an ecological systems perspective in different ways, attending to different dimensions of ecological systems childhoodnature framing including theory-reality gaps, new imaginings of theories and practices, and narratives from across cultures and countries, including indigenous perspectives. Each chapter in this section challenges the status quo, focusing predominantly on the influences of culture, education, lived experiences, and adult determinations that shape children's development and learning of their childhoodnature. The chapter authors in this section explore ways of escaping from assumptions and entrenched ways of thinking in childhood development, nature experiences, education, health promotion, science, and outdoor education. The chapters consider the morphology of childhoodnature through an ecological systems framing in a range of global contexts, with different age foci (young children to adolescents), from historical to present-day influences, and with many focusing on practical dimensions such as pedagogical approaches, managing children's nature interactions and connecting to lived experiences of being and knowing nature. All use an ecological systems framing of childhoodnature to re-read and re-conceptualize ways of embedding children with/in natural ecological systems.

There is a convergence in many of the chapters in this section around Bronfenbrenner-influenced theorizing, research, and practices. This focus gives an indication of the deep entanglement of the human social systems with nature and how difficult it is to disengage from our human perspective. The reality is that we cannot truly divorce ourselves from our human perspective so

this inevitably must influence our inquiries, but the authors in this section of the Handbook direct attention to the tensions between the social and ecological in a systems framing of childhoodnature. Sue Elliott with Julie Davis and Bryan Wee in particular challenge assumptions about human centricity and social hegemony – Sue Elliott and Julie Davis critique and re-conceptualize Bronfenbrenner's model, while Bryan Wee includes exploration of cultural and language influences beyond Majority world perspectives. Broadening ecological systems framing of childhoodnature to diverse cultural contexts also extends to: ▶ Chap. 48, "Ara Mai He Tetekura: Māori Knowledge Systems That Enable Ecological and Sociolinguistic Survival in Aotearoa" Cross- and trans-disciplinary considerations and practicalities extend the ecological systems thinking about childhoodnature in this section with ▶ Chap. 47, ""She's Only Two": Parents and Educators as Gatekeepers of Children's Opportunities for Nature-Based Risky Play".

Each of the chapters in this section uses an ecological systems perspective in a different way. This is both the value and the danger of using a systems framing – systems conceptualizing is a tool, a device, that assists in organizing thinking and developing understanding, but as a construct it is open to interpretation. There is a survive and thrive, self-sustaining "intentionality" associated with living systems (Wadsworth, 2010) that contrasts with a purely posthuman notion of assemblages of elements, so it is not surprising that the chapter authors take a purposeful focus (e.g., early childhood education, health and wellbeing promotion, risk management, science education) for their explorations of childhoodnature through an ecological systems framing. Holistic systems thinking is challenging. There is a danger of collapsing into perpetuating fragmented and separatist human-nature thinking with single-focus systems explorations, but all chapter authors have resisted such narrowing with throughlines of posthuman and childhoodnature perspectives woven through their inquiries. This "level jumping" between focused perspectives and the whole systems perspective means the chapters in this section have opened up spaces for (re)discovering, (re)considering, and (re)imagining childhoodnature.

Conclusion: New (Posthuman) Ecological Systems Thinking in Childhoodnature

The chapters in this section illuminate possibilities and potentials for considering childhoodnature through a posthuman ecological systems framing. However, these chapters do not represent the full scope of such possibilities, rather a start in this work. Adult translations of an ecological systems approach to childhoodnature dominated this Handbook section. The agency of children and young people (adolescents) was only connected through Helen Widdop Quinton

with Ferdousi Khatun and Marianne Logan's chapters that incorporate children's voices. Expansion of a posthuman ecological systems consideration of childhoodnature in the future could include children and young people's agency and activism.

Other areas for expansion of the discussion we hope for in the future are building on Bryan Wee's consideration of power and privilege in the research, pedagogy, and language of nature, through explorations of other aspects of power and privilege such as colonialism, social and ecological justice, and gendered critiques. Inclusion of virtual and augmented realities and hybrid thinking could also advance discussion of posthuman ecological systems thinking about childhoodnature in a world of "new nature," that is, nature that has changed through human influence (Braidotti, 2013; White et al., 2016).

Coupling the established history and familiarity of ecological systems approaches with childhoodnature conceptualizing and a posthuman turn opens up ecological systems into new productive spaces for thinking and enacting different childhoodnatures suited to the Anthropocene. The multiple ecological systems subjectivities explored through the chapters in this section signal future directions in research and pedagogy for enabling vibrant childhoods as nature. Membership of Earth ecological systems is at the heart of childhoodnature. Privileging a posthuman perspective through new theorizing in educational approaches and attention to cultural and educational practices that establish childhoodnature revives ecological systems thinking as essential for enabling children and young people to become integral with the life sustaining living systems of the world.

Abstract

Ecological systems thinking is indispensable in order to build a sustainable society, and fostering an ecological worldview should begin from birth. However, learning about ecology in formal schooling is often superficial and insufficient. For example, in Japan, the content related to ecology appears first in the national curriculum only at the third grade (aged 8 years) of primary school, and for younger children there are no clear descriptions of ecological concepts in the national early childhood curriculum. As a result, early childhood teachers in Japan have little concern with providing opportunities for children to experience activities related to an understanding of ecology. On the other hand, early childhood education has recognized the significance of nature-based activities for young children's development since Froebel in the early nineteenth century. Early childhood education in Japan has been strongly influenced by this traditional pedagogy, and Japanese educators have practiced nature-based activities, such as gardening and caring for animals, since this time. Recently, interest in education for sustainability (EfS) has increased within early childhood education and has reemphasized the importance of nature-based learning activities. The question now asked is, "How can we distinguish nature-based activities for the purposes of EfS, which constructs an ecological worldview, from the traditional nature-based activities in early childhood education that have been in use since the nineteenth century?" To answer this question, this Chapter demonstrates through three vignettes how toddlers and young children might begin to realize the relationships between animals and the natural environment and their own connectedness to the natural world in a Japanese early childhood education and care center. The potential of learning from traditional primary industries or indigenous cultures and the importance of transforming the educator's lens in order to foster an ecological worldview about nature-based activities in early childhood are also considered.

Ecological worldview · Early childhood · Japanese perspective

Introduction

Human population grew four-fold, and global fossil fuel consumption increased by 15 times during the 100 years of the twentieth century (Ritchie & Roser, 2017; Roser & Ortiz-Ospina, 2018). These characteristics of the Anthropocene epoch have caused numerous and complicated environmental issues (Steffen, Crutzen, & McNeill, 2007). Human society has recognized the importance of protecting our shared environment resulting in many governments having environmental policies and the development of Environmental Education (EE) in schools in some countries; many industries have listed environmental protection as their corporate social responsibility since the 1970s. For example, alerts about global warming started in the early 1970s; the international convention against climate change was concluded in 1992; many governments made management policies to reduce CO2 emissions under the Kyoto protocol (1997), and the Paris agreement (2015) will demand further policy changes in

each government; and textbooks for schools began describing global warming (e.g., Choi, Niyogi, Shepardson, & Charusombat, 2010; Koro, Nasu, & Kita, 2005). However, we are still confronted with climate change and environmental crises caused by global warming. This reality implies that existing strategies have not had enough effect in preventing the progression of environmental crises. Therefore, it is important to reflect on existing strategies and find new ways to change the world. This Chapter reflects on how the long history of existing nature-based education in Japan has lacked a focus on learning about ecology and ecological systems. I use the term "traditional nature-based activities" to describe the pedagogy for existing nature-based education such as caring for animals, gardening, and outdoor play, which have been practiced in Japanese early childhood education settings since the nineteenth century. Then this Chapter also introduces a new pedagogy for Japanese early childhood education to foster an ecological worldview, a view that is seen as indispensable to creating a sustainable society.

Fostering an Ecological Worldview

Ecology and the Anthropocene

As one of the fields in biological sciences, ecology has had a long history. The term "ecology" was first named by Haeckel, a German biologist, in 1869, and ecology became one area of biological science in the early twentieth century (Worster, 1985). In this Chapter, the terms "ecology," "ecological," "ecological systems," and "ecologist" are used in the sense of biological ecology, in contrast to discussions involving socio-ecological theory in social science or ecologism as a political ideology (e.g., Bronfenbrenner, 1979). The ecosystem concept, which was proposed by Tansley in 1935, describes living organisms and inorganic components interconnected with one another in a complicated network. The interconnected ecosystems that make up the Earth's ecosystem are not static; rather, they are dynamic, as they are always changing and moving. Human beings are also one of the components of the Earth's ecosystem. In the history of life on Earth, some organisms such as cyanobacteria radically changed the Earth's geology and ecosystems, but these changes took place over two or three billion years (Canfield, 2014). However, the speed of human-caused impacts now is extremely high – there has been no similarly rapid change evident in the Earth's history (Ceballos et al., 2015). Many scientists have termed the present world as "the Anthropocene," an epoch noted for human impact on the Earth's geology and ecosystems (Braje, 2015; Lewis & Maslin, 2015; Waters et al., 2016). In the Earth's history, there have been five mass extinctions of multiple species (Elewa, 2010), and many biologists have warned that we are now in the era of the sixth mass extinction (Kolbert, 2015). Although the causes of the past five mass extinctions are not scientifically clarified, it seems that there was a catastrophe that destroyed the environment and led to the mass extinctions (Benton, 2005). These previous mass extinctions present a warning to current human populations that a dramatic environmental change, such as we are experiencing with climate change, may be a catastrophe that could impact on the Earth's ecosystem and

therefore our human species survival (Ripple et al., 2017; Scheffer, Carptenter, Foley, Folke, & Walker, 2001).

Recently, the contemporary ecologist Schmitz (2016) describes the role of ecosystems in an ethos of sustainability: "from an ecological standpoint, sustainability means that ecosystems have the enduring capacity to be productive" (p. 4). This requires a holistic approach to ecosystem health as even nondominant species, which may not appear to have a significant role in the ecosystem, have been found to be important elements in maintaining the whole ecosystem (Schmitz, 2016). While the concept of sustainability is usually described as being equally divided into economic, social, and environmental (ecological) perspectives, the former two perspectives are impossible to achieve without ecological sustainability as our human systems would not be possible without the basis of human survival – Earth's ecosystems. Thus, it is necessary to maintain the Earth's present ecosystem (with its subsystems) and to regard this planetary ecosystem, not as a natural resource just for the human economy, but as a dynamic system for all life, including humans. As the Earth is considered a dynamic ecosystem, then humans (including children) and nature are one (childhoodnature) interrelated with all nonhuman others in the Earth's ecosystem; thus, the notion of the separation of humans and nature must be rejected. But as Schmitz highlights, "societies still tend to hold the worldview that humanly based and nature-based systems are largely independent entities" (Schmitz, 2016, p. 131). The perspective of childhoodnature where humans are recognized as nature and members of the Earth's ecosystem is not shared by everyone and is generally ignored in social or economic activities, as is illustrated in the following section which looks at ecology in education in Japan.

Learning Ecology in Education in Japan

In Japan, ecology as a subject is included in the national curriculum and ecological concepts – such as the relationship between organisms and their surrounding environment – first appear in the "science" learning area in third grade of primary schools (aged 8 years). Predator-prey relationships are included at sixth grade of primary school in Japan (aged 11 years) and students learn concepts, such as ecosystem, food chain/webs, producers, consumers, and decomposers in lower secondary school. Therefore, students of primary and lower secondary schools, which constitute the compulsory education levels in Japan, learn about those ecological concepts described in the national curriculum at age eight to fourteen. However, learning about ecosystems in Japanese schools does not seem to include the role of humans, and ecosystems are presented as static entities. As a result, even university students often report that they have never thought of humans being part of ecosystems or as one of the consumers whose lives interconnect with those of the producers and decomposers (other organisms on Earth) (Inoue, 2005). This implies that learning ecology in Japanese schools has given students superficial textbook knowledge, which does not influence their thoughts and behaviors in terms of environmental concerns. Research in EE or environmental psychology has also revealed that although people may have concern and knowledge about environmental issues,

those concerns and knowledge do not necessarily influence people's behaviors (e.g., Bamberg, 2003: Liefländer & Bogner, 2016). It seems that, for most people, environmental issues exist in a separate world and that ecosystem issues are not their problems, but rather other people's problems. In order to understand the significance of humans being part of the Earth's dynamic ecosystem and that human activities impact on this system, it is important to develop an ecological worldview.

Ecological Worldview

The concept "worldview" emerged in German philosophy in the nineteenth century, and since then, it has been given various meanings; therefore, this concept is often complicated and confusing. Worldview in this Chapter reflects the simple and standard dictionary meaning, that is, "conception of the world," which has been described as a holistic framework of both cognitive and noncognitive factors such as knowledge, beliefs, values, and emotions (Koltko-Rivera, 2004; Naugle, 2002). As worldviews are constructed through the influence of cognitive and non-cognitive factors, a person's worldview can be developed through life and so is individually and culturally acquired. An ecological worldview has been described in some literature as referring to environmentally responsible behaviors (e.g., Blaikie, 1992). For the purpose of this Chapter, however, an ecological worldview is simply defined as a worldview based on ecology, which regards human beings as one component of the Earth's ecosystem. This approach is aligned with that of Goldsmith (1988) and Krebs (2008); Krebs is a contemporary ecologist, who uses the phrase ecological worldview in contrast to an "economic worldview." People watch, explain, and interact with the world based on their worldview. An ecological worldview is, therefore, more than knowledge of ecological concepts or love of nature; it is a way of being in the world. We can find examples of an ecological worldview in many indigenous societies such as the Aboriginal Australians and the First Nations in Canada. Traditionally, the lives of indigenous people in many countries were guided by their ecological worldviews (Breidlid, 2012; Pierotti, 2012). These indigenous ecological worldviews, including traditional indigenous knowledge, have been transmitted from generation to generation by informal education in the community (Berkes, Colding, & Folke, 2000). Therefore, a philosophy of ecology as the basis of life was embedded in all aspects of their everyday lives. How then might people who live in the contemporary urbanized world develop their ecological worldviews?

Fostering an Ecological Worldview for Sustainability

Why Should Education for Sustainability Start in Early Childhood?

The rapid economic growth after the Second World War changed the local ecosystems and created many environmental issues in developed countries (Meadows, Meadows, Randers, & Behrens, 1972). Subsequently, those environmental issues,

such as climate change caused by global warming, desertification, and ozone depletion, have become more widespread globally (Meadows, Randers, & Meadows, 2012). In the 1970s people began to be aware of the relationship between human activity and changes in the environment (e.g., United Nations Conference on the Human Environment, 1972), and it was then that EE was first recognized. In the early 1980s, the concept "Sustainable Development (SD)" was articulated (International Union for Conservation of Nature and Natural Resources [IUCN], 1980), and in the 2000s, Education for Sustainable Development (ESD) was internationally recognized after the Johannesburg Summit in 2002 (United Nations Educational, Scientific and Cultural Organization [UNESCO], 2014). As a result, the United Nations launched the United Nations Decade of Education for Sustainable Development (UNDESD) initiative from 2005 to 2014. Extending on this history, Education for Sustainability (EfS) emerged as an important educational theme in the twenty-first century for building a sustainable society, although the background history and relationship among these concepts are complicated and confusing (e.g., Bonnett, 2002; Fien & Tilbury, 2002; Hopkins & McKeown, 2002). EE emerged in the 1970s, and academic research has been conducted since then; however, early childhood EE research literature emerged later, firstly led by Wilson in the United States and then by Davis and Elliott in Australia (Davis, 2009; New South Wales Environmental Protection Agency [NSWEPA], 2003). In the 2010s, research concerning early childhood EfS/ESD increased (Cutter-Mackenzie, Edwards, Moore, & Boyd, 2014; Davis & Elliott, 2014; Huggins & Evans, 2017; Siraj-Blatchford, Mogharreban, & Park, 2016).

Recent research on infants' and young children's development strongly supports starting EE/ESD/EfS in early childhood (Samuelsson, 2011). Soon after birth, infants show sympathy with other humans, and this emotion develops through further experiences in human relationships (e.g., Eisenberg, Spinrad, & Sadovsky, 2006; Gopnik, 2010; Spinrad et al., 1999). Even new-borns are distressed after another infant begins to cry (Dondi, Simion, & Caltran, 1999). Then, after sympathy, empathy develops. The development of empathy could influence a sense of social justice in the future (Hoffman, 2001). Sympathy and empathy seem to be inherent characteristics of human beings gained by evolutionary process (Boehm, 2012); however, these emotions need to be fostered and developed through experiences. Sympathy can influence children's prosocial behavior (Malti, Gummerum, Keller, & Buchmann, 2009). A longitudinal study by Eisenberg et al. (1999) reveals that the emergence of a prosocial personality in early childhood is consistent over time. If sympathy with nonhuman nature (animals, plants, and other organisms) is fostered in early childhood, it may be possible to develop empathy toward nonhuman others, which then evolves into a sense of social justice with environmental matters. Many studies report that nature-based experiences in childhood correlate with future environmental behaviors and thinking (e.g. Chawla, 1998; Hosaka, Sugimoto, & Numata, 2017; Prévot, Clayton, & Mathevet, 2016).

To further reinforce the importance of sustainability/ecological learning in early years education, especially after the United Nations Convention on the Rights of the

Child (1989), young children are increasingly regarded as active agents with a right to participate in society and in matters of concern to them. Even young children have many opportunities to recognize environmental issues and their causes – recent research in EfS for young children has shown high interest in this agentic perspective with studies revealing that even young children can act to promote sustainability (Davis, 2008, 2014; Mackey, 2012). Promoting sustainability in early childhood education includes children's active participation and also critical thinking (Somerville & Williams, 2015). However, I contend that people who critically think and actively participate in the world based purely on an "economic worldview" may not be able to comprehend the true meaning of sustainability. People with an "economic worldview" regard the Earth as a natural resource just for human use and give priority to economic growth. An economic worldview approach may include critical thinking and active participation regarding protection of natural resources, but this is primarily for the purpose of economic use, for sustainable economic growth. Such economic sustainability thinking and participation appear to be appropriate for EE/EfS at first glance. Critical thinking and active participation are important for EE/EfS indeed; however, these views should be fostered based on an ecological worldview, not on an economic worldview, to build a sustainable human society.

Furthermore, it is recommended to start education for social justice as early as possible because children already have biases by the age of two (e.g., gender, ethnicity, and disability), and it is more difficult to change these biases after children reach their teens (Bussey & Bandura, 1999; Sparks, 1994). Many studies have revealed the existence of social stereotyping and prejudice by the age of four (Brown & Bigler, 2005), and salient social groups seems to influence children's developmental processes (Bigler & Liben, 2006). At age five, children in different cultures already show different prosocial behaviors and emotional reactions to the same experimental situation (Trommsdorff, Friedlmeier, & Mayer, 2007). These studies imply that even a toddler has already been influenced by the values of people, community, and society that surround her/him. This is also explained by Bronfenbrenner's child development theory (Bronfenbrenner, 1979), which focuses on the influences of quality and context of the child's environment. Social biases are developed by various factors in multiple levels, such as families, peers, or teachers (Bronfenbrenner's "microsystem"), the social media ("exosystem"), and cultural values ("macrosystem"). The fact that a child can be affected by the social values of their surrounding social environment at an early age could also apply to biases towards positioning children and nature. These biases could include children being considered as separate to or superior to nature and to natural systems, in contrast to the childhoodnature perspective where children and nature are inseparable, hence the importance of education for social justice in the early years.

Incorporating these ideas from the research relating to the importance of sustainability/ecological learning in the early years, I propose four key concepts to reshape early childhood EfS:

1. Critical thinking
2. Children's active participation

3. An ecological worldview
4. Empathy with (nonhuman) nature (Inoue, 2014a)

The latter two concepts are the focus of this Chapter. They are not widely recognized as important issues within early childhood education research, although they are supported in the general EE research literature over the last few decades (Gough, 2013; Palmer, 2002). Combining an ecological worldview and empathy with nature concepts, with established early childhood education approaches of critical thinking and children's active participation, creates possibilities for fostering young children's interconnections with nature.

How to Foster an Ecological Worldview from Early Childhood

As has been shown, learning ecology is indispensable for EE/EfS because human beings are a part of the Earth's ecosystem and cannot survive outside of it. In Japan we have much knowledge of ecology today, from school education and various media sources, however, this knowledge is separated from our own social and economic lives. It is argued that this human–nature divide can promote a view that ecological matters are not our problem; instead, these are considered the natural world's problems and exist outside the sphere of human lives. Such a view will prevent the creation of a sustainable society because it is not holistic or systemic and is in contrast to the childhoodnature concept. As noted earlier, indigenous worldviews are often described as "ecological" so it follows that learning from indigenous cultures can potentially nurture an ecological worldview. Indigenous ecological worldviews have traditionally been fostered through informal education in the community and embedded in all phases of social and economic lives. Sometimes, cultural resources such as ceremonies, rituals, stories, myth, legends, and songs have taken key roles in the development of the ecological worldviews (Cajete, 1993). Although it is difficult to apply indigenous informal education pedagogy into nonindigenous formal education due to dissimilarities in various aspects such as cultural backgrounds, values, and beliefs between them, there are examples of the application of indigenous perspectives among kindergarten teachers in New Zealand and Australia. National curricula in New Zealand and Australia require indigenous perspectives to be included in early childhood education (Department of Education, Employment and Workplace Relations [DEEWR], 2009; Ministry of Education, New Zealand, 1996, 2017), and early childhood services in both countries have started to incorporate indigenous cultural materials and provide opportunities to experience cultural events. Some centers have applied more holistic and whole-center approaches beyond just displaying materials or experiencing sporadic events (Duhn & Ritchie, 2014; Lee, 2012; Ritchie, Duhn, Rau, & Craw, 2010). In this way the teachers cooperate with indigenous people in local communities in order to incorporate resources such as traditional knowledge, stories, and legends. As a result, local indigenous practices and ecological worldviews, such as respect for the land, have started to influence early childhood practice including

activities for sustainability (Jacobs, Bursill, Lee, & Morgan, 2013); this has the potential to contribute to the development of children's ecological worldviews.

Nevertheless, there is evidence that many countries have lost or are at risk of losing their indigenous cultures with the disappearance of informal indigenous education in today's urbanized world (Johansen, 2003; United Nations, 2009). For example, in Japan the indigenous group of people, the Ainu, have lived for a long time in Hokkaido, a northern island of Japan. The Ainu people have been persecuted especially after the nineteenth century, and the Japanese national curriculum has not described the Ainu culture positively or included Ainu traditional knowledge; therefore, learning about the Ainu culture and ways of being is not promoted, especially outside Hokkaido (Ueno, 2014). As an alternative to learning directly from indigenous cultures, especially where such cultures are declining or absent from the local community, I propose learning from traditional primary industries. Primary industries are part of the economy and they have also contributed to the onset of the Anthropocene. However, traditional primary industries were conducted in more sustainable ways than modern ones. For example, in the last two decades, Japanese stakeholders for sustainability have been concerned with a Japanese term, "Satoyama," which was first used in the eighteenth century and is defined as "secondary woodland and grassland adjacent to human settlements" (Takeuchi, Brown, Washitani, Tsunekawa, & Yokohari, 2003, preface), "traditional forest and agricultural landscape" (Kobori & Primack, 2003, p. 307), or "a mosaic of ecosystems including wetlands, grasslands, woodlands, farmlands, paddy fields, and settlements" (Cetinkaya, 2009, p. 28). In the past, Japanese people who engaged in traditional primary industries had to maintain "Satoyama" (local woodlands and grasslands) to sustain their industries; therefore, "Satoyama" not only provided a variety of natural products for human living but also preserved rich biodiversity. In the process of maintaining "Satoyama," Japanese people had abundant knowledge about the natural world and how to live with the rest of nature. These traditional primary industries are completely different from modern ones which are dependent on fossil fuels and artificial chemicals; therefore, traditional primary industries can provide a resource to learn about sustainable living. Although "Satoyama" symbolizes a traditional Japanese way of living based on sustainable primary industries, including agriculture, fishery, and forestry, we can still find similar traditional, ecologically sustainable, ways of living elsewhere (Bélair, Ichikawa, Wong, & Mulongoy, 2010). For example, Garavito-Bermúdez and Lundholm (2017) reported Swedish traditional fishers had stronger place attachment and showed deeper understanding of ecosystem structure and dynamics than nontraditional ones. As an agriculture-based society for over 2000 years, especially rice farming, Japan has many kinds of traditional ceremonies, stories, songs, and folk arts that are specific to each district. These practices often express the human-nature interconnection, which has been transmitted through traditional informal education in the community. Although many traditional practices have been lost with the urbanization and globalization of the twentieth and twenty-first centuries, our food is still produced by primary industries that are informed by understandings of the natural world and some of traditional knowledge and cultural resources still exist. Therefore,

rediscovering and experiencing traditional primary industries could help promote childhoodnature and foster an ecological worldview.

As I have shown, in order to develop an ecological worldview, children need to understand the concept of ecosystems and how society, economy, and the natural environment are interdependent. However, in modern, urban life in Japan, young children tend to learn from their families about consumer society by going to the shops for food and other necessities; I argue that these experiences foster an economic, not an ecological, worldview. Anecdotal evidence from Japanese early childhood educators suggests that many young children in their care believe their food originates in shops and supermarkets. Similar misconceptions about the origins of food have been identified internationally (e.g., British Nutrition Foundation, 2013; Purvis, 2011). Experience of a modern economy results in a lack of awareness about the fundamental role of the Earth's geological, hydrological, and biological systems in food production. Components of food production include: soils, rain, water, sunlight, air, pollinating insects, invisible soil biota, energy (often from fossil fuels) for machinery and transportation, and human labor. These processes can be called shadow processes because the processes exist in reality, but the people who buy food at the shops may have no awareness of them (Vileisis, 2010). I argue that it would be helpful to experience traditional primary industries and think about these shadow processes in modernized life in order to promote an ecological worldview. The questions then follow: Does early childhood education recognize the importance of fostering an ecological worldview? Does early childhood education provide children's activities, such as experiencing primary industries, which could lead to an awareness of the ecological systems relating to food production? In the next section, I reflect on activities in the existing Japanese education framework relating to traditional nature-based activities.

Children and Nature in Early Childhood Education in Japan

Nature-Based Activities in the History of Early Childhood Education

The pedagogy of early childhood education has a long history of recognizing the significance of traditional nature-based activities. For example, Comenius, in the seventeenth century, believed young children learned about the natural world through their five senses (Comenius, 1962). Froebel, in the nineteenth century, from the Christian perspective, regarded nature-based activities as important because they lead children to understand how and why God made the world for human beings, "the natural world is the presence of direct achievement by God, the first revelation of God" (Froebel, 1972, p. 127). He thought young children become aware of God's revelation by caring for plants in their own gardens in the kindergarten and that such awareness produces the understanding of themselves as created by God. Therefore, nature-based activities were prioritized in Froebel's pedagogy. Montessori, in the early twentieth century, also regarded caring for animals and gardening as benefitting the development of young children (Montessori, 1971).

Centre-based early childhood education emerged in Europe in the nineteenth century, such as the first infant school established by Owen in 1816 in New Lanark, Scotland, and the first kindergarten by Froebel in 1837 in Bad Blankenburg, Germany. This movement spread worldwide with center-based early childhood education being established in many countries. In particular, Froebel's pedagogy influenced these movements. In Japan, early childhood pedagogy was imported from European countries after the Meiji government achieved power in 1868, and the first public kindergarten was established in 1876 as an attached school of Tokyo Women's Teachers College in Tokyo, Japan (the present Ochanomizu Women's University) (National Institute for Educational Policy Research, 2009; Phillips & Schweisfurth, 2014). Japanese early childhood education was explicitly based on Froebel's pedagogy in the early days; therefore, the first Japanese kindergartens used Froebel "gifts" (set of play materials) and created children's gardens in the playground. In 1881, the regulations for the first Japanese kindergarten noted that "outdoor play was most important for young children" and "playgrounds should have trees, flowers, fish, and birds for children's observation and joyful activities" (Ministry of Education, Japan, 1979, p. 59). The first Japanese national law for kindergartens (the Kindergarten Law) was amended in 1926 to include five learning areas, one of which was "observation" with the requirement that young children should observe their surrounding environment. Since this law was enacted, every following guideline for early childhood education in Japan has emphasized the significance of traditional nature-based activities (Inoue, 2000).

Early childhood education in Japan has had a dual system since the nineteenth century: nursery centers for children of working mothers aged from birth to 5 years old, and kindergartens for children aged 3–5 years as part of the formal school system. In 2006, the Japanese government started a new type of early childhood service called "Centres for Early Childhood Education and Care (CECEC)." Thus, at present, there are three kinds of early childhood services under three different national guidelines; however, the early educational curriculum is aligned in these three sets of guidelines. All kindergartens are legally required to have their own outdoor playgrounds, and over 90% of all registered nursery centers and CECEC also have outdoor playgrounds. Then, this poses the question do Japanese early childhood teachers practice traditional nature-based activities as established under the national curriculum guidelines?

In 1925, the Japanese Ministry of Education conducted a nationwide survey of kindergartens, which revealed that kindergarten children usually experienced gardening, caring for animals, and excursions to nature spaces in the community. After the Kindergarten Law in 1926, gardening and caring for animals were practiced more frequently (Kurahashi & Shinjyo, 1980). These traditional nature-based activities are still practiced in Japanese early childhood services. For example, I conducted surveys on practices related to traditional nature-based activities in kindergartens and nursery centers three times in 1997, 2004, and 2013. In all the surveys, teachers frequently practiced traditional nature-based activities such as gardening, caring for animals, and outdoor play (Inoue, 2002, 2017; Inoue & Muto, 2006). Thus, Japanese early childhood teachers have understood and been

following the national guidelines, and they have continued to practice traditional nature-based activities since the nineteenth century.

Traditional nature-based activities in early childhood education are recognized as important in not only Japan but also other countries. The surveys conducted in Australia and Korea by applying the same survey questions between 2012 and 2014 revealed that traditional nature-based activities such as gardening and caring for animals were also well practiced in Australia and Korea (Inoue, O'Gorman, & Davis, 2016; Ji, Huh, Baik, & Chung, 2015). Overall, this is to be expected because, as mentioned earlier, the early childhood education systems and pedagogies in each of these countries were constructed on the theories and practices of pioneers such as Froebel, although there were also influences based on their own cultures and histories. Early childhood centers across the globe have their own playgrounds often with flowers and trees, although the size and quality may vary. Furthermore, these spaces sometimes provide young children with opportunities of traditional nature-based activities.

Significance of Traditional Nature-Based Activities in Early Childhood Education

How, then, has the significance of the traditional nature-based activities been conceived throughout the history of Japanese early childhood education? Have they included any reference to ecology, systems thinking, or ecological worldviews? In 1904, the curriculum of one public kindergarten described that gardening and caring for animals fosters awareness of natural laws, instills love, and concern for the natural world and contributes to children's physical and mental development, whereas outdoor excursions can develop a sense of beauty (Ministry of Education, Japan, 1979). After the Second World War, the Ministry of Education published *Nursing Guideline* in 1948, which listed 12 categories of preferable activities for young children. One of the categories was "Observation of the natural world"; it was noted that gardening, such as cultivating soils, planting seeds, and watering plants, could develop the love of plants and observation of nature and deepen children's concern for nature. Such ways of emphasizing the significance of traditional nature-based activities are embedded in the latest national guidelines. *The Course of study for Kindergarten* (the national curriculum for kindergarten) includes five learning areas, and the descriptions referring to nature (emphasized in bold letters by the author) appear in four learning areas (Table 1).

This commitment to traditional nature-based activities aligns with the statements that early theorists and practitioners used in early childhood education, together with more recent research and advocacy. For example, Louv (2006) and Sobel (2008) describe nature experiences as significant for various aspects of child development such as physical and mental health, creativity, concentration, imagination, or environmental stewardship, while Harlan and Rivkin (2010) demonstrate that nature-based learning is necessary for foundational science education. Furthermore, in

Table 1 Descriptions about nature learning in the Japanese national curriculum for kindergarten (Ministry of Education, Culture, Sports, Science and Technology, 1998, 2008, 2017)

Learning areas	Descriptions
Health	Children should be encouraged to expand their interest in and curiosity about the outdoors, given the fact that free physical activity and play in a natural environment stimulates **the development of bodily functions**
Human relationship	In the learning area of "'Human Relationship," teachers are recommended to encourage children to **develop rich emotions** through close contact with surrounding nature, animals, and plant life
Environment	Teachers should devise processes whereby children can deepen their relationship with nature, given that the foundation for **rich emotions, curiosity, the ability to think, and expressiveness** is cultivated through direct contact with the grandeur, beauty, and wonder of nature, something which is very important to experience during early childhood This should be done in such a way that these various relationships enable children to foster **a sense of attachment and awe toward these things, as well as a respect for life, a spirit of social responsibility, and an inquisitive mind**
Expression	Children's **rich feelings should be fostered** through encounters with beautiful, excellent, and moving things during deep interaction with nature and their surrounding environment

Japan, there is a view that outdoor play contributes to young children's physical development (Sugihara et al., 2010; Sugihara, Kondo, Mori, & Yosida, 2006). Ogata, Shimada, and Seki (2013) report that the scores of physical skills were higher than the nation-wide average in children who attended a Japanese forest kindergarten. In environmental psychology, many studies have reported that nature spaces influence human physiological and psychological conditions (e.g., Alcock, White, Wheeler, Fleming, & Depledge, 2013; Mitchell & Popham, 2008; Park et al., 2007; Pretty, Peacock, Sellens, & Griffin, 2005; Ulrich, 1984). While most of the latter studies targeted adults, the evidence suggests that engaging activities in nature spaces also influence children's mental and physiological health positively. In a review of studies about the relationship between children and animals from the perspective of developmental psychology, Melson (2005) reported that caring for animals has a positive impact on children's mental health and their development of emotions and responsibility. Recent research on nature-assisted therapy and its contributions to public health provides further evidence for the benefits of nature-based activities (Logan, 2016; Selhub & Logan, 2014; Song, Ikei, & Miyazaki, 2016). However, when we reflect on the significance of traditional nature-based activities practiced in the long history of early childhood education and the more recent evidence-based research, we cannot find clear descriptions that relate to ecology, systems thinking, or ecological worldviews. Traditional nature-based activities tend to present a more instrumental view of people and nature interactions. Has the recent inclusion of EE/EfS/ESD into the educational setting, shifted nature-based activities in early childhood education to a focus on developing an ecological worldview?

Nature-Based Activities in Early Childhood Education for Sustainability

In the relatively short research history of early childhood EE, nature-based activities have also been recognized as appropriate practices. For example, one of Wilson's early works about early childhood EE entitled "*Fostering a sense of wonder at the early childhood level*" describes the importance of playing in outdoor nature spaces using the five senses (Wilson, 1993). *The Early Childhood Environmental Education Programs: Guidelines for Excellence* also identifies that "personal perceptions, attitudes, and connections with nature are the key goals at this [early] stage" (North American Environmental Education Association [NAAEE], 2016, p. 3). Furthermore, in Japan, the official *Teacher's handbook for environmental education* for kindergartens and primary schools describes similar content and goals (National Institute for Educational Policy Research, 2014). As a result of such learning, does playing in outdoor nature spaces, caring for animals, or gardening foster a sense of wonder and empathy with nature? Furthermore, does or can it contribute to building a sustainable society? Carson (1998) and Cobb (1993), seminal thinkers about the relationship between childhood and nature, describe the value of having a sense of wonder about the natural world, but they do not explain how this links to pro-environmental behaviors; behavior urgently needed now to address our environmental disasters. More contemporary EE, EfS, and ESD activities are targeted towards such behaviors.

For EfS or ESD, as an evolved version of EE, nature-based activities in early childhood education have been recommended. For example, OMEP (World Organisation for Early Childhood Education and Care) created an Environmental Rating Scale for Sustainable Development in Early Childhood (ERS-SDEC). To gain a "good" rating in the environmental sustainability section requires that "many resources are available including animals and plants in the setting" (Organisation Mondiale pour l'Education Préscolaire [OMEP], 2015 p. 3). In this scale, animals and plants are regarded as recommended learning resources. However, considering animals as resources represents an anthropocentric view, as it suggests that humans are separate to and have dominion over other animals, and these animals are there for the benefit of humans (children). The scale also refers to recycling, resource conservation, or environmental issues; however, it, too, does not mention about the value of developing ecological systems thinking or ecological worldviews in the early years.

Nowadays, much of the current human population live in cities where we cannot find abundant outdoor nature spaces. Until the middle of the twentieth century, more people were engaged in primary industries, which were closer to the natural world, such as agriculture, pasturing, forestry, and fishery. Children of past generations could experience nature-based activities more frequently, and these activities were closer to their ordinary lives. In addition, as previously discussed, children have had opportunities to attend schools or early childhood centers and experienced nature-based activities since the nineteenth century, because the importance of nature-based activities for child development has been recognized in theories of education. However, it is those past generations who have damaged the many ecosystems and

have triggered our current environmental crises. We can see this reality, not only in Japan, but across the globe. Reflecting, then, on the application of the theories and nature-based practices of traditional early childhood pedagogy and the daily lives of past generations in the nineteenth and early twentieth centuries, simply experiencing traditional nature-based activities in a kindergarten does not appear to foster widespread ecological systems thinking or ecological worldviews. This suggests that traditional pedagogy, which emphasizes the significance of nature-based activities, has not supported pro-environmental behavior. Nevertheless, experiencing nature-based activities in everyday life is still important. This is because the understanding of ecology and of the niche of human beings in the Earth's ecosystem through direct experiences and interrelating with other natural elements is indispensable. However, I argue that this is not enough to build a sustainable society.

Learning Ecology from Infancy: Vignettes from Japan

As described in the previous overview of the significance of developing an ecological worldview and the lack of fostering such a view in existing education, it is necessary to rethink early childhood education from the viewpoint of fostering an ecological worldview. In this section, I explore three vignettes from one Japanese early childhood service that indicates that toddlers and young children can learn ecology.

When early childhood teachers engage in their practices, the teachers encounter various words and behaviors of children in activities. For evaluating their teaching practices, the teachers have to focus on and identify specific words and behaviors. For example, when a teacher aims to promote learning ecology, she/he may intentionally observe how children see, observe, and talk about plants, animals, and the habitat. In Japan, traditional nature-based activities are frequently described in studies by researchers, magazine articles by experienced teachers, website pages and center curriculum documents by early childhood services, or other documentation recorded by teachers. However, they seldom refer to ecology, ecosystems, ecological systems thinking, or ecological worldviews (Inoue, 2009). When teachers focus only on children's development, they might overlook children's words and behaviors that refer to the learning of ecology; and so, they cannot support the children's deeper ecological learning. Therefore, to foster children's ecological worldview, teachers should attend to children's words and behaviors from the perspective of ecology. Furthermore, teachers should be conscious of their role in developing and exploring appropriate values for the environment, ecosystems, ecological system thinking, or ecological worldviews. Do teachers try to enhance children's understanding and encourage their sympathy or empathy with living things? I use the descriptive phrase, "ecological lens" to describe the teacher's consciousness of ecology, ecological systems thinking, and ecological worldviews.

Tomioka-Nishi Centre for Early Childhood Education and Care (CECEC) is located in a residential area of Sakai City (the city next to Osaka City in Japan). This center has developed a "practice study," which is a form of professional

development that is common in Japan, under the theme of EE, and I have supervised the "practice study" since 2010 (Inoue, 2014b). The teachers have improved the learning environment, reflected on children's activities, and conducted monthly meetings to discuss their practices as a result of their engagement. In this particular practice study, the teachers focused on learning about ecology. I encouraged the teachers to use an ecological lens when they arranged the learning environment, observed children's activities, and documented children's learning. The teachers gradually renovated the center's outdoor playground to increase biodiversity by planting various trees and indigenous grasses. The children and teachers use composting to learn about ecological cycles and relationships between the everyday lives of human and nonhuman organisms. This center has its own kitchen with a professional nutritionist and kitchen staff who prepare daily handmade lunches and snacks (this is a legal requirement for children aged from 0 to 2 in long day care type centers in Japan). Children take scraps of vegetables or fruits, which were produced in the cooking processes of their lunch and afternoon snacks, to the compost and then observe the compost process. Sometimes, they mix the compost and then use the matured compost soil in the vegetable garden. There are six age groups (0–5) at the center, and the teachers also care for small animals such as snails or insects in all classrooms. The teachers always consider animal welfare with children: some animals caught in the playgrounds are cared for a short while, for observation, and later released; others are brought by families or community people (usually from shops or breeders) and the teachers look after them throughout lives because it is inappropriate to release these animals to disrupt the local populations' genetics and habitat. Children of all age groups tend to harvest the vegetables in the garden. These vegetables are usually cooked in the center's kitchen for lunch or afternoon snacks. Sometimes, children over 2 years old assist in the cooking process.

5 year old children also experience the full process of growing rice (plant seeds, tending to the seedlings, harvesting, threshing, polishing by hand). They also make sea salt from sea water collected by some families during their summer vacation trips. The children make "Onigiri" (rice balls) with the handmade sea salt and the harvested rice. These simulated experiences of traditional ways of primary industries contrast with the children's everyday lives, where the family would buy rice, sea salt, and vegetables at the shops, potentially enhancing an economic system view through their shopping experiences. As part of the ecological systems learning at the Centre, the teachers prepare children's books and posters appropriate for learning the life cycles of plants and animals, eco-friendly life styles, and environmental issues. Children also attend excursions to the nature conservation park (four times a year for the 5 year old class, once a year for 3 and 4-year-old classes) and engage in EE programs conducted by outside professionals. The teachers frequently make newsletters for the families and ask them to participate in the Centre's activities. As the Centre aims to develop child-centered pedagogies, the teachers have always tried to achieve this by promoting children's talk and interests and using questions to promote children's thinking and problem solving skills. The teachers continually reflect on their practices and write an annual report from the EE

viewpoint at the end of the school year. The following three vignettes highlight three examples of ecological learning described by the teachers in the annual reports.

Vignette 1

Although caring for animals in the classroom is not a usual practice in lower aged classes (children aged 0–2 years), around 70% of Japanese early childhood services do care for small animals such as insects. The Japanese rhinoceros beetle is a large insect and popular with Japanese children (Fig. 1). Nowadays, it is difficult to find wild Japanese rhinoceros beetles in urban areas because of habitat loss. Usually, teachers would buy the larva or adult beetles at the shops and care for them until their death. Teachers of Tomioka-Nishi CECEC tried to find and care for the insect eggs after the adults' death and made opportunities for the children to learn about its life cycle. Female beetles lay their eggs in the end of summer, the larval stage generally lasts for 8 months, and a beetle develops to an adult in early summer after several weeks of a pupal stage. The larva is around 8 cm at its last stage, and the large larva attracted children; it was easy even for infants to recognize the large larva.

The 0 year old class of Tomioka-Nishi CECEC cared for two Japanese rhinoceros beetle larvae. Officially, the 0-year-old class has children aged from 2 months to 1 year 11 months. Because of their young age, the children could not care for animals by themselves; therefore, the teachers attended to the beetles. The teachers removed large piles of excrement, cleaned the beetles' case, and regularly moistened the soil with a spray to create a suitable environment for beetle larvae. This daily care work was undertaken on the floor where the children could observe the work closely. Sometimes, the teachers showed the large larvae and invited children to touch them. Children tenderly touched the larvae with their small fingers. Three months later, a larva turned into an adult, and the teachers named it "Kabumaru." The teachers continued to care for the beetles and the children continued observing.

Fig. 1 Young children fascinated by a Japanese rhinoceros beetle. (Photograph taken by a teacher)

One morning, Osamu (1 year 3 months) came into the classroom. First, he approached a beetle's case and said "n, n" to one teacher while pointing to the case. The teacher approached him, and they looked into the case together. When the teacher said, "Good morning, Kabumaru," Osamu said, "n, n" again while looking at the teacher and the case alternately. Then, the teacher asked him, "do you want to see Kabumaru?" Osamu nodded. The teacher put the case on the floor. Other children gathered to see the case, and all looked into it when the teacher opened the lid. Osamu stood up, went to the shelf, and pointed to a spray there. When the teacher asked Osamu, "do you want to give Kabumaru 'Shu-Shu'?" (onomatopoeia of spraying in Japanese), he nodded eagerly. Then, the teacher took the spray and sprayed water into the case. Osamu touched the bottom of the bottle as if he had helped the teacher. Osamu observed the beetles and the way the water changed the color of the soil in the case. After spraying, Osamu pointed to the direction of the place with the jelly food for the beetles. The teacher asked him again, "do you want to feed Kabumaru?" Osamu nodded with a smile. When the teacher took some jelly food and opened the lid again, Osamu held out his hand. The teacher put the food on his palm. He gently put it on the soil and observed the movement of the beetles. When the teacher took some more jelly food, another child, Daishi (1 year 1 month), also held out his hand. Daishi also put the jelly gently, just like Osamu. They then looked into the case for a while (Onaka et al., 2016).

Vignette 2

There were plants and small animals in the 1-year-old classroom. A red swamp crawfish named "Momo" had been cared for from when the children were in the 0-year-old classroom, and Momo moved with the children to their new classroom. The children guided a new teacher to Momo's case and told her its name. The teacher, realizing that the children cared about Momo, put cases of plants and animals on the shelves at the same height as the children. The children also loved to observe the larva of a small white butterfly and called the teacher when its food, "Japanese mustard spinach," was finished. When the larva turned into a butterfly, the children asked the teacher to set it free while saying "ah, ah" and looking at the window. The children also loved picture books about the animals they cared for. When snail eggs hatched, the children took a picture book and showed a page of snails that were eating leaves to the teacher. Even the children in the 1-year-old class were aware of other animals' needs. This class started to then care for two Japanese rhinoceros beetles and named them "Chacha" and "Chee" (Fig. 2).

One day, the teacher read a children's book about Japanese rhinoceros beetles. One page showed a picture displaying a beetle taking tree sap from a branch. After reading the book, one boy named Ryota (aged 2 years and 4 months) hurried to the case with the beetles. He looked into the case and the book alternately and said "no, no." He also approached his teacher and said "no tree" and "no leaf." Ryota seemed to be aware of the difference between the natural habitat described in the picture book and the case environment in the classroom. When the teacher said, "we had never seen Chacha and Chee fly, had we?" the children showed expressions of

Fig. 2 The 1-year-old children checking the water spray bottle used to moisten the beetles' caring mat. (Photograph taken by a teacher)

deliberation. Then, the teacher asked the children where they could find trees and leaves. The children answered "outside!" The teacher also proposed that the children release the beetles outside, and they agreed (Onaka et al., 2014).

Vignette 3

The children in the 4-year-old class loved animals and plants. They cared for a turtle and enjoyed finding and observing small creatures in the playground outside. They also tended to the vegetables in the garden (Fig. 3). In mid-May, children planted seeds of asagao (Japanese morning glory). The teacher prepared two large garden planter boxes, and the children put soil bought at a shop into the boxes. The teacher proposed an idea that the children should also add soil from the garden compost. The children mixed the compost soils into one box. When the teacher asked them, "in which soil would the asagaos grow better?" most children answered, "compost soil!" They could answer the questions because the children already knew that compost soil is more nutritious than normal soil. After the small leaves sprouted, the children went to see the boxes, compared them, tried to find the differences, and reported what they found to the teacher. In July, the asagao plants grew well, and the children were delighted to see and observe them carefully: They exclaimed, "the asagaos are starting to go up!" and "all the asagao plants twine to the same direction!"

One day in July, Hiroki (aged 4 years and 7 months) called the teacher and said, "there are different leaves on the asagao." The teacher realized it was a small cherry tomato. However, the teacher just answered, "Yes, we saw similar leaves somewhere else, didn't we?" Although Hiroki started to think about it, he could not get the answer at that time. Several days after, Hiroki called the teacher again and took her to other garden planters where cherry tomatoes were grown. Hiroki said "this leaf is the same!" Then, Hiroki and the teacher picked one leaf from the cherry tomato and went to the boxes of asagao to compare with the leaves of the unknown plant which had leaves that were exactly the same. Hiroki was satisfied with the result.

Fig. 3 The 4-year-old class checking their vegetable garden. (Photograph taken by a teacher)

Several days later, Hiroki told the teacher abruptly, “since then I’ve been thinking.” His statement was so abrupt, and the teacher could not understand what Hiroki was talking about, so she responded, “of what?” Hiroki said, “why a cherry tomato came up in the compost soil? We didn’t plant seeds of cherry tomato.” The teacher was surprised to know Hiroki had held his question about the cherry tomato for several days. Although she knew the answer, again, she just answered “yes, we just planted the seeds of the asagao. It is mysterious, isn’t it?” She did so because she wanted Hiroki to find the answer by himself.

In September, the children tidied up their vegetable garden after harvesting the summer vegetables. The children completed their gardening role by pulling out old cucumbers, eggplants, green peppers, and cherry tomatoes. The teacher found small fruits on the pulled-out stalks. She picked those small fruits and split them in half. The children looked inside and talked together as follows: “it’s a seed, isn’t it?” “the seed looks like a sesame!” and “we can have green peppers and tomatoes when we plant these seeds!” Then, the children cut and took those stalks to the composts. At that time, Hiroki suddenly said, “I got it! There were tomato seeds in the compost soils, and that is why tomatoes grew there!! I didn’t realize it because a tomato seed was hidden in the soils!” The teacher agreed with Hiroki’s solution by saying “a tomato seed had been ‘sleeping’ in the compost soils, hadn’t it?” Hiroki was excited to have found the answer to his long-held question. Afterwards, he reported this to the other teachers and his mother. When the cherry tomato that was grown with the asagao plants died it was taken back to the compost (Onaka et al., 2016).

Discussion of the Vignettes

The children of Tomioka-Nishi CECEC engaged in nature-based activities daily. In these nature-based activities, the children observed animals, plants, and other natural materials. They thought critically, derived questions, sought answers, and felt

empathy with the animals. Such activities have been recommended in early childhood education for a long time to contribute to children's emotional, moral, and cognitive development, as described in the Japanese national curriculum. However, I picked the above three vignettes not because they described the children's developmental achievements but because they included the processes of learning about ecology.

In vignette 1, Osamu cared about the insects and learned that other species also need food and water like humans but in different ways. The understanding of factors to sustain life is the starting point of learning ecology. Food and water are the basic and indispensable factors for all organisms on Earth, including human beings. However, the sort of food and the ways to get food and water differ among species. Osamu also placed the insect jelly "gently" into the caring case. It seems that even a 1-year-old child could feel empathy for other species.

Vignette 2 also described how a 2-year-old child could realize the difference between an artificial caring environment and a real habitat. It included two phases. First, Ryota realized that the beetles in the case and the beetles drawn in the picture book were the same animal. Then, Ryota recognized that the two environments (quality of habitat) were quite different. He understood that it was necessary to have trees in the environment for beetles from the book; therefore, he talked about the absence of trees in the artificial case. From his words, he knew that an environment with trees was better for beetles than an artificial case. This implies that Ryota already had developed basic caring values towards living things and the natural environment. The teacher agreed with his thought, shared his thought with other children, and encouraged his finding by releasing the beetles outside.

In vignette 3, Hiroki observed young leaves very carefully and recognized the difference between asagao and cherry tomato. In addition, this 4-year-old child had kept his question for 2 months. The knowledge gained through one's own experiences might have better retention and deeper understanding than the knowledge given as information from adults. A life cycle is an important factor in ecology; therefore, the recognition of a life cycle through experiences might contribute to learning ecology. In this case, the child understood about the life cycle of a cherry tomato: germinating from seed, sprouting, growing, flowering, fruiting, and dying. This cycle requires 1 year. It is easier to understand a life cycle by observing real plants and fruits. However, it might be more difficult for young children to imagine seeds dropping into soils and being dormant for half a year. In this case, the teacher selected familiar vegetables for the garden every year and used the compost soils for planting flowers and vegetables. In addition, the teacher had faith in Hiroki and waited for him to solve the problem by himself.

These vignettes show that young children including toddlers can learn basic ecological concepts. Even toddlers could understand the necessity of food and appropriate habitat for animals, and care about them. The 4-year-old child could understand a life cycle of a plant. These vignettes could be called traditional nature-based activities (caring for animals and gardening), and we can recognize many aspects of children's development within these vignettes. However, the teachers practiced these nature-based activities for not only the children's physical, emotional, moral, and cognitive

development, but also for the learning of ecology. It is the latter which will decide whether the activity is a practice of education for sustainability or not. The teachers at the Centre now always create learning environments from the perspective of learning ecology (e.g., compost, selection of children's books, vegetable garden, and caring for small animals in the classroom) and enhance children's awareness of the relationship between living things and their environment with their ecological lens. The learning and teaching experiences at the Tomioka-Nishi CECEC demonstrate that it is also important to connect different activities and repeat similar experiences many times from the viewpoint of learning ecology.

Ways to Rethink Children and Nature in Early Childhood Education

Fostering Teachers' Ecological Lens

Fostering an ecological lens perspective might be difficult for Japanese early childhood teachers because they have been provided with few opportunities to learn ecology in school themselves. As mentioned previously, although all Japanese students are provided opportunities to learn ecology in schools, the ecology they learn is very basic and superficial. In addition, preservice education for early childhood teachers in training schools (4 years in the university or 2 years in college), which is strictly regulated by the government of Japan, provides various subjects under the national law and regulations. However, most subjects are related to pedagogy, psychology, sociology, or teaching skills. Most training schools do not offer enough opportunities to learn environmental science, EE, and teaching skills for nature-based activities (Inoue, 2008). There are also few opportunities to learn ecology or sustainability in the teachers' professional development once they are in the workforce (Inoue, 2017). As a result, Japanese early childhood teachers may not have deep knowledge of ecology, and this knowledge has limited influence on the teacher's thinking, beliefs, and teaching; that is, the teachers' education and professional development rarely support their development of an ecological worldview.

Japanese early childhood teachers already have many resources for teaching traditional nature-based activities through professional development, books, and professional magazines. However, I argue that simply using materials or programs of traditional nature-based activities will not foster an ecological worldview. As shown in the vignettes, the teachers with an ecological lens can plan activities with appropriate aims of learning ecology, arrange an appropriate learning environment, and observe children's words and behaviors from the viewpoint of an ecological worldview. At the early stages in the 8 years of the practice study by Tomioka-Nishi CECEC, the teachers were unable to focus on words and behaviors that indicate children's awareness or experiences of ecological systems. The teachers just talked about children's development. Teachers with an ecological lens do not regard animals and plants, which are the components in the Earth's ecosystem, as teaching resources or materials just for human benefit. When a

teacher looks at a leaf through an ecological lens, she/he may find a hole on it and think of what caused the hole or find the tree from which the leaf came and imagine what kind of insects, birds, or other animals will use the fallen leaf or the tree. This extension of concepts through an ecological lens might lead early childhood teachers to reflect on their practices. To foster an ecological lens in early childhood teachers beyond a textbook knowledge of ecology, it is necessary to strengthen preservice teacher training curriculum and professional development from the viewpoint of ecology.

Pedagogy for Fostering an Ecological Worldview

The vignettes of Tomioka-Nishi CECEC focused on nature-based activities such as caring for small animals, gardening, and outdoor play. Although the vignettes were based on the children's on-going activities and seemed to be fragmented at a glance, such real activities were not fragmented in the children's daily lives. For example, the children encountered a variety of organisms, managed compost, and recognized life cycles and food webs through gardening. They were able to observe the same vegetables that grow in their Centre garden being sold in shops, the cost of the vegetables, and the separation of the vegetable wrappings or waste from vegetables from the Earth's ecosystem in contrast to their composting of scraps. They were also able to consider how and who produced and transported the vegetables in the shops. Through these experiences, the children learned how economic and social events are fundamentally related to the natural world. So the children's various experiences in their everyday lives could be connected and integrated as a whole to foster an ecological worldview.

Summary and Conclusions: A New Role for Nature-Based Activities

In the late twentieth century, EE/ESD/EfS emerged as a new educational field in response to the environmental crises of the Anthropocene. Furthermore, in recent years, such forms of education are recommended to start in early childhood (Davis & Elliott, 2014). Although the role of ecology has always been described as one element of sustainability concepts, ecological systems thinking or ecological worldviews have not been identified as a high-priority topic in education. However, a sustainable society is actualized only on the basis of ecological worldviews, not of economic worldviews (Krebs, 2008; Schmitz, 2016). Therefore, the proponents of EE/ESD/EfS have recognized the importance of nature-based activities such as gardening, caring for animals, or playing in outdoor nature spaces to promote ecological worldviews. However, for example in Japan, such traditional nature-based activities already have been included in formal early education for a long time (since the nineteenth century), and their aims and objectives have focused on children's development per se, and not on

the development of ecological systems thinking or ecological worldviews that might contribute to addressing sustainability concerns. The vignettes from a Japanese early childhood center illustrate that even children at the earliest stages of their lives have the potential to learn ecology and that it is possible to foster an ecological worldview at this age. I propose that learning from traditional primary industry practices or indigenous cultures might contribute to fostering ecological worldviews; however, the teacher's role in this is most important. As the Japanese vignettes presented in this Chapter show, those teachers with an "ecological lens" can rethink existing nature-based activities to foster learning about ecology.

In Japanese early childhood education, theorists and practitioners recognize that the quality of the learning environment is extremely important for children's development. However, for many teachers, the natural world is just a material or an educational resource. This paradigm is homogeneous with a worldview that the natural world exists for the use of human beings and contradicts the childhoodnature perspective that is central to this Handbook. Education in this paradigm reproduces people whose economic worldviews place value mainly on their own selves. However, the health of the natural world is the most fundamental and essential factor for sustainability where humans are recognized as nature and thus interconnected with nonhuman nature, as represented by childhoodnature. Therefore, a paradigm shift from education based on the economic worldview to education based on the ecological worldview is necessary for sustainability. This signals a new role for nature-based activities in education, including early education. Education remains one of the important strategies for building a sustainable society, as Dewey (1916) aptly summarizes in the following: "In directing the activities of the young, society determines its own future in determining that of the young" (p. 48).

Abstract

We appeal to non-human nature as the standard against which human uses of natural resources should be judged, while childhood is often viewed as a natural state of being that is universal across all settings and children. Yet there is no natural childhood, and nature is a profoundly human construct. I offer this perspective as one way to frame childhoodnature. This Chapter explores the fundamental essence of childhood (*its nature*) and problematizes childhood vis-à-vis nature in order to question the assumptions with which we articulate our world. Integrated into this Chapter are memoirs of my life as a child and a scholar. A systems approach draws

attention to the networks of power and privilege that shape the physical as well as lived realities of children. Children's drawings from different countries are presented to highlight how visual, written, and unspoken narratives normalize culturally based ideas of people-place relationships. They reveal children's connections to the environment and help us understand not only what children are thinking, but also what they are being taught to think. Recognizing the nature of childhood in childhoodnature is to confront this reality.

Keywords
Childhood · Nature · Symbolism

Introduction

This photograph of a young child at the annual National Western Stock Show in Colorado, USA (Fig. 1) portrays the symbolic and at times, paradoxical nature of childhood. Notice how she is dressed in ways that conform to sociocultural conventions (e.g., Stetson, boots) and gendered norms (e.g., pink clothing) at the Stock

Fig. 1 Image of child at the National Western Stock Show, Colorado, USA (photographed by author)

Show. She is being acculturated into a known adulthood yet unable to, as a child, inhabit adult spaces. Dressed as a "cowgirl" and juxtaposed against the whiskey bottle in the background, she is simultaneously in and out of place.

The Symbolic Nature of Childhood

I begin with this image and interpretation because childhood "is more often than not the outcome of negotiating and enduring the mythologies of social reproduction" (Aitken, 2001, p. 59). Childhood is a human construct embedded in cultural and political structures that regulate (via social reproduction) the ways children think, how they act, and critically for this Chapter, how we think and how we act with regard to children. Furthermore, the symbols that we use in our research and teaching, such as language, are governed by a collective set of beliefs about what childhood is/is not. Dewey (2000) emphasizes the importance of symbolism in human experience when he writes that:

> Symbolism dominates social organization...rites, designs and patterns are all charged with a significance which is immediate and direct to those who have and celebrate them. Symbols are...condensed substitutes of actual things and events, *which embody actual things with more direct and enhanced import than do the things themselves* [italics added] (pp. 82–83).

Examples of symbolism in childhood include myths of "childlike purity" (Cronon, 1996) and romanticized views of children as innocent beings (Baader, 2016). Piaget's (1969) stages of natural development categorized learners' cognitive growth based on age, a symbol of linear maturation. A greater recognition of sociocultural influences on learning (Vygotsky, 1962) has promulgated development of the whole child (Dewey, 1990) but this ideology continues to be contested in modern industrialized societies, particularly schools (Stevenson, 2007). Schools embody an enlightenment view of the child as *tabula rasa* – a blank slate on which societal norms and values are inscribed (Baader, 2016). Symbolically, therefore, schools are institutional spaces for children, governed by adults' perceptions of appropriate knowledge and behavior (Stevenson, 2007; Thomson, 2007). By extension, the practice of schooling serves to prepare children for participation in adult society. We have, by and large, popularized views of children as naive learners and childhood as a relatively deterministic process by which children simply "become" adults (Holloway and Valentine, 2000). More recently and specific to this volume, research has shown that children tend to invest nature with symbolic qualities, e.g., anthropomorphism, as well as moral imperatives, e.g., anthropocentrism (Kellert, 2002; Wee, 2012). Linked to these broader themes of child-environment relationships is the modern-day crisis of children missing out on symbolically valuable experiences in nature, as children in Minority western nations spend more time indoors and are increasingly disconnected from their surroundings (Hayward, 2012; Louv, 2005).

My intent is not to point a critical finger at the ways we have constructed meanings about childhood or the meanings themselves. Instead, I wish to highlight

the prevalence of symbolisms in our everyday moments of life and describe how symbols and their meanings structure the-way-things-are for children. I am hopeful that this Chapter will examine carefully accepted norms with regard to childhood and nature, so as to "bracket the inescapable presuppositions and biases of our horizon" (Chawla, 2002, p. 205). As Jones (2002, p. 18) astutely notes, "if we wish to readjust [human-nature relationships], we have to excavate and critically examine the understandings and assumptions with which we articulate the world." We need to ask where or how things came to be, and where possible, investigate the contexts within which this happens. Consequently, the goal of this Chapter is to explore the fundamental essence of childhood (*its nature*), then to problematize it vis-à-vis nature in order to clarify and advance the concept of childhoodnature.

Systems and Childhood

This focus on the symbolic nature of childhood vis-à-vis nature is intended to encourage a deeper appreciation of the fact that we are bound together in interdependent, complex networks of people-place relationships, or systems. Systems refer to an ensemble of interacting parts that is more than just the sum of its components (Chen and Stroup, 1993). Systems thinking de-emphasizes reductionism, where parts are examined independently and without consideration of contexts (Simon et al., 2013). Relationships within/between components of systems are integral to understanding how they operate as pieces of a larger, interconnected whole. The use of systems in this context sensitizes us to people who are either spatially removed or on the margins of societies, as well as to places we may not be directly connected to but are nonetheless impacted by our actions or inaction (McEwan and Goodman, 2010). For example, Project WILD is an environmental curriculum written in the US but implemented with a broad, cut-and-paste approach worldwide, e.g., Japan. A systems perspective helps us to recognize the challenges of translating words as well as meanings across socio-linguistic settings. It also illustrates how children's agency is materially constituted through performative practices e.g. environmental learning with Project WILD in Japan is framed by a different (US) set of cultural views and values (Spyrou, 2016; Wee and Mason, 2016).

More specifically, systems help us understand and appreciate childhood as a construct shaped by "asymmetries of power and privilege" (McLaren 1989 in Aitken, 2001, p. 170). During a study with children in Stockholm, I asked them whose responsibility it was to solve environmental problems. In one interview, a 13-year-old boy explained that:

> Adults should 'handle' the environment. Kids can do it too, but the adults know more than children, and they can tell the children what to do (translated from Swedish).

Contained in this quote are references to different systems of power and privilege. Firstly, there is the hierarchical power structure that governs adult-child interactions, e.g., "adults know more than children" and "adults can tell children what to do."

There is also the material reality of this child's life, where his perceived ability to affect environmental change ("kids can do it too") may reflect a privilege in Stockholm relative to children in other cities or countries.

Systems also help us consider how childhood interacts with the processes of globalization, and the corresponding spatial representations of power and privilege (Massey, 2013). For example, back-to-nature movements that involve getting children outdoors are an increasingly common phenomenon in Minority western nations, particularly as spaces urbanize. However, the accompanying global discourse about children's safety (or lack thereof) robs them of their autonomy as local places are systematically transformed into structured landscapes where children can "safely rehearse for a known adulthood" (Aitken, 2001, p. 177). Any discussions about childhoodnature, therefore, need to consider not only the physical realities of our world, but also the systems that shape the lived realities of children who inhabit it.

Children | Childhood | Nature

While children and childhood are terms that overlap in use, they are not synonymous with each other. For instance, children who interact with their surroundings represent, "the familiar world of everyday life characterized in terms of the individual" (Barab and Roth, 2006, p. 7). Childhood, on the other hand, embeds children's interactions in cultural systems that determine what it means to be a child. In other words, children inhabit the socially defined world of childhood. Intended to be distinct from adulthood, childhood is in fact largely determined by adults (Thomson, 2007). Toys, playgrounds, textbooks, illustrations, and other primary forms of learning in childhood are typically designed, constructed, written, drawn, and taught by adults for children. Likewise, children are typically presented with an adult-driven idea of nature (in children's literature, television, animated films, games, and other media), symbolized by scenes of wild nature or visions of pristine landscapes that are really more about aesthetic, perhaps even artificial, vistas than they are actual places (Proctor, 1996; Jones, 2002). These are, according to Bavidge (2006), some of the most powerful ways by which nature is interpreted for and explained to, children. Not surprisingly, children's references to nature tend to conjure images of natural habitats untouched by humans when in reality, only a handful of places remain that exist independently of humans. Indeed, any decision to maintain a place in its natural state is already a human imprint, if only abstractly.

Placing childhood and nature on either end of a human–non-human spectrum, however, is misleading because it does not represent those extremes. We appeal to non-human nature as the standard against which human uses of natural resources should be judged (Cronon, 1996), and childhood is often viewed as a natural state of being that is universal across all settings and children. Yet there is no natural childhood, and nature is a profoundly human construct. I offer this perspective as one way to frame childhoodnature. For example, my experiences as a child were shaped by a particular versioning of childhood in the early seventies, and it influenced how I view nature. Similarly, because nature is a construct that exists in a

socially-defined setting, that in turn influenced my experiences as a child and gave rise to different ways of accessing natural spaces. This interdependent relationship between children, childhood, and nature has led geographers like Yi-Fu Tuan (1977) to describe how we dwell in places, that is, how human feelings and experiences render new spaces familiar over time. When children attach meanings to places, they carry these attachments with them to guide their interactions with nature. To better appreciate these connections, therefore, we need to understand how children (how we) dwell in places. We need to know their (our) stories.

The following sections ("My Childhood;" "My Early Years as a Scholar: Children's Environmental Views;" "My Later Years as a Scholar: Children's Environmental Discourse") are personal narratives or memoirs that describe a life lived along the contours of childhood and nature. They also point to our responsibilities as researchers to approach our work with more nuance, intentionality and respect for the lives of children. *We are our stories* (H. Mason, personal communication, July 9, 2017).

My Childhood

Growing up in what was then a racially diverse, backwater space in Singapore, I ran around barefoot, played in storm drains, and whenever I could, tried to avoid adults and their rules about acting more like a "grown-up." They could not understand why someone would spend hours squatting at a ditch trying to spot/catch a multicolored rainbow fish, or why I cried when the tadpoles in my hands stopped wriggling. Thankfully my parents recognized this early affinity for living things, and over the years I was afforded the privilege of caring for a menagerie of animals. When I was allowed to read during school break (books were considered a distraction from homework), I would go to the public library and immerse myself in the adventures of James Herriot and Dr. Doolittle.

I never considered myself a child raised "in nature" – this was simply the environment I grew up in, and I adapted to its opportunities as well as constraints. For example, I hated staying at home because that meant I had to listen to my parents yell at each other or at my grandmother. As a child, therefore, the very first thing I saved up money to purchase was a bicycle. I relished the freedom it provided, the power to escape bickering adults, to choose where I would go, and to learn about the place I lived. I traveled along tree-lined roads, up and down hills, and eventually across the entire island several times. As a youth, I volunteered at the local animal shelter, took a position as a zookeeper and cleaned cages while learning how to breed/raise endangered bird species. Following that, I surveyed populations of feral pigs and invertebrates on an offshore preserve for the national parks board. At the time, I felt I had exhausted all the opportunities that (a rapidly urbanizing) Singapore could offer in terms of nature-related experiences. And so, I ended up in a land far from everything familiar to pursue graduate studies in conservation biology and later, environmental education. By then, I had effectively become isolated from my peers and family. I was in my thirties and still in school, studying a subject that was

not really understood or appreciated. I had no full-time job and massive student loans. Swept up with my new life abroad and consumed by my studies, I did not maintain relationships. To my friends in Singapore, I was an anomaly. To my parents, a disappointment.

My Early Years as a Scholar: Children's Environmental Views

How did I end up on such a trajectory? Was my childhood, with its privileged affordances to nature, a turning point in my relationships with places and people? These questions drove me to explore children's environmental views. It is important to note that I was unfamiliar with the construct of childhood at the time. My motivations for research with children were grounded in personal experiences rather than a notion of the individual/child nested within broader cultural systems. I based my work on social constructivist views of learning, surmising that children actively construct meanings from diverse interactions with (in) their environments. As a result, different children will generate different ideas about the environment, and these vary by place. This necessitated inclusive approaches not only in educational practice but also in the ways I engaged research with children (Barratt Hacking et al., 2007). For example, I spent one semester in a middle school classroom getting to know the teacher and students as people (not as participants) before gathering data for my dissertation. Mixing the expertise of my graduate advisors with personal interests in photography, I utilized qualitative and visual methods (drawings, photo-elicitation, interviews) to ask children from different countries one essential question: **What is the environment?**

My research about children's environmental views spans four countries and three continents: US, China, Singapore, and Sweden, each representing different geographical, sociocultural, and linguistic contexts. All the while I strove to understand the environment from children's perspectives – how did children view the environment, what were the dominant themes if any, that permeated their thinking and guided their actions? Table 1 outlines a typology of children-environment relationships that have emerged from over a decade of this work (see for example, Wee et al., 2006; Shepardson et al., 2007; Wee, 2009, 2012; Wee and Mason, 2016).

For children, the environment is largely synonymous with non-human nature; it exists separately from humans. In this drawing of the environment (Fig. 2), the child

Table 1 A typology of themes that consistently appear in children's drawings of the environment

Theme	What is the environment
Nonhuman nature	The environment exists separately from humans
Stewardship	The environment needs to be protected and cared for by humans
Anthropocentrism	The environment allows humans to survive and/or thrive e.g. oxygen from trees, food from plants and animals
Positive nature | negative humans	The environment is "in balance." When the environment is "out of balance" it is primarily due to large-scale human impacts, e.g., deforestation, climate change

Fig. 2 Drawing of the environment as non-human nature, USA

writes, "open fields that no one pays attention to." This dualism between humans and nature, however, exists in varying degrees. Children living in highly urbanized settings, such as Singapore and China, are more likely than their counterparts in rural areas to include human elements such as roads and buildings. It makes sense that life in different places represents different sets of realities for children. Children inhabiting cities, for example, tend to be immersed in built environments. Over time, these landscapes become part of children's everyday lives. How then, to explain the dominance and consistency of children (from different countries) viewing the environment as being synonymous with non-human nature? It is plausible that in addition to place-specific qualities, children's realities are also embedded with dominant environmental discourses that interpret the environment *for* children (Hajer, 2000). As noted earlier, this can take the form of textbooks, children's literature, social media and other outlets where formal as well as informal environmental learning occurs.

In addition to a synonymy with nonhuman nature, children's representations of the environment tend to include ecosystems "in balance." Animals are happy, symmetrical trees are always in leaf and the sun is shining (Fig. 3). Very few children, if at all, include dynamic environmental systems e.g. predator-prey relationships or changing weather patterns. This echoes the point made earlier about the prototypical version of nature that is presented to children by adults. Within this hierarchical power structure, children internalize nature as pristine and static. When ecosystems are thrown "out of balance," these are typically attributed to human activities (e.g., deforestation) rather than natural events (e.g., hurricanes). Negative human impacts are often extensive and visible. For example, air pollution (smoke stacks, car exhaust fumes), water pollution (toxic or solid waste), and more recently, climate change. Humans are also regarded by children as environmental stewards, e.g., since trees provide oxygen and clean the air, humans are responsible for the long-term care and protection of trees.

Children's environmental views are well documented (see for example, Kahn Jr., 2002; Kellert, 2002). It is not the purpose of this Chapter to delve into that literature,

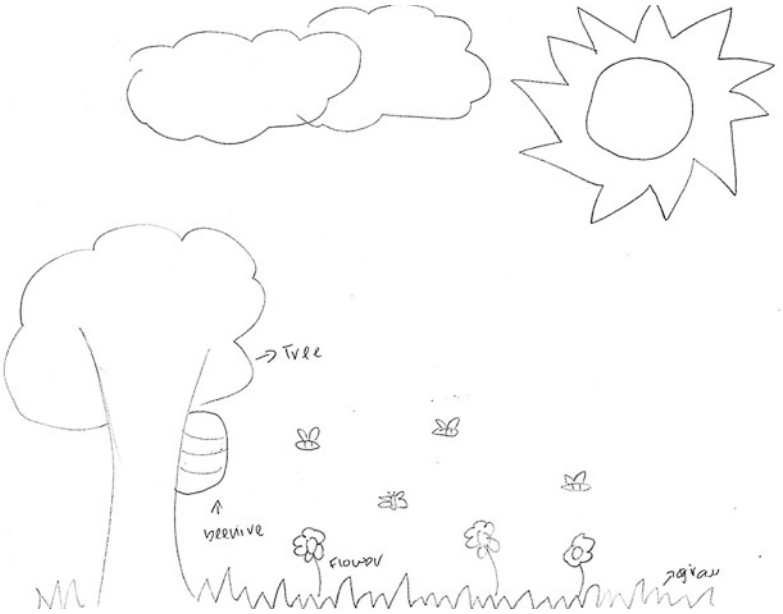

Fig. 3 Drawing of the environment "in balance," Singapore

suffice to say the stewardship ethic described above continues to reinforce the stereotype that nature exists to serve people's needs. When natural resources are key to the wellbeing of individuals and communities, the extrinsic (rather than intrinsic) value of nature tends to guide decision-making. Though well intentioned, this places human welfare at the forefront of political action and moral concern, whereby humans are both a part of yet above nature (Kopnina, 2012). This form of anthropocentrism also "divides the contiguous fabric of life into oppositional binary categories" (Whitehouse, 2011, p. 296) – human and non-human. Consequently, there are those who argue for an egalitarian viewpoint, one that embraces the intrinsic value of all life as a rationale for environmental protection. Deep ecology, for example, views humans as one of many species that is no more or less important in terms of value to healthy ecosystems (Capra, 1995). My goal is not to debate the varied positions but to ask deeper questions about the social norms and discourses that regulate children's environmental views.

My Later Years as a Scholar: Children's Environmental Discourse

Why do children's environmental views seem almost ubiquitous across time and space? That the environment is embedded with discursive meanings did not occur to me until I began to wonder about repetitive patterns in my findings. Language, in particular, is one of the (many) contexts within which meanings are defined, accepted and carried over from one generation to the next. Furthermore, the meaning of the word

"environment" is related to something outside itself, and it shapes research in/with/about the environment. In the English language, for example, the environment is typically defined as the abiotic and biotic factors that affect an organism. This in turn objectifies the environment, turning it into an entity that can be managed to insure survival. This "nature-as-object" perspective is reinforced when the environment falls within the language of the natural sciences, which is often the case in English-speaking countries (Bonnett, 1999). Conversely, Whitehouse (2011) describes how indigenous Djabugay in Australia have no externalized environment in their language. For the Djabugay, people and places are expressed linguistically as the sum of their parts.

It dawned on me that research on children, childhood and nature had primarily been conducted in English, the dominant language within higher education and indeed much of the developed world. By extension, it made sense that the sociolinguistic properties of "environment" might be different in different languages. For example, there is no equivalent word for "environment" in Chinese. Translational equivalency does not always exist, nor should it, because different realities are constituted differently by different languages (Whorf, 1956). With that in mind and given my sociolinguistic heritage, I elected to shift my focus toward the Chinese language, and how children used it to describe the environment. China and Singapore are two places where I have engaged in this work. Both nations showcase rapid economic growth spurred by local as well as foreign investments, political structures that allow for unilateral decision-making, and guarded optimism about progressive cultural changes. In that regard, these countries represent a unique mix of "Western and Asian."

The fact that Chinese-speaking children held similar environmental views to their English-speaking counterparts suggested to me that there might be a standardized account of the environment, reinforced by language and other forms of discursive practices (Wee, 2012). For example, China and Singapore draw heavily on western ideologies to inform environmental and educational policies. In some instances, environmental education curricula are directly translated from English to Chinese, then applied wholesale in classrooms (Wee and Mason, 2016). For children to communicate effectively in linguistic communities, they are required to use words and meanings that are made available to them through learned behaviors. In other words, the language used to describe the environment tells us not only what children are thinking, but also what they are being taught to think.

Language and discourse are examples of hidden mechanisms in systems that maintain power once words have achieved the status of "common sense" (Foucault, 1972). Yet we are rarely asked to articulate the fundamental essence of words. We do not have to redefine words like environment because they represent,

> ...relations and identities which have themselves been reified into institutions...the discursive constitution [of these terms] does not emanate from a free play of ideas in people's heads but from a social practice which is firmly rooted in and oriented to real, material structures (Fairclough, 1992, p. 92).

The prevalence of similarities in children's environmental views across cultures suggests that default modes of thinking are being utilized. If so, then problematizing

childhoodnature presents an opportunity to uncover the wider social and institutional relations within which children's language and discourse about the environment is situated, and ultimately shaped.

Problematizing Childhoodnature

The term "problematize" does not refer to a critical analysis of childhoodnature discourses but rather, the questioning of deeply held assumptions. In this regard, problematizing is similar to the notion of "troubling," where to trouble is "to unsettle," to "reject the all-too-easy and unproblematized desire to render children and their worlds comprehensible and transparent" (Spyrou, 2016, p.106). As a graduate student and even as a tenure-track faculty, I was never encouraged to problematize or trouble my research. There was simply no incentive to transgress boundaries or to embrace resistance, especially when the consequences of doing so could prove dire for tenure, funding and/or my perceived credibility in academia. Instead, I shaped myself into a scholar who, like many others, never explicitly questioned if research efforts reproduced stereotypes or reaffirmed inequities. For example, while I advocated for the rights of children and for the validity of their perspectives, I never really considered that my positionality as an adult might inadvertently reinforce certain views of childhood. I was trained to be introspective as a researcher, but not to recognize myself as co-shaper of children's realities through discursive practices in research. It is for this (and other reasons) that I have tried to illuminate the processes that gave rise to my voice, and from there, to provide an entry point into a critical look at childhoodnature.

Childhoodnature

Childhoodnature offers a unique opportunity to touch on the subtleties of our scholarship in ways that emphasize dynamic relationships between children and nature. For example, children *as* nature rather than children *in* nature represent a decidedly less anthropocentric perspective. Similarly, Whitehouse (2011) describes how in Australia, the term "country" has been adopted in lieu of "environment" to emphasize relationships between humans and the land, "to recover the concept of caring for country as a means of managing the environment" (p. 300).

Childhoodnature offers a timely response to the realities of a rapidly changing world. De-emphasizing an anthropocentric relationship between children and nature can promote the intrinsic value of natural environments. At the same time, however, this should not cloud the fact that childhoodnature as a concept operates at a cultural interface, whereby an implied ethic filters and dictates views of our scholarship. As described earlier, research and teaching is governed by a collective set of beliefs about what childhood is/is not. These are manifested in our languages and practices. When we advocate for children's rights, greater agency for children or a shift away from anthropocentrism through our work in childhoodnature, we are using moral and epistemological standards to address broader issues. This is not to say that we should

never attempt to advocate for a particular worldview. On the contrary, it is precisely this type of dialogue that helps us identify broader material transformations (Aitken, 2001). It does entail, however, the need to be cautious in our efforts to claim something as being better or true because even well-intentioned efforts could potentially end up privileging one set of imperatives over others (Kopnina, 2012). As Tuan (1991) notes, "speech – the right to speak and be heard, the right to name and have that name 'stick' – is empowerment" (p. 685). Any consideration of childhoodnature, therefore, needs to include discussions about whose childhood we are referring to, as well as recognition that contestations of nature constitute everyday realities for children.

Whose Childhood?

When Proctor (1996) asks "whose nature" is being prioritized in resource conservation, he is referring to a dominant viewpoint established within a cultural-based idea of nature. In the same vein, one could ask "whose childhood" is being prioritized in childhoodnature. In the Environmental Education Research special issue on Childhood and Environment, Barratt Hacking et al. (2007) describe ways to engage children more equitably in research and to support children's participation in environmental learning. While commendable, there was no explicit mention of the need to first reveal the underlying norms that presuppose our expectations of research processes and outcomes that are deemed inclusive. For example, we seek "authenticity" in our research by building trust and using methods that are accessible to children. However, we also seek data that are "usable." Armed with a compulsion to systematically capture children's voices from our perspectives as researchers, we may unintentionally render children silent (Spyrou, 2016). Features of childhood that are incongruent with our methodologies are likely to escape us, along with nuanced meanings of what children are trying to say. Lather (2009) in Spyrou (2016) adds that the desire for empathy establishes oneness between researchers and children when in fact respect for differences should guide our inquiries. This enables us to move beyond fixed points of knowing that exist within pre-conceived categories of childhood (Spyrou, 2016).

Childhood learning is not only about the degree of choice that children have in exercising their options, but also about the choices that are made for children, either intentionally or unintentionally. For example, "charismatic megafauna" continue to dominate the characters used in children's books, as well as mainstream television programs and animated films for children. Nature also plays a significant role in children's stories about the development of morals and identities (Kellert, 1993). In fact, Mergen (2003) asks the difficult question of whether we are, as adults, imposing our preferences on children because we are the ones who wish to live vicariously through them. This suggests that the argument to be in/as nature is for *everyone*, not only children. We create archetypes when we accept without question, the everyday, even though it is "an important sphere of contestation, struggle and resistance" (Giroux, 1992), and it reiterates the need to question our assumptions of childhood.

Children in Nature Contested and Resisted

In the US, a popular view of children in nature involves idealized experiences such as climbing trees, digging holes, peering under rocks, getting dirty, and generally being immersed in the textured details of their immediate surroundings (Mergen, 2003). In this case, nature refers not only to the setting where children's activities take place but also the presumed "naturalness" of children's behaviors. Yet this idea of children in nature is frequently *contested* as children face increasing concerns about their safety, which results from adults' fear of crime, bullying as well as inadvertent injuries. Importantly, even if children were given the spaces and freedoms to behave instinctively, not all children would necessarily lean toward these idealized interactions. Children from racial minorities residing in low-income urban neighborhoods, for example, *resist* stereotypes of nature-based interactions when they prefer to run in the streets or simply hang out with relatives (Wee and Anthamatten, 2014). Baylina et al. (2011) found that children in Mexico City frequently used playgrounds located under busy highways. Children and youth living in densely populated, high-rise apartment buildings in Singapore spent time at the "void deck" (open spaces at the base of these buildings) instead of natural spaces such as gardens or house yards that they had no access to (Skelton and Hamed, 2011).

Our views of childhood and nature often end up dictating children's experiences. For example, the stereotype that nature is dangerous may result in fewer outdoor experiences for children (Kong, 2000). When children are "in nature," our expectations of childhood places them under such scrutiny that they are, ironically, discouraged from seeking their own adventures. Children also face immense pressure to follow adult-sanctioned rules. Physical and social borders firmly entrench children in their position as "adults-in-waiting." We put up fences in playgrounds or parks, and post signs that issue a list of acceptable behaviors (Thomson, 2007). Gender norms are also a contributing factor, where girls are given less freedom than boys at the same age to travel afar (Wee and Anthamatten, 2014). In Singapore, adults maintain spatial hegemony over children and youth by policing for "delinquent" actions in public spaces (Skelton and Hamed, 2011).

Rules regarding "proper" behavior distances children from the environments they inhabit, making it much more difficult for them to interact with (in) nature. Is it any wonder then, that we worry about children losing their spontaneity and creativity to fully experience their surroundings, or that they grow up to become adults who prefer seeing breathtaking views from the comfort of their car than they might on a trail? This is not to suggest that there is a right way for children to experience nature. Instead, we should recognize how childhoodnature is inherently shaped by the normalizations of childhood. Children growing up in an information and technology era, for example, have different views and realities about nature. Hayward (2012) describes how young children growing up on Google earth (in reference to the free software program that provides real time aerial as well as street-level views) are more comfortable learning about places on computers than they are actually exploring them in person. In his study of Boys and Girls Clubs in Denver, Martz (2017) found that experiences "in nature" were not significant enough to warrant inclusion in children's journals. These children spent one week engaged in outdoor activities at a camp with less adult supervision than

they encountered on an everyday basis. When these children were later asked to provide pictures of places where they enjoyed spending time, they chose familiar, urban spaces (e.g., fast food outlets) where they "hung out" with friends and/or family.

The Nature of Childhood in Cities

Worldwide, the majority of children live in cities (UNICEF, 2012). It is important, therefore, to consider the relationship between urban spaces and childhood, especially how systems of power and privilege affect children. With urban growth and development on the rise, green spaces gradually become adult spaces as children become less prominent in the design/use of urban terrain. For example, children who "hang out" in public parks or streets in the United Kingdom "transgress the boundaries defined by adults [through the] nonconforming usage of places" (Matthews and Limb, 1999, p. 69). Contrary to such practices in Minority western countries, children in Singapore are actually welcomed in shopping malls as these are considered "training grounds" for consumptive practices that are encouraged by the government (Skelton and Hamed, 2011). Nevertheless, spaces for children have undergone transformation as the intensity of urban living increases. Removing unofficial uses of spaces for imaginative play also removes children as a feature of contemporary life in cities and leads to the withdrawal of children from public urban spaces.

The city also presents a symbolic tension between romanticized notions of childhood as a state of innocence, and the urban as a place of corruption and danger (Jones, 2002). This dichotomy is problematic as adults' expectations and assumptions about children change in urban spaces, e.g., safety concerns may limit the types of activities children engage in, where and with whom they play. Berg (1972) in Jones (2002) notes that, "cities hate children because of the lack of contact with nature, because of the fear which confines them, and because of the control placed on them" (p. 22). In response, people have moved to suburban areas where families are afforded more "freedom." As Malone (2007) points out, however, children in these places still end up being "bubble-wrapped" for protection, with few opportunities for individual mobility or autonomous explorations/play. Adult expectations of childhood continue to persist regardless of setting (urban or suburban). This places constraints on children's lives and how they choose to live them. Furthermore, this "flight from the city" may bring with it unintended consequences such as gentrification, where rising property prices driven by middle class in-migration isolates poorer families, and ironically makes it more difficult to access children's places such as schools and parks (Malone, 2007).

Malone (2007, p. 525) argues for a shift away from this "protectionist paradigm" toward communities where parents and children can feel safe, and for teachers to engage students in active learning. Gill (2008) suggests a space-oriented approach that would provide easy and welcoming access to public areas, a child-friendly transportation system, and school grounds that are freely available when the school day is over. Here, the emphasis is not on bringing children to nature or vice versa (both of which accentuate the human-non-human divide), but on changing our conceptions of children, childhood and nature. In addition to these proposed changes, there are facets of

modernity that have brought advantages to children in a rapidly urbanizing world, e.g., the ability to view nature through high-resolution images on smartphones (Barton, 2012). This, however, physically distances children from natural spaces, e.g., there is no need to venture outside if nature is available on the phone. It is also important to recognize that access to technology is a privilege in a digital world, e.g., there are over 300 million children and youth who are not connected to the internet (UNICEF, 2017). According to Jones (2002), these tensions represent the globalization of childhood, with Internet and communication technologies reconfiguring how children inhabit urban environments and how they access public outdoor spaces.

Conclusion

This childhood we are discussing is different than those of our parents and their parents. Children's lives today "seem more confined, pressurized and commodified, and yet maybe they are liberated in other ways too – through access to information, technology and related lifestyles and identities" (Jones, 2002, p. 17). This new world exists for children in ways that as adults we may never know or come to understand. Recognizing the nature of childhood in childhoodnature is not only to confront this reality, but also the boundaries of our/children's existence. Borders are drawn for children within differentiated systems of power and privilege. Childhood and nature are managed in ways that conform to adult expectations. We recognize the need for children to be in nature but are reluctant to let children do so themselves. It is a contradiction maintained by normalizations and discourses, as evidenced by this sign at the zoo that reads, "have fun playing in nature but stick to the pathways, please." (Fig. 4).

Fig. 4 Image of a sign at the Denver Zoo (photographed by author)

This paradox brings the concept of childhoodnature into sharper relief and highlights the need to further explore its fundamental assumptions. Whose ideals does childhoodnature represent and what roles do children have in that vision? Children's realities are either expanded or constrained based on the representations of childhood that are imposed on them. Will future generations of children simply echo our voices of change or can they become the change that this world needs? The answer to that question requires us to move beyond the what of childhoodnature to further investigate the *why* and the *how* of it.

context of childhood that is increasingly screen mediated. Priveleged, Minority western modernity perspectives dominate, with a harking back to a romantic view of (usually young) children frolicking in nature. Rarely is there consideration of diversity within the discourse, in terms of lifestage or cultural, geographic, and socioeconomic contexts. In this Chapter, adolescents from a range of Majority (world) situations in India, Nepal, and Bangladesh contribute their perceptions, conceptualizations, and practices of nature in their lives as researchers within a "child-framed" methodology (Barratt Hacking et al., 2013). Socioecological factors influence the adolescents' nature knowledge, attitudes, and pro-environmental behaviors. The adolescents in these Majority contexts live intimately connected to natural systems, but the life for these adolescents in India, Nepal, and Bangladesh is very different to that of dominant conceptualizations of Minority western-style childhoodnature. The factors that influence their nature connectedness provide alternatives for conceptualizing and nurturing childhoodnature.

Ecological literacy · Majority (non-Western) context · Nature connectedness · Socioecological · Adolescents · Culture

Introduction

> This grasshopper has two different colour – one is green and the other is a golden and black, so it looks a nice colour. A natural creation, the gift of natural. (We) enjoy the jumping. (Adolescent boy, Chuikhim village, India)

Orr (2011) describes people who have no recognition of their connectedness with natural systems as "ecological yahoos" (p. 252), as ecologically illiterate with little or no knowledge of the natural environment and natural systems. Orr's colorful language reflects popular contemporary concerns about the increasing separation of people and nature in a context of global attention on the need to enhance nature connectedness and pro-environmental behaviors. Such perspectives predominantly originate in privileged, Minority western contexts and do not reflect the realities of many children and adolescents in Majority world countries.

This Chapter explores silences in the "New Nature Movement" (Louv, 2011) and disrupts the often nostalgic view of childhoodnature through the nature connectedness and ecological literacy of adolescents in less privileged, Majority world regions in both rural and urban areas of Bangladesh and remote Himalayan regions of India and the Kathmandu Valley of Nepal. We share a collection of "stories" from adolescent researchers (aged 14–17 years) involved in different studies in these regions to highlight possibilities for enabling and enhancing adolescents' nature connectedness. The childhoodnature experiences of the adolescents portrayed here are different from the carefree and romanticized idyll Louv (2005) promotes in his call to reconnect children with nature. Such differences serve as a reminder that childhood does not follow a universal pattern and childhoodnature perspectives drawn from mostly affluent Minority western perspectives are not the only indicators for our attention.

Through their photographs, drawings, and conversations, these adolescents give voice to their childhoodnature perceptions, beliefs and practices, and the position of natural systems in their daily lives. Their voices disrupt the dominant childhoodnature discourses and aspirations that permeate the "New Nature Movement" of "No Child Left Inside" (Louv, 2011) and recognize alternative perspectives and approaches. Sociocultural influences, postcolonialism, neoliberal realities, and indigenous perspectives impact on these adolescents' childhoodnature experiences; this illuminates key determinants of environmental knowledge construction, practices, and meaning making and extends our understanding of childhoodnature to rarely explored Majority world contexts.

Conceptualizing Childhoodnature

Systems thinking influences our exploration of adolescents' nature connectedness in India, Nepal, and Bangladesh. By systems thinking, we refer to consideration of the constituent elements and interconnections that are structured into a productive "whole" (Meadows & Wright, 2008), be this a system in nature or a human-created system. Systems thinking focuses our attention on parts, connections, and "flow" of

the dynamic sociocultural and ecological systems of adolescents' lives. Systems insights direct attention to factors influencing childhoodnature connections following Capra's proposal that "to understand a (system) pattern we must map a configuration of relationships" (1997, p. 81).

Making connections with nature has been recognized as an essential element of human development (Brody, 2005; Hasbach & Kahn, 2013; Kahn & Kellert, 2002). Humans, particularly children, have been observed to have a natural affinity and curiosity with nonhuman nature. Wilson (as cited in Orr, 2004) called this phenomenon *biophilia*, a term that has been used by many to describe this human affinity with nature across time and cultures (Kahn, 1997). Natural systems are at the basis of all life on Earth. The global apex species humans are powerful manipulators of nature, such that many are now identifying a new geological era, the Anthropocene, to recognize human environmental impacts on a planetary scale (Steffen, Grinevald, Crutzen, & McNeill, 2011). Despite human changes to natural systems, our basic survival needs are still ultimately dependent on the networked ecosystems of the planet. Humans are also embedded in our social systems – the cultural, political, economic, and more recently techno systems of our lives. Historical philosophizing on human ways of being created a nature-culture dichotomy of thinking that has only recently come under challenge (see, e.g., the writings of Haraway, 2003; Latour, 1993, 2005). Perceptions of a separateness of humans from nature, and the dangers of this in the light of concerns for the sustainability of natural systems, are increasingly part of academic and popular discourse. As Jordan poses, "the split with nature is at the heart of our environmental crisis" (2009, p. 30).

The term childhoodnature introduced in this handbook reflects challenges to the traditional nature-culture divide that is encapsulated in Haraway's term "naturecultures" (Fawcett, 2013; Haraway, 2003), reflecting the inseparableness of nature and culture. Complex, mutually defining interrelations occur between culture (the human way of interacting with the world) and nature (the networks of natural systems human biologies are situated in). Aligned with this is now the term childhoodnature introduced in this handbook that we are using as a provocation and reminder of the embeddedness of children and childhood as part of the natural world, guiding our exploration of the lived experience of nature for adolescents in India, Nepal, and Bangladesh.

What do we mean by nature? Williams (1983) identifies "nature" as complex and difficult to define. The "nature" adolescents interact with is variously described, with related terms including the outdoors (outside), the (natural) environment, the "nearby nature" (Kaplan & Kaplan, 1995) of created and landscaped "green" locations (parks, gardens, etc.), and relatively undisturbed natural (wild) ecosystems. Our use of nature encompasses any green, white, or blue (Korpela, Borodulin, Neuvonen, Paronen, & Tyrväinen, 2014) nature-rich setting. This includes house gardens, crop fields, the snow-covered Himalayan mountains, water catchment areas, forests, and urban rooftop gardens. Human "nature" is another version of nature entirely as Williams established in his five-page discussion of the meaning of this key (English) word. For our purposes, we consider the cultural "rules" that permeate human societies, as well as the personal meaning making of psychological processes (such as self-discovery that is particularly relevant to the lifestage of

adolescence), as the "culture" dimensions of naturecultures and childhoodnature (Matsumoto & Juang, 2008). A lens selected for manageability while still recognizing that this is a narrowing of the encompassing concept of naturecultures (and childhoodnature).

Increasingly nature or natural systems (biology and ecology) are coupled with social/cultural processes to frame onto-epistemological explorations of human-nature relationships and interactions. Examples of these new merged ways of thinking are Ingold's notion of humans as "biosocial becomings" (2013, p. 9), while White, Rudy, and Gareau call for imagining a future through "hybrid social natures" (2015, p. 215). Similarly a socioecological lens for conceptualizing learning and being is becoming more widely used (Brown & Harris, 2014; Kyburz-Graber, 2013; Wals, 2007; Wattchow, Jeanes, Alfrey, Brown, Cutter-Mackenzie, and O'Connor, 2014) to focus consideration of nature-culture entanglements. The dynamic interplay of environments and cultures that impact on a person's experience of the world is represented by the well-known ecology of human development framework proposed by Bronfenbrenner (1977, 1979, 1993, 1995) and Moen, Elder, and Luscher, (2001). Bronfenbrenner describes a hierarchy of influences based on a systems approach to locating the complex array of factors and interchanges through which an individual gains their knowledge, makes sense of their world, and in turn impacts on the world. We have found that Bronfenbrenner's nested systems of dimensions (shown in Fig. 1), that an individual interacts within,

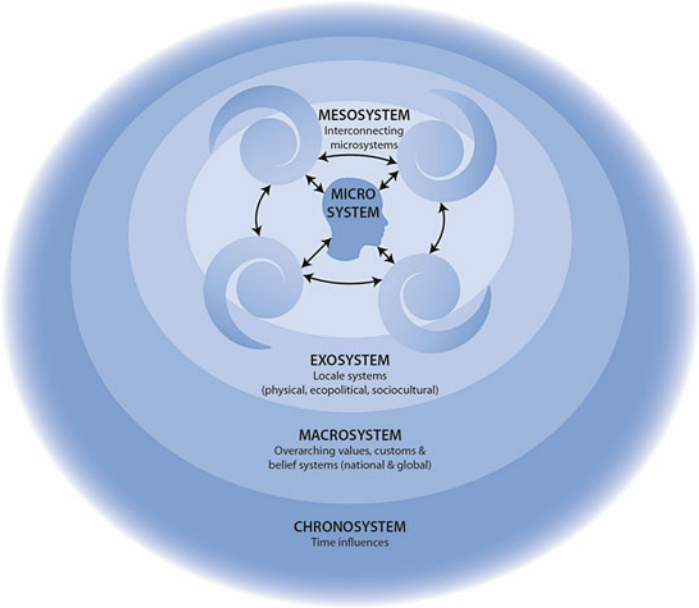

Fig. 1 A representation of the socioecological influences in an adolescent's life based on Bronfenbrenner's (1977, 1993) social ecology systems theory of human development (Widdop Quinton, 2015)

provide a framework for analyzing the people, places/spaces, and cultural factors that are important to adolescents in their nature-connectedness explorations and for making sense of their positioning of nature. We realize that Bronfenbrenner's theorizing is problematic with its marginalization of the natural environment and a strongly human-centric focus. So we use the framing of intersecting systems of natures and cultures, overlaid with a focus of attending to the natural and more than human, to aid our conceptualizing of nature-connectedness mediation factors in the context of Majority world cultural.

Nature Deficits?

The proposal of "nature-deficit disorder" popularized by author and journalist Louv (2005, 2009) has generated much interest in popular and academic discourse about the need for promoting children's experiences in nature and local natural places. Nabhan and Trimble (1994) and Pyle (2002) previously posed concerns regarding modern lifestyle impacts on childhood experiences of nature; however, Louv's writing has catalyzed a passionate response in the wider education and environment communities which has led to the slogan "No Child Left Inside" (Louv, 2007). Louv maintains that there is an absence of nature in the lives of today's "wired" generation of children. Griffiths has continued this emotive portrayal of modern childhood as "unnatural" and disconnected from "kith" or homeplace nature (2014, p. 11). Going further, Louv links the lack of connection to nature in children's lives to some of the most worrying childhood trends: obesity, severe anxiety, attention deficit disorders, and depression. The trends reported by Louv were initially taken up more strongly by the wider community than the academic community, although research in the early childhood field in relation to children's nature connectedness has increased more recently (Munoz, 2009).

Ecological literacy or ecoliteracy has been used to describe a person's understanding of natural environment elements and systems, including the interconnectedness of people, societies and nature, and the application of this understanding for sustaining socioecological systems (Capra, 1997; Cutter-Mackenzie & Smith, 2003; Orr, 2011). There is some consensus related to concerns of declining environmental or ecological literacy evident in affluent Monority western societies (Baker, 2007; Cutter-Mackenzie, 2004; Orr, 2011). However, the childhoodnature experiences promoted by the popularist "New Nature Movement" (Louv, 2011) are not necessarily a realistic picture of childhood experiences in nature, based as they are in romanticized affluent Minority western perceptions (Munoz, 2009). The rural childhood idyll of the nostalgically portrayed "good life" is in fact not the case in many contemporary contexts (Government of India, 2014; Matthews, Taylor, Sherwood, Tucker, & Limb, 2000). Louv's work is problematic in that it is based solely upon trends in the USA and does not acknowledge other contexts, such as the Scandinavian tradition of *friluftsliv* – of spending time outdoors (Henderson & Vikander, 2007). There is limited knowledge about the environments that children experience in diverse cultural contexts (Barratt Hacking, Barratt, & Scott, 2007; Chawla, 2007;

Fawcett, 2013; Sobel & Orion Society, 1996) despite some recognition that contextual factors shape children's nature connectedness differently (Collado, Íñiguez-Rueda, & Corraliza, 2016; Müller, Kals, & Pansa, 2009).

The focus on (re)connecting children with nature is primarily on younger children (see, e.g., Louv, 2007), while older children/adolescents' nature relationships are underrepresented (Mannion, Sankey, Doyle, & Mattu, 2006; Pointon, 2013). This may be due to an observed decline in interest in nature during adolescence (Hart, 1979; Kaplan & Kaplan, 1995, 2002; Korpela, KyttÄ, & Hartig, 2002; Nabhan & Trimble, 1994; Sommer, 1990), such that researchers are dissuaded from pursuing research with adolescents. it would seem, however, that this area of research is crucial in order to identify the most effective means of keeping adolescents connected with nature in a climate of concern about humans perceiving themselves as separated from natural systems.

All nature experiences and relationships are not the same. Popularist views of child-nature interactions are primarily restricted, even somewhat prescriptive, representations with little recognition or understanding of childhoodnature beyond nostalgic, affluent Minority western conceptualizations. The adolescents' stories from Bangladesh, India, and Nepal highlighted here extend consideration of childhoodnature beyond early childhood and Minority western contexts as a way of broadening our understanding of factors that shape adolescents' relationship with nature and natural system connectedness.

Nature Benefits

Apart from nature and natural systems powering all life on Earth and supporting humankind's physical well-being as discussed earlier, human-nature relationships can also benefit people's psycho-emotional health and well-being. The restorative effects of time in nature are recognized with theorizing of attention restoration and stress-recovery responses (see, e.g., Basu, Kaplan, & Kaplan, 2014; Hasbach & Kahn, 2013; Kaplan & Kaplan, 1995) and the body of work on environment restoration by Korpela & Hartig (1996), Korpela, Hartig, Kaiser, and Fuhrer (2001), Korpela et al. (2002, 2014). Nature connectedness for children (and all humans) is vital for holistic health and well-being. Indigenous ecohealth scholar, Arabena (2006), goes as far as posing socioecological impacts she terms a "disconnect disorder" for the layered disconnection of people and nature-referent ways of being. She identifies this disconnect for both indigenous people and for those "ensnared" (p. 45) by the ultimately empty and unrewarding consumerism of affluent modern life (2006). Considering nature connectedness at a community and planetary level, many scholars pose interactions that lead to a bonding with nature as an important first step in fostering a nature-caring ethos necessary for sustaining the planet (Chawla, 2007; Gruenewald, 2003; Leopold, 1966; Orr, 2011; Sobel, 2004). How adolescents' nature connectedness is constructed through their many and varied socioecological experiences is therefore important to explore – for people and planetary well-being.

Child-Nature Relationships

In exploring people-place relations, such as our focus here of how adolescents in India, Nepal, and Bangladesh position nature in their lives, the theoretical understandings of the role place plays in the human psyche are connected. This is particularly relevant for the adolescents at this time in their lives that is characterized as one of self-discovery (Marcia, 1983). Place interactions affect a person's perceptions of themselves as "places hold and shape our experiences" (Greenwood, 2013, p. 93). In environmental education, there is a growing interest in linking connections between perceptions of self in relation to natural places and caring for nature behaviors (Clayton & Opotow, 2003; Devine-Wright & Clayton, 2010). Descriptors of ecological identity (Thomashow, 1995) and environmental identity (Clayton, 2003) as specific examples of self and place identity have developed in the discourse, and Orr (2011) poses a sense of place that connects with nature as promoting ecological literacy (what he describes as proficiency in knowing nature). Self-place interactions align with Bronfenbrenner's human ecological systems theory that informs our research.

Time spent in nature does not necessarily promote ecological identity and pro-environmental behaviors; however, nature experiences enhanced by positive emotional connections are more likely to strengthen adolescents' affinity with nature (Müller et al., 2009). There is a large body of work about significant life experiences that influence affinity with nature and pro-environmental behaviors. Positive childhood experiences in nature, often mediated by an adult guide, is a key factor in enhancing nature connectedness (see, e.g., Chawla, 2002a, 2007; Palmer & Suggate, 1996; Palmer, Suggate, Robottom, & Hart, 1999; Wells & Lekies, 2006). Families in particular are the social conduit to an environmental ethos (Francis, Paige, & Lloyd, 2013; Payne, 2010; Robottom, Malone, & Walker, 2000). Indigenous ways of knowing nature and the land are similarly socially mediated (Cameron, Mulligan, & Wheatley, 2004; Cameron & San Roque, 2003; Wheaton, 2000; Yunkaporta & Kirby, 2011).

Previous explorations of self-nature relationships categorize young people's positioning of nature as ranging from simple (object) perspectives of nature as elements and background to more complex cognitive, embodied, and affective (relational) perspectives of nature integrated within their lives (Cheng & Monroe, 2012; Collado et al., 2016; Loughland, Reid, & Petocz, 2002). Beyond childhoodnature studies, theorizing also identifies anthropocentric (human-centered) and ecocentric (nature-centered) perspectives of human-nature relationships (Eckersley, 1992). In an interesting departure from the object-relational, anthropocentric-ecocentric binaries, Evernden (1989) poses a third category of "nature as wonder" that does not seem to have permeated the literature. Minority perspectives dominate such self-nature theorizings. Our research with adolescents prompts us to ask are such relationships universal to childhood or expressions of cultural conditioning?

"Child-Framed" Research

Majority world children's worldviews in our research illuminate alternative child-nature relationships. Working with adolescent research partners following a "child-framed" methodology (Barratt Hacking et al., 2013) contributes an insiders' perspective, giving adolescents agency and voice in the research. Taking a child-framed approach addresses calls for greater representation of young people's perspectives (Rickinson, Lundholm, & Hopwood, 2009; UN, 1989) and pragmatically recognizes that places and nature significant to children and adolescents may not be identifiable by adults (Fawcett, 2013; Gold & Gujar, 2007; Hart, 1979; Korpela et al., 2002; Nabhan & Trimble, 1994). Our qualitative, child-framed approaches have generated visually rich narratives that we draw upon here.

The Nepalese, Indian, and Bangladeshi adolescents' contributions to this chapter are childhoodnature highlights from four separate qualitative studies involving adolescents as active research participants exploring connections to the natural environment in their lives:

- In Nepal, four adolescents, aged 14–15, contributed to a study on community reuse of water.
- In the Eastern Himalayan region of India, 12 adolescents aged 15–17 in a remote rural village and 10 adolescents aged 14–16 from a semi-urban area researched the most important places in their lives.
- In Bangladesh, participants exploring adolescents' ecological literacy were aged 14–15 years, with 42 from an urban area and 42 from a rural area contributing their ideas, with 25 of these adolescents undertaking their own research and participating in group discussions and interviews.

Most of the Nepalese and Indian participants were Hindu or Buddhists of the Nepali cultural group, while the Bangladeshi adolescents were predominantly of Muslim faith.

Despite geographic, language, political, spiritual, and social differences between these adolescents, they are historically and culturally connected. All three countries are South Asian and have some shared historical influences including a recent history of British colonization and exploitation in the seventeenth to early twentieth centuries. Both India and Bangladesh were occupied by the British, and Nepal fought for territory dominance with the British East India Company with the British eventually becoming a highly influential ally. The current postcolonial situation in India exhibits a huge divide between the wealthy elite and the majority, rural, subsistence poor (Guha, 2010/1999) that is mirrored in Bangladesh and Nepal.

We must point out that although our young partners had agency in the research activities, their contributions may have been subjectively skewed to what they regarded as acceptable to share with us. This was inevitably influenced by the situational dynamics inherent in the created research relationships between our

adult selves and these adolescents. This was compounded at times through some language barriers. Only one of us is of Majority world background, so some of the research activities were conducted with the assistance of local translators and guides. As adults and visitors to the adolescents' communities, we were always mindful of researching ethically and with sensitivity to minimize the impact of our relationship power or personal interpretations, ensuring the adolescents could authentically "voice" their ideas. A focus on visual representations (photographs, maps, and drawings) elicited powerful expressions of the adolescents' nature connectedness that were not reliant on self-reported or translated perceptions and behaviors.

Childhoodnature in Bangladesh, India, and Nepal

Exploring childhoodnature – how children are part of and relate to nature – was not necessarily the main focus of our research activities with the adolescents in India, Nepal, and Bangladesh. Yet the importance of their relationship with nature, the position of nature in their lives, and their lives in relation to natural systems is evident through the adolescents' photographs, drawings, maps, and conversations.

Nature is not just a pleasant background to their lives. The adolescents regularly identify nature as an actor and affiliate in their everyday lived experiences. Nature permeates their lives, often determining their activities – be this working with life-sustaining resources, engaging with community-significant natural places, mediating culture and spirituality meaning, or enabling positive emotions such as enjoyment and relaxation.

In India, Nepal, and rural Bangladesh, the adolescents roam freely around their community. Their lives evidence a seamless integration of their socioecological systems including home, family places, village or community spaces and the nearby nature of gardens and crops, and the wild nature of the forest, with much of their day spent outdoors. Bangladeshi urban boys are free to roam their communities, similar to the Indian and Nepalese adolescents, but the Bangladeshi urban girls are more restricted due to social and safety factors. In urban Bangladesh, adolescents tend to spend more time inside and experience nature through rooftop gardens, parks, and ornamental lakes. Their wild nature experiences occur through visits on family holidays and on school excursions.

Despite most of the young researchers living in close contact with nature, this was not an idealized nature frolic characterized in affluent Minority western children-in-nature discourses (Munoz, 2009). The tough realities of survival translate into a focus on nature as a providing partner with the adolescents' prime motivator for nature relationships as family and community wellbeing. Acknowledging the physical demands associated with many of the community's rural, subsistence lifestyle in nature, one of the adolescents, Laxmi, in India comments about his photograph (Fig. 2) of a villager using a traditional basket to transport materials (rocks, cut foliage for the animals, wood, etc.) around the village and surrounds and states that "In our village the people work harder, they work very hard on their land."

Laxmi's comment suggests a personal experience of the hard work associated with the village, rural lifestyle that is consistent with the contention that adolescents in Majority

Fig. 2 Laxmi's photograph of the hard work associated with village life

contexts are positioned differently to adolescents in affluent Minority societies. Brown, Larson, and Saraswati (2002) characterize adolescents in India as dutifully engaging with societal expectations and responsibilities in a society shaped by the echoes of colonialism and the caste system, a hierarchical social system. So the adolescents' local economic and physical factors (Bronfenbrenner's "excosystem" influences) and overarching cultural influences (Bronfenbrenner's "macrosystem" factor) are indicated in the adolescents' development of their relationship with nature. This situation contrasts with the affluent Minority western positioning of childhood as a time free of responsibilities (Munoz, 2009). Laxmi's recognition of the collectivist efforts for community good is echoed in other Majority world and indigenous contexts (Appuhamilage, 2017; Gold & Gujar, 2007; Panelli & Tipa, 2007). The Indian, Nepalese, and rural Bangladeshi adolescents' experience of their outdoor life is in direct contrast to the romanticized view of a carefree, rural childhood often portrayed in affluent Minority western discourses, particularly those related to childhoodnature connectedness (Munoz, 2009). The Government of India (2014) also recently recognized the harsh conditions of adolescents marginalized by "structural poverty" (2014, p. 21).

Nature as Community Life

The adolescents in the research studies identify the importance of nature in their lives through a lens of value to their family and community. This is consistent with collectivist good and interdependence as dominant cultural values observed in Majority world contexts, where the cultural imperative is for the family/community/societal greater good in contrast to the predominantly individualistic approaches in many affluent Minority western contexts (Appuhamilage, 2017; Panelli & Tipa, 2007). Culture shapes people's relationship with nature (Evernden, 1989; Mead, 1977). In Nepal plants are deeply culturally significant (Kunwar & Bussmann, 2006). A shared conservation ethos and careful consumption of natural resources are embedded in Bangladeshi culture (Islam, 2006) and

Indian traditional philosophies (Almeida & Cutter-Mackenzie, 2011; Ravindranath, 2007; Sarabhai, 2004). This ethos of nature care combined with a cultural preferencing for collectivist value is evident in the adolescents' positioning of nature as valuable in their lives.

In the villages in India, the forest areas around the village are identified by the adolescents as essential for firewood for cooking and fodder for the animals, as well as appreciated for their views, as cultural symbols and for "refreshment." The adolescents are aware that their lives depend on natural systems, identifying cultivated and wild nature around the villages as important to them. Suvo in rural Bangladesh comments that "The land of Bangladesh is very fertile. Different types of fruits and crops such as rice, jute, wheat are produced in this land. Most of the people depend on this land for food." Similarly, the adolescents in Nepal identify their connection with natural systems through the story of water in their lives. Pragya explains, "We use well water. We also get water from the stone tap in the rainy season. Well water is enough for us in summer but we face problem in winter. Then we buy water from the water supply agency but that water is expensive and it takes time to provide water." Their most common source of water in the area is underground water from wells. Most families use well water for bathing, cooking, washing, and cleaning. Scarcity of water has necessitated the use of waste (gray) water. Bijay comments, "We use waste water for watering plants and flushing toilet." Pragya demonstrates her prioritizing of family and community by commenting "First we should educate our family members and then the community people about the reuse of waste water." Bangladeshi adolescents also recognize water recycling as an essential element of their socioecological systems through schematics such as in Fig. 3.

Gustafson (2001) proposes that self-place-others factors interplay to determine meaning making in relation to place relationships. The "self" appears less visible in the adolescents' narratives of nature in their lives in Bangladesh, India, and Nepal. This reinforces for us the value of using a socioecological systems lens for framing our inquiry into adolescents' nature connectedness. Informed by Bronfenbrenner's socioecological framing (1977, 1979, 1993, 1995), we identify the overarching cultural context of the adolescents' lives, that values family and community ahead of individuals, as a factor that shapes their perceptions of nature.

Nature as Spirituality

There was also a spiritual dimension to the cultural positioning of nature in the Indian, Nepalese, and Bangladeshi adolescents' lives. Small forest shrines (such as in Lungta's photograph, Fig. 4), prayer flags disseminating prayers on the wind through the trees and via streams, and even ancestors' graves dotted over the countryside depict an integration of the land with cultural spirituality. This visible interweaving of spirituality with nature has unique meanings specific to the adolescents' cultures, while also analogous to traditional ways of being connected to the land recognized in other indigenous contexts (see, e.g., Arabena, 2015; Rose, 2013; Wheaton, 2000).

Rashed from rural Bangladesh believes that if people plant trees and enjoy fruits from the trees, it will make Allah happy and that they will be rewarded. Rashed

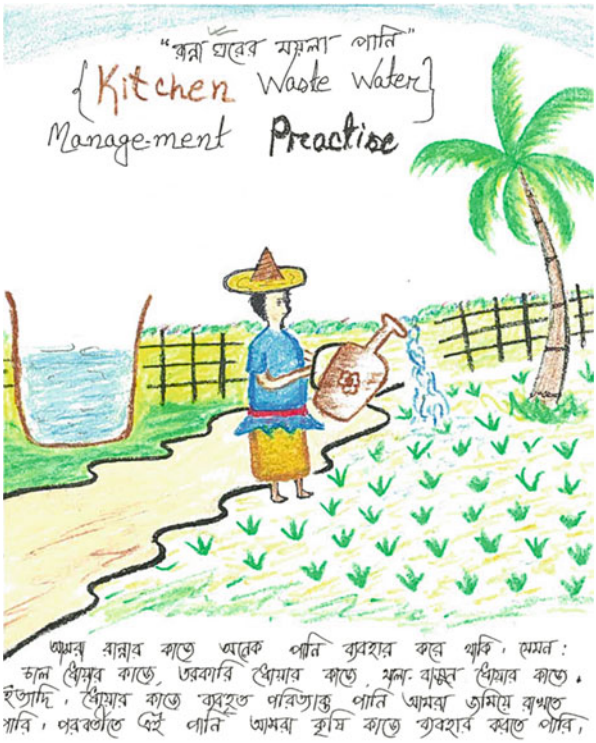

Fig. 3 Rashed's drawing about kitchen wastewater management practice in urban Bangladesh demonstrates "reuse" of wastewater. (Translation of Bangladeshi text: We use a lot of water for cooking such as washing rice, washing vegetables, washing utensils, etc. We can collect this wastewater after washing things, and we can use this water for irrigation later.)

Fig. 4 Indian adolescent Lungta's photograph of a small forest shrine – "Here the travel people use to worship – fire gods, other gods so this is one place outside of their house to worship the nature"

indicates that "In Islam, if we produce fruits and public eat that fruits without any cost then we will be rewarded." He displays a photograph of a custard apple tree in his rural community where "people enjoy fruits from this tree without any cost." Bangladeshi adolescents also talk about environmental cleanliness as an important

Fig. 5 Dia's drawing of "a polluted environment" that requires sweeping

aspect of Islam. Dia's drawing (Fig. 5) shows what she considers "a polluted environment" that a woman is cleaning with a broom made from coconut leaves.

Evernden's (1989) early classification of nature connection relationships included "nature as miracle" for relationships not bounded by scientific/pragmatic views of the world. This categorization is in addition to the more standard object and relational views of nature (see, e.g., Fawcett, 2013; Loughland et al., 2002). For the Bangladeshi, Nepalese, and Indian adolescents, nature provides for their physical needs but also generates wonder, awe, and devotion, nurturing their spirituality and their well-being. For these Muslims, Hindus, and Buddhists, "nature is a blessing" (Islam, 2006, p. 67). The comments about the grasshopper as a gift of nature by Laxmi from India at the beginning of this chapter echo this philosophy.

Ecological Literacy and Identity

The adolescents in remote India, Nepal, and rural Bangladesh live immersed in the natural world with their lives constantly connected to their natural surroundings via their subsistence lifestyle and through their spiritual connections with nature. It is obvious they have an intimate knowledge of their local nature through their detailing of the nature nooks and crannies and their expert knowledge of elements of natural systems that is only possible through highly developed ecological literacy.

This ecological literacy of the Indian adolescents was apparent through the variety and detail displays in their photographs of the sometimes astonishing natural elements of their area, for example, a huge butterfly (Fig. 6). This is just one of the many examples of ecosystem elements the adolescents in India photographed. Bangladeshi adolescents similarly demonstrate expert ecological knowledge about the natural elements and system events of their area. Himu, who lives in a rural location, said "In Bangladesh, Sundarban Mangrove forest is different to

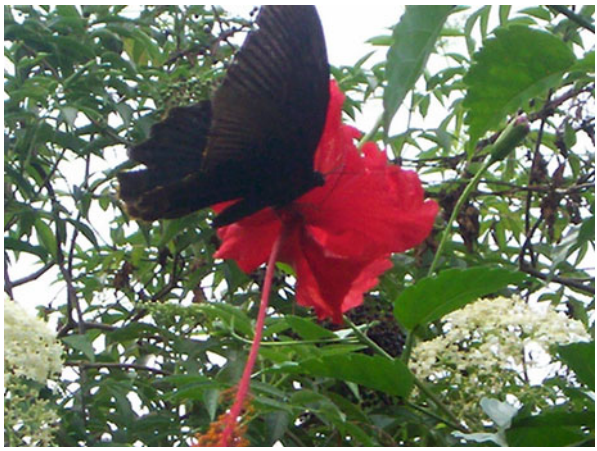

Fig. 6 Pabitra's photograph of a large, black butterfly in India

me. Different types of trees are found in Sundarban such as sundari, shal, gewa, goran etc. We can find medicinal plants in the forest too. Royal Bengal Tiger and beautiful deer are seen in Sundarban." And Bornali, also from a rural area, adds, "Seasonal variation of Bangladesh is very charming which is important to me. In summer we eat a lot of mangoes, jackfruits, berries and litchis (lychee). In the rainy season rain helps farmers and keeps cool the environment. In autumn we can see the beautiful white Kash flowers at the bank of the river. In the late-autumn we celebrate special festival with new rice." While Dipa identifies sustainability actions with the comment, "Climate change can be solved partially by planting trees. For example, neem plants keep the environment healthy and works as pesticides." Gold and Gujar (2007) and Tilbury, Stevenson, Fien, and Schreuder (2002) also note the highly developed ecological literacy of people in other remote areas of India, suggesting this is a widespread trait of the people in this region.

The urban Bangladeshi adolescents' daily lives are not as closely connected to nature through physical proximity, as has been observed with urban dwellers in other parts of the world (Orr, 2011), although the urban Bangladeshi do maintain their nature connectedness through their cultural philosophies and practices. Plants, particularly flowers, are symbolic of different cultural events and festivals. Photographs of flowers, such as the marigolds in Figs. 7 and 8, are a feature of all the adolescents' photographs.

The adolescents' highly developed ecological literacy and connections with nature indicate an opposing positon to the generally accepted Minority conceptualization of adolescence as a time of disconnection from nature (see, e.g., Kaplan & Kaplan, 1995, 2002). The adolescents in India, Nepal, and Bangladesh demonstrate that a disinterest in nature is not an inherent characteristic of this lifestage.

In addition to their appreciation of nature as integrated with their lives, the adolescents exhibit pride and a sense of identity connected with the unique nature of their area, an ecological identity, as is exemplified by Indian adolescent Hima's explanation of a particular spider that is "no ordinary spider you can't find like this in the region." Ecological or environmental identity is advanced as a self-identity

Fig. 7 One of the many images of marigold flowers taken by the adolescent in India of this medicinal and festival plant

Fig. 8 Rian's photo of marigold flowers used to mark the Language Memorial in urban Bangladesh

variant that incorporates nature as an integral element of self-identification (Clayton & Opotow, 2003; Thomashow, 1995). Enhancing this ecological aspect of the adolescents' identity construction is the sense of belonging to "country" that is recognized in indigenous people elsewhere, such as in Australia and Canada (Arabena, 2015; Parkes, 2010; Rose, 2013). As Santo comments, "Bangladesh is our motherland." Santo makes reference to a song written by Dijendrolal Roy, "*Emon deshti kothao khuje pabenako tumi, shokol desher ranee seje amar jonmovumi*" (Translation: *Created from dreams anchored by memories, nowhere else a place of such luminous glories*). Santo continues with discussion of the geography of Bangladesh saying, "These (Bangladeshi) rivers carry silty soil which makes our land very fertile. Different types of crops are produced in Bangladeshi land. Cox's Bazar sea beach is very large and Sundarban mangrove forest is biologically diverse. We have beautiful tourist places."

Socioecological Systems Thinking and Entanglements with Neoliberal Realities

The adolescents' awareness of their lives as co-created by their entwined social and ecological systems is evident through their attention to the systems impacts of change: water scarcity in Nepal (as recounted earlier), earthquakes and landslides in India, and floods in Bangladesh, in addition to general change related to globalization and tourism.

In the remote villages in Eastern Himalayan India, the regular natural occurrence of landslides associated with earthquakes has a big impact on the land and the people that all the adolescent researchers highlight. Landslide damage, such as that pictured in the background of Fig. 9, changes huge areas of the countryside and has ecological and social impacts. Pabitra explains that the landslide has cut them off from access to the food supply of the lower village "because they used to get food there – this land is not accepting them because of landslide." Lungta also comments on the impact of the landslide that forced families to relocate after being segregated from the village community when the road (Fig. 9), the only road to the other side of the ridge, became blocked by the landslide: "That no longer this is our main way for walking, there's no other route to come over here. So there is only a single way. There is no other optional way."

The regular flooding of the river delta system in Bangladesh maintains soil fertility as Santo noted earlier, but this also creates social impacts for coastal dwellers as graphically depicted in Fig. 10 of "homeless" flood victims.

Living within constraints of natural systems is just part of life for the adolescents. Reciprocal caring is part of community life as urban Bangladeshi adolescent, Adronida, describes: "We can reuse our used things. For example, after washing vegetables we can use water for watering plants to keep them healthy. We can also make composts by using fruits and vegetables peels for applying to the plants. Thus, we can improve our environment."

The expanding social ecologies of modern life have resulted in some shifting within the adolescents' socioecological systems under neoliberal pressures, with the press toward free-market tourism business practices. These "dissolving qualities of capitalism" (White et al., 2015, p. xvi) can be at odds with the Indian, Nepalese, and Bangladeshi traditional ways of interacting with nature. Tourism is now a key income source for these areas, but the presence of tourists has an impact on the very places of nature tourists come to visit. The tension between the traditional philosophies of environmental care and connectedness (e.g., Gandhi's vision of ecological care as enshrined in the Indian constitution) and the newer neoliberal realities is evident in some of the adolescents' stories. Both Indian and Bangladeshi adolescents identified the value of their unique natural environments as attractions for tourists for economic benefits to their community but also highlighted the impact of tourism activity on nature. The newer economic imperatives of the market economy experienced by the adolescents are out of alignment with their overarching traditional culture of valuing nature when mapping this to Bronfenbrenner's socioecological systems

Fig. 9 Lungta's photo of the road and the landslide in the distance that now blocks access

Fig. 10 Durijoy's drawing of homelessness of coastal people during floods in Bangladesh

(1977, 1979, 1993, 1995). This discord is evident in the adolescents' accounts that follow:

Liya enjoys the sunset and the marine environment at the iconic Cox's Bazar beach but also highlights all the tourist activity with her photograph (Fig. 11).

Fig. 11 Liya's photo of all the tourists at Cox's Bazar beach in Bangladesh

Fig. 12 Pralay proudly displays the Himalayan mountains that surround his home

In India, Pralay glories in the mountain views from his home (Fig. 12), proud that this majestic site is part of his heritage and brings many tourists to the area. He also demonstrates his concern about the modern-day litter (Fig. 13) that is unsightly

Fig. 13 Litter in the Eastern Himalayan area that disturbs Pralay

and detracts from the beauty of his home, saying that "it is very dirty and when tourist come."

A number of the adolescents in Bangladesh, particularly from urban regions, indicate concerns about the deterioration of the natural environment due to human actions, highlighting problems of pollution, deforestation (Fig. 14), pesticide use, litter, and flooding. Rajon explains, "I do not feel good about the environment. Our environment is worsening day by day because of pollution. Our lifestyle is changing. Over population and industrialisation are the causes of environmental pollution." An apprehension shared by many Bangladeshi about impacts of modernity (Islam, 2006).

Nature Knowing

How did the adolescents of India, Bangladesh, and Nepal develop their nature knowing? The ecological literacy that enabled them to recognize the turbulence in their socioecological systems due to changes in nature relationship practices has not developed through formal school learning. Schools in India, Nepal, and Bangladesh are characterized as a formal, regimented echo of colonial British approaches (Gold & Gujar, 2007; Widdop Quinton, 2015). For example, in Bangladesh, Najura describes "I have participated in an environmental cleaning program and tree plantation program through our school Girl Guides," and Adronida photographed the rose in the school garden (Fig. 15) – both are examples of nature relatedness through nonformal learning, albeit with echoes of colonial influences.

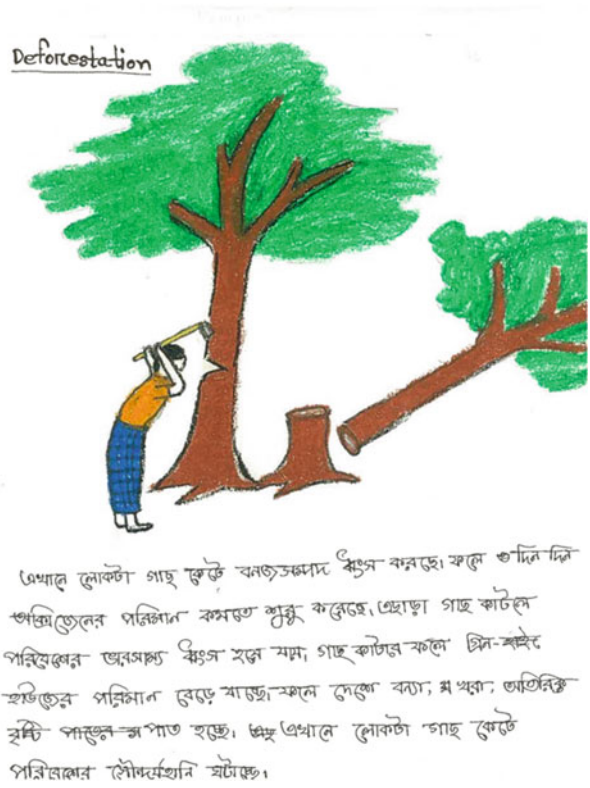

Fig. 14 Durjoy's drawing of "a man is cutting down two trees" indicates "deforestation" (Bangladeshi text translation: A man is destroying the forest by cutting down trees. As a result the amount of oxygen is decreasing day by day. Cutting down trees imbalances the environment and contributes to greenhouse gases so flood, drought and heavy rainfall occur in the country. Here, the man is interrupting the beauty of nature by cutting down trees)

Environmental and sustainability education is rare and at best marginalized in schooling in these countries (Almeida & Cutter-Mackenzie, 2011; Tilbury et al., 2002). In Bangladesh, for example, there is no environmental education as a separate subject; environmental and sustainability aspects are incorporated into other subjects (Haque, 2014). Schooling predominantly focuses on regimented, direct instruction toward high-stakes testing (Chowdhury, 2004; Hossain, 2015). Traditional or indigenous ways of learning and knowing, particularly relating to ways of knowing the land, are identified as different to formal education/school learning (Wheaton, 2000; Yunkaporta & Kirby, 2011). The adolescents develop high-level ecological literacy skills through lived experience, a socially, culturally, and family-mediated traditional way of learning and connecting with nature. Nature-knowing processes are embedded in their way of life with family, culture, and experience being the "teachers." Rural Bangladeshi adolescent Sakib explains that "Many young people learn farming from elderly people. I think culture influence young people's ecoliteracy."

The adolescents' nature connectedness through everyday experiences of nature is consistent with other context findings that proximity to nature (Cheng & Monroe, 2012), family as environmental teachers (Cheng & Monroe, 2012; Gold & Gujar, 2007; Payne, 2010), and supportive life experiences (see, e.g., Chawla, 2002a, 2007)

Fig. 15 Adronida's photo of the rose in the school garden

are implicated in mediating deep connection with nature. The Indian, Nepalese, and Bangladeshi adolescents' display of nature knowing grounded in social processes aligns with increasing recognition of social learning intertwined with ecological learning (Brody, 2005; Hart, 2007; Kyburz-Graber, 2013) and with traditional knowledge practices (Islam, 2006).The stories of nature connectedness from the adolescents in Bangladesh, India, and Nepal also illuminate the powerful influence of a collectivist, interdependent culture on enhancing child-nature relationships. Furthermore, the sacred relationship with nature through indigenous ways of knowing the land enfolds the adolescents into the weave of "country" (Griffiths, 2014). The sort of childhoodnature the adolescents describe is different to the Minority western-styled childhoodnature Louv (2005, 2009, 2011) and others describe. The Nepalese, Indian, and Bangladeshi adolescents' childhoodnature supports their ecological and cultural understandings, nourishes their self-discovery, and provides strengthening solace through spiritual connections and restorative interactions with nature. Their nature connectedness is essential for their healthy development and wellbeing. Their childhoodnature is shaped by the inter- and intra-actions of their socioecological system elements. Considering the positioning of culture as the substrate of social ecologies, it is not surprising to discover the profound impact of the adolescents' collectivist and traditional-caretaker cultural philosophies on their childhoodnature perceptions, values, and behaviors.

Child-Nature Relationship Reimagining Through Childhoodnature Alternatives

Through the Nepalese, Bangladeshi, and Indian adolescents' contextual childhoodnature described in this chapter, we are able to disrupt some of the current child-nature relationship thinking outlined in the introductory sections of this chapter and provide some Majority world childhoodnature alternatives:

1. **Childhood and nature are not disconnected in the Majority world**
   As Cutter-Mackenzie, Malone, and Barratt Hacking argue in the introduction to this Handbook, children are nature, and suggesting a disconnect between children

and nature, as Louv postulates (2005), is therefore problematic. The adolescents from Nepal, India, and Bangladesh demonstrate through their photographs and ideas that they are not disconnected from nature. Rather, nature is intrinsic to their functional, cultural, and spiritual way of being in the world. The dynamic interrelationships and interactions with the natures and cultures of their socio-ecological system shape their sense of belonging, their spirituality, and their identity. They are intimate with nature and literate in nature's ways. These Majority world children from three countries are not only connected with nature in a utilitarian and spiritual sense, but they also recognize their membership of ecological systems and their mutually defining relationship with nature.

2. **Childhoodnature is not all romance**
   Claiming a fundamental lack of a commodity in the lives of children certainly gains attention with the focus not on some abstract "other" but on our familiar and cherished vulnerable young. The language of "deficit" (Louv, 2005) and childhood as "imprisoned" (Griffiths, 2014) in relation to more than human nature experience has sparked a reaction. Interest groups and "movements" are prospering in mainly white, middle-class, affluent, Minority western contexts. However, addressing the concern of nature deficit in modern childhood through a Disney-style fantasy (Taylor, 2011) of nature (re)connections is limiting and exclusionary. A one-size-fits-all vision of nature connectedness devalues alternative realities. As the adolescents here have demonstrated, nature connectedness is not necessarily the romanticized idyll portrayed in the dominant childhoodnature discourse, of carefree, nature-savoring experiences in the wild, "about awakening to creation" (Louv, 2005, p. 333). The representations from adolescents of Bangladesh, Nepal, and India open the discourse to alternative possibilities. Yes their lives were closely connected with nature, but they were not necessarily living the "good life" of a bucolic childhood frolicking in nature. Their lives had to accommodate the often-harsh realities of Majority world subsistence living. This is not to deny the call for re(connecting) children with nature; instead it serves as a reminder that childhood does not follow a universal pattern and conclusions drawn from an affluent Minority western perspective are not necessarily generally applicable. For the adolescents here and other Majority world contexts (Appuhamilage, 2017), childhoodnature is not always a utopian, positive product or process. Sometimes childhoodnature is uncomfortable and gritty.

   This is not to say that the adolescents in Nepal, India, and Bangladesh are necessarily living a repressed, downtrodden, and negative life. The adolescents' relationship with nature is a positive and mutually supporting one, saturated with reverence and values of loyalty and care. Places that nurture young people, sometimes termed "holding environments" (Chawla, 2002b; Malone, 2004), are those that fulfill their needs and support their development. Such places do not have to be perfect, as Bannerjee and Driskell (in Chawla, 2002b) found when working with young people in a "slum" town in India; despite the material deprivations of their lives, the children from this slum were "confident, connected and happy" (p. 135) as a result of living in their socially and culturally supportive environment. Their natures and cultures were not privileged but nurturing

and cohesive, sustaining their development and wellbeing, like those of our adolescents in Bangladesh, India, and Nepal.

3. **Adolescents relate to nature**
   The adolescents of Nepal, Himalayan India, rural Bangladesh, and to a lesser extent urban Bangladesh demonstrate strong connections with nature. This is not just because they do not have the distractions of constant connectivity and shopping malls as do their counterparts in Minority western contexts; their connections to nature are embedded in their culture and their self-sufficiency way of life. This adolescent nature connectedness is highly significant. The adolescents do not evidence a disinterest in nature, disconnecting in favor of interacting with peers, as has been advanced as a characteristic of adolescence by Kaplan and Kaplan (1995, 2002) and others, thus demonstrating that a disconnect from nature during adolescence is not an inherent characteristic of this lifestage.
4. **Childhoodnature is a multiplicity**
   There are versions of "truth" about child-/person-nature relationships that have become acceptable classifications. Cautionary awareness that these are constructed labels for convenience and not reality prevails, but by the power of their existence, these classifications shape thinking. The binary of an object view or a relational view of nature is a common example (see, e.g., Loughland et al., 2002). Anthropo-, eco-, and biocentric conceptions are another group of categorizations of people's positioning of nature often found to be useful (see, e.g., Fawcett, 2013). Others from place psychology are also commonly used – place affordance, dependence, attachment, and identity (see, e.g., Gibson, 2000; Kudryavtsev, Stedman, & Krasny, 2011). Similarly the New Nature Movement's (Louv, 2011) image of the return to the "nature child" of Romanticism has shaped views of possibilities and goals for nurturing child-nature interactions – another "centric," affluent, Anglo-/Eurocentric view (Taylor, 2013a). Our use of Bronfenbrenner's socioecological systems framing enables us to focus on the basics of child-nature interactions and embrace many possibilities. We follow Taylor's (2013a) strategy of deconstructing with an eventual goal of identifying ways to reconstruct for beneficial alternative conceptualizations. Comparisons with other framings led to our position that child-nature relationships are more entangled and complex than commonly applied categorizations allow.

   The adolescents in Nepal, Bangladesh, and India simultaneously hold object and relational views of nature. Although more relationally slanted in their views, with recognition of humans as elements within the natural systems of their place, the perception of nature as a resource to support their lives and to be used for community advancement still permeates their ideas. Hegemonic neoliberal pressures for (industrialized) growth have been identified as a key contributor to the Anthropocene planetary changes (Steffen et al., 2011). The adolescents in both Bangladesh and India map tensions between their communities' economic and nature-valuing imperatives. The adolescents' research suggests they feel the seductive power of the global call for economic growth, but a harmonic incorporation of such modernity within their traditional philosophies is an unresolved issue for them. Some of the adolescents' special places of nature attract tourists

to their region, which they value for supporting local businesses and jobs. Such special places (e.g., Himalayan Mountains) are also significant within the adolescents' culture and religion, so the impact of visiting tourists (e.g., increased litter) concerns them. The adolescents' cultural influences for valuing and living with/in nature appear to prompt critical reflection on behaviors that negatively impact on nature. This suggests such socioecological influences warrant further investigation.

Layered over the functional and cultural categories of nature interactions the adolescents describe is the spiritual dimension of their childhoodnature. This "lost" category of Evernden's classification (Evernden, 1989; Fawcett, 2013), "nature as miracle," is also a vibrant child-nature interaction in the adolescents' lives. Their perspectives are simultaneously human-/social-centered and nature-/ecological-centered, challenging classification boundaries and the normalizing portrayals of romanticized nature connectedness. The Indian, Nepalese, and Bangladeshi adolescents' reality of childhoodnature is one of layers, complexity, and entanglements. The research suggests that, for these adolescents, nature is provider/carer/mother, a cultural symbol and guide, a story, identity, faith, hard work, kith and kin, a joy, and more.

We do not advance the Bangladeshi, Nepalese, and Indian adolescents' socioecological influences as the ideal to follow, not wishing to set up divisions into cultural binaries or stereotypes, as the limitations of such are clear (Appuhamilage, 2017; Smith, 2012). We also acknowledge there may be a performative aspect to the adolescents' development of their Majority world childhoodnature but contend that the adolescents were not passive recipients of their socialization. Their awareness of the impacts of new economic practices being in discord with their traditional nature-valuing ethos indicates they are active agents shaping their own childhoodnature. Our purpose then is to be guided by the adolescents' voices to illuminate possibilities of alternative ways of being and becoming, a multiplicity of childhoodnatures. Such possibilities for multiple mind-body-spirit childhoodnature interactions, following traditional ways of engaging with nature (Arabena, 2006), disrupt and add richness and possibility to the "New Nature Movement" (Louv, 2011) discourse.

Conclusion: The So What – Childhoodnature as Assemblages of "Socioecologicalization" Interactions

The alternatively constructed childhoodnatures of Majority world adolescents in India, Nepal, and Bangladesh challenge the highly visible orthodoxies of the "New Nature Movement" (Louv, 2011). We present these Majority world context versions of childhoodnature as assets to inform consideration of factors that enrich nature connectedness.

We share a deep unease with many others that humanity's damage to Earth's ecological systems is linked to concerns that modern life separates people from their fundamental connection with nature. Perceptions of children's "nature-deficit

disorder" (Louv, 2005) and "disconnection disorder" (Arabena, 2006) such that there is a "soul sickness" (Griffiths, 2014) permeating modernity, weave people's well-being with planetary wellbeing. Many scholars are calling for new imaginings of ways forward. The stories from the adolescents in India, Nepal, and Bangladesh enable us to consider alternative possibilities for thriving by being closely connected to nature. The adolescents' childhood bonding with nature supports the notion that such experiences predispose adult pro-environmental approaches (Chawla, 2007; Leopold, 1966; Orr, 2011; Sobel, 2004). The multiplicity of their sociocultural, individual, and ecological agents of co-construction of their childhoodnature opens up possibilities to attend to.

Deconstructing these alternative enactments of childhoodnature to the dominant Minority western conceptualizations identifies key sociocultural influences shaping the adolescents' development as well as their positioning of nature in their lives. Sociocultural influences are posed as shaping different expressions of childhoodnature in different contexts (Collado et al., 2016; Müller et al., 2009), strengthening our position that socialization in combination with bonding experiences of nature ("ecologization") nurtures strong nature connectedness. That is, childhoodnature develops through "socioecologicalization." The Bangladeshi, Indian, and Nepalese adolescents' "socioecologicalization," although varied locally, indicates commonalities of interdependence and traditional values shaping their childhoodnature. Their nature knowledge and relationship are not via formal learning but through an experienced, embodied, and socially mediated learning, a traditional or indigenous epistemology. The adolescents' lifeworld experiences add support to calls for considering indigenous ways as valuable to invigorate sustainability thinking (Kahn, 2010; Somerville, 2007; Wheaton, 2000; Yunkaporta & Kirby, 2011). Concerns about applying indigenous ways out of context have been raised (Nakagawa & Payne, 2011; Nakata, 2002), but indigenous scholar Kerry Arabena sweeps aside these concerns by posing everyone as indigenous to the universe. She proposes we step outside current boundaries and be guided by indigenous ways to connect and unite in thought and action for plausible people and planet-sustaining "lifeways" (2015). This is not to suggest that the indigenous and collectivist culture framing of the Indian, Nepalese, and Bangladeshi adolescents' childhoodnature is an imperative. Instead we draw attention to their ethos of collaboration and the high status of nature in their culture as potential pathways for broadening the conversation about child-nature relationships and pedagogies.

The Bangladeshi, Indian, and Nepalese adolescents' stories in this chapter add Majority world context diversity to socioecological factors implicated in supporting children's development of their nature connectedness. Such alternatives suggest possibilities for assemblages of situational and opportunistic experiences for nurturing nature connectedness in childhood, for including more collectivist and spiritual onto-epistemological negotiations of childhoodnature. The adolescents' stories invite us to take advantage of the coalescences of any storied, embodied, scientific, cultured, spiritual, mindful, contemplative, collaborative, playful, practical, community-mediated, enchanted, traditional, technological, or elder-mediated ways of being and becoming nature as strategies for enhancing

childhoodnature – not to just follow one defined pathway to childhoodnature. The Indian, Nepalese, and Bangladeshi adolescents' versions of their childhoodnature recounted here open up possibilities to more "heterogeneous, thrown together and entangled naturecultures" (Taylor, 2013b, p. 16). The Anthropocene emergency necessitates shifts in the way humans think and act to rehabilitate our social and ecological systems in crisis. Resilient childhoodnature, and human nature, will be needed. Possibilities for strengthening child-nature relationships are indicated from the Bangladeshi, Nepalese, and Indian adolescents' accounts of their childhoodnature in this chapter.

The authors wish to acknowledge the work of our adolescent research colleagues in India, Bangladesh, and Nepal who have made essential contributions to our research.

Abstract

Exploration of the natural world begins in infancy and is a vital part of a childhood that includes rich nature-based experiences. Children need opportunities to take age-appropriate risks in natural outdoor settings. The social ecology model suggests that children's experiences are influenced by a variety of contexts in their environment. As such, adults often act as gatekeepers of children's nature-based risky play opportunities, either promoting or restricting such experiences, within cultural and regulatory contexts. Therefore, a greater understanding of

early childhood educators' and parents' attitudes and practices in relation to nature-based risky play for children is needed. Even though there are a variety of possible dangers inherent in the exploration of nature, it is natural that children are drawn to these experiences regardless of the safety concerns of modern parents. This Chapter takes an ecological systems and cross-cultural approach to discuss the role that nature-based risky play has in children's exploration of the natural world, its importance in quality early childhood education (ECE), and its benefits. The authors draw on studies of parents and early childhood educators from Australia and the United States to explore perspectives and practices related to the provision of opportunities for children to engage in nature-based risky play. Beyond the typical discussion of implications for research and practice, further insights are given for parents and educators alike on the ways in which outdoor risky play can be promoted, with a focus on connecting children with the natural environment.

Introduction

Most young children naturally seek out and enjoy challenging outdoor, nature-based play experiences (Stephenson, 2003). Opportunities to engage in outdoor, nature-based risky play from a very early age are beneficial for children's development of a variety of skills, developmental abilities, ecological literacy, thinking and identity (Little & Wyver, 2008), including but not limited to confidence, self-esteem, concentration, problem-solving, creativity, and resilience (Faber Taylor & Kuo, 2009; Brussoni et al., 2015). Studies link nature-based outdoor play to developmental milestones such as positive motor development (Fjørtoft, 2001, 2004) and decreased risk of developing myopia (Sherwin et al., 2012). Importantly, risky play may serve an evolutionary function, whereby children learn to regulate their fear and adapt to the current environment. This time exploring the natural world uninhibited assists children in developing ecological literacy, which can protect them from ecological risk factors (Sandseter & Kennair, 2011). Ecological literacy is important as it involves understanding the interconnections between natural and human systems and consideration of how human actions can impact the natural world (Stone & Barlow, 2005).

Through their exploration of natural outdoor environments and materials, children's risky play can also support their skills and attitudes of environmental citizenship (Blanchet-Cohen & Elliot, 2011) through increased positive attitudes toward the natural world. However, opportunities to engage in nature-based risky play are often influenced by various factors in the child's life, including but not limited to, parental beliefs and practices, early education environments and pedagogical practices, cultural beliefs, and regulatory factors. Individual characteristics of the child interact

with these factors to create unique situations for each child in relation to nature-based risky play.

Risky play is defined here as an outdoor, nature-based thrilling, and exciting activity that includes some risk of injury; such as balancing, climbing, sliding, and hanging upside down (Tovey, 2010). Often, risky play provides children with opportunities to challenge themselves, test limits, explore boundaries, and learn to make decisions about injury and risk (Little & Wyver, 2008; Sandseter, 2007). There is no doubt that in today's increasingly regulated and controlled society, safety concerns have led to reduced opportunities for children to engage in risk-taking play outdoors (Tovey, 2010). Although children's risk of injury may be reduced by limiting the risks they can take, there may be long-term negative effects associated with lack of risky play opportunities, such as diminished psychological well-being (Tranter, 2005) and other detrimental effects associated with inactivity (Little & Wyver, 2008). In fact, in Minority western cultures, children today spend more time watching television and being indoors than they spend being active in outdoor environments (McCurdy, Winterbottom, Mehta, & Roberts, 2010).

There is growing recognition of the value of children's interactions with the natural environment (Warden, 2010). The recent movement of nature kindergartens and forest schools in some Nordic and European countries supports this notion of the importance of providing rich opportunities for children to connect with and explore the natural environment (Lysklett, Emilsen, & Hagen, 2003; Nilsen, 2008). In such early childhood environments, nature serves as a pedagogical environment, rich with natural resources to support children's learning (MacQuarrie, Nugent, & Warden, 2017). Early childhood connections with nature – in this case through forest schools – have been shown to increase environmental attitudes (Turtle, Convery, & Convery, 2015). Attitudes toward conservation of the natural world may depend on deepening connections between children and the outdoor environment (Gill, 2014).

Research has found that there are a variety of factors which influence children's opportunities to experience outdoor risky play (Lester & Russell, 2008). The social ecology model (Bronfenbrenner, 1979, 2001, 2005) can be applied to this topic as a framework for analyzing the ways in which different systems interact to promote or limit these opportunities for children. Indeed, children's opportunities for nature-based risky play occur in a variety of contexts, including ECE environments, at home, in the community, and within cultural, political, and environmental contexts. The outdoor natural settings that children have access to are important environmental contexts that can support children's deepening connection to nature. These different "systems" and the adults and natural barriers within them can act as filters for children's available opportunities to engage in nature-based risky play. Although research indicates that it is important for young children to develop independence, learn to manage risks, and explore the natural world, adults' desires to keep children safe can impede opportunities to develop these skills particularly within natural settings (Lester & Russell, 2008; McFarland & Laird, 2017). Therefore, it is important to examine contextual influences in relation to providing children with nature-based risky play opportunities.

When exploring the connections between sociocultural theory and the natural world, connections between these spheres can be difficult to illustrate, as research exploring the psychological links between humans and the natural world began more recently in the latter part of the twentieth century. From the commonly referenced biophilia hypothesis (Wilson, 1984) to modern psychological studies of connections with nature (Schultz, 2002; Nisbet, Zelenski, & Murphy, 2009), a plethora of research shows our inclination to explore the natural world stems from a long and deep relationship with our environment. However, although humans remain inherently connected to the natural environment, particular sociocultural factors can impede or promote opportunities for children to directly engage with nature. For example, a child who lives in an inner-city apartment complex may not have regular access to green space, or children in certain early childhood education settings may not have access to extended outdoor free play due to health and safety regulations. Such restrictions on children's exploration of nature may in turn impact their future development and possibly even later conservation behaviors and actions (Muhar et al., 2018, see Fig. 3, p. 10).

Although some research on children's outdoor, nature-based risky play do exist (Cevher-Kalburan & Ivrendi, 2016; Little, Wyver & Gibson, 2011), this chapter builds on this research in several ways. First, by examining the issue using the framework of the social ecology model, we review the literature and present new research in the context of children's contextual systems in relation to nature-based risky play. Secondly, we discuss new research findings focused on children under 3 years of age. This is important as most studies in this area have focused on older children. The findings related to children under 3 years are significant as the early years are a period of rapid development in brain growth and cognition. Finally, we review literature and include new research from a sample of early childhood educators and parents in two countries (the United States and Australia) in both rural and metropolitan areas. Though examining two different countries' findings in relation to facilitators and barriers to children's opportunities for risky outdoor play, we acknowledge that much of the research has come from a middle-class, Minority Western view. Implications of this minority world view will be discussed.

Children's Play

It is common in the early childhood sector to use the phrase "learning through play." The Early Years Learning Framework (EYLF), which is Australia's national early childhood curriculum framework, describes play-based learning as "a context for learning through which children organize and make sense of their social worlds, as they actively engage with people, objects and representations" (Department of Education, Employment Workplace Relations [DEEWR], 2009, p. 46). But what exactly constitutes play? Although there is no one definition, there are a number of generally agreed-upon characteristics of play (Barblett, 2010). Play is a pleasurable activity but can sometimes include frustrations, challenges, and fears. Play also often includes "pretend" elements and requires some sort of action, whether it be physical,

verbal, or mental engagement with materials, people, ideas, or the environment. Play is freely chosen, process-oriented, and rewarding to the player (Shipley, 2008). Play is a necessary and healthy part of childhood.

Characteristics of Risky Play

There is some variation in the literature in relation to what constitutes "risky play." Most literature suggests that risky play is a natural part of children's play and that children actively seek out opportunities to challenge themselves (Sandseter, 2007; Stephenson, 2003). There is also agreement that risky play typically involves some sense of thrill and excitement for the child (Tovey, 2010). Children report that risky play evokes positive emotions, such as fun, enjoyment, pride, and self-confidence (Coster & Gleeve, 2008). Risky play also involves some chance that injury can occur and some sense of fear (Stephenson, 2003). At times, the outcome of risky play is not positive. If the child is unable to manage the risk, unpleasant emotions, such as fear and anxiety, can be experienced. Children report that the risky play is both fun and scary at the same time (Coster & Gleeve, 2008). Most of the time, in early childhood education settings, risky play takes place in the outdoor setting during unstructured, free play time (Sandseter, 2011). The development of forest schools in Minority western view countries is relatively new but provides greater opportunities than any other school setting to engage children in outdoor, nature-based risky play (Maynard, 2007; Waters & Begley, 2007). Risky play is commonplace in forest schools and often considered a positive aspect of the children's interaction with the natural environment.

It is important to distinguish between a *risk* and a *hazard*. A *risk* is something that can be negotiated and something that may be appropriate for particular situations and children; however, a *hazard* is something that is inherently dangerous and needs to be fixed or removed (Curtis, 2010). A "safe" risk means that the potential benefits outweigh the risk of possible harm and the consequences of the risk are likely to be minor (Kennedy, 2009). Risky play has many distinct classifications (Sandseter, 2007) including, *great heights, high speed, dangerous tools, dangerous elements, rough-and-tumble, and disappear/get lost*. This last risky play category has developed over time to become a major fear of many Minority western world parents (McFarland & Laird, 2017).

Benefits of Risky Play

There is copious evidence that risky play offers benefits for children in a variety of ways (Brussoni et al., 2015; Tremblay et al., 2015). Importantly, risky play allows children opportunities to develop decision-making skills about what risks they are capable of taking. In doing so, children learn to assess risks in particular situations, extend their personal limits, and learn important life skills (Tovey, 2010). For example, a child may decide that they want to climb to the top of a tree in the

park. The child then needs to work out how to go about doing this in a way that minimizes the chance of getting hurt. On the first attempt, the child might try to hoist themselves up by clutching a branch with their hands and hook their legs around the branch. However, the child might tumble to the ground when they realize the branch is too high to get enough momentum to hoist the rest of their body onto the branch. In this case, the child has to problem solve and may realize that if they move a large rock near the tree and stands on it, they would get enough height to be able to hoist up. In particular play situations that involve risk taking, children may sometimes succeed and sometimes fail. These failures can be learning opportunities in that they allow children to work out different ways of doing things in future situations (Tovey, 2010). As a result of this trial and error, emotional development is supported in that children's sense of motivation to accomplish goals and master new challenges is further developed (Stephenson, 2003). These failure experiences can be quite positive for children over the long term. Risky play can also lead children to experience positive emotions, such as feelings of fun, excitement, pride, and achievement (Coster & Gleeve, 2008), thereby increasing overall wellbeing. O'Brien (2009) reported increases in student self-esteem and confidence as a result of their forest school experience. These educators also noted social skills were improved along with their motivation and concentration, including the inspirational moments that come from new experiences in the natural world.

Social skills also develop from risky play as children build resilience and social competence when interacting with others (Kennedy, 2009). In engaging in risky play with others, children learn to express their opinions and make decisions. In group situations, children engage in give-and-take as they negotiate and confront risks. Additionally, the large and fine motor movements that children practice in risky play contribute to the development of balance, coordination, and body awareness. Children who have limited opportunities to engage in risky play may not be confident in their own physical abilities, have poor balance, and develop a fear of movement (Greenland, 2010).

A recent review of studies related to the benefits of risky play concluded that risky play impacts positively on various physical and social health indicators and behaviors in children (Brussoni et al., 2015). In one experimental study, children aged 4–6 years were exposed to a 14-week risky play intervention in their classroom setting, including within the classroom itself, and in a gym. The intervention was linked to improved risk detection and competence, increased self-esteem, and decreased conflict sensitivity, in relation to their pre-intervention performance, and when compared to a control group (Lavrysen et al., 2015). Other research has found evidence that risk taking in early childhood is related to positive outcomes in adolescence. Thus, experience with taking risks during childhood could help develop risk management strategies. This could in turn impact adolescents' ability to negotiate decisions about substance use, relationships, and sexual behavior (Gill, 2007; Ungar, 2007).

Nature-based risky play clearly provides many benefits for children (Fig. 1). However, there are certainly individual differences in how children experience these opportunities. For example, there is some evidence that boys and girls perceive

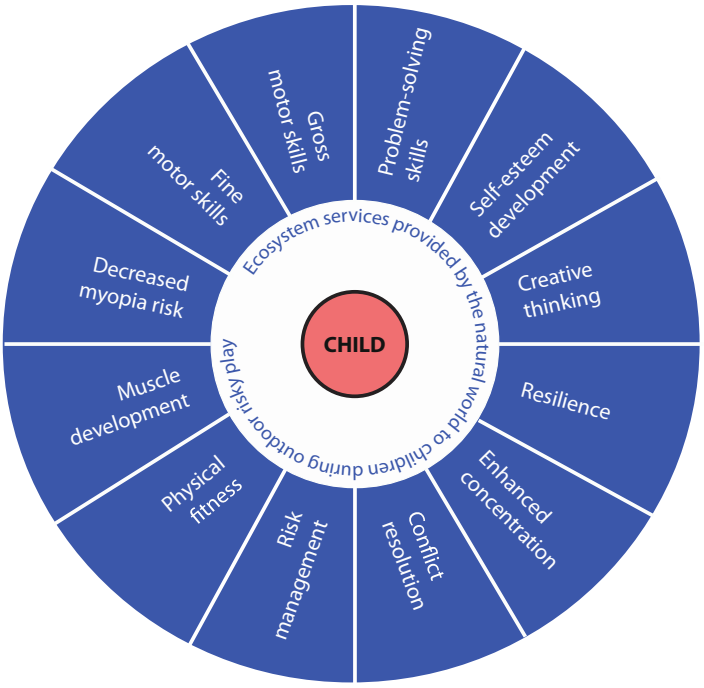

Fig. 1 Ecosystem services provided by the nature-based risky play interaction

opportunities of risky play differently – boys are more likely to assume they will not be injured, compared to girls (Morrongiello, Midgett, & Stanton, 2000; Morrongiello & Rennie, 1998). Also, different children will perceive and interpret their environments differently in relation to what they can do there and what types of play they can engage in (Sandseter, 2011). Children with particular behavioral disorders or disabilities may be less aware of how to manage certain risks in the outdoor environment (Kern & Wakeford, 2007).

Importantly, children's ages and developmental stages and their associated physical and decision-making skills need to be considered (Kennedy, 2009). Adults who care for children must be aware of general child development and have age-appropriate expectations of what children can and cannot do. However, an ages and stages approach should not be the only determining factor in the provision of opportunities for risk tasking. Thus, the assumption that a child cannot do something because he or she is too young can be restrictive. For example, it is sometimes assumed that babies and toddlers are "too young" to take risks (McFarland & Laird, 2017). However, there are endless possibilities for risk-taking opportunities for very young children. What is important is that adults consider a variety of factors related to the specific needs and skills of each individual child. As Rinaldi (2006, p. 94) states, "We need to raise our level of listening, our dialogue and attention toward children, to observe them and to stay close to them, but not to

Fig. 2 Temporal ecosystem interaction and engagement

scrutinize them, spy on them, impede them from maintaining their privacy, and above all not to inhibit their curiosity and joyous outlook on the world."

Children are naturally inclined to explore their immediate environment. Even as infants, children roam as they are able and use tactile and oral connections to explore the world around them. Though modern, some Minority western cultures have chosen to keep children in largely sterile and indoor environments, whereas exploration of soil, grass, and bush are common in many other parts of the world. These outdoor nature-based activities might be limited in scope by children's developmental level but can be designed to scaffold experiences for children based on where they fit (developmentally and spatially) into the ecosystem itself (Fig. 2). Although it is the case that all children, regardless of age and development, interact with elements and organisms in nature, very young children may be well-suited to interact with ground-level plant and animal communities, observing insects and grasses, whereas older children may participate in a more broad interaction with trees of

all heights and various larger plants and animals. As they continue to grow, the scope of children's interaction with nature can become more regional or even global in scope. Older children and teenagers are more likely to engage with a myriad of ecosystems and ecoregions through greater opportunities for travel and exploration.

A Systems Approach

Given the body of research, it is clear that many factors impact on children's access to and opportunities for outdoor risky play (Cevher-Kalburan & Ivrendi, 2016; Little et al., 2011). Two theoretical models which examine the influences of various systems in a child's life can provide useful frameworks to further examine early childhoodnature interactions, as both models consider a range of environmental and biological factors which can interact to influence uniquely and be influenced by individual children. The social ecology model (Bronfenbrenner, 1979, 2001, 2005) and Morrongiello and Lasenby-Lessard's (2007) model of psychological determinants emphasize the ways that multiple systems interact to influence children's risky play opportunities. Children exist as a part of these overarching systems and are influenced just as they themselves influence the natural world (Muhar et al., 2018, see Fig. 1, p. 2).

In order to understand the ecological models that exist in relation to children's risky play, Morrongiello and Lasenby-Lessard's (2007) model is first discussed. An ecological model focusing specifically on children's risky play, Morrongiello and Lasenby-Lessard's (2007) model emphasizes individual, parent/family factors, social/situational factors, and macro-level factors (e.g., neighborhood, economics, and culture) as determinants of children's decision-making in risky situations. In this model, children's opportunities for outdoor risky play are described as occurring in a variety of contexts, including early childhood education environments, at home, and in the community (Little et al., 2011). Therefore, the adults in these contexts act as filters or "gatekeepers" for children's available opportunities to engage in outdoor risky play.

The social ecology model takes a broader view than Morrongiello and Lasenby-Lessard's (2007) model and includes a wider variety of possible influences on the child. This model focuses on the direct and indirect impacts on the child of the "enduring environment in which he (sic) lives" (Bronfenbrenner, 1974, p. 2). This enduring environment, or ecology, consists of five nested systems of interaction: the *microsystem, mesosystem, exosystem, macrosystem,* and *chronosystem.* All of the systems influence and are influenced by the individual child. According to the social ecology model, the child is not a passive recipient of experiences within the systems. Rather, the child helps to construct these settings (Santrock, 2007). At the heart of these nested systems is the individual child and her or his characteristics, such as age, gender, health status, etc. (Fig. 3).

Although there is a strong human emphasis in the social ecology model, this model can also be used to examine interactions with ecological systems. In doing so, children's interactions with the natural world are seen as important factors in the

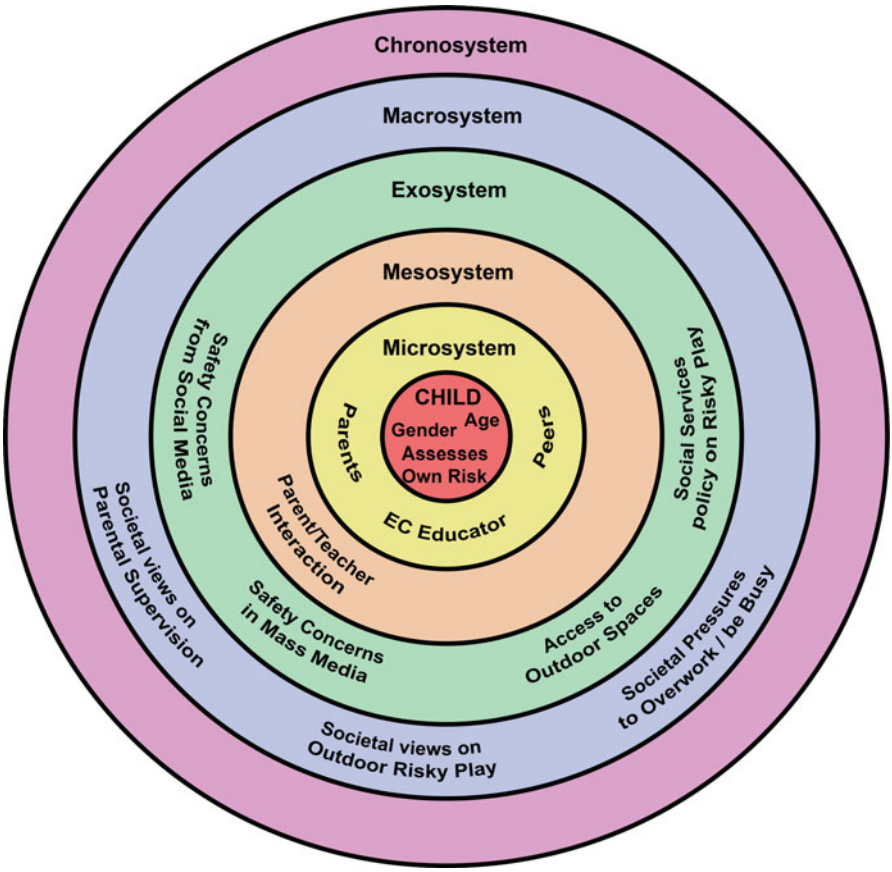

Fig. 3 A systems approach to risky play

development of ecological literacy (Stanger, 2011). Indeed, it is problematic to focus only on "human" systems when examining children's development and in particular, their opportunities for nature-based risky play. According to Stanger (2011), "if we are to use ecosystem-based language, it needs to describe the complex interrelationships that support the long-term integrity of living systems rather than the short-term singularity of human-designed marketing" (p. 167). Stanger (2011) further suggests that the true ecology that sustains and affects humans, including but not limited to, food systems, energy systems, biological systems, nutrient systems, water systems, and atmospheric systems is underrepresented in Bronfenbrenner's traditional social ecology model of human development. Thus, it is important to keep in mind the overrepresentation of the human influence when applying this model to examine children's nature-based risky play.

The *microsystem* includes the settings in which the child is immediately involved, including the interactions and activities within these settings. Bronfenbrenner also

defines the microsystem to include the "particular physical and material characteristics" of a setting (1979, p. 22). Here is where the most direct interactions with social agents occur, such as with parents, peers, and educators. The microsystem is also where the materiality of settings is important; these can include children's exposure to nature elements and/or nature-rich environments. In this chapter, the influences of several microsystems factors, such as parents and early childhood educators, on children's opportunities for risky outdoor play are examined.

The *mesosystem* involves relationships between different microsystems or connections between contexts. Important mesosystems for young children include relationships between the home setting and the early childhood setting or school, home and neighborhood, and early childhood or school and neighborhood. Indeed the early childhood setting and home setting mesosystem is particularly significant to the child's development and wellbeing (Garbarino & Plantz, 1980). Bronfenbrenner (1979) suggests that children's development is enhanced when there is frequent supportive communication between the home and early childhood settings. In relation to children's outdoor risky play, this mesosystem is important as early childhood educators and parents must work together to ensure appropriate opportunities are provided for children.

The *exosystem* includes social settings that have power over children's lives, yet in which the child does not have an active role. Exosystems can include education systems, mass media, social media, and social welfare services, to name a few. The exosystem can have an influence on children's opportunities to engage in outdoor risky play. For example, safety regulations and other regulatory factors and curriculum documents in the educational setting can support or hinder these opportunities.

The *macrosystem* includes the broad ideological and institutional patterns of a particular culture. A macrosystem is "the norms about how development proceeds and the appropriate nature and structure of microsystems, mesosystems, and exosystems" (Garbarino & Plantz, 1980, p. 12). In relation to children's opportunities for risky play, the exosystem is where a child's cultural beliefs and practices become important. Additionally, cultural beliefs of important adults in the child's life can impact the mesosystem. For example, it is possible that early childhood educators and parents will have different cultural views and practices in relation to encouraging children's risky play.

Finally, the *chronosystem* involves the patterning of environmental effects, transitions, and sociohistorical circumstances over the life course (Santrock, 2007). Essentially, the chronosystem is the "time" that passes throughout one's life. Certainly in relation to children's risky play, the chronosystem has an influence as throughout history, general attitudes, opportunities, and practices related to outdoor risky play have changed. In modern society risk taking during play has become increasingly regulated, managed, and controlled. At times, opportunities for risky play have been removed completely (Tovey, 2010). In Minority western countries in particular, there are fewer opportunities than ever before for children to engage in risky play. Today, children spend more time watching television and playing indoors than they do engaging in physically active outdoor play (McCurdy et al., 2010).

It is clear that children in Minority western societies are more sedentary and spend more time indoors than they did in past generations; this limits opportunities to engage meaningfully with nature (Louv, 2005). The reduction in children's direct exploration of nature may also impact opportunities to engage in risky outdoor play. There are various reasons why this is the case. Using the social ecology model as a framework, the impact of multiple systems in a child's life can be examined in relation to children's opportunities to engage with and connect to nature, including opportunities for risky play (see Fig. 3). As discussed, Morrongiello and Lasenby-Lessard's (2007) model can also be used to specifically apply to contextual influences on children's risky play. Given the numerous benefits of outdoor risky play, it is important to understand how these systems work together to support or hinder such opportunities for children.

Facilitators and Barriers from a Systems Perspective

Here, we examine our own (McFarland & Laird, 2017) and others' research focused specifically on the two most important microsystems and how they influence children's opportunities for nature-based risky play: the family and ECE context. In doing this, we also discuss aspects of the exosystem and macrosystem which influence these microsystems. Finally, we address how the family-early childhood education setting mesosytem can work together to support children's nature-based risky play.

Parents/ Carers. One role of the parent is to provide opportunities and time for their children to participate in a broad variety of experiences to prepare children for broader aspects of life as they grow up. Not only do parents determine the extent to which their children get to spend time outdoors in natural settings, parental figures further extend this influence through their allowing for greater opportunities for their children to engage in nature-based risky play. Parents may also act as role models for children, as they model their own engagement with nature. In our research that surveyed a sample of parents from city and rural areas of the United States and Australia, the majority of parents recognized the importance of risky outdoor play and letting their children explore their own boundaries. Risky play was considered an important part of the childhood experience by many of the parents, particularly as it related to their own childhood experiences of gardening and outdoor free play (Laird, McFarland-Piazza, & Allen, 2014). This recognition of the importance of outdoor risky play was evident across all parents, regardless of whether they lived in the city or a rural area and whether they lived in the United States or Australia.

However, despite the recognition that risky outdoor play was beneficial, parents expressed concern as they considered the increased risk of injury and harm to their child through this type of unsupervised experience. Though the parent ultimately has the greatest amount of control over how much outdoor risky play their young child can participate in, the influences from outside the immediate microsystem of parent/child are easily seen though the parents' discussions exploring barriers to providing their children with such opportunities. For example, one parent stated that her

daughter "needs supervision in the front yard because of traffic" and another parent stated, "Our home is not an ideal space. . .we live on a busy street. We have a small fenced backyard, but it has steep terraces and drop offs." Additionally, outdoor risky play for parents seemed to come in a variety of levels, from high-risk play such as allowing children to play beyond the yard unsupervised to very low-risk play, such as playing with a parent close by on the ground.

Parents did not want to be seen as "helicoptering" their children. The phrase "helicopter parent" refers to a parent who is overprotective to an excess. This concern seemed much more deeply rooted in their own insecurities as a parent, and the perception others might have of them, than it was about any detriment to the children caused by the act of helicopter parenting itself. Research has also found that parents socialize boys and girls differently in relation to risky play (Morrongiello & Dawber, 1999, 2000). This is a microsystem factor, which can be influenced by exosystem (mass media-fear tactics) and macrosystem (norms of the culture). This means that boys possibly receive more experience at risk taking at a younger age thanks to the encouragement they receive to take greater risks or even just to play outside in general (Little, 2010).

Exosystem factors play a large role in parental attitudes toward children's risky play. Popular media can often present the world as an unsafe place, thus influencing parents' attitudes and parenting practices. For example, parents are often too concerned about traffic, the threat of kidnapping, wild animals, and other perceived dangers to allow their children to play and explore freely in the natural environment. This inflated level of fear created by popular media may influence parents to restrict their children to playing in their back yards or local parks, which may fail to offer appropriate nature-based risky play opportunities (Brussoni, Olsen, Pike & Sleet, 2012; Little & Wyver, 2008; Little et al., 2011). Other exosystem factors that can play a role in parental attitudes toward children's risky play include their own neighbors, neighborhoods, and social services. In recent years, US neighbors have called police officers to check on children seen in their own yards playing unsupervised (see Roy, 2014), which can lead to an investigation by local child services departments for neglect. This fear of punishment from child protective services departments or police departments can be shocking for privileged parents but could even have more dire consequences for families that already struggle under systems that disproportionately disadvantage certain populations. The survey indicated that access to safe outdoor spaces in which to explore was a concern of the respondents in trying to provide nature-based risky play opportunities for their children. In acknowledging our primary research experience and focus here comes from our middle-class and minority world view, we can identify that these exosystem factors might be further influenced through attitudes across the broader culture. Thinking about society's expectations for parents concerning their child's participation in outdoor risky play, macrosystem influences may vary greatly.

Since its release in 2005, Richard Louv's book, *The Last Child in the Woods*, has greatly influenced many middle-class minority world parents through its reflection on a simpler time when children roamed the woods unimpeded in nature-based

outdoor risky play. This unimpeded nature-based outdoor risky play described by Louv (2005) is often the type of early play experienced and recalled by adults. In our study, many parents discussed their early outdoor play experience, consisting largely of unsupervised and unimpeded exploration of the outdoors (Laird et al., 2014). This look back toward an ideal risky play type, based in a largely middle-class context, means that parents might find other types of nature-based risky play unacceptable or not "real" or "authentic" outdoor experiences (Dickinson, 2013). Children from low-income households might undertake risky behaviors through engaging in play outdoors in open spaces or vacant lots nearby. Children from urban areas might explore a local manicured park as their only possible access to a natural-type outdoor setting. However, these spaces may not be considered as "authentic" as the wooded setting of a forest school or the rolling hills of an open grassland. These cultural biases on what constitutes "authentic" nature-based risky play have created an oversight in the literature based on the experiences most likely to have occurred in the middle class Minority western parents who are more likely to be involved in research studies. Our own research goes some way to address cultural biases by including participants in urban and rural areas in both Australia and the United States.

There was a certain level of privilege in our sample groups, both urban and rural in both Australia and the United States. One response that seemed to have a strong macrosystem level embedded cultural view from the parents was that their child, no matter how young, was too young to be participating in outdoor risky play. Parents would say, "she's only two," or "he's only five," noting that they should not be left on their own unsupervised at any moment. This idea seemed pervasive across the two countries and urban and rural parents. Certainly anyone who has spent time outside of this privileged ideal of constant parental supervision knows that many children in other countries or socioeconomic groups are allowed to explore on their own around their own yards, neighborhoods, local areas, and/or perhaps even villages or towns from quite young ages, either from necessity or due to cultural differences in child rearing practices. This idea that there is a certain age when it becomes acceptable for children to participate in outdoor risky play may be a concept based in the Minority western, middle class culture of our participating parents. Another consistent macrosystem level cultural view observed from the parents was the concept of temporal restrictions on outdoor risky play. The parents reported positive views on children engaging in outdoor risky play but then note their largest barrier is too little available time to spend engaging in that way. Barriers cited included homework and after preschool activities, along with arrival at home after dark in the evenings. Certainly, the concept of "busy-ness" is relatively constrained to Minority western, middle class cultures as well.

Early Childhood Educators. Early childhood educators are no doubt, important influences in children's lives. Increasingly, young children are spending more time in ECE settings. For example, in Australia, the majority of children between the ages of 3 and 5 years attend some form of ECE programme. Rates of children under the age of 3 in formal ECE are also increasing in Australia (Baxter, 2015). In the United States (Child Trends, 2016) and England (Department for Education, 2016), the rates of attendance in ECE

settings are similar to that of Australia. The rates of children under 3 attending formal ECE settings in Nordic countries, such as Denmark, the Netherlands, Iceland, and Norway, are well above 50%. In some European countries, such as France, Spain, Belgium, and Italy, the average enrolment rate of children between 3 and 5 years in formal preschool education is around 100% (Organisation for Economic Co-operation and Development [OECD], 2014). Clearly, for many children around the world, the early childhood setting is a microsystem that will play an important role in their lives.

In relation to nature-based risky play, Greenfield (2003) argues that ECE settings play an important role in providing young children with opportunities to safely to take a variety of risks and extend their skills and capabilities safely. Environments such as this can empower children to construct their own learning and develop confidence and resourcefulness (DEEWR, 2009). The national curriculum documents of various countries provide early childhood educators with an overarching framework for curriculum and pedagogy. The curriculum documents represent an *exosystem* influence on children's opportunities for risky play.

Directly related to risk taking, the Australian Early Years Learning Framework (EYLF) states that children can reach the outcome "Children have a strong sense of identity" by taking considered risk in their decision-making and learning to cope with the unexpected (DEEWR, 2009). Other early childhood curriculum frameworks, while not specifically referencing risky play, discuss the importance of the development of physical skills, managing their environment and asking for help when needed. For example, England's Early Years Foundation Stage Framework (EYFS) states that ECE settings should provide "opportunities for young children to be active and interactive; and to develop their co-ordination, control, and movement" (p. 8) and that children should be encouraged to "investigate and experience things, and 'have a go'" (Department for Education, 2017, p. 10). Certainly in Nordic countries, the value of children's experiences in rich, natural outdoor environment and engagement in risky play is advocated by educators and parents alike (Aasen, Grindheim, & Waters, 2009). This wide acceptance of the value of such experiences is well supported by the Framework Plan for the Content and Task of Kindergartens (Norwegian Ministry of Education and Research, 2011), which states that "(staff must) facilitate and provide inspiration for safe and challenging physical games and activities for everyone, regardless of gender and physical, psychological and social circumstances..." (pp. 35–36).

Despite the exosystem influence of national curriculum documents and their support for children being engaged in physically active and exploratory play, opportunities for this type of play vary as this is controlled by early childhood educators and determined by teacher beliefs (Little et al., 2011). For example, when educators' personal attitudes about risky play are more positive and when they enjoy being outdoors themselves, they are more likely to support children's risky play (Stephenson, 2003). Similarly, Sandseter (2007) found that when educators have a more positive view about the benefits of risky play, they are not likely to prevent risky play on grounds of possible injury alone. Additionally, Waters and Begley (2007) found that educators at a forest school, where there is a heavy focus on outdoor play, were

more likely to support children's risky play compared to educators at a traditional preschool.

Of course, even if early childhood educators hold positive beliefs about the importance of outdoor risky play, they need to balance children's safety with such play. Educators must apply mandated safety regulations to their work with children, which is another exosystem influence. For example, in Australia, ECE settings are mandated by the National Quality Standards (NQS), which is intended to maintain quality and consistency across settings (Australian Children's Education and Care Quality Authority [ACECQA], 2012). Related to provisions for outdoor risky play, Quality area 2 of the NQS "Children's Health and Safety" mandates that "Each child is protected" (Standard 2.3) and that "Every reasonable precaution is taken to protect children from harm and any hazard likely to cause injury" (Element 2.3.2) (ACECQA, 2012). Clearly, in light of safety regulations, a risk-benefit analysis needs to be undertaken where the possibility of children's injuries is weighed against the potential benefits of children's outdoor risky play (Sandseter, 2011).

Evidence suggests that due to the growing culture of litigation, early childhood educators are increasingly concerned about being held liable for injuries to children in their care (New, Mardell, & Robinson, 2005). early childhood educators do indeed have legitimate concerns over injuries and want to avoid taking the blame for accidents (Tovey, 2011). However, in an attempt to avoid injuries and liability, early childhood educators may often put restrictions on children's play based on their own perception of what is risky or dangerous, rather than assessing individual children's capabilities of managing risks (Sandseter, 2011). As such, early childhood educators may at times enforce controls on children's outdoor activities that they perceive as risky. These restrictions, in turn, may lead to children feeling disempowered (Stan & Humberstone, 2011). It is sometimes assumed that by removing all risks, children will be safer in their environment. However, this assumption fails to acknowledge that risk taking is a positive feature of children's play, learning, and development (Tovey, 2011). Sandseter (2010) suggests that this safety-obsessed society could result in children who are less physically fit and skilled and who have less ability in managing risks. Additionally, reduced opportunities for children to engage in outdoor risky play may result in an impoverished relationship with nature, as risky play provides opportunities for children to interact in meaningful ways with nature.

The mesosystem of the early childhood setting is also impacted by *macrosystem* influences related to cultural attitudes and norms around outdoor play in general. Waller, Sandseter, and Ärlemalm-Hagsér (2010) note that even between world Minority western countries, there is great variability in the culture of childrearing and what types of care are considered normal or acceptable. For example, the rise of forest schools in some Nordic countries may have emerged trhrough Nordic cultural preference for outdoor recreation and emphasis on social engagement in the ECE environment versus the more academic emphasis of more English speaking countries (Waller et al., 2010). The forest school approach facilitates student learning through immersion in the outdoor environment and even focuses on child-led experiences (Maynard, 2007; O'Brien, 2009; Turtle et al., 2015), with these experiences being increasingly important as a part of the early childhood experience (Knight, 2009, 2011). As early

childhood educators and education centers take notice of the increasing movement to get children connecting with the natural world, these cultural influences will result in more intentional outdoor learning in environments such as forest schools, increasing the possibilities of outdoor, nature-based risky play for children.

The preceding discussion has illustrated some of the challenges facing early childhood educators in managing children's opportunities for outdoor risky play. Using the social ecology model (Bronfenbrenner, 1974), we have identified a complex interplay between children's *individual* characteristics (age, developmental abilities), *microsystem* (the home, ECE setting and educator and parent beliefs), *exosystem* (national curriculum documents and mandated safety regulations), and *macrosystem* influences (cultural perspectives). Clearly, early childhood educators have a role to play in the provision of outdoor risky play for children. Importantly, however, so do parents. Educators and parents must therefore work together within cultural and regulatory systems in order to ensure appropriate opportunities for risky play are provided for children.

Implications for Childhoodnature and Early Childhood Education

There is clearly great value in children's interactions and explorations with the natural environment (Warden, 2010). Therefore, it is important to provide rich opportunities for children to explore nature in meaningful ways (Gill, 2014; Lysklett et al., 2003; Nilsen, 2008), as there are a range of physical, social, and emotional benefits (MacQuarrie et al., 2017). One way to promote and enhance children's connection to nature is to allow opportunities to engage in risky outdoor play. Through outdoor risky play, children are able to interact with nature in a hands-on way, where they not only develop their physical, social, and cognitive abilities but also an appreciation of nature.

In order to make risky outdoor play available to children in ECE settings, it is necessary to create a well-supervised and supportive environment where the benefits of risky play can be balanced by decreasing the risk of injury. In doing so, early childhood educators must recognize the benefits of risky play and use their own professional judgment to create opportunities that are appropriate for the children and families at the setting. Risky play opportunities must also be set up in a way that is age appropriate (Richardson, 2013). However, accidents do happen even in the most well-planned and supervised setting, and it is important for educators, as well as children, to learn to deal with them (Richardson, 2013). As Warden (2011, p. 13) suggests, "The adult role is to remove hazards that the children do not see, not the risks within the day." Little and Eager (2010) found that allowing children to have input into the design of playgrounds or risk-taking opportunities can encourage them to take more appropriate risks. When only low-risk opportunities were provided to the children in their play time, children were more likely to use play equipment incorrectly, increasing their risk of injury.

Importantly, potential barriers that could restrict children's opportunities for outdoor risky play, both in ECE and in relation to educating parents,

need to be addressed. Firstly, some further education may be necessary on the part of ECE training institutions to provide up-to-date information to future early childhood educators on the importance of nature-based risky play for young children and the ways that children can explore taking risks in the outdoor environment. early childhood educators also have the opportunity to influence the parent perceptions of outdoor risky play through positive talk or reports on risk-taking accomplishments of their children each week. For example, when sharing children's portfolios and documentation with parents, emphasis can be placed on the various skills children acquire through outdoor risky play. Resources and newsletters can also be distributed to families about the benefits of outdoor risky play (Wilkinson, 2015). ECE centers might consider offering parenting seminars or workshops focused on topics important to the centers, including the importance of managed risks in the development of young children. Obviously from the plethora of sources noted here, there are many ECE professionals and researchers who are promoting the importance of risky play, but this information is not reaching parents or the public in a way that is influencing their behavior. Parents need to understand that some injury may result from any activity within the early childhood setting, including activities that are not necessarily considered risky. Some parents noted a lack of time or being too busy as a barrier for their child to participate in outdoor risky play; however, these parents may already be benefitting by their children participating in an ECE center that allows children to take appropriate risk, as many of our center educators noted was valued. Some of the other barriers parents note are more difficult to address, including access, safety, and age because these influences lie at the exosystem and macrosystem level of Bronfenbrenner's social ecology model and are not as easily changed.

An understanding of developmentally appropriate risk for parents is necessary for children to receive the appropriate opportunities for outdoor risky play outside of the ECE center environment. Inclusion of nature enrichment experiences and risk accomplishments in weekly reports to parents, just as they would report for other accomplishments like learning new words or skills, could contribute to a more positive view of risk by parents and carers. Practice for the parents may help in overcoming their fear response, perhaps even with a coach on the playground or outdoor environment that could help parents understand the age-appropriate risks involved in various activities. Many parents may not know that very young children are likely to gain positive experiences from activities as simple as playing in sand, experiencing different textures of different plants or grass types, or playing near structures they may need to crawl over. Parents of young children may not be aware of how developmentally capable children are and may need clarification on how to promote particular age-appropriate developmental skills related to outdoor risky play, for example, independent climbing up a rope structure. Parental understanding of the capabilities of young children is needed to counteract the exosystem bombardment of mass media messages of safety concerns for children. The importance of the mesosystem connections between ECE professionals and parents here cannot be underestimated. This interaction has the potential to influence the child/parent relationship and ultimately help to create

more opportunities for children to engage in outdoor risky play, thus, building children's meaningful connections to nature.

Conclusion

The benefits of childhood risky play in nature are plentiful and natural. The exploration of potential barriers to and methods for encouraging risky play by children allows for a deeper understanding of the childhoodnature relationship. Through a systems approach, using the social ecology model as a guide, we reviewed the importance of an integrated approach across system dynamics in order to create more opportunities for outdoor and nature-based risky play in early childhood. Many of the barriers to children having access to outdoor risky play opportunities lie at the macrosystem and exosystem levels of this model. Such issues are more difficult to tackle with individual parents or ECE centers on a microsystem level. However, ECE centers and professionals have a great deal of opportunity to engage with parents at the mesosystem level, influencing the lives of the children through engaging their parents in meaningful discussion and even illustration of the importance of appropriate risk, especially in the form of outdoor risky play.

The interactions of early childhood educators and parents could play a vital role in overcoming the macrosystem and exosystem barriers to the provision of outdoor risky play opportunities by parents in the home environment. Parents may not fully understand the importance of outdoor risky play and therefore do not make it a priority for their children during out of school and work hours. Focusing on the views of parents that the outdoor environment is unsafe or that their children are too young to engage in outdoor risky play, early childhood educators could provide educational opportunities for parents to overcome these limiting views. Inclusion of nature enrichment experiences and risk accomplishments in weekly reports to parents, just as they would report for other accomplishments like learning new words or skills, could go a long way in providing a positive view of risk by parents and carers. ECE centers could also provide parental professional development as they often do for other parenting issues that engage parents in learning about early childhood development and the risks appropriate for each age group, as well as how to assess needs based on their own child's ability level.

Some parents also reported access as a barrier to providing opportunities for their children to engage outdoors; this issue has been relaxed recently through the movements to get children outside. Hopefully these infrastructure projects will continue, and access will no longer be a barrier for parents or children.

Though the cross-cultural variances observed in the literature are interesting, overall Many minority western countries tend to be very risk averse. Little literature exists on outdoor risky play outside of the Minority western view countries. Opportunities for children to take risks, and thus enhance their development, need to be provided purposely by adults, as children face very few risks daily in these countries. The Scandinavian countries seem to be more advanced in their prioritizing of providing outdoor risky play opportunities, particularly through their focus on

outdoor recreation and forest schools. The growing popularity of the forest school movement in many English speaking countries seems to be increasing the focus on the positive impacts of outdoor risky play in these countries as well.

Given the plentiful benefits of outdoor risky play, particularly in risk averse Minority western countries, offering these opportunities is increasingly important in ECE settings. Though they may be hesitant, ECE professionals and educators who understand and promote outdoor risky play need to engage more with the socio-ecological exosystem and macrosystem level factors that are influencing parents' hesitancy to provide outdoor risky play opportunities for their children. Writing more mass media articles or appearing on social media as a proponent of outdoor risky play is a possible way to influence these spheres that ultimately will influence parents. As the media and cultural systems begin to emphasize the importance and acceptability of outdoor risky play for young children, greater opportunities to engage in risk will advance early childhood development.

Abstract

This chapter offers an in-depth exploration of Māori systems of knowledge, outlining an ecological literacy grounded in a deep interconnectedness to land, rivers, and other geographical features made available to children through their integral engagement with whenua (land) and whānau (extended family). This

ecoliteracy was symbiotically emergent in relation with the cohabitants of these places, generating a mutually beneficial biocultural diversity. This biocultural diversity, that is, the Māori language, their lands, and the biodiversity that previously thrived upon these, has all been threatened by the onslaught of colonization, of which the ultimate result is monocultures of the mind and of the land. The complexity of Māori onto-epistemologies, their belief and knowledge systems, is illustrated with an explanation of how their complex navigation systems enabled their settlement of Aotearoa and ongoing navigation around their own islands, as well as between those of the South Pacific. These knowledges are passed on intergenerationally through children's participation in biocultural practices such as sustainable mutton-birding. Tribal sayings serve as detailed identity markers and also preserve wisdom that is thus transmitted to young children. Finally, some key Māori values that relate to biocultural sustainability are explained, along with some examples of their application within early childhood care and education settings.

Keywords

Biocultural sustainability · Ecocultural literacy · Māori · Indigenous · Early childhood

Glossary

Aotearoa	Land of the Long White Cloud
Aroha	Respectful mindfulness, love
Atua	God, deity, supernatural beings
Hapū	Sub-tribe/pregnant
Harakeke	Flax
Iwi	Tribe, people, bones
Kaitiakitanga	Guardianship, stewardship, trusteeship
Karakia	Highly ritualized ceremonies, prayers and incantations
Kaupapa Māori education	A distinctly Māori, philosophically and linguistically enriched, education system
Kōhanga Reo	Māori language nest
Kura	School
Kura Kaupapa Māori	Kaupapa Māori immersion schools
Māhutonga	Southern Cross
Mana	Prestige, authority, control, power, influence, status, spiritual power
Manaaki	To support, take care of, give hospitality to, protect
Māori	Indigenous People of New Zealand
Marae	Formal Māori gathering place
Mātauranga Māori	Māori knowledge

Mirimiri	Similar to massage/physiotherapy
Mokopuna	Grandchild
Moutere Tītī	Muttonbird Islands
Ngāi Tahu	Tribal group, South Island
Pākēhā	Non-Māori New Zealanders
Papatūānuku	Mother Earth
Pepeha	Tribal sayings
Pūrākau	Narratives and storytelling
Rangatiratanga	Chieftainship, right to exercise authority, chiefly autonomy, sovereignty, chiefly responsibility
Rāhui	Restricted access, prohibition
Rakiura Māori	Southern tribal grouping
Rangi	Sky
Ranginui	Sky Father
Ritenga	Incantations and rituals involved with healing
Rongoā	Physical remedies derived from trees, leaves, berries, fruits, bark, and moss
Tamaiti	Small child
Tamariki	Children
Tangaroa	God of the Seas
Taniwha	Powerful creature, chief, powerful leader, something or someone awesome
Tāngata whenua	People of the land
Tapu	Sacred, prohibited, under protection, restricted
Te ao Māori	Māori worldviews
Te ao Pākehā	Pākehā worldviews
Te Moana Nui a Kiwa	The Ocean of Kiwa or Pacific Ocean
Te reo	The language
Te Waipounamu	South Island
Tikanga	Custom, cultural ways of being and doing
Tino Rangatiratanga	Right to exercise authority, chiefly autonomy, self-determination
Tiriti o Waitangi	Treaty of Waitangi
Tītī	Sooty shearwater
Titiro, whakarongo, kōrero	Look and listen before you speak
Tōhunga	Reader of signs from nature, spiritual expert, and healer
Wairua	Spirit
Waka	Canoe
Whakapapa	Genealogy
Whakarongo	Listen
Whakatauākī	Proverbial saying according to someone
Whakataukī	Proverbial saying

Whānau	Family (including extended)
Whanaungatanga	Relationships, connectedness
Whare	House
Whāriki	Flax mat
Whatumanawa	Inner heart, core
Whenua	Land

Introduction

Māori, the Indigenous peoples of Aotearoa (New Zealand), have their own ecological literacies, ecological thinking, and ecological identities, grounded in their own onto-epistemological systems. Connectedness and interrelatedness with their lands, mountains, rivers, lakes, languages, and oceans is at the center of these systems. Genealogically, Māori, as descendants of Papatūānuku and Ranginui, the Earth Mother and Sky Father, are related to these ancestral landmarks, and to the trees and creatures that coinhabit with them, and are required therefore to exercise kaitiakitanga (Māori words are translated on the first appearance and also listed in the glossary section.) and rangatiratanga, that is, guardianship, care, and responsibility in relationship with all manner of beings and things. Indigenous languages are an integral part of the cosmology and onto-epistemology. They bridge the spaces between knowledge/knowing and experiential/physical domains and reflect both cosmological thought and the biocultural diversity of the land. Indigenous languages are embodied languages and grow out of the lands, seas, and skies. They exemplify critical knowledges of global ecological systems and are crucial to their sustainability. Beginning with an explanation of Māori ecological literacies as key to understanding Māori onto-epistemologies, this paper explains traditional applications of these ecological literacies in the realms of navigation and sourcing food sustainably. Key constructs such as rangatiratanga, kaitiakitanga, and rāhui (protective prohibitions) are then explained, followed by some examples of these constructs as they were applied in early childhood care and education settings. In this paper we draw upon our own research in the field of critical early childhood studies and Māori pedagogies.

Reading the World

The term "biocultural diversity" represents the interlinkages between linguistic, cultural, and biological diversity as interrelated components representing life on our planet (Skutnabb-Kangas, Maffi, & Harmon, 2003). Indigenous languages are integral to Indigenous onto-epistemologies, and therefore these must be supported if global biocultural systems are to be sustained (Skutnabb-Kangas et al., 2003). A biocultural perspective recognizes the interdependence of all living organisms, plants, animals, bacteria, and humans, living and flourishing together in networks of complex and delicate relationships. Further, it understands that damage to any part

of the network (with or among humans or the ecosystem) will result in unforeseen, perhaps unintended, and likely harmful consequences for the whole system. It is the diversity across the delicate and complex network of the ecosystem, which reflects eons of coevolutionary symbiosis, that continues to provide the potential for further adaptation and diversity (Flannery, 2010). Our human histories are characterized by increasing adaptation and diversification as we settle into new environments, adapting to new landscapes, ecosystems, and climatic conditions. Languages too diversify and adapt as they connect to new lands and the ecosystems therein. Linguistic diversity and biological diversity are, therefore, seen as inseparable. Moreover, in the language of ecology, the strongest ecosystems are those that are the most diverse. That is, diversity directly relates to stability; variety is important for long-term survival. Uniformity endangers species by providing inflexibility and inadaptability (Skutnabb-Kangas et al., 2003). Our success on this planet has been due to an ability to adapt to different kinds of environments (cosmic, atmospheric, and ecological as well as cultural-linguistic) over millennia (Flannery, 2010). Survivability and sustainability are born out of diversity and adaptability. Linguistic and cultural diversity maximizes chances of human success and adaptability; our futures are dependent on it. Creation and innovation are born out of it. Therefore, as Skutnabb-Kangas et al. (2003) assert, the diversity of life goes beyond respecting biodiversity to include cultural and linguistic diversity, which is what is meant by the term "biocultural diversity."

Māori are the tāngata whenua (Indigenous people of the land) of Aotearoa. Te reo Māori (the Māori language) is the terralingua of Aotearoa, the Indigenous language of this land. It is the first language mapped on to this land, finely tuned to the geography and ecology of this space and place, with a lexicon that was created and adapted to the biodiversity that is Aotearoa. The language and/or the land are intricately interwoven into what can be described as a "tāniko" (detailed weaving) of fine ornamentation, presenting a delicate network of personification, symbol, metaphor, aphorism, and allegory, recording tribal histories, memories, genealogies, narratives, cultural activities, beliefs, and spirituality. The language and land comes together bundled up in symbiotic relationship with, and alongside, seas, skies, and all manner of creatures. McLintock (1949) alluded to this close relationship between Māori and their deeply embedded relationship with Papatūānuku (Earth Mother) when he proclaimed Māori were simply part of the geography "set in motion" and as such indivisible from more-than-human nature. He argues:

> In the remote past the physical environment of a society was its dominant factor, and even among primitive people, such as the pre-European Māori, the human being was largely at the mercy of omnipotent nature. Natural phenomena dominated his (sic) thoughts, controlled his life and shaped his religion. In a very real sense, such history could be regarded as merely geography set in motion. (p. 7)

Traditionally, Māori children (mokopuna, tamariki, tuakana, teina) were positioned alongside adults in an inseparable pattern of relationships between the gods, ancestors, elders, and wider family members. Mokopuna (the etymology of which stems from moko meaning facial markings or ancient and puna, a sacred spring) then translates to "the ancient spring, or blueprint, of your ancestors," in today's world

commonly understood to be grandchildren. Tamariki (translated to mean "the descendents of the Gods") is commonly understood today to mean "children," tuakana (elder or senior relations to either brothers, sisters, cousins, and/or distant cousins), or teina (younger or junior relations to either brothers, sisters, cousins, and/or distant cousins). The networks or patterns of relationships were a fine-tuned one. The way these terms were used explained the nature of the relationship, whether close or distant, past or future. The "modern" constructs of childhood, child, and grandchild did not exist traditionally but are often transposed today onto Māori society, as is the construct of the nuclear family for "whānau" which, traditionally, also had a much wider compass, not the confined, self-contained entity of "family" in the English language sense. Traditionally children were born into much more dynamic systems of whakapapa (kinship and genealogical ties) and were positioned as representative of all their whakapapa ties, in all facets of their lives in traditional Māori society. Salmond (2017a) argues that it is the relationship itself and its relationality (not its quality or the parties involved) that is ontologically prior. She recalls one of the very first missionaries, the Reverend Samuel Marsden from the Church Missionary Society, commenting on the role of children in the early 1800s. He said

> The Chiefs are in general very sensible men, and wish for information upon all subjects. They are accustomed to public discussions from their infancy. The Chiefs take their Children from their Mothers breast, to all their public Assemblies. They hear all that is said upon Politics, Religion, War &c by the oldest men. Children will frequently ask questions in public Conversation, and are answered by the Chiefs. I have often been surprised, to see the Sons of the Chiefs at the age of 4 or 5 years sitting amongst the Chiefs, and paying such close attention to what was said… There can be no finer children than [those of] the New Zealanders in any part of the world. Their parents are very indulgent, and they appear always happy and playful, and very active. (cited at p. 114)

Salmond argues that Marsden "…failed to connect their happiness, however, with the absence of contemporary British child-rearing practices which included harsh physical punishment" (p. 114). The biblical notions of "spare the rod, spoil the child" and "children are meant to be seen, not heard" imposed through British colonialism were foreign concepts to Māori of the 1800s. The imposition of these British values and attitudes had a dire impact on both traditional and contemporary Māori child-rearing practices, colonizing the relationships between adults and children as well as their relationships with nature.

Drawing on reading the world through nature and natural phenomena, the following provides an exploration of the intimate relationships and interconnectedness across the delicate networking of the bioculture, across the sociolinguistic spaces and ecological diversities.

Interconnectivity Across the Bioculture

The concept of natural phenomena dominating Māori thought, life, behavior, and spirituality is inextricably entangled in our expressive Māori language, which reflects this coexistence. The colonization of the province of Otago provides an

example of how Indigenous peoples coexisted with Papatūānuku rather than seeking to conquer and control nature. In *The History of Otago*, McLintock (1949) raises what he considers to be the age-old "historical problem" of dualism of the actions of "Nature on Man" (sic) or "Man on Nature." Lack of understanding of Māori onto-epistemologies leads McLintock to hypothesize the nature of the relationship as being one of nature dominating human life, rather than coexisting, and thus the invader deciding the necessary reaction to be one of promoting human determination to control and subdue nature. He argues that the colonization of Otago provides the scope for an effective study of these two phenomena, so effective was that colonization process. The Nature on Man environment is argued as being stark and unsympathetic, where the people (Māori), merely part of the geography, must also be living stark and unsympathetic lives. In the colonial mind-set, that arrangement needed to change, to make way for "progress." McLintock writes:

> It is difficult to-day. . .to envisage the Otago landscape as it appeared to the pioneers, and—perhaps more difficult-to recapture the wonder it must have aroused within their minds. For those who assembled on the decks of the John Wickliffe and the Philip Laing to gaze with anxious eyes upon the land destined to be their home were greeted with a vista of what must have seemed an endless sweep of that sub-tropical rain forest, not the least among New Zealand's glories. .. Even to land-hungry immigrants, the virgin beauty of the scene must have made a strong appeal until the soon familiar sound of axe and saw shattered the brooding spell of centuries. (p. 15)

Southern Māori had cohabited with Papatūānuku for over a thousand years – had lived according to the principles of "rangatiratanga" and "kaitiakitanga" (responsibility and the protocol of giving and taking only what was needed) and manaakitanga (extreme care). But all too soon Papatūānuku became "it," an apparatus for western colonialist and capitalist expansion and exploitation, something now distanced from the closely respected inter-relationality of a Māori worldview. The mahinga kai (food gathering places) were commodified, cleared, and drained for farming or polluted by excrement by the invader state politics. Such encroachment led to the corresponding disappearance of the forests and birds;

> But the unique experiences [of the settler pioneers] were all too fleeting and soon, very soon, a solitary bird-note became the echo of a once lovelier song. For it was a tragedy, little understood or heeded in those early decades, that the native birds were fated to disappear at a rate corresponding to the destruction of the forest. (McLintock, 1949, p. 22)

Indigenous people either died of introduced diseases, were killed, or forced into a new (hierarchical) modality of life. Lands were carved up; Indigenous peoples lives decimated in terms of the destruction of whānau (extended family), hapū (sub-tribe), and iwi (tribal) structure of Māori. When the invader colonizers arrived, they did not see, understand, respect, or even heed, as McLintock alluded to, the beauty of Aotearoa and her resources. They quickly set about establishing deeds of ownership to turn the majesty of Te Waipounamu (the Greenstone Waters) into Her Majesty's commodity, essentially farms. As the native birds were fated to disappear at the rate of the destruction of their native habitats, so too were the languages and knowledges which were the voices of those habitats fated to disappear.

Māori Ecological Literacy: Navigation

Drawing on the navigation tradition of Māori people provides a closer example of reading the world through nature and natural phenomena. Prior to discovering the southernmost Pacific Islands that they were to name "Aotearoa," the ancestors of Māori already knew there was a large southern land mass because of the migratory pathways of varieties of birds, whales, and other marine life. They navigated by the signs of Tangaroa (God of the Seas) and Papatūānuku (Earth Mother) and Ranginui (the Sky Father) including stars, clouds, land, and sea swells. The migratory pathways of birds around the entire Pacific Rim provide many signposts.

The tītī (sooty shearwater) is one such bird. The flight of the tītī is spectacular, powerful, and direct, with wingspans giving the impression of an albatross, yet enabling them to plunge the oceans to depths of 16 m and to swim to depths of over 60 m. During migration, tītī travel on average a remarkable 74,000 km around the Pacific Ocean, which is the longest animal migration ever recorded electronically (Moller, Charleton, Knight, & Lyver, 2009). The flight takes them as far across the Pacific as Chile, Alaska, the coast of California, across to Japan, and back to the nesting grounds in the deep south of New Zealand, known to Rakiura Māori (the Southern tribal grouping) as the Moutere Tītī (Muttonbird Islands). Tītī survive and depend on the natural balance and harmony that nature provides while at sea and on land and are an integral part of the ecosystem in Aotearoa/New Zealand. Any disruption to this natural balance such as pollution, the annihilation of fish stock such as the krill, illegal commercial fishing, and the disasters like the deepwater horizon oil spill in the Gulf of Mexico and the Fukushima Daiichi nuclear meltdown disaster have profound repercussions for our wildlife in the South. The saying "He manawa tītī" refers to the fortitude and sheer power of flight possessed by the *tītī*, and so a person who is resilient and of strong spirit may be described as a possessing a "manawa tītī," the heart and substance of the tītī.

Māori Ecological Literacy: Food Gathering – Rapu Tītī (Mutton-Birding)

Every year some Rakiura Māori families migrate south with the birds to the Muttonbird Islands to gather a bioculturally controlled harvest. Ecological signs guide the migration and provide clues as to the nature of the breeding season that is coming. For several months before heading south, the moon is studied intensely, along with the flowering of the harakeke (flax) plants around Christmas and the feeding patterns of native birds in summer. The way the adult tītī birds sit in the water provides a sign, as well as the color of the ocean plentiful with krill. Māori traditional ecological knowledge of natural systems over time adds valuable ecological data to more conventional scientific studies, which are more of a snapshot at a particular point in time (Wehi, Whaanga, & Roa, 2009). It has been shown that the traditional "take" has little to no impact on total tītī population, but its significance for those families in terms of the intergenerational transmission of knowledge is

invaluable to Rakiura Māori, to Ngāi Tahu (wider tribal group of the South Island). It is a time to gather, rekindle whakapapa (genealogical links), practice tikanga (specific Rakiura Māori ways of doing things), remember those who have passed on, share stories, forge new relationships, renew old relationships, and participate in, and adapt, a tradition that has been fine-tuned over a thousand years. However, this tradition is currently threatened by dangerous "consumer-driven" wasteful and polluting lifestyles.

A recent study provides an example of how our western consumerism is having long-term devastating impacts on wildlife (Wilcox, Van Sebille, & Hardesty, 2015). It reports that plastics could taint 99% of seabird species by 2050 and that the impact of biodiversity loss on ocean ecosystems has unknown consequences. Seabirds have ingested bottle caps, children's toys, and other debris that they mistake for food. Then they die of starvation – if they do not succumb to the toxicity of the plastics first (Wilcox et al., 2015). Rakiura Māori are deeply concerned as a tribe and have been involved in ongoing scientific studies incorporating Māori traditional ecological knowledge based on a collective base of understanding our Earth Mother ancestor, Papatūānuku, and her descendants. The collective base is founded on how the people and environment live together in complete awareness of each other and diversify together through time.

Ancient Māori navigators also followed the whales and other marine life whose rate of travel is slow and easily within the cruising speed of Māori double-hulled canoes or "waka hourua." Ngāi Tahu Māori descend from Kahutia-te-rangi (also known as Paikea), who came ashore to Aotearoa on a whale. The time that the whales migrate south coincides with the appearance of the stars and planets most useful for navigating – particularly Māhutonga (the Southern Cross). The night sky was a map, and the sea was also a source of vast information, especially in terms of the relationship between lands and seas as navigation indicators. Changes in cloud color, sea color, fish species, ocean currents, and night skies are all important markers. There was no need for lighthouses or radar, so intimate was the relationship between people and the environment.

In Hawaii they say "Nana i ke Kumu" (Look to the Source), a saying often used by Hawaiian ancestors as a means of educating young people to seek answers from the elderly people. It also meant that one must study nature itself with all its wisdom in the forest and streams, the oceans and the skies, with all their life forms and the air that keeps them alive. In Ngāi Tahu we say "Mō ka uri e whai ake nei," emphasizing the importance of bringing the relationship between our ancestral knowledges and future generations together. But when the relationships are disrupted, so too is the delicate network between the people and the environment and their ability to read one another. They all begin to suffer. Wehi et al. (2009) argue that oral traditions offer a wealth of information that is frequently overlooked, in part because of the language shift that occurs with colonization. This shift gives rise to the lack of knowledge of the language, which in the context of Aotearoa is the Māori language. The relationships between what happens to the lands then have a close impact on the languages of those lands and the way those languages are transmitted to following generations.

Learning from Elders

Māori, having navigated their way down across Te Moana Nui a Kiwa (the Ocean of Kiwa or Pacific Ocean) to settle on the islands of Aotearoa, were faced with a very different, temperate climate along with a different set of flora and fauna. Many of the plants they had brought with them from their tropical homelands failed to thrive in the colder climates of Aotearoa. However, through their attunement with forests, wetlands, oceans, and rivers, Māori were able to develop an extensive, in-depth understanding of how to sustain their wellbeing in their new lands. Integral to Māori wellbeing were spiritual beliefs and practices that linked them on a regular daily basis with the Atua (departmental Gods) from whom they sought guidance. Māori children were thus inculcated into a range of wellbeing modalities which included the use of "ritenga and karakia (incantations and rituals involved with healing), rongoā (physical remedies derived from trees, leaves, berries, fruits, bark and moss), mirimiri (similar to massage/physiotherapy), [and] wai (use of water to heal)" (Ahuriri-Driscoll et al., 2008, p. 15). The particular practices were integrally related to the specific places in which each tribe (iwi), sub-tribe (hapū), and extended family (whānau) cohabited with local flora and fauna and imbued with spiritual interconnectedness (wairua) (Penetito, 2009). Whaea Rangimārie Rose Pere, who was born in the early 1930s, describes her childhood raised in the traditional way by her grandparents in the remote Urewera forest region:

> When the children of the Urewera got involved with aspects of mahi [work] alongside the adults on their daily pursuits they learnt the disciplines associated with each task they were expected to perform. The gathering of berries and vegetation such as pikopiko shoots, within a selected location, involved ritual and consideration for the patupaiarehe (supernatural folk) and other supernatural influences. The children quickly became accustomed to and respectful towards the bush and its inhabitants. The learnt how to lure or trap birds and could imitate their calls and sound patterns to perfection. . .. It was obvious from the expertise that Te Au [Whaea Rose's great-grandmother] and others of her generation had in regard to bush-lore, that Tuhoe-Potiki [her tribe] had a thorough practical training course for their young. There is no doubt that the way for children to learn is through first hand experiences involving the sense, alongside knowledgable, skilful people. (Pere, 1983, pp. 58–59)

As has been shown, Māori had a particular affinity with the many birds of their forests, wetlands, foreshores, and islands (Keane, 2010). Much tribal wisdom was encapsulated within tribal sayings, which reflected the respect for and knowledge gleaned from close observation of indigenous birds and their ecologies. The intergenerational disruption of those tribal sayings being handed on to successive generations through colonization meant not only were the sayings lost, but the tribal wisdom and knowledges that those sayings reflected were also lost.

Tribal Sayings

Māori, like other Indigenous peoples, many of whom had resided in their lands for thousands of years, had developed not only extensive pharmacological knowledge

systems but also had proactively developed sustainable plant production systems and protection protocols for local fauna (Wehi & Lord, 2017). Long periods of cohabitation enabled coevolutionary reciprocity that sustained biocultural well-being in which the Indigenous people positioned themselves in service to their cohabitants, their more-than-human kin which include the land, rivers, mountains, oceans, and all creatures residing in these spaces. Indigenous knowledge systems are, therefore, of the land and interdependent with it. Māori metaphorical understandings and wisdom are transmitted in whakataukī (proverbial sayings), such as "He pā tīkapu e takahia e au, he pā harakeke e kore e takahia, he tapu, he tapu, he tapu." This is translated by Pou Temara as: "A flax [Phormium] cultivation is sacred and not to be treated as if it were a grove of tī trees" (as cited in Wehi, 2009, p. 270). According to Māori elders such encapsulated statements of wisdom "provide a blueprint for human behavior, thus emphasizing the older–younger sibling relationship of plants and humans that is accepted in Māori philosophy" (Wehi, 2009, p. 269).

Our ecological spaces continue to be destroyed by settler-colonial exploitation of lands, rivers, forests, and fisheries, in breach of the 1840 Tiriti o Waitangi/Treaty of Waitangi, which is now considered to be New Zealand's founding document and which had explicitly protected these. Not only is the unique biodiversity increasingly severely endangered (Parliamentary Commissioner for the Environment, 2017), but Māori face the challenge of maintaining the language specificities and cultural knowledges that emanate from those powerful connections and long histories of cohabitant reciprocity (Wehi & Lord, 2017). Elders today may likewise struggle to pass on their knowledges to their mokopuna (grandchildren) as children are often no longer in their care; in urban settings Māori families lack access to traditional ecosystems (Wehi & Wehi, 2010).

Embodied (Land and Language) Knowledge

Māori knowledge melded Māori ancestors to the lands in Aotearoa and the surrounding oceans for over a thousand years (Walker, 2004). Elders embodied knowledge and a strong desire to perpetuate certain forms of knowledge through their close relationships with young children, the mokopuna (Best, 1924). It has been argued that Māori knowledge is also inscribed on the landscape and language-scape in a variety of forms: through naming people, places, phenomena and things, waiata (songs), karakia (highly ritualized ceremonies, prayers, and incantations), whakapapa (genealogy), pūrākau (narratives and storytelling), through tikanga (cultural ways of being and doing), spirituality, and beliefs, passed on by the elders. According to Jackson (2011), Māori knowledge systems allow us to know who we are, our environment, and all aspects of the ecosystem and thus enable us to face challenges through broadening thinking, providing pathways into the future. Metge (2015) discusses the two sides of Māori knowledge systems, the sacred aspects (those that are "tapu") that are not always readily available to everyone and the knowledge that is available to all (the "noa") that is needed for daily living and well-being. These knowledge systems related correspondingly to each other. So too does

the notion of "ako," teaching and learning. Māori language (intimately related to the environment) both forms the fundamental basis of "ako," which in turn shapes thinking and Māori worldviews. Māori patterns of thinking and relating which shape Māori worldviews and identity are bound up with one's mountains, rivers, lakes, streams, marae (formal gathering places), and other landmarks. When Māori meet and introduce themselves, it is generally prefaced by words which may follow the format of the pepeha (statement of identity) outlined here:

Ko Te Arawa te waka – Arawa is the tribal canoe.
Ko Matawhaura te maunga – Matawhaura is the mountain.
Ko Te Rotoiti te Moana – Rotoiti is the lake.
Ko Taurua Pā te Marae – Taurua Pā is the gathering place.
Ko Ngāti Pikiao te Iwi – Pikiao is the tribal grouping.
Ko Ngāti Te Rangiunuora te Hapū – Ngāti Te Rangiunuora is the sub-tribe.

These cosmological and biocultural identity shapers and markers not only demarcate the tribal landmarks, waterways, ancestral groupings but weave and entangle people, places, and practices in an intricate network of relationships. Such biocultural identity markers are embedded in the lands, elements, creatures, and bodies that inhabit those lands and waterways. They are also the focus of young children's learning in early childhood centers dedicated to Māori language and tikanga (cosmo-biocultural practices) regeneration. This gives children a secure tūrangawaewae (a place to stand, sense of belonging) or connection with those identity markers enabling them to remain profoundly linked to their histories, their genealogical roots, their language, and their ontologies in important and enduring ways.

Karakia (Māori ancient traditional spiritual rituals) also play an important role in the intergenerational transmission of language and knowledge. Karakia serve as a guide in the present and into the future. The following karakia was recited daily in our Kōhanga Reo (Māori language nest) and is an example of contemporary Kōhanga Reo pedagogy:

Tēnei au, tēnei au, ko te hōkai nei o taku tapuwae
Ko te hōkai nuku, ko te hōkai rangi, ko te hōkai o tōku tīpuna a Tānenuiārangi
I pikitia ai ki ngā rangitūhāhā ki te tiho o Manono
I rokohina atu rā, ko Io-Matua-Kore anake
I riri iho ai ngā kete o te wānanga, ko te kete Tuauri, ko te kete Tuatea, ko te kete Aronui.
Ka tiritiria, ka poupoua, ki a Papatūānuku. Ka puta te ira tangata ki te wheiao, ko te ao marama.
Haumi e, hui e, tāiki e!

This karakia is about a journey:

It is I who is here, on a sacred journey, the range and breadth of which is vast, spanning the earth and the heavens; in the way that my ancestor Tānenuiārangi journeyed into the beyond; to the limits of the outermost layers of Manono, to come upon a pure parentless source; there

> to acquire the baskets of knowledge known as Tūāuri, Tūātea and Aronui; the baskets of sacred knowledge, ancient knowledge, knowledge pertaining to all life. These were then cultivated and nourished by Papatūānuku, our Earth Mother, to unfold the essence of all human beings into the realm of light and enlightenment. So let us unite and progress the reason why we are here. So be it!

The karakia not only provides the impetus for the pursuit of knowledge but it speaks to the interconnectedness of all things ancient and new, past, present, and future. It provides the blueprint for respecting the sacred, seeking the ancient understandings to help us to understand the present and to provide the unity and purpose in working together, across boundaries, for our common well-being and human enlightenment. The means by which Tanenuiārangi ascended through the outer layers, into the heavens, was by way of a vine called "Te Aka Matua." The ancient and the present are interconnected in the same way that the ecosystems and terralinguistics are entwined. Harm to any aspect of the bioculture is harmful to the whole system. Everything and everyone needs to be valued and treated with the utmost respect.

Ontological Values: Rangatiratanga

The Māori word "Rangatira" means something (or someone) of high rank, of high esteem, and to be revered. The suffix "tanga" at the end is a noun-forming suffix so that rangatiratanga is often translated to mean sovereignty, or something which stands in high esteem, in its own right, that is, self-determining. The 1840 Tiriti o Waitangi/Treaty of Waitangi explicitly protected the rangatiratanga of the sovereign chiefs and all their lands, rivers, forests, fisheries, and "taonga" (all things treasured) from exploitation (Orange, 1987).

It is interesting to note that the prelude to Te Tiriti o Waitangi was a Declaration of Independence called *He Whakaputanga o te Rangatiratanga o Nu Tireni*, A Declaration of the Independence of New Zealand, drafted in 1835, with signatures being collected up until the time of the signing of Te Tiriti o Waitangi in 1840 (Walker, 2004). The first clause of the Declaration of Independence designated Nū Tireni (New Zealand) to be an independent country, and the United Tribes (Te Wakaminenga) also declared that the lands were indeed "he Wenua Rangatira," or lands to be revered, chiefly lands. There has, however, been a long-standing historical struggle between Māori and Pākehā (non-Māori) over the Māori concept of rangatiratanga (rights to sovereignty), exacerbated in the proclamation by Judge Prendergast in 1877 that the Treaty was a "simple nullity" (King, 2003, p. 325). While both documents guaranteed Māori their rangatiratanga (sovereignty), Prendergast contested it. There has been a struggle over whether Māori were a sovereign people, and what exactly was ceded, ever since. Smith (2012) argues that notions of struggle "in the margins" is that, when attached to a political idea such as rangatiratanga, not just the margins but all space in New Zealand can be regarded as Māori space. Rangatiratanga then is akin to a call for the sovereignty of space

(with all lands, resources, and chiefs being sovereign). Both the Declaration of the Independence (1835) and Te Tiriti o Waitangi (1840) were signed by Māori chiefs with that in mind.

A rangatiratanga theoretical frame can be considered to be political and to address issues of sociopolitical and biocultural subjugation. In education, it contests the positioning of Māori knowledge, language, and Māori children as subservient to assimilatory interests, and it challenges the notion of masterful teachers in control of young children's lives. It also resists the idea of linguicism, rejecting the construct of linguistic hierarchies. All languages are powerful. All children have the right to move beyond the master/servant relationships of colonization. "Te rangatiratanga o te whenua" (translated here as the sovereignty of land) then is not just about resistance to injustice and the inversion of colonial rule but the assertion of Māori sovereignty over Māori lands and language in "our place," all of it and everywhere. It is the right to assert Indigenous worldviews over Indigenous lands through Indigenous languages and power by breaking the illogic and harm of coloniality. From that view, rangatiratanga is a metaphor for Indigenous rights, as made explicit in the United Nations' (2007) *Declaration of the Rights of Indigenous Peoples*.

Te Awa Tupua: Landmarks Are Ancestors

Māori identify strongly with their traditional tribal landmarks, viewing these as ancestors deserving of great respect and protection. These ancestral landmarks are frequently cited in pepeha, identity statements of tribal and land affiliation. As mentioned previously, water is key to many Māori healing rituals. They have understandably been extremely distressed by settler-colonial practices, which continue to this day, of dumping sewerage and other waste into rivers. The irony of the New Zealand government's tourism promotion of our country as "100% pure" has recently been challenged by both Dame Anne Salmond, a prominent New Zealand anthropologist and public scholar, and a recent newspaper editorial by the Christchurch Press (Christchurch Press, 2017; Salmond, 2017b). The reality is in fact far from this with not only sewerage but farm and forestry runoff contributing to a very dire situation for the country's rivers (Joy, 2015).

The people of the Whanganui River, Te Ati Haunui-a-Pāpārangi, have a pepeha:

> E rere kau mai te awa nui nei
> Mai te kahui maunga ki Tangaroa
> Ko au te Awa
> Ko te Awa ko au
> The river flows from the mountain to the sea
> I am the river
> The river is me. (Waitangi Tribunal, 1999, p. 79)

During the hearing for the claim made by the Atihaunui about government breaches of the Tiriti o Waitangi in relation to their river, an elder made the statement: "If I am the river and the river is me - then emphatically, I am dying"

(as cited in Salmond, 2016). Iwi (tribes), such as Atihaunui and Waikato, have sought to regain the right to exercise kaitiakitanga (active guardianship) over their rivers, given the despoliation that has occurred under settler/colonial governance. After very many years of struggle, in 2017 the New Zealand Parliament passed legislation that affirms the ancestral status of the Whanganui River, Te Awa Tupua (New Zealand Parliament, 2017). It is to be hoped that the reaffirmation of ancestral relationships and knowledge, occurring through the succession of settlements of historical grievances that have been achieved by long-standing Māori commitment struggle and sacrifice, will enable current and future generations of children to be deeply connected via their whakapapa (genealogy) to their ancestral lands, rivers, forests, wetlands, foreshores, islands, and oceans and the knowledges these uphold.

Tribal Rāhui

The function of "rāhui" or prohibition is to place a sanction on something, either a resource, a place, or a thing. It is form of "tapu" which means the place of the rāhui, for the duration of the rāhui, is sacred or absolutely restricted. Any breach of the rāhui, especially if placed by a chief or tōhunga (reader of signs from nature, spiritual expert, and healer), could have dire implications, even death. Quite often a rāhui would be placed in an area where there had been a significant event, for example, a lake where there had been a drowning. A rāhui would be put in place so that there would be no activity in that place until the body had been recovered and for a significant period of time after the drowning. Other forms of rāhui would establish a certain place, for example, a lake, the bush, or rivers, to be off-limits for fishing or the harvesting of food, to allow those places to be restored. This would enable the resources to be protected. A modern-day example of the way rāhui is exercised at the tribal level is through the establishment of the Mātaitai reserves which are areas in which the local tribal members manage all noncommercial fishing by making bylaws. These bylaws apply equally to all individuals, not just the tāngata whenua (people of that place). These are effective restrictions to prevent the overfishing of marine reserves.

Rāhui in and Early Childhood Care and Education Setting

An example of rāhui being applied in an early childhood center occurred in a research project focussed on "caring for ourselves, others and the environment" (Ritchie, Duhn, Rau, & Craw, 2010). At Richard Hudson Kindergarten in Dunedin, the teachers determined their teaching and research focus to seek answers to their research question: "By learning about Rakinui/Ranginui [Sky Father] and Papatūānuku [Earth Mother] can we inspire our children and whānau to consider making ecologically sustainable choices?"

After researching the concept, the teachers added "rāhui" to their focus on caring for the environment through "Reducing, Reusing, and Recycling." One of these

teachers wrote this description of the problem to be addressed through application of a rāhui:

> We have some flower troughs on the entrance steps at kindergarten. They are blooming beautifully with pansies at present – and that's the problem. Some of the children have been picking the flowers. When other children notice, they pick them too. That is why a rāhui has been placed on the picking of these flowers. It has afforded an opportunity for us to introduce the concept of conservation through rāhui. If everyone picked a pansy or two today, there would be none left for tomorrow. So we are admiring them without picking them.

The teachers integrated Māori knowledges alongside western ones, engendering respect for Tāne Mahuta, the Atua (Spiritual Guardian) of forests, birds, and insects, and for Ranginui and Papatūānuku, the original parents of all beings. They described how:

> These concepts have been reinforced through teaching about the food chain, photosynthesis, growing bean seeds, planting a lemon tree that was given to us, conservation through rāhui and respect for Tāne's children, and references to Papatūānuku and Rakinui/Ranginui.

Kaitiakitanga

The meanings underpinning the Māori concept of kaitiakitanga are also deep and enduring, reflecting relationships across time and space. Tiaki means to look after, to conserve, or to protect. Combined with the prefix "kai" and the noun-forming suffix "tanga," it reflects people valuing or having a deep respect for and guardianship of Papatūānuku. The New Zealand early childhood care and education curriculum, *Te Whāriki: He whāriki mātauranga mō ngā mokopuna o Aotearoa early childhood curriculum* (Ministry of Education, 2017), discusses the notions of kaitiakitanga: "Kaiako [teachers] support mokopuna [children] to engage respectfully with and to have aroha (respectful mindfulness, love) for Papatūānuku. They encourage an understanding of kaitiakitanga and the responsibilities of being a kaitiaki by, for example, caring for rivers, native forest and birds" (p. 33). They do this "...by providing children with regular opportunities to connect with the wider natural environment and materials drawn from nature" (p. 35) and that kaitiakitanga is integral to children expressing "...their respect for the natural world in terms of respect for Papatūānuku, Ranginui and atua Māori" (p. 46).

Kaitiakitanga in Early Childhood Care and Education Setting

In the same project, the teachers from another kindergarten chose to focus on the notion of kaitiakitanga as the focus for their teaching and research. Prior to participating in the project, the kindergarten had already had a strong focus on education for sustainability. Their engagement with the project enabled them to bring te ao Māori conceptualizations into their philosophy and practice. This was particularly

relevant since the kindergarten is located in a small, rural, predominately Māori community. The teachers wrote that:

> We began to think about how Maori values, practices and culture tie in with the principles we wanted to promote. The concept of kaitiakitanga (being guardians over the well-being of the environment and the creatures in it – including us) gives a holistic view of what we are doing.

As with Richard Hudson Kindergarten, the Koromiko teachers began introducing the concept of kaitiakitanga along with the Māori cosmology of Ranginui and Papatūānuku and of Tāne Mahuta and the other Atua:

> Talking about the Earth as an entity (Papatūānuku – the Earth Mother) and the Gods who are guardians of various areas, such as the forest and sea – Tāne and Tangaroa – gives the children a concrete focus for caring for the environment and all living things in it. We can read books about this, see pictures of the living things in the forest or the sea and begin to see that we have a part in caring for them too. The things that the Earth provides, whether shells and driftwood at the beach or any other items, especially living things, are gifts from Papatūānuku and, therefore, need to be treated with respect.

The teachers reported how the mother of one of the kindergarten children described her son's practices of kaitiakitanga:

> T. enjoys whitebaiting with his Dad. Last time they only caught a few. When it was time to go, and they didn't have enough whitebait for a meal, he decided to put the ones he had caught back into the water. He didn't want them to die without being eaten. He also said that he might catch them again and a few more next time so that he had enough to eat.
>
> T., on numerous occasions, will walk past rubbish left at the beach or on the footpath and pick it up to put into the rubbish bin. He talks about 'these naughty people leaving their rubbish on the ground' and 'why don't they just put in into the rubbish bin?' I have never seen T. litter himself – he always puts things in bins or, if he can't see one, he asks me to hold it or asks where he can put it.

Children's empathy for Papatūānuku and Ranginui, the Atua, and for the creatures who are the offspring of the Atua was featured strongly in the data gathered in this project. It is such dispositions that will engender concern and respect for our planet in the future. They offer a different positioning from the exploitative paradigm of colonization and current capitalism that dominates many societies.

Concluding Thoughts

This Chapter argues that the whole ecosystem including humans live and flourish together in networks of complex and delicate relationships. It is the diversity across those complex and delicate networks that provide the potential for adaptation and further diversity. That is, diversity maintains diversity. Diversity also maintains robust ecosystems and strong biocultures and increases the chances of long-term planetary survival. Our future on this planet relies on the bioculture's ability to

preserve and continue its diversity. Human beings, and the languages we speak, are an integral part of the complex and delicate networking. Linguistic diversity and ecological diversity are inseparable. They come together in what has been termed as biocultural diversity (Skutnabb-Kangas et al., 2003). However, it has been argued that Māori face the challenge of maintaining the language specificities and cultural knowledges that emanate from the deeply embedded interconnectivity and long histories of cohabitant reciprocity (Wehi & Lord, 2017).

In this Chapter examples have been provided through an Indigenous lens of the intimate relationships and interconnectedness across the delicate networking of the bioculture, for millenia. But with colonization, Indigenous people either died, were killed, or forced into a new (hierarchical) modality of life. Lands were carved up; Indigenous people's lives decimated in terms of the destruction of whānau, hapū, and iwi structure of Māori. Drawing on Indigenous onto-epistemological lives, Māori ecological literacies of mutton-birding, learning from the elders, tribal sayings, and the nature of Māori knowledges being embodied in both the lands and languages, and being interwoven, have been examined. Some of the values that underpinned those onto-epistemologies included rangatiratanga which provides a theoretical frame to address issues of sociopolitical and biocultural subjugation. That frame is transferred into an educational context to signify children as agents of their own thinking, learning, and lives. It also resists the idea of linguistic hierarchies based on racist philosophical frames in which Indigenous languages are regarded as having no value. The reverse is promulgated – te rangatiratanga o te reo (or the sovereignty of language) along with te rangatiratanga o te whenua *(*the sovereignty of Papatūānuku).

Drawing on recent political events, the people of the Whanganui River exercised their rangatiratanga in their claim made about government breaches of the Tiriti o Waitangi in relation to their ancestral river. They sought to regain their right to exercise kaitiakitanga (active guardianship) over their river and have recently won the battle to affirm the river with the ancestral status of a person. This right presents a challenge for many New Zealanders who fail to understand the interconnectedness of Indigenous peoples to the bioculture. However, it is argued here that a pedagogy of hope (Freire, 1994) can be infused throughout early childhood care and education to enable current and future generations of children to be deeply connected via their whakapapa (genealogy) to their ancestral lands, rivers, forests, wetlands, foreshores, islands, and oceans, through their Indigenous languages and the knowledges that these uphold. It is also hoped that the values of rāhui and kaitiakitanga, as shown in the research in early childhood settings, will continue to cultivate the dispositions that will stimulate concern and respect for our planet in the future for all children present. They offer a different positioning from the exploitative paradigm of colonization and current neoliberalism that permeates Minority western capitalism and its institutions. Our long-term survival is dependent on it.

> E kore au e ngaro; he kākano i ruia mai i Rangiātea.

This whakatauki [proverb] refers to the original seed from Rangiatea, the spiritual homeland for Māori, stating that this seed will not be lost. It thus asserts both

continuity and resilience and implies that for Māori, their language and culture are the sustenance of this resilience (Grace & Grace, 2003, p. 29).

Abstract

A significant theorist in the early childhood education field is Urie Bronfenbrenner who, in 1979, proposed his "ecological systems theory," sometimes referred to as the "ecological framework for human development." This theory offers a multidimensional systems model for understanding the influence of family through to economic and political structures; thus, it presents a way of understanding the human life course from early childhood through to adulthood. In this theory, the ecological framework enables the mapping of information about individuals and their contexts over time in order to understand their diverse systemic interconnections. A critique of this model, however, from a childhoodnature stance, is that it ignores consideration of human-nature interconnections. Thus, it is a deeply anthropocentric model of human development that is at odds with emergent posthumanist thinking that seeks to de-center the human condition. In this Chapter, we argue that the pervasiveness of this human-centered systems approach works against sustainability, in that it reinforces the sociocultural, political, and economic dimensions of being human at the expense of environmental interconnections. Drawing on systems theory, posthumanist theory, new materialism, a critical lens to pedagogy, and new sociology of childhood, we propose alternative ways of approaching Bronfenbrenner's work that, both, facilitates human connections and strengthens children and nature connections that have implications for early childhood education philosophy and pedagogy.

Bronfenbrenner · Systems theory · Post-humanist theory · Critical theory · New materialism · Sustainability · Early childhood education · Anthropocentricism

Introduction

> The most telling criterion for evaluating the health of a society is "the concern of one generation for the next." (p. 1) (Bronfenbrenner, p. xii cited in Pence, 1988)

In 1979, Urie Bronfenbrenner proposed his "ecological systems theory," sometimes referred to as the "ecological framework for human development." This theory is a multidimensional systems model for understanding human development within sociopolitical and cultural contexts and has significantly impacted the early childhood education field over almost four decades. Bronfenbrenner's model (1979) is often foregrounded as core to understandings of young children's development both in research (Ballam, 2013; Dillon-Wallace, 2011; Rodgers, 2009) and early

childhood education practice (Arthur, Beecher, Death, Dockett, & Farmer, 2015; Bowes, Grace & Hodge, 2012; Sims & Hutchins, 2012). In particular, the child is perceived as both influenced and influential within the nested social systems they inhabit in this ecological model. The mapping of the dynamic interconnections between individuals and their contexts over time has invited a deepening of educators' understandings about each child's human-centered ecologies and trajectories in life.

As a psychologist, Bronfenbrenner was embedded in a significant period of change in the 1970s when shifts from developmental to sociological approaches first emerged, from describing and explaining human development to promoting the best for human development through examining individual-context relations (Lerner, 2005). He advocated the linking of human development to questions of social policy, in other words creating a theory-application bond. Bronfenbrenner's (1979) model was recognized as groundbreaking and transformative at the time. It must also be acknowledged that Bronfenbrenner's model (1979) signaled a revision of the images of children, from children as objects of developmental study to their positioning as socially active participants in the world and investigated in context. This revision was subsequently strengthened by the United Nations Convention on the Rights of the Child (UNCRC) (UNICEF, 1989), theories of new sociology (Corsaro, 2005), and images of children as agentic (Jones, 2009; James, Jenks, & Prout, 1998). As co-authors, we are not the first to call for revisions to Bronfenbrenner's model. For example, Christensen (2010) has proposed her own enhancement of his model based on her critique of the place of the individual's role in relation to other actors, while Stanger (2011) has questioned the absence of ecological influencers in this human-centric model and argued for eco-sociological models. However, our examination focuses on nonhuman interrelationships. While much has been achieved with Bronfenbrenner's model (1979) based on human-human interconnections, now, four decades later in the new global epoch of the Anthropocene (Steffen, Crutzen, & McNeill, 2007), we can no longer ignore human-nature interconnections as imperatives when considering young children's development and well-being.

Bronfenbrenner's model (1979) stands as an anthropocentric model of human development; thus, it is not conducive to understanding or underpinning matters concerned with global issues and global futures in the current epoch that is defined by the now dire and detrimental impacts of humans on the Earth. The continuing prioritization of human needs, wants, and relations is untenable when the strongest evidence is that humans are continuing to support lifestyles, systems, and structures that are destroying the life-giving capacities of the planet. Because we humans seem to need constant reminding, humanity's ecological footprint has already exceeded the Earth's capacity to regenerate and risen to the point where 1.6 planets are needed to provide resources sustainability. Further, the biodiversity index has fallen by more than 50% (World Wildlife Fund (WWF), 2016) as populations of nonhuman species continue to decline, greenhouse gas emissions have almost doubled, and diverse climate change impacts have become increasingly apparent (Howes, 2017; Oppenheimer & Anttila-Hughes, 2016).

Allied with ecological footprint impacts, there is clear evidence of rising inequalities on a number of indexes within and between countries and regions, with strong evidence of increasing gaps between generations (Currie & Deschenes, 2016; Olshansky et al., 2005). This final point makes a clear link between our concerns about sustainability and the ideas of Urie Bronfenbrenner who, as illustrated in the opening quotation to this chapter, himself, comments that the concern of one generation for the next is the true measure of societal health. Thus, we have taken the liberty of drawing on Bronfenbrenner's own words as our starting point for this critique of his ecological model for human development, in the belief that he would have some measure of understanding of our concerns about its shortcomings in the era of (un)sustainability. This affords us the opportunity to think further about Bronfenbrenner's concept of the chronosystem, as a way of thinking more critically and expansively about the time dimension in human development.

Further, Bronfenbrenner's model is counter to emergent posthumanist thinking that has arisen in the humanities and in education in recent times that seeks to de-center the human condition (Taylor & Hughes, 2016). We argue that Bronfenbrenner's (1979) more human-centered systems model works against sustainability – and, by extension, the development and wellbeing of children – in that it reinforces the sociocultural, political, and economic dimensions of being human at the expense of human-environmental interconnections. As outlined in the UNESCO (2010) dimensions of sustainable development framework, all dimensions are integral to achieving global sustainability, clearly identified as one of the "wicked problems" (Rittel & Weber, 1973) that impacts us all, but more so on children and future generations who will be around the longest bearing the brunt of (un)sustainable ways of living. This necessitates radical solutions – both in thinking, actions, and relationships to promote childhoodnature.

Lerner (2005) describes the reciprocity of relations fundamental to Bronfenbrenner's model as "exchanges between the person and his or her ecology that function to benefit both" (p. xix). In this phrasing, "ecology" refers to a person's social context; we note this may be feasible or optimal in the social worlds of humans, but humans have overstepped the mark in their relational reciprocity with the Earth. This incomplete appreciation of reciprocity within a human-centered idea of ecology is a point of interest for us and is reflected in solid rather than broken lines depicted in the concentric circles of Bronfenbrenner's (1979) hierarchical systems (Rogoff, 2003). Similarly, Stanger (2011) has argued for a recasting of the model stating "if we are to use ecosystem-based language, it needs to describe the complex interrelationships that support the long-term integrity of living systems rather than the short term singularity of human-designed marketing" (p. 167). He advocates the inclusion of humans and the physical/natural environment at each system level and also introduces a nanosystem level to denote the ecological systems beyond the naked eye. These points have caused us to think further about Bronfenbrenner's use of the language of ecology.

"Ecology" was coined in the mid-1860s by German Scientist Ernst Haeckel, with connections to ancient Greek philosophers such as Hippocrates and Aristotle and their studies in natural history. Modern ecology became a more rigorous science in

the late nineteenth century, with a surge in interest in 1960s commensurate with the rise of the environmental movement (Dritschilo, 2004). There are now strong historical and scientific ties between ecology, environmental management, and protection. The scope of ecology is organized into a nested hierarchy from the micro (genes and cells) to species, populations, communities, and ecosystems, through to the planetary (biosphere).

The idea of an "ecological niche" dates to 1917 with advances in the concept attributed to Hutchinson (1957) who defined the ecological niche as the relational position of a species or population in an ecosystem. The physical environment is seen as an integral part of the niche because it influences how populations of organism's affect, and are affected by, resources and competitors. Use of the term "ecological niche" is prevalent in Bronfenbrenner's theory and models and used extensively within child development literature. Berthelsen (2009), for example, writes "Bronfenbrenner argued that every child's ecological niche is unique because each child experiences and takes part in different relationships and processes of interactions across proximal contexts" (p. 4). Further, in the context of new sociology theory, children are identified as "co-constructors, active creative social agents who produce their own unique children's cultures while simultaneously contributing to the production of adult societies" (Corsaro, 2005, p. 3). Given such widespread usage to explain the uniqueness of children's experiences, however, it is perhaps surprising that interactions with physical or natural environments in shaping children's experiences is mostly absent from his model of human development.

Ecology is as much a human science as it is about the nonhuman and has led to the parallel/intersecting field of human ecology. Rachel Carson, for example, in her 1962 seminal book *Silent Spring* was one of the first biologists/ecologists to raise awareness of the power of humans to alter the world significantly. Similarly, at the time Ehrlich (1968) was the first to question population growth and the capacity of the Earth to sustain exponential human population growth. Human ecology is viewed by many as a truly interdisciplinary science that attracts psychologists, sociologists, anthropologists, geographers, and epidemiologists, for example, whose interests lie in human relations and natural systems. In the seminal work of human ecologist Gerald Young written in 1974, human ecology commonly has three ways of thinking about human-nature relationships: (1) the study of humans as the ecological dominant in plant and animal communities and systems; (2) humans as simply another animal being affected by and affecting the physical environment; and, (3) humans as different from animal life in general with interactions with the physical environment in a distinctive and creative way (Young, 1974). A truly interdisciplinary human ecology most likely addresses all three perspectives. The human and ecological transformations of the so-called Anthropocene has ushered in a new science referred to as "coupled human and natural systems" (Liu et al., 2007) reflecting a somewhat earlier systems theory notion of structural coupling (Maturana & Varela, 1987). This is described as two-way interactive relationships whereby the organism and the context change, recognizing that each impacts the other over time as in coevolution. Critically, the context is not inert or passive as viewed from a position of human dominance over nature, and in the epoch of the Anthropocene,

this contextual view is blatantly untenable. Thus, the field of human ecology must seek to generate new integrated knowledges aimed at understanding the complexities of human-nature interactions as central to the quest for both human well-being and global sustainability.

It is interesting, however, that Bronfenbrenner's use of terminology including "ecology," ecological systems, and niches is unrelated to ecology's predominant links with nature and natural systems. Of interest is that while the study of ecology is not treated as separate or distinct from humans by ecologists, Bronfenbrenner's use of ecological terms as a psychologist was not inclusive of nature and natural systems, although he does make reference to "particular physical and material characteristics" of a microsystem setting (1979, p. 22). This oversight, we presume, is because the field of ecology was only becoming popularized at the time of his writing (Dritschilo, 2004). However, contemporaries of Bronfenbrenner were theorists with an interest in human-nature relationships including systems theorist Bateson (1979), deep ecologist Berry (1988), and, most notably, Lovelock (1979) and his Gaia hypothesis. Further, Berry (p. 240) explicitly stated "the natural world is the larger sacred community to which we belong. To be alienated from this community is to become destitute in all that makes us human. To damage this community is to diminish our own existence." Undoubtedly, there are systemic impacts for human development to be recognized here. We can only surmise that while Bronfenbrenner was obviously aware of the field, he was not able or prepared to incorporate key ideas about human-nature interactions into his thinking and model of human development at the time.

Pivotal Career Moments from Our Professional Narratives

In further articulating this critique of one of early childhood educations' "holy men," both authors recognize pivotal career moments when we – quite separately – had reasons to question or found shortfalls in Bronfenbrenner's ecological systems model (1979). Davis was co-lecturing in an early childhood education course conducted in Papua New Guinea (PNG) with local early education "trainers" who were adding to their qualifications and experiences as elementary teacher educators. The unit of study combined families and community studies with a focus on Bronfenbrenner's model (1979), sustainability aspects employing the UNESCO four-dimensional model of sustainable development (2010), and health promotion education – using both an ecological health-promoting schools model and Hancock's mandala of health model of the human ecosystem (Hancock 1985). While the combined content fitted well together, Davis questioned the lack of recognition of the physical/natural environment in discussions about Bronfenbrenner's work especially when this was so much a part of the livelihoods and knowledge systems of many PNG families and communities (Department of National Planning and Monitoring (DNPM), 2010). Recognition of their dependence on market gardens and subsistence farming that nurtures family and community health and well-being was unrepresented when using Bronfenbrenner's model (1979) yet was clearly evident in the sustainability and health models being

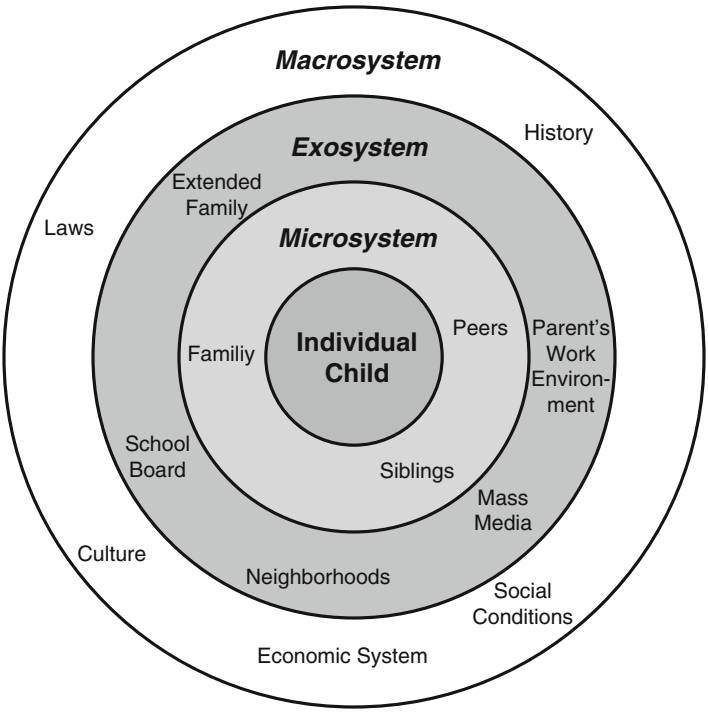

Fig. 1 Bronfenbrenner's ecological model of human development (1979). Retrieved from https://openi.nlm.nih.gov/detailedresult.php?img=PMC2676270_1471-2458-9-94-1&req=4

considered. Similarly, Elliott who led the establishment of early childhood environmental education in Australia during the mid-1980s (Elliott & Emmett, 1991) can recall many attempts to seek appropriate literature to support practitioners in the field to think about environmental and sustainability issues as having pedagogical relevance with young children. She was captured by the title "ecological" in Bronfenbrenner's work only to be disappointed that the model did not include any aspects of the physical or natural environment. Sharing these past career moments cemented our resolve to offer this critique, and potentially, new ways forward in thinking about how the theories and practices of early childhood education and education for sustainability can be brought together to better fit with the challenges and opportunities of the twenty-first century (Figs. 1 and 2).

Thus, in this chapter, we draw on our academic, professional, and research experiences as well as our theoretical leanings toward systems theory, post-humanist theory, new materialism, critical theory, and new sociology of childhood to challenge Bronfenbrenner's model (1979). We begin by offering an overview of his ecological systems model. Next, we outline the relevant theoretical underpinnings to our critique then offer specific critiques from our axiological and ontological stance. We attempt to offer some resolution to our concerns with vignettes from current early childhood education practice that challenge ways of facilitating children and

nature connections with implications for early childhood education philosophy and pedagogy.

Bronfenbrenner: An Ecological Model for Human Development

In examining Bronfenbrenner's (1979) ecological model, we firstly contextualize his model within the theoretical and discipline milieu of the time and then offer an overview of the model's iterations with links to sustainability. We further provide some examples identifying how this model has been variously employed within the early childhood education sphere.

A Theoretical and Discipline Milieu

We acknowledge that there has been some literature investigating Bronfenbrenner's theory and model(s). For example, Tudge, Mokrova, Hatfield and Karnik (2009) discussed the uses and abuses of his theory, but there appears to be a lack of rigorous academic critique (Taylor, 2016). We are aware of the work of Boon, Cottrell, King,

Stevenson, and Millar (2012) who found value in applying his theory in a field allied with sustainability – natural disasters and community resilience. However, we argue that our discussion is the first to critique his work from the perspective of early childhood education and sustainability.

As previously acknowledged, although his initial model was recognized to be groundbreaking and transformative at the time of publication – perhaps even a theoretical disruption – we recognize that it occurred when shifts toward sociocultural theorizing were underway within the field of human development (Vygotsky, 1978). Perhaps Bronfenbrenner can be seen as a pioneer in breaking down the disciplinary silos of the time. Vygotsky's theories of social constructivism and social constructionism, first translated in 1978, had instigated a movement away from earlier developmental theorizing (Gesell, 1950; Piaget & Inhelder, 1962). The field of human development was evolving at this time as demonstrated by Berthelsen, Lunn, and Johansson (2009, p. 184), and this strengthens our argument for an urgent reevaluation now, four decades later, when anthropocentric models are ill-equipped to foster sustainable futures for all. As has been already commented upon, "Bronfenbrenner moved the field from being an area of scholarship that described what 'is' in human development to a science that, through its collaborations with policy makers, practitioners, and other social change agents, envisioned what 'could be' about human development" (Lerner, 2005, pp. xii–xiii). Similarly, we question what "could be" and what "must be" envisioned about human development in the global epoch of the Anthropocene (Steffen et al., 2007).

In essence, the point we make here is that Bronfenbrenner's (1979) ecological model was framed within the human-centered sociopolitical-environmental context of its time. Concerns about the state of the environment were only beginning to be understood, for example, Rachel Carson's *Silent Spring* (1962) had just been released, and Erhlich's (1968) population predictions were alarmingly dire. However, concerns as a global issue and connections between human health and well-being were yet to be widely recognized. The United Nations Conference on the Human Environment (Stockholm Conference) in 1972 was the UN's first major conference on international environmental issues and marked a turning point in the development of international environmental politics. Also, pertinent to this milieu are the then-contemporary environmental education initiatives such as *The Brundtland Report* (WCED, 1987) and *Agenda 21* (UNCED, 1992) which demonstrated a shift in thinking toward sustainability as comprising multiple dimensions, namely, economic, social, and environmental; and this prompted longer-term human thinking and action for the intergenerational equity of all species. Concurrently in the field of health promotion was the World Health Organization's Ottawa Charter for Health Promotion (1986) that emphasized that "Good health is a major resource for social, economic and personal development and an important dimension of quality of life. Political, economic, social, cultural, environmental, behavioural and biological factors can all favour health or be harmful to it" (p. 1). We question, was Bronfenbrenner (1999, 2001) aware of these shifts as he continued to reframe his original ecological model, through the 1990s, to become the bioecological model of 2001? We see our reevaluation of his model as being in the same vein.

Iterations on the Model

In referring to Bronfenbrenner's ecological model, it is important to recognize that the first iteration published in 1979, and most often referred to in the literature, was not the only version. This initial model is frequently described as contextually focused acknowledging the diverse social contexts influencing human development. Bronfenbrenner depicted these social contexts as concentric nested circles comprising the *microsystem*, *mesosystem*, *exosystem*, and *macrosystem*. The *microsystem* alerts us to the child's immediate settings, those settings that a child participates in on a daily basis including his/her home, school, or early childhood center. The *mesosystem* is about interactions and interrelationships between the microsystems, and in our tertiary teaching experience this is a somewhat perplexing system level given the lack of specific settings or entities. The *exosystems* are those social structures or settings both formal and informal where a child is not directly involved but may have indirect impacts for a child such as a parent's workplace or extended family. The most outer system is the *macrosystem* that comprises the broader level policies, political institutions, and cultural beliefs that have import for all systems. These system-level contexts and interactions were initially reflected as given points in time, but Bronfenbrenner subsequently added the *chronosystem* to denote dynamic system changes over the human life span. Also, although he aligned the model with nested Russian babushka dolls (Bronfenbrenner, 1979, p. 3), the various systems or structural levels are not discrete, but integrated throughout the course of human development. Bronfenbrenner (1999, 2001) engaged in an ongoing reassessment and critique of his original model leading to various iterations over time. Here we highlight key aspects of these iterations relevant to our critique.

A focus in Bronfenbrenner's later 1990s theorizing is the person-process-context-time (PPCT) model where the interrelationships between these four concepts come to the fore (Lerner, p. xv), overriding the contextual-only focus of his original model (1979). In this later iteration, interrelationships were framed as proximal processes – reciprocal, enduring, and increasingly complex (Bronfenbrenner, 1995, 1999) – such descriptors resonate well today.

However, we raise concerns when such interrelationships most often allude to everyday anthropocentric objects and symbols such as toys and hobbies (Bronfenbrenner, 1999) when it is obvious that people also interact intimately on a moment-by-moment basis with the physical environment, for example, daily weather ranging from the inconvenience of rain or wind to extreme weather events impact human lives. Only now with climate change modeling are the impacts of changing weather patterns on human life courses, particularly children's, evident and the reciprocity of these interrelationships with the physical environment being recognized (Zivin & Shrader, 2016). In addition, while the PPCT model acknowledges the personal or dispositional characteristics that any individual brings to their active interactions in social contexts (Bronfenbrenner, 1995), he describes such active interactional focus as "proclivities to set in motion, sustain and enhance processes of interaction between the organism and particular features of persons, objects and, symbols in its environment" (Bronfenbrenner, 1995, p. 634). We hold

no argument with such proclivities and view them as core to transformative processes for sustainability. We consider that these dispositional characteristics do not go far enough. Our main argument is that a deeper and broader interpretation of environment needs to be part of systems where these tendencies are enacted. In the context of our critique, might we now include sustainable worldviews, ethics, and values held by the individual?

Considering Time

In support of his theorizing, Bronfenbrenner (1999) also offered four guiding life course principles that highlight change over time. He acknowledges each individual's life course is shaped by conditions and events during their historical life period, and the timing of biological and social transitions throughout this period is key. In Bronfenbrenner's (1917–2005) own lifetime, the challenges of human-centered social and economic change ranging from world wars to industrialization and evolving family dynamics were at the fore as evidenced by his examples (Bronfenbrenner, 1999). As we have indicated previously, the current global historical period of the Anthropocene (Steffen et al., 2007) and the now ongoing transitions in human lives attributed to climate change (Currie & Deschenes, 2016) offer a compelling rationale for rethinking Bronfenbrenner's model and its various iterations (1979, 1999, 2001). Bronfenbrenner (p. 22) reminds us in Life Course Principle 4, for example, that "within the limits and opportunities afforded by the historical, cultural and socioeconomic conditions in which they live, human beings themselves influence their own development – for better or for worse -through their own choices and acts." The inherent sentiments are clear; our argument is to also include nonhuman environmental conditions and to consider all "choices and acts" as having consequences beyond those of current individuals, i.e., to consider the intergenerational legacy of our choices and acts.

Furthermore, in reviewing his original model, Bronfenbrenner (1979) recognized the role of biological determinants of the individual, and a bioecological model was proposed (Bronfenbrenner, 2001), thus, bringing together human social ecologies and individual human biological determinants into a more comprehensive whole. However, we argue that this development is still not comprehensive enough for those advocating for childhoodnature aligned worldviews that integrate humans and nature and who have concerns for long-term intergenerational sustainable futures. Stanger (2011) has previously stated that the chronosystem must be extended to include evolutionary time scales. Further, we might provoke, is the nonhuman and/or physical environment potentially framed beyond these nested human systems and all encompassing, or situated within and impacted by human social systems, or integral and across all nested systems. Reframing these intersections over more than a human lifetime offers a unique challenge that we return to in later pages of this chapter.

Lastly, we do not purport to offer a comprehensive overview of Bronfenbrenner's theorizing and iterations here but have targeted those aspects that most invite critique alongside offering support from our global sustainability and eco-centric stance. We

acknowledge the challenges inherent in this approach as others have cautioned about the overly simplistic interpretations of Bronfenbrenner's work which abound in both research and practitioner literature (Tudge et al., 2013). Nevertheless, we are inspired by Bronfenbrenner to proceed when he states "the possibilities of ecologies as yet untried . . . hold a potential for human natures yet unseen, perhaps possessed of a wiser blend of power and compassion than has thus far been manifested" (1979, p. xiii).

Bronfenbrenner's Model and Early Childhood Education

Along with the theories of Vygotsky (1978), Bronfenbrenner's theory (1979) has been significant in shaping early childhood education worldwide (Härkönen, 2003; Sims & Hutchins, 2012; Penn, 2005) including in early childhood teacher education, as a theoretical basis for early childhood education curriculum and pedagogy and in research. The following diverse examples offer insights into the range and depth of impacts.

In the early 1960s, for example, Bronfenbrenner was specifically engaged with the early childhood education field through the American government-funded Head Start program (American Psychologist's Association, 2004). At a time of national social justice concern, the program aimed to address the deficits experienced by young children living in poverty through early intervention. The program involved coordinated efforts by professionals, communities, and parents (Hinitz, 2014), and the intent was to offer a more holistic approach to promoting young children's development through early childhood education. The Head Start program has been sustained over decades now and facilitated interventions with some 32 million children (Head Start Office, n.d.). Multiple research studies have identified benefits, but questions are still raised about the longer-term outcomes for children (Hinitz, 2014). Bronfenbrenner's (1979) approach to human development as occurring within multiple interactive social systems continues to underpin the Head Start programs today, but rethinking is needed given continuing social inequities and especially those being exacerbated with climate change (Currie & Deschenes, 2016).

More recently, Krishnan (2010) described a Canadian provincial early childhood development-mapping project that utilized an Early Development Index (EDI) instrument based on Bronfenbrenner's model (Janus & Offord, 2007). The overall EDI aim was to offer estimates of child development at the time of school entry with a focus on the multilevel systems and interactions that accounted for each child's development. Implementation of the mapping project led to development of a conceptual ecological model taking into consideration individual and environmental factors, again with a focus on addressing social inequalities. In reporting this project, Krishan (2010) recognized the "physical environment" as a variable within the broad scope of neighborhoods and community, proffering examples including urbanization, nonprofit organizations, and transportation resources, thus retaining an anthropocentric lens. However, Krishan (2010, p. 14) notes as a concluding limitation to the conceptual ecological model "Among other things, an aspect not addressed in the

proposed model but critical to children's development is that of physical environment, including exposure to toxins and pesticides in a variety of contexts." This limitation offers a glimpse into a less anthropocentric lens, akin to the health models previously noted, but from our stance much more is feasible.

Further, we highlight an early childhood education tertiary text, one of a number citing Bronfenbrenner's model (1979) as foundational to the publication (Arthur et al., 2015; Bowes et al., 2012; Page & Tayler, 2016). The text by Sims and Hutchins (2012) focuses on program planning for infants and toddlers supporting a holistic approach to embracing the multiplicity of systems and interactions that critically impact on early development. Advocacy for infant and toddler programs to best support their learning and development is applauded; however, these authors only refer to the physical environment for the establishment of appropriate indoor and outdoor playspaces. This is not the global physical environment related to environmental and sustainability crises that we identify as a "blind spot" (Wagner, 1993) for many early childhood education authors. We argue that continued reference to Bronfenbrenner's (1979) anthropocentric model fails to fully convey the impacts of the physical environment in the Anthropocene (Steffen et al., 2007). For example, Zivin and Shrader (2016) state that higher global temperatures are linked to increasing global rates of childhood disease, plus water and food scarcity with potential to seriously impede early development leading to lifelong consequences. This is not to deny the complexity of human social, economic, and political system factors impacting very young children but to argue for a more inclusive and eco-centrically informed consideration of all local and global factors.

In these examples, we note how Bronfenbrenner's model has contributed to shaping early childhood education as anthropocentric, and its use continues almost without question to create explicitly human-centered approaches when examining children's learning and development. One exception is McCrea and Littledyke's (2015) adaptation of Bronfenbrenner's (1979) model that offers practical guidance for educators seeking to link his model to education for sustainability and the pillars of sustainability with a focus on children's health and well-being. While this adaptation offers much potential, our intent here is to theorize more deeply our concerns for the early education more broadly, particularly with reference to posthumanist thinking. Overall, the exemplars above give little or no place for more eco-centric and holistic views of human/child interests as shaped both by and with the physical environment. The world has changed since the 1970s, and Bronfenbrenner's work needs reconceptualizing or disrupting to account for the contemporary challenges of the Anthropocene (Steffen et al., 2007).

Theories Driving Our Reevaluation of Bronfenbrenner's Models in Early Childhood Education

In this section, we discuss five theoretical perspectives that have influenced our critique of Bronfenbrenner's (1979) model and offer a way forward for addressing the dilemmas that have become evident through this critique. We believe these offer

new insights into thinking about and enacting early childhood education in light of the sustainability challenges and complexities of lived experiences and relationships in the twenty-first century.

Systems Theory Perspective

Systems theory is core to the discussions here, and we recognize the contemporary systems theorists who built interdisciplinary bridges by examining mathematical systems, biological systems, and human social systems. In particular, Bateson (1979), and Maturana and Varela (1987) identified the primacy of relationships over objects in the interweaving of social and ecological systems in a holistic manner. "A system may be defined as a set of elements standing in interrelation among themselves and with the environment" (Von Bertalanffy, 1972, p. 417). A key tenet of systems is that they self-regulate to maintain stability through a constant messaging and responsive recalibration to promote ongoing stability and adaptiveness. If humans and nature are considered as a dualism, as was the case in the 1970s and still is for many, we can posit humans as unable to perceive, respond, and adaptively recalibrate. The resulting disequilibrium now has a name, the Anthropocene (Steffen et al., 2007). The current disequilibrium reflects dynamic systems theory (Thelen & Smith, 1994), which emphasizes the ongoing fluctuations of systems over an extended time frame from simplicity to complexity and back again.

Further, the persistence of dualism can be linked to the conceptualization of systems as open or closed proposed by Von Bertalanffy (Weckowicz, 2000). An open system is characterized by ongoing exchanges between internal elements of the system and the environment, whereas closed systems are discrete or removed. Perhaps for too long, humans have perceived their existence within closed "human-centric systems" like Bronfenbrenner's model (1979), removed from the physical environment and without responsibilities for ongoing reciprocal exchanges. Bateson doubted we could survive as a species if humans persisted in viewing the world in terms of dualisms. He asserted (Bateson, 1979) that mind and nature were one organism and the influential interrelationships between mind and nature promoted stability as in one whole organism akin to Lovelock's (1979) Gaia hypothesis. Humans are only part of the Earth's systems and can never control them; hence, the dynamics and reciprocity of interrelationships between humans and nature must be recognized in any theorizing about human development.

Posthumanism

As previously noted posthumanist thinking seeks to de-center the human condition and challenge entrenched human-nature dualisms. posthumanism is not one distinct paradigm with a readily traceable lineage, but "a constellation of different theories,

approaches, concepts and practices" (Taylor, 2016, p. 6). Links are evident to ecofeminism, queer theory, Indigenous theories, deep ecology, systems theory, new materialism, and eco-centrism. In essence posthumanism invites an exploration of different ontologies about being in the world with a relational and ethical focus to others, both human and more-than-human. In moving beyond dualisms, Latour (2004) proposed "common worlds" as collective and relational spaces with shared agencies. Common worlds are "full of entangled and uneven historical and geographical relations, political tensions, ethical dilemmas and unending possibilities" (Taylor, 2013, p. 62). Bronfenbrenner's model (1979) does suggest an entanglement of human interrelationships over time, but we echo posthumanist Braidotti (2013) in seeing the "potential to contest the arrogance of anthropocentrism and the exceptionalism of the humans" (p. 66). The implications of posthuman theorizing are now being acknowledged in the education field (Taylor & Hughes, 2016). Common world pedagogies aim to avoid children-as-subjects learning about nature-as-object; it is about learning with or becoming worldly with the others in the human and more-than-human collective (Taylor, 2013). Further, Rooney (2016) describes "common worlding" as a pedagogical approach to exploring these messy, shared, and enmeshed worlds with generative potential for thinking differently about ethics and relations. Post-humanist thinking brings a unique ethical lens to how humans perceive themselves in the world with others and challenges the anthropocentric foundations of Bronfenbrenner's model (1979).

New Materialism

Closely aligned with posthumanist thinking, "new materialism" – also sometimes referred to as socio-materialism – is a term applied to a series of theoretical movements across several fields including philosophy, biology, and the human sciences that critiques anthropocentrism and links social and material conditions (social relations, other species, physical context, objects) to human consciousness and learning (McKenzie & Bieler, 2016). Such a critique challenges the long-held idea of human exceptionality over other entities (Weldemariam, 2017). It emphasizes the self-organizing powers of many nonhuman processes, explores dissonant relations between such processes and human/cultural practices, rethinks the sources of ethics beyond the human, and commends the folding of a planetary dimension more overtly and regularly into studies of global, international, and national and state governance (Connelly, 2013). A new materialist perspective, rather than promoting nature/environment as something to be saved, controlled, or mastered, emphasizes the mutually constitutive and entangled relationships between humans within a "common world" (Latour, 2004; Taylor, 2013). Exploration of relations from a new materialism framework does dramatically portray the fragility of "materials" and relationships today. As a theoretical tool, it forces us to problematize anthropocentric thinking and invites us to rethink human relationships with the physical world/environment.

Critical Theory

Critical theory is a social theory oriented toward critiquing and changing society as a whole, in contrast to theories oriented only to understanding or explaining how societies and social structures work or do not work. Critical theory provides a basis for investigating power relationships, and, as a result, it has a strong focus on the marginalization of some social groups (Freire, 1999 first published 1972; Habermas, 1971). Historically, these groups have included the poor, women, people of color, and gays and lesbians. Critical theories aim to dig beneath the surface of social life and uncover the assumptions that keep us from a full and true understanding of how the world works. Critical theory can be recognized today in many feminist theories and feminist approaches to conducting social science, critical race theory, cultural theory, gender and queer theory, and in media theory and media studies. It has also infiltrated the ways that scholars do research with, for example, critical action research and critical discourse analysis (CDA) being just two approaches derived from applying a critical orientation to research problems.

As it relates to environmental and sustainability matters, marginalized groups include children, future generations, as well as nonhuman species (Borkfelt, 2011), places, and even natural elements, such as water, soil, and air. There is a significant body of work that investigates and theorizes, specifically, issues of the environment from a critical theoretical lens, for example, Luke (2003).

Critical theory also assists in understanding how education systems have played their part in this marginalization (Stevenson, 2007). In particular, Stevenson (2007) argues that there is a fundamental contradiction in purpose and practice between what schools do, i.e., primarily construct a workforce to build and maintain capitalism perceived by many as the root cause of the problems, and issues confronting the globe; thus, growing inequalities and environmental/climate disruptions are evident. The goals of a critical education are to seek to empower learners to identify the social and cultural issues that lead to such exploitation and to change things for the better. The application of Freirean ideas of emancipation – with a focus on giving voice, engaging in dialogue and transformation – has been embraced by several educationalists (Apple, 1996; Giroux, 1992; McLaren, 1989) and is known as critical pedagogy with application across a broad range of schooling subjects (Haque, 2007). These principles are also deeply embedded in approaches to environmental and sustainability education. In McLaren's recent work (2015), he has updated his discussions linking environmentalism and critical pedagogy and now uses the term "critical ecopedagogy" that is discussed later in this chapter.

New Sociology of Childhood

Lastly, we refer to the new sociology of childhood (Corsaro, 2005) and perceive this theoretical lens as firmly aligned to the empowerment of learners and change for the better as described above. Childhood is most often recognized as a predetermined biological stage, but James et al. (1998) have long-argued childhood is constructed,

culturally determined, and changes over time. Emerging in the 1980s alongside the UNCRC (1989), the new sociology of childhood departed from traditional images of childhood where children were seen as incomplete individuals disconnected from society at large, or as a universal cohort passively enculturated by adults (Corsaro, 2005). New sociology positions children as active contributors to and interpreters of their social worlds; they are social actors in globally diverse social systems with individual accounts and voices to be valued, respected, and responded to by others (James et al., 1998). These accounts largely resonate with Bronfenbrenner's model (1979), but across the spheres of early childhood education and education for sustainability, such images strongly impact educators' pedagogical approaches and offer potential for researching *with* children. Christensen and James (2000) initially promoted a shift toward authentically recognizing young children as research participants and experts about their experiences; and, this approach often underpins early childhood education for sustainability research (Davis & Elliott, 2014). In these contexts, children are perceived as more than participatory individuals across multiple social systems; they are active social change agents with potentially far reaching impacts (Mackey, 2014).

In summary, we argue – through the alternative theoretical perspectives introduced above – that continued reliance on Bronfenbrenner's theory of child development in early childhood education works against ideas embedded in sustainability and education for sustainability (EfS). These include ideas about humans as interrelated with nature and the more-than-human world rather than as separate from; humans as critical thinkers and ethical social beings with collective potential for change rather than as disempowered individuals; and, humans as integral to the dynamics of interactive global systems beyond human life times. We postulate that reliance on human-centric systems is both outdated and deeply inadequate in the twenty-first century and serves to alienate and disempower children in dealing with contemporary lives and challenges as much as it has served to support and nurture their development in positive ways. However, as stated earlier, we consider that Bronfenbrenner's idea of the chronosystem offers a bridge between human-centric ideas of growth and development and our contemporary concerns with sustainability because of the reference to time, the future, and intergenerational connections.

What Might New Ecological Models of Human Development Look Like?

As we have researched for, and authored, this Chapter, we have played with several models of our own about how to represent Bronfenbrenner's ideas within the contemporary milieu of sustainability. In our reconceptualization of new ways of looking at the work of Bronfenbrenner (1979), we have engaged in a playful dialogic of models. Here we share our initial possibilities for (re)presenting his work. We have not come up with a "best" model. Indeed, we have three models – each using Bronfenbrenner's more recent bioecological model (2001) as a starting point.

Model 1: Overlay Bronfenbrenner's Model with UNESCO's 4 Dimensions

Initially struck by the circularity of both the UNESCO (2010) model of sustainability incorporating four dimensions and Bronfenbrenner's (2001) model, can we simply superimpose one on the other? If so, *all* dimensions of sustainability are overtly seen to overlay and impact all the hierarchical systems levels of Bronfenbrenner's social model (2001), adding significant depth and relational complexity. For example, the natural/conservation dimension which comprises "all living things resources and life support systems" (UNESCO, 2010) intersects and can be mapped to the individual, the microsystem, mesosystem, exosystem, and macrosystem at any point in time and over time as the hierarchical human systems and natural world evolve and change enmeshed together (Fig. 3).

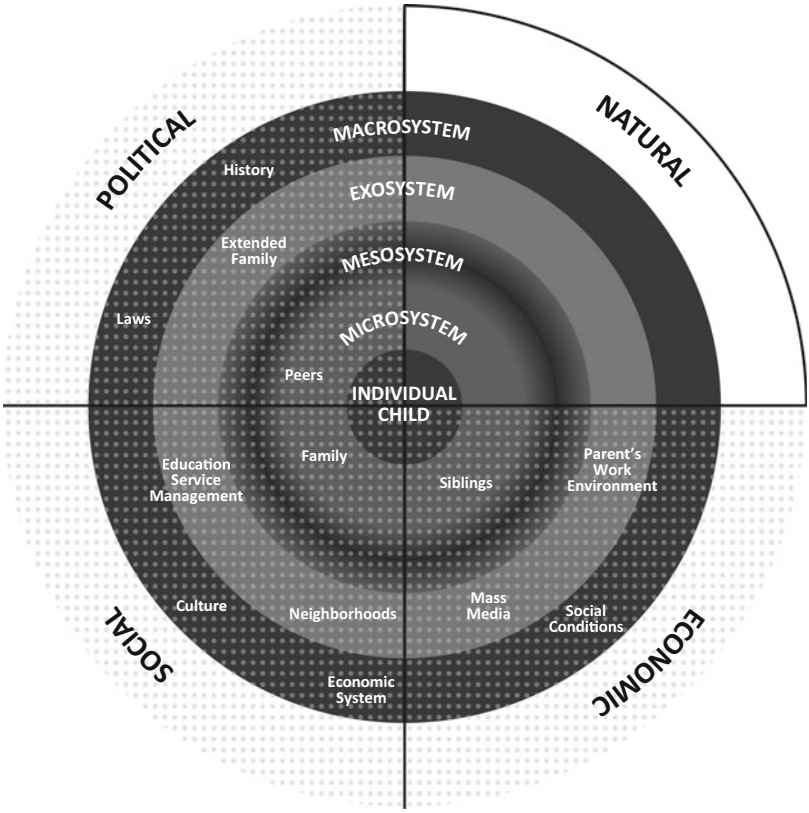

Fig. 3 Model 1: Overlay Bronfenbrenner's model with UNESCO's 4 dimensions

Model 2: Add a Biosystems Level as All Encompassing Around Bronfenbrenner's Macrosystem

Another possibility is to recognize biosystems (physical and nonhuman elements) as an additional hierarchical level for Bronfenbrenner's bioecological model (2001), depicted as an additional outer concentric circle. Hence, biosystems become all encompassing beyond the *macrosystem* of human-centric policies, values, and cultural beliefs. The outer biosystems level has impacts at all levels in the human-centered hierarchy of systems, and, equally, humans are impacting the biosystems as realized in global climate change. We move beyond broken lines to depict the permeability of the hierarchical systems (McCrea & Littledyke, 2015; Rogoff, 2003) to a shaded model depicting systemic embeddedness. These changes acknowledge that the dynamics of biosystems ultimately determine human development and global sustainability as a whole (Fig. 4).

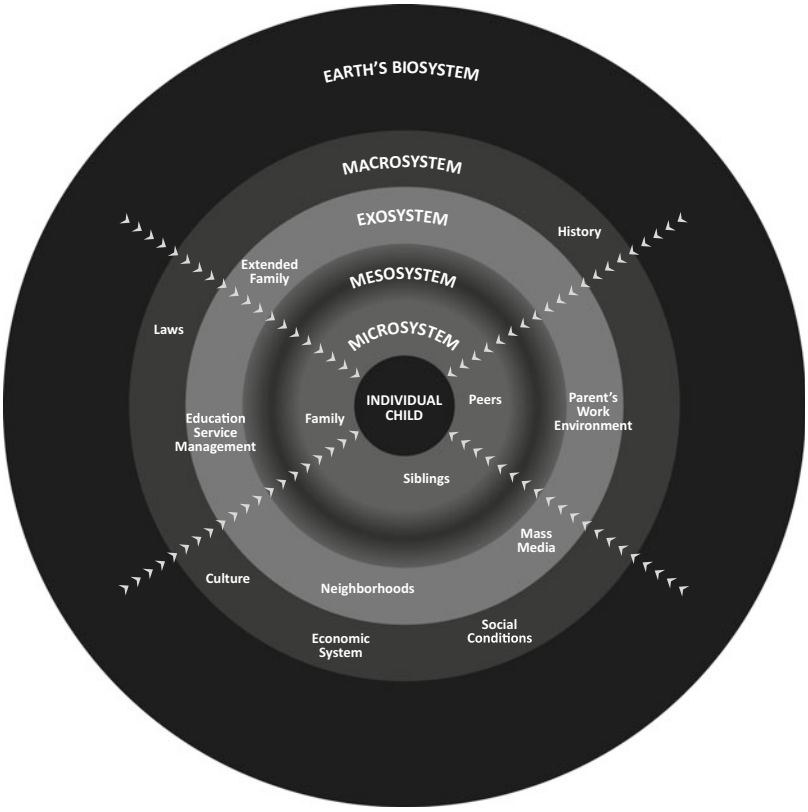

Fig. 4 Model 2: Add a biosystems level as all-encompassing around Bronfenbrenner's macrosystem

Model 3: Add a Biosystems Level Both Centrally and Outside Bronfenbrenner's Macrosystem

There may also be merit in strengthening human interrelationships with biosystems by recognizing biosystems centrally in Bronfenbrenner's model (2001) as well as beyond the macrosystem as in Model 2. The individual at the center is intimately and daily actively interacting with local biosystems, whether or not humans are aware of this relationship – with capacities to drive agentic change that may ripple outward. This combined model reflects the "act local, think global" maxim of the environmental movement and identifies individuals and the microsystems they inhabit with capacities for action and change across the hierarchies of social systems and complexities of global interrelationships over time (Fig. 5).

We have no one preferred model or response at this time, but are keen to continue playing with Bronfenbrenner's model to give it relevance for today in early childhood education.

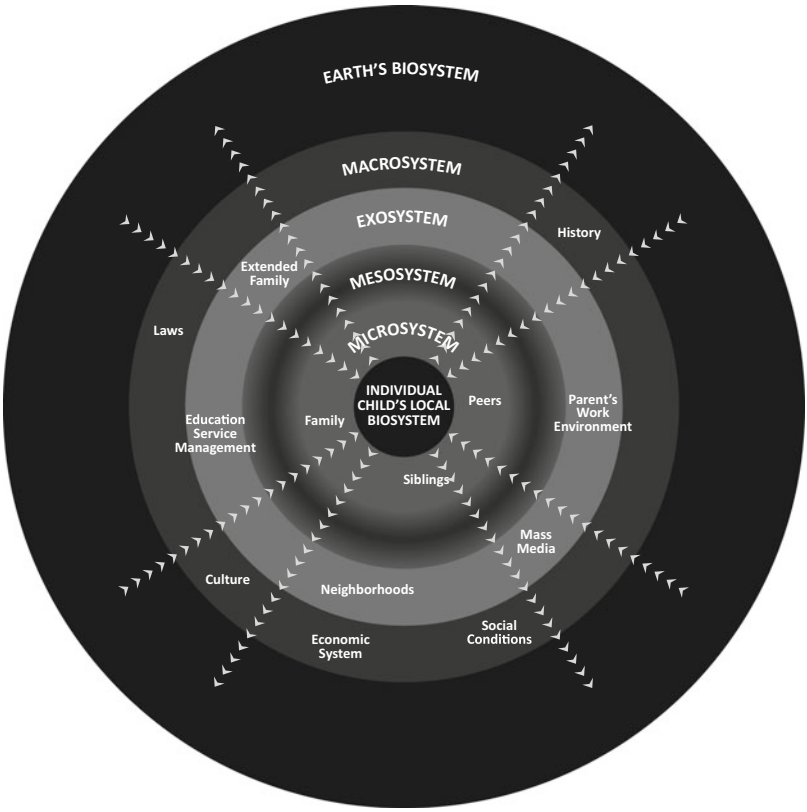

Fig. 5 Model 3: Add a biosystems level both centrally and outside Bronfenbrenner's macrosystem

Some Resolutions to Addressing the Shortcomings of Bronfenbrenner's Theory in Contemporary Early Childhood Education

From our positions as specialists and researchers in early childhood education for sustainability over the past 25 years, we know that there is a small but growing number of educators who have engaged with newer frames of early childhood education with sustainability in mind. In this section, three vignettes contributed by leading educators in early childhood pedagogical practice demonstrate how reimagined Bronfenbrenner (1979, 2001) models that account for a sustainability paradigm might look in practice. Following the vignettes, we offer a tabulated analysis of links between the approaches described in the vignettes and our critiques and theorizing. For the time being, we collectively call such approaches "critical eco-pedagogies for early childhood education," after the work of McLaren (2015).

Vignette 1: Bubup Wilam Aboriginal Child and Family Centre, Victoria Lisa G. Thorpe, Gunditjmara, Gunnai woman CEO and Angie Zerella, Education and Training Manager

Bubup Wilam is a self-determined Aboriginal Child and Family Centre catering for the education, health, and well-being needs of Aboriginal children aged 6 months to 6 years and their families. The purpose and the philosophy of the Centre was developed by the local Aboriginal community for Aboriginal people. Underpinned by Aboriginal, social justice and rights-based pedagogies, we aim to support children in collaboration with their families to build strong and proud Aboriginal identities as their foundation for lifelong learning health and well-being.

With the inequities in health, well-being, and educational outcomes for Aboriginal people in Australia, Bubup Wilam strives to provide children and their families with the support they need to be self-determining in their own lives enhancing their opportunity to reach their full human potential. This requires a holistic pedagogical approach which is underpinned by an Aboriginal perspective. This is inclusive of children's spiritual connection to country, connection to kin, and connection to where they are from and who they are. This incorporates ways of the past, present, and future and respects those that have walked this land before them, those that walk with them now, and those that will walk this land in the future.

Our connection to country program supports children's spiritual connection to their world and respects the interdependence between human, animal, and nature. It challenges them to critically reflect on their custodianship rights and responsibilities. Our children respect the spirit of the land and are taught not take anything off country as you remove the spirit and disrupt the space. We only use what we need while on country and leave as little damage behind as is possible. The hierarchy of human as dominant is challenged as the life and spirit of all things is acknowledged, and respect and equity for everything in our space is embedded in the way interactions occur within it.

Modern-day tools are not used due to the damage they would inflict on whatever they come into contact with. When relationships are formed with land, life is given to the two parties and the interactions are respectful and considerate. Our children learn about all living things that they share their space with, and they research habitats, respect potential dangers, and learn to live respectfully and in unison with all aspects of their world and all who share it with them. They learn to appreciate the complexities of life and their responsibility in keeping their world healthy, well, clean, and nourished.

Our children know the country they are from and the extra responsibility they have as traditional owners of that land. This gives them strength and connects them strongly to their identity as young Aboriginal children. They know that when on other people's country, they have responsibility to respect their country to look after it and ensure it is cared for. For our children, we are on Wurundjeri country and we acknowledge this every day. This naturally ensures a world for sustainability is embraced; this is through a relationship of historical connections, respect, and equity.

The challenge for our center in embracing this pedagogy is the cost of taking our children out on country in local bushlands, but this is far outweighed by the outcomes for our children and their families. Many of our families participate in the program which brings a richness of knowledge that is shared with the children. Being on country enables our children to connect to nature in a much richer way than in the yard at our service as they have a much deeper respect for the way they interact with their world and are activists for social change in sustainability as there is so much to protect. Connecting with country so richly has changed the way both children and educators interact with country back at our service where we extend on the richness of learning provided to us.

Urie Bronfenbrenner's ecological model focuses on the impact of human connections and relationships on the lives of children. This is also inclusive of the political context and the time, era, and place that the child grows up. However, it silences the importance of the natural world and the impact this has on children's lives. For our children this is central to their healthy life outcomes and to their identity. Family connections and ancestry is vital in developing strong identities, but this is never in isolation to knowing the land one is from and the stories of that land over time. Protecting land through an Aboriginal lens is central to health and well-being. A true ecological systems theory cannot silence the importance of this (Fig. 6).

Vignette 2: Bunyaville Environmental Education Centre, Queensland Noeleen Rowntree, Principal

Bunyaville Environmental Education Centre (EEC) sits in the middle of the forest. To enter this forest, you rumble along a dirt road with car wheels crunching on gravel. As you step out from your vehicle onto the earth, you are surrounded and immediately dwarfed by very tall gum trees. The many bird sounds chatter around you. You have arrived in the "classroom" of the Bunyaville EEC – the forest and the

Fig. 6 Bubup Wilam Aboriginal Child and Family Centre, Victoria

bush. Bunyaville EEC is a Department of Education and Training of Queensland facility. Bunyaville EEC accommodates all ages from birth to adult, formal school years P-Year 12, kindergarten, and early childhood from birth to 5 years.

At Bunyaville EEC we value a world where people care for themselves, others, and place (connecting to country), taking learning outside through experiencing, connecting, and enabling everybody to be part of sustainable futures. For us, it is about learning naturally and relationships matter, both to others and the Earth (country). Bunyaville as a place is very important, and it is the place that shapes our pedagogy across all age groups. As all of us from birth onward live more and more urban lives, connection and/or reconnection to natural places needs to be scaffolded. Across the years perceived fears of the bush have shaped our program design particularly in the early years. Most children are with us for the whole day with children from birth to 5 years spending 2 h with us outside. Whatever the age, it is important for the experience to be positive and joyous. For our visitors, time becomes irrelevant once we have entered the forest. Time doesn't seem to matter as we explore, play, discover, learn, tell stories, feel, smell, and touch the natural world with each person immersed totally in the moment of being in the natural world. It is this total immersion that suspends time. We believe this full immersion provides the experiences and helps connect individuals to the natural world.

What does it look like when place is at the center of your pedagogy? Purposeful program design and teacher pedagogy scaffold the learning for everyone. The learner, no matter what their age, is placed at the center of the learning seen as a component and capable problem-solver. Purposeful program design moves the learner from the familiar into the less familiar forest experience. Every learner spends time in the forest. So, if I am 2, 3, or 4 years of age, I arrive to see some

familiar things that I can do. Maybe there is a cardboard box, storybooks, wooden blocks, paint brushes, and water that I can use immediately. This invites young children to engage in readily recognizable opportunities for play. Remembering that this may be my first time as a child to have been in a forest, the familiar provides an easy place to start. Meanwhile, the forest sits and waits, going nowhere while I play with the familiar. Ever present the forest waits, and in a very short time we all eagerly transition seamlessly into the forest.

When in the forest, it is the many different places that drive the learning. Every place in the forest provides different opportunities. The natural materials, the special animal homes, the fallen log, and giant tree become the places for learning. Being attentive to the many parts, developing stories, adopting an inquiry approach, being in naive fellow, or empowering children to look, touch, feel, and see and encouraging children to ask questions, by answering with a question such as "I wonder . . .," can deepen the engagement, the experience, and ultimately, the connection.

Knowledge of the place matters here also. This is knowledge of what works best in what part of the forest. For example, knowledge of where to sit children comfortably to tell a story, where to invite children to explore freely, and how to set boundaries with children when there are no walls. Knowledge of where conversations are best had and where might the wallaby sleep on a hot day? Where will we need extra equipment to add to the captured moment? How to help children to see the micro in the vastness of the forest? Also, knowing the coolest route to walk after a hot morning. The teacher needs to understand and to have experienced the place. The place drives what you do. As the teacher, the place speaks to you about the relevant pedagogy as you flow through the natural area. It is when you are outside in the forest that humans begin to see that they are part of the whole, and not the whole itself.

From being in the forest human-nature interconnections develop and deepen. The teacher extends the learning by being in, doing, resting, reflecting, and questioning. Children may arrive wondering what "monsters lurk in the corners of the ponds" and depart telling you that they want to stay forever as they want to be a plant to help the forest. In a very short space of time, fears about the forest melt. Children understand the interconnections of the natural world, understand ecological issues, understand the environmental issues and problems and, most importantly, understand their role and how they can make a difference. It is not a case of waiting until I am grown up to do something. It is about right now; and, this is what I can do.

This approach works; however, the biggest challenges are adult perceptions about learning outside. Many adults perceive that no learning happens outside of four walls, and in the formal school years, teachers can be told to stay inside to learn. In the before school years, adults and caregivers may feel afraid of being outside, and it is the adult fears that become the barriers. When teaching a pedagogy of place, the teacher trusts the learner as being competent and capable. The teacher is a co-learner and model with each child. If the teacher is content-focused only, the human-nature interconnections is diminished as naming and labeling moves learning into the head and away from the heart and hands – the experience and

Fig. 7 Bunyaville Environmental Education Centre, Queensland

connection. The program design and pedagogy slows time for the learner. Two hours is but a moment (Fig. 7).

Vignette 3: Quirindi Preschool Kindergarten, New South Wales Director Alison Thompson

Quirindi Preschool Kindergarten is a rural community-based not-for-profit preschool with a commitment to EfS, community connections, arts in nature, and bush programs. Our learning framework values play-based learning, sensory integration, and learning-style groups organized around how each child learns. When considering these groups, educators observe children at play and reflect on how much space each child needs and how actively engaged they need to be to learn. Each educator's intentional teaching practices scaffold children's learning to promote an inclusive learning environment where each child's play skills and communication are extended. Our pedagogy includes a commitment to indoor/outdoor learning where the spaces invite the groups to move through the preschool environment designed to absorb the activity of the children.

Our preschool has also made a commitment to being active within the community to make the children's learning visible with the aim of strengthening community connections. Together educators, children, and their families are developing a growing awareness of our community, the community in which we live, and seeing our community landscape as being our broader family. Our definition of community landscape is what makes up our community the bush, the urban, and the social; collectively this is our natural environment. Thus, we are exploring the notion that a natural environment is not only related to our bushland program but makes up our

community, for example, farming, transport, employment, buildings, bushland, community groups, businesses, and government initiatives at a local, state, and federal level. Also, using different art forms, for example, ephemeral nature-based art incorporating all our senses, promotes children's sharing of their stories while looking beyond the surface of the community landscape. Our "Collaborations with Children" 2015 and 2016 project with artist Shona Wilson was successful in holistically promoting children's senses and stronger dispositions for learning, critical thinking, while also building the foundations for environmentally engaged adults.

Our service philosophy is our recipe. A traditional recipe offers a strong foundation of ingredients and methods but also strength for change. Our recipe ingredients are educators who value children's ability to play plus their wonder and curiosity, take time to listen and value children's perspectives, and also value families' traditions and community connections. Blended together, these are the basis for challenging and promoting educational change.

Further, collaboration between educators, children, and families promotes educators' strengths to step outside our space and to view the world beyond what we see on top but to look beneath and above. The aim is to view our learning community and our broader local community as all part of a community ecosystem, and each one of these parts is interconnected. Our small community is also part of a larger global community. If you take away one part of the many parts of the world that interconnect, there is a chance it will perish. We need to explore, imagine, reflect, and evaluate with separate views, but if EfS is to be strong, we need to bring these views together to merge as a community of thinkers striving for the connections between EfS and larger social change.

We draw on pedagogical sources (Carter & Curtis, 2008; Edwards, Gandini, & Forman, 1998) that promote connectedness to community and a belief that educators are in a strong position to foster relationships with children, families, and people of our community, urban, commercial, and natural worlds. Educators are in a strong position through positive engagement and listening to children. They are able to understand individual children and feel empowered to challenge children and themselves with provocations. Provoking conversations encourages shared thoughts, questioning, and interests that can strengthen our thinking, creativity, and ideas, so that together we strive to see the interconnections between education and larger social change. Teaching intentionally from observing and actively being with children and collaboratively with community, thus, give our teaching energy to learn together and to want to learn more. To critically engage with children around EfS, educators need to use their imagination, act with ethical ingredients and challenge themselves to step outside their spaces, just as we ask the children to challenge and extend their thinking.

First and foremost, we are a community preschool which is strongly reflected in our philosophy and practices and links our preschool to the Bronfenbrenner model. The community system connections flow through our work and support children to understand what makes up their unique community landscape. Our educational team is learning that EfS is a growing journey for children, families, and educators.

Fig. 8 Quirindi Preschool Kindergarten, NSW

Services whose early childhood settings are situated in the city, on top of buildings, or in metropolitan areas have to create their own journeys in EfS. Our educational team feel strongly that if you value community and explore and document your community, you will find there are many possibilities to share the exciting, challenging, and risk taking journey of "EfS" (Fig. 8).

Our Analysis Linking Practice to Our Reconceptualized Bronfenbrenner Model

In Table 1, we offer our analysis of these three vignettes of contemporary early childhood educational practice using the theoretical frames outlined earlier; this takes us beyond the anthropocentrism inherent in Bronfenbrenner's models (1979, 2001) of human development.

Conclusion: Rethinking the Theoretical Tenets in Early Childhood Education

Peter McLaren, one of the architects of critical theory and critical pedagogy, argued persuasively in 2015 about the need for a dramatic shift in how we think about education and has called for a new emphasis and shift from pedagogy to ecopedagogy (p. 307). He commented that, while progressive education's emphasis on identity politics as a solution to creating a more vibrant, inclusive, and critical

Table 1 Linking critiques with theories and critical ecopedagogies for early childhood education

Critique	Theory	Key ideas	Practice implications	Vignette examples
Language	Critical theory as linked to critical discourse analysis	Contextualizing language and the dynamics of changing meanings	Interrogating language and making meanings with children	*QP – our definition of community landscape is what makes up our community the bush, the urban, and the social; collectively this is our natural environment*
	New sociology of childhood	Children recognized as active social participants and their perceptions valued	Positioning children as skilled and knowledgeable social learning participants	*QP – educators who value children's ability to play plus their wonder and curiosity, take time to listen, and value children's perspectives*
				BEEC – the learner, no matter what their age, is placed at the center of the learning seen as a competent and capable problem-solver
Contexts and relationships	posthumanism	Encompass more-than-human relationships	Examining what defines ethical relationships with the human and more-than-human world with children through pedagogical practices for sustainability	*BW – when relationships are formed with land, life is given to the two parties, and the interactions are respectful and considerate*
	New materialism			*BEEC – relationships matter, both to others and the Earth (country)*
		Ethical relationships	Inviting immersion in natural contexts to facilitate relationships	*QP – educators are in a strong position to foster relationships with children, families, and people of our community, urban, commercial, and natural worlds*
				BEEC – we believe this full immersion provides the experiences and helps connect individuals to the natural world

Systems	Systems theory	Systems as interactional at all levels and not entity focused	Acknowledging and/or mapping all relationships with children	*BW – children's spiritual connection to country, connection to kin, and connection to where they are from and who they are*
	posthumanism			*BW – respects the interdependence between human, animal, and nature*
	New materialism	Systems as comprising human and nonhuman entities and interrelationships	Recognizing the reciprocity and responsiveness of interrelationships as integral to the functioning of open systems	*BEEC – it is when you are outside in the forest that humans begin to see that they are part of the whole, and not the whole itself*
		Systems as open and not closed or human-centric only		*QP – the aim is to view our learning community and our broader local community as all part of a community ecosystem, and each one of these parts is interconnected. Our small community is also part of a larger global community*
Time dimensions	posthumanism	More-than-human life histories, global time frames	Discussing equity issues now and for future generations both human and nonhuman	*BW – this incorporates ways of the past, present, and future and respects those that have walked this land before them, those that walk with them now, and those that will walk this land in the future*
	Dynamic systems theory	Dynamics of change over time		
			Acknowledging both human and nonhuman change over time	*BW – family connections and ancestry is vital in developing strong identities, but this is never in isolation to knowing the land one is from and the stories of that land over time*
				BEEC – meanwhile the forest sits and waits, going nowhere

(*continued*)

Table 1 (continued)

Critique	Theory	Key ideas	Practice implications	Vignette examples
The individual	Systems theory	Systems are collective with impacts from one entity influencing all parts of the system	Contextualizing with children about the impacts each individual sustainability action has for collective well-being of others both human and nonhuman	*QP – together educators, children, and their families are developing a growing awareness of our community, the community in which we live, and seeing our community landscape as being our broader family*
			Developing skills for sharing perspectives and working collectively in and with the community for change	*QP – collaboration between educators, children, and families promotes educators' strengths to step outside our space*
				QP – we need to explore, imagine, reflect, and evaluate with separate views, but if EfS is to be strong, we need to bring these views together to merge as a community of thinkers striving for the connections between EfS and larger social change
				QP – together striving to see the interconnections between education and larger social change

Children's agency	Critical theory	Children as empowered and global change agents through active social participation	Practicing advocacy and action for sustainability with children in relation to meaningful issues	*BW – critically reflect on their custodianship rights and responsibilities*
	New sociology of childhood		Questioning sustainable practice norms, ethics, and interrogating dilemmas and conflicts	*BW – they know that when on other people's country, they have responsibility to respect their country to look after it and ensure it is cared for*
				BW – activists for social change in sustainability as there is so much to protect
			Recognizing and listening to children's voices	*BEEC – encouraging children to ask questions but by answering with a question such as an "I wonder . . ." can deepen the engagement, the experience, and, ultimately, the connection*
			Inviting and promoting children's active participation in social change	*BEEC – children understand the interconnections of the natural world, understand ecological issues, understand the environmental issues and problems and most importantly, and understand their role and how they can make a difference*
				QP – to critically engage with children around EfS, educators need to use their imagination, to act with ethical ingredients and challenge themselves to step outside their spaces. Just as we ask the children to also challenge and extend their thinking

public sphere has met with some success, "issues of environmental sustainability [have] maintained but a lifeless presence, including within critical pedagogy" (McLaren, 2015, p. 308). He suggests that now is the time – emboldened by the activities of various global social movements and motivated by deepening planetary crises – when critical ecopedagogies have "arrived" and can offer powerful arguments for how to respond to the Anthropocene crisis. Further, he argues for a "revolutionary critical ecopedagogy" as a reconfiguring force. Drawing on its Marxian roots, this has the potential to re-center on essentials, suggesting a reining in of unsustainable, exploitative practices with a shift away from materialism to the expression of natural and acquired talents and the promise of improved ecological stewardship.

Further, McLaren (2015, p. 316) reemphasizes the necessity for linking ecopedagogy with praxis, but not any kind of praxis. Drawing on the liberatory tenets of Freire, this should be praxis that is philosophically founded in ethics and recognizes the languages and discourses of the oppressed and marginalized. He recognizes that ecopedagogy must join up with existing decolonizing struggles of all kinds as natural allies in the battles against unsustainable world capitalism.

Drawing on McLaren's views, we argue that a radical ecopedagogy must inform, and reshape, early childhood education as much as education generally. Moss and Petrie (2002, p. 136) would agree; pedagogy cannot be neutral; it is "a political and ethical minefield in which choices are to be made." One way to move to a transformative pedagogical stance is to continue shifting the theoretical underpinnings of early childhood education – of which Bronfenbrenner himself was once a revolutionary pioneer – toward critical ecopedagogies for early childhood education. We further argue that the vignettes presented in this chapter offer ways that such critical ecopedagogies might be enacted. As Mackenzie and Bieler (2016) emphasize, operationalizing critical education approaches must go "beyond critique and deconstruction to encompass the production and practice of alternatives" (p. 6).

In this chapter, we have presented arguments for rethinking the theories and models of Bronfenbrenner (1979, 1999, 2001), who for the last 40 years or so has been a key figure in directing how the early childhood education field thinks about children's development and well-being and how this is enacted in practice. We have offered critiques based on the changing times and pressing issues of the twenty-first century with particular reference to sustainability in the Anthropocene. We have proposed new ways of representing/updating Bronfenbrenner's (1979) work and have presented vignettes where educators are exploring ecopedagogical approaches that go beyond the anthropocentrism of Bronfenbrenner's theorizing (1979). We do not pretend to be putting forward a replacement of Bronfenbrenner's (1979) theories/models, though in the future there may well be models that have not yet been thought of and that better fit contemporary circumstances. What we hope to do, though, is instigate a conversation about Bronfenbrenner's (1979) work and its dominance within early childhood education. Therefore, we invite others to critique his theories and models, and our ideas as presented in this Chapter, and to propose new and/or better ways of reconstructing early childhood education, childhood, environment, and childhoodnature, for a flourishing twenty-first century.

keeping children healthy and in helping them to understand the relationship between ecosystem health and their own health. By understanding these interconnections, children can learn that they are not separate from or superior to nature. Rather, these settings become sites where children can refresh and reimagine understandings of nature and their relationships *as, within, of, and to* nature. Healthy settings are, we believe, a foundation for healthy children. A focus on health is particularly timely for two reasons. First, there are mounting international concerns about children' health – be it around issues of physical activity, mental illness, social resiliency and belonging, overweight and obesity, and spiritual grounding. But it is not only children's health that is of concern: there are deep and mounting international concerns about the health of ecological systems, be it around issues of global warming, acid rain, species loss, air pollution, urban sprawl, waste disposal, ozone layer depletion, and water pollution. This Chapter is framed around the World Health Organization's definition of health and explores the ways in which local nearby natural childhoodnature settings can promote physical, mental, social, and spiritual health and well-being of children. To illustrate these concepts in action, we profile a case study from our research in Australia. This chapter concludes with a discussion on the ways that healthy childhoodnature settings can unite, inform, and support the interests of educators, environmentalists, and children's health advocates who have an interest in the health of children and ecosystems.

Introduction

This Chapter explores the ways in which healthy "everyday, local, nearby" green/natural settings in urban spaces, such as school grounds, playgrounds, backyards, and community settings, can play powerful and enabling roles in promoting health for children.

A focus on health is particularly timely for two reasons. First, there are mounting international concerns about children's health (World Health Organization, 2016) – be it around issues of physical activity, mental illness, social resiliency and belonging, overweight and obesity, and spiritual grounding. In response to these health concerns for children, it is widely recognized that health promotion must extend beyond interventions that target individual behavior to a more comprehensive and ecological "settings approach" model that addresses the wider contexts where people live, work, and play. From this perspective, "everyday, local, nearby" places where children spend time, and which are the focus of this chapter, are important "settings" for understanding and promoting the multiple dimensions of health (Maller, Townsend, Pryor, Brown, & St Leger, 2006).

But it is not only children's health that is of concern: there are deep and mounting international concerns about the health of ecological systems, be it around issues of

global warming, acid rain, species loss, air pollution, urban sprawl, waste disposal, ozone layer depletion, and water pollution (Barnosky et al., 2011; Pimm et al., 2014). It has been argued that the human-induced change is so significant and dramatic that it should constitute a new geological epoch, which has been informally called the Anthropocene (Crutzen, 2002). The interrelationship between ecosystem and human activity is central to this new epoch. On one hand, there is despair at the pace of change, while others argue that this time can be generative and productive and call to action for changes for both ecosystem and human wellbeing (Braidotti, 2013; Latour, 2014).

The links between children's health and the health of ecosystems are both obvious yet complex. By way of examples, densely populated urban spaces present health challenges to ecosystems in terms of habitat loss for birds and animals; they also present health challenges for children who find it difficult to walk or bicycle around their local communities. School grounds, local parks, and backyards that use pesticides to eliminate "weeds" contaminate soil, water, and other vegetation and are toxic to a host of other organisms including birds, fish, insects, and nontarget plants; children who are exposed to these pesticides can suffer from a range of serious illnesses and diseases, ranging from respiratory problems to cancer (Gilden, Huffling, & Sattler, 2010).

In this Chapter, we highlight the central role that we believe that healthy, vibrant, and functioning "everyday, local, and nearby" childhoodnature ecosystems can/should play in both keeping children healthy and in helping them to understand the relationship between ecosystem health and their own health. By understanding these interconnections, children can learn that they are not separate from or superior to nature. Rather, these settings become sites where children can refresh and reimagine understandings of nature and their relationships *as, within, of, and to* nature. Healthy settings are, we believe, a foundation for healthy children.

We begin this Chapter with an overview of the "greening" movement that is transforming urban childhoodnature settings where children spent time. We then briefly introduce the concept of a "settings approach" to health promotion and also examine the relationship between healthy, vibrant, and functioning ecological systems and the health and wellbeing of children. The majority of the Chapter is framed around the World Health Organization's definition of health and explores the ways in which local, nearby, natural play spaces can promote physical, mental, social, and spiritual health and wellbeing of children. By adopting a broad interpretation of "health," we seek to expand the children's health and wellbeing discourse beyond the "physical," and we disrupt the notion that playgrounds are exclusive places to "burn up steam." We also disrupt the notion that children are separate from nature but are instead connected to and part of nature. We point to the powerful and diverse ways that healthy local settings can support children's health and wellbeing. To conclude our Chapter, we illustrate these concepts in action by profiling a case study from Monica's (second author) research on the ecological, pedagogical, and health benefits of school and community settings in Australia. The case study shows how children work to create and support healthy ecosystems and, in doing so, create spaces that promote their own health and well-being. Our Chapter concludes with the contention that healthy local childhoodnature settings are places that can unite,

inform, and support the interests of educators, children's health advocates, and environmentalists who are concerned about the health of ecosystems.

Green Everyday, Local, Nearby Childhoodnature Settings

Around the world, children's everyday, local, nearby settings, such as school grounds, public playgrounds, and backyards, are changing. Homogenous environments comprised primarily of asphalt and/or grass that are noted for being hot, hard, and barren (Fig. 1) are being transformed or "greened" into places designed to include a variety of natural elements such as vegetable gardens, wetlands, trees, frog ponds, murals, and butterfly gardens (Figs. 2, 3, and 4).

For the purposes of this Chapter, we use the term "green" to describe the changes that settings have experienced. We recognize, however, that some changes to settings, particularly in the southern hemisphere, like Australia, where our case study takes place, may actually result in the setting become more "brown," but for the purposes of this chapter, we have chosen to use the term "green" as it reflects an international movement dedicated to transforming children's settings.

Children's everyday, nearby, local outdoor settings are ideal sites that serve to decenter humans and where interactions with the more-than-human world provide possibilities for challenging the "ontological position of separateness combined with the colonizing politics of anthropocentrism and human exceptionalism" (Blenkinsop, Jickling, Morse, & Jensen, in press; ▶ Chap. 22, "Wild Pedagogies: Six Touchstones for Childhoodnature Theory and Practice"). While informal settings, such as backyards and some urban parks, might be left to speak for themselves through informal education, additional powerful learning can occur in more formal settings, such as school grounds. In these formal green settings, learning can be enhanced by "brave, insightful and rebel teachers," who are keen to wild their pedagogy and can help "bring voices of the voiceless to their students, and to

Fig. 1 Homogenous urban settings, such as this school ground which is comprised primarily of asphalt, are hot, barren, and hard

Fig. 2 A "green" school ground setting for children with a vibrant and healthy food garden

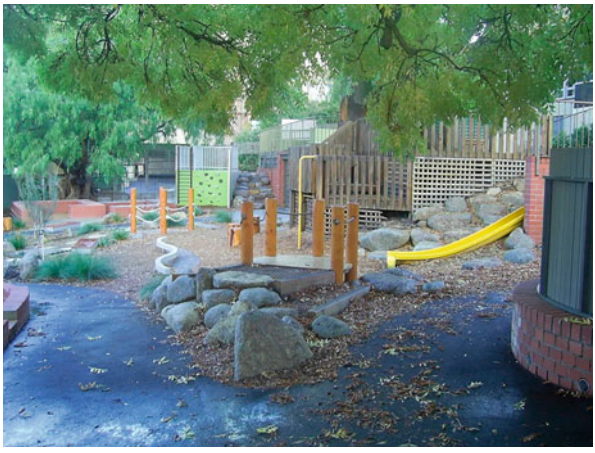

Fig. 3 A "green" early childcare setting for children with a diversity of natural play spaces and lovely shade

Fig. 4 A "green" community playground with art-enriched spaces for meeting and gathering. Mature trees provide healthy habitats for animals and birds as well as shade for children

enact pedagogies that are less objectively oriented and more co-constructed, less expertly known and more spontaneous, less universal and testable and more place responsive" (ibid, p. y).

Given the mounting evidence base pointing to the powerful role healthy local settings can play in the lives of children (Dooris, 2009; Dooris et al., 2007), it is internationally recognized and supported as evidenced by the large number of not-for-profit organizations that support the process of greening children's local outdoor settings. Organizations and programs such as *Evergreen* in Canada, the *Centre for Ecoliteracy* in the United States, *Learnscapes* in Australia, *Movium* in Sweden, *Ecoschools* programs in South Africa, and *Learning through Landscapes* in the United Kingdom continue to grow in their profile and scope. These organizations provide guidance, funding, and resources to administrators, community members, teachers, and parents who are interested in beginning the process of greening.

Settings Approach to Health Promotion

The prospect of seeing "settings" as possible sites for promoting health has a long international history. It was first advocated in 1986, with the Ottawa Charter, which stated that "health is created and lived by people within the settings of their everyday life; where they learn, work, play and love" (World Health Organization, 1986). It subsequently has been promoted in the Sundsvall Statement (World Health Organization, 1991) which called for the creation of supportive environments with a focus on settings for health. Finally, the Jakarta Declaration (World Health Organization, 1997) noted the value of settings in their role in implementing far-reaching strategies and providing a framework for health promotion.

A settings approach locates health action in the "everyday life" with a recognition of the social, cultural, and physical spaces in which people live, learn, and play. In the settings approach, health promotion is reoriented from developing personal competencies toward creating healthy policies, reshaping environments to support health, and building partnerships and creating sustainable change through participation, empowerment, and ownership of change throughout the setting (Whitelaw et al., 2001).

Since its inception, a variety of "settings" have adopted the approach – such as universities, hospitals, prisons, workplaces, and schools (Dooris, 2009). What is consistent across these various settings is that they are all seen to be "systems." The settings approach adopts a socio-ecological perspective, which explicitly recognizes the contextual and environmental factors that influence health. Interventions therefore target the physical, organizational, and social contexts in which people are found, not just the people contained in or defined by that setting (Poland, Krupa, & McCall, 2009). While we find great merit in the socio-ecological approach to health promotion, we are somewhat troubled by what we see to be the privileging of human (socio) health over the environmental (ecological) health. We wish to disrupt this privileging in this chapter – specifically human health over ecosystem health.

We hope this brief theoretical overview of settings approaches will help the reader understand why healthy "everyday, local, nearby" green childhoodnature settings, such as school grounds, backyards, community grounds, and playgrounds, can be seen as settings that can promote health of children. These are places where children engage in regular formal and informal activities. In these spaces, environmental, organizational, and personal factors can all interact to influence health and wellbeing. By their design, these settings can support children in developing healthy behaviors and help children understand their relationship to and with more-than-human world. As children learn to care for these local spaces and to nurture the health of these ecosystems, they become decentered from a position of privilege over more-than-human nature, and they are encouraged to participate in different kinds of physical activity; they are provided with opportunities for social inclusion and mental wellness; and they are gifted with opportunities for spiritual understanding.

Childhoodnature Turn On the Dimensions of Health

The next section of this chapter profiles the ways in which everyday, local, nearby green places are examples of a settings-based approach and explores the ways in which these healthy childhoodnature settings can promote children's health across a range of dimensions – including physical, social, mental, and spiritual.

Childhoodnature and Physical Health

Green outdoor settings can result in many physical health benefits for children, some of which are relatively straightforward. When pesticides are eliminated and shade is increased in family yards, school grounds, or childcare playgrounds, for example, there are benefits to both the ecosystem and children. Healthier ecosystems are created, and there is a reduction in children's exposure to harmful chemicals and ultraviolet radiation. With respect to both issues (pesticide use and shade provision), environmental research points to the damaging effects for surrounding flora and fauna (Goulson, Nicholls, Botías, & Rotheray, 2015; Potts et al., 2010), and medical research indicates that children are a particularly vulnerable population (Francesca, Elliott, & Crighton, 2014). By way of another example, the provision of shade is an important structural change to outdoor environments that makes it a healthier place for both the ecosystem and the children. For example, shade trees provide habitat and food sources for birds, squirrels, and butterflies in temperate ecosystems (Seamans, 2013); they also provide cool spaces for children to protect themselves from the damaging impacts of ultraviolet radiation (Shanahan et al., 2015).

In addition to these obvious benefits, greening can also enhance physical health in more subtle ways. However, to appreciate these, we must address two common misconceptions about the design of outdoor settings. The first is the belief that the uniform, wide-open spaces of conventional outdoor environments minimize physical risk and maximize children's safety because there is little that children can fall

down from and little to block the sight lines of the adults on playground duty. From this perspective, it may be feared that green outdoor settings increase the risk of injury – for example, by having children fall from rocks or trees, slip into ponds, or get stung by insects attracted to the vegetation or compost. In addition, there may be concern that bushes, trees, and other natural features will impair supervision.

While concerns about these risks are very real (often becoming barriers for encouraging children's play in outdoor settings), research into the contributions of children's outdoor interactions helps to correct the imbalance in this perspective. For example, a study of 45 schools in Toronto, Canada, indicates that green outdoor settings can actually calm the movement patterns of children and soften play surfaces so that there are, in fact, fewer "knock-and-bump" injuries (Dyment, 2005). With proper planning, furthermore, vegetation can be placed and pruned so that adequate sight lines are maintained.

Other studies have helped reframe "risk" in play settings arguing that the sterile landscapes of conventional children's outdoor settings present a much greater health risk than rocks and trees – the risk of depriving children of the quality and variety of experiences that are crucial to their healthy development (Little & Wyver, 2008; Sandseter, 2007, 2009; Stephenson, 2003). This risk is greatest for the growing numbers of children who have little access to the natural environment. Green local outdoor places provide regular opportunities for children to interact with the more-than-human world and be with and in and part of the natural world.

A second misconception about the design of outdoor settings pertaining to physical health is the belief that flat turf and asphalt provide ideal surfaces for burning off excess energy and are therefore best suited to promoting physical activity. Again, recent studies offer a more balanced perspective. They indicate that physical activity is best supported in outdoor settings comprised of a diversity of landscape features that respond to a wide variety of children's interests and capabilities (Bell & Dyment, 2006; Boldemann et al., 2006; Coe, Flynn, Wolff, Scott, & Durham, 2014; Dyment, Bell, & Lucas, 2009; Fjortoft, 2004; Moore & Cosco, 2014). A Canada-wide survey of 59 elementary schools suggests that greening school ground diversifies children's play repertoire and creates opportunities for boys and girls of all ages, interests, and abilities to be more physically active (Bell & Dyment, 2006). Complementing the rule-bound, competitive games supported by asphalt and turf playing fields, greened areas in children's outdoor settings invite children to jump, climb, dig, lift, rake, build, role-play, and generally get moving in ways that nurture all aspects of their health and development. Of particular significance is the potential to encourage moderate and light levels of physical activity by increasing the range of enjoyable, noncompetitive, imagination-based, open-ended forms of play in green outdoor settings. In these spaces, children can make discoveries and have experiences that challenge what they think they know. When children embrace the unknown, learn to deal with complexity, and be open to the spontaneous (Blenkinsop et al., in press), they can "step back from the centre. . .in order to allow other ideas, possibilities, spaces, beings and imaginations to emerge" (p. x).

Another physical health benefit offered by green local outdoor settings is the opportunity to promote better nutrition through children's participation in food gardening. Rates of obesity are rising among children in Australia, Canada, the United States, and other industrialized nations, with significant physical, mental, and social health impacts (World Health Organization, 2016). Health officials are therefore striving to improve dietary behaviors and are calling upon schools and childcare centers to support healthy eating choices. While attention is focused on the food choices offered in school cafeterias and childcare centers, food gardening offers a complementary means of supporting nutrition programs through the design and use of the outdoor settings. By planting, tending, harvesting, and eating a variety of vegetables and fruits, children can gain hands-on knowledge about nutritious food and its production (Bell & Dyment, 2006; Evergreen, 2006; Gottlieb & Azuma, n.d.). Incorporating a vegetable garden into health programing can thus have a positive effect on children's eating preferences, habits, and nutrition knowledge (Gibbs et al., 2013). The interrelationship between healthy soil and healthy children is critical here: food gardening with an organic focus also promotes a healthier ecosystem, allowing for rich soil generation and the growth of pesticide-free food that in turn sustains healthy children.

Childhoodnature and Social Health

Local nearby green outdoor settings are an important setting for social learning and development (Evans, 1995, 1997). By their design and culture, they influence social behaviors and relationships (Horning, Liden, & McMorris, 2017; Robinson & Zajicek, 2005; Titman, 1994; Waliczek, Bradley, & Zajicek, 2001). Green outdoor settings can play an important role in enhancing social health by providing a more diverse environment that better responds to the needs and interests of more children and by creating opportunities for children, communities, parents, and families to work together toward shared goals. In so doing, green outdoor environments promote social inclusion and equality and can foster greater civility, cooperation, and communication among children and between children and adults.

In her influential work on children and school ground design, Wendy Titman (1994) found a positive correlation between the conditions of the school ground and the behaviors and attitudes of children. She revealed how school grounds, in themselves, function as a "hidden curriculum" and a "form of mass communication" with a "vocabulary and grammar" of their own (pp. 16–17). Children in her study considered school grounds to be inextricably connected to the school buildings and believed that those who were responsible for the design of the school ground "made it like that" for a reason (p. 57). Thus, when school grounds failed to meet the needs of children, thereby making time in the school ground unenjoyable, they believed that this was a conscious decision by people in positions of authority who did not care.

Building on the work of Titman, others have examined the relationships between the design of outdoor settings, play opportunities, and social hierarchies and

interactions (Barbour, 1999; Cheskey, 2001a; Moore & Wong, 1997). American researcher Ann Barbour (1999) compared play behaviors on two school grounds: one that primarily provided opportunities for physical play and another that provided for a diversity of play opportunities. At schools that only provided opportunities for active and physical play, social hierarchies were established through these means, and children with low physical competence or desires were often socially excluded. Conversely, at schools where a diversity of play opportunities was afforded, students who were less physically competent could still engage in types of play that were more in line with their abilities and interests.

Conventional outdoor settings, by their design, provide a limited range of play opportunities that privilege certain individuals. Expanses of pavement and manicured grass offer opportunities primarily for large group, competitive, rule-bound games. They satisfy some children but provide few choices for those who prefer to play in smaller groups, who do not wish or are not able to compete, or who prefer more open-ended or creative kinds of games. Research suggests, for example, that conventional playgrounds cater to only a portion of the population – primarily boys, older students, and students with high physical competence who tend to dominate large open spaces and play equipment (Cunningham & Jones, 1996; Dyment, 2005; Nabhan & Trimble, 1994; Ridgers, Stratton, Curley, & White, 2005).

In contrast, green outdoor settings present the possibility of alternative, less oppressive approaches to dealing with these issues, in large part by satisfying the desires and needs of a wider variety of children. In their study of a green school ground in Berkeley California, for example, Robin Moore and Tony Wong (1997) found that children were able to "expand the play repertoire" (p. 91), engaging in less organized play and more unorganized or "free" play. On the green school ground, they observed an increase in active play, creative play, pretend play, exploratory play, constructive play, and social play, compared to the original school ground. They noted:

> This was a far cry from the old school ground, where girls hung around admiring the boys' prowess at playing ball or felt excluded because they were not attracted by the crowded play equipment; and where nonathletic children were ridiculed for not participating in the unchanging routines of ball courts, game lines, and metal bars. (Moore & Wong, 1997, p. 91)

A diversity of play opportunities is key for the facilitation of social skills. Citing an Australian study of over 4000 children in 21 primary schools, Evans (1998) notes that "the most active playgrounds with the happiest children were those containing the greatest variety of play areas" (p. 15).

Gardening activities in particular seem to provide ongoing opportunities to build positive relationships among students, staff, and parents, a key element in establishing a healthy school culture (Chawla, Keena, Pevec, & Stanley, 2014; Horning et al., 2017; Maller, 2005; Robinson & Zajicek, 2005). Some have argued that these benefits can be even more dramatic if children are involved in the full process of greening, from planning and design to implementation and maintenance (Green, 2014). In such cases, children typically have opportunities to work with a

range of individuals from both within and outside the school or childcare center. They are able to share interests, values, and time with other students, teachers, parents, and community members as they work toward common goals. They also learn important social life skills, such as teamwork, cooperation, and persistence (Alexander, Wales North, & Hendren, 1995; Horning et al., 2017).

Because greening projects tend to encourage broad community involvement, the social benefits can extend beyond the immediate school or early years setting, affecting the social health of the broader community (Barker, 1994; Herrington, 1999; Maller, 2005; Maller & Townsend, 2005). Greening outdoor environments provides a process and a place where people can meet, make friends, and build a sense of community and purpose (Dyment, 2005; Horning et al., 2017; Lewis, 1992). As projects evolve, and outdoor spaces become greener and more inviting, they embody the effort, care, and vision of those involved, sending a powerful message to the broader community. (Of course, if projects are untended or abandoned, the opposite is also true.) According to an Australian study, students who were involved in greening initiatives felt a greater sense of commitment to and from the broader school community as well as more links with other schools, parents, and the local community (Maller, 2005).

Childhoodnature and Mental Health

It has been long acknowledged across a range of cultures that plants, gardens, and gardening can have positive impacts on the mental health and wellbeing of humans (Ulrich, 1999). The tradition of using landscapes as a therapeutic healing tool has endured since ancient Egypt, when court physicians would prescribe walks in palace gardens for royalty who were mentally unwell (Davis, 1998). Likewise today outdoor spaces around some facilities, such as hospitals and prisons, are being consciously designed with a view to promoting mental wellness (Kellert, 2002; Lewis, 1992).

A growing body of literature points to the therapeutic role of more-than-human environment, particularly as this relates to mental health (Kaplan, 2001; Olds, 1989; Ulrich, 1984, 1999; Ulrich & Parsons, 1992; Ulrich et al., 1991). A basic premise is that contact with the natural world can provide relief from stress. Much of this research has been conducted with adults, although there is evidence of similar benefits for children. For example, Wells and Evans (2003) found that the presence of natural elements moderated the impacts of stressful life events on children aged 6 through 12 years who lived in a rural context. The authors discuss the policy and design implications of their findings, noting that "natural areas closer to housing and schools are essential features in an effort to foster resilience of children and perhaps to promote their healthy development" (p. 327). This assertion is particularly relevant for health-promoting schools and the green outdoor environment movement. Stressful events negatively influence children's disposition for learning, rendering them less able to

concentrate, overly anxious, and lacking in self-esteem. If nature can play a restorative role, then potentially it can also enhance children's ability to learn.

Indeed, research indicates that contact with nature supports attentional functioning (Faber-Taylor, Kuo, & Sullivan, 2001; Kuo & Taylor, 2004; Wells, 2000) and can enhance human effectiveness and make life's demands seem manageable (Kuo, 2001). A study focusing on children with attention deficit disorder (ADD) examined the relationship between children's exposure to nature through leisure activities and their attentional functioning (Faber-Taylor et al., 2001). Parents were surveyed regarding their child's attentional functioning after activities in several settings. Results indicate that children with ADD function better than usual after activities in green settings. Further, the "greener" a child's play area, the less severe his or her attention deficit symptoms tend to be. Thus, contact with nature may benefit a population of children who desperately need attentional support.

Other studies also point to the ways that green outdoor settings support mental health of children. A recent American study demonstrated that green school grounds were seen as "havens" for children that allowed them to escape stress, focus, and build competence (Chawla et al., 2014). Another American study also lends support to the relationship between green outdoor settings and mental health of children by specifically exploring how natural environments promote self-determination (Kochanowski & Carr, 2014). The authors found that play in more-than-human natural environments encouraged children to demonstrate choice making, problem-solving, self-regulation, and engagement.

Finally, on green outdoor settings, participation in gardening and greening activities has tangible results, creating opportunities for students to feel good about their accomplishments and to gain a sense of pride, responsibility, and self-confidence (Dyment, 2005; Maller, 2005; Moore & Wong, 1997). The broader body of horticultural therapy literature supports this contention and identifies a number of health benefits for children from working with plants. These include improved interpersonal relationships, constructive channelling of energy, heightened sense of productivity, improved self-esteem, and an improved disposition for learning (Pentz & Strauss, 1998; Relf, 1998).

Childhoodnature and Spiritual Health

Although spiritual health is recognized within the health-promoting settings movement, it is not easily defined or discussed. For our purposes here, we turn to a recent conceptualization of spiritual health offered by Schein (2014) who defines spiritual wellbeing/health for children as:

> A system of children's deep connections leading first to self-awareness, and later to the nurturing of basic and complex dispositions ignited by moments of wonderment, awe, joy, and inner peace that develops into the prosocial personality traits of caring, kindness, empathy, and reverence. The system requires love and attachment. . . (p. 78)

In light of this definition, it makes sense to consider how healthy green childhoodnature settings can foster wonder, awe, and joy which in turn might generate caring, kind, and empathetic traits in children. To begin, a common purpose of green outdoor settings is to create a place for other more-than-human life where children will have regular, ongoing opportunities for interaction with plants and animals and for understanding and experiencing themselves as interconnected with the whole (Bell, 2001; Cheskey, 2001b). As they listen or watch for birds, follow animal tracks, or explore for caterpillars or ladybugs, children can become attuned to the comings and goings of other beings and to their purposeful existence. As children are provided regular (possibly even daily) opportunities to encounter in these spaces, there is opportunity for powerful decentering of the taken for granted human voice and a re-centering of more-than-human voices (Blenkinsop et al., in press).

As they plant seeds, fill bird feeders, or mulch trees, children assume a nurturing role and develop a sense of relationship and intimacy with a living world in which they can actively participate (Bell, 2001; Pivnick, 2001). Gardening in particular can provide an opportunity to deal with losses and failures and to experience the responsiveness of plants to care and nurturing. As Charles Lewis (1992) explains: "from a human perspective, the strength of gardening lies in nurturing. Caring for another living entity is a basic quality of being human" (p. 58).

The Toronto study cited above indicates that these potential benefits are being widely realized on green outdoor settings. Questionnaire respondents indicated that students were more likely to explore widely (90%), to learn about their local environment (91%), and to have a greater sense of wonder and curiosity (92%) after their school ground had been greened. Over 90% of respondents also indicated that student environmental awareness and stewardship had increased on the green school ground.

As environmental awareness increases, there is reason to believe that children's sense of hope and commitment to their local environment and to the living world around them is also enhanced (of course it could be also argued that stewardship might serve to promote the nature-culture binary which has been critiqued through a posthumanist perspective in this Chapter). Through hands-on involvement with the human and natural communities of which they are a part, children learn that barren patches of pavement and manicured grass can be successfully transformed into diverse and welcoming places that better respond to their own needs as well as those of other living beings. Depending on their level of involvement in the greening project, they can also learn that they have a right to participate in decisions that affect their quality of life (Dyment, 2004; Hart, 1997). Research shows that children, when given the opportunity, are able to critically evaluate their play spaces, identify alternatives, and evaluate the outcomes (Hart, 1997; Jensen, 2002). When fully involved in the greening process, children can acquire skills related to democracy, participation, and citizenship that they can potentially carry forward into adulthood (Dyment, 2004; Hart, 1997).

Ultimately, green outdoor settings can help to nurture a deeper sense of purpose and meaning. As Robin Moore (1999) contends, gardening, working, and playing

with plants allow children to "participate in the processes of life" (p. 326) and to foster a sense of identity and belonging. Through personal, ongoing, and caring engagement, they can develop a stronger sense of place attachment, a benefit described in the horticultural therapy literature and associated with public involvement, altruistic behaviors, stress reduction, reduced crime, and a sense of coherence and health (Hill & Vigo, 1992).

Childhoodnature Healthy Settings Case Study: The Waterford Landcare Program

Introduction to Case Study

In this section of the Chapter, we apply some of the highlighted theoretical aspects to a specific case study as a way of illustrating how green childhoodnature settings can be seen as health promoting settings. We do this by drawing on Australian-based empirical research that investigated the impact of school ground pedagogies on children's health and the health of the ecosystem. Central to the research were emergent findings that stressed the benefits of children's health and wellbeing through active participation in school ground and community-based projects. Another central finding was the interrelationship between the ecosystem health and the health of the children. Many of the projects involved children working to make the local ecosystem healthier, more vibrant, and more functioning. This occurs as the children help in designing and maintaining gardens, working in conservation- and art-based projects alongside community people as part of everyday learning in everyday places. One of the key features of the case study is the way in which the school's physical spaces and its wider community are understood, utilized, and valued for children's health, learning, and relationship with/to/as nature.

Background Context to Case Study

Waterford school (not its real name) is located on the banks of the D'Entrecasteaux Channel, which is a major coastal waterway between the Tasmanian mainland and Bruny Island in southern Tasmania, approximately one hour's drive from the capital city of Hobart. Historically an old working farm, the school is set on 10-hectares and has a unique school ground ecology that features a wetland, tree woodlot, local foreshore, grasslands, and small food gardens (Fig. 5). The sites are pedagogically integral to a whole-school Landcare (The term "Landcare" refers to place-based ecological activities including tree planting, organic food gardening, recycling, and waste and biodiversity projects) curriculum that encompasses site-specific projects across the school population.

The Landcare curriculum was developed over a decade ago by a motivated environmental education teacher. Its key aim was to promote children's participation in nearby everyday places through engaging with local knowledge, history, heritage,

Fig. 5 A classroom without walls: promoting children's health and well-being

geography, and ecology via the framework of education for sustainability. Student immersion in the coastal school ground was informed by the teacher's belief that children's interactions with local ecologies have significant social and emotional value, anchoring them in place and revealing much about themselves and the world they inhabit. In Landcare learning, children's capacity to comprehend and connect with landscape ecologies, including the systemic and cyclical patterns, coastal waters and marine life, vegetation and fauna, soil, and the numerous other more-than-human life forms and the ongoing exchanges with those life forms, is highly prioritized, as evidenced by the Landcare teacher:

> I think it's really important for kids to know where they live and there's such a rich resource in outside the classroom, outside the school. . .[it] is often neglected. . .it's important to really foster that sense of wonder about their place. . .to get to know it, identify with it, be the expert and caretaker of that patch, and develop an awareness of the changes that occur in that place.

In what follows, children and teacher testimonials accentuate the four pillars of health – physical, social, mental, and spiritual – that are enacted, supported, and advanced within the Landcare program as part of a whole-school approach to student wellbeing.

Physical Health

Waterford's place-based Landcare program is undertaken across the broader school ground landscape and utilizes diverse features appropriate to students' interests and capabilities. As with most schools, the central grounds constitute a combination of conventional hard surfaces, netball and basketball courts, manufactured playing equipment, and sandpits, which are complemented with accessible and modest native gardens and food gardens. Beyond the main school, the grounds expand outward to encompass a football oval, a wetland with surrounding fields of native

Fig. 6 Embodied learning in a coastal classroom

grasslands, an extensive chicken shed, arboretum, and a capacious coastal foreshore, as highlighted in Fig. 6. While the younger students (ages 5 and 6 years) care for little gardens closer to classroom buildings, the older students venture to more out-of-the-way sites where they plant trees, make compost, collect native seed from the arboretum to raise seedlings, and build and maintain more expansive food gardens. At the commencement of each Landcare class, students meet at the garden shed to partake in customary rituals that support their transition from indoor work to embodied practical outdoor learning. After putting on gum boots and gloves and selecting the required tools – secateurs, shovels, wheelbarrows, and watering cans – they head off to their allocated projects.

For the younger students, this includes maintaining a newly finished native garden designed to attract local fauna. While weeding around the plastic tree guards, one young student tells us:

> In this garden, we run around in the bushes and we do a lot of dodging things. Sometimes we have hide and seek. I like playing in there too [points to a tree that has open branches where a cubby hole has been made]. This hakea bush [a small endemic plant with spiked leaves] is just about special to everyone because it's spiky and gives protection to birds. And it also gives some good material for making stuff, and the plants next door to it sometimes have nutritious flowers for the birds, so it's a double thing really, they get protection and food. (Sam, 9 years old)

Established as part of the students' Landcare lessons, the garden is now an everyday site where children run and play, exchange materials for building cubbies, and observe the comings and goings of the more-than-human world. The physical construction and inhabitation of this particular site is a good example of how students physically occupy the space through structured teaching and learning, open-ended, self-directed, and spontaneous play.

Similarly, in their wetland work, older students dedicate several Landcare lessons to maintaining the health of the site – clearing weeds, digging trenches, and planting

grasses – as a way of improving effective wetland functionality, such as filtering inland water runoff that will eventually find its way (unhindered) to the foreshore. Students show their understanding of the renewed ecosystem health that has emerged, in part, as a result of their efforts:

> I reckon the wetland has changed a lot. It used to have weeds growing up twice as high as it is now. When we came here it was covered in combungi [invasive weed], it was everywhere. Over there we found it was leaking water into the dam making it worse. There was a giant puddle so we ended up digging a big trench all the way to the dam to fill it up. Otherwise the combungi was just growing, thriving. (Aden, 11 years old)

> The wetland helps the other plants to grow and lets the water flow through. We've been pulling out the combungi weed, it drinks up all of the water. We get our chopper things [machete] and we cut the tops off. We have to make sure we have to get the seeds off and we pull the weeds out. It is so much fun doing it as a class. It gets all muddy and you have to be quick on it, so you go like this [chopping motion] and then you start sinking [in the mud]. And once someone sunk right into it so they had to get Pete and Gary [the grounds men] to pull them out. (Alex, 11 years old)

We view the physical and embodied nature of the Landcare work cited above as multidimensional and worthy of examination. Firstly, the lessons afford an important opportunity to advance children's physicality – digging, planting, mulching, cutting, making gardens, harvesting and cooking food, etc., which ultimately contributes to their own physical health and wellbeing. Secondly, their physical work has a direct bearing on renewing the health of the physical school ecosystem. In this sense, children view their work as instrumental in maintaining the ecological integrity and health of their coastal landscape, which ultimately supports their physical health. Through these various physical acts of sustainability, children are able to pay attention to how they and the place itself are changed and shaped as a consequence of their physical work.

Social Health

The Landcare program provides a number of social health benefits, which can be observed through the utilization of distinctive outdoor learning environments to meet the diverse needs and interests of students. As a school facing considerable socioeconomic and educational challenges, the Landcare initiative supports many students who have spent much of their schooling life alienated by an academically privileged curriculum. The origins of the program, which stem from the environmental teachers' initial outings with small groups of disconnected students, transpired through reengaging them in socially oriented school ground planting activities. In discovering the social benefits of students working together in shared projects as genuine learners and leaders, the program was expanded across the school community through several sustainability-based projects.

At the time of conducting research at the school, the Landcare program was identified by the school principal as a contributing factor in school culture renewal:

> This is a local place and community where there isn't a huge amount of money; our students feel that they're second best. I heard the term 'bush pig' for the first time when I first worked here. The students had this feeling that maybe other schools are better or other parents care about their kids more, so they might send them to other schools. So, there's a feeling of inferiority and cringe amongst the kids that we actually needed to turn around.

One of Landcare's key innovations is inviting community into the school, which has triggered ensuing partnerships with the wider community: farmers, beekeepers, gardeners, flower growers, composters, ornithologists, local artists, and orchardists who bring substantial levels of knowledge and expertise into the school. Known as community-based curriculum, the approach underpins the development of intergenerational relations and communication between community members/elders and organizations and the school community. According to the Landcare teacher:

> This community is a unique community in that it's a beautiful coastal environment, but there's still a traditional sort of community that is part of the old farming ways. Then you've got the enterprising people. I guess it harks back to that sense of who we are as a community and for kids to understand who we are as a community. Kids can work one on one working with these community people who are really passionate about what they do. That's the really important thing about the community, whoever they are . . .we need different people with different views of the world. This is what education should be about.

Similar notions of community are exemplified in the art-based *Flotsam and Jetsam* (Fig. 7) exhibition along the 1 km foreshore-walking trail below the school grounds, involving local artists and other nearby schools. Installations made from miscellaneous objects and materials collected from the foreshore represent diverse interpretations of coastal relations, connections, and inhabitation. Unlike traditional educational approaches that contain teaching and learning within school boundaries (and classrooms), often with one teacher, and which tend to separate schools from the broader community, community-based pedagogies offer important social opportunities that connect students with their community through new relationships and shared engagement.

Fig. 7 Local artists work with school children to create the art-based Flotsam and Jetsam exhibition that features along the foreshore-walking trail

Mental Health

Building on its capacity to support children's social health, the Landcare program characterizes how children's mental health, including resilience, sense of identity, and belonging, is cultivated. A key aim of the program is to encourage children's ecological stewardship or, in other words, a sense of care and empathy for the more-than-human world that includes plants and animals. This also extends to care and empathy to other human beings. One such example is the entrepreneurial chicken project involving a group of older boys challenged by conventional classroom-based learning. Once assigned to the project (focusing on raising chickens and selling eggs), the teacher allocated each of the boys' leadership roles and tasks that provided genuine responsibility, engagement, and outcomes. As the leader of the project described:

> We've got a lot of responsibility here. When I first took over the chickens you would walk outside your class and you'd see a chicken run past, they were everywhere around the school. Me and my team ended up rounding them up, putting them back in their pen and fixing up all the holes in there. And my work has finally come through and we have two, three new baby chickens. He [chicken farmer mentor] talked about how to get rid of mites and black mites which is in their feathers. He said we should have some railing up for roosting that we built in the afternoon. . . we had to paint their legs with used cooking oil and ash to stop mites. Now they can walk easier because the leg mites stopped them from walking. Did you know the mites bury their heads into the chickens and suck their blood? My chickens at home have never looked better. I treat them with the best respect. (George, 12 years old)

George's description of his work with a local chicken farmer highlights the new skills and knowledge acquired from the group about managing the animals with care and respect. The project exemplifies how the boys' sense of identity and self-esteem has shifted. According to their teacher, "They feel proud about what they've done, and they get an opportunity to talk about what they've done." Her observations align with those of the principal who voices a broader perspective of the program:

> The overall strength of the program is its ability to generate success by connecting kids to their place and to their community, so that they now feel really proud of the place that they live in. There's a sense of pride from the whole community so it's not just a school thing. The community has taken it on. And the strength of this program is that it connects kids to their place, to their community. It generates success. And that success is really positive. We're actually setting kids up to have skills and to have values that are going to help them make choices later on in life. (School principal)

As the program develops and gains statewide and national recognition, children conduct student-led tours throughout the school ground property, showcasing diverse sustainability and ecology projects that position children at the forefront of action-based learning. Asking one of the older students to explain the rationale behind the high levels of interest in the program, the student responded:

> I guess they're kind of interested to see what children can do when they put their minds to something. . .what we have done over the last maybe five years is to help this beautiful place become what it is today. We've had lots of schools coming to try and do what we've been

> doing here. So, we've actually influenced others to help the environment and that's such a brilliant feeling. (Catrina, 12 years old)

The student-led tours provide an important opportunity for children to confidently showcase their Landscape work. Additionally, the tours reveal children's sense of purpose in their learning (from a desire to act based on something that matters), deep layers of knowledge, and their intrinsic motivation to defend and preserve an ecological landscape. As participants in a "Landcare" tour, we observed overarching notions of identity, dedication, stewardship, attachment to place, and sense of pride in children's communication.

Spiritual Health

Despite being an often-overlooked dimension of western education, spiritual health or spiritual development is a fundamental element of the Landcare program, which is promoted through children's sense of wonder and connection to the human and more-than-human world. Predominantly, spiritual health is fostered through children's encounters with the living systems and via their emergent interactions with ecological life forms and forces that make up the school grounds – the soil, trees, birds, platypus, the foreshore, gardens, ladybugs, and the weather, all of which are linked to broader ecological themes such as biological diversity, interdependence, food webs and ecological communities, and connectivity.

While children instinctively pursue these exchanges with and without the permission of adults, their immersion in the wonderment and awe of coastal ecologies is also fostered by an explicit pedagogy of care that is relayed and modelled by their environmental teacher, who encourages their alertness to and respect for the wonderment of all life forms.

> My philosophy is to encourage kids to develop a sense of place in the sense of understanding of where we live, where they live and to get to know their place and first to get to know it and understand the sense of wonder about their place. It's not so much about the end product but more about the processes that allow the students to care. It's that development of nurturing and caring for the planet, for our environment and for our place because that develops ownership. Eventually [the children] feel really proud of the place that they live in.

Coming to know a place by simply being in it is encouraged by the teacher, who, at the end of each lesson, invites children to find a "magic spot" and sit contemplatively for a few minutes to pay attention to the "specialness" of their place. As evidenced by the photo below (Fig. 8), these places are often well-known to children and hold particular meaning and purpose. This spiritual perspective of learning was typified when children showed us their favorite school ground sites: trees and bushes, food gardens, a refurbished wetland, a newly built chicken shed, and a foreshore with newly planted grasses. For the children, these are places of purpose, empowerment, inhabitation, connection, and ownership which they intimately embody through everyday interactions.

Fig. 8 Fostering spiritual health through connections with special places

Case Study Conclusion

The Waterford case study represents an important and far-reaching snapshot of how the various aspects of health – physical, social, mental, and spiritual – are constituted through its Landcare program. More than just an environmental initiative, Landcare pedagogies and curriculum have been instrumental in reshaping and expanding the capacity of the school community, equipping it to better support the health and well-being of the local ecosystem, which in turn supports the health and wellbeing of students, teachers, families, and community. Through building partnerships and creating sustainable change through participation, empowerment, and ownership of change throughout the school setting (Whitelaw et al., 2001), the program's evolution can be understood as a major catalyst for cultural, social, and environmental awakening within the wider school community.

Conclusion

In this Chapter, we have profiled how healthy everyday, local, nearby childhoodnature settings, such as school grounds, backyards, and community grounds, serve to promote health across a range of dimensions. In doing so, these spaces stand to be an important part of the "settings approach" to health promotion. We have also showcased, from a posthumanist perspective, how these critical childhoodnature settings help children understand their relationship to and with the more-than-human world.

As academics, we find the theoretical evidence base across the four dimensions of health areas to be comprehensive, convincing, and compelling. In our role as researchers who have studied the impacts of greening initiatives in Australia (Monica and Janet) and Canada (Janet), our research endeavors and associated

findings lend strong support to the ideas presented in this Chapter. Equally important, in our role as teacher educators and practitioners, we have worked with and alongside children, teachers, and community members (such as those profiled in the case study) to create healthier vibrant and functioning ecosystems. Our personal experiences add further credence to the contention that healthy everyday, local, nearby childhoodnature settings have an important role to play in promoting children's physical, social, mental, and spiritual health. Overwhelmingly, in all of our roles as academics, researchers, teacher educators, and practitioners, we witness these settings as valuable contexts for cultivating children's sense of dwelling and belonging. One of the many ways to develop this sense of interconnectedness is through proactive processes that invite children to inhabit their local places through embodied and experiential opportunities. Taken to the next level, these experiences support and encourage children's ecological, personal, and social understandings of the world, and provide a gateway into their comprehension of, and commitment to, the places that sustain ongoing human and ecosystem health and wellbeing.

Abstract

As we enter the Anthropocene, it is apparent that Earth has been severely impacted by human activities and the very systems that sustain life are challenged (Crutzen, 2002; Zalasiewicz et al., 2010). There is a call for increased awareness and action relating to degraded ecological systems particularly in the approach to the education of children and young people. Science curricula often promote anthropocentric/technocentric attitudes toward the environment. In fact STEM

(science, technology, engineering, and mathematics) education in Minority western such as Australia and the United States is seen to be driven by neoliberal values where government economic agendas cultivate individualistic and competitive behaviors (Carter, 2016, p 33). With this neoliberal "technical growthist" perspective predominating in science and STEM education (Smith & Watson, 2016, p 5), how can deep respect and understanding of the Earth's systems be fostered within education? There have been calls for decades to shift thinking in science education from looking at components of the Earth's environment separately, such as looking at humans as being apart from nature, to, instead, looking at the components "within the context of the whole" (Capra, 2007). The systems concept can be difficult to grasp, but the emphasis is always on the "wholeness" and the "harmonious integration of the various components" (Orr, 2014). In an ecological systems approach, humans are just one of numerous, interdependent, and diverse life-forms in an ecological system, and there is no separation of childhood and nature, as they are one. Such an alternative view has an impact on how science education is manifested. This chapter challenges an anthropocentric (or technocentric) approach to science curricula. Research into approaches in science and STEM education that are ecologically sustainable and holistic in nature and incorporate relevant socio-scientific issues is explored. A science education that offers young people knowledge, values, and firsthand experiences of ecological systems in their everyday lives and the incorporation of intercultural approaches to science education are promoted. Ecoliteracy, ecological literacy, and ecological thinking are examined in a science education context. Elements of the more recent posthumanist theoretical approach underpin this chapter; an ecological systems approach is adopted in contrast to Bronfenbrenner's socioecological theory.

Introduction

It is now evident that we have entered the Anthropocene, an era where humans have severely impacted the Earth, and as a consequence the very systems that sustain life are challenged (Crutzen, 2002; Zalasiewicz, Williams, Steffen, & Crutzen, 2010). In 1992 David Orr warned that "we have a decade or two in which we must make unprecedented changes in the way we relate to each other and to nature" (p. 3) to ensure life as we know it exists into the next century. As we now progress through the twenty-first century, there is clear evidence of the climate changing such as 2016 being the hottest year on record (Steffen, Hughes, Alexander, & Rice, 2017), marine temperatures rising leading to coral bleaching; sea levels rising, recent extreme flooding events, and intense forest fires (Steffen et al., 2017). However, despite these clear signs of a changing climate, many politicians and others are questioning the reality of human-induced climate change while they continue to view the Earth as

a resource to be consumed. This way of thinking fails to see the interrelationship of human actions and the Earth's ability to sustain life (Capra & Luisi, 2014); the realization that we depend on all other living things is lost (Lovelock, 2000). It is becoming more apparent that people need to understand how the Earth's systems maintain themselves and how human actions impact these systems. Unfortunately, science and technology have been, and continue to be, central to the human quest to conquer nature (Orr, 1992); however, science and STEM (science, technology, engineering, and mathematics) education have the potential to introduce a change in thinking toward an ecological systems approach. Scholars have long argued that in order to move toward environmental literacy, particularly an understanding of human impact on the Earth's systems, young people need to understand the scientific concepts that underpin the Earth's natural processes. Ecological systems thinking can assist young people to move toward a more sophisticated understanding of the Earth's natural processes particularly in real-world contexts (Assaraf & Orion, 2005; Sterling, 2003). With an emphasis on an ecological systems approach in science and STEM education, practices such as water conservation, energy efficiency, and sustainable waste management can be introduced in a holistic context rather than in isolation. An example of a holistic approach is where young people learn about the Earth as a dynamic system with natural cycles where water use and pollution impact waterways and groundwater (Assaraf & Orion, 2005; Batzri, Assaraf, Cohen, & Orion, 2015) and greenhouse gas emissions impact ecological systems. This Chapter challenges the anthropocentric approach to science education, where humans are perceived to be separate from other living things and where environmental conservation practices are for the benefit of humans. Instead a more holistic ecological systems approach to science education is promoted within a posthumanist framework. Traditional socioecological systems theory fails to promote holistic systems thinking relating to the interrelationship of humans and nonhuman others. The socioecological systems and the posthumanist theoretical underpinnings of this Chapter are elaborated on further in the following section.

Socioecological Systems Approach and Posthumanism

Urie Bronfenbrenner's socioecological systems theory, first developed in 1979, dominates systems thinking applied to human systems and has been foundational in education, particularly early childhood education. Bronfenbrenner's model includes four, and subsequently five, nested interconnected systems relating to external influences on the growth and development of the child over a lifetime (1994). The innermost system of the model is the microsystem which includes the child's immediate relationships, such as family, friends, and school systems. The meso- and exosystems surrounding the microsystem include factors that might influence a child such as the relationships between the school and the family or relationship between family members and their workplace. The child may or may not enter these systems, but these systems may impact the development of the child. The outer

system is the macrosystem, which includes cultural or policy factors that influence the development of the child (Bronfenbrenner, 1974). Later Bronfenbrenner introduced the chronosystem which relates to changes in the person's life or social environment, including changes in family structure or marked changes in society that might influence the person's development (Bronfenbrenner, 1994).

Bronfenbrenner's socioecological systems theory however, is not aligned with ecological systems thinking, as it is human centered and in fact silences the essential connection of the child with natural ecological systems. This Chapter takes an ecological systems approach which differs from socioecological theory, as the ecological systems approach taken here is underpinned by a posthumanist lens. It is important to move away from the human as central in our world in order to fully understand an ecological systems approach. The posthumanist approach decenters humans as being "the measure of all things" and shifts thinking to humans as just one organism in relation to all other organisms and other elements, therefore reversing the traditional view of being human (Braidotti, 2013, p. 1). Malone (2018), taking a posthuman/new materialist approach, describes the relationship between the human and more than human world as "existing in an ecological collective of messy entanglement" (p. 19). This describes a world where humans, other organisms, rocks, air, and water interrelate. It does not make sense to consider young people as somehow being separated or disconnected from nature as young people are part of nature. We cannot separate ourselves from the air that we breathe. In fact, the human body itself is populated by a multitude of organisms that are essential to living a healthy life, such as bacteria and other microorganisms, and these organisms are part of who we are (Malone, 2018). The wastes and contaminants that are the products of industry and the human lifestyle, such as plastics, heavy metals, and radioactive waste, become part of nature, and that means they enter the human body as we are nature. The human body is part of and entangled with systems and networks of a multitude of natural organisms and elements, and when we pollute nature we pollute ourselves (Malone, 2018).

To be aware of our place in nature is central to the concept of childhoodnature, where young people gain understanding of how and why humans are an integral part of nature, as are all other living and nonliving elements in the Earth's systems. In education it is important to embrace this holistic systems approach toward nature where there is no separation between humans and other (Capra & Luisi, 2014). This holistic approach is in contrast with the anthropocentric view that predominates much of traditional science education, a view where humans are separated from the untamed, wild, natural world (Rodriguez, 2016) and the dimensions of the world are compartmentalized into biological, chemical, physical, and geological (Gough, 2011). This traditional view attempts to separate young people from nature, but that is not the reality as children are part of nature.

The following section elaborates on the holistic nature of ecological systems that promotes the interconnection of biological and physical systems and highlights the key ideas behind ecological systems thinking that frame this Chapter. This section explores systems thinking generally, with an outline of the Gaia theory of the Earth as a dynamic system and consideration of the terms "ecology" and "ecosystems."

Systems Thinking

The term "system" is broad and can relate to natural systems, social systems, or technological systems (Assaraf & Orion, 2005). Systems thinking is not new; it emerged in Europe in the 1920s, in a number of fields, but largely in the area of biological sciences (Capra & Luisi, 2014). Systems thinking more recently is commonly used in relation to organizational change, particularly in business (Sterling, 2003).

Systems thinking is a way of looking at the unified whole rather than its parts in isolation. Sterling (2003) states that systems thinking is:

> Relational rather than non-relational; systemic and connective rather than linear and fragmentary; concerned more with process rather than substance, with complex dynamics rather than limited cause-effect, with pattern rather than detail, with wholes rather than parts. (p. 102)

Therefore "relationships, connectedness, and context" are at the forefront of systems thinking (Capra, 2007, p. 12).

Assaraf and Orion (2005) describe a system as a unit that continues to exist and operate as a whole through the interrelationship of its elements. Each element needs to have a particular role, and all elements need to be present so that the system can carry out its function. Capra's (2007) description illustrates the complexity of living systems:

> When we walk out into nature, living systems are what we see. First, every living organism, from the smallest bacterium to all the varieties of plants and animals (including humans), is a living system. Next, the parts of living systems are themselves living systems. A leaf is a living system. Every cell in our bodies is a living system. Finally, communities of organisms, including both ecosystems and human social systems such as families, schools, and other human communities, are living systems. (Capra, 2007, p. 11)

To think in terms of systems means understanding and interpreting these complex systems (Evagorou, Korfiatis, Nicolaou, & Constantinou, 2009, p. 655).

Systems theorists emphasize that in systems thinking "the whole is more than the sum of its parts" (Capra & Luisi, 2014, p. 64) as the properties that define the system as a whole are different to the properties of the individual elements in the system (Assaraf & Orion, 2005). Therefore if systems are pulled apart and analyzed separately, some of these properties are destroyed (Capra & Luisi, 2014). By reducing a system to its parts in isolation gives an incomplete and sometimes inaccurate picture. Thus systems thinking requires "contextual thinking" within the context "of the larger whole" and is the opposite of "analytical thinking," where something is pulled apart in order to understand it (Capra & Luisi, p. 66). An example of the importance of interactions and/or processes as essential elements of systems is feedback processes. Feedback loops occur in systems, where each element impacts on the next and eventually the last element feeds back to the first. With such feedback loops, the

whole system is regulated and the first element in the system, "input," is impacted by the last element in the system, "output" (Capra & Luisi, p. 89). Norbert Wiener in 1932, alluding to the theory of "cybernetics," describes how in a natural system the feedback is part of "homeostasis" that enables the system to regulate itself and maintain a balance (as cited in Capra & Luisi, p. 91). Without systems thinking such important processes may be ignored in deconstructive, component-based approaches.

Some examples of feedback loops occur in Australian sclerophyll forests after fire disturbance (Sclerophyll: refers to trees and shrubs with hard, stiff (sclerophyllous) leaves. Sclerophyll forests are prevalent in Australia with dominant species such as *Eucalyptus, Acacia*, *and Casuarina* (Harden, McDonald, & Williams, 2006).). Many Australian *Eucalyptus* trees have dormant epicormic buds that are protected from the fire under the bark, but with the heat of the fire disturbance, they are stimulated to grow. This fire-regulated system promotes the growth of leaves and branches and enables the trees to survive and regrow after fires. The Australian sclerophyllous communities also have other regulation mechanisms for fire disturbances such as the woody seed pods of some *Eucalyptus* and *Banksia* species that open and release seeds following the heat of a fire. The release of seeds and the heat and/or smoke of the fire often results in the prolific germination of seedlings that grow up to restore the forest system. Fires are an integral part of much of the sclerophyllous Australian landscape and play an important role in the regulation of the system to keep it healthy and in balance. However rising temperatures associated with climate change are resulting in changes to the frequency and intensity of fires, so these sclerophyllous ecological systems are challenged and threatened (Steffen et al., 2017). If the fires are too intense or more frequent than the plants' regrowth feedback system can cope with, the trees do not survive, and this impacts the whole ecological system that is based on the resources and habitat the trees provide.

It is important to look further at the terms, "ecology" and "ecosystem," as these terms underpin the ecological systems thinking underpinning this chapter. Ecology was coined by Ernst Haeckel in the nineteenth century, and he defined the term as "the science of relationships between the organism and the surrounding outer world" (Haeckel, 1866 as cited in Capra & Luisi, 2014, p. 66). The term "ecosystem" was created by A. G. Tansley (1871–1955) and was originally positioned in relation to animals and plants. However, the more recent interpretation of ecosystem is "a community of organisms and their physical environment interacting as an ecological unit" which has shaped recent ecological thinking and promotes an ecological systems approach (Capra & Luisi, 2014, p. 67). The Gaia theory of the Earth, proposed by James Lovelock in the 1960s, built on the ecology concept to encompass the whole Earth as a dynamic, self-regulating system, and originally the emphasis of this theory was on living organisms. Lovelock revised the Gaia theory and moved away from the emphasis on the living organisms alone, to emphasize the interrelationship between the living and the nonliving. In this model the entire surface of the Earth, the living biosphere, is a "self-regulating entity," and this

includes the oceans, rocks, and air (Lovelock, 2000, p. 76). Lovelock's revised definition of Gaia is:

> A complex entity involving the Earth's biosphere, atmosphere, oceans, and soil; the totality constituting a feedback or cybernetic system which seeks an optimal physical and chemical environment for life on this planet. The maintenance of relatively constant conditions by active control may be conveniently described by the term 'homoeostasis.' (Lovelock, 2000, p. 424)

Within this dynamic Earth system are networks of systems interacting with other systems. A wetland ecosystem could illustrate this interconnection. The interaction of geological, atmospheric, biological, and hydrological systems, on a micro (local), meso (regional), and macro (continental) level, over time resulted in the formation of the wetland system. These interactions of systems continue to maintain the wetland system. Each organism in the wetland ecosystem is itself a system composed of subsystems. The network of interacting organisms within the ecosystem, such as plants, animals, and other microorganisms, is interdependent for food, oxygen, and habitat. The waste from one organism in the ecosystem is food for another (Capra, 2007). Any disturbance in one component of the system, such as prolonged drought or diversion of water for farming purposes, might cause a chain reaction within the wetland system and interrelating systems. It is important for young people to explore the interconnection of micro-, meso-, and macro-systems relating to the transfer of energy and matter between the systems rather than looking at micro-systems in isolation (Assaraf & Orion, 2005). In this chapter the term the "Earth's systems" refers to the Earth's ecological systems encompassing macro-, meso-, and microsystems.

Sterling (2003) argues that systems thinking requires a "change of consciousness. . .to some degree" (p. 103), and in some parts of society in the late twentieth and early twenty-first centuries, moves toward more ecological systems thinking were taken up (Sterling, 2003). The Gaian principles of the Earth as a self-regulating system are behind "Earth system science or geophysiology" (Lovelock, 2000, p. 146). However, despite ecology being part of the curriculum in many countries, the paradigm predominantly in school science teaching and learning appears to be "analytical thinking," where science is segregated into separate disciplines which are analyzed in isolation (Jacobson & Wilensky, 2006; Gough, 2011). In this compartmentalized model of science education, it is assumed that young people make connections and understand the interrelationships between the different components, such as the connection between geology and living organisms, but often they fail to see the connection (Evagorou et al., 2009). Mathematics, technology, and engineering skills fit well within a systems approach. By integrating the disciplines of science, technology, engineering, and mathematics within STEM education, science curricula could break out of the traditional compartmentalized model of science education. However, there are concerns from environmental educators relating to the drivers of STEM and how this impacts STEM education as discussed below.

STEM Education and Economic Growth

The acronym STEM has been used since the 1980s and originated within the American National Science Foundation (NSF) in the 1990s (Bybee, 2010, p. 30) although some anecdotal evidence suggests that the term was coined earlier in the 1980s (Carter, 2016). The term is predominantly used with a mathematics and science focus, and the technology and engineering aspects are often downplayed in education (Bybee, 2010). STEM education is being widely promoted internationally, and the value that is placed on STEM is echoed by the Australian Chief scientist, Alan Finkel: "Our best future is a future that builds on technology, innovation, ideas and imagination. It is a future with STEM. And it is a future that is ours to build" (Office of Chief Scientist [OCS], 2016, p. iii).

Some STEM programs have a strong sustainability and childhoodnature focus, where young people are encouraged to explore natural elements that drive ecological systems and how human actions impact the Earth's systems. For example, the STELR (Science and Technology Education Leveraging Relevance) project in Australia provides high-quality resources for young people in secondary school to investigate the impact of fossil fuels on the Earth's systems and explore energy transformation using alternative energy sources (Australian Academy of Technology and Engineering [ATSE], 2016). However, these environmental and sustainability issues do not necessarily gain sufficient attention within the STEM agenda, despite claims such as the following from Australia's Office of Chief Scientist in the position paper of 2013 (OCS, 2013, cited in Smith & Watson, 2016):

> Australia's STEM is respected for its contribution to international solutions to global challenges, especially in systems science where, for example, oceans, atmosphere, space and epidemiology are global responsibilities. (p. 23)

Instead economic prosperity is seen as central to STEM education, particularly by governments, and this is evident from a quote in an Australian report from the Office of the Chief Scientist: "the importance of STEM skills to the prosperity of economies is not only recognised by governments, but also by employers" (OCS, 2016, p. 4). The economic priority of STEM is also reflected in Coble and Allen's 2015 report looking at the US global competitiveness and the role of education:

> Improving mathematics and science education in the United States belongs near the top of the policymaking agenda. America's role as a leader in the world's economy and its capacity to produce wealth and quality jobs for its future citizens depend directly on the ability of our education system to produce students who can compete in the math- and science- dominated industries of the future. (cited in Carter, 2016, p. 35)

The economic growth and prosperity focus of STEM is seen by environmental educators as problematic, as it is recognized that rapid economic growth along with increased carbon emissions is impacting climate and degrading natural ecosystems (Thiele, 2016). Just looking at consumption alone, the goods that are

consumed, predominantly in minority countries, have components requiring resources extracted from often fragile ecosystems across the world. These components require energy for processing and transportation involving numerous countries, and the discarded waste that is produced in these processes impacts ecosystems far into the future (Thiele, 2016). Building on the idea of Volkmar Lauber, Orr (1992) states "growth makes the wealthy more so, but it also gives substantial power to government and corporate elites who manage the economy, its technology, and all of its side effects" (p. 86). Orr (1992) sees economic growth as having a fundamentally flawed ideology where "the faster a growing volume of materials flows from mines, wells, forests farms, and oceans through the economic pipeline into dumps and sinks the better" (p. 11). It is the emphasis on economic growth as central to STEM education with sustainability or reference to the Earth's systems being scarcely mentioned or tokenistic that has led to wide criticism of STEM education from environmental educators (Smith & Watson, 2016).

Economic systems are framed by capitalism and open markets. Thiele (2016) highlights the main factors that have led to the substantial economic growth in the postindustrial years as:

- Exploitation of resources (including human resources)
- Cheap energy sources (coal, oil, and gas being at the forefront)
- Development in technologies including mechanization, communication, transportation, and infrastructure
- Population growth resulting in demand for products and services

Building on Georgescu-Roegen's (1971) entropy law, Daly describes the impact of our growing economic systems as increasing "throughput," where ecosystems provide the input of low entropy raw materials and energy and outputs include high entropy waste (Daly, 1996, p. 33; Thiele, 2016). The entropic costs are "depletion and pollution" (Daly, 1996, p. 33). Put simply in systems language, throughput is the measure of energy and raw material flow, and waste, that enters and leaves the system (Thiele, 2016). Economic growth largely fixates on generating growth by increasing throughput, and this is clearly unsustainable with the Earth's finite resources and fragile ecosystems. The result is the impact on our "complex ecological life support services rendered to the economy by nature" (Daly, p. 33). Common sense would suggest that there should be limits to economic growth, but this is not predominantly the case. Cook in 1982 stated:

> The concept of limits to growth threatens vested interests and power structures; even worse it threatens value structures in which lives have been invested. (p. 198, cited in Daly, 1996, p. 35)

Despite numerous initiatives and actions by various governments, organizations, and citizens in the area of sustainability and protection of the Earth's systems, the sentiment described in Cook's quote appears to still dominate in the twenty-first

century. Neoliberalism, the political paradigm that has predominated internationally in the past six decades, particularly in the Minority west, has continued the "economic growth at all costs" sentiment. Carter (2016) described neoliberalism as:

> The deliberate intervention by government to encourage particular types of entrepreneurial, competitive and commercial behaviour in its citizens with the market as the regulatory mechanism. It is also the management of populations to cultivate individualistic, competitive, acquisitive and entrepreneurial behavior. (p. 33)

One of the principles of the Earth Charter Initiative (ECI), which is a universal expression of ethical principles, is to:

> Adopt patterns of production, consumption, and reproduction that safeguard Earth's regenerative capacities, human rights, and community well-being. (ECI, 2000, Principle 7)

Neoliberalism is at odds with this viewpoint, and with Ghandi's philosophical observation, "Earth provides enough to satisfy every man's need but not for every man's greed" (cited in Krishna, 2014, p. 156).

Carter believes that neoliberal thought has been "naturalized, normalized and ritualized" (2016, p. 34) to such an extent that this ideology is the only way we know and science itself is largely shaped by neoliberalism. Science organizations and scientific communities over the past two decades have shifted from an ideology of "advancement of knowledge" to the "creation of wealth" (Krishna, 2014, p. 142). Science, particularly STEM, has been associated with neoliberalism; Carter warns that this neoliberal agenda in science has intensified "to the exclusion of all else" (p. 34).

In order to see the significance of science education and, more recently, STEM education in the context of childhoodnature and sustainability, it is important to be aware of the history of the science education and environmental education relationship.

The Relationship of Science Education, Environmental Education, and Sustainability Education

There has long been tension between environmental educators and science educators. The term environmental education was used from the 1960s where it mainly focused on the study of nature or ecological/biological studies and at that time people generally looked to science to solve environmental problems. During the 1970s environmental education emerged in its own right (e.g., international conferences tracking the emergence of environmental education: United Nations at Stockholm, 1972; UNESCO (United Nations Educational, Scientific and Cultural Organization (UNESCO)) at Belgrade, 1975; UNESCO and UNEP (United Nations Education Program(UNEP)) at Tbilisi, 1997), and even at this early stage, some scientists

identified that science alone could not solve the emerging problems associated with the environmental degradation taking place on a global scale (Gough, 2011). As early as 1970 scientists looked to environmental educators to bring about environmental awareness in young people. At an Academy of Science Conference in Australia in 1970, Boyden emphasizes the urgency for education in schools to inform young people about the detrimental effect of human activities on the Earth's systems resulting in "social and biological problems" (as cited in Gough, 2011, p. 265), but this detrimental impact was related more to the impact for humans rather than for the Earth's systems. During the 1980s the term sustainable development came into use, and in the 1990s the term "environmental education" was frequently replaced with education for environment and sustainability or education for sustainable development. The term "sustainability" kept the environmentalists happy, and the term "development" kept the business community and "bankers" happy (Orr, 1992, p. 23).

The United Nations (UN) Brundtland Commission's, *Our Common Future*, report defines sustainable development in 1987 as:

> Development that meets the needs of the present without compromising the ability of future generations to meet their own needs. It contains within it two key concepts:
>
> - the concept of 'needs,' in particular the essential needs of the world's poor, to which overriding priority should be given; and
> - the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs. (World Commission on Environment and Development [WCED], Chapter 2, IV)

It is important to note the anthropocentric context of this definition of sustainable development, where the emphasis on human "needs" is in contrast to a holistic context where the Earth is a dynamic system and humans are one organism with needs in the system. In fact, the term "sustainability" can be quite problematic as it has numerous interpretations. David Orr (1992) coined the terms "technological sustainability" and "ecological sustainability." The technological sustainability viewpoint (also referred to as a technocentric or anthropocentric viewpoint) sees the Earth as a resource for human benefit, and technical and market solutions can be applied to solve any associated environmental or social problems (such as sophisticated nuclear technology or carbon sequestration to address the energy crisis) (Cutter-Mackenzie, 2011; Orr, 1992). With a "technological sustainability" mind-set, humans have dominion over nature and shape nature for their needs. A "technological sustainability" mind-set promotes economic growth as being essential for sustainable development, whereas "ecological sustainability" is a mind-set where the Earth's systems are valued, nature is a model, and ecological principles set the agenda (Cutter-Mackenzie, 2011; Orr, 1992). An ecological sustainability viewpoint sees human activity as upsetting the balance of the natural systems unless it fits within the "carrying capacity of the natural systems" as "ecological systems are the only systems capable of stability in a world governed by the laws of

thermodynamics" (Orr, 1992, p. 35). Linking back to the previous section on STEM education and economic growth, ecological sustainability is where throughput is kept in check – a mind-set that aligns with ecological systems thinking.

The change in the terminology from "environmental education" to "education for sustainability" or "education for sustainable development" is seen as problematic by some environmental educators, particularly due to the range of interpretations of sustainability. The Thessaloniki Declaration (UNESCO, 1997), which was a charter for education for sustainability, is seen by Knapp as the "beginning of the end of environmental education" (2000, p. 32). Knapp believes that the spirit of environmental education is being neutralized, and he urges environmental educators to defend the underlying intentions and goals for environmental education. These goals include fostering an awareness, sensitivity, and concern about the Earth and its human impacts and environmental education being a guide for people to live environmentally responsibly by reducing their impact on the Earth (Knapp, 2000). Some environmental educators support the change in terminology toward sustainability and sustainable development. Fien and Tilbury (1996) in their report "learning for a sustainable environment" believe sustainable development and sustainability concepts are underpinned by:

> The hope that the impact humans have on the earth and the way we organize the flows, production and distribution of resources and wastes can be mitigated in both the short and the long-term. The idea of sustainability asks governments, communities and individuals to consider the needs of future generations in what political scientists define as the essential questions of public policy. (1996, p. 9)

This statement by Fien and Tilbury, relating to the concepts of sustainability and sustainable development, highlights a "technological sustainability" perspective (or an anthropocentric viewpoint) where human needs are at the forefront. In contrast the environmental education goals outlined above by Knapp (2000) are more in line with "ecological sustainability" where ecological principles are at the forefront. The period from 2005 to 2014 was declared by UNESCO as the decade for education for sustainable development. However more recently the terms, environmental education, education for sustainable development, and education for sustainability, have been used interchangeably, particularly in Australia (Malone & Somerville, 2015). The term sustainability generally has been adopted widely by governments and in the case of Australia has been incorporated into the national curricula. Despite sustainability being a focus in the Australian Curriculum, actually incorporating sustainability elements into the classroom is problematic, as is demonstrated through the Australian example.

Curricula Incorporating Sustainability: The Australian Example

In Australia a new national curriculum was implemented in 2012, and sustainability was incorporated as a "cross curriculum priority" where it was intended to underpin all subject areas at all school levels (ACARA, 2017) (The Australian Curriculum has

three "cross curriculum priorities," sustainability, Aboriginal and Torres Strait Islander histories and cultures, and Asia and Australia's engagement with Asia (ACARA, 2017)). This priority was guided by the *Melbourne Declaration on Educational Goals for Young Australians,* established in 2008 by the education ministers from all states and territories, and has a strong environmental, economic, and social sustainability emphasis (MCEETYA, 2008, as cited in Gough, 2011). The sustainability cross curriculum priority's goals, which also reflect the "Our Common Future" document (WCED, 1987), include:

> Sustainable patterns of living meet the needs of the present without compromising the ability of future generations to meet their needs. Actions to improve sustainability are individual and collective endeavours shared across local and global communities. They necessitate a renewed and balanced approach to the way humans interact with each other and the environment. Education for sustainability develops the knowledge, skills, values and world views necessary for people to act in ways that contribute to more sustainable patterns of living. It enables individuals and communities to reflect on ways of interpreting and engaging with the world. (ACARA, 2017)

The Australian Curriculum, Assessment and Reporting Authority (ACARA) (2017) statement goes on to proclaim:

> Sustainability education is futures-oriented, focusing on protecting environments and creating a more ecologically and socially just world through informed action. Actions that support more sustainable patterns of living require consideration of environmental, social, cultural and economic systems and their interdependence.

At first glance the statement above appears to be a positive step in moving toward an education system that promotes ecological sensitivity and responsibility as well as informed action toward an ecologically sustainable future. This is particularly pertinent in the Australian context with its unique, fragile ecological systems and ongoing loss of biodiversity resulting from human impacts on the Earth's systems (Whitehouse, 2011). Ecological systems thinking underpins the first set of key concepts behind the sustainability curriculum priority:

- The biosphere is a dynamic system providing conditions that sustain life on Earth.
- All life-forms, including human life, are connected through ecosystems on which they depend for their wellbeing and survival.
- Sustainable patterns of living rely on the interdependence of healthy social, economic, and ecological systems. (ACARA, 2017).

Despite having this strong underpinning of environmental, social, and economic sustainability, the Australian Curriculum fails to translate to subject level. In the four main curriculum areas of mathematics, English, history, and science, there is only one mention of "sustainability" in an elaboration of the descriptors within the curriculum throughout all Foundation to Year 12 Level curriculum descriptions (Kennelly, Taylor, & Serow, 2011).

Some aspects of environmental sustainability are embedded into the science curriculum with reference icons to the sustainability cross curriculum priority (such as with the curriculum descriptors, "Energy from a variety of sources can be used to generate electricity"; and "The growth and survival of living things are affected by the physical conditions of their environment" (ACARA, 2017)). However, there are no explicit elaborations in the curriculum descriptions, and so when implementing science lessons, teachers are left to make the sustainability connection guided only by the presence of the icon that indicates the link. The curriculum largely falls short of its intention for Australian education to develop "the knowledge, skills, values and world views necessary for people to act in ways that contribute to more sustainable patterns of living" (ACARA, 2017) and is left to individual teachers or schools to enhance this mind-set in their teaching (Kennelly et al., 2011). An Australian national study into education for sustainability carried out by the Australian Education for Sustainability Alliance (AESA), looking at the preparedness of Australian teachers to integrate the sustainability curriculum priority into their lessons, revealed that 80% of practicing Australian teachers "don't comprehensively understand education for sustainability," 35.9% of teachers were unaware that sustainability was a cross curriculum priority, and less than 2% were effectively integrating education for sustainable practices into their classroom (AESA, 2014, pp. 89, 90). Furthermore, the Australian science curriculum is quite conservative in its traditional and analytical breakdown of the sciences to biological, earth, chemical, and physical sciences (Gough, 2011). This curriculum promotes a largely anthropocentric or technocentric position. This is evident in Rodriguez's (2016) review of science in the Australian Curriculum, where she revealed the separation of humans and other animals or living things and the absence of values of care for other animals. In this curriculum humans are placed as "managers and administrators of nature and other species" with the Earth as a resource for the benefit of humans (Rodriguez, 2016, p. 1018).

In contrast, David Orr (2012, p. 2) argues passionately for school curricula that trigger environmental change and transform communities, where the connection between "people, places, and nature" is evident. David Orr sees ecological literacy at the heart of building sustainable societies.

Ecological Literacy/Ecoliteracy

> The failure to develop ecological literacy is a sin of omission and of commission. Not only are we failing to teach the basics about the Earth, and how it works, but we are in fact teaching a large amount of stuff that is simply wrong. By failing to include ecological perspectives in any number of subjects, we are teaching students that ecology is unimportant to history, politics, economics, society, and so forth. From television they learn that the Earth is theirs for the taking. The result is a generation of ecological yahoos without a clue about

> why the color of the water in their rivers is related to their food supply, or why storms are becoming more severe as the climate is unbalanced. The same persons, as adults, will create businesses, vote, have families, and above all, consume. If they come to reflect on the discrepancy between the splendor of their private lives and the realities of life in a hotter, more toxic and violent world, as ecological illiterates they will have roughly the same success as one trying to balance a checkbook without knowing arithmetic. (Orr, 1992, pp. 83, 84)

In 1992 Orr uses the terms "environmental literacy" and "ecological literacy" interchangeably, redefining environmental literacy (originally coined by Roth in 1968) to emphasize the building of sustainable communities and to reform education (McBride, Brewer, Berkowitz, & Borrie, 2013). Orr sees the ecological crisis that the Earth is experiencing as being linked to education, and he believes that in order for citizens to become ecologically literate, there needs to be a change in the education system, particularly in the Minority west. He poses ecological literacy as underpinning the building of sustainable societies as this capability is based on an understanding of the interdependence and interrelationship of species within the Earth's systems (McBride et al., 2013). In 1997, building on Orr's work with ecological literacy, Capra conceived the term "ecoliteracy" which he defined as "an understanding of the principles of the organization of ecosystems and the application of those principles for creating sustainable human communities and societies" (McBride et al., 2013, p. 14). There is a view that to become ecologically literate we need to think "from the parts to the whole, from objects to relationships, from quantities to qualities" (Capra & Luisi, 2014, p. 353). Capra's connectedness view is in stark contrast to the fragmented science education practices in Australia. In ecological literacy the strong emphasis is on developing knowledge about, and competence toward, the Earth's systems where we are encouraged by a sense of wonder about our Earth (Orr, 1992, p. 86). To study single organisms in isolation from other organisms and their environment is failing to grasp a complete understanding of the organism (Orr, 1992). The understanding of how ecosystems have evolved over time to become organized systems is central to "ecological literacy" (Capra, 2007, p. 10). Ecological literacy is at the heart of ecological systems thinking and the "wisdom of nature is the essence of ecoliteracy" (Capra & Luisi, 2014, p. 353). Learning about environmental problems in isolation, such as water pollution, without looking at the connected hydrological, geological, biological, and atmospheric systems, does not provide young people with a comprehensive understanding in order to make informed decisions about environmental issues (Assaraf & Orion, 2005). Aspects of systems thinking are evident in science curricula, such as the study of ecosystems in the biological sciences or the study of the hydrological cycle in Earth and space/geological studies. However, as demonstrated earlier with the Australian Curriculum, science curricula tend to promote discipline-based science, and the young people are left to make the connections between the disciplines, which they often fail to do (Gough, 2011), for example, between a rainforest ecosystem and the hydrological cycle.

Strategies for Incorporating Ecological Systems Thinking in Science Education

Assaraf and Orion (2005) found that after carrying out their systems thinking program with young people in secondary science, most young people significantly improved their systems thinking and the young people's thinking became more holistic. Drawing on the work of Assaraf and Orion (2005), Evagorou et al. identify six levels of skills for systems thinking. Young people need to gain each level of skill before being able to move to the next level. These skill levels are:

(a) Identification of the elements of a system
(b) Identification of the spatial boundaries of a system
(c) Identification of the temporal boundaries of a system
(d) Identification of several subsystems within a single system
(e) Identification of the influence of specific elements of the system on other elements or the whole system
(f) Identification of the changes that need to take place in order to observe certain patterns
(g) Identification of feedback effects in a system (Evagorou et al., 2009, p. 663)

A brief outline follows of five key strategies highlighted by Assaraf and Orion (2005) (strategies 1–4) and those from other researchers (strategies 5–7) that have been found to strengthen a systems thinking approach in science education and promote a deep understanding of the interconnectedness of the Earth's systems:

1. Introducing the basic steps of systems thinking in primary school
   Introducing a basic systems approach in primary school, such as the ability to identify at least two components in a system, provides young people with the foundations to move toward more complex systems understanding in secondary school (Assaraf & Orion, 2005). Hung (2008) emphasizes how systems thinking can help young people move toward complex understandings of concepts that they often find challenging, such as complex ecosystems, and is particularly successful in providing them with understanding relating to the interrelationship of living organisms with nonliving elements (Evagorou et al., 2009; Riess & Mischco, 2010). There are few research studies relating to systems thinking with young people at primary school as most studies have focused on systems thinking with young people at secondary school or students in higher education. However, the few studies that have been undertaken with young people at primary school do indicate that they can move toward systems thinking (Evagorou et al., 2009). In a study in Cyprus with young people at primary school, Evagorou et al. (2009) found that most participants developed some systems thinking skills when supported by an appropriate learning environment catering to their cognitive abilities.
2. Inquiry-based approach where young people explore and discover

When implementing systems thinking in science education, it is important for young people to work with an inquiry-based approach. With an inquiry-based approach, the young people are provided with the opportunity to explore, question, investigate, make decisions, and build on their prior knowledge, in contrast to the passive learning of facts where teachers are at the center of the classroom (Assaraf & Orion, 2005; Evagorou et al., 2009). An effective inquiry-based approach assisted the young people in Assaraf and Orion's (2005) research study to move from having "islands of knowledge" of the Earth's systems to conceptual understanding where they made links between the systems. The big question behind the program was, "How should we act in order to preserve our water resources?" (Assaraf & Orion, 2005, p. 524). The young people worked collaboratively throughout the program to answer the question by exploring the Earth's systems and the interrelationships between the systems including the impact of humans.

3. Working with young people in outside settings
   Young people often fail to see the relevance of science to everyday contexts (Bybee & McCrae, 2011); therefore it is important to connect science with the young people's everyday lives. Bybee and McCrae's research demonstrates that taking the young people outside enabled them to grasp systems thinking more effectively and connect their understanding with firsthand examples in their everyday lives. Assaraf and Orion (2005) identify ways to make use of outside settings; this included firsthand experiences such as visiting local waterways or ecosystems to enable young people to experience the Earth's systems and put their learning into context. Orr (1992) emphasizes experiencing the Earth's systems firsthand as being key to understanding these systems and connecting young people to their local place. Ecological systems thinking strengthens the childhoodnature position that young people are interconnected with all other living things and nonliving things in the Earth's systems. Young people are systems or networks themselves within systems like all other living things; in fact young people are nature.
4. Knowledge integration activities
   Assaraf and Orion (2005) identify using tools to integrate knowledge throughout the learning cycle as an important aspect to assist young people in moving toward the conceptual ideas in a systems approach. These activities included "concept maps, drawings and summarizing the outdoor experiences," in order for the young people to understand the water cycle as a "dynamic, cyclic system" (p. 525) and create relationships and connections between the components of the system and subsystems. Using diagrammatic representation and summaries of their experiences can assist the young people to consolidate their ideas and understand the relationships between the systems.
5. Utilizing computer technologies
   A number of researchers advocate the use of computer technologies when introducing a systems approach in the classroom. In 1999, in the early days of computer implementation in schools, Wilensky and Resnick implemented

a computer StarLogo modeling language to introduce a systems approach in science lessons, and they found young people developed rich understandings, particularly between the connections in ecosystems (1999). Evagorou et al. (2009) integrated a systems approach using computer simulations where the young people worked with a forest ecosystem system to develop basic systems thinking skills. Riess and Mischo (2010) also found a forest ecosystem computer simulation worked well in developing systems thinking with young people in junior secondary school in Germany, particularly when incorporated with other modes of implementing systems lessons.

6. Incorporating indigenous views
   Providing young people with the opportunity to experience living systems and to learn from the people who have lived by the "grace of these systems" (Orr, 2012, p. 1) can be effective in connecting science with the young people's everyday life. Indigenous science knowledge tends to be more relational and applied to everyday contexts in contrast to mainstream science education which tends to be non-relational and compartmentalized (Augare et al., 2017). Therefore, indigenous ways of thinking are holistic and more in line with systems thinking as Aboriginal peoples "of many societies" demonstrate a balanced and harmonious relationship with the Earth's systems (Fien & Tilbury, 1996, p. 22). Countries with colonial oppression and the strong Eurocentric curricula are positioned within a colonial (conquering) mind-set such that incorporating indigenous (relational) views into science, particularly ways of living in nature, has not been readily taken up (Aikenhead & Elliot, 2010; Lowan-Trudeau, 2018; Whitehouse, 2011). In Australia "Aboriginal and Torres Strait Islander Histories and Cultures" is a "cross curriculum priority" for all subject areas within the Australian Curriculum (ACARA, 2017). However, it requires teachers to bridge the divide of the traditional indigenous ways of knowing and science worldviews in order for both indigenous and non-indigenous young people to make this connection (Gondwe & Longnecker, 2015). Gondwe and Longnecker advocate going beyond tokenistic activities to incorporate cultural worldviews and how these worldviews influence values, attitudes, and beliefs of peoples of other cultures: for example, the contrasting values, attitudes, and beliefs toward humans' interrelationship with the Earth's systems. Aikenhead and Elliot refer to indigenous views in science as "wisdom tradition" of "thinking, living, and being" in contrast to the traditional Eurocentric views of disconnected "intellectual thinking" (p. 325). In Australia, indigenous Aboriginal and Torres Strait Islanders use the term "country" that "means far more than 'land', 'landscape' or 'environment'. Country is a relationship — a contiguous way of seeing, being and acting. Country is tens of thousands of years of accumulated knowledge and understanding," and with country there is no separation between humans and other (Whitehouse, 2011, p. 230). Orr (1992) and Capra (2007) emphasize the extensive knowledge and practices of indigenous peoples over thousands of years of being in their local areas as being important to ecological sustainability. Learning traditional indigenous knowledge is a benefit to all young people; it

can lead them towards a more holistic understanding of local areas, and in particular it increases the knowledge and engagement of the local indigenous young people (Augare et al., 2017).

7. Debating and discussing socio-scientific issues
   In order for young people to move to more holistic thinking about the Earth and to understand the significance of human impact on the Earth's systems, it is important to involve young people in debating and discussing socio-scientific issues in the science classroom. Young people need to look critically at our society and its values and, furthermore, how it could be changed to "achieve a more socially just democracy and ensure more environmentally sustainable lifestyles" (Hodson, 2003, p. 654). Research has revealed that even though young people in Minority western schools may be interested in scientific issues that they perceive to be relevant to their lives, such as health issues or environmental issues, they often see little connection between science in the classroom and the socio-scientific issues that link to, or impact, their everyday lives (Bybee & McCrae, 2011). Such connections can be achieved by providing the opportunities for young people to study, discuss, and debate issues that confront them and that are relevant to their lives (Hodson, 2003) and can be enhanced using an ecological systems approach. This socio-scientific connection with everyday lives was evident in a school in Chicago (United States) where young people identified the problem of their local river system being polluted due to illegal rubbish, soil, and rocks being dumped on the banks of the river (Bouillion & Gomez, 2001). The young people voiced their desire to address the pollution problem, and they worked collaboratively with teachers, local council, community, and scientists to clean up the riverbank. The teachers encouraged the students to use an ecological systems approach in this project where they explored their own connection to ecological systems. The students investigated the impact of pollution on the river system by measuring oxygen levels and investigating the impact of low oxygen levels on fish and other living organisms in the river (Bouillion & Gomez, 2001).

The following vignette outlines an ecological systems program that incorporates six of the seven strategies identified above for integrating a systems approach into science lessons (using computer simulations was the only strategy not utilised).

Learning About Ecological Systems in Science Education: The Big Scrub Rainforest Program

This place and community-based program in the North Eastern region of the Australian state of NSW involved 120 young people from four schools, three primary and one high school. The young people investigated their local critically endangered subtropical rainforest ecological system, The Big Scrub Rainforest, and learning took place within the whole community (Smith & Sobel, 2010). This example illustrates the cyclic nature of ecosystems where nutrients are continually

recycled along the feedback loop pathways and where organisms have evolved over time to "use and recycle the same molecules of minerals, water, and air" (Capra & Luisi, 2014, p. 354). The Big Scrub Rainforest program in the schools was facilitated by the Northern Rivers Group of Environmental Educators (Cindy Picton, Tamlin Mackenzie, Simone Blom, Lyn Thomson, Barbara Jensen, Georgina Jones, Linda Tohver, Ian Judd, Graeme Patterson) and the Custodian of Nyangbul Country (Lois Cook). Funding was provided by Australian Association for Environmental Education and the NSW Government's Environmental Trust.

Context

The Big Scrub Rainforest ecosystem is an ecological community with geological links to the supercontinent, Pangea (325 million years ago) and subsequently Gondwana supercontinent, when Australia was linked to Antarctica and other continents (Holland, 2017, p. 34). When the continents broke apart, tectonic activity resulted in the formation of volcanoes. The lava flows from this volcanic activity in the Big Scrub region are important as they are "conduits" for the aquifers that give rise to the springs which drive the hydrological systems behind this ecosystem (Holland, 2017, p. 35). The soils of the Big Scrub area result from a combination of eroded basalt from Wollumbin (a volcano that formed in the area 23 million years ago) and soils that originate from Pangean and Gondwanan times. The soils support a rich rainforest ecosystem with a multitude of organisms including tall trees, shrubs, vines, palms, herbs, epiphytes (high up in the canopy), birds, invertebrates, bats, marsupials, humans, fungi, microorganisms, and other plants and animals, some of which are endangered.

Prior to European settlement, the Big Scrub Rainforest was the largest continuous lowland rainforest in Australia (Parkes et al., 2012). The Big Scrub Rainforest is part of the land of the local Widjabul people from the Bundjalung nation, who lived in this area for "many thousands of years and cared for the country" (Gordon, 2017, p. 26), and is also significant to the Nyangbul people and all the Bundjalung tribes. The peoples from the Bundjalung nation "lived with their environment," and their cyclical relationship with this land is closely tied to "seasonal changes and renewal" (Gahan, 2017, p. 104).

After colonization of Australia, new settlers viewed this rich ecosystem very differently to the local Bundjalung peoples who had an interconnectedness with this ecosystem – their country. The rich diversity of the Big Scrub was seen by the settlers as a resource to use as they wished. The magnificent red cedars that had grown to a great height on the volcanic red soils, with girths of over 3 m (Gahan, 2017), were prized for valuable timbers. Following the "cedar getters" in the second half of the nineteenth century, "spurred by imperialist and capitalist ideology," the Big Scrub, with its rich fertile rainforest soils, was cleared for agriculture largely by colonists from England, Ireland, and Scotland (Gahan, 2017, p. 108). During this period, the NSW Government encouraged free selection so any colonists could obtain land in

the area if they "occupied and improved" their chosen land, in other words cleared the land for agricultural purposes (Gahan, 2017, p. 109). By the end of the nineteenth century, the rainforest was reduced to less than 1% of its original extent, with the remaining remnants scattered throughout the Big Scrub area (Parkes et al., 2012). This lowland rainforest is listed as an endangered ecological community under the NSW Threatened Species Conservation Act 1995 (TSC Act 1995) and as a critically endangered ecological community under the Federal Environmental Protection and Biodiversity Conservation Act 1999 (EPBC Act 1999) (cited in Parkes et al., 2012). The rainforest consists of scattered remnants that contain threatened animal and plant species, some being close to extinction (DECCW, 2010).

Implementation of the Big Scrub Rainforest Program

The Big Scrub Rainforest place and community-based program integrated six of the seven key strategies for incorporating a systems approach into science lessons using the following processes:

Strategy 1: Introducing Systems Thinking in Primary School

Young people in both primary and secondary school were included in this Big Scrub Rainforest program where they explored their local ecological system over time. The young people identified the elements of the interrelating systems. The feedback systems were explored relating to the mechanisms that enable this critically endangered system to regenerate.

Strategy 2: Inquiry-Based Approach Where Young People Explore and Discover

A strong inquiry-based approach was employed where young people worked collaboratively with their peers, to build on their knowledge about this ecological system and build on their ecological literacy. Botanists, bush regenerators, environmental educators, and Landcare representatives worked with the young people to answer their questions and provide background information relating to the geological, atmospheric, hydrological, and rich biological systems surrounding this ecosystem.

Strategy 3: Working with Young People in Outside Settings

Young people worked outside in rainforest remnants within, or close to, their school where they identified plants, animals, and microorganisms, and assisted with regeneration processes. The young people supported regeneration of the rainforest by planting rainforest species (Fig. 1) and carrying out rehabilitating exercises (such as weed removal in the remnants and riparian [riverside] plantings). By exploring the rainforest remnant systems close to their schools and helping to regenerate the forest, the young people discovered the biodiversity of the forests and saw examples of the interdependence of the elements of the rainforest ecosystem.

Strategy 4: Knowledge Integration Activities

Fig. 1 A student co-researcher planting a rainforest tree in a riparian area next to the school grounds

Diagrams, concept maps, and drawings were used by the young people to explore the interrelating systems over time and to assist them with their understanding of the spatial and temporal boundaries of the rainforest.

Strategy 6: Incorporating Indigenous Views

A local Aboriginal custodian of the Nyangbul Country worked with the young people to discuss the significance of the Big Scrub Rainforest to her people and shared "dreamtime" (indigenous lore) stories.

Strategy 7: Debating and Discussing Socio-scientific Issues

The young people addressed socio-scientific issues surrounding the clearing of vegetation for human use. The devastation of the clearing of the Big Scrub, particularly on the biological systems, was discussed. The impacts of the removal of vegetation on the geological and hydrological systems were also reviewed. The young people explored both calls to protect this rainforest and protests that were conducted in the area dating from the late nineteenth century to the present day (Gahan, 2017). Poems, raps, artworks, and media releases surrounding the protests and the clearing of the rainforest were created by the young people.

Embedded within the Big Scrub Rainforest program was a critical participatory action research/A/r/tography project with a group of 12 young people as student co-researchers (aged from 9–13 years). (The researchers who supported the student co-researchers in this project were Marianne Logan, Simone Blom, and Steven Andrews.) The aim of this research project was to investigate young people's knowledge of, and values and attitudes toward, their local critically endangered ecological community. The project sought to position young people as active researchers where they shared their knowledge, values, experiences, and research findings, to inspire young people both locally and beyond, to take action toward their local natural ecosystems.

The young people shared their immersive creative experiences (such as narratives, drawings, photographs, and poems) in their researcher journals, written texts,

Fig. 2 Year 7 student co-researcher Niamh Montgomery's illustration of where "Cold iron sliced the forest apart"

Fig. 3 Niamh Montgomery and Megan Elliot (student co-researchers in year 7) illustrate their understanding of the spatial and temporal boundaries of the ecological system over time

and online blogs in order to inspire other young people to take action to protect their local ecosystems. The following narrative and illustration (Figs. 2 and 3) by a student co-researcher, Niamh Montgomery (year 7), is the voice of the forest in response to the clearing of the Big Scrub Rainforest:

> The rainforest used to be quiet. Birds sang quietly to themselves in the trees and unseen creatures rustled the leaves that lay undisturbed on the ground. The wind whistled and we whistled back, and everything stayed silent, the same. That was until some new creatures arrived. They were bigger than others and they feared them. The new creatures were loud. They trumped around as if they owned the land. They made light that ate wood. It flickered. The forest flickered back. Then they brought their tools. Cold iron sliced the forest apart. Leaves curled and died. They started a war. They lay our fallen friends in the river and washed them away. The river raged. They raged back.

As a result of taking part in the program, the young people built on their knowledge about this local critically endangered ecosystem. The majority of young people agreed or strongly agreed that they had learnt a lot of things about the Big Scrub Rainforest (86%), that they cared about the future of the Big Scrub Rainforest (83%), that they liked planting trees and shrubs (88%), and that they had a deep understanding of how their actions affect the natural world (77%).

The young people's responses, such as the exemplars below, about what they learnt in the program demonstrate that they were able to build on their understanding of the importance of natural ecosystems and feel empowered to take action:

- *I knew nothing about the Big Scrub Rainforest now I know a lot.*
- *We have spread the word and planted trees.*
- *I now feel a connection.*
- *I love this Big Scrub rainforest so much now.*
- *I think it is an important forest that preserves invaluable habitat for native animals.*
- *The Big Scrub Rainforest is amazingly beautiful and sacred. We need to keep it from disappearing forever.*
- *I think it is a very precious and fragile part of Aboriginal landmarks.*

The young people were working with the rainforest in their school grounds and in some cases their own neighborhood. The following response from a young person demonstrates being able to identify their own local forest after participating in the program: "I now know that the massive rainforest behind my house is the big scrub." By addressing the key strategies for implementation of an ecological systems approach in science education, these young people had the opportunity not only to build on their ecological knowledge but also to develop values and attitudes toward, and their interconnection with, their local ecosystem. Young people's appreciation of their interconnection with the Earth's systems is the essence of childhoodnature.

Conclusion

This Chapter has considered ecological systems and how a systems approach could be incorporated into science curricula. In the Minority west where Eurocentric curricula dominate science and STEM education, and economic prosperity is at the heart of a system driven by neoliberal ideology, science education tends to be compartmentalized into separate disciplines, and learning is centered around the Earth as a resource for the benefit of humans. This economically driven curricuoum tends to dominate, despite moves to incorporate sustainability and, in some countries, indigenous cultures and values. By looking at science curricula through a post-humanist, systems thinking lens, in contrast to the anthropocentric view of mainstream science education, a holistic approach is encouraged where humans are not viewed as separate, but we, like all other organisms, are interdependent on other

living and nonliving elements in the Earth's systems. Incorporating an ecological systems approach in science education encourages young people to look at the Earth as a dynamic system with subsystems such as the geological, atmospheric, hydrological, and biological systems rather than looking at the Earth's systems in isolation. With a systems thinking approach, young people can begin to see how the behavior of every organism in an ecological system depends on the behavior of many others and how humans impact ecological systems.

Ecological systems-based science and STEM education can draw on tens of thousands of years of indigenous knowledge, attitudes, and values, to enrich science education and learning about first people's interconnection with the Earth's systems. Through inquiry-based approaches, young people explore and investigate ecological systems in everyday contexts and connect with their local ecological systems, even within the school grounds or on balconies, and move toward ecological systems thinking. It is important to provide opportunities for young people of all stages, from early childhood to secondary, to debate and discuss current issues that impact their lives, particularly the significance of the Anthropocene.

I am not suggesting that increasing scientific knowledge relating to environmental degradation will lead to environmental action (Selby & Kagawa, 2010). However it is argued that by enabling young people to build on their knowledge, values, and attitudes relating to complex scientific concepts in a holistic way through ecological systems thinking, particularly in the context of their local region, they will begin to move toward childhoodnature understanding, that is, the inseparability of themselves and nature.

Abstract

The "animal turn" in academia has been described by researchers like Weil (J Fem Cult Stud 21(2):1–23, 2010) as an increasing scholarly interest in the status of animals beyond that of the utilitarian or agricultural scientific study of animals

In the wake of poststructuralist and postmodern decenterings that have displaced the human as a standard for knowledge, theory finds itself in a similar predicament. It cannot avoid seeing the animal suffering around us, but has contradictory foundations on which to judge the good or the right thing to do about it. Responding to an urgent call for concern, those of us working on "the animal question" may only be able, like Red Peter, to make a report, but hopefully such reports will enable us to make decisions (for that is our human prerogative and responsibility) that will, to the best of our imperfect and partial knowledge, enhance the lives of all animals, ourselves included (Weil, 2010, p. 20).

and the larger-than-human degraded ecological times we are living in. The human condition has always been defined and studied in relation to the animal, from ancient to contemporary posthuman thinkers, where the study of animal relations forms a large component of this ontological turn, with shifting aspirations to decenter anthropocentric interactions and challenge human assumptions of more-than-human lives. Human-animal studies, while still firmly planted within disciplinary margins, "have been edging towards the mainstream" (Ritvo, Environ Hist 9(2):204–220, 2004, p. 205), becoming increasingly popular, respected topics of inquiry (Ritvo, Daedalus 136(4):118–122, 2007). Creative opportunities for experimentation therefore exist where new terms, becomings, and conceptualizations are underway.

The chapters in this section provoke a diversity of such (re)thinking of child-animal relations within Western families, communities, and education where the complex relationships with children, animals, and environments provide a space for ethical considerations to the social positioning of animals in education and society. The chapters address ideas, conceptualizations, and possibilities of alternative ontologies with some authors venturing into pedagogical territory that attempts to reshape pedagogy and practice. Authors grapple with the taken-for-granted interspecies relationships in their messy, complex, and multiple forms, to look beyond to see the hidden, the marginalized, the unexplained, and the ill-considered. This questioning of multiple relatings has the potential to (re) imagine new models, theories, and ways of crossing boundaries that blur the illusion of separation between children, nature, and animals, where animals can be elevated as crucial components of living together in perilous times. As section editors who engage with human-animal research, ethics of concern, and activism in our work and everyday lives, we acknowledge the "contradictory foundations" of the animal question, and this is reflected in the diverse and sometimes opposing contributions of the chapters in this section. Readers will find a choice of theoretical, educational, and sociocultural representation and discussion in these writings, and this introduction offers signposts to guide the reader through the twists and turns. The authors enhance the explosive range of human-animal studies now underway in diverse disciplines, including arts, humanities, media studies, science, and social geographies, drawing attention to the question of the animal that is under-researched and underrepresented in education. The chapters in this section of the handbook offer alternatives to humanistic thought and actions, and our hope is that these contributions will legitimize the study of human-animal relations, prompting others to join us in research and practice that embraces ethical multispecies futures.

Introduction

Red Peter, the fictional chimpanzee referred to in the quote above, gives a report to the academy about what he is learning through his transformation to becoming human. Kafka (1917) positions Red Peter in the short story *Letter to the Academy* within liminal spaces of human and animal becomings. He has a foot in both camps where being ape and becoming human means never belonging to either world. Red Peter has learned to speak, stand, and dress as a human but will always be betrayed by his animality, and this animality in turn has been disrupted leaving him stateless, world-less, and species-less as a human-animal representation that is neither human nor animal. Kafka's story is an important fable for human-animal studies, as it characterizes the challenges of animal representation and co-species entanglements. Writing about these entanglements has become a popular aspect of human-animal studies, as scholars draw upon flat ontologies like those of philosophers Spinoza, Whitehead, Latour, Deleuze and Guattari, and Stengers. The complex variations of these worldviews offer thought-provoking ways to position (or not position) the detailed richness of the immanent world of things (human, more-than-human, objects), taking us out of our anthropocentric impasse and enabling multiple pathways to appear. The blurring and entanglement of hierarchical categories of human and more-than-human is a key feature of this handbook; however, where "the animal" is integrated within muddled hybrid terms and flattened ontologies, there is a danger that power relations can become silenced and overlooked, resorting to the privileging of human knowledge over the lived realties of other beings. After all, the fictional Red Peter who is stolen from his family in West Africa, as a young chimpanzee, robbed of his childhood, and trained through violence to perform for and as human is based on countless acts of violence, where this was (and still is) a reality (Gray, 2004). The animal turn therefore brings into question the scale of the "animal question," as we face the perilous environmentally vulnerabilities of current earthly life. The animal turn demands our attention, to (re)learn the art of paying attention to new modes of resistance that requires "new powers of acting, feeling, imagining and thinking" (Stengers, 2015, p. 24).

In our search for alternative ecological lifeworlds, we acknowledge the importance of multispecies relationships and ecological aesthetics that attune with ethics of concern. Until recent times human-animal relations have received minimal attention from social science research, have been a blind spot in philosophy (Derrida, 2008), and have rarely focused on how children learn about and experience animals. Environmental education research has also minimized the question of the nonhuman animal (Oakley et al., 2010), failing "to integrate nonhuman animal advocacy as a serious educational issue" (Kahn & Humes, 2009, p. 179), where we know that animals matter in the lives of children (Melson, 2001; Myers, 2007; Tipper, 2011). We are grateful to the editors of this International Handbook who have chosen to privilege the study of these human-animal relations within a separate section, in recognition of this research gap. This could be seen as a point of contention. Indeed,

many could argue why a separate section for animals in a handbook about how childhoodnatures co-constitute the world and why not plants, rocks, and oceans? We maintain that as we are now ensconced in the epoch of the Anthropocene where humans are described as a geological force (Crutzen & Stoermer, 2000), there is a crucial need to comprehend how humans are enmeshed in cultural, political, and environmental relations with (and as) animals. The animal turn in academia has enlivened recent discussion, sparking hopeful elevation of animals as subjects with shared vulnerabilities, where previously they were relegated to the sidelines as objects of study. Human relationships with animals have always been ambivalent and ambiguous, as pests, pets, and products, where we remove, revere, exploit, and overlook them. This exclusion is a focal point of this section where the authors work in ways to question and challenge human-centric assumptions that acknowledge the importance and benefits of animals in children's lives and children in animal lives.

Many of the chapters including Harwood, Rose, Whitty and Elliot, and Boileau and Russell from Canada; Tammi, Rautio, Leinonen, and Hohti from Finland; Myers and Russell and Fawcett from the USA; and Young and Bone from Australia adopt multispecies ethnography as a way to integrate animals into the inquiry process. Fieldwork with children and animals in education reveals shared threads of understanding and experience where human children, dogs, insects, and worms cross geographical boundaries. Animal relation ethnographic studies require sophisticated techniques and creative approaches that challenge speciesism and the epistemologies that pit the all-knowing human against the passive, dumb, and insentient animal. This is no easy task, for documented research pathways, methodology texts, and studies are still being made and unmade in these early stages of the animal turn. Finding methods and practices that embrace animality demands less-linear and less-obvious approaches, hence the popularity of affective ontologies in this research space. How do you write, for example, a methods chapter in a doctoral study with an animal as a participant? How can researchers include the perspective of a dog or the species-specific worlds of a stick insect? How can we also acclimatize to animal resistance that might be more obvious when listening to the grieving wails of a mother cow whose calf has been taken away hours after birth, but far more difficult when observing the frenetic activity of ants whose nest has been disturbed? While this section does not have the scope to answer these questions, it does provide examples of multispecies, posthuman attunement, widening the inclusive approach that ethnography offers to the study of human-animal relations:

> This is because, with its ability to pay close attention to the symbolic forms, practices, objects and discourses of everyday life, it is a technique that creates a multi-dimensional picture of interactions in their subtle, nuanced and often contradictory cultural context. It does this by encouraging the researcher to engage physically, discursively and emotionally with those under investigation. In other words, it moves us from seeing research "objects" to seeing— and often working alongside—research "subjects" and places these roles as complementary rather than separate or oppositional. This lends itself to regarding humans and other animals in relations and entanglements not as so very different that they cannot be researched together. (Hamilton & Taylor, 2017, p. 9)

Roadmap of Section Chapters

This animal relations section of the handbook has been loosely designed with the intention of ordering the chapters within four parts: (1) theoretical reviews, mappings, and conceptualizations, (2) cultural constructs, (3) lived and fabricated lives, and (4) pedagogical potentialities and conceptualizations. We embrace the disorderly spillage of content and ideas that fall across chapters, for neat ideas are not part of the messy contradictions of the topic under study.

Theoretical Reviews, Mappings, and Conceptualizations

Theoretical mappings and contextual analysis assemble in the first part of this section in diverse and contradictory ways. Children and animals form common and connecting threads between distinct disciplinary methods, theoretical approaches, and familiar concepts of developmental psychology, sociology, media studies, and humane education. The concept of childhoodnature weaves through childhood development, film culture, and pedagogy attempting a renewal and awakening of these onto-epistemologies, endeavoring to embrace the various creaturely others, who are always, already there.

The opening chapter is a contribution from Gail Melson, arguably one the first scholars to address the question of what animals mean to children, resulting in the much-cited book *Why the Wild Things Are* (2001). In this handbook Melson's ▶ Chap. 53, "Rethinking Children's Connections with Other Animals: A Childhoodnature Perspective," offers an overview of child-animal relations through the domains of developmental psychology. The concluding discussion offers a helpful summary of ideas and a challenge to acknowledge animals in the lives of children through existing developmental paradigms, where they are currently overlooked. Are there possibilities, we wonder for developmental paradigms to blur the boundaries of childhoodnature by thinking through how animals experience concepts like attachment, schemas, or moral reasoning? Following Melson are two prominent scholars of Critical Animal Studies, Matthew Cole and Kate Stewart, who approach and address the question of child-animal relations as that of socializing superiority: the cultural denaturalization of children's relations with other animals. ▶ Chapter 54, "Socializing Superiority: The Cultural Denaturalization of Children's Relations with Animals" builds on their existing research of popular culture and cultural representations of nonhuman animals, targeted to children and with the aim of socializing children into simultaneously affective and exploitative relations toward nonhuman animals. An intriguing focus of this chapter is the critical analysis of four mainstream animated movies: *Zootropolis* (Spencer, Howard, & Moore, 2016), *The Secret Life of Pets* (Meledandri, Healy, & Renaud, 2016), *Finding Dory* (Collins & Stanton, 2016), and *The Jungle Book* (Favreau & Taylor, 2016). Through discursive analysis of the movies, the authors show how exploitative relations are (still) variously reproduced and how critical awareness is needed to disrupt the cultural modelling of loving and using animals.

In ▶ Chapter 55, "Re-examining the Human-Nonhuman Animal Relationship Through Humane Education", Maria Saari presents a non-speciesist framework as the potential of humane education with the reexamining of the human-nonhuman animal relationship through humane education. She suggests that assessing the interconnected forms of social justice and oppressive systems, humane education can instigate initial moves away from dominant beliefs of society. Saari discusses how nonhuman animal issues are widely neglected in research and practices of education – even in environmental or sustainability education. She then proposes that humane education takes environmental education further, reflecting the desired curricula of interspecies education, an approach based on compassion and justice focusing on the interconnectedness and interdependence of all life.

Cultural Constructs

The second part of the section engages the cultural situatedness of child-animal relations in recognition of the importance of understanding geographical and cultural contexts. Both chapters explore social, cultural, and political norms and practices through animal death, identifying death as highlighting the conceptual boundary between humans and animals in a given context.

Debra Harwood, Pam Whitty, Enid Elliot, and Sherry Rose present storied encounters between children, educators, animals and the more-than-human, as located within specific social-cultural-political contexts entitled: ▶ Chap. 56, "The Flat Weasel: Children and Adults Experiencing Death Through Nature/Culture Encounters". This fourth chapter centers on ideologies and practices of and around animal death that occupy spaces of early childhood. The authors discuss encounters with a weasel, an owl, and a raccoon as fostering a practice of becoming witness, of being and learning together with children and animals, and of making meaning with animals and their deaths. The authors present a situated lens of co-mattering in relieving the tensions of childhoodnature–animal-matter relations.

Experiences of animal death in childhood memories are the topic of the fifth chapter by Nora Schuurman. ▶ Chap. 57, "Experiences of Pet Death in Childhood Memories" Scrutinizing memories of animal death in childhood, based on narratives on human-pet relations, Schuurman pays special attention to the ways in which cultural conceptions, norms, and practices define the appropriate ways of relating to and grieving the death of an animal. Animal death is frequently contextualized in the experiences of growing up, and both children and adults are reflected on in the narratives. Schuurman finds that special meanings involved in relationships with animals in childhood are epitomized in the experiences of animal death. The historical perspective accessible through the data analyzed for this chapter allows Schuurman to present a long-term overview: the memories analyzed illustrate the position of animals as friends and family members already in agrarian times, before pet-keeping became a central part of home and family.

Lived and Fabricated Lives

A pedagogisized mass incarceration of certain animal species is what the third part of this section provocatively brings to the fore. The case of earthworms dangling in tweezers and being washed "clean" for inspection, or the case of "creepy crawlies" or insects being crushed to death when children learn to take care of them. Keeping and caring for other animals for the sake of human education – even worms or insects – is questioned, and grounding questions remain. What is, in fact, being taught? Who is, in fact, a subject of concern, requiring care, as a subject of their own life?

Tuure Tammi, Pauliina Rautio, Riitta-Marja Leinonen, and Riikka Hohti are the authors of the sixth chapter, ▶ Chap. 58, "Unearthing Withling(s): Children, Tweezers, and Worms and the Emergence of Joy and Suffering in a Kindergarten Yard" in which children and the nonhuman animals that cohabit a kindergarten yard are conceptualized as "withlings" and the processes they engage in as "withling" (verb). Focusing on one event in which children unearth, carry, and inspect earthworms, the authors discuss how different versions of human (child) and animal (earthworm) emerge, or, indeed, don't emerge, as part of practices including participation of different technologies (such as tweezers). While the worm rally made possible the meaningful participation of pupils in the practice of science education and evoked emotions on this regard, it seemed to suppress the compassionate affectivity in human-nonhuman bodily encounters and end up lethal for the particular worm withlings. The burning question remains for educational professionals: "What is being taught when nonhuman animals are removed from their assemblages and relocated within new ones?"

As if continuing where the previous chapter left off, the seventh chapter by ▶ Chap. 59, "Insect and Human Flourishing in Early Childhood Education: Learning and Crawling Together" discusses the pedagogical and ethical implications of various ways of encountering and using insects in education. In learning with and from creepy crawlies, Early childhood interspecies education for human and insect flourishing, they raise the question of who benefits and who is cared for – as a subject of their own life. The discussion of insect-human relations – which are often also unpleasant and troublesome – evokes powerfully what being ethical really is. The authors present a comprehensive review of research on insect-human relations, also with children, and point out that children receive ambiguous and conflicting messages of what "appropriate" or ethical relationships with insects might be like. And so, a particularly valuable contribution of the chapter is the portrayal of the role educators can play in helping children (re)interpret their experiences with insects.

Pedagogical Potentialities and Conceptualizations

Education in the broadest sense of the word can be defied as encompassing complex, dynamic ways that human beings live, work, consume, play, feel, construct, and share knowledge and learn to be in the world (Rowe, 2012). The following chapters

in this section highlight the promise and potential of interspecies exchange and the mutual provocation of learning to live together. The authors have been compelled to think with praxis, exploring pedagogies, educational activities, and the role of the teacher.

Joshua Russell and Leesa Fawcett ponder conviviality – the shared joys, pleasure, and problems of multispecies living in the eight chapter of the section: ▶ Chap. 60, "Childhood Animalness: Relationality, Vulnerabilities, and Conviviality." Highlighting bodily experiences of child-animal relations, they proceed to decenter the anthropocentric visions of individual development and to build a pedagogical vision of conviviality. The authors review pioneering research by Gene Myers, especially focusing on children's "theory of mind" and their experiences of intersubjectivity. They argue that children often recognize vulnerability in their relationships with animals and that a shift in developmental focus on child-animal relationships, one that takes animal agency and children's animality as a starting point, is due.

Chapter nine with the intriguing title, ▶ Chap. 61, ""I Don't Know What's Gotten into Me, but I'm Guessing It's Snake Germs": Becoming Beasts in the Early Years Classroom", outlines how Casey Myers follows children's animal play in an early years classroom by collapsing the human/nonhuman animal binary through attunement to animals. She maintains a loyal viewpoint of how the children themselves articulate the material-discursive particulars of becoming (with) animals within everyday acts of classroom living. This leads her to discuss the (im)proper animals – the beings between the adult-sanctioned animal presences and the children themselves, kinds of more-than-human beasts. Myers presents four cartographies of these beasts, complex, real-life events for young children, and suggests that they might allow us to consider alternatives to the traditional roles allocated for animals within early years education.

Tracy Young and Jane Bone complete the final chapter in the animal relations section of the handbook with ▶ Chap. 62, "Troubling Intersections of Childhood/Animals/Education: Narratives of Love, Life, and Death". They adopt a critical posthuman stance to mobilize attention toward the detrimental effects of violence concerning animals that takes place during childhood and within early childhood education settings that is not conducive to the shared lifeworlds required for ecological futures. They share this chapter with Kosi, a "pedadog" who helps them contemplate a framework of "roaming pedagogies" offering possibilities for teaching and learning about, for, and with these vital human-animal relationships. The oppression and commodification of animal species in early childhood compels them to not just to (re)imagine common worlds pedagogy or to rethink the basic tenets of their interactions but to take steps to (re)imagine relational ecologies of education by (re)making ways of living together with ecological justice in both thought and action.

Conclusion

Casey Myers poses a question in her chapter that sums up a key part of this section of the handbook. "Does the notion of 'child-animal relations' itself need rethinking, as the beasts that emerged through these research assemblages suggest a hybridity that

overruns the stable categories of 'child' and 'animal'?" By beasts she is referring to how the children in her research named a process of becoming-animal (but not quite, and much more) consisting of physical transformations, environmental limitations, adult expectations, material affordances, and children's conceptions of and relationships to various animal actors. There is much to unpack in what is meant and actually researched under "child-animal relations," and many chapters in this section engage in this conceptual and onto-epistemological groundwork.

The work compiled in this collection steers clear of the simple conception of child as the savior of animal and steward of nature, with the framing of childhood as the pivotal time to set their paths straight – for two reasons well accounted for: firstly, not to colonize and reduce the lived lives of younger people into stages and phases engineered and defined by those beyond it and, secondly, in realization that ethical acts and a more just world for all animals are always issues including but essentially beyond the individual requiring complex conglomerates of social, cultural, political, historical, material (and more) interdependencies. Having said this, however, does not release humans of any age, of the responsibility to act with concern in mind and try to "acknowledge what may not be possible to say" (Weil, 2010, p. 4). In this summary of the animal relations section, we report like Red Peter to the academy about our collaborative foray into childhoodnature with animals as our thinking, acting and living companions. We question how we can honor these companions in ways that do not distort or appropriate animal lifeworlds. Our shared aspiration is "to the best of our imperfect and partial knowledge to enhance the lives of all animals, ourselves included" (Weil, 2010, p. 20).

Abstract

The study of child development has traditionally focused exclusively on ties with other humans. In recent decades, however, scholars have recognized the pervasive presence of and children's interconnections with nonhuman animals, other life forms, and both natural and built environments. Ecological and systems perspectives on development have encouraged a "paradigm shift," whereby child development is viewed as inherently contextual. Using these frameworks, I address the "animal world" of children, documenting how interwoven children's lives are within the animal world. This "animal world" is broad and complex,

A note on terminology. Although humans are obviously animals, I follow customary usage to refer to human animals as "humans" and other species of animals as "animals." In addition, I use the terms "pets" and "companion animals" interchangeably. I employ the term "pet ownership," to refer to humans who have responsibility for the welfare of animals in their possession. Some critics have argued against terms such as "pets" and "pet ownership" as objectifying animals and diminishing their rights. Instead, the term "companion animal guardian" has been advanced (Staats et al. 2008). I take no position on the moral or ethical arguments underlying various terms but opt for consistency with customary usage.

encompassing not only the involvement with living animals, such as pets, but also wild animals, animal analogues, such as virtual pets and robotic animals, as well as animal symbols in various media. Child development cannot be separated from this myriad animal world. To illustrate this, four domains of child development are considered in turn: physiological, cognitive, socio-emotional, and moral. Within each domain, a childhoodnature approach reveals how children's development is embedded within the lives and contexts of other species. Because empirical research in many areas remains sparse, hypothesis generation is the focus. Suggestions for a programmatic childhoodnature approach to children's lives are described.

Introduction

Traditional disciplines studying children and their development have, until recently, almost exclusively focused on their ties to other humans. Even as theoretical perspectives such as ecological systems theory (Bronfenbrenner, 1979) and dynamic systems theory (Fogel, 2008) urged attention to the contexts of children's development, those contexts were viewed through an "anthropocentric" lens (Melson, 2001). Perhaps understandably, given the importance of parents, other family members, teachers, and peers, relationships and contexts were conceptualized solely in terms of human social relationships and human created environments.

However, in the last several decades, the long-neglected contexts of other species and the natural environments we share with them have emerged from obscurity. When in 1986, the US National Institutes of Health convened the first research workshop on human-animal relations, few scholars or practitioners took interspecies connections seriously. However, even then there was recognition, if one knew where to look, that animals were significant for human functioning. For example, Freud and other psychoanalytically oriented scholars had noted children's fascination with animals, the frequent appearance of animal symbols in dreams, and the role of animals in myths and stories (Freud, 1950, 1965; Von Franz, 1972). Pioneering therapists, notably Boris Levinson (1997), began strategically including animals within the therapeutic context. With his dog Jingles as "co-therapist," Levinson demonstrated how a friendly dog might create a non-threatening atmosphere, provide a safe outlet for expression, and even facilitate therapeutic insights. His classic book, *Pet-oriented Psychotherapy*, originally published in 1969, launched a new field, "animal-assisted therapy." Finally, the publication in 1984 of *Biophilia*, by E. O. Wilson, introduced a compelling hypothesis, namely, that humans coevolved with many other species and, hence, are genetically predisposed to selectively attune to other forms of life.

These insights situated children's development within the "living world," not just the world of other humans (Melson, 2008). At the same time, researchers from

multiple disciplines, including psychology, sociology, veterinary medicine, history, and economics, began to focus on the richness and complexity of human engagement with other animal species. More recently, studies in human-animal interaction (HAI) have recognized bi-directional influences, documenting reciprocal effects for both humans and animals. As an example, Handling (2012) showed that oxytocin levels of adult female dog owners and their dogs were positively correlated.

These historical roots of the expanding field of HAI have engendered a shift from "anthropocentric" to "biocentric" theory and research. "Biocentric" refers to the situating of human relationships within a network of other living species and contexts (Melson, 2001). This trend is likely to continue for a number of reasons: (1) growing ecological awareness amid concerns about climate change, species extinction, and environmental degradation; (2) pioneering work by therapists and other practitioners incorporating animals into treatment, education, and enrichment; (3) the contribution of genomic studies to documenting our genetic kinship with other species; (4) the proliferation of interdisciplinary approaches to HAI; and (5) the growth of systems perspectives in many fields, spurred by cybernetics and computer science.

Countervailing trends persist, however. A cursory examination of widely used college textbooks on child development still reveals little or no mention of children's ties with pets or other animals and little recognition of the significance of children being enmeshed with multiple environments. Unfortunately, psychological research too often ignores the ecological rootedness of children's development. The "biocentric" perspective, most often seen in HAI and environmental psychology, remains confined in a conceptual "silo," poorly integrated into the study of children's social and emotional relationships with humans. Nonetheless, there is growing recognition that children's development unfolds in specific geographical and physical spaces, environments in which children, other humans, and other species live together. In this way, the construct, "childhoodnature," captures the indivisibility of human development, other life forms, and the significance of place.

The Animal World of Children

From a biocentric perspective, children's physical and social worlds are replete with other species and life forms. Pets share children's homes. Wild animals are not just creatures to visit in zoos or nature parks but are all around, underfoot, and in the trees (Melson, 2013b). Animals of the imagination – in dreams, play, and various media – are pervasive elements of children's culture. Human-built analogues of animals, through video games, virtual pets, and robotic animals, are increasingly common. As a result, it is impossible to speak of children's development without addressing the importance of animals.

Pet ownership: The field of HAI has stimulated demographic research into rates of pet ownership. Although government census activities, such as the US Census Bureau, survey the population every 10 years, such assessments are restricted to human household members. This has led to less precise measurement of those nonhumans who share households. With this caveat in mind, international surveys

concur in very high rates of pet ownership. Both the American Veterinary Medical Association (AVMA) and the Humane Society of the US (HSUS), in independent national surveys, estimate that 62% of all US households had pets in 2012, with 36.5% owning dogs and 30.4% owning cats. (Ownership of multiple pets is typical of pet-owning families.) A 2014 survey by the American Pet Products Association (APPA) found 68% of American households had at least 1 pet, with over 77 million dogs and over 93 million cats in residence. Similar high rates exist in Western Europe. In developing countries and in developed societies in Asia, such as Japan and South Korea, pet ownership rates are rapidly approaching those in the West. In fact, given demographic trends toward smaller family size and lower birth rate, increasingly households are more likely to have pets than children. For example, in Australia, 66% of all households have pets, while 64% have children under 18 (Mathers et al. 2010).

While pet ownership is high across all households, those with children under 18 years of age are most likely to have resident animals. For example, in a study of a UK birth cohort, 74% of families with a 10-year-old also had at least one pet (Westgarth et al. 2010). Moreover, outside the home, children engage with companion animals. When 7- and 10-year-old California children were asked to identify "special friends" in their neighborhood, on average, they included at least one neighborhood pet (Bryant, 1985). Animals are common in the classrooms of young children as well. A survey of 30 California schools found that 59% of elementary school teachers had classroom pets (Zaslow, Hart, & DeArmond, 1999). Rud and Beck (2003) report that half of all Indiana elementary school teachers surveyed either had or wanted to have classroom pets. Thus, pets are pervasive in the important settings of a child's life – family, neighborhood, and school. This fact alone would argue for inclusion of pets in the study of children's relationships and settings.

Attachment to pets. The presence of an animal makes it potentially an important relationship. There is evidence that, for most families, pets are considered "family members," with many pet owners celebrating birthdays, displaying pictures, and giving gifts as they would to human family members. In one survey, 94% of adult pet owners identified their dogs and 84% their cats when queried about "close relationships." For comparison, 87% mentioned mothers and 74% mentioned fathers (Pew Research Center, 2006). Children too rank pets as important ties. In one study, 6–10-year-olds viewed their pets as more important than even friends or parents as a relationship "most likely to last no matter what" and "even if you get mad at each other" (Furman, 1989). In an interview study with 5-year-olds, all of whom had pets at home, 42% spontaneously mentioned their pet when asked to whom they would turn to share the emotions of anger, sadness, or happiness or the need to tell a secret (Melson, 2001). While children, in general, report a close bond with their pet, dog-owning children who spend more time caring for the dog have been shown to be more attached and the dog to be more responsive (Hall et al. 2016).

Wild animals. Even in urban, industrialized societies, children observe and sometimes try to interact with wild animal species. These encounters are often structured, in visits to nature parks, butterfly farms, aquariums, zoos, bird

sanctuaries, and other similar settings. An estimated 98% of all Americans report visiting a zoo at least once (Dunlap & Kellert, 1994). In one survey, 37% of all visitors to such UK wildlife venues were children (Turley, 2001), and most family groups organized the visits "for the children."

Even more common are unstructured daily encounters with wild animals in and around the child's home, neighborhood, and school. Although we seldom consider these as encounters with the wild, children regularly see birds, butterflies, rabbits, squirrels, frogs, and other small creatures. Backyard wild bird feeders are common. Even in a small patch of dirt, worms, snakes, ants, slugs, and beetles might be unearthed. Almost all families share their homes unwillingly with at least some of the following wild creatures: ants, spiders, flies, cockroaches, mice, and bedbugs. It is unrealistic to imagine a child's daily life without coming upon wild animals.

However, as noted elsewhere (Melson, 2013b), increasingly children's encounters with wild animals are mediated through technological media. In one interview study (Nabhan & Trimble, 1994), US children living near wilderness areas reported seeing more wild animals on television and in the movies than in direct, live encounters. Although this study has not been replicated, existing trends suggest that this "vicarious view of nature" (Nabhan & Trimble, 1994, p. 86) has only accelerated in the last 23 years. Even children living in less industrialized societies are meeting wild animals "at a remove." Thus, young children from Malta identified lions and tigers as their favorite wild animals, although they were not found locally and were experienced only through toys, animal-themed clothing, and school supplies (Tunnicliffe et al. 2008). In general, children are now observing wild animals primarily in nature documentaries, through popular television programs such as Animal Planet and in cartoon depictions. These presentations shape emotions using background music and film editing to create cultural depictions of animals through narrow lens where they perform "amusing antics" or frightening predation and killing.

Such mediated exposure reflects and also increases anthropomorphism, the tendency to attribute human characteristics and behaviors to other species (and even to objects). Such anthropomorphism is ubiquitous in children's media (Geerdts, 2016). Casting animals in human garb and speech is most likely among those with the least knowledge and experience of real animals, both domestic and wild, making children prime candidates for anthropomorphic depictions. In addition, there is a long tradition, dating from Aesop's fables, if not before, of using anthropomorphic animals to convey human stories and morals. In sum, the mediated world of animals is often a highly anthropomorphic one.

Animal symbols. As Kellert (2002) notes, animal symbols, in cave paintings, totems, and legends, are as old as the species *homo sapiens*. In contemporary life, animal names adorn sports teams, animal logos cover clothing, and animal names – "foxy lady," "big bear of a guy," and "wolfish grin" – describe human features. Certain animals have been coopted as holiday symbols, for example, the Easter bunny and the Christmas reindeer, while other animals are integral to religious ritual, as in the worship of cows in Hinduism. In sum, consistent with the biophilia

hypothesis, animals are a ready vocabulary with which we humans make meaning out of our world, including our fellow humans.

Children, in particular, are surrounded by animal symbols, from stuffed animal toys to animal-themed pajamas and bed linen. Animals that children often identify as "favorites" include dolphins, penguins, and lions (Myers, Saunders, & Garrett, 2004), followed closely with extinct animals such as dinosaurs that feature heavily in films, in toys, in games, and in other aspects of children's culture.

Animal analogues. Technological innovation has given rise to new animal forms. Children (and their parents) now have ready access to virtual pets, robotic pets, zoo-based webcams, augmented reality safaris, and animal apps. In the app "Virry," for example, children can watch live video of wild animals, such as rhinos and lions, and even "interact" with them by "feeding" them and communicating in other ways.

Unlike stuffed animals or windup toys, robotic animal analogues, such as the robotic dog AIBO, have embedded within them sophisticated computer technology that allows them to respond contingently to the child, to "learn" over time and to appear to "develop." These characteristics have led scholars to use the term, "embodied objects," to reflect the way computer-aided interactive capacities are merged with organic forms, such as a dog. Emergent research on children's understanding of and behavior with such objects reveals that children view them as neither living animals nor inanimate objects but as something in between – a "thing" that acts much like an animal or an "animal" that has features of a "thing" (Melson, 2013a; Melson et al. 2009b). Thus, as the animal world of children expands into the technological realm, new categories of animal and new relationships with animals emerge.

In summary, children's lives are saturated with animals – pets, wild animals, and animal symbols and analogues. It is impossible to consider children except in relation to other living beings and their symbolic representations. However, the ubiquity of animals is not the same as their developmental importance. One must show that animals are developmentally significant. In what follows, I address four important (but by no means exhaustive) domains of development – physiological, cognitive, socio-emotional, and moral. While these domains are interdependent and form a single complex system of development, one can conceptually distinguish them. Doing so illustrates how, in each domain, this animal world is not simply a critical part but is intrinsic to the understanding of human development.

The Importance of Animals in Child Development

Animals and physiological development. Since children's lives are intertwined with animals of all kinds, it is reasonable to hypothesize that other living beings and their natural environments would affect physical development. Several lines of inquiry have pursued this question. One explores the relation between dog walking and physical exercise and fitness. A study in Liverpool, UK, with 9–10-year-olds reported dog walking as an important activity where dogs were walked on average, several times per week (Westgarth et al. 2013). However, do these walks result in

more exercise and fitness? These results are mixed. When demographic variables associated with pet ownership are controlled (e.g., age, social class, and residence), Utz (2014) found no association between dog ownership and level of exercise. Nonetheless, many pet owners self-report more exercise and better health than do their non-pet-owning counterparts. For example, female dog owners (in China's major cities) say they exercise more and have better fitness, sleep, and overall health, compared to a matched sample of non-dog owners (Headey, Na, & Zheng, 2008). Similarly, New Zealand college students with dogs, compared to non-owners, reported more positive physical quality of life (Lewis, Krageloh, & Shepherd, 2009). Among both US college students and adult community members with dogs, the second most common response to the question: "What does your pet do for you?" was "keeps me active" (Staats, Wallace, & Anderson, 2008). Methodological difficulties abound in these studies, among them: the unreliability of global estimates of activity, the varying samples (some convenience, some population based), bias inherent in self-reports, social desirability effects (whereby owners may feel they *ought* to be walking their dog more), and variations in attachment to and responsibility for the dog. Beyond pet ownership, one must know more about the quality of the relationship between human and pet. As an example, a survey in Victoria, Australia (n = 928), of adolescents' activities on randomly selected school and non-school days found that over 88% of teens had pets but reported little interaction with them. No association between pet interaction and self-reported health was found (Mathers et al. 2010).

A second line of inquiry explores the relation between pet ownership variables and other aspects of physical health, for example, levels of stress hormones, such as cortisol, or glycemic levels. When the quality of the pet relationship is assessed (beyond simply noting pet ownership), the findings are encouraging. Thus, Maranda and Gupta (2016), in a study of 9- to 19-year-olds with type I diabetes, assessed not only children's pet ownership but their involvement in responsible care. Those who had pets and who cared for them responsibly were 2.5 times more likely to control glycemic levels than were children without pets. Other studies, thus far of adults only, have linked levels of the neuropeptide, oxytocin, to the human-dog relationship. For example, oxytocin levels are correlated in women and their dogs who have a close, bonded relationship (Handling, 2012).

A third, more speculative line of inquiry addresses the potential physiological and other benefits of rough-and-tumble (R & T) play, seen in human-dog interactions. R & T play is characterized by vigorous physical movement, such as play wrestling and chase games, and often accompanied by positive emotions such as laughter. Child development experts point out its developmental benefits, not only in physical exercise but in self-regulation of emotion and turn-taking skills (Pellegrini, 1987). However, adults, including early childhood educators, often mistake R & T peer play for aggression and seek to curb it (Storli & Sandseter, 2015). Hence, for some children, playing with their dog may provide an outlet for beneficial R & T play, although this has not been verified empirically (Melson, in press).

Negative health effects of pet ownership. Exposure to animals may be associated with zoonotic diseases, dog bites, cat scratches, and pet-related allergens. However,

proper hygiene can avoid the transmission of disease, while dog training and child education together can reduce the risk of dog bites. As for allergens and allergies, a large-scale study of over 22,000 children who had pets during the first 2 years of life found no relation to later asthma or allergy (Carlsen et al. 2012).

Animals and cognitive development. As the biophilia hypothesis posits, human beings have evolved to selectively attend to animals (and other living things). Thus, we orient toward animals and focus on them and their surroundings to gain information. For example, consider the information provided by birds circling slowly in a blue sky versus the loud squawking of a mob of birds in a darkening sky. In such ways, the animals that surround us are part of a continuous feedback loop of information.

Since attentiveness is a necessary condition for learning, the biophilia hypothesis suggests that children are predisposed to learn from and by animals. Thus, it is not surprising that much of the learning materials for young children uses animal figures and imagery. In fact, the first English language alphabet books featured animals – barnyard and wild – to teach the ABC's (Melson, 2001). Research on young children's attentiveness to living animals supports the biophilia hypothesis. Infants under 1 year of age are more attentive to and more positively engaged with living animals as compared with toy animals (Kidd & Kidd, 1987). In another study, babies reacted with most interest and approach to an unfamiliar living animal, a rabbit, as compared to a friendly but unfamiliar adult or a novel toy, a wooden turtle that moved, made noises, and flashed lights (Ricard & Allard, 1992).

Human and nonhuman animals operate with inherently complex, dynamic "information-rich" systems, behaving in unpredictable yet not totally random ways. Consistent with Piaget's theory of cognitive development (1960), animals provide the ideal stimulus to learning, i.e., "moderate discrepancy" from established "schema" or categories of thought. In this way, animal behavior is somewhat familiar but also contains elements that are surprising or unexpected. Consider the example of a toddler who has a cat at home. On a visit to a park, the child sees a squirrel for the first time and calls out "kitty!" In Piaget's terminology, the child is "assimilating" this creature to the "schema" or concept of a cat. But, then the child notices that this creature looks somewhat different and acts differently. An adult might point and say "squirrel!" encouraging the child to "accommodate" or develop a new "schema" or category of thought. In this example, it is precisely the ways in which the squirrel is both like and unlike the cat – moderate discrepancy – that stimulates new ways of thinking.

"Naive biology" refers to the everyday notions about living beings that children develop from birth into maturity. These notions include understanding what it means to be "alive" versus "not alive" or "dead," what the properties of biological entities are (they reproduce, they develop, they grow), and how various biological entities are grouped (i.e., animals vs. plants). Such ideas are fundamental to understanding of one's environment, the various beings within it and oneself. As children observe, touch, examine, hear, and think about the animals they encounter, they are developing a naïve biology. There is evidence that children involved in caring for pet animals develop more accurate ideas about their biology and are able to generalize those

ideas to other species, for example, frogs, that the children never cared for (Inagaki & Hatano, 2002). Pet-owning children also develop ideas about animal welfare needs (Muldoon, Williams, & Lawrence, 2016). There also is evidence that adult pet owners show more support for species conservation and protection (Shuttewood, Greenwell, & Montrose, 2016), raising the possibility that this might be true of children as well.

Animals and socio-emotional development. There is ample evidence that children view pets as companions, friends, and family members, in short, significant social beings. Both children and adults readily compare their ties to pets with those to other close human relationships. For example, adult pet owners reported that their pets were comparable to their siblings in terms of emotional closeness and support (McConnell et al. 2011). Even unfamiliar pets, owned by others, are viewed as socially significant. When 9–13-year-olds were interviewed after a short play session with an unfamiliar, friendly dog, most children agreed that the dog would be a friend, could play with them, and could understand them (Melson et al. 2009b). According to parent reports, children from ages 5 to 13 play with and care for pets on a regular basis, as much as they do with younger siblings, if available (Melson & Fogel, 1996). In addition, children in this age range also identify neighborhood animals as "important friends" (Bryant, 1985).

Encountering an animal, domestic or wild, is always a social encounter. In light of the previously discussed narrow representation of wild animals in documentaries and television shows, do children perceive wild animals as social beings, with emotions, intentions, and rich thoughts? Observations of preschool children as they encounter such animals as turtles, rabbits, monkey, or snakes reveal not only that the children are fascinated and want to engage but also that they treat these creatures as subjects, as beings like themselves, and not as objects (Myers, 1998).

As noted earlier, children report unique features of pets as friends and companions. They are seen as available, nonjudgmental, affirming, and trustworthy (Furman, 1989). The dependent nature of animals in households means that pets provide opportunities to practice care and nurturance (Fogel, Melson & Mistry, 1986). In this way, the social bond between child and pet has both horizontal (i.e., egalitarian) and vertical (i.e., stratified) qualities, making this relationship more comparable to older-younger sibling than to other ties. Perhaps because of this quality, pet-owning children without younger siblings are more likely to play with and care for their pets than do their counterparts with sibs (Melson & Fogel, 1996).

This finding also raises the possibility that social ties with pets may compensate for deficits in human bonds. Consistent with this is the finding that young children from single parent families express more attachment to their pets than do children from dual-parent families (Bodsworth & Coleman, 2001). Similarly, adults who report feeling anxious about human social ties seek more social support from their pets (Paul et al. 2014). However, overall, evidence on the connection between human and nonhuman social relationships is mixed. While some studies find a compensatory role, others conclude that pets may complement human ties. For example, adult female dog owners derived social support from their dogs, feeling less depressed and lonely, even after controlling for human support (McConnell et al.

2011). In interviews with 10-year-olds, Hall et al. (2016) found that children's attachment to their dogs was not related to attachment to parents, suggesting that each type of attachment bond was distinct. In this way, pets did not substitute for human social support but provided a distinct contribution over and above that support.

Still others (Melson, 2001) have suggested that supportive social bonds may be positively correlated across species. Perhaps children or adults who are skilled at seeking out and maintaining supportive social relationships do so in many contexts, with family, friends, and even pets. In support of this hypothesis, 9–11-year-olds who reported close ties with their dog also were more likely to report being securely attached to their mothers and fathers (Kerns et al. 2017). Much animal-assisted therapy (AAT) rests on the assumption that warm, accepting ties with animals will form a "bridge" to better social and emotional relationships with other humans (Melson & Fine, 2006). This presupposes generalization from ties with animals to humans. Yet, there is remarkably little research clearly demonstrating this.

In summary, the association between intra- and interspecies social bonds remains unclear. Future research on this question may not reveal a simple answer. Perhaps, depending upon context, type of relationship, and characteristics of both human and animal, ties with animals may compensate, complement, amplify, or be unrelated to human-human social bonds.

What are children learning in their social ties with pets? Considering social cognition, bonds with pets are likely to challenge perspective-taking and, thereby, stimulate empathy. When one engages in play with another species, one must imaginatively put oneself into another's "paws" not simply shoes, understanding very different behaviors and communication. Do ties with pets promote empathy, perhaps even extending to empathy in human relationships? In interviews with adult couples, those who owned pets believed that they helped the couple be more empathic toward one another. In fact, when empathy was directly measured, levels increased with the number of years the couple had owned the pets (Cloutier and Peetz, 2016).

Ties with pets may sensitize individuals to animal welfare issues more generally. In a survey of British adults with and without pets, those who had pets were more supportive of species conservation and protection efforts and less likely to prioritize human needs over those of other species (Shuttewood, Greenwell, & Montrose, 2016). Much of humane education rests on the premise that promoting sensitivity to animal welfare generalizes naturally to the way humans treat one another (Melson, 2001). Here, evidence is sparse, although suggestive. Pet ownership alone does not seem to affect empathy toward animals or humans (Daly & Morton, 2003). However, school-based humane education may be more effective. Ascione (1992) found that a 1-year program in humane education for first and fourth graders resulted in higher reported empathy (toward humans as well as animals), and this increase persisted up to 1 year after the program. Evaluation of a 10-week humane education program for first graders that also included visits from therapy animals found increases in self-reported empathy attitudes but not in self-reported behaviors

(Nicoll, Trifone, & Samuels, 2008). Surveys of elementary school teachers find widespread belief that humane education and live animal "visitors" to classrooms promote empathy development in young children (Daly & Suggs, 2010).

In addition to empathy, nurturance and caregiving may be outcomes of involvement with pets. As noted elsewhere (Melson, 2001), children in modern industrialized societies have little exposure to caregiving opportunities, either indirectly or through observation. Smaller family size (and, hence, fewer babies), more professionalization of care, and gender bias in socializing caregiving, all contribute to this trend. The pervasiveness of pet ownership, together with the close bonds most form with pets, means that nurturing animals is one of the few daily caregiving opportunities children have. A study of Chinese children found that pet attachment was correlated with willingness to care for others, including humans (Zhou, Zheng, & Fu, 2007). As we've noted before, such correlational data should be interpreted with caution. Children who are more prosocial, more oriented to helping others, may form closer attachments to their pets as part of that general disposition. Research to disentangle direction of effects is needed.

Moreover, since pet care, unlike human care, is less likely to be gender-biased (i.e., perceived as appropriate for females but not males), this caregiving is equally available to boys as well as girls (Melson & Fogel, 1989). This suggests that pets may provide one of the few socially and culturally encouraged avenues for nurturing that boys have as they are growing up (Melson, 2001).

Animals and moral development. Because even young children view animals, both pets and wild animals, as subjects, not objects, children accord moral standing to animals. In other words, children may view animals as having certain rights, including potentially rights to be free from harm, to have autonomy, and to exercise intention. Moreover, animals may incur obligations upon humans, especially those who have taken on responsibility for their welfare, as all pet owners do. Such obligations, justified as morally necessary, include meeting the animal's need to be appropriately fed, housed, exercised, and socialized. Moral obligations extend to giving affection, companionship, and medical care, consistent with the developmental needs of the animal.

Although the moral standing of animals has received little research attention, there is some evidence. Melson et al. (2009a, b) showed that children ages 7–13 accorded a friendly but unfamiliar dog, named Canis, both moral rights and human obligations. Overwhelmingly, the children stated that it was "not OK" to harm Canis, to refrain from giving needed medical care, or to give away Canis if you did not want him anymore. When asked to explain why such actions were "not OK," children referred to the moral claims of the dog, as a feeling and thinking individual who deserved individual rights. Many children made explicit comparisons with humans and their moral standing.

There appear to be parallels between children's reasoning about moral treatment of other humans and of animals. Dunlop (1989) found that adolescent boys' reasoning about moral dilemmas concerning animals followed the same stages

that Kohlberg (1976) outlined for such dilemmas involving humans. Indeed, while evidence remains spotty, it appears that moral reasoning is not compartmentalized into separate human and animal categories. This is another example of the way in which children's development reflects a "childhoodnature" perspective.

These findings are consistent with Kellert's typology of values applied to nature and living beings in general (2002). According to Kellert, as children mature, they gradually shift from a personal, egocentric stance to an other-oriented moral stance. While this developmental shift in emphasis has support based on questionnaire studies, direct observation and in-depth interviews with children reveal the roots of this other-oriented moral orientation much earlier, even during the preschool years (Myers, 1998). In support of this, interviews with children from Houston, Portugal, and Brazil, all in areas suffering from environmental degradation, showed that concern was widespread and often based on views that environmental harm, especially to wild animals, was morally wrong (Kahn, 1999). Moral development in children should include "eco-morality" as an integral part (Melson, 2013c).

Conclusion: A Childhoodnature Perspective

The ubiquitousness and developmental significance of nonhuman animals has been, by now, well established. It is an artificial distinction to consider children and their environments without the multitude of living beings that share them. Yet, as noted earlier, traditional disciplines, such as psychology and sociology, have not yet transformed from their anthropocentric roots into biocentric disciplines (Melson, 2001). The construct of "childhoodnature" may help stimulate that transformation. This perspective situates children within nature and nature within childhood. Some general guidelines for child development researchers who wish to work within a "childhoodnature" perspective are:

1. Assessment of demographic data on research participants should always include the nonhuman members of households.
2. Social network and social support studies should always consider nonhuman animals as potential network members and support providers. Many instruments ask a variation of the following question: "What people are important in your life?" thereby excluding consideration of nonhumans.
3. Scholars working within an attachment theory perspective now recognize that children form multiple attachments to various individuals. Yet, measurement of pet attachment is not routine.
4. Ecological systems approaches tend to focus on the culturally built contexts of school, peer group, religious organization, or neighborhood. Such studies should always add characteristics of the natural environment, including other living things.

5. As shown in the above discussion of animals and moral development, children are thinking about both human and nonhuman animals in similar ways. This should prompt scholars to include routinely assessments of both.

These guidelines are suggestive only and, hopefully, will stimulate the addition of others. In general, this essay, and others in this volume, urges a "paradigm shift" or new Gestalt, which returns children (and all humans) to the environments in which they evolved, the buzzing, blooming natural world of other living things.

Abstract

Children's relations with other animals in minority (Western) cultures are shaped by a paradoxical socialization process: affective relations with some nonhuman animals (such as "pets") are inculcated alongside norms of exploitation (such as "meat"-eating). That illogicality is central to positive self-concepts of caring for other animals while being complicit in the perpetration of routinized acts of violence against them. Caring and killing share an assumption of human superiority founded on childhood denaturalization, such that nonhuman animals are respectively civilized or commodified through their human encounters. In this chapter, we discuss the development and application of a conceptual model which

"maps" this childhood socialization process. The "map" is populated by research which explores how children are encouraged to compartmentalize nonhuman animals into "types" that legitimate their existing uses, so that those uses are culturally reproduced (Cole and Stewart, Our children and other animals: the cultural construction of human-animal relations in childhood. Ashgate, Farnham, 2014; Stewart and Cole, Food Cult Soc 12(4):457–476, 2009). Cultural reproduction in the mass media, especially Hollywood films, is highlighted in this chapter: the use of anthropomorphized nonhuman animal "characters" in children's films is enduringly popular (four of the top six films at the 2016 worldwide box office feature CGI animal "characters"). Such films invite children to develop affective relations with fictional anthropomorphic animals while diverting concern from real exploited nonhuman animals. Such an approach also reveals the precarity of the socialization process and is therefore suggestive of means for its disruption, especially through the deconstruction of human exceptionalism and the reintegration of children in particular, and humans in general, with other animals as natural beings.

This chapter draws on and continues to develop our theoretical and analytical focus on the socialization of the human use of other animals specifically in the context of childhood in the contemporary West. These uses include food, clothing, sport, entertainment, scientific research, and many other areas of activity relevant to childhood socialization (see Cole & Stewart, 2014, 2016, 2017; Stewart & Cole, 2015). In this chapter we return our focus to mainstream animated movies aimed at children. Nevertheless, our previous research suggests that the patterns, styles, and processes of representation which legitimate and/or obscure the uses of nonhuman animals are ubiquitous in all cultural artifacts targeted at children.

Nonhuman animals are abundantly represented in children's stories in whatever medium those stories are articulated. Children are thereby tacitly constructed as closer to nature, through their willingness to suspend disbelief and inhabit imaginative worlds in which nonhuman animals are subjects on a par with humans. Recognizing other animals as subjects is routine in children's films, and these stories can have powerful, enduring effects on us. However, maturation is partly predicated on denaturalizing children as they grow older, by circumscribing intersubjective relations with nonhuman animal characters as infantile conceits that should be abandoned. Our analyses of these stories therefore consider how narrative traditions contribute to a socialization process whereby children learn to conceptually distance animals they have an emotional-ethical bond with, from animals they eat, wear, or otherwise use. Childhoodnature is therefore currently exploited by the culture industries, but then foreclosed by a socialization process that requires commitment to human exceptionalism.

Popular media artifacts, such as the movies discussed here, are produced in specific social, cultural, and historical contexts and can therefore provide insight into society at a particular place and time (Brennan, 2013). For scholars of Critical Animal Studies (CAS), a close reading of such sources helps us unravel dominant discourses around human-nonhuman animal relations, allowing identification and critical analysis of dominant discourses (see Cole and Morgan, 2011a, b; Morgan & Cole, 2011). That critical analysis is a necessary step toward forging counter-discourses that can disrupt the prevailing exploitation of other animals, linking research with activism in CAS and providing an important ethical motivation for our research. In the course of our discussion in this chapter, we highlight instances where children's movies potentially destabilize dominant discourses and how these might be developed.

In broad terms, those dominant discourses center on nonhuman animals being primarily defined according to their perceived utility to humans. These definitions instantiate human-nonhuman animal relations that are fundamentally skewed toward the favoring of human interests. They have elsewhere been analyzed to generate typologies (e.g., Benton, 1993; Cudworth, 2008; Hirschman & Sanders, 1997), membership of which circumscribes the probable fate of nonhuman animals when they enter into contact with humans. Examples include "wild animals," "pets," "vermin," or "food animals." However, these judgments of utility and category membership are contingent and socially constructed, as demonstrated by cultural and historical variability in the species and individual animals assigned to particular types. As we discuss below, that contingency is also demonstrated by the ways in which filmmakers can and do play with nonhuman animal typologies for comic or dramatic effect, albeit typically as a prelude to their reassertion. Animal typologies are therefore transmitted, we argue, through the diversion of polymorphous and nondiscriminatory affective forms of relation between children and other animals, into culturally defined routes: children first learn to love, but then to use, other animals in line with social norms.

In exploring the ways in which cultural artifacts communicate appropriate practices, or uses, relating to nonhuman animals, we have moved away from using typologies and categories, instead developing a framework that supports a more context-specific theoretical exploration of animal use and its representation (Cole & Stewart, 2014; Stewart & Cole, 2009, 2015). As an analytical approach, the framework we use is informed by our acknowledgment that such categories themselves are a product of practices and discourses rather than providing the starting point for critical analysis of representations. This framework is visualized as a relational typology or conceptual map (see Fig. 1). The map reproduced here is a simplified version of an earlier version (see Cole & Stewart, 2014) and shows how human-nonhuman animal relations are produced through human practices and discourses, in ways which tend to privilege humans at the expense of other animals. In other words, nonhuman animals themselves have little recourse to asserting an independent ontology that evades human use. This framework illustrates the contingency and riskiness of other animals' relationships with humans, by virtue of the differential

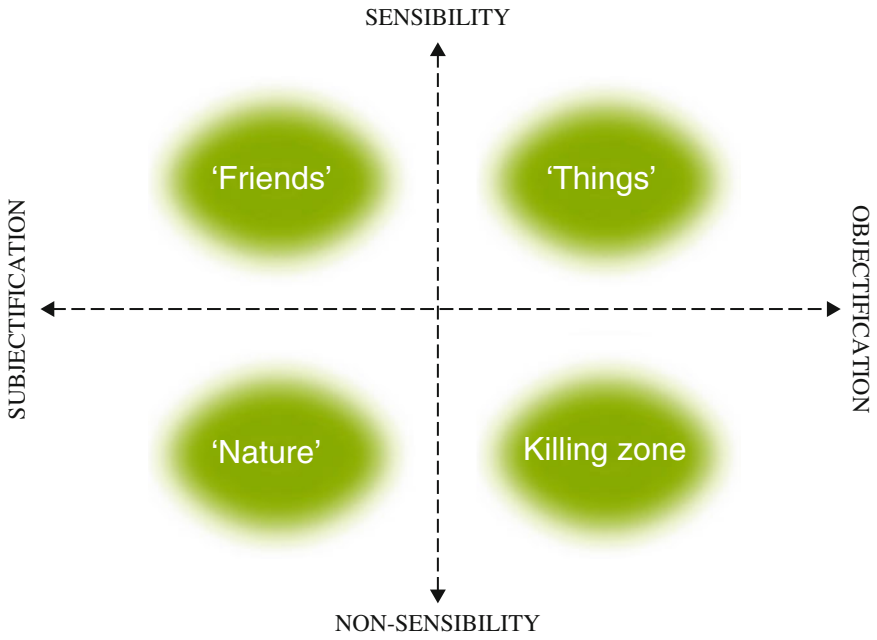

Fig. 1 A conceptual map of the social construction of "other" animals

levels of subjectivity and sensibility afforded them by human practices and discourses.

The framework helps us to identify how different practices and representations shift and interact in different contexts, through the ways in which nonhuman animals are positioned and repositioned. The horizontal axis of the framework represents the extent to which we construct other animals as exploitable objects or as autonomous subjects, or agents. The vertical axis relates to the extent to which different "types" of animals are both culturally and physically sensible (i.e., visible, audible, etc.). The central theme is that Western societies tend to encourage attention and affection for those who need it least – relatively protected animal companions, or cultural representations of animals granted greater levels of subjectivity and/or sensibility – and not on those who need it most: those who are exploited or exterminated in the southeast killing zone of the map.

Methodology

Cultural artifacts and media like films, magazines, TV programming, and games facilitate analysis of the social, cultural, and historical context of their production (Brennan, 2013). For scholars of CAS, these sources provide a useful resource for understanding dominant discourses and practices around human-nonhuman animal relations. In this light, the movies analyzed in this chapter were treated as discursive

documents to be "read," both in terms of the script-as-text and by interpreting the meaning of visual and audio representations on screen. We therefore employed a qualitative analytical approach. This involved analyzing our data with reference to the theoretical framework developed in our previous research and elaborated above (Cole & Stewart, 2014; Stewart & Cole, 2009, 2015). In practical terms, this involved repeated viewings of each movie, independently taking notes before comparing and dialogically refining our interpretations. Particular attention was paid to the ways in which nonhuman animals were situated across the geography of Fig. 1, how they were moved across it, and how they were differentiated from each other in terms of their ethical significance according to their relative positions. Discourse analysis explores how data both describes and performs – content conveys information, but how it is conveyed performs an additional layer of meaning. Thus, discourse analysis shows how versions of the world around us are discursively produced in the way in which information is presented (Silverman, 2015). This approach allows us to analyze exemplars of animal representations in children's culture, with a view to understanding the mass media's role in reproducing our conceptual map.

Conceptually Mapping Childhood Socialization

We have previously applied this conceptual framework in four empirical contexts: the family, education, mass media, and digital media (Cole & Stewart, 2014). Although the focus of this work has been in the UK, much of it is relevant to wider Western society and beyond, especially in light of the globalizing reach of many of the cultural representations of other animals that we have studied. Space prevents us from recapping the full scope of this research, but to place our movie analyses in context, we next briefly review our previous findings in relation to the mass media.

Mass Media

Mass media representations aimed at children are marked by a "cute" style of representation that can also be seen in many of the other areas we have studied, such as representations on clothing or food packaging. These representations are typically of cartoonized anthropomorphized versions of the nonhuman species they are meant to depict: infantilized animals with big eyes, rounded facial features, and expressions subtly distorted to mimic more human appearance. The cutification of nonhuman animals also includes representations of "real" ones in photographs, notably in a genre of UK magazines featuring animals aimed at pre-teenage girls (Cole & Stewart, 2014). The photographs almost exclusively depict infant animals gazing down the camera lens, implicitly giving and receiving adoration with the viewer.

Our previous analyses of films aimed at children that feature nonhuman characters (as very many films aimed at children do) show how these representations

reinforce dominant practices of human use of nonhumans. For example, *The Lion King* (Hahn et al., 1994 and see Stewart & Cole, 2009) clearly reinforces a discourse of a "natural order" where the chief protagonists (with whom the audience are invited to identify) are presented as rightfully and naturally having dominion over other species. Other films we have analyzed (see Stewart & Cole, 2009), for example, *Babe* (Miller, Miller, Mitchell, & Noonan, 1995), communicate a message that it is deviation from "nature" that invites subjectification. Babe's capacity to herd sheep as a unique "sheep-pig" is an example. That is, the appealing quirks of Babe et al. enable them to stand out from the usually massified interchangeable members of their species in the southern regions of Fig. 1. On that basis only are they representationally uplifted toward the northwestern "friends" region of the conceptual map. Our analysis of *Puss in Boots* (Ouaou, Aguilar & Miller, 2011 and see Cole & Stewart, 2012) explores the intersection of these species-related distinctions with discourses that marginalize humans according to gender, race, and class, illustrating how processes communicating subjectivity and sensibility are also mobilized to reinforce patriarchal, ethnocentric, and classist discourses.

Denaturalizing and Renaturalizing Human-Animal Relations in Hollywood Films

In the remainder of this chapter we continue this focus on the mass media and specifically four Hollywood children's films released in 2016 featuring nonhuman animal "characters": *Zootropolis* (Spencer, Howard, & Moore, 2016), *The Secret Life of Pets* (Meledandri, Healy, & Renaud, 2016), *Finding Dory* (Collins & Stanton, 2016), and *The Jungle Book* (Favreau, Taylor, & Favreau, 2016). The discussion of *Finding Dory* is combined with an analysis of its prequel, *Finding Nemo* (Walters & Stanton, 2003). This selection was guided by the commercial success of the 2016 films, all of which featured in the top six at the worldwide box office in their year of release (Box Office Mojo, 2017a). In order, *Finding Dory* took $1,028,570,889 for third position, *Zootropolis* took $1,023,784,195 in fourth, *The Jungle Book* took $966,550,600 in fifth, and *The Secret Life of Pets* took $875,457,937 in sixth place for a combined total of approaching 3.9 billion US dollars. *Finding Nemo* was similarly successful, taking $940,335,536 worldwide for second spot in the 2003 box office league table (Box Office Mojo, 2017b). This scale of commercial success clearly entails a wide viewership, augmented by DVD, Blu-ray and streaming releases of the films for domestic consumption.

Zootropolis

Synopsis

Zootropolis (Spencer et al., 2016, entitled *Zootopia* in some territories) is a CGI animation film depicting a multispecies nonhuman mammal community living harmoniously in an urban environment, albeit one that hosts species-appropriate

habitats such as "Little Rodentia" or "The Rainforest District." The plot centers on the young rabbit Judy Hopps as she pursues her ambition to move from a rural carrot farm with her parents to Zootropolis to become a police officer. The alternate title *Zootopia* alludes to the utopian resolution of interspecies conflict in the city, specifically the cessation of predation, which carnivorous animals have "evolved" past in the film. However, in the course of the film, Judy uncovers and foils a plot to instate a prey hegemony over Zootropolis by the assistant mayor Bellwether, a female sheep. The plot involves drugging members of former predator species, precipitating their atavistic return to "savagery" and thereby justifying their incarceration.

Analysis

The city of Zootropolis is a multispecies melting pot that echoes the human ethnic diversity of an idealized US metropolis, populated with immigrants with multiple trajectories but who all find a home within it. It also models the American dream, as Zootropolis is a place "where anyone can be anything." The species of different characters do not confine them to a single stereotyped destiny, exemplified in Judy Hopps' turning her back on the safe option of remaining a carrot farmer with her parents. This identity fluidity is arguably intended to be a point of identification and inspiration for the human audience and especially to ease the growing pains of children who may be experiencing bullying, discrimination, or the stigmatic application of outcast identities. Judy is shown as having been subject to bullying by the fox Gideon Grey in childhood, who physically and verbally intimidates her, including taunts about the pre-evolution predation of rabbits by foxes. Judy Hopps' determination and success therefore defies her species stereotyping as merely "cute" and ineffectual and models the capacity to transcend othering processes. For instance, on arrival at her police precinct, Judy is greeted by Benjamin Clawhauser, a cheetah who admiringly says, "I've gotta tell ya you are even cuter than I thought you'd be." Judy replies, "you probably didn't know but a bunny can call another bunny cute but when other animals do it, that's a little. . .." The sentence is left unfinished, but the audience is invited to transpose the implied "speciesism" to "racism" and/or "sexism" given Judy's species uniqueness as a rabbit police officer and her female gender. Judy is therefore fully aware of her species identity and the demeaning stereotypes that have been applied to it, but asserts her right to define herself nonetheless. Similarly, she later declares that, "I'm not just some token bunny," riffing on the tokenism deployed in an attempt to placate and defuse various social movements throughout the history of progressive politics. Clawhauser himself subverts an image of cheetahs as dynamic and athletic by being portrayed as a stereotypically obese doughnut-loving police officer, but one with a distinctively camp persona.

Judy is also an empowering figure for others in the film, notably the fox character Nick Wilde. Wilde's surname highlights his outlaw status as a petty criminal, but also his resignation to species stereotypes as inescapable destiny. As he says to Judy, "you can only be what you are [. . .] sly fox, dumb bunny." Nick's resignation is later revealed as a consequence of his having been the victim of anti-predator bullying

and subject to labeling with stereotypes of foxes as shifty and untrustworthy. After being enrolled as an initially reluctant co-investigator by Judy, Nick ends the film having realized his capacity for self-actualization and transcending the limitations of the "sly fox" stereotype. As Judy insists, "you are so much more," an assertion that pays off at the end of the film when Nick has become a police officer and is teased by Judy with a "sly bunny, dumb fox" one-liner. As such, Nick models a path to redemption through cooperating in the restoration of the social order of Zootropolis.

Zootropolis therefore models the denaturalizing of intra-human difference, and thereby an anti-essentialist message, but uses nonhuman animals as ciphers for doing so. This is a less threatening option in a film targeting a young audience than directly confronting racism, sexism, etc., but it also means that the implications it has for speciesism are not developed as they could, arguably should, be. For example, Judy's appearance remains circumscribed by "cute" style, such as her outsized forward-pointing blue eyes and a figure based on a woman as much as a rabbit, with a bipedal gait, prominent hips, and a bustline under her police tunic. There is an echo of the highly sexualized cartoon rendering of Jessica Rabbit from *Who Framed Roger Rabbit?* (Marshall, Watts, & Zemeckis, 1988) which in turn played on the *Playboy* bunny motif and sexualized "bunny girl" outfit. The feminizing of rabbits simultaneously cutifies the species as a whole and women by association in cultural representations. By contrast, the male rabbit characters of Roger Rabbit or Bugs Bunny are markedly non-sexualized. In other words, Judy is resisting a patriarchal-speciesist nexus that predates (pun intended) the film and which is divorced from the "nature" of real rabbits. But she does this within the film without contesting the sexualized feminization of rabbits, or in other words, without undermining the anthropomorphic appropriation of rabbits as human cultural symbols. To contest the distribution of rabbits across Fig. 1, *Zootropolis* would need to portray rabbits as contesting their misrepresentation as human cultural symbols and to assert their nonhuman animality, their "rabbitness."

Other animals remain circumscribed by stereotypes with little hint of their capacity for fluid identity transformations. At the extreme, the film abominates skunks when Nick is upbraided by Mr. Big, a comically diminutive arctic shrew portrayed as a Godfather-mafia character, for selling him a fake woollen rug made from "the fur of a skunk's butt." This is an exceptional instance of the film objectifying nonhuman animals and alluding to real-world violence against them, although it is possible to imagine that the filmmakers intended the rug to evoke the shearing of a skunk rather than the execution and skinning that is integral to the fur industry. This is not to deny the exploitative character of the sheep's wool industry, but to acknowledge its representation in children's culture as unproblematic, notably in the Oscar winning CGI animation film *Shaun the Sheep Movie* (Kewley, Lockhart, Burton, & Starzak, 2015) and also through the presence of sheep characters like Bellwether within *Zootropolis*. The film largely avoids representing food consumption by its characters and therefore suppresses the problem of explaining what (or who) obligate carnivores eat in Zootropolis, implying their transition to a largely plant-based diet. Nick himself describes blueberries as delicious near the end of the film. "Nonviolent" food consumption is alluded to by the presence of a juice bar in

the railway station, the selling of ice cream in a shop staffed by elephants, a brief appearance of a "Frozen Yakcurt" shop, the frequent appearance of doughnuts, a bakery operated by the adult Gideon Grey, and fresh vegetables sold by Judy's parents. Clawhauser's first appearance shows him eating a bowl of cereal called "Lucky Chomps," depicted in milk. The expropriation of milk and eggs in "dairy" or baked goods is absent from the narrative, so the film does not have to explain how, for instance, cows or hens are able to be "anything" when they are still being exploited. The Frozen Yakcurt shop suggests a yak-based dairy industry, but only a male yak – Yax – appears as a character in the film. Notably neither cows nor chickens are represented as characters in *Zootropolis*. The absence of hens is explicable in the mammals-only speciesist line drawn in Zootropolis. This is also hinted at in the fleeting appearance of a large building with a sign proclaiming "Fishtown Market" and a smaller one signed "Clarks Halibuts" in the Tundratown district, suggesting the consumption of fishes by its mammal inhabitants. The species logic of Zootropolis collapses altogether with the appearance next to Fishtown Market of a restaurant called "Blubber Chef," suggesting the killing and consumption of whales. Zootropolis therefore retains a southeastern killing zone from Fig. 1, which is almost as tricky to spot as it is in the nonfictional world.

The irony of the denaturing effects of anthropomorphism is exposed for comic effect by Yax, a yak proprietor of a naturist club that Judy visits in the course of her investigation. In relation to the presumed weirdness of naturism, Yax comments that, "you know what I say is weird? Clothes on animals!" As he speaks, an unclothed elephant and giraffe are shown engaged in a yoga routine. So, their "natural" nudity is undercut by their anthropomorphic performance of a human cultural practice. The fact that the inhabitants of Zootropolis have "evolved" entails that they have become uplifted toward an approximation of humanity. It is their very civilization which makes naturism worthy of comment and defense by Yax. The cultured and herbivorous yoga practitioners contrast with the "savagery" of the atavistic carnivores as the plot develops. The investigation leads Judy and Nick to an interview with Mr. Big, who asserts that, "we may be evolved, but deep down we are still animal," with "animal" being a signifier of irrationality and violence. Mr. Big's warning of atavism is fulfilled by the drugged otter Mr. Otterton, who is described by Mr. Manchas, a jaguar chauffeur attacked by Otterton, thus: "he was an animal, down on all fours, he was a savage." Manchas himself is soon revealed as having been drugged and is described by Judy as a "jaguar gone savage" when he falls to all-fours and attacks them. The equation between animality and irrationality is highlighted by Nick when he accusingly asked Judy whether "you think I might go nuts?"

In summary, *Zootropolis* offers a surface subversion of stereotyping and othering processes and a celebration of the capacity to transcend inequality and freely construct identity. There is a limited disturbance of speciesist constructions of nonhuman animals in Fig. 1, such as the meta-commentary on "cute" style and the inversion of "sly fox, dumb bunny." However, in the main the film depends on the reproduction of stereotypical constructions of nonhuman animal characters: it reduces them to ciphers to facilitate the exploration of the experiences of growing

up and the problems of maintaining orderly diverse human communities. Meanwhile, nonmammalian animals in particular (and some mammals in the case of whales and "dairy" cows) remain thoroughly objectified as "food" but are otherwise absent. The movie ironically subverts childhoodnature as Zootropolis is a purified urban space. While it plays on the ubiquity of nonhuman animal representations in children's culture, it anthropomorphically domesticates them, rather than capitalizing on their potential to encourage children to empathize with nonhuman (as well as human) others. Zootropolis is anything but a peaceable interspecies community, but instead is a metaphorical representation of a utopian human community purged of nonhuman others.

Finding Nemo/Finding Dory

Synopsis

Finding Nemo (Walters & Stanton, 2003) and its sequel *Finding Dory* (Collins & Stanton, 2016) are CGI animation films in which the titular fishes are captured and imperilled and whose whereabouts are sought by their nonhuman friends. In the original film, after capture by a diver, the clownfish Nemo is confined in a tank by a dentist as a gift for his uncaring daughter. Nemo is sought by his father Marlin and Dory, a blue tang, who he meets en route. In the sequel, Dory, aided by Nemo and Marlin, seeks out her long-lost parents at a Marine Life Institute.

Analysis

Although *Finding Nemo* is 14 years old at the time of writing, the appearance of a sequel in 2016 makes its analysis highly relevant. As well as featuring characters in common and a similar visual style and plot, the sequel stimulates renewed interest in its predecessor, as well as providing an opportunity to package and sell the two films together for home release. It is also possible to discern continuities and differences between the two films.

Both films share overt problematizations of human-nonhuman animal relationships, especially in terms of critiquing the captivity of aquatic creatures as unnatural and contrary to their interests and wishes. *Finding Nemo* includes a moral lesson in the form of Darla, the daughter of the dentist who keeps Nemo in a tank in his surgery, along with other aquatic creatures. Darla is described as a "fish killer," whose curiosity and fascination for fishes is not matched with sufficient empathy to avoid harming them. There is an implicit invitation for young viewers to disidentify with Darla and eschew maltreatment of fishes. Furthermore, Gill, one of the other captives in the tank, asserts that, "Fish aren't meant to be in a box," and a key plotline in the film involves the fishes plotting their escape from the tank. However, the admonishment to not mistreat fishes presupposes contact with them in situations of power where maltreatment is a possibility. That may well include the potential for both films to stimulate desire for the keeping of "exotic" fishes despite Gill's assertion, as well as the desire to spectate them in captive environments such as "aquaria." The latter is immodestly confirmed by a filmmaker in the *Finding Nemo*

home release additional features: "internationally it's in the lexicon of aquarium viewers now" (i.e., the clownfish species of which Nemo is a representative). In *Finding Dory*, there is an attempt to partially redeem this risk in the critical representation of a "touch pool" at an aquarium, a shallow enclosure designed for young children to be able to lean over and touch aquatic animals under water. The experience is portrayed as painful for the fishes, who struggle to avoid being touched by human hands. Furthermore, Claire Parkinson (in press) reports that the writers of *Finding Dory* adjusted the script to be more critical of captivity in the wake of the *Blackfish* (Cowperthwaite, Oteyza, & Cowperthwaite, 2013) documentary, by replacing a SeaWorld style attraction with a Marine Life center that operated under a "Rescue, Rehabilitation, and Release" slogan. The film adds a further layer of environmentalist critique absent from *Finding Nemo*, in that Dory is initially caught in a discarded plastic can holder. The defilement of "nature" is highlighted as another moral lesson for the viewer.

The signs of progress in *Finding Dory* may also be found in its downplaying of fishes as food for humans compared with *Finding Nemo* while retaining a theme of fishes as potential food for other animals that injects dramatic tension. The latter is of course justifiable, and even the simplistic claim that "we all know nature's a predatory world" by a filmmaker in the *Finding Nemo* home release additional features acknowledges the reality of the risk of predation in nature. However, predation in the films is represented as a threat to the survival of *subjectified* characters and therefore all the more horrific. Meanwhile, the representation of fishes as human food depends on their objectification, that is, their limited screen time and relative lack of characterization, which therefore does not attract an equivalent response of revulsion. The film's principle characters are not members of species typically consumed by their majority Western audience. While the latter are not personified in *Finding Nemo* and do not invite empathy to the same degree as the "exotic" Nemo et al., there is the potential to transfer empathy to their real counterparts in the oceans. For instance, near the end of *Finding Nemo*, the sight of an approaching fishing trawler is met with screams from fishes who swim away from the net in panic. A shoal is nevertheless caught, but then encouraged to swim downward in unison, which is an act of collective resistance that rips open the net and allows them to swim to freedom. Here, the intervention of a CGI representation facilitates the crossing of the meridian of Fig. 1 from the southeastern "killing zone" to the southwestern "nature" zone. The uplifting of fishes into the upper reaches of the northwestern region is however foreclosed by their massification and relative lack of subjectivity and initiative compared with the "exotic" film characters.

This scene, perhaps more than any other in either film, opens the possibility of genuine challenge to the normality and acceptability of the human consumption of sea-living animals. That is, while *Finding Dory* does not reproduce conventional human consumption practices of aquatic animals, neither does it do much to explicitly contest them. An exception is a passing concern expressed by Marlin that they might be en route to a restaurant and therefore implicitly be at risk of consumption. Meanwhile, the practice of "factory fishing" is portrayed in *Finding Nemo* as decidedly unnatural, destructive, and terrorizing. However, the overt

connection between this nightmarish construction and mundane consumption practices is not made. For example, earlier in the film a seaside restaurant is depicted in the background with a sign advertising, "Hot Dogs Snacks Fish n Chips Cold Drinks." Human consumption practices are also voiced by aquatic creatures when "where's the butter" is a clue given to Dory and Marlin by a shoal of fishes who organize themselves into the outline of a lobster in a guessing game. The use of "dairy products" and cooking underwater are of course nonsensical, but together with the sign, it undercuts the problematization of the objectification of aquatic animals and positions them in the southeast "killing zone" of Fig. 1 alongside land animals killed for "hot dogs" or exploited for "dairy." The critique of "factory fishing" is also allowed to stand as an exceptionally objectionable practice that still leaves room for welfarist constructions of "humane" fishing practices to survive unremarked and uncritiqued. The undercutting is completed in the home release additional features, in which a filmmaker group reminiscence about the film's production and reception includes the joking report that, "I'm still getting emails of sushi and Nemo." More telling still is the recollection that, "the number one question we were always asked is if we were going to have sushi at the wrap party [. . .] which we did." There is scant reason to assume that the filmmakers had emancipatory intentions in creating *Finding Nemo*.

Although *Finding Dory* does not include an equivalently direct critique of "fishing," it does mark the captivity of aquatic animals as morally questionable: "it's our [a rescue centre] goal that any animal we rescue will eventually be returned home, where they belong." This explicitly repositions such animals in the southwest zone of "nature" and not as captive entertainment in "aquaria," as 'pets', or as (human) food. The assertion of freedom is more poetically evoked by Bailey, a captive Beluga whale, who opines that, "there are no walls in the ocean," and is graphically represented in the tortured experience of the "touch pool" described above. As Parkinson argues (2018), the character of Bailey is also significant for deploying echolocation to outwit humans and in so doing tempering anthropomorphism with a "specie-specific trait" that emphasizes difference from humans, but not thereby inferiority.

In *Finding Nemo* and *Finding Dory*, the degree of cutification of nonhuman animals is central to their relative subjectification. As we discussed in relation to its use in mass media representations of nonhuman animals, cutification entails a distinctive style of childlike anthropomorphic representation. This includes oversized humanlike eyes, a range of quasi-human facial expressions, and the capacity to speak in human language. This is in spite of the claim made in the additional features on the home release of *Finding Nemo* that "he [the director] didn't want overly anthropomorphized fish." In a pivotal scene near the end of *Finding Dory*, road traffic is literally stopped by the adoption of cute poses in a "cuddle party" by a lineup of otters in the road. The otters in turn forgo the predation of the "cute" subjects Dory et al., one of them cuddling Dory herself in this scene. Contrastingly, nonhuman predators are represented as more or less monstrous. Early in *Finding Nemo*, the cute clownfish are menaced by a predator fish who roars, but does not

speak. Later on, a deep-sea angler fish also roars threateningly without speaking. Likewise, early in *Finding Dory*, a squid attacks and also lacks the subjectifying characteristic of a voice. Predation is thereby portrayed as uncivilized, animalistic, and barbarous, and therefore there is a disidentification between the audience and "natural" carnivory of living and "raw" prey.

The civilizing of carnivory is represented by the greater subjectification afforded to a predator self-help therapy group of three sharks, led by Bruce, a great white. The sharks are anthropomorphized, but more adult and thereby less cute than the films' heroes. Bruce voices his desire to reidentify as a cultured and civilized subject: "I am a nice shark, not a mindless eating machine. If I am to change this image, I must first change myself. Fish are friends, not food." The therapy session jokingly evokes the demonizing media construction of sharks exacerbated in popular culture by *Jaws* (Zanuck, Brown, & Spielberg, 1975) and its sequels. Bruce goes on to announce that "today's meeting is step five: bring a fish friend," but his instinctive carnivory is aroused by the scent of blood in the water when he excitedly declares, "I'm having fish tonight!" The scene also jokingly exposes the cutification process. The hammerhead shark's rejoinder to Bruce's assertion of fish as friends is "except stinking dolphins," to which the other shark adds, "Dolphins! Yeah they think they're so cute." The sharks' struggles to suppress their natural appetites are contrasted with the unrestrained predatory greed of a flock of gulls who menace Marlin and Dory. Massification, a common technique used to deindividualize and desubjectify nonhuman animals (such as the stampeding wildebeest in *The Lion King*), is here deployed to construct predation as mindless and animalistic. The gulls also lack human speech and are relatively uncutified. Their utterance is restricted to a growing cacophony of "mine!" as they approach potential prey, signaling their collectively expressed selfish greed. There is an interesting contrast here with the more usual tendency to massify herbivores and elevate the subjectivity of carnivores, as also to be found in *The Lion King*. The abomination of the gulls is compounded by Nigel, a subjectified stork who rescues Marlin and Dory, who accuses the gulls of being "rats with wings," discursively condemning them to the "killing zone" as "vermin."

This pair of films then obliquely invokes childhoodnature, especially through the problematization of abusive child-nonhuman animal relations in the figure of Darla in *Finding Nemo* and the "touch pool" in *Finding Dory*. That is, they critique the construction of fishes as spectacles or objects of amusement, by which children are estranged from nature. Ironically, they do so within movies that depend on the construction of certain charismatic aquatic animals as colorful spectacles and, as conceded by the filmmakers, contribute to the "lexicon of aquarium viewers."

The Secret Life of Pets

Synopsis

The Secret Life of Pets (Meledandri et al., 2016) is a CGI animation film in which anthropomorphized and cutified "pets" in a contemporary urban US setting (New York) are able to converse with each other in English, although humans

only hear them making nonhuman vocalizations (such as barking) rather than speaking any human language. The "pets" are depicted as enjoying a "secret life," while their human companions are absent during the working day, socializing and using domestic appliances, for instance, a poodle using a stereo to indulge a liking for heavy metal music. The narrative centers on Max the Jack Russell Terrier, who is upset by the arrival of Duke, a rescued mongrel, into the household he shares with his human owner Katie. The initial schism between the dogs is gradually healed through the course of the film. They are captured by an Animal Control patrol, incidentally rescued by a gang of abandoned "pets," before in turn escaping the gang who turn out to be bent on revenge against humans and traitorous willing "pets." Meanwhile, their friends (other "pets" in their neighborhood) search for them. The film climaxes with the abandoned "pet" gang and Max and his friends uniting to thwart the Animal Control officers and being returned to human "owners" and willing "pet" status.

Analysis

The Secret Life of Pets (Meledandri et al., 2016) has an overt moral message for viewers about the importance of treating "pets" with care and of not allowing them to be abandoned to the precarity of the pound. Loving relationships with animal companions are positively modeled, while abusive or neglectful relationships are portrayed as damaging. The former bookend the film: an early scene in a park shows dogs enjoying walking with their human companions, and the central protagonist, Max the Jack Russell terrier, describes his relationship with his human companion Katie as, "[. . .] love stronger than words." At the end of the film, a montage plays out in which humans return to their homes to be joyfully reunited with their animal companions. Abusive relationships are represented by a group of "flushed pets" who are alienated from humans as a result of their prior maltreatment and seek violent revenge. As the leader of the flushed pets, Snowball the rabbit, puts it; "our primary mission – the downfall of the human race." The "flushed pets" therefore exhibit a "wildness" in terms of rage and violence – they are depicted as driven by irrationality, to the point of an obsessive mental instability. For example, Snowball describes a "flushed" viper as, "fueled by a diet of anti-human rage," and it is notable that the raging viper does not speak. Despite their anthropomorphism then, the "flushed pets" are discursively positioned toward the southwest of Fig. 1, as threats to the owner-"pet" domestic order, similar to the construction of urban foxes discussed earlier. By contrast, the heroic "pets" who have not been abused in the film remain civilized by their association with humans and seek to avoid violent confrontation. In both respects, however, the character of nonhuman animals is shaped by their relations with humans, foreclosing the thinkability of their having independent lives as free-living beings: the "flushed pets" seek revenge rather than escape to a human-free utopia. All nonhuman animals are therefore enclosed within the terrain of Fig. 1. The dramatic narrative of *The Secret Life of Pets* inheres in the disturbance and restoration of the conceptual map in Fig. 1. The transgressive positioning of nonhuman animals in "the wrong place" (both the "flushed pets" and the civilized "pets" while separated from their human owners) introduces a tension that is

resolved by their conventional repositioning at the end of the film – the beneficent reuniting of both flushed and civilized "pets" with humans.

However, the drama re-models the real-world conceptual separation of legitimate nonhuman victims of human violence (especially "food animals") from legitimate nonhuman recipients of human "care" (especially "pets"). This is illustrated early in the film when Chloe the cat is shown eschewing the "cat food" left by her owner and instead eating a cold roasted chicken from the refrigerator, followed by a cake. The separation is reproduced by imputing a humanlike agency to Chloe – indulgence of hedonistic pleasure in eating and especially in eating nonhuman animals (with nothing to indicate a vegan householder, we can read the cake as including hen's eggs and cow's milk, butter or cream as well, in line with the conventional omnivory among the intended audience). There is a point of identification made between the human viewer and Chloe – "we" can recognize her appetite for consuming nonhuman animals in the same form that "we" do, rather than in the impoverished form of "cat food." This is compounded by the later fleeting appearance of remnants of chicken's wings, as well as a pizza, as a meal having been consumed by a sleeping human in an apartment that the "pets" run through. The twin scenes of Chloe and the sated sleeper communicate the pleasures of gluttony on nonhuman flesh, as long as that flesh is disconnected from the nonhuman animals it was taken from (living chickens do not appear in the film). The agency of real "pets" is therefore dragged northwestward toward the position occupied by humans, by means of the intervention of the anthropomorphic representation of Chloe. At the same time, chickens are thoroughly objectified, so that the representation of the bird compounds the objectification of real chickens – in this case the representations intervene to reproduce the cultural visibility of consumable dead animals while distracting attention from real exploited animals.

Later in the film, Max and Duke stumble upon a sausage factory while on their way to finding the home of Duke's previous owner:

> Duke: "sausage [. . .] you smell that? Sausage!"
> Max: "We're coming for you baby!"

Max's excited promise imputes agency to the objects of his desire, as if they could be satisfied and fulfilled by this response to their allure, and subtly reproduces the heteronormative mingling of gustatory with erotic pleasure. As Carol Adams (2004) has extensively documented, the association between the flesh of nonhuman animals and the bodies of women is frequently linked in Western cultural representations and especially when targeted at imagined male consumers. In this case, the diminutive "baby" uttered by Max connotes a sexually desirable young woman, despite the ironically phallic associations of sausages. The factory is called "Weiner Kingdom" (weiner also being common US slang for penis), and the factory sign is adorned with a logo of an anthropomorphized smiling sausage wearing nothing but a golden crown. The kingly status of weiners reinforces their gendering as masculine food, but nevertheless they are feminized as objects of consumption later in the scene, as described below. On entering the factory, Max and Duke are confronted with an

overview of the production process: "meat" (uniform neat cuts) hanging from conveyors is dropped into a mincer and then formed into sausages by another machine, on which the dogs begin to gorge themselves. The process by which nonhuman animals are fragmented into "meat" is absent, so that flesh is dissociated from killing and butchering, stifling sensibility of the southeast region of Fig. 1.

As they eat voraciously, the dogs begin to hallucinate the sausages coming to life: a clothed sausage appears and beckons the dogs with the words "Come on boys" into a fantasy sausage theme park populated with singing and dancing sausages, leading Duke to exclaim "holy schnitzel!" The sausages are singing "We go together," the closing song from the musical film *Grease* (Stigwood, Carr, & Kleiser, 1978). The invocation of *Grease* emphasizes the celebration of Americana in *Secret Life*, not least through the association of "meat"-eating (especially hot dogs) with US culinary, cultural, and heteronormative masculine identity. The same articulation is made in the R-rated CGI animation *Sausage Party* (Ellison et al., 2016), in which personified "fancy dog" sausages are packaged on a US Independence Day display (Cole & Stewart, 2018). In this case, the protagonist sausages themselves are icons of heteronormative masculinity who become aware of their fate as human food, but unaware of their previous existence as nonhuman animals. The fantasy *Secret Life* sausages do not attain even that limited consciousness: while one band of sausage singers perform on stage (dressed in hula skirts made from gherkins and thereby feminized), Max and Duke appear – Max bites off one of their heads, while Duke swallows the others whole, without the song being interrupted or any alarm being expressed by these or any other sausages – a decapitated sausage continues to dance. The camera then sweeps across a bridge populated by sausages feminized by wearing bikinis fashioned from yellow mustard – the sausages leap into the river as if evading the onrushing dogs – a unique expression of alarm in the scene, though their alarm might equally be read as meta-alarm at the intrusion of the camera itself. A dancing line of sausages then walk into Duke's mouth while he lays on his back, before the dogs are shown falling into a huge bowl of inanimate sausages, while animate sausages continue to sing and dance around the bowl. At this point the sausages repeat the refrain "we'll always be together" from the end of the song: the shared experience of gluttony cements Max and Duke's burgeoning friendship, but also the song asserts that the consumption of nonhuman animals will always be a part of their lives. While the lyrics might symbolize Max and Duke's relationship, it is the fantasy sausages who are singing it and who are implicitly included in the "we" being referred to in the lyrics.

The scene recalls medieval fantasies of the Land of Cockaigne, pseudo-utopian stories in which food (including "animal products") falls from the skies into the mouths of supine gluttons, relieved from the troubles of labor and deprivation. Such tropes may be interpreted as escapist relief from the reality of class inequality and exploitation while reproducing species inequality. In *The Secret Life of Pets*, a similar reading is available, and it may even have a critical undertone, as it makes visible the extent to which animal companions' appetites are subject to strict human control and their lack of freedom to feed themselves as and when they wish. However, Weiner Kingdom supplies unlimited satisfaction only on the basis of the

representationally suppressed killing of other nonhuman animals, as well as asserting that "pets" have food preferences that align with those of their owners – they are enrolled as unwitting co-producers of the discursive terrain of Fig. 1. If Weiner Kingdom is a version of the Land of Cockaigne, it is a fraud, one in which nonhuman subjugation continues unabated and unrecognized even while it welcomes valorized nonhumans into its utopian world. Furthermore, the dogs' hallucinatory departure from reality dramatizes their irrational inability to control their appetites, contrasting with rationality as the defining characteristic by which human exceptionalism is culturally asserted and which legitimates the human control of "pets."

It is difficult to assign the "meat" in Weiner Kingdom to any specific species due to its generic appearance in the factory scene, but it is notable that species commonly butchered to produce sausages such as cows are absent from the film. Predatory threat toward nonhuman animals is only represented *between* nonhuman species, not from humans, notably by a domesticated hawk named Tiberius toward Gidget, a female Pomeranian who is romantically attracted to Max. As a dog, Gidget avoids the risk of reminding the audience of the fates of species conventionally consumed by US audiences. When meeting Gidget, Tiberius struggles to suppress his "killer instinct":

> 'You're sweet too [. . .] but not too sweet. There's also a salty gamey thing going on [. . .] You're a very thoughtful food. Food? I didn't say that. I said friend.'

Tiberius succeeds in asserting self-control as he increasingly acknowledges Gidget as a fellow subject rather than an object/prey, according with the audience's pre-existing disposition to afford some measure of subjectivity to dogs. The threat to Gidget is defused and exploited for comic effect. However, a more critical reading is possible: Tiberius could be argued to model the enduring affective dividend from constructing nonhuman animals as "friends," usurping the transitory pleasures of constructing them as "food." This more critical reading opens up a path toward restoring childhoodnature, as against the use of nonhuman animal representations to reassert their radical difference and distance from the child viewer as "types" in Fig. 1. Such a reading is tenuous though, as *Secret Life* as a whole asserts the normality of encountering nonhuman others primarily as genetically manipulated, denatured, subordinate companions, in human-dominated urban space.

Despite the absence of representations of living cows or chickens, the film does include a pig character named Tattoo as one of the "flushed pets." Tattoo is so named because "I lived in a tattoo parlor, the trainees used to practice on me. Until they ran out of space." One of the tattoos alludes to the fate of the majority of "domesticated" pigs: "right rump" is tattooed onto Tattoo's backside, which may suggest his relegation to the killing zone given the exhaustion of his usefulness to the tattooists. Other than this, his unusual former life in a tattoo parlor repositions him *away* from the southeast of Fig. 1 and therefore away from associations with

sausages that might disturb his promotion to the northeastern region as a character. That is, Tattoo is not given a backstory of escape from a factory farm or slaughterhouse, which would force audience confrontation of the objectification of real-world pigs, much as *Babe* achieved. Tattoo is a vengeful "flushed pet" because of his misuse in an entertainment context, if we interpret the use of tattoos in contemporary urban contexts as primarily driven by the construction and performance of identity through consumption practices. He shares this position as an "entertainment" animal (albeit a particularly lowly one) with Snowball, who recalls being "a magician's rabbit" when asserting that all of the "flushed pets" have "suffered at the hands of man" in a speech to Max and Duke: "[. . .] humans say they love us. But then they turn around and throw us out like garbage." Snowball's anger is depicted as justified, albeit exaggerated, and thereby the message is reinforced to the audience to treat "pets" well and to eschew their reductive positioning as objects of "entertainment," but decidedly not to forgo "pet-keeping." There is an irony in the CGI characters being created precisely so as to entertain, and of course the entire film reasserts how "entertaining" "pets" are for their human companions, albeit in conditions of domesticity rather than as unwilling laborers for tattooists or magicians.

This is compounded by the portrayal of the violent "wildness" of the "flushed pets" and, by implication, of real-world animal liberationist activism. Snowball first appears engaged in direct action to rescue his colleague Ripper, a bulldog, from the Animal Control van in which Max and Duke are also imprisoned. After effecting the rescue of Ripper, Snowball excitedly outlines his ideology: "The liberation has begun! Liberated forever! Domesticated never!" He goes on: "We are flushed pets, thrown away by our owners, and now we are out for revenge. It's like a club, but with biting and scratching," and later, "long live the revolution, suckers!" Max implores Snowball to "take us with you," but Snowball resists: "I don't think so, pets. Yeah you got the stench of domestication all over you." Snowball later denounces Max and Duke as "leash lovers" when instructing the viper to capture them. The viper is squashed and killed in the melee as Max and Duke escape, upsetting and further enraging Snowball. It is noteworthy that the viper is constructed as monstrous, mute, and therefore killable in the film, unlike the voiced nonhuman characters. The campaign against "domestication" is therefore perpetrated by irrational, violent, embittered individuals who are ultimately pacifiable by being re-pettified and finding their place once more within Fig. 1.

In summary, *The Secret Life of Pets* reaffirms the status quo of human-nonhuman animal relations, tempered by gentle welfarist critiques of misuses of nonhuman animals for entertainment and admonishments to provide them with the love and care they deserve as "pets." The proper place for nonhuman animals in children's consciousness is as denatured subordinate companions, not as free-living beings, and definitely not as exploited, confined, and killed victims. As Max says to Duke of his erstwhile owner (an elderly man who they discover had passed away rather than abandoned Duke to the pound), "of course he liked you, he was your owner." Without their "owners," nonhuman animals are depicted as being at risk from regression to violence and irrationality. The duty

incumbent upon humans is to attend to their duties as civilizing carers, uplifting their companions into a sentimentalized domesticity. It is through this assertion of a civilizing duty that childhoodnature is subverted, as human ontology is constructed as removed from nature, exclusively occupying the northwestern terrain of Fig. 1.

The Jungle Book

Synopsis

The Jungle Book (Favreau et al., 2016) is a CGI remake of the famous 1967 Disney animation and adaptation of the 1894 story by Rudyard Kipling. The film traces the coming of age of Mowgli, an orphaned boy discovered abandoned by Bagheera, a panther. Bagheera leaves Mowgli in the care of a wolf pack, who raise him as one of their own. The pack and the other animals are menaced by the tiger Shere Khan, and it falls to Mowgli to lead a resistance against and finally overthrow him. Unlike the 1967 version, the 2016 film ends with Mowgli rejecting a return to a human village after vanquishing Khan and choosing to stay with the other animals instead, overtly asserting childhoodnature in a way that none of the other films analyzed above do.

Analysis

The realistic aesthetic of *The Jungle Book* makes it visually distinct from the more cartoon style of the other four films, albeit a realism undercut by anthropomorphism such as the use of human language by some nonhuman characters and fantasy elements, such as the gigantic size of the orangutan antagonist King Louie. The film does however share a theme of problematizing and civilizing predation. All four films tackle the issue with (sometimes comically) monstrous constructions of predation: the regressively "savage" carnivores in *Zootropolis*, the viper and Tiberius the hawk in *The Secret Life of Pets*, the deep-sea angler fish in *Finding Nemo*, the squid in *Finding Dory*, and most threatening of all, Shere Khan the tiger in *The Jungle Book*.

Shere Khan is constructed as a moral threat to the "law of the jungle" because of his pursuit of power as an end it in itself, exemplified in the charge leveled at him by Raksha the wolf, Mowgli's adoptive mother: "Hunting for pleasure, killing for power." For the other hunters, predation is civilized by the jungle law which can suspend carnivores' right to hunt in certain circumstances. For instance, the law dictates that "hunting is forbidden" at the "peace rock," a watering hole where all species can gather and drink free from the threat of attack. Khan is a transgressor of this natural law and is also revealed as being the killer of the infant Mowgli's human father. Raksha's indignation at Khan signals the wolves as more civilized hunters, though their own hunting also depends on an othering process that is less obvious to the audience in that it does not involve the explicit denial of subjectivity that Khan's degendering of Mowgli accomplishes. For example, early in the film the wolves want to "get the deer" and suggest, "let's go chase some mice." These predatory instincts are used to highlight Mowgli's difference: "I realise you weren't born a

wolf, but couldn't you at least act like one?" Mowgli's liminality is set in motion here, not quite in place within the wolf pack, but also estranged from human society – childhoodnature is a problematic construction. The deer and mice share no such liminality of course; they are othered as prey by the wolves through being massified and undifferentiated. Neither species are granted anthropomorphic subjectivity in the film, lacking voices, names, or individual characters. *The Jungle Book* shares this construction of herbivorous "prey" animals with *The Lion King*, most clearly in the strikingly similar stampede scenes in each film. In the latter, Simba the cub narrowly evades being trampled by stampeding wildebeest; in the former Mowgli escapes from Khan by jumping onto and riding a stampeding buffalo. No members of either herd speak, bear names, or are constructed as distinct individuals with a narrative trajectory in the films. It is examples such as these which typically attenuate the subjectivity of herbivorous, or we might say vegan, animals relative to more charismatically constructed carnivores or omnivores in children's films. As discussed above, the subjectivity of carnivores may also be attenuated in order to other them as threats to human or nonhuman protagonists, but their very threat still represents a greater degree of agency than massified herbivorous herds. The very capacity to threaten or consume others is itself a marker of subjectivity; that is, the exercise of power is represented as the capacity to both act as an autonomous subject and to constrain the autonomy of others.

Predation also assumes a monstrous and both literal and metaphorical constraining form in the python character Kaa (it is Kaa who reveals Khan's responsibility for his father's death to Mowgli). Khan's anthropomorphic construction is heavily gendered, relying on masculine constructs of physical strength, bravado, and intimidation. The female Kaa is contrastingly anthropomorphized by stigmatized feminine attributes of emotional manipulation and seductive deception. That is, while Khan presents a threat of overwhelming force, Kaa presents a threat of psychic control. Mowgli is rescued from Kaa's coils by Baloo the bear, a beneficent representative of masculine physical strength who takes on a role as Mowgli's educator. In Baloo's company, the film takes on a comic tone, with Baloo shown eating pawfuls of "funny ants" and informing Mowgli that bees make honey "just for you." The denial of subjectivity to insects is unproblematic in the film, corresponding with their lowly status in general.

From the discussion so far, it can be argued Khan can stand as an allegory for human environmental despoliation and the self-interested disordering of nature, while Mowgli's resistance of Khan allegorizes a model of human stewardship of nature that maintains or restores order. Khan's hunting is excessive and therefore *evil*, which is subtly indicated in his degendering of Mowgli when he utters, "Mowgli? They've given *it* a name" (emphasis added). Here Khan employs a typical trope of objectifying discourse by degendering the "other." The use of "it" is likely to jar with a human audience used to being acknowledged and addressed as gendered subjects. Khan's disparaging insult resonates with the audience indignant at being discursively positioned eastward in Fig. 1 by proxy or in other words rudely dethroned from the privileged northwestern corner. The film therefore dramatizes a

struggle by Mowgli and his nonhuman allies to reassert their subjectivity and autonomy in opposition to Khan's rule.

On the surface, Mowgli therefore invites audience identification on the basis of constructing (some) nonhuman animals as "friends" and agential subjects of responsibility to an ordered and harmonious (albeit still predatory) nature and thereby acknowledges and amplifies childhoodnature. The film simultaneously invites deidentification with Khan's willingness to use violence and intimidation to objectify and subjugate humans and other animals. In other words, the film promotes a notion of humans (especially children) as partially enmeshed within nature, rather than wholly distanced from it in order to dominate it, as embodied in Khan's tyranny. Here the film comes up against an historical tension between the more straightforwardly demonizing construction of Khan as a "man-eater" in Kipling's original story and the recent deployment of tigers as one of the most charismatic endangered species in conservation discourses. The construction of Khan in *The Jungle Book* is therefore somewhat against the Western cultural grain, but arguably a quasi-demonic Khan is a necessary fictive construct to sustain not only the dramatic narrative of the film but also to justify its subtle promotion of the human stewardship of nature. In other words, Khan has to be constructed as an "unnatural" tiger who transgressively exits the southwestern quadrant of Fig. 1, in order to provide a foil for the positive construction of Mowgli as nature boy.

However, the positive construction of humans as "natural" beings has limits in *The Jungle Book*. Mowgli occupies a liminal space between nature and culture, because it is his tool use, and especially his ability to wield fire that is used as a marker of human exceptionalism in the film. His tool use is problematized by other animals in the film and denigrated as a human "trick." His adoptive wolf-mother Raksha admonishes Mowgli's tool use, and Bagheera later instructs him that his "tricks" are out of place in the jungle. However, it is this exceptional ability of tool use that enables Mowgli to act as a savior and protector of the other animals terrorized by Khan. It is also possible to read Mowgli's tool use as a proxy for human intelligence and reasoning capacity. For example, Mowgli demonstrates the value of his "tricks" by using ropes to rescue an infant elephant from a pit. This impresses Bagheera, who is earlier shown revering elephants. Despite the vaunted intelligence of real elephants though, elephants in *The Jungle Book* lack speech or individual characterization. They, and in particular the infant, are thereby constructed as more helpless and dependent on Mowgli as their human savior. Baloo uses Mowgli's "tricks" to admonish Bagheera; "you gotta let him be what he is." This is also highlighted in the contrast between Mowgli's ontological fulfillment and the attempted ontological transgression of King Louie and his army of other nonhuman primates. Louie uniquely possesses the capacity for human speech among his army, with his followers only being able to imitate speech. Nonhuman primates, Louie partially excepted, are impoverished subjects relative to humans. Louie envies human exceptionalism and captures Mowgli expressly to extract the secret of controlling fire from him, which Louie believes will give him access to the "top of the food chain." Louie apes human exceptionalism (pun intended) and is thereby in denial of his own nonhuman ontology, which makes

him monstrous in the film. His monstrosity is represented by his Kong-like gigantism and a lust for power that matches Khan's but takes a different route – appropriating the human other and overcoming species-specific limitations, rather than overwhelming the human other with superior physical prowess. When Louie is frustrated though, he regresses to "animalistic" violence to assert his will, demonstrating his unworthiness of the human "throne" in the northwest of Fig. 1. Mowgli's worthiness is ultimately demonstrated by his use of cunning rather than violence to defeat Khan, following Bagheera's injunction that, "you're not a wolf, fight him like a man." Mowgli first attempts to use fire to thwart Khan, but in doing so accidentally sets the jungle aflame, inspiring fear in the other animals. Mowgli tosses aside his flaming torch, symbolically rejecting an imperial construction of human ontology that seeks the domination of nature. The narrative journey of Mowgli is therefore the fulfillment of a more nuanced human ontology, one that is tempered by his civilized and compassionate use of his species-specific power relative to Shere Khan's megalomaniacal use of his. Khan perishes in flames having been lured by Mowgli onto a tree branch that cannot bear his weight, but his grisly death is therefore framed as a just punishment for his tyranny.

In summary, *The Jungle Book* disturbs some of the terrain of Fig. 1, only to at least partially restore it by the end of the film. This restoration is in accordance with contemporary norms of human responsibility to care for the natural environment and to recognize our involvement with it (but not our full inclusion within it), rather than to reinforce our radical separation from it. Different types of animals, humans included, are put back in place in terms of Fig. 1, albeit *somewhat* closer together. The relative realism of *The Jungle Book* from our sample of four films makes it simpler to transpose subjectivity from the characters to their real "wild" counterparts. But this is also a less risky endeavor as the film does not directly confront human exploitation of "farmed" animals or others confined to the southeastern killing zone. Shere Khan is an aberrant and excessive subject, arguably proxy for the excesses of capitalist exploitation of nature, but the rewriting of the original Kipling story does not extend to critiquing the destruction of jungle habitats for "livestock" ranching (see Nibert, 2013). King Louie is also an aberrant and excessive subject, seeking the usurpation of human supremacy and punished for his temerity. But again, an opportunity for a critical commentary on human exploitation of nonhuman primates is missed. The contrast between the justice of the ape uprising against human violence in the recent sequence of *Planet of the Apes* remakes and Louie's moral turpitude is striking. Mowgli by contrast represents an enlightened subject, using his power for the good of others, but still doing so by ascending gradually toward the northwest from the southwest of Fig. 1. The shift is not as abrupt in the 1967 cartoon, where Mowgli is so entranced by the sight of a human girl that he ultimately finds it straightforward to exit the jungle in favor of the human village (Stewart & Cole, 2009). Growing up is no longer such a simple matter of eschewing "nature" and the companionship of other animals as it was in 1967. However, neither is childhoodnature straightforwardly recognized and celebrated: it is arguably still a matter of embracing an ontology of human

exceptionalism and a civilizing (rather than dominating) mission as regards "nature" and the other animals who inhabit it.

Conclusion

The five films analyzed in this chapter make for an interesting set of comparisons and contrasts, as despite their broadly similar financial success and superficial genre similarities, each populates the conceptual map in Fig. 1 quite differently. *Zootropolis* positions nonhuman animals as full agents in urban space, that is, in an environment that is recognizably "human" precisely because it is denatured. The replacement of humans with other animals in what remains a quasi-human urban environment in the film makes it easy to read the nonhumans as proxies of human characters, with accompanying moral messages about civilized human conduct. Among the four films, nonhuman animal characters therefore come closest to the northwestern corner of Fig. 1 in *Zootropolis* by virtue of their maximal anthropomorphism, but thereby audience sensibility toward real nonhuman animal is arguably attenuated: human audience identification with the nonhuman characters is primarily engendered by the modeling of moral lessons for the transcending of human differences, rather than for the envisioning of an interspecies community. *Finding Nemo/Dory* positions nonhuman animals primarily as "wild" inhabitants of "nature," such that they tend to be presented as out of place in captive environments. They are therefore afforded greater subjectivity than is typical for the southwestern region of Fig. 1, but primarily again through means of their anthropomorphizing. *The Secret Life of Pets* is the most conservative in its positioning of animal companions as quasi-subjects who willingly submit to their own domestication. It therefore reproduces the positioning of "pets" in Fig. 1. Despite the use of anthropomorphism to afford subjectivity to some of the film's nonhuman characters, that subjectivity remains in thrall to human control. Finally, *The Jungle Book* differs from its Disney cartoon progenitor by "rewilding" the human child Mowgli to some extent and thereby collapsing some of the conceptual distance between humans and (some) other animals. It therefore does the most to encourage childhoodnature as pivotal to self-identification among its young audience and therefore to dethrone humans from the northwestern imperial seat of Fig. 1. It envisions an interspecies community with human participants. However, human exceptionalism remains present in the film's narrative, and Mowgli's identity remains liminal, with "animal"/natural and "human"/cultured worlds irreconcilably bifurcated despite his personal choice to remain in the jungle – in other words, Mowgli cannot take us all with him, and childhoodnature is exoticized rather than normalized.

In this analysis, we hope to have drawn attention to the importance of mass media representations in the socialization process as regards childhoodnature. In our sample of movies, little progress is made toward a reconciliation of children with "nature," insofar as asserting a shared animal nature between humans and nonhumans. Such a recognition might help to reconfigure the socialization process

such that human humility and animal kinship with other species is fostered in childhood, rather than human exceptionalism. Instead, exploitative relations are variously reproduced, obscured, or at best left uncritically accepted. However, despite the problematic features of *The Jungle Book*, the updated character of Mowgli takes us closest to a sustained critique of the status quo through his ultimate choice of "nature" over "culture." In its modeling of interspecies companionship and community, *The Jungle Book* at least opens the hope for a future evacuation of the conceptual map. Mowgli's life outside of human culture suggests that it is (speciesist) culture itself that is responsible for our estrangement from other animals and from our own animal natures. This is not to call for a primitivist manifesto but for a critical awareness of the profound damage that is done by denying childhoodnature and denaturalizing children through the socialization process.

Abstract

In the time of the Anthropocene, the human species' destructive effect on the planet and other nonhuman species is evident. The socialization process of children plays a significant role in the preservation of a speciesist Western society, as the exploitation, captivity, and instrumental use of nonhuman animals are normalized through the reproduction of speciesist messages in the educational setting, through children's media and our language use, which all reinforce the idea of nonhuman animals as *the other*. Speciesism, the underlying ideology that excludes nonhuman animals from the sphere of moral concern and legal protection, is dependent on its reproduction, just as other dominant ideologies. The exploitation of nonhuman animals and human-nonhuman animal hierarchy is further normalized through environmental education and welfare education and the notion of the *humane* use of nonhuman animals. Can our treatment of nonhuman animals be characterized as *humane*? What does it mean to be *humane*? This chapter examines how humane education can refute speciesist messages, as it offers children the tools to identify and critically assess

Humane education · Speciesism · Human-animal relationship

Introduction

Nonhuman animals undoubtedly play a central role in the lives of humans; we use them for food, entertainment, and sports, as tools for research and trade them as mere commodities. The exploitation of nonhuman animals is legitimized by their legal status as property – objects for humans to own and use as they see fit. Humans have granted themselves dominion over the planet and all other species, creating a hierarchy in which humans are the definition and measure of everything worthy. This anthropocentric worldview, what Bekoff (2013) considers our "rampant anthropocentrism" can be seen to act as a wall between humans and all other species and the natural world, as we not only ignore nature out of convenience, but in Western society many are also physically removed from nature, reinforcing our mental disconnection and detachment from other species and the destructive effects of our actions. The destructive effects of our actions has led some scientists to call this era the Anthropocene, the age of man, defined by deforestation, water and air pollution, environmental destruction, species extinction, and animal exploitation on an immense scale. Animal and environmental protection organizations have long campaigned for greater protective measures, but the baby steps of legal reforms come too slow and too late and fail to challenge the morality of animal exploitation.

Due to the various, involuntary, roles nonhuman animals have in our lives, the consequent relationship we have with them is of great complexity and controversy. Goodall and Bekoff (2003, p. 18) aptly identify how Western societies appear to be confused about the way we think about nonhuman animals, as many of us are unable to broaden our emotional connection and compassion from our pets to other nonhuman animals. Francione (2004, p.108) rightly echoes this concern, calling our relationship with nonhuman animals one of "moral schizophrenia," where we claim to care about nonhuman animals, but our actions contradict our words. How has this morally schizophrenic relationship come to be, where we claim to care about nonhuman animals, but shut our eyes to their plight, and allow exploitation to continue?

Our worlds are entwined with those of other species in numerous ways each day even though many of us do not have physical encounters with nonhuman animals. This seemingly invisible entanglement is the most prominent of all, as it encompasses exploitation, captivity, violence, and death on a massive scale, and the most common "interaction" with nonhuman animals can be seen to be when we are eating them (Adams, 1991). Our lives are abundant with representations of nonhuman animals and the human-nonhuman animal relationship is constructed from a young age. Since childhood, many of us are exposed to a variety of representations through

different media, but have little contact with real nonhuman animals. The limited connection we have with nonhuman animals is restricted to institutionalized contexts, which we erroneously see as normal and natural, such as the confinement of nonhuman animals in zoos.

The way in which children relate to nonhuman animals (Melson, 2005; Myers, 2007; Cole & Stewart, 2014) and the role education can play in challenging the dominant narratives of human-animal relations in society (Pedersen, 2004, 2010; Goodall & Bekoff, 2003; Caine, 2009, 2015; Weil, 2004, 2016) has recently been increasingly emphasized by scholars from various fields, nonetheless research on these issues has been limited. Goodall and Bekoff (2003) identify the significant potential children have in making a great difference in society, which is often overlooked by adults, echoed by humane educators and researchers (Jalongo, 2004; Weil, 2004, 2016; Caine, 2009, 2015). Pedersen (2004) recognizes the role schools play in normalizing the objectification of nonhuman animals, as they are framed in an anthropocentric and hierarchical discourse, and highlights the need for schools to re-examine their speciesist curricula. Caine (2009, 2015) similarly identifies how current pedagogy and curricular design teach children an anthropocentric worldview where nonhuman animals and the environment are viewed as mere resources for human use, stressing the need for a new didactic to shift the existing paradigm.

This chapter looks at the potential of humane education (HE) in offering a nonspeciesist lens through which to critically examine our interactions and relationships with nonhuman animals. Echoing the principles of interspecies education (Andrzejewski, Pedersen, & Wicklund, 2009), HE offers a comprehensive framework to assess the interconnected forms of social justice and oppressive systems and can instigate a move away from the dominant, sometimes hidden, beliefs of society.

Teaching Children to View the World Through a Speciesist Lens

It can be argued that the instrumental use of nonhuman animals, their captivity, and the idea of "happy" or "humane" exploitation is normalized through a speciesist socialization process, where children are taught to give different value to nonhuman animals based on species membership. The way we are socialized to see the world has great influence on how we act in it and "is broadly responsible for re-creating the social and economic processes that keep people and animals in oppressed positions" (Nibert in Torres 2007, p. 4). Children learn to view nonhuman animals as *the other,* which serves to legitimize their oppression and distance humans from other species. Nonhuman animals are categorized according to their use and man-made labels and social positions can grant them a life of pampering as a pet or condone them to a life of torment in a laboratory or factory farm, or a fate of hounding when considered a pest. By creating labels and categories, children are encouraged to view nonhuman animals according to their use, resulting in the normalization of their exploitation and instrumental use. For example, *circus animal* suggests a natural category of tigers, while *farm animals* and *zoo animals* create false categories of nonhuman

animals where children grow up to view the incarceration of nonhuman animals in zoos as normal and legitimize our use of nonhuman animals for food (Dunayer, 2001, p. 8).

Cole and Stewart (2014) identify how children grow up to view nonhuman animals as either friends or objects of use. Although this distinction is twofold, it is far from simple. The difference between friends and objects of use is not always clear-cut and the boundaries between different nonhuman animals make our relationship with nonhuman animals confusing. Caine (2015, p. 5) is critical of the invisible line we draw between different species and our moral concern, calling it a monumental social hypocrisy and a conflict of moral and ethical reasoning. We deny the commonality between species, such as pigs and dogs, treating one with kindness and companionship and condemning the other to a life of pain and death for our palate pleasure.

It is doubtful that children are born speciesist and that these man-made categories are inherent to them; instead it can be argued that the categorization of nonhuman animals is learned through an anthropocentric and speciesist socialization process. How do children learn to view the world through a human-nonhuman animal hierarchy? How do we create a distinction between nonhuman animals as our friends and those who are not? Language is a crucial tool we use to teach children about nonhuman animals and it can be used to promote and enforce certain beliefs. Speciesist views are reinforced through our language use, which shapes our relationship with, and our attitude towards, nonhuman animals. We use language to classify and denigrate nonhuman animals and to distance humans from other species. Language helps a child make sense of the world as we begin to label the things around us in order to understand them. However, Goodall and Bekoff (2003, p. 41) argue that by labeling and categorizing the world around us, we simplify the diversity of living beings and the natural world. The problem of language begins with the very definition we give the word *animal,* as definitions, such as "any such living organism other than human" (Oxford Dictionaries, n.d.) isolates humans from other species and legitimizes "a human monopoly on moral and legal rights" (Dunayer, 2001, p. 2). By differentiating ourselves from all other species, we highlight their presumed *otherness*. Through our language use, we classify nonhuman animals as objects by using the pronoun *it*, erasing their gender, and by speaking of other nonhuman animals as one species, we turn "unique individuals into a generic species representatives" (Dunayer, 2001, p. 6). Nonhuman animal terms are also used to insult or denigrate humans, which further legitimize the exploitation and oppression of nonhuman animals, as "negative animal idioms normalise and trivialise violence towards animals" (DeMello, 2012, p. 285). Language portrays nonhuman animals as lesser beings and characteristics are imposed on different species: criminals are labeled *animals*, someone crazy becomes *a bat*, cowardly behavior makes someone *a chicken*, to say someone is stupid we call them *a birdbrain*, and to call someone *a pig* connotes gluttony or dirtiness.

Not only is language a dangerous tool, but the false imagery children are exposed to through stories, cartoons, movies, toys, and advertisements play a key role in shaping the way children view and connect with nonhuman animals. A prime of

example of false imagery is the representation of nonhuman animals used for farming purposes. Children's storybooks and toys provide false idyllic portrayals of old-fashioned farms where nonhuman animals enjoy their lives happily. Children are not encouraged to question the practice of farming; instead it is a concept that is normalized and grow up to view a farm as a natural place, never questioning whether it is acceptable to use nonhuman animals for our own purposes or understanding the reality of animals exploited on factory farms. Children's stories perpetuate the false belief that animals live a happy life, as well as the idea that they must die in order to provide us with food (Singer, 1999). Advertising campaigns for animal products replicate similar idyllic old-fashioned farm seen in children's literature, using images of happy pigs, cows, and chickens to advertise their own flesh to consumers, grossly misrepresenting and hiding the true nature of modern factory farming. Humans have claimed ownership over their representation and thus can represent them as they wish and create a narrative that serves human purposes.

Anthropocentric Education

Education functions as a subsystem of the total social system, transmitting knowledge that meets the needs of the society, not to address the needs of an individual. Despite the role of education in the upkeep of dominant ideologies, it can also be used to "initiate social changes by bringing about a change in outlook and attitude" (Patil, 2012, p. 205). Environmental education and welfare education have largely failed to address the "animal question" limiting their approach and scope to solely human-centered and speciesist views of the world and have largely failed to challenge the underlying anthropocentric and speciesist values of the human-nonhuman animal relationship. Weil (2004, p. 49) aptly acknowledges how nonhuman animal issues "are generally neglected in education, even in sustainability education, environmental education, character education, social justice education, and media literacy education." While environmental and sustainability education focus on conservation efforts and environmental and climate protection, the exploitation of nonhuman animals is often overlooked, particularly nonhuman animals used for farming purposes, despite the crucial role it plays in both climate change and environmental destruction. Caine (2009, p. 10) identifies how nature is framed as a resource and "traditional environmental education often prescribes stewarding, managing and controlling nature for the sake of humankind."

Horsthemke (2009, p. 209) argues that environmental education has flourished in schools because "it has been demonstrated that its cause ultimately benefits people" where nature is framed as a resource and commodity (Kopnina, 2014), analogous welfare education, where the human-nonhuman animal relationship is framed through utilitarian discourse where nonhuman animals are ultimately represented as resources and commodities for humans. Oakley et al. (2010, p. 97) recognize the "curious silence about animals" in environmental education research and the neglect of human-nonhuman animal relations in environmental education, highlighting the importance of blurring the boundaries and fictional divides between "human,"

"animal," and "nature" and the need to question our own animality (Oakley et al., 2010, p. 90). Kopnina (2014, p. 296) identifies the difficulty in surpassing the anthropocentric focus of environmental education and the need to challenge the ethical assumption of human superiority, as even when the interconnectedness of humans and nature is acknowledged, the idea of human superiority remains.

Caine (2009) recognizes the limitations of current schooling, arguing that career building and monetary success are framed as benchmarks for becoming productive members of society, while references to the natural world and the needs of other species are practically nonexistent. The study of the natural world and other species is largely left to the natural science domain, in which humans and nonhuman animals are studied within separate discourses and value systems, establishing a subject-object relation between humans and nonhuman animals (Pedersen, 2004). This subject-object relation, however, is established long before students enter biology lessons, and the objectification of nonhuman animals is established when children are at a young age. Despite speciesist curricula, Pedersen (2004) sees the possibilities of transformation offered by education, as schools can be seen as agents in the reproduction processes of certain ideals and knowledge, and thus have the potential to critically reassess its role in mediating value messages, affirming how the relation between humans and nonhuman animals is not predetermined by force or natural order, but is entirely within the control of humans beings to change the relation. But how many want to change the relation?

The increase in public awareness of animal protection issues has led many animal protection organizations and some governmental institutions to offer forms of *welfare education*. However, welfare education endorses the idea that the exploitation of nonhuman animals is acceptable, as long as we do so in a *humane* way, perpetuating the property status of nonhuman animals and demonstrating the difficulty of educating children through an unfiltered lens. Welfare education fails to "demand that we understand the subjugated status of nonhuman animals in our society as related to or concordant with the historical reality of oppressed human groups as well as with the domination of nature generally" (Kahn & Humes, 2009, p. 181). Welfare education assumes human dominance over other species and thus portrays our use of nonhuman animals as natural. The idea of the *humane* use of nonhuman animals is an oxymoron and it is highly debatable whether our treatment of nonhuman animals be described as *humane*. The word *humane,* originally defined as qualities pertaining to a human being, is also defined as:

- showing kindness, care, and sympathy towards others, especially those who are suffering (Cambridge Dictionary, n.d.)
- having or showing compassion or benevolence (Oxford Dictionaries, n.d.)

Showing kindness, compassion, and sympathy may be true for a small percentage of nonhuman animals, such as some we categories as pets, but for billions of nonhuman animals who suffer and die at the hands of humans, the idea of showing kindness, sympathy, or compassion is an implausible concept. Torres (2007, p. 26) points out that *humane* forms of exploitation as when "we use another being instrumentally, we

have denied that being its right to exist on its own terms, whether that being is human or non-human." Francione (2004) argues that if we are to make true our claim to take nonhuman animal interests seriously is to accord them basic right not to be treated as things and that sentience, subjective awareness, is the sole factor that matters.

Humane Education

The earliest form of HE, the Band of Mercy was formed in Britain in 1875 with an anthropocentric focus, as the aim of promoting kindness towards nonhuman animals was rooted in the idea that cruelty towards nonhuman animals transferred to inhumane acts towards humans (Brake & Demoor, 2009). Members of the Band of Mercy, formed in the United States in 1882, pledging to try to be kind to all living creatures and try to protect them from cruel usage (Unti & DeRosa, 2003). The educational focus of the animal protection movement normally centered on acts of individual cruelty and failed to address socially sanctioned forms of animal abuse (Unti & DeRosa, 2003, p. 32). HE has since extended its scope from its original *kindness-to-animals ethic* focusing on compassionate treatment of companion animals to a more intersectional approach looking at social justice issues as an interconnected web of oppression (Caine, 2015).

Although HE is often used as an umbrella term to cover welfare and responsible pet ownership programs, it extends beyond these approaches. Many HE programs approach the human-nonhuman relationship through a posthumanist viewpoint, placing "all creatures, both human and nonhuman animals, in a non-hierarchical web" (Morris, 2015, p. 43), unlike welfare education. Whilst welfare education promotes the idea of the *humane* use of nonhuman animals, HE aims to uncover the immorality and interconnectedness of exploitative practices, aiming to demonstrate how "our daily lives are inextricably connected to institutionalized brutality, injustice, and environmental devastation" (Weil, 2004, p. 49).

One of the objectives of HE is to widen children's circle of empathy, leading children "to embrace what was previously categorised as *other*" (Jalongo, 2014, p. xvi) and to build a generation of *solutionaries* – people who identify inhumane, unsustainable, and exploitative systems that affect people, nonhuman animals, and the Earth and develop practical, effective solutions to replace these systems with ones that are restorative, healthy, and just (Weil, 2016, p. 5). Caine (2009, p. 9) highlights the importance of empathy, as it is the bridge to compassion and understanding the connections we share with nonhuman animals, stating that "if we can empathize with the experiences of other living beings and place ourselves in the shoes (or paws, claws, fins) of a suffering other, we can begin to develop compassion for this *other.*"

In many schools, the discussion of social issues or anything controversial has become taboo (Weil, 2016, p. 18) and many educators lack the necessary training and resources to handle controversial and emotive issues in the classroom, and HE is sometimes criticized on the assumption that social justice issues are too complex or abstract for young children to comprehend, underestimating the intellect and

emotional intelligence of children. However, according to Jalongo (2014, p. xi), the thinking of adults if frequently "too limited and developmentally inappropriate to communicate effectively with the very young" and often adults can be seen to stand in the way of educating, as teaching children kindness to all living beings requires a change in perspective of adults and rethinking speciesism connects too closely to the reality of curricula (Oakley, 2011, p. 10) and our everyday lives.

HE aims to provide accurate information that is hidden from school curricula and popular media, covering a vast range of topics, including the exploitation of nonhuman animals, genetic engineering of food, aquaculture, factory farming, species extinction, resource depletion, and deforestation. It also tackles social injustices including racism, sexism, and homophobia. HE reflects the proposed curricula of *interspecies education*, an approach based on compassion and justice focusing on the interconnectedness and interdependence of all life forms on Earth (Andrzejewski et al., 2009). HE topics can be infused into any subject area, for example, a mathematics lesson on percentages can look at the rates of extinction and provide data on the number of nonhuman animals killed each year in different geographical settings because of hunting, disease, or agricultural expansion (Caine, 2009). Students are encouraged to critically assess how our choices are linked to the suffering of others and reassess practices we are taught to view as normal, as well as re-examine the man-made categorizations of nonhuman animals. HE can help students assess the biased and carefully framed narratives behind corporate funded materials and critically think about what information is not included in school curricula. For example, students can uncover the biases and motivations behind dairy advertising in schools and other corporate funded materials. HE promotes c*uriosity, creativity, critical thinking* with the aim of teaching children "how to scrutinize information with a critical eye and to uncover the hidden links between our product choices and the suffering they may cause to others" (Weil, 2004, pp. 15).

HE aims to nurture *reverence*, *respect*, *and responsibility* to encourage positive action and choices that benefit nonhuman animals, the earth, and other humans. Visits to sanctuaries and refuges are an important part of HE programs, allowing children to have direct contact with nonhuman animals and learn about where they have been rescued from and why these exploitative systems exist. They also allow children to connect with nonhuman animals on an individual level, enforcing the fact that they are sentient beings with individual needs and interests. Visits to sanctuaries are an alternative to the usual visits schools organize to zoos, aquariums, petting zoos, or circuses, which maintain the status quo and enforce a speciesist worldview, enforcing the divide between the human and nonhuman and normalizing the captivity of nonhuman animals. The HE approach introduces children to a range of challenging issues that may seem overwhelming and offering positive choices, and giving examples of people who have made a difference, students see that they have the power to instigate change that positively affects the lives of nonhuman animals, the environment, and humans. Caine (2009) highlights the value of introducing real-world topics into lessons as it can instigate discussion and critical thinking about the ways in which human behavior contributes to species extinction and what can be done about it. Once students are introduced to real-world topics and identify the

oppressive systems and how we contribute to exploitation, they can identify ways in which they can make a difference.

HE programs are tailored according to age group and take shape in many forms, including in-classroom instruction, visits to animal shelters and refuges, camps, animal protection clubs, books, and videos, and antispeciesist children's literature, and various animal protection organizations, and HE providers offer tailored lessons plans. Despite an increase in HE programs, there is limited research on its effects. According to Weil (2004, pp. 43), secondary school students who take part in humane education are less susceptible to media messages, become critical thinkers, take more responsibility for their actions, have increased self-confidence and respect, demonstrate leadership skills, develop more compassionate attitudes towards others, and are empowered to make a positive change. HE programs have reportedly demonstrated an increase in a child's empathy towards nonhuman animals (Nicol et al., 2008) and an increased awareness on environmental issues, which have prompted schools to create different committees and programs tackling issues such as waste and nonhuman animal protection. According to Weil (2004, p. 43), secondary school students who take part in HE are less susceptible to media messages, become critical thinkers, take more responsibility for their actions, have increased self-confidence and respect, demonstrate leadership skills, develop more compassionate attitudes towards others, and are empowered to make a positive change. HE has primarily focused on younger learners, as children are more flexible in their habits and attitudes (Jalongo, 2004), but the importance of HE reaching older students and infusing HE topics into higher education and teacher training has been highlighted by Gómez Galán (2005) among other scholars.

Conclusion

If children are the future, what should we teach them? Given the current state of ecological destruction and the rising number of nonhuman animals exploited, it is crucial to re-examine the values that govern society and re-examine the human-nonhuman animal relationship starting from a young age. Although the changes we now make will come too late for the millions of nonhuman animals who now suffer and the countless species already extinct, it can help spare the suffering of others (Goodall & Bekoff, 2003). Weil (2004) believes that by educating future generations to be compassionate, we can change the disastrous path we are on and help prevent future suffering. However, the prevention of future suffering depends on reshaping the relationship we have with nonhuman animals and the natural world. HE takes environmental education a step further, extending on the prior's failure to integrate nonhuman animal advocacy as a serious environmental issues (Kahn & Humes, 2009). HE offers a holistic approach that tackles the interconnected injustices and critically questions the frameworks currently embedded in the socialization process of children and in Western society and offers a platform for cooperation between environmental and animal protection movements through its intersectional approach.

Abstract

The children's storybook, the *Flat Rabbit*, by Bárdur Oskarsson, explores complex ethical dilemmas experienced by the dog and rat after they discover the rabbit flattened on the road. Similarly, in our collective experiences with children and educators in three nature programs across Canada, we take up complex

ethical dilemmas experienced by our unanticipated encounters with various deaths in the outdoors, including those of baby squirrels, a raccoon, and an owl. Common world (Latour. *The politics of nature: How to bring the sciences into democracy*. Cambridge, MA: Harvard University Press, 2004) theoretical framing helps in positioning the child as an "indivisible part of the natural and more-than-natural world." This natural and more-than-natural world provides the impetus for children's development of understanding and working theories related to sensitive concepts such as death (Mankiw & Strasser. *Young Children, 68*(1), 84–89, 2013). We identify and examine ideologies and practices around death that continue to occupy early childhood spaces (Haraway. *Staying with the Trouble: Making Kin in the Chthulucene*. Durham, UK/London, England: Duke University Press, 2016). In reimagining child-nature-animal entanglements, we posit that "staying with the trouble" (Haraway. *Staying with the Trouble: Making Kin in the Chthulucene*. Durham, UK/London, England: Duke University Press, 2016) disturbs sedimented embodied ideologies so that we might listen and foster a "practice of becoming witness" (Rose & Chrulew. *Extinction studies-stories of time, death, and generations*. New York: Columbia University Press, 2017). We are working toward a more performative, storied, and experimental way of being and learning together with children and animals, "learning to stay with the trouble of living and dying in response-ability on a damaged earth" (Haraway. *Staying with the trouble: Making Kin in the Chthulucene*. Durham, UK/London, England: Duke University Press, p. 2, 2016).

Child-animal relations · Common worlding · Co-mattering · Early childhood education pedagogy · Death

Introduction

In this chapter, our aim is to think together across the country about encounters with deaths of animals that children and educators have experienced in natural environments such as forests, shorelines, and bluffs. These encounters provoke us to trouble the Anthropocene era and move toward that of the Chthulucene which as Donna Haraway (2016) articulates as "learning to stay with the trouble of living and dying in response-ability on a damaged earth" (p. 2).

Facing a dead owl, a dead raccoon, and the gaze of the living weasel brings educators and children to questions of the vulnerability of all life. How might we pedagogically "stay with the trouble" to explore the affect, emotion, and child-animal co-mattering and explore what it means to be kin (Haraway, 2008, 2010)? By paying attention to the ways in which human/more-than-human entanglements unfold, we explore the connectedness between animal and child, realizing that each species is intricately linked to the other. New narratives are possible, narratives that account for ideas of children "becoming with" the whole world (Haraway, 2008),

where humans are considered "members of multispecies communities that emerge through the entanglements of agential beings" (Rose et al., 2012, p. 4).

Much Western thinking has positioned humans as placing culture over nature, with culture dominating (Ritchie, 2012). Death disrupts this power relation. Observing a dead vole or raccoon and watching maggots or bugs wiggle out of the animals' bodies are concrete and dramatic illustrations of the inevitable fate of all organic matter. Yet, our anthropocentric frame of reference has the effect of blocking our "sensitivity to and knowledge of the nature, blocking humility, wonder and openness in approaching the more-than-human" (Plumwood, 1999, p. 109). Here, we argue for a messier, entangled, enmeshed, intra-active, and co-shaping conceptualization of children/nature (Taylor, 2013). A common worlding framework helps to challenge human centrism and romantic notions of child innocence and purity that often separate children from nature (Malone, 2016; Pacini-Ketchabaw, Taylor, Blaise, & Finney, 2015). The framework helps in recognizing childhood as part of a situated, collective, unequal, political, ethical, messy, and unsettled world (Pacini-Ketchabaw, 2017), as well as guiding queries focused on the "ethical and political challenge of learning how to live well together and to flourish with difference" (Taylor & Giugni, 2012, p. 109).

Lenz Taguchi's (2010) "ontology of immanence" also assists here in highlighting the interdependence and interconnection of all human and nonhuman matter. She explains an ontology of immanence as meaning "that we need to go beyond the human/non-human divide, as we understand our existence as a co-existence with the rest of the world" (p. 15). Thus, as humans we do not live separate from, rather we are part of, entangled with, and enmeshed with the lives of others (both human and nonhuman) (Haraway, 2010; Taylor, 2013). Questioning the human-animal boundaries of this relational "throwntogetherness" of our world (Massey, 2005) helps further our understanding of mattering (and co-mattering) of all kin, where "to be kin in that sense is to be responsible to and for each other, human and not" (Haraway, 2010, p. 54).

Common worlding serves as a way/means of problematizing the "romantic view of childhoodnature," which is the separation of the "child" and "nature" rather than the positioning of the child as nature and the animal as nature (Malone, 2016; see also ▶ Chaps. 31, "Rats, Death, and Anthropocene Relations in Urban Canadian Childhoods", ▶ 26, "Situating Indigenous and Black Childhoods in the Anthropocene", this volume). The promulgation of the "new nature movement" (Louv, 2006; Sobel, 2013) seems somewhat rooted to Anthropocentric views entangled with nostalgia, what Dickinson (2014) calls a "fall recovery narrative." This fall recovery involves a form of reminiscing and romanticizing of a utopian past where children and nature were entwined, a problematic discourse according to Dickinson in how the commentaries have created "a blind spot to the realities of the majority of the world's children, who live in a diversity of 'childhoods'" (p. 44). Alternatively, a discourse of common worlding (Latour, 2004; Taylor, 2013) might offer means of "deliberately reposition[ing] children within the full, heterogeneous and interdependent multispecies common worlds in which we all live" (Taylor & Pacini-Ketchabaw, 2015, p. 507).

A common world framework also offers new pedagogical potentials when we stay with messy, entangled, complex, ethical dilemmas; when we stay with the

trouble, learning through specific unanticipated animal deaths, we make meaning in human and more-than-human contexts, re-narrating death and drawing out new meanings and "situated pedagogical responses" (Nxumalo & Pacini-Ketchabaw, 2017; Pacini-Ketchabaw & Taylor, 2015). How do children and children and adults together make meaning of their relationships with animals and ultimately their deaths? Like Affrica Taylor (2013) we also ask: how might we approach the relationship between childhood and nature without rehearsing nostalgic adult idealizations, sentimentalized attachments, or heroic rescue and salvation appeals?. How might pedagogies shift when we encounter animal deaths in the outdoors and knowledge is conceptualized as "being-of-the-world" (Lenz Taguchi, 2010)? For us, the animal, child, adult, material, space, place, land, experience, and so on are inseparable, and teaching and learning are enacted in the intra-action among all these facets, "the spaces in between" (Lenz Taguchi, 2010, p. 58).

We preface our discussion of child-animal co-mattering with a brief introduction of the spaces, places, and lands where the three respective nature-based programs are enacted. We invite readers to think with place in mind as we retell the stories of child-animal-death encounters, recognizing that our retellings are partial and incomplete. Purposefully, we have selected "stories that create openings, stories that can help us to inhabit multiply-storied worlds in the spirit of openness and accountability to otherness" (Rose, Dooren, & Chrulew, 2017, p. 3). We offer these stories as a way of questioning and complexifying pedagogies within early childhood education, advocating for "staying with the trouble" (Haraway, 2016) and questioning the child/nature divides that fail to account for the entanglements and co-mattering of child-animal relations. This is an ongoing journey that we as researchers are just beginning. However, we propose by paying attention to the messy entanglements and "thinking through" (Nxumalo & Pacini-Ketchabaw, 2017) death; we can help query the potential of pedagogies that foster "a practice of becoming worldly with" (Haraway, 2008, p. 3).

Spaces, Places, Land, and Treaties: Troubled Inheritances

In the forest spaces of our respective studies, children, educators, animals, and the more-than-human are co-located within very specific social-cultural-political contexts. The geological history of New Brunswick dates to the Precambrian period of 4.6 billion to 542 million years ago to the present. The province itself is mapped upon the traditional territories of the Wabanaki Confederacy composed of the Mi'kmaq, Wolastoqey, Passamaquoddy, Abenaki, and Penobscot Nations. Wabanaki translates into English as People of the Dawnland, and in 1993, the Confederacy was revived. Recent archeological excavations within these traditional territories have uncovered artifacts indicating that the Wabanaki peoples have been living here for 13,500 years. Following the 2010 Declaration of Rights of Indigenous People (UNDRIP), Wabanaki leadership emphasized the continuing role of the Confederacy in protecting natural capital. One of its leaders advised:

> When we talk about Wabanaki people, we're also talking about Wabanaki people being the land, being the trees, being the animals, because in that cultural perspective, we're all related...The Wabanaki are in a far better position to defend the land," says Gkisedtanamoogk. "No land was ever ceded, and that's acknowledged by both the province and the federal government. So, on the basis of the treaties, what we're suggesting is that you and I have a common responsibility to the land under those treaties." – Gkisedtanamoogk, the Gathering's fire keeper. (Wabanaki quotation is from Howe, Miles (2012). "Rebuilding the Wabanaki Confederacy," Halifax Media Co-op).

The children and educators in the University of New Brunswick's faculty-based program regularly visit a small wooded area, centrally located on the university grounds. These woods, and the university itself, sit upon the traditional lands of the Wolustoquy people. There are no cultural markers of these shared and troubled colonial histories, and their entanglements are invisible to children, educators, faculty, or anyone who visit this land and the occupying university buildings. This lack of representation works to continue to erase shared colonial histories between settlers and indigenous peoples, a troubling oversight when clearly place matters (Pacini-Ketchabaw & Taylor, 2015), and particularly land dis-/ownerships impact inheritances.

Cajete (1994) informs us that for indigenous peoples, "the Earth was alive and had its own sense and expression of consciousness and being" (p. 89). He continues to speak of a "natural democracy" where "plants, animals and other entities in the natural world, have rights of their own and must be given respect" (p. 89). The Sooke Nature Kindergarten (NK) is located on the Coast Salish territory on Vancouver Island, British Columbia, a place of rocky shoreline, sandy beaches, coastal bluffs, and wooded hills with coastal Douglas-fir and western hemlock ecosystems. There are many streams throughout this landscape which are home to fish and a habitat to bears, cougars, and deer. Dave Elliott Senior noted in 1980 (as cited in Turner & Hebda, 2012, p. 11): ". . . ours was an abundant land. Our forests, meadows, creek sides, marshes and seashores offered many plants for our use" (p. 11). Coast Salish has been on these lands for over 10,000 years (Turner, 2005), and the land has supported and nourished it until recent colonial history when our "scientific sophistication has not been matched by our caring for the Earth" (Turner, 2005, p. 11).

In the Ontario context, the children and animals coexist within a unique biosphere comprised of diverse varieties of trees, mammals, birds, plants, insects, and a geological history that is estimated to be 430–450 million years. Indigenous peoples have lived and entangled their lives with the animals and more-than-human materials of these Ontario woods for at least 10,000 years. The Anishinaabe and Haudenosaunee peoples' original territory encompasses the region where the Ontario children of the nature program now play. One aspect of traditional knowledge that Anishinaabe peoples value is referred to as "Gnawaaminjigewin," that is, "firsthand knowledge – which brings an appreciation of the relationship between the observer and the observed" (Nokomis, n.d.). Rasunah Marsden (n.d.) describes:

> the knowledge that the observer and the observed are not separate, they are 'related' and that a teaching and learning process is inherent in this action. The key learning which arises from

> Gnawaaminjigewin is that we are all related ("All My Relations") – a learning that eventually applies to everything that can be observed: earth, plants, animals, human beings and the spirit world infused within all creation and which binds them together.

Briefly stated, the Haudenosaunee worldview is predicated on balance and reciprocity and equality of all life forms, human and nonhuman alike (Venables, 2010). Venables citing Oren Lyons (an Onondaga Haudenosaunee leader and spokesperson) stated:

> In our perception all life is equal, and that includes the birds, the animals, the things that grow, things that swim. All life is equal in our perception. (Lyons, 1979 as cited in Venables, 2010, p. 27)

What we hope to highlight, while also acknowledging our collective Westernized backgrounds and limited representation of indigenous world views of the first peoples whose land the programs occupy is that across the three distinct contexts (New Brunswick, Ontario, and British Columbia), there are significant commonalities. Each space is situated on traditional lands where cultures have lived for thousands of years (or time immemorial as most indigenous peoples recognize) coexisting, enmeshed, and balanced lives with human and non-human. Other ways of thinking, being, learning, are relating are possible, ways that value living relationally and contest the human-animal boundaries that are more dominant within Western epistemologies. Leanne Hinton, a language revitalization scholar of Native American languages, wrote a song based on her experiences living and working with the Havasupai people. Her lyrics are an important reminder of the importance of thinking/living relationally (the chorus is cited here):

> For the land knows you're there
> And the land knows you're there
> And the rocks and trees and rivers
> Give you friendship and care. (Hinton, personal communication, 2017)

Greenwood (2013) notes "people, and other species, live embodied and emplaced lives" (p. 93) and place-conscious learning includes the "historical, socioecological, and ethical dimensions of place-relations" (p. 97). (See also ► Chap. 9, "In Place(s): Dwelling on Culture, Materiality, and Affect" by Sue Waite, in this volume.)

Co-Mattering and Questioning the Human-Animal Boundaries

Children themselves have long noted the importance of animals within their own lives (e.g., Hallden, 2003; Morrow, 1998; Rasmussen & Smidt, 2003). Yet, research on the influence/importance of interspecies relations seems in its infancy. As Tipper (2011) critiques, the ubiquitous attention paid to psycho-developmental explanations or the "biophilia hypothesis" in examining child-animal relations seems grossly

inadequate. Most children develop an understanding of animals' needs at a young age related to realistic conceptions, greater ecological awareness, and insights into conservation need, these aspects changing as a child matures (Myers, Saunders, & Garrett, 2004). Clearly "animals matter in their own right...as individuals with whom children relate and for whom they care" (Tipper, 2011, p. 149); thus paying close attention to the child-animal inter-and intra-relations within early childhood education is paramount.

Co-mattering occurs in the Anthropocene (and the myriad of alternative terms Capitalocene, Misanthropocene) (Haraway, 2015). Certainly, companion animals like family pets are often viewed as social actors sharing a social-emotional life with humans, quite capable of complex animal-human relations (e.g., deception) (Heberlein, Manser, & Turner, 2017) and corelations (Haraway, 2003). Donna Haraway's (2003, 2008) notion of kinship or relations is important here, fully recognizing human-animal coevolution, mutuality, and symbiosis with what she has labelled "naturecultures," "companion species," and "becoming with" (Haraway, 2003, 2008, 2016). Haraway's influence is also evident in Taylor and Pacini-Ketchabaw's (2015) explorations with children, worms, and ant encounters. These early childhood scholars advocate for a "reimagining of agency and our place in the world" (p. 511) to foster a common world understanding where educators "encourage children to develop a multispecies ethics" (p. 511). The child's ethical relations and fondness for his or her dog, cat, or hamster are easily recognizable. But what of other species like the weasel, owl, and raccoon (species we discuss in this chapter)?

Taylor and Pacini-Ketchabaw (2015) draw upon Myra Hird's (2010) work with bacteria to highlight the interdependence of human lives on the "less glamorous and often invisible" creatures of the world, such as worms and ants that they encountered with children. As these scholars aptly point out, earthworms and ants predate humans by 100–600 million years; they are diverse and adaptive creatures that are vital to the ecosystems that we humans also inhabit. In their research, the child-ant and child-earthworm encounters invited opportunities for children to relationally and ethically respond while also experiencing tensions and the vulnerabilities of other species. Taylor and Pacini-Ketchabaw among many other scholars cited in this volume (e.g., Mindy Blaise, Amy Cutter-Mackenzie, Fikile Nxumalo, Margaret Somerville) advocate for common world pedagogies within early childhood education, practices that recognize and support the multispecies interdependence of all things (human and more-than-human), and humans learning *with* other species. Albeit, "decentering the human" is a daunting task (Harwood & Collier, 2017; Taylor & Pacini-Ketchabaw, 2015). Perhaps, a lens of co-mattering can help in responding to the binaries and tensions of childhoodnature-animal-matter relations. The weasel, owl, and raccoon each figured prominently in the ethical encounters within the three distinct woodland early childhood programs located across Canada. In this chapter, we revisit these multiple encounters to question and contest culture's seductive appeal to use nature in purifying, romanticizing, and simplifying (Taylor, 2013) Western conceptualizations and pedagogical approaches to the topic of death.

Staying with Death: Confronting Decaying, Decomposing, and Predation

> We relate, know, think, world, and tell stories through and with other stories, worlds, knowledges, thinkings, yearnings. So do other critters of Terra, in all our bumptious diversity and category- breaking speciations and knottings. . . .Critters are at stake in other in every mixing and turning of the terran compost pile. (Haraway, 2016, p. 97)

In her chapter, "The Camille Stories: Children of Compost" (pp. 134–168), Donna Haraway (2016) narrates, along with others, Camille's imaginative transformation over five generations, as she shape shifts from (the) Anthropocene to living more fully in and as Chthulucene. Here, we tell stories of children of the present encountering death with animals over the past few years in the forest spaces these animals inhabit and where these children regularly play. We take this as a starting place to think consciously about being and becoming within a Chthulucene era. Our account and our thinking with kin and death, with decaying and decomposing, circulates through a series of what Sara Ahmed names as "fleeting encounters" (2012, p. 12), encounters that, for us, have become storied moments. These storied moments occurred among children, educators, parents, and specific critters in the context of the various early childhood programs. We weave these encounters as means of practicing education otherwise, engaging in a pedagogy that might "bring a larger number of values into cohabitation" (Latour, 2013, p. 11). Our intent is to speak to the co-mattering of all critters of the Terra, grounding pedagogies within a powerful presence, as one way to shift from a posthumanist way of being to that of a "compost-ist, where we inhabit the humusities rather than the humanities" (Haraway, 2016, p. 97).

Pacini-Ketchabaw (2012) speaks eloquently to the ethical challenge of decolonization while illuminating a premise of powerful presence. Against any one dominating body of knowledge or experience, powerful presence proclaims the idea of relationality, asserting the mutuality and connectivity of all things; opening spaces between existing binaries is possible and needed to make visible the complexities. Within our efforts to gather up complexities, we strive to release ourselves from the dialectical habits of binaries (Braidotti, 2013) limiting enacted values specifically related to animal death as experienced within classrooms and wooded spaces. By staying with the complexities of these fleeting encounters, we recursively return to death as experienced between critters, plants, children, and educators. We ask: What children's theories get taken up or are even able to be voiced? What happens when we stay with the trouble of death?

Strange Kin: Children-Squirrels-Weasels-Mothers-Chickens

Childhood innocence as a discourse often acts to keep us from engaging in conversations with children about death and decomposition of animals. For example, in this children's space in New Brunswick, indoors and out, children and adults together

have studied decomposing plant matter in a range of ways. These decomposing studies include vermiculture, garden composting, and the watchful act of observing a jack o' lantern decay over several months, long enough that a new pumpkin plant emerged from the rotting pulp. In contrast with this collective engagement with decomposing plant matter, we bury critters who die during the process of hatchings, ducks, and chicks. We hide from the children the animals who emerge from eggs malformed. We bury classroom pets, and, initially, we buried dead animals found in the woods. What might this mean? Is it our own vulnerability as mammals that provokes us to bury the animals, burying with them mammal decomposition and decay? How might we approach the relationship between children and nature without romanticism or protectionism?

A Weasel Encounter

The children are aware that there is a red squirrel nesting in the tree hollow. They have been feeding the baby squirrels and chickadees each day as they play within the wooded patch located centrally within our university grounds. They look forward to seeing these small creatures when they enter the forest. On this day, a mom meeting the children within their wooded patch helps the children up to peer into the tree hollow. To their surprise, they came face to face with a weasel (Fig. 1). Enthusiastic

Fig. 1 Weasel as strange kin

about encountering the weasel, the mom held each child up so they too could peek in at the weasel, a repeated action that may have disturbed the weasel.

Upon returning to the classroom, the educator shared the weasel encounter explaining that it looked as if the squirrel family was most likely gone, devoured, or cached as dead kill, as it appeared that a weasel had moved into the hollow. Collectively, the children and adults wondered if the weasel had killed the squirrel babies. The educator expressed concern that the mom held the children up to see the weasel. Was her concern of the effect of this action on the weasel's home a concern over the threat of the weasel as predator or the knowledge that the weasel had predated the baby squirrels? This educator asks aloud, "Well, would you have held the children up?" The researcher (Sherry) is surprised by the question, and this in turns raises other questions. How do children engage with the animals they encounter in the forest? How do they encounter their homes? What do they know of the predation cycle? Are ideas of death and prey and the predation cycle itself considered taboo topics for young children? How do we respectfully visit a space, that is, for the most part, the home of others – spaces that have been transgressed by humans to our ends. Potentially, the presence of the weasel, the absence of the baby squirrels, and the predation cycle disrupt the "innocence" of childhood while introducing the vulnerability of all lives – squirrels, weasels, and humans, all of whom live with the constant presence/threat of death and with land that has multiple occupants – nonhuman and human. Protecting children and ourselves from direct confrontations with death is somewhat limiting and naive, particularly given that unscripted encounters with death in nature can provide ample opportunities for complex learning experiences (Ghafouri, 2014).

Lingering with the embodied complexity of children-educator, weasel, mother, and squirrels, Sherry encountered a weasel in the outer room of her hen house just prior to leaving for a family trip, as she was quickly watering and feeding the chickens.

> My son and daughter are with me, I open the door and come face to face with a weasel perched on top of the wood pile. The weasel looks directly at me and I at the weasel. The children call out gleefully, "oh isn't he cute." I am thinking silently that my chickens are at risk in this month of January when winter hunger may be at its peak. Looking around the outer room I find one of my roosters behind the woodpile partially consumed. What is to be done? The car is packed and the family is waiting. I leave the rooster and the weasel, who now will be cohabitating with the flock of chickens. Two days later we return home. I look in to feed and water the chickens. The weasel is not visible but evidence of his predation is visible in the increasingly consumed rooster. I research the weasel and learn that as in the case of the squirrels, this weasel has moved into the den of its prey to consume and survive. I decide to leave the half-eaten rooster to the weasel, thinking that if I remove it, the weasel will only be enticed to kill another chicken. Over the winter the weasel consumes the rooster, leaving a skeleton with only wingtip feathers intact. No other chickens are taken and the weasel has moved on.

At the child care center, the squirrels are never located. Collectively, the group assumes that the weasel in the tree meant the death of the baby squirrels who became the weasel's food cache. Unlike an earlier dead mouse encounter in these same

woods, there was no call for a burial as the deaths of the squirrels were essentially invisible. Conversely, with the dead mouse, the children and educators took up burial rituals associated with specific religious beliefs, and similar to those enacted by the children in Margaret Wise Brown's *The Dead Bird* (Brown, 1958): a hole was dug, the mouse covered with dirt, and its burying place marked with a stone. A few weeks later, when a girl wanted to dig up the mouse to see what had happened to it, she was encouraged to leave the gravesite undisturbed – out of respect to the deceased mouse.

When Sherry and Pam relayed this burial story to Enid at a conference, she in turn shared the owl encounters described below. We took her story back to our educators. It was a story that as Donna Haraway (2015) writes "was just big enough to gather up the complexities and keep the edges open and greedy for surprising and new connections" (p. 101). Sharing the owl story provoked new insights for the educator, and with a more recent death encounter of a rabbit, the children and educators did not bury the animal. Rather, they chose not to bury it, leaving it to decompose naturally while keeping an eye out on the process and its ultimate integration with the earth.

A Death on the Path

In the first year of the Sooke NK program, the children found a dead owl lying beside the path that they walked each morning as they headed to the site (Fig. 2). The children's first response was sadness that the owl had died and then curiosity as they looked more closely at the bird. They were concerned that it had been hurt and

Fig. 2 Walking the trail to Sooke NK

possibly suffering when it died, and they hoped he or she had had a nice life and that his family would not miss him/her too much. They all wanted to acknowledge him or her by saying something nice to the owl, and so going around the circle, they did just that. Each day as they passed, they spoke of their sadness about the owl's death and their interest as they watched the decomposition. The children narrated multiple feelings, thoughts, and questions, complexities that were documented for later critical reflection and reexamination (Fig. 3).

A couple days after the discovery, Muriel, the class' Aboriginal Support Worker, was with them. She shared with the class that one indigenous belief is that by seeing an owl, this can mean a death. She explained that it did not necessarily mean the death of a person or creature, but that it could signal a time to give up something that might be preventing your growth or harming you. This information invited a discussion about habits or attitudes that might impede one's right action or thought. The children shared thoughts of what ideas or actions might prevent them from being kinder or more focused or more inclusive. Muriel's story helps to highlight for the children their responsibilities in face of death. Similarly, Nancy Turner (2005) shares Mary Thomas' memory of her grandmother who was Secwepemc from British Columbia's interior region, "Our grandmother would tell us a little legend and at the end of the legend she would say, 'Now you see, if you don't do it this way. . ..' They always used something in Mother Nature to teach us our lessons, our values" (p. 77). Robin Kimmerer (2013), botanist and member of the

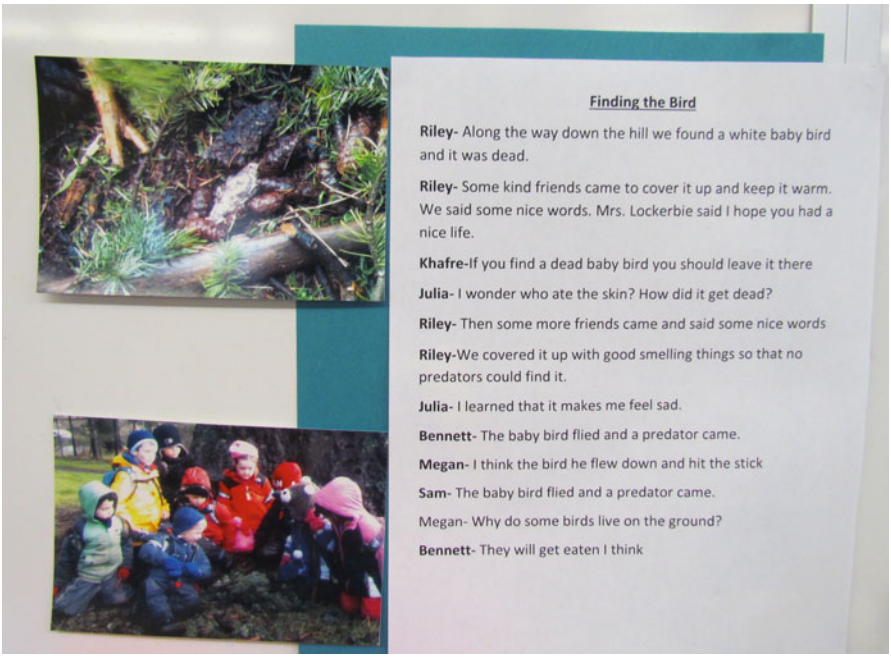

Fig. 3 Documenting the dead owl

Potawatomi Nation, "One of our responsibilities as human people is to find ways to enter into reciprocity with the more-than-human world. We can do it through gratitude, through ceremony, through land stewardship, science, art and everyday acts of practical reverence" (p. 191).

Seeing the owl closeup, motionless, and dead stopped the children in their normal walk along the path. Birds are most often seen in flight, in motion, and at a distance. To see the owl on the ground motionless was thrilling, intriguing, and terrifying. The children reacted with their feelings first: they were sad. But seeing the bird on the ground, lying still, also provided an opportunity to see him or her up close, see the feathers, the feet and talons, and the beak. This is an "in-the-moment sensuous experience that can have the most vivifying, enlivening effect..." (Bai, 2009, p. 143). It also brought feelings of sadness as children connected to other deaths in their lives and perhaps suggested they too could die.

Children were aware of cougars in the forest and their own vulnerability as prey, because at the beginning of the year, they practice what to do if they meet a cougar. Do they make a connection to the dead bird and birds that hunt other creatures to the cougar possibly hunting them? Like Pam and Sherry indicate above, as adults we often carefully hide from our possible identity as prey. Yet, perhaps the dead animals awaken some sense in the children of their own immortality, an affinity and positioning of oneself as prey and a "need to acknowledge our own animality and ecological vulnerability" (Plumwood, 1995, p. 34).

The children experienced the death of the owl and their questions about the owl as a community, as an opportunity to listen deeply, to be affected by the environment around them, impacted by forces which as humans we are often unaware (Brigstocke & Noorani, 2016). Each child seemed to emotionally respond to the owl's death individually and as a member of the group, an experience in a particular place and time. Ingold (2000) reminds us that "ways of life are not therefore determined in advance, as routes to be followed, but have continually to be worked out anew. And these ways, far from being inscribed upon the surface of an inanimate world, are the very threads from which the living world is woven" (p. 242).

"Look! He died happy!" the Dead Raccoon

The Ontario children stare intently at the carcass of the raccoon. The educator and researcher (Debra) stand alongside the children looking down onto the animal. One boy asks, "I wonder how he died?" The children take their time to closely observe the raccoon pointing to different body parts that are visible. They are familiar with terms like skeleton and stomach, and the educator labels the intestine that is also visible. "Look he died happy!" pronounces a boy. When asked why he thinks so, the child points to the visible teeth and explains that the raccoon was smiling when it died (Fig. 4). Later that morning as we revisit the dead raccoon, the boy asks again, "what happens when you die?"

Raccoons are common in the Ontario forest where the children and educators have made an outdoor classroom that they refer to as "the clubhouse." Throughout

Fig. 4 Observing the dead raccoon

the weekly forays into the forest, we had observed raccoon tracks and droppings as well as evidence of multiple other animals typical of this woodland space. Our animal-human encounters were plentiful, serving as pivotal meaning making moments and ethical encounters. For example, the raccoon's death helped the children to empathize with the animal, recognizing him/her as distinct and separate being while also acknowledging the vulnerabilities. The raccoons lived within the forest near the university campus, and the children had observed (and responded to) some of the impacts of human garbage and fast-moving traffic, as well as the effects on the environment from the extreme weather that was experienced (e.g., long dry spells without rain or erosion from spring flooding). Until these raccoon encounters in the woods, the animal was something the children had only experienced in storybooks, a somewhat romantic and innocent notion of the animal. Given the environmental complexities the children confronted, this innocence is problematic, particularly within early childhood education where the "romantic coupling of innocent young children and perfect nature" (Taylor, 2013, p. 53) is so deeply ingrained.

Pacini-Ketchabaw and Nxumalo (2015) refer to the raccoon as "boundary crossers" and highlight the complexity of the "actual, messy, unequal, and imperfect worlds that raccoons, educators, and children inherit and co-habit along with other human and nonhuman beings and entities" (p. 152). At first glance, the raccoon carcass provides a wonderful impromptu science lesson for these young children (e.g., decomposition, physiology of the animal, etc.). But perhaps, something far more complex is happening here. The entangled encounters of child-animal-nature suggest a co-mattering, the child being affected by and coming to understand his/her own role and vulnerabilities in this world within this human-animal relational context. Like Sherry, Pam, and Enid's descriptions above, the death sparked interest in the idea of vulnerabilities and threats to the natural habitat of the raccoon, as well as discussions about one's own mortality. For example, children reacted by

collecting and recycling garbage, placing signs on the road for cars to slow down, and picking wild apples and placing them throughout the forest for the animals to find. Additionally, a "rights" discourse also ensued in relation to ideas of habitat, use of the land, and burying the raccoon. The children visited the dead raccoon over several weeks, monitoring its decomposition while also marveling and imagining the animal's death and life. At varied points throughout the weeks, the carcass appeared to have been moved and placed at different angles.

The children conversed about this development, requesting that the educator recall prior images from previous weeks on her digital device so they could investigate. They were perplexed by this activity, and as time passes (like the children from New Brunswick), these children decide to perform a burial for the raccoon. Initially, the decision to bury the remainder of the raccoon was not a unanimous one, with one boy, objecting to the idea, stating matter of factly that the carcass was food for the bugs and other creatures. The educator opted to support the majority will of the group and a type of Westernized ritual was initiated. The raccoon was buried, crosses were fashioned from sticks (the children's idea) with the lone dissenter choosing an X configuration "like a treasure map," and the children took turns saying goodbye (Fig. 5). After several weeks of being buried, the children return

Fig. 5 The raccoon burial

to the spot to discover the animal had been dug up. The children remark on the state of decomposition (a word they have learned previously in relation to plants). The original dissenter appears to feel somewhat vindicated, commenting how "the coyotes weren't done yet." The remaining children now seem content to leave the carcass as originally suggested. The children continue to check on the decaying raccoon each time we pass the spot in the coming weeks, and eventually, only a tuft of hair from the raccoon remains hanging in a nearby tree.

For these eight children, death was a relatively new phenomenon, and none had much experience with death. Potentially, the raccoon's death helped to heighten within the children an "awareness of the function of death [and] acknowledgement that life is a relational web incorporating a variety of objects, subjects, and bodies along a spectrum of animation, vitality, and decomposition" (Russell, 2017, p. 76). Certainly, the ecology of the children's experiences and framing included both human and animal relations, interactions that were entangled, meaningful, and complex. This co-mattering was evident in a subsequent encounter this time with a live (albeit sickly looking) raccoon.

The children, educators, and researcher are gathered on logs around the fire pit discussing what they have liked most about the year in the forest. Several children call out excitedly, "raccoon!" The adults are momentarily stunned by the response but soon realize the children are pointing and jumping up and down to indicate a raccoon pilfering through the wagon of supplies that they have brought to the forest. One educator uses a stick to bang on logs to make loud noises to "scare" the raccoon away; the children join in with the stick banging. The raccoon slowly saunters down the trail with a somewhat uneven gait (Fig. 6). The educator returns to an animated group of children all talking at the same time. The children seem quite aware that this

Fig. 6 Encounter with a live raccoon

is a somewhat atypical behavior for a raccoon. After their last encounter with the dead raccoon, they have used resource books and videos to learn information about the animal's behavior and habitats (e.g., primarily nocturnal). One of the children flops to the ground and calls out that he's a raccoon, embodying the swaying motions and uneven gait of the raccoon he has just observed. Play resumes in the forest until the educator hears the raccoon returning. The group decides to leave the forest for the day. Once we are back on the trail adjacent to the forest, the children inquire about the raccoon, "is he sick, old, hungry, lost, dying?" The educator explains that perhaps the raccoon's erratic behavior and appearance might be a result of any one these factors or that the animal might be looking for a place to die. The children affirm the animal's right to the forest home, recognizing that perhaps we were disturbing the raccoon in some way. The children emotionally respond to another potential death of a second raccoon. The educator reminds the children of the commonalities between our own organic nature with that of the raccoon(s). This kinship seems confirmed by one girl who verifies that all things die "just like us." Reaffirming these similarities, another boy moves around in a circle among the group pointing to each of the adults, the children, the leaves, and the trees and so on stating how we were all going to die when we were old.

In some ways, the children seem to be attuned with the raccoon; they were affected by the animal's death and life, responding emotionally and ethically in the ways they cared for the animal's environment. The children's understandings here are entangled with the experiences of the dead and living raccoon. The children (and adults) demonstrate an intensity of feelings and a complexity of the web of relations within this place in the woods; in brief the child (person) is indivisible from place-animal-nature.

"Staying with the Trouble"

Perhaps, "staying with the trouble" of death can help to foster generative ways of being with the world. Deborah Bird Rose and Thom van Dooren (2017) call for an ethical approach with the more-than-human world, a *practice of becoming witness*. They describe this practice as:

> an openness to others in the material reality of their own lives: noisy, fleshy, exuberant creatures with their multitude of interdependencies and precarities, their great range of calls, their care and their abundance along with their suffering and grief. . .a mode of responding to others that exceeds rational calculation, one that arrives through encounter, recognition, and an ongoing curiosity. (pp. 124–125)

For most of the children and animals storied throughout our chapter, we engaged in acts of becoming witness. Death itself was somewhat of a taboo and uncomfortable topic within early childhood education. Yet outdoors, death was an organic relational experience, one that was entangled with the children and adults' encounters in the woods. The owl, weasel, and raccoon and their deaths, or the deaths they

instigated, are "worthy of attention" (Loveless, 2013), enmeshed and meaningful engagements with others (human and nonhuman). The children and animals' curiosities, encounters, and recognitions were foundational. Although our focus of the chapter was largely centered on the practice of becoming witness, the animals in our storied encounters co-mattered, and we advocate for staying with the trouble as an important aspect of exploring the multitude of situated and ethical responses that are possible.

Arguably, much more research and dialogue is needed to contest dominant and Western ways of viewing death, burial customs, and ethical actions within early childhood education; perhaps an appreciative and place-based discourse and situated responses related to death could help to further complexify and decolonize practices within early childhood education (Pacini-Ketchabaw & Taylor, 2015). Clearly more research beyond our collective stories is called for, research that also fosters "the overturning of binaries that separate human from nature, and human from animal; an interest in affects and intensities; and the imperative to map becomings, encounters and relations between bodies" (Gannon, 2017, p. 95).

Conclusion

Moving outside of the four walls of the classroom provides multiple opportunities for children to engage with life including death, diverse materials and challenges, and the relationships that rocks, trees, weasels, raccoons, worms, and owls offer. While one never knows what might present itself in this context, these children in these encounters were affected by and ready to see and seize upon the opportunities for relating to the nonhumans of the forest world, while adults often must (re)learn to do the same. Undoubtedly, it is a challenge to move beyond the physical walls of the classroom and the mental maps that are often constructed within our adult minds. Yet, the materialities that outdoor life, and in this case death, present significant encounters for young children.

Aligned with Lenz Taguchi's (2010) ideas, we view binaries such as nature-culture, life-death, child-animal, and indoors-outdoors as naive and exclusionary. As these storied moments highlight children and adults and are entangled beings, coexisting with the rest of the world (Lenz Taguchi). The weasel, owl, and raccoon co-mattered alongside the children, adults, rocks, sticks, mosses, and so on of the places that we have described. We posit that by listening, engaging in the practice of bearing witness to the multiple stories of place ethical actions can be fostered. By "staying with the trouble," that is, the uncomfortableness and messiness of an entangled world, we are invited as educators and researchers to confront and (re)consider the ways in which place, human, and the more-than-human are "alive and thinking" (Watts, 2013, p. 21). These frictions in the forests, depicted with our human encounters with dead animals, contribute to a reconceptualization of beliefs and pedagogies, challenging us all to embrace entanglements and think *with* forests and animals (Pacini-Ketchabaw, 2013).

Abstract

Studying relationships with animals in childhood illustrates cultural conceptions of animals as well as those about children and childhood. Similarly, childhood experiences related to animal death demonstrate associated rituals, practices, and conceptions. This chapter scrutinizes the memories of animal death in childhood, based on data comprising narratives collected in a nationwide writing collection on human–pet relations in Finland. The data used includes the authors' memories of animal death in childhood. Theoretically, the study draws on recent studies about childhood and about human–animal relations, with a relational viewpoint that emphasizes emotions and embodiment.

The study suggests that there are special meanings involved in relations with animals in childhood, and these are epitomized in the experiences of animal death. The memories analyzed illustrate the position of animals as friends and family members already before pet keeping became a central part of home and family. Animal companions have been lost and killed, buried, and mourned,

and their death is frequently contextualized in the experiences of growing up. In the childhood memories analyzed in this study, the human–animal boundary does not appear clear-cut, but instead, mourning the loss of an animal bears similarities to mourning the death of a human. However, grief for a dead animal has been culturally forbidden, which is seen in parents' relative silence and the challenges faced in communicating the grief between parents and children.

Introduction

The practices and conceptions concerning animal death are closely associated to the different ways in which the conceptual boundary between humans and animals is understood, transgressed, and reinforced. The norms and practices that shape death are different in the case of humans and that of nonhuman animals, and, therefore, transformations in the conceptions regarding death, killing, and mourning of animals illustrate the complexity of the human–animal boundary. Moreover, the boundary is always contextual (Charles & Davies, 2011). In can be asked, for example, how is animal death experienced and understood in the context of childhood, in regard to the human–animal boundary?

In late modernity, keeping pets in families with children has become increasingly common, at the same time as child–pet relationships have been promoted as beneficial for the development of children (Russell, 2016; Tipper, 2011). However, relatively little attention has been paid to individual relationships with pets in childhood, let alone experiences of the death of a pet. When a pet dies, there are several issues to consider: relationships between humans and animals, children and adults, and children and pets, as well as children and death. Studying relationships with animals in childhood illustrates cultural conceptions regarding animals and their death as well as children and childhood.

This chapter scrutinizes memories of animal death in childhood, based on data comprising narratives on human–pet relations collected in Finland. The study aims to make visible the ways in which human–animal relations and death are understood in the cross-generational context, based on the narrators' memories of experiences ranging from agrarian times to the urban pet-keeping culture. The question is, in what ways are experiences of animal death described in childhood memories? The focus is on the loss and grief experienced at the death of animals understood as pets by the narrators. Special attention is paid to the ways in which cultural conceptions, norms, and practices that define the appropriate ways of relating to and grieving the death of an animal for both children and adults are reflected on in the narratives. The methodological challenges regarding the study of adults' childhood memories are also discussed.

Theoretically, the chapter draws on discussions of relationality, emphasizing the emotional and embodied aspects of human–animal relationships (Acampora, 2001).

Child–animal relationships have often been described as a phenomenon that is natural to childhood, and children, perceived as innocent, have been paralleled to animals (Tipper, 2011). In more recent studies, however, children have been understood as active agents with meaningful social relationships with others, including animals (Tipper, 2011; Wyness, 2012, p. 62). In this study, the naturalization of child–pet relationships is rejected and the subjectivity and agency of children is appreciated, similarly to those of animals.

Companion Animals, Childhood, and Death

Animals that share their lives with humans in close companionship can be termed pets or companion animals (Charles & Davies, 2011). A pet is given a human name, it shares the home with a human, and its body is not used for human consumption (Thomas, 1983, pp. 112–115). These animals are often understood as conscious and sentient subjects and agents, who interact with humans and share their everyday life with them in meaningful ways (Charles, 2014). Relationships with animals based on kinship in such a way have a possibility to blur the categorical boundary between humans and nonhuman animals, resulting in interpretations of "posthuman families" (Tipper, 2011).

A substantial number of pets in Western countries live in families with children, which suggests that "families place children and pets firmly together within the sphere of domestic life" (Russell, 2016, p. 83). Pets are often acquired on children's initiative, and children call them siblings, best friends, and confidants (Charles, 2014). Children know the animals they live with individually, and they interact and communicate with them and describe them as close friends who listen to them in moments when adults cannot (Leinonen, 2013, p. 70; Morrow, 1998). Children tell their pets their secrets, and especially dogs give children an opportunity to move outside the home (Morrow, 1998). Pets are part of the family network, and their position as family members is largely based on the duration of their cohabitance with humans and the quality of the relationship (Tipper, 2011).

When pets die, the practices and understandings concerning their death illustrate the position of pets and cultural conceptions regarding human–pet relationships, but they also reflect recent transformations in the ways of relating to death in the West. It has been argued that death has become a silenced subject and expressing grief openly has become forbidden in modern societies. Bauman (1992, p. 134), for instance, writes that "death has become a guilty secret." Giddens, on the other hand, (1991) suggests that death has been moved away from the public sphere, rendering grief a private process. The idea of death as a taboo has increasingly been challenged, suggesting that "relationships between the living and the dead are being rediscovered" (Howarth, 2007, p. 19). It is characteristic to human death in late modern society that it can partly be controlled by the medical science, as terminal illnesses can increasingly be managed (Bauman, 1992). The death of animals is controlled by humans to a far greater extent, as most "domesticated" animals are killed by humans (Marvin, 2006). Killing animals emphasizes the hierarchical

boundary between humans and animals, as the human is the only animal whose killing is considered murder (Haraway, 2008, pp. 79–80).

Animal death, including pet euthanasia and grieving for the loss of a pet, is regulated by cultural norms and practices (Redmalm, 2015). They include norms regarding the ethically appropriate killing of animals in different circumstances, but they also define the rules concerning feeling and expressing emotions about the death of animals (Morrow, 1998; Turner & Stets, 2005, pp. 26–36). The death of a pet is mourned in much the same way as a human's death, but, according to Redmalm (2015), it is ambivalent in the sense that it reflects the status of animals as either resembling humans or different from them. The animal is often mourned as a separate, sentient being and a partner in a social relationship, comparable to a close human. In situations where expressing the grief is risky or too much of a burden to the mourner, the pet is distanced to the position of an animal different from humans.

The next section discusses the methodology of this study, followed by an analysis of the emotions and meanings attached to the grief over the death of a pet, the difficulty of parental support, and experiences of unjustified killings, before drawing conclusions on the analysis.

Using Childhood Memories as Data

Childhood relationships with animals have been investigated by studying children themselves but also by exploring adults' childhood memories, as in this chapter. The data for this study comes from a nationwide writing collection under the title *The cat, the Dog, and the Horse – The Animal as a Family Member (Kissa, koira, hevonen – eläin perheenjäsenenä)*, organized by the Folklore Archives of the Finnish Literature Society in 2014–2015. The writing collection was announced widely in Finnish magazines and social media. People were encouraged to write about their memories and experiences of sharing their life with pets, including experiences of animal death. The author of this chapter personally involved in designing the themes for the collection.

Narratives collected in writing collections are typically autobiographical (Latvala & Laurén, 2013). Autobiographical narratives about human–animal relations can be used to explore shared experiences between the human and the animal and the cultural meanings given to them (Leinonen, 2013, p. 67). Smith and Watson (2010, p. 15) nevertheless point out that the concept of truth in autobiographical writing is not easily defined: "[a]ny utterance in an autobiographical text, even if inaccurate or distorted, is a characterization of its writer." As Jones (2008, p. 199) points out, in researching childhood "we need to be extra vigilant and reflexive about how we approach, engage with and render the other in our research accounts and conceptualisations of children/childhood." This is especially true about research based on adults' childhood memories as data. Memory is relational, and in narrating childhood memories, the authors engage with their childhood self (Russell, 2016). Jones (2003, p. 27) notes that "[m]emory is not just a retrieval of the past from the past, it is always a fresh, new creation." This means that the child of the past as well

as the others remembered in the narrative – human and nonhuman – is always represented by the one who writes the narrative (Russell, 2016). In experiential narratives such as the ones analyzed in this chapter, the authors reflect on their own life events and experiences in a way that makes sense to themselves (Latvala & Laurén, 2013). Narrated experiences are part of cultural meaning-making as they provide access to past experiences by giving them meanings in the present. They thereby assist in understanding temporality and change.

For the writing collection, 193 responses were received, comprising 1187 pages in total. For this study, 111 descriptions of animal death experienced in childhood were selected. Of the 65 narrators whose texts were included, 60 were women and five men. The authors were born in the years 1919–1998, and the data thus includes childhood memories from the 1920s to the early 2000s, reflecting the transformations from the agrarian culture to the present. For the purposes of the analysis, the data was thematized in three themes: the emotions related to animal death, the role of adults, and how the author experienced the event ethically. Throughout the analysis, attention is paid to the ways in which the authors reflect on their memories at the time of writing them.

Grief Over the Death of a Pet

In the narratives, childhood relationships with animals are described in detail, and nearly all narratives end in the death of the animal. Animals typically died in accidents or were killed in different ways. Very rarely did they die naturally. The authors describe their attachment to animals in childhood as a strong emotional experience. They often grew up with puppies and kittens but also with foals, calves, lambs, and piglets, which they cared for and considered pets, close friends, and family members (see Leinonen, 2013, p. 71). This chapter concentrates on relationships with animals understood as pets, leaving out the slaughter of farm animals.

The death of a close animal is remembered in the data as a very sad event. As one author states, "you experience the death of an animal more strongly when you are a child, and I also mourned Riku for a long time" (SKS KRA. Pets 40–43. 2015). According to Jones (2003), children's lives are more emotional than adults' lives. This is evident in childhood memories, also because memories not only consist of past events but also of emotional responses to those events (Jones, 2003). Many authors express a longing for an animal they have lost as a child, even as they are writing about the event as adults, as in the following example from the 1970s: "I dreamt about Netta every now and then until only a few years ago. These dreams only ended – almost – when our own dog Pike came into the household in 2009" (SKS KRA. Pets 189–190. 2015). When the dead pet is defined as "only" an animal, different from humans, it can easily be replaced with a new one (Redmalm, 2015). If, on the other hand, the pet is seen as a friend or family member comparable to humans, it is perceived as irreplaceable, at least immediately after death. Such a case is described in the following example from the time of WWII:

> For a few years, he was our joy. Then he got distemper and was paralyzed. Mother knew a car driver who carried a gun, and he euthanized our friend. Life felt empty after Evacuee's death. Aunts, uncles, cousins and Father were away from home at the war front, and the animal friend was also gone. Already then I decided that I would never have a dog myself, as losing it is so hard. (SKS KRA. Pets 92–115. 2015)

In agrarian times, it was common to kill kittens, sometimes also puppies, because there were simply too many animals. This was sometimes the case in the countryside even in the 1980s: "Grandpa put them down by throwing them against a rock. It still feels horrible, because I saw it with my own eyes" (SKS KRA. Pets 922–927. 2015). Animals were usually killed at home, because there was no other way, and the neutering and euthanizing of small animals by veterinarians were not common practice before the 1960s. For children, the frequent killings of young animals were a painful experience.

In the narratives, there are several references to pet burials in the decades following WWII, usually at the farmyard or summer cottage. With the development of pet-keeping culture, features of human death rituals, such as burying and mourning practices, have been adapted to the death of pets (Kean, 2013). According to Tipper (2011), the body has a special significance in childhood, and this is evident in detailed descriptions of the bodies of dead animals. These descriptions reveal the significance of the event to the author:

> Soon after this White Spot was hit by a train. He was completely cut in two in the middle, and his open green eyes stared at the sky. It took a long time before I stopped mourning him, because he was my cat. His remains were buried in the garden. (SKS KRA. Pets 116–117. 2015)

If the animal died in wintertime when the ground was frozen, digging a grave was not possible. In the following example, the animal continues its embodied presence in the life of the author during a long liminal phase between death and disposal of the body: "The cat could not be buried in winter, so he was kept in a cardboard box in the greenhouse. I went there every now and then to pet the cat's body" (SKS KRA. Pets 441–442. 2015). Here, touching the body of the dead cat is described as a pleasant experience, which serves the purpose of mourning the feline friend. In the narrative it is presented as an embodied memory, epitomizing the emotional and embodied relationship with the childhood pet (cf. Russell, 2016). It can also be interpreted as representing the child's agency in actively managing the continuation of the relationship after death (Howarth, 2007). There are also examples in the data of the agency of the animal at the moment of death, as in the following memory about the death of a guinea pig in the 1970s:

> I remember the morning when I was leaving for school and we looked each other in the eye. Tiku was very weak and reaching for me, his gaze still touches me. It was a farewell gaze and those stay with you forever. There is a lot of feeling in them. I think animals understand more than people understand that they understand. (SKS KRA. Pets 607–609. 2015)

Again, the relationship appears to continue after death, this time in the narrator's interpretation of the pet's gaze as an eternal "farewell gaze." The narrator further contemplates the gaze, to the extent of attributing significant understanding to it. She thus acknowledges the animal's agency, which dissolves the hierarchical human–animal boundary (Charles & Davies, 2011). It also contributes to the grief felt, as without acknowledging the animal's agency, it would be much easier to encounter the death of the pet and the end of the relationship.

The Challenge of Parental Support

Human–animal relations are always situated in the surrounding world of social relations, norms, conceptions, and practices, and this is also the case in childhood (Russell, 2016). In the data, it is evident that in agrarian times, killing animals has been the realm of adults, regardless of the relationship between the child and the animal: "We, the children, felt sad when the grown-ups decided to put Terri down. Maybe he was not a good hunting dog. Children's views were not asked nor heard" (SKS KRA. Pets 655. 2015). Children were not permitted in the world of death, and, in several accounts, parents tried to protect them from seeing the killing of a beloved animal. Instead of keeping the children happy, this practice has apparently resulted in some of the most painful memories of animal death. They also illustrate the distances between children's and adults' experiences and understandings of animals, emotions, and morality (cf. Jones, 2008).

In the narratives, memories of the loss of a pet appear as isolated experiences in childhood. According to Giddens (1991, pp. 167–169), a sudden encounter with death can be a shock. The authors write about close and meaningful relationships with animals in childhood, and their own emotional reaction to the death of such an animal is remembered vividly. In contrast, the narratives reveal the relative absence of parental support at the moment of loss:

> One day, when the inseminator arrived at the yard, Misse hid herself under the car, in front of the back wheel. And when the inseminator left, she went too. I don't know where, but only a little lifeless body was left. Someone came and picked it up. I did not cry. I did not say anything. And I was not taken on the lap by anyone. (SKS KRA. Pets 266–332. 2015)

What is striking in the narrative is the absence of any expression of grief or consolation. Mourning a dead pet has been considered an instance of "forbidden grief" that cannot, according to cultural norms, be expressed openly (Taylor, 2013). The experience of loss and the relationship between the mourner and the deceased are not recognized, leading to a difficulty in sharing the grief and a lack of consolation to the mourner. The lack of parental support in the context of animal death is an example of how forbidden grief may be experienced in child–adult relationships. For adults, the death of an animal is a controversial event, and expressing the emotions related to it may not have been possible without ridicule

(Tipper, 2011). As one author states, "in the old times it was not allowed to show grief over the euthanasia of a pet, at least if you were an adult" (SKS KRA. Pets 404–405. 2015). The silence over the grief over losing an animal emphasizes the difference between humans and animals and therefore reinforces the human–animal boundary.

Emotional attitudes toward animals are not a new phenomenon. Instead, expressing these emotions has become more acceptable after urbanization distanced farm animals from everyday life and pet keeping gained in popularity (Charles, 2014). In child–adult relationships, on the other hand, the transformations following WWII led to more open communication between children and adults (Cunningham, 2013, pp. 213–219). Both of these developments are visible in the narratives. Accounts of more recent events illustrate how the grief over animal death is shared with parents, as in the following example from the early 2000s:

> I remember how Mother came to my room late at night and said that we may have to put Nana down. At first I did not understand what Mother meant, but gradually I realized the sad truth. I remember my last day with Nana, when I hugged her and hoped that time would stop and Nana would not leave my side. Soon we sat in the car outside the vet clinic and watched Mother lead Nana away. I prayed for Nana to come back. I was struck by grief when I saw my mother walk back without Nana. (SKS KRA. Pets 473. 2015)

Here, the mother takes the child all the way through the experience while still protecting her from seeing the actual killing. The experience is very different from those in the memories of agrarian times. The changes have, however, been slow and difficult, as can be seen in the example from the 1970s, where the parent tries, in vain, to protect the child from the shock of killing:

> I stroked Lotta for the last time. Father took her out and I stayed inside with Mother. After some time I went outside. I noticed Father there and started walking closer. Then, suddenly, I saw him sling the cat against the stone wall of the outbuilding. We both flinched. I, for seeing the violent death of my dear pet, he, for me to be staring there. Father's expression was not delighted. (SKS KRA. Pets 607–609. 2015)

Experiences of Ethically Unjustified Killings

It is a recurrent theme in the narratives that children's possibilities to control the death of animals are limited. Many respondents recount the practice of killing a pet without first telling the child about it. Sometimes the fate of the animal has remained a mystery, as in the following example from the 1960s:

> I was 15 or 16 years old. One day, when I came home from school, Mirri wasn't there anymore. I never got to know the full truth about Mirri's death. My impression was that one of my father's co-workers had euthanized our pet. Why? By whom? Where was Mirri buried? (SKS KRA. Pets 2–5. 2015)

Many authors feel that the killing of their pet was unjustified. It has been hard to understand the adults' motives for killing, as these have not been openly discussed in the family. Emotions felt for an animal assist in remembering the specific events related to its death, and the descriptions of unjustified killings are often detailed:

> Pörri's life was very short. Aunt Riitta died in December 1961 and Irja from Mustola was preparing the funeral. Her brother Antti took her to our house, and I heard my father say to Antti that there was a "black hare" in the house. That night Pörri disappeared. I decided then, although being a minor, that this was the first and last dog that anybody killed without my permission. (SKS KRA. Pets 335–343. 2015)

In another example from the 1950s, the author describes the unexpected killing of the children's pet dog as cruel:

> The most terrible shock came when, close to Christmas and after this visit, we went to my uncle's. My aunt invited us 'big girls' upstairs to see a surprise. And what a surprise! By the door to my uncle's study there was a smallish black dog skin. "There's Tarjukka now!" my aunt said and added something that was even more shocking: "Tarjukka was euthanized by shooting in the head, at the Pengerkatu police station." (I haven't as yet been able to decide whether my aunt was a conscious sadist. For us girls Tarjukka's death was a matter of grief, and showing/using the skin was cruel). (SKS KRA. Pets 153–172. 2015)

Both narratives reveal a feeling of powerlessness expressed by the authors, regarding the fate of their pet. In the first excerpt, the author feels that she should have had the right to decide on the life of her own pet. In the second one, the adults' actions render the death of the pet purely material, epitomized by the use of the dog's skin. Although preserving the skin of animals was quite common in agrarian times, for the author the dog is a sentient animal, and keeping its skin is not perceived as an acceptable way of managing its death. In both cases, the authors describe their shock and frustration of being dependent on adults' understanding of their pet as "only" an animal and the dismissal of their emotional relationship with the pet.

The reason for their emotions can be associated to the blurring of the animal category: pets are not considered animals that can be killed without a reason, especially not for human consumption (Leach, 1964). The narratives, however, illustrate intergenerational differences in the interpretations of the acceptability of killing animals. What has been presented as a justified killing by adults may have been experienced as unjustified by children – even as adults, at the time of writing the narratives. By transgressing the categorical boundary that defines pets as companions and family members, the pet has been "made killable" by the adults, in the sense that they have not needed to justify its killing (Haraway, 2008, pp. 78–80). For the authors, however, the boundary could not be transgressed. The emotions evoked by this controversy are expressed strongly in the narratives, suggesting that memories are, first of all, *emotionally felt* (Jones, 2003).

There are also cases in which the death of a pet has been caused by an outsider, as in the following memory from the 1980s: "When the cat was about four years old I found her dead in the woods. Somebody had poisoned her. The grief was enormous

and the cruel deed of the human was difficult to accept" (SKS KRA. Pets 629. 2015). Encountering death as an isolated experience causes not only shock and grief but also contemplations of morality (Giddens, 1991, pp. 144–180). In this case, such contemplations concern the place of animals in a just world. Often found in the narratives, they suggest that such experiences and the emotions they evoke have a profound meaning in childhood, one that is not easily forgotten.

According to Tipper (2011), children are conscious of intergenerational dynamics and power relations. The data used in this study support this notion. The authors of the narratives reveal a feeling of injustice regarding the ways in which adults have understood animal death and carried it out. Killing an animal without telling about it to the child becomes an ethical issue. The pain and bitterness expressed in the narratives suggest that the denial of communication and grief on the part of the adult is a central part of the memories created of the experiences. Also, the narratives reflect a generational change in the ways of relating to animals as companions. For the authors, expressing painful memories of lost pets is supported by contemporary pet-keeping culture which increasingly allows the mourning of pets. Their parents' reactions, instead, indicate that such an openness in both human–animal relationships and adult–child relationships has previously been restricted.

Conclusion

This chapter has explored childhood memories of experiences related to animal death in autobiographical narratives. The study suggests that the special meanings involved in relationships with animals in childhood are epitomized in the experiences of animal death. The memories analyzed illustrate the position of animals as friends and family members already in agrarian times, before pet keeping became a central part of the home and family. The narrators do not always make a clear difference in how they write about humans and animals: both are described as persons participating in relationships with (other) humans (Tipper, 2011).

It seems that in childhood, the human–animal boundary does not appear as clear-cut, but instead, mourning the death of an animal is comparable to mourning the death of a human. Children appear to have been willing to recognize their pets as conscious agents, often in situations where there are no adults present. Acknowledging animal agency at the moment of death, however, makes mourning the death more difficult (Redmalm, 2015), also for children. Expressing emotions related to animal death have also been culturally forbidden, which is seen in parents' relative silence and the challenges faced in communicating the grief between parents and children. By emphasizing the human–animal boundary, adults seem to have "lost sight" of their children and the agency they have displayed in their relations with animals. Recent changes in allowing the expression of emotions toward animals therefore also contribute to parent–child relations and to acknowledging children's own agency.

Jones (2003) notes that in memories of something permanently lost in childhood, mourning it easily becomes intertwined with the lost childhood itself. In

remembering the deaths of close animals, the authors of the narratives may express feelings about their childhood more comprehensively, including parent–child relations and the general happiness or unhappiness that characterized their everyday life as a child. It is evident, however, that in the relational networks of childhood, animals and their lives and deaths are an inseparable part of everyday existence.

Abstract

While there have been several attempts to account for relationships between humans and nonhuman animals in the social sciences and humanities, the discipline of education has, until recently, steered clear from the so-called animal turn. Drawing on post-anthropocentric theorizations, we introduce a concept of withling(s) and develop it empirically in the context of early years education. In particular, we zoom into one practice of science education at a kindergarten in order to consider what kind of child-animal relations are and might become invoked. Our concept of withling(s) is not an a priori positive relatings, as during the dance between earthworms, pupils, teachers, and technologies, both joy and suffering are invoked simultaneously.

Introduction

This chapter is based on a wider study of children's emergent more-than-human literacies explored at early education contexts in Australia and Finland (Somerville et al., 2016). The data grounding this chapter was produced mainly with children and chest-mounted action cameras during a total of eight research visits (c. 16 h of audiovisual material) to a kindergarten in Finland, in the spring of 2016. In this chapter one selected episode from this data is discussed in detail. The theoretical-methodological approach of the chapter embraces post-anthropocentric qualitative inquiry, multispecies inquiry in specific (e.g., Kirksey & Helmreich, 2010; Wilkie, 2015). The novel, yet rapidly emerging approach of multispecies ethnography sees animals as embodied individuals sensing and making meaning of their environment and thus legitimate participants in ethnographies of shared lives (Buller, 2014).

We conceptualize children and the nonhuman animals that cohabit the yard as "withlings" and the processes they engage in as "withling" (verb). This chapter is an exploration and discussion of how withlings and withling help us further understand complex and often conflicting emergence of child-animal relations. While in many ways akin to Donna Haraway's (2008, p. 330) critters as a "motley crowd of lively beings" that are "always relationally entangled rather than taxonomically neat," the construct of withling(s) – simultaneously a noun and a verb – encompasses mattering for those involved (on mattering see, e.g., Rautio & Jokinen, 2016). Where critters can be microbes and fungi that matter bio-physiologically but often implicitly to a human child, withling targets those co-beings children themselves identify as mattering for them. This is a neglected aspect as child-animal relations research tends to emphasize developmental views beyond children's own experiences and actual, particular, and contextual encounters (Rautio, Hohti, Leinonen, & Tammi, 2017; Tipper, 2011).

There are many attempts to account for relationships between humans and other animals in the social sciences and humanities. Majority of human animal studies (HAS and/or critical animal studies or CAS) are conducted within or stem from anthropology (e.g., Hurn, 2012; Ingold, 1988, 2013; Noske, 1997), geography (e.g., Buller, 2014; Wolch & Emel, 1998), cultural and literary research (Fudge, 2002; Wolfe, 2003), or more recently also sociology (Irvine, 2004; Taylor, 2012; Wilkie, 2015). Rhoda Wilkie (2015) points out that each discipline embracing human animal studies both shapes HAS and is shaped by it. For example, the increasing interest of sociologists in HAS both animalizes sociological imagination and socializes HAS.

The discipline that has, until recently, stubbornly steered clear from HAS (and CAS in particular) or only dealt with it via psychology is education. Conversely, most of HAS research (excluding psychological studies) have not explicitly dealt with children or educational thought. And so, the recent advances in early childhood education (e.g., Pacini-Ketchabaw & Nxumalo, 2015) and environmental education (Lloro-Bidart, 2016; Spannring, 2015, 2017), as well as educational philosophy (e.g., Pedersen, 2010; Snaza & Weaver, 2014) of engaging HAS can be thought of as beginning to animalize education and perhaps in time to also child-orient HAS.

The so-called animal turn (Armstrong & Simmons, 2007) in the social sciences and humanities has been reviewed efficiently, for example, Reingard Spannring (Spannring, 2017; or Oakley et al., 2010) from the viewpoint of environmental education, Teresa Lloro-Bidart (2015) from feminist (posthuman) scholarship and education, Birke, Bryld, and Lykke (2004) from the viewpoint of feminist science studies, and Rhoda Wilkie (2015) within sociology. These reviews present conceptualizations of human-animal relations that often foreground performativity. This means a focus on mutual creative becoming where the smallest unit of analysis is not the participating individual but the relation (Haraway, 2003) or in other words the interdependence (Pickering, 2005) of beings.

Donna Haraway (2008, p. 249) talks about tangled species as infoldings engaged in "dance of world-making encounters." For Andrew Pickering (2005), the dance is that of agencies. Both include a multitude of other actors or technologies and things beyond the human(s) and the animal(s) in the choreographies. Vinciane Despret (2004) in turn focuses her conceptualization closer to the animal bodies and talks about anthropo-zoo-genesis where bodies of different species accomplish something together because of each other and the ways their bodies are able to "attune" to each other. Traci Warkentin (2010) calls for an "interspecies etiquette" for meeting up with other animals and emphasizes attending with one's body, rather than only verbally or by looking.

Relying on species constructs and on human-animal engagements between adult humans and the animal individuals as if ageless, the existing research can appear slightly "off" when working with younger humans. This is because the species constructs that the earlier research aims to unsettle are only in the process of being constructed in the everyday lives of younger humans. And, arguably, this is taking place through an intense phase of socialization into speciesism and anthropocentrism (Pedersen, 2010). So rather than focusing on undoing of something already settled (a habit of thinking anthropocentrically or through the construct of species), research with children focuses *also* on the ways in which that something is continually in the process of being normalized, sedimented, or "striated" (Deleuze & Guattari, 1987) within the historical-social-cultural-material contexts of the child-animal relations.

Following the outdoor playtimes of circa 20 kindergarten children for 2 months, we became drawn to generative "world-making" events in which dances of agencies produced children and the animals encountered not as entangled companions but distinct and hierarchically anthropocentric. To begin to address what was happening – and why other possibilities were not actualizing – we begun to craft a conceptual tool the use and definition of which is the focus of this chapter. The concept of withling(s) will focus us on the ways in which the dances and choreographies of Haraway and Pickering can also end up creating, repeating, and reinforcing speciesism and binaries – in children's lives in particular (Russell & Fawcett, 2013; Spannring, 2017).

Taking seriously the need to renew our concepts for the benefit of processually entangling onto-epistemology (Deleuze & Guattari, 1987), we now turn to introduce our concept of withling(s). After a short introduction to the empirical context in which the concept emerged, we provide an episode we have named "worm rally" in

order to put it to work. Finally, we move on to a more specific conceptualization in order to make future experimentations possible.

Emergence of Withling(s)

The concept of withling(s) functions as both a noun and a verb, thus interfering the commonplace linguistic separation of the subject, object, and the direction of the doing. As a noun, it points toward the participants who comingle in the process of "becoming (different)" (Deleuze & Guattari, 1987) – withlings. As a verb, it suggests the ongoing assembling, collaborative and relational doing – withling. As a consequence, thinking with this concept allows us to consider what comes together in the analyzed events, as well as what other kinds of withling could also become possible in the given developments. Thus, it resembles the Bergsonian insight of descending and ascending and Deleuzo-Guattarian (Deleuze & Guattari, 1987) translation of it as virtual and actual, possible and real.

This chapter is based on a wider study of children's emergent more-than-human literacies explored at early education contexts in Australia and Finland (Somerville et al., 2016). The data grounding this chapter was produced mainly with children's chest-mounted action cameras during a total of eight research visits (c. 16 h of video) to a kindergarten in Finland, in the spring of 2016. In this chapter one selected episode from the data is discussed in detail – that of a worm rally. In the whole data, there are altogether more than ten different children who take turns in carrying the camera. In the worm rally depicted in this chapter, the camera is carried by one 6-year-old boy during a 2-h outdoor playtime in the morning.

The theoretical-methodological approach of the wider study, as well as our approach to the overall theme of this handbook, childhoodnatures, locates within the rapidly emerging "posthumanist" (i.e., beyond or after humanist, human-centered) approaches to educational research (e.g., Snaza et al., 2014). Posthumanism is often seen as converging with "sociomaterialism," "post-anthropocentrism," "new materialism," or "new empiricism" and is mobilized by theorists such as Haraway (2008), Braidotti (2013), Latour (2004), Bennett (2010), and Stengers (2011). At the core of these approaches, there is a focus on the *relations between partaking entities* rather than on the individual (human) actors or groups of humans. This means that emphasis is on the shared processes through which relations take place rather than on individual (human) views of these relations or exclusively human sociality and meaning making where the environment remains as a mute context for human activities. This approach highlights a premise for childhoodnature according to which humans and their nonhuman surroundings do not exist as independent of each other (Malone, 2015; Pedersen, 2010; Rautio, 2014; Snaza & Weaver, 2015).

Aligning with posthumanism as a theoretical approach, the emerging approach of multispecies ethnography (Kirksey & Helmreich, 2010) foregrounds all animals as legitimate participants in ethnographies of shared lives (Buller, 2014). According to Maurstad et al. (Maurstad, Davis, & Cowles, 2013, p. 323), "these ethnographies

allow for a radical rethinking of natural and cultural categories for analysis." Multispecies ethnography of withling(s) focuses on human-animal coexistence in terms of not only what the individuals are (biologically) but what they do (biosocially) and not as beings but as becomings creating themselves together through action and interaction within their surroundings (also Ingold, 2013). These becomings can be viewed through Ingold's ideas about the relational constitution of being (Ingold, 2006, p. 12) where organisms are thought of "as trails along which life is lived." They form a meshwork, a web of lines of growth. Also persons "extend along the multiple pathways of their involvement in the world" (Ingold, 2006, p. 13) with other becomings and withlings.

The materials produced by chest-mounted action cameras provided us audiovisual material of children's biosocial cominglings in the yard of a daycare center. As the cameras were propped on humans and due to our natural(ized) ontological attitude and our adjacent training as scholars, we had to intentionally resist perceiving the "child" and "environment" as separate from each other. Instead of reducing children's doings to intentional actions in an environment that functions as if a backdrop of affordances for the humans, we focused on viewing the engagements as ontologically a priori to "child" (or to any single individual element). This is to say that we focused on how different kinds of doings emerge temporally, spatially, and materially, producing different variations of a "child" (and of other individualizable elements or beings). This is how the notion of withling(s) begun to emerge. We realized we were searching for simultaneous relational emergence of subjects and doings – withlings and withling.

Worm Rally

The kindergarten yard comprises sand, rocks, pebbles, pine trees, toys, recycled play materials, slides and jungle gyms and swings, three smaller and one bigger playhouse, a storage building, teachers, a researcher, and many other animals such as earthworms. There is a compost behind one of the buildings. In the middle of the yard, there is a long table with benches. A child with an action camera is running back and forth between the compost and the table, delivering worms from the former to the latter. In what follows, we will first describe the event we named a worm rally. The description remains fully anthropocentric and is then followed by a rereading with the concept of withling(s) to exemplify how it highlights non-anthropocentric and relational emergence of subjects and doings.

> The child is walking from the compost towards the table. He is holding a worm with tweezers. He keeps his other hand palm open under the worm as if for safety. He goes to the table, takes the worm from the tweezers, drops it into a small plastic cup with water in it and after rinsing the worm, he moves it to another container with other washed up worms. There is also another worm in the water container, which he tries first to take with the tweezers but decides after all to take it with his hand. "Dirty work", he utters, drops the worm in the container with washed worms and looks at his hand.

There are also magnifiers, containers, gloves, hats and a book on the table. Other children's voices echo the many games that are evolving in other parts of the yard.

The child looks at the worms, "Jaakko, we're not going to wash that [worm] – that one is not at all dirty", he comments to the teacher, who agrees. Then the teacher begins to organize the table. The child spends time by the table, looking at the worms with a magnifier. Then he checks what other kids are doing. While chatting with them, he presses his own finger with the tweezers.

The child returns to the table and lifts one of the worms from the container. He then heads back towards the compost. At the compost there is a teacher (Anna) and another child digging the ground. "Anna, I have grippers". Anna glances at him and returns to digging. The boy starts to look for worms using both his hands and the tweezers. His friend finds a worm. There is a lot of excitement in the movements of the children. He places the worm on his hand and tries to catch it with the tweezers. It takes a while before he succeeds as the worm squirms. As he succeeds, he cries out: "Now it won't be able to flee!" He bypasses Jaakko and repeats: "Now it won't be able to flee". He rinses the worm and places it in the container with other cleaned up worms. And then starts heading back to the compost, now with increased speed. He is running.

The children at the compost have found two worms. The child with the camera takes them in his tweezers and walks back to the table with a faster pace. "Jaakko, again two worms in the grippers!" Rinses them. Puts them in the other container. Runs back at the compost. Takes another worm and places it in the tweezers. Drops the worm half way to the table. Picks it up in his hand. "This is so little that it's not possible to have it in the grippers!" He checks quickly what others are doing. And runs again. "Worm alert, worm alert!", he exclaims to another boy.

The child has now one worm in the tweezers and another on his hand. "No, no, no!", he comments when the worm almost drops from the tweezers. "Here come many worms to be washed!", he yells excitedly to those at the table as he approaches.

This worm rally is repeated quite a few times during the outdoor playtime. Worms start to pile up in the container, some of them now very still. Children are leaning against the table, watching the worms, and studying them with magnifying equipment. The child with the camera runs and delivers, every now and then jumping over obstacles, and checking what the others are up to, at some point telling a joke, but delivering the worms with tweezers is the doing that he sustains. When we listen carefully, we hear his heartbeat speed up as the worm rally repeats and repeats.

Worm-Child Withling(s) During the Worm Rally

The worm rally is an example of a repetitive pattern of the daily outdoor playtime: whenever the children encounter an animal, usually a bug of some kind, they call for

Jaakko (one of the teachers) who then proceeds to fill the long table with equipment for inspecting the found creatures. As he is preparing the setup, the children form a neat queue at the end of the table. Everyone knows this choreography by heart.

On the surface, and through a conventional humanist and anthropocentric reading, this kind of practice reflects the participatory and child-centered ideals of contemporary pedagogical practices. The looseness of the adult-led instruction provides opportunities for the children to initiate, to explore, and to engage in activities that are commonly valued and to rehearse meaningful tasks and skills such as collecting samples and practicing fine motor skills with tweezers. The recurring nature of the worm rally is not exhaustive in that it becomes continuously interrupted by various encounters between pupils and teachers at the yard. It works its way through various rhythms, accelerations, and slowing downs in between of which it becomes continuously reenacted. For example, the rally is continuously augmented by greeting of others, chatting, and observing what else takes place at the yard among fellow humans. In sum, the worm rally is an example of the material practices of (science) education in the given kindergarten. This practice is intensive because it becomes reenacted almost on a daily basis and is thus able to endure and become routinized.

Our concept of withling(s) encourages us to reconsider the worm rally, however. A focus on the comingling of humans, nonhuman animals, and technologies, including the worm's perspective, affirms the critique that animals are often objectified, especially in educational practices (Pedersen, 2010). Animals are engaged as objects of human vision and practices (Haraway, 2008; Spannring, 2017). When the magnifying loops are brought to the table to study the worms, they become objects of inquiry. As they are carried with tweezers to the washing spot at the table and put afterward to another container with other rinsed worms, they are actively separated from their commonplace set of relations where dirt, microbes, birds, and compost play a significant part. They become relocated in another assemblage where shovels, containers, tweezers, science books, and magnifiers among others participate in the emergence of "child," "worm," and "education." This child-worm-education "meshwork," a field of interwoven lives (Ingold, 2006, p. 13), consists of lines of material flow that are also the "pathways of biosocial becoming" (Ingold, 2013, p. 18).

The ongoing withling in the worm rally is sustained and facilitated by certain technologies, namely, the tweezers, books, and magnifiers that work on both the worms and the children: the withling that children and worms participate in is giving birth to certain kinds of worms and children, certain kinds of withlings. As the worms are literally washed away much of their previous "wormness," they become what might be called techno-scientific worms – as do the children. The pathways of children and worms are pedagogized with the "worm-kit," tools for investigating the worms, and formed into a meshwork of children, worms, adults, soil, water, and tools.

The ethical consideration that the worms are also living becomings with experiences and that they are valuable as what they do (see also Shapiro, 2002) is nonexistent in the recurring worm rally. What Haraway (2008, p. 20) calls "a simple obligation of companion species" has to do with the curiosity about what the

companion "might actually be doing, feeling, thinking, or perhaps making available" to the other participants in the situation by "looking back at" them. The bodies of (earth)worms are assembled in a way that doesn't enable them to look back in a literal sense. They do not have eyes through which to sense the depths of their becoming. They don't have a "face" even though they have a mouth and a body, for example.

Understood as embodied and relational becoming, the concept of withling(s) allows us to consider a variety of ways in which humans and worms comingle – not all of which are desirable from the viewpoint of all involved. In short, withling takes place and produces withlings simultaneously. Whether the outcomes are good or bad or something in between is up for ethical discussion. For example, when the child in the worm rally places the worm on his bare hand, the two living bodies inevitably touch each other. There is a subtle collaboration of these two bodies, an attunement (Despret, 2004). Now, the important question arises: *how come this touch between living bodies does not begin to matter?* Why doesn't this dance draw an empathetic line of flight from the striated patterns of objectifying inquiry? Would it be possible for such an encounter to trigger "joy of withling," of cohabiting the world as mattering and interdependent becomings?

Instead, we interpret such a joy emerging as the child becomes enmeshed with the practice of science education as it materializes in the kindergarten yard in relation to adults, books, magnifiers, containers, and tweezers among other things. As the child is running between compost and the table, carrying worms, the space that comprises all of these processes becomes striated hierarchically (Deleuze & Guattari, 1987). This is supported by the historically formulating technologies and discourses regarding what it is to study nonhuman animals. This analysis yields an important thought for conceptualizing withling: *it is possible for joy and excitement (of the human) to become mingled with patterns of objectification and domination.* In the case of the worm rally it is thus worth mentioning that after the excited and joyful exploration and studying of worms, the worms were left in a plastic container with little soil and a lid for over a week, resulting to their drying out and dying.

Instrumental in perception, conceptualization, and treatment of other species is their cultural meaning and place in "sociozoologic scale" (Irvine, 2009). Worms are at the very bottom of the scale in a Finnish cultural context, far from culturally revered species such as bears or horses, which can also be included in the so-called charismatic megafauna, majestic or cute animals that have characteristics that appeal to humans (DeMello, 2012, p. 53; Lorimer, 2007). Withling(s) as an analytic tool directs attention to the emerging of such scales: how things and beings become certain kinds of things and beings, and not other. How an earthworm becomes a techno-scientific worm and not, say, a compost-dancing worm, or a fish-luring worm, or a bird-food worm.

Withling(s) is a tool that maps relations and becomings as complex, often simultaneously positive and negative. And it yields us insights of how engaging with "just a worm" transforms also us, and not just the worms. From an ontological presupposition that emphasizes relationality, entanglement, comingling, and

co-dependence (e.g., Deleuze & Guattari, 1987; Haraway, 2008), there is no such thing as only a worm. And as a provocation, is it not so that a kind of micro-fascism (Deleuze & Guattari, 1987) was actualizing in the case of worm rally? A mass incarceration, experimentation, and eventual slow death. This is a far cry from the cute and innocent representations of child-animal relations well known in the Western cultural imaginary (Taylor & Pacini-Ketchabaw, 2017).

On the Possibilities of Alternative Worm-Child Withling(s)

In what follows, we will briefly discuss whether the emergence of techno-scientific withling(s) really had an alternative in the worm rally. From the get-go, the tweezers had a significant role in "striating" the space of the worm rally (Deleuze & Guattari, 1987), building a distance between bodies, thus defining the possibilities for *touching* in withling. The tweezers can be understood as actors that, in relation to magnifiers and other tools, work to produce a distinction between a knowing subject and a known object – they bring with them the power to set living bodies apart. Tweezers carry with them, as participants of the striating space, the way in which humans, in their attempts to understand what a worm is, come to construct a worm that did not exist before this act. Each particular worm with each particular child (not to forget the adults) becomes enmeshed with the techno-scientific assemblage. Yet, many of the potential directions regarding what it is to be a worm – and a child – remain unexplored or at least uncognitized. Maybe the bodily worm-child encounter was not intensive enough in the given relational assemblage to trigger care regarding the wormly other.

Ethologically thought (e.g., Lorimer, 2007), worms and humans have differing capabilities to affect and become affected. The bodies of worms in the particular circumstances did not allow them much opportunities to resist or flee. The material-discursive practice within which the worm rally emerged, on the other hand, did not allow the child (or adults) opportunities to attune with the movements (such as potential resistance) of worms. While the worms became techno-scientific worms, the human participants became enmeshed with the technologies and the anthropocentric histories they brought along. Yet, these were being actively practiced and, on the human part, enjoyed as well.

Haraway (2008), among others, asks if there are ways in which it is even possible to us to *learn to respond*, to the suffering, joy, and quotidian, of the multiplicity of others. Which invitations to respond can we recognize when they are offered; how can we foster sensitizing to withlings that might open up new movements in response-ability? As Haraway (2008, p. 35) firmly puts it: "When species meet, the question of how to inherit histories is pressing, and how to get on together is at stake." Withling(s) is not a positive or negative concept. Rather, the concept of withling(s) invites us to consider multiplicities and the ways in which they become produced. The worm rally exemplified how joy and excitement can coexist with objectification, domination, and suffering.

Conclusions: Conceptualizing Withling(s) in the Context of Education

The inventive etymology of withling(s) can be located in the notion of "earthling," the meaning of which is derived from science fiction. Conceptualizing the critters of planet earth as earthlings allows for distancing and belittling considerations. Our own species is seen as part of other earthly species from a distance (maybe by extraterrestrials). The diminutive -ling suffix allows us to question the ongoing production of hierarchies and human exceptionalism as it positions all critters as changing and learning becomings, assemblages of forces stable enough to undergo continuous transformation (see also Braidotti, 2006).

While earthling refers to the species and individuals cohabiting our planet, withling(s) emphasizes the connections, relations, and entanglements of these bodies: their co-constitution in movement, or dance, following Haraway (2008) and Pickering (2005), among others. Here we have focused on human-animal withling(s) and how different versions of human (here, child) and animal (here, earthworm) emerge or, indeed, don't emerge, as part of earthly practices including participation of different technologies (such as tweezers) as well. Withling(s) refers to the ways in which bodies become different as they take part in each others' corporeal (physical, chemical, psychical) and social life. Withling(s) is corporeal and real, affective and practiced.

Withling(s) is a political concept as it allows us to ask and speculate, what certain encounters made possible for its participants and, importantly, what might also have been possible. In Deleuzian words, what kind of molecular de- and re-territorializations were taking place? Withling(s) is not loaded merely with positive and emancipatory meaning but takes seriously the potential presence of both joy and suffering in the process of repeating while becoming different (Deleuze & Guattari, 1987). Philosophically, withling(s) directs us to questions, such as what is it to be and become with, what are the conditions in the situation to become with, with what else are we becoming, and what are the potential and actualized directions of withling(s)?

As our data is situated within an educational context, we will now turn briefly to consider some emergent pedagogical issues. Recently Spannring (2017, see also Taylor & Pacini-Ketchabaw, 2016) has pointed out a tension between the practices that objectify nonhuman animals and the aim for fostering sustainable futures. The objectifying and commodifying practices, such as animal dissection and holding nonhuman animals in captivity for the sake of human curiosity and learning, may intensify desensitization among students (Spannring, 2017). This argument begs a question: what is being taught when nonhuman animals are removed from their assemblages and relocated within new ones as was the case in the worm rally? While worm rally made possible the meaningful participation of pupils in the practice of science education and evoked emotions on this regard (e.g., excitement as manifested in increasing speed of the repetition and of the heartbeat), it seemed to suppress the compassionate affectivity in human-nonhuman bodily encounters and end up lethal for the particular worm withlings. Could other pedagogical practices be

crafted in order to promote compassionate affectivity and making oneself available (Despret, 2004) much needed to tackle the Anthropocene?

There are some promising studies regarding what these practices might be. Among others, these include Warkentin's (2011) study regarding the potential in nature journal keeping in a particular spot, "a slow pedagogy of place," Fawcett's (2002) encouragement to keep journal on the changing relationship with the chosen nonhuman animal, and considerations regarding the ways in which animals, such as a spider, living in the classroom participates in the daily life of pupils and teachers (Affifi, 2011). Likewise, Gannon (2015) has argued for "open-ended interdisciplinary inquiries" enabling a range of modes of response, such as rap songs, picture books, and dances.

Our concept of withling(s) is one further attempt in this direction. Our argument is not so much that treatment of worms in particular should be our main interest in answering the issues related to the Anthropocene and sustainable futures. Rather, we have taken pupil-worm-teacher assemblages as an example of the way in which nature-culture divide is being performed in material-discursive science education practices in kindergarten and ask, whether conceptualizing such encounters as withling(s) might contribute to developing responsible, respectful, and attuned encounter between humans and their supposed others. We hope this will inspire and invite further analyses and experimentations as well as contribute to "animalizing" educational practices while not forgetting the child, teacher, technologies, and the striating histories they all may bring along.

Abstract

Insects and children cohabit common worlds, both subjects of their own lives and active agents. Their encounters may be characterized by mutual curiosity, indifference, or fear and can lead to multiple outcomes. Some children will be bitten or stung while others will be unhurt; some insects will not survive an encounter while others will be cared for as friends. The literature on insect/human relations indicates that many people have negative perceptions of most insects, which can have profound material consequences; consider the many challenges insects face at the individual, population, and species level due to human activity. Insects feature in various ways in early years and elementary education, from highly anthropomorphized charismatic microfauna in children's media and literature to pinned collections of dead bodies, from captives in classroom terrariums and in insectariums to encounters inside and outside the classroom both planned and serendipitous. Drawing on our own teaching experiences and writing in critical animal studies, environmental and interspecies education that focuses on our

relationships with other animals, and common world pedagogies, we question the anthropocentric nature of many of these encounters and ask how we might offer young children opportunities to develop ethical and caring relationships with insects, including those who are commonly feared, disliked, or simply overlooked. We argue that intersubjective learning that goes beyond the human and that recognizes the messiness and complexity of insect/human relations holds promise for multispecies flourishing.

Introduction

> Insects are reminders that we are ecologically entangled in ways we often only dimly perceive and are impacting the environment and other species in damaging ways we frequently ignore. (Loo & Sellbach, 2015, p. 80)

Why do some children stomp on insects while others treat them as friends or pets? How might attending to young children's lived experiences with, and perceptions of, insects help us better understand the common worlds that humans and insects share so that we can offer children opportunities to develop respect and care not only for charismatic insects like butterflies but also those who more typically evoke fear or disgust? How might an early childhood educator make the most of chance encounters with insects? What are the pedagogical and ethical implications of going outside to purposely seek out insects, taking a field trip to an insectarium, keeping captive insects in the classroom, or displaying dead insect bodies? In what ways might these various pedagogical interventions contribute to protecting ecologically vulnerable insect species as well as other creatures facing extinction, extirpation, or harm? To help us explore these questions, we draw on writing on human/insect relations, common world pedagogies, and environmental and interspecies education to argue that attending to and encouraging young children's relationships with other animals, particularly the "creeping crawling critters disdained by others" (Haraway, 2016, p. 151) and the overlooked ones "deemed unworthy of consideration" (Bell & Russell, 1999, p. 74), holds much potential.

We also are drawing on our professional experiences in Canada. Elizabeth has worked as a preschool teacher, instructed preservice early childhood education courses at the community college level, and for 3 years was a scientific interpreter at the Montreal Insectarium. Constance has been involved in environmental and interspecies education for close to 30 years, working with children and adults in both formal and informal learning environments, some of which has included pedagogical explorations of insect/human relations. In all our work, we seek to help create

conditions for humans, other life, and the land to thrive, that is, for multispecies flourishing (Ginn, Beisel, & Barua, 2014; Haraway, 2016).

In this chapter, we begin by offering a rationale for the inclusion of insects in early childhood environmental education then turn our attention to research on insect/human relations to provide some context. We then review the growing literature on insect encounters in education before wrapping up with a call for educators to work towards both insect and human flourishing.

Why Insects?

First and foremost, insects matter intrinsically. They are subjects of their own lives, and as with all members of the more-than-human world, their existence need not be justified on human terms (Bell & Russell, 1999, 2000). Alas, we live in profoundly anthropocentric times, so regular reminders that humans are not the center of the universe nor inherently superior to and entitled to dominate other life appear to be necessary. Insects appeared approximately 400 million years ago. Their long history of adaptation on earth in almost every terrestrial ecosystem makes them a hugely diverse group of animals today. There are more than 925,000 named species, although there could be five to ten times more species that have yet to be scientifically observed (Bourassa, 2011). Indeed, the majority of species yet to be identified are probably insects (Bernhardt, n.d.).

Insects are greatly affected by human activity such as "destruction of both wintering and breeding habitats, heavy use of pesticides, shortage of natural insect and plant food, and artificial light pollution causing errors in migratory navigation" (Wilson, 2016, p. 60), leading many species to extinction. Cardoso, Erwin, Borges, and New (2011) note that "when corrected for knowledge bias, data from invertebrates show even higher extinction rates and proportions of threatened species than those of well-known taxa such as birds and mammals" (p. 2648). Insects are disappearing before our eyes, and it feels like a race against time to build sufficient knowledge about how we might help them, especially given underfunding of research on insects and other invertebrates (Cardoso et al., 2011) and limited attention to human relationships with most insects (Lemelin, 2013; Lloro-Bidart, in press; Loo & Sellbach, 2015), especially the "unloved others" (Beisel, Kelly, & Tousignant, 2013, p. 114). Even though more attention is being paid to insects than in previous decades, there is still a long way to go in understanding insect distribution, abundance, ways of life, and sensitivity to habitat changes (Stewart, 2012). In Canada, for example, of the 1001 species currently found on the official wildlife species at risk list, there are about twice as many birds (131 species) and mammals (144 species) as there are arthropods (68 species) (Environment Canada, 2017) despite the fact that arthropods outnumber other species significantly (Biological Survey of Canada, 2014).

Essential to sustaining ecosystem balance vital to the survival of other life, including humans, insects make contributions as pollinators, decomposers, prey, and predators. Without the "service" of insects and other arthropods, it is highly

likely that major food webs on earth would collapse (Wagler & Wagler, 2014). Insects have also been considered important as a source of food and medicine, a focus of scientific and leisure interest, and an inspiration for art and music (Kellert, 1993; Lemelin, 2013; Wagler & Wagler, 2014).

Insects also can play a significant role in the lives of young children. They can be observed with curiosity or as subjects of study, cared for as pets, feared, or simply ignored as insignificant creatures. Conversely, children also can play a major role in insects' lives as they have the power to kill or protect these small creatures. Given the many challenges insects face at an individual, population, and species level at the hands (or feet) of humans and given that the tenor of insect/human relations is thought to be established early, we argue that it would benefit insects if children developed respect for and a desire to protect them. Or, at the least, in recognition that some insects do bite or sting or threaten other life and that there are no innocent moves in multispecies flourishing (Haraway, 2016), to not despise and wish to eradicate them entirely.

Since insects and young children encounter each other daily, both indoors and outdoors, how they affect each other merits examining and a number of early childhood educational researchers, notably those interested in common world pedagogies, have done so. Indeed, besides companion animals, insects appear to be the most commonly researched animals other than humans in common world pedagogies (e.g., Atkinson, 2015; Blaise, Hamm, & Iorio, 2017; Nxumalo & Pacini-Ketchabaw, 2017; Taylor & Pacini-Ketchabaw, 2015), and they also feature in other writing on environmental education with younger children (e.g., Bell & Russell, 1999; Blenkinsop, Piersol, & De Danann Sitka-Sage, In press; Edwards, Moore, & Cutter-Mackenzie, 2012; Guyton & Connington, 2013; Lyman, 2014). That insects are often readily available to young children as well as to the researchers observing them partially explains their presence in this work, but some educators offer other rationales for their inclusion that we consider even more compelling.

Bell and Russell (1999), for example, are concerned about creatures who seem to rarely merit consideration and who find themselves facing "another form of discrimination – a sort of intolerance by omission" (p. 74), a phenomenon they argue has implications far beyond insect/human relations. We also think there is much to be learned by "considering how multispecies flourishing works when the creatures are awkward, when togetherness is difficult, when vulnerability is in the making, and death is at hand" (Ginn et al., p. 114). As Ginn et al. (2014) observe, "Many nonhumans we consider unpleasant or disgusting are our companions—consider for instance ant colonies in our kitchen, water bugs in the shower, or slugs in the vegetable patch" (pp. 115–116). Such insects and other invertebrates are typically labeled *pests* and *vermin,* which can "set fatal contours to our relationships with creatures so designated" (Bell & Russell, 1999, p. 73). Mayo (2016) asserts that "our relationships with animals or any kind of vermin need not be pleasant in order to be ethical. Indeed, ethical relationships that happen to be pleasant, we know, are the easiest sort" (p. 191). We agree with Haraway (2016) who suggests that we must learn how to "stay with the naturalcultural multispecies trouble on earth" (p. 40) that insect/human relationships can so powerfully evoke.

Insect/Human Relations

It is argued that one of the main challenges facing insect conservation is that many people do not appreciate insects. Early research conducted by Kellert (1993) on perceptions of invertebrates suggested that adults generally have a "negativistic attitude" (i.e., fear, dislike, indifference) towards them and that the "most infrequently encountered attitudes toward invertebrates included affection, ethical concern, or scientific curiosity" (p. 850). In the same vein, Davey (1994) found that invertebrates evoked fear responses more than other types of animals. Lockwood (2013) suggests that humans tend to fear insects due to their quick unpredictable movements, their ability to invade what we consider to be our space, and that some insects bite or sting us. They also can be perceived as disgusting because some are vectors of infection and disease, contaminants in our food, or are found in garbage dumps and sewage as well as on carcasses (Lockwood, 2013). Some researchers rationalize such negative reactions to insects on the grounds of "biological preparedness," arguing that humans are prone to an aversion of insects and other invertebrates such as spiders because these are potentially hazardous to human survival (Breuer, Schlegel, Kauf, & Rupf, 2015; Gerdes, Uhl, & Alpers, 2009). Others assert that insects cannot cross the "neoteny barrier," referring to the characteristics that some mammals share with human youngsters, like large eyes, a small nose, a round body shape, and short appendages (Borgi & Cirulli, 2015; Estren, 2012), implying that few insects invoke human empathy simply through their morphology.

Lemelin (2013), however, questions much of the research on insect/human relations, asserting that it "has tended to support a human–animal binary of humans vs. animals, pest vs. friend, biophilia (the love of living things) vs. biophobia (the fear of living things), entomophilia (the love of insects) vs. entomophobia (the fear of insects)" (p. 155). He criticizes such research for being simplistic as well as for reinforcing speciesism and entomophobia. Instead, he has found that ethnographic studies have offered more nuanced understandings, revealing that "the fear of insects is not universal, nor does it always result in disgust and the fright response. Indeed, some of these encounters are met with indifference and apathy while others can actually result in awe, jouissance, and epiphanies" (p. 157). The universalizing discourse about generalized humans in much of the research on insect/human relations is indeed problematic and would benefit from engagement with writing that seeks to decolonize animal studies (e.g., Lloro-Bidart, 2017) as well as with multispecies ethnographies that feature insects and other critters alongside humans (e.g., Atkinson, 2015; Lloro-Bidart, in press; Nxumalo & Pacini-Ketchabaw, 2017; Taylor & Pacini-Ketchabaw, 2015).

A common refrain in studies of insect/human relations is that our perceptions of insects are formed early (e.g., Borgi & Cirulli, 2015; Schlegel, Breuer, & Rupf, 2015). As an example, Elizabeth shares this recent encounter with one of her nephews, aged 4:

> Working on a craft project, he cut out animal pictures from National Geographic magazines, carefully categorizing them and gluing them on a large cardboard to create a visual representation of his views of animals. He had a section for what he called the "cutest" and the "not cute" which he then subdivided into "ugly" and "scary" (although it should be noted that he said that he did not find many of them scary himself but was imagining which animals other people would find scary). According to him, "cute" animals are those who look like babies and that are small like mice, rats, frogs, birds, and his current favourite, tapirs. Viewing his final creation, I noticed a brightly coloured butterfly in the "cutest" section. All other invertebrates (scorpion, mantis, centipede) were seen to be ugly or scary.

Indeed, butterflies seem to be an exception to the generally negative perception of insects. Often adored as a symbol of beauty and grace and more easily tolerated because of their perceived harmlessness to humans, butterflies have been collected since the nineteenth century and their popularity continues as demonstrated by the recent growth in butterfly gardens and monarch conservation efforts (Lemelin, 2013). It was clear to Elizabeth from her experience working at the Insectarium that, for many of the visitors, butterflies are not *really* considered insects.

Few other insects appear to be as generally well liked in Western society as butterflies, but even they elicit mixed responses. For example, Elizabeth recalls from her time working in the Insectarium that some children, mainly young girls, became suddenly terrified upon entering the live butterfly exhibit. The only way to calm their panic was to escort them out of the exhibit and attempt to talk to them out of their fear, illustrating an important role educators can play in helping children (re)interpret their experiences. In short, then, responses to insects are complex and a number of factors are in play. Lemelin, Harper, Dampier, Bowles, and Balika (2016) list direct experiences in childhood as an important influence on insect/human relations. For example, wasp and bee stings can be quite painful and may even be life threatening in the case of allergic reactions. Therefore, getting stung can be "individual conditioning experiences" (Davey, 1994, p. 553) that might lead someone to associate those insects with pain and develop phobias (King, Ollendick, Murphy, & Muris, 2000).

Still, it is important to remember that not all children react in fear towards insects that bite or sting. Consider this observation from Taylor and Pacini-Ketchabaw (2015) of children interacting with ants:

> Sometimes, ants run up the children's legs or into their clothing and bite them. This is usually a form of retaliation against the children's provocations, or when the children simply do not notice that they are standing in the middle of a swarming ant nest. There have been some highly charged moments when frenzied ants scurry and bite and panicked children scream and squash. These fight and flight, life and death moments are marked by the rush of alarm pheromones and adrenalin and by the smell of formic acid. But the children who calmly observe the ants rarely get bitten. (p. 524)

It is not only direct experiences such as these that influence future insect-human relations. Lemelin et al. (2016) suggest that the portrayal of insects in popular culture, media, and scientific discourse also has an impact. In a study by Snaddon and Turner (2007), children were asked to draw a picture of their favorite insect and

these correlated with the insect's general popularity rather than the local abundance of a particular insect.

Timmerman and Ostertag (2011) point out that from the time they are newborns, children encounter representations of animals in books, toys, and wooden puzzles, and on clothing and bedsheets. Idealized charismatic megafauna and farm animals dominate whereas local invertebrates rarely feature, or when they do, barely resemble any creature actually in existence. Research by Claessen (2015) found that the portrayal of five invertebrates (ants, beetles, spiders, wasps, worms) in children's fiction, nonfiction, and comics were generally highly anthropomorphized. As Lemelin (2013) puts it, "even when we do incorporate insects into our popular culture (Bugs Life, Fern Gully, Bee Movie), we anthropomorphise these creatures into human-like protagonists, thereby reinforcing the notion that we can only admire those creatures most like us" (p. 157). While we share these authors' concerns, we also recognize that anthropomorphizing is not necessarily always a bad thing. Rautio (2013) suggests that it can open up imaginative encounters that can lead to befriending of other animals. Fawcett (2014), who conducted research on 5- and 10-year old children's perceptions of bats (who, like insects, are often feared and reviled), shared:

> One of the more startling results was that the younger children thought of the animals as their friends and were rarely afraid of them. . . The kindergarten children's stories contained the acknowledgement of difference, alongside elements of reciprocity, playfulness, empathy, and imagination between human beings and other animals. In their stories, the younger children described the animals as other subjects, both like and unlike themselves. (p. 265)

Describing what she called a "kinship ontology," she found that the "children's storied experiences transgress in authentic and irreverent ways the boundaries between humans and other animals, and productively play with Western ideas about friendship, kinship, and anthropomorphism" (p. 262).

Given the sheer numbers of insects and the fact that many of them co-occupy ground-level territory with children who are small, children and insects have the opportunity to share many moments together. Melson (2001) posits that "each creature presents a new vitality, a distinct form of aliveness, for the child to consider" (p. 82). For some, as Lemelin (2013) notes, this includes "the appeal of the negative sublime (the attraction of 'creepy-crawlers' and the 'yuck' factor)" (p. 157). While some young children may be content to merely observe the fascinating comings and goings of insects, many want to engage more actively. Some do so in caring ways. For example, Askerlund and Almers (2016) note that in their research on young children's relationships with nature in a forest garden, "the most prominent feature of the children's descriptions of the relationships was how they cared for the organisms in the forest garden, not least the insects" (p. 195). Still, as Atkinson (2015) observed in her research, one day children might be found caring for a slug and another day be killing ants. Indeed, many young children have stomped on bugs, pulled wings off insects, or roughly handled a small animal (Melson, 2001).

▶ Chap. 53, "Rethinking Children's Connections with Other Animals: A Childhoodnature Perspective," suggests a variety of reasons for this behavior, including children struggling with aggressive urges or replicating family violence. Further, she argues that there is an important power dynamic at play since small animals might be the first living creatures children feel power over: "when those in power are inexperienced, with uncertain dominion over their own rages, and carrying the history of their own utter dependency … the probability of cruelty, casual mistreatment, and neglect increases" (p. 162). Although ▶ Chap. 53, "Rethinking Children's Connections with Other Animals: A Childhoodnature Perspective," focuses more on children's relationship with pets, this power discrepancy is also evident with insects. A young child can easily crush an insect and feel a rush of power in deciding which creatures will live or die. A haunting example of this dynamic can be found in Loo and Sellbach's (2015) analysis of a story from Le Clezio's novel, *Terra Amata*. In the original story, a young boy examines a group of potato bugs, first observing them with curiosity. The tone of the encounter soon changes, however. Naming himself the potato bug god, he imposes order by containing them in small individual enclosures. When one refuses to stay put, the boy pulls off the legs of one of his "subjects" as punishment and eventually crushes it to death.

Developmentally, young children are exploring their environment, engaging with all their senses, and testing out their predictions of how the world functions. Children pulling legs off an insect may not always realize that they are causing the ants to suffer (Carruthers, 2007), but sometimes they are very much aware of what they are doing and stories of deadly encounters litter the literature on insect-child interactions. For example, Blaise et al. (2017) describe a young boy stomping on a wasp while shouting, "I don't like bugs!" (p. 41). And Blenkinsop et al. (2017) share a powerful anecdote of a young boy squashing two ants in direct response to another boy and a female teacher showing interest in and affection for ants in an act of what they call "splash violence" (p. 2). Wondering if the boy doing the killing is testing boundaries of power or showing "the beginnings of an estranged relationship with the other" (p. 5), they state that:

> Our intention here is not to convict David for being a malicious child – that would go beyond the evidence, the developmental realities of a six year-old, and the whole *truth* of the matter – but simply to situate David's behaviour as what is considered perfectly innocuous and "normal" in modern Western culture for a "boy." So normal, in fact, that such violence is all too quickly and easily dismissed as just "boys being boys." (p. 5)

Several studies on children and insects show that there can be a marked gender differences. For example, Snaddon and Turner (2007) found that boys indicated a greater preference for beetles and spiders whereas girls preferred butterflies and ladybirds. Borgi and Cirulli (2015) found that "in comparison with girls of the same age, boys show a higher appreciation of animals which evoke fear, such as alligators, snakes, and sharks, and biting and stinging invertebrates (e.g. scorpion, spider, beetle, bee)" (p. 55). These findings are echoed in Schlegel et al.'s (2015) study that found girls were less favorably inclined towards invertebrate species that they perceived as threatening. The reasons for these gender differences are not yet well

researched, but gender seems to play a role in insect-child relations and, in line with calls for greater attention to gender in environmental education research (Gough, Russell, & Whitehouse, 2017), merit further attention.

Cruel behavior towards insects is usually reprimanded by adults (Carruthers, 2007). Still, a child may get scolded for crushing an ant on the sidewalk but not in the house, may watch adults running from bees outside but then be read books about cute honeybees, and be encouraged to catch and release butterflies with a small net but learn to be disgusted by tent caterpillars busy defoliating a tree. Children receive ambiguous and conflicting messages, and it is no doubt a challenging task for them to determine what "appropriate" relationships with insects might look like. Some educators have attempted to influence these relationships to which we turn our attention next.

Insect Encounters in Education

Insects are not uncommon presences in young children's early years and elementary education. Some insects live in terrariums in classrooms while others are ghosts, their dead bodies pinned to display collections. Still others are encountered inside and outside the classroom in both planned and unexpected ways.

A most disturbing way young children can learn about insects is through constructing pinned collections. Writing in *Green Teacher*, Guyton and Connington (2013) advise teachers that they can help children develop their motor skills and become "young scientists" by capturing, freezing, and mounting or pinning insects. We argue that the hidden curriculum of such practices is not unlike that of dissection in higher grades, which as Oakley (2009) suggests, positions them as mere resources for human use and fosters "a decreased sensitivity to other life" (p. 61). At the Montreal Insectarium, exhibits of pinned scientific collections are shared with visitors with the goal of promoting appreciation for insect biodiversity, adaptation, and conservation, but private collecting is discouraged, given these do not contribute to scientific research. Several alternatives exist to needless insect killing, such as digital photography and observing and then releasing insects. The irony of promoting conservation through the display of dead bodies appears to be lost in most museums (Pedersen, 2010). Indeed, in many edutainment venues where dead or captive animals are on display, it appears that, "There is very little attention to them as individual subjects of their own lives; rather, they act as representatives of their kin or their ecosystems, martyred in the name of conservation" (Lloro-Bidart & Russell, 2017, p. 48).

Keeping live insects in the classroom is recommended by some researchers and practitioners. Wagler and Wagler (2014), for example, argue that using living arthropods (e.g., insects, spiders) in the elementary classroom can be an effective way of decreasing fear and disgust and can promote support for their conservation. Insects are, in fact, quite popular classroom pets in North America with ants, crickets, cockroaches, praying mantises, and walking sticks/stick insects recommended to teachers seeking "low maintenance" pets. But as Nxumalo and

Pacini-Ketchabaw's (2017) research illustrates, caring for animal others of any sort is not as straightforward as some suggest. They offer a sophisticated analysis of teachers' and children's experiences with Vietnamese walking stick insects that had been part of an early childhood education center for years until they became so "unmanageable" (p. 1) that they were given to children's families to take home, donated to an entomology lab, or killed. Noting the anthropocentric, colonizing, and racializing dimensions of the ethical and pedagogical issues that arose (e.g., keeping the insects in captivity, the impact of the globalized pet trade on the species, the fear of the insects becoming invasive species, the need to control the insects' reproduction, culling), they observed the teacher's affective struggles: "They questioned who these acts of caring benefitted – the children? the stick insects? themselves?" (p. 10).

There are alternatives to keeping insects captive in the classroom, of course, although these too can raise ethical issues and the specter of death. Lyman's (2014) experience with a spider who became "an excellent team teacher" (p. 48) in her economically, racially, and linguistically diverse grade 3 classroom is illustrative (even if spiders are not insects but arachnids). One of her students found the spider in the bushes outside the classroom, brought her in, and Lyman placed the spider on a bookcase. The next morning, Lyman and the students arrived to find that the spider had stayed put, built a web, and soon they were watching her eat a grasshopper she had caught: "'Awesome!' soon overtook 'ewwww!' as the students watched the spider feast" (p. 48). The spider was named Charlotte and the students treated her as an individual with particular needs and likes. When Charlotte laid an egg sac, the class discussed the best way to proceed, settling on donating the sac to a local nature center they had visited on a field trip. As anticipated given what they knew about the life cycle of this spider, not long after laying her egg sac, students witnessed Charlotte dying, held a funeral service, and buried her under the bushes where she was found.

Lyman (2014) felt the opportunity to witness, talk, and write about Charlotte's death opened up an important pedagogical opportunity, which resonates well with Russell's (2017) research on animal death and pedagogies of remembrance. Similarly, Taylor and Pacini-Ketchabaw (2015) share a story of a worm who was inadvertently broken in two by a child attempting to rescue it, concluding that: "No easy response exists for either the earthworm or the children in these ordinary encounters. This is a case of learning to live with each other for survival and to always be mindful of each other's vulnerabilities" (p. 520). Such is the case for all early childhood educators whose charges interact with insects outside, whether in planned or serendipitous encounters. The writing on common world pedagogies abound with stories of young children learning with insects in myriad ways and with diverse outcomes (e.g., Atkinson, 2015; Blaise et al., 2017; Nxumalo & Pacini-Ketchabaw, 2017; Taylor & Pacini-Ketchabaw, 2015).

Searching for insects and other invertebrates outside and small conservation projects such as butterfly gardens and building insect hotels can provide opportunities for children to attend to local insect species. Given research that indicates that many children lack knowledge of local insect species and that children who can name insects have been found to have a higher affinity towards them

(Schlegel et al., 2015), engaging in natural history practices with children may be an effective strategy. This may be particularly so for disliked or demonized insects (Bell & Russell, 1999; Lemelin, 2013) as well as the common and familiar (Fawcett, 2014), the mundane and ordinary (Atkinson, 2015; Taylor & Pacini-Ketchabaw, 2015). That is not to say that the practice of natural history is some sort of magic solution for improving insect-human relations. As Russell (1999) argued, the easy linearity often implied in much of the outdoor education literature is simplistic; nature experience does not automatically lead to knowledge and then to caring and then to action, and we educators need to be more humble and more cognizant of the complexity of these encounters.

There are encouraging signs in recent literature that indicates more careful attention is being paid to the complexity of pedagogical efforts to facilitate multi-species flourishing, including with insects. For example, in a recent research project with early childhood educators (Edwards et al., 2012), some activities were found to be more useful than other in terms of educating young children about the biodiversity around their center. Although child-initiated play is commonly accepted as an important part of an early years curriculum, offering children the opportunity to dig in the soil and look for insects and other invertebrates does not result in as much learning as when the teacher guides children towards an understanding of these creatures and how to respectfully observe them. One educator in the study noted how her students went from screaming, pretending to be scared, or wanting to kill insects to being more curious following what the authors call a *purposefully framed play* session (Edwards et al., 2012). Similarly, Askerlund and Almers (2016) reported the positive impacts of teachers framing the experience of children learning in a forest garden in nonanthropocentric terms: "Rather than asking what these organisms can do for me/us, they pose the question: What can I/we do for the bugs/plants/bees?" (p. 187). And Atkinson (2015) shares an anecdote about young children initially reacting with squealing at finding a wasp nest and how the educator, Cara, responds calmly and quietly: "She asks the children to move slowly, to closely watch how the wasps move, to use quiet voices. The children are calmed by her voice, her stillness. They watch as the wasps disperse. No one is stung" (p. 70). As Atkinson observes, "In this moment Cara shifted away from conventional notions of protecting children from wasps, in which wasps are identified as dangerous creatures to be feared. Instead Cara recognized mutual vulnerabilities, that both wasps and children were affected" (p. 71).

Not all educators, however, are quite so skilled in negotiating insect-child interactions. Even in well-meaning educators, fear or disgust may send a stronger message than any activity they facilitate. Writing about spiders, Lemelin and Yen (2015) suggest:

> Educators can have a significant influence on children, but there is a problem if the teachers are scared of spiders themselves. Researchers have noted that educators and naturalists can be in a tenuous position if they possess the same negativity toward invertebrates as the general public but have been employed to teach their students about the very invertebrates they dislike. (p. 222)

Teacher education therefore is important, but there has been very little written on this topic related to insects. An exception is Wagler and Wagler (2011) who provided preservice elementary teachers with "frequent direct contact with Madagascar hissing cockroaches" (p. 243) and found that their attitude towards these insects changed from extremely negative to positive and that they were more willing to consider including these insects in their future teaching. This newfound interest did not extend to any other type of insect, however.

It is clear that early childhood education for insect and human flourishing is challenging, yet it is also clear that we must try. Urging environmental educators to incorporate "interspecies articulation" into our work, Rautio (2013) argues that we need to acknowledge "how humans and nonhuman animals continually create the conditions for each other's existence" (pp. 446–447). Intersubjective learning that goes beyond the human holds promise for diverse outcomes (Bell & Russell, 2000; Lloro-Bidart, in press). As Taylor and Pacini-Ketchabaw (2015) write,

> It seems the children are on a number of different routes towards responding to the risks and vulnerabilities they share when they bodily engage with these small creatures. Their actions portend different kinds of learnings. The children who goad ants might learn that there are consequences to their actions and that even small creatures can become formidable foes. Those children whose feet inadvertently get in the way might learn the consequences of not paying attention to the lifeworlds of smaller creatures. Those who carefully seek intimacy with the ants might learn about the precarity of life through (literally) holding the responsibility for another life, and at the same time, through risking making themselves vulnerable to another species. (pp. 524–555)

Conclusion: Towards Insect and Human Flourishing

In concluding this chapter, we do not intend to offer pedagogical recipes or tidy solutions to the problems currently facing insects, humans, and other life. We have pointed to a few promising approaches above that warrant further attention. As well, Bell and Russell (1999) offer a number of general pedagogical suggestions that may help educators strengthen "life ties":

- Call into question the us/them, human/nature divide
- Work from and convey an understanding of the ways the oppressions are connected
- Draw attention to the ways that words shape our understandings and experiences
- Help students to recognize and move beyond stereotypes [about both people and other animals]
- Acknowledge diverse cultural perspectives and the fact that all cultures have not interacted with nature in the same way
- Anticipate and try to mitigate the trauma that children may experience as they delve into [these] issues
- Work from and convey an understanding of others as experiencing subjects of a life, in some ways similar to and in some ways different from us
- Encourage students to remember their deep-seated connections with other life
- Bring more fully embodied, sensual experiences into the . . . curriculum (pp. 75–81)

Further, like Rautio (2013), we also want to "embrace the thought that teachers – those who invite, guide, support, and steer us – can also be other than human beings" (p. 454). We end this chapter, then, with a reminder that children are not the only actors in pedagogical encounters with insects. Just as children react, so too do the insects who may approach, flee, hide, squirm, sting, or sit calmly. Atkinson (2015) wonders in reflecting on an encounter between a boy and a bee:

> We often notice children playing with small creatures, carrying worms, poking at ants. But what might emerge if we were to consider this moment differently? What if we put aside the notion of playing and consider that Carter is relating to the bee and the bee is responding to Carter? What if we think of Carter as learning, along with the bee, how to be together? Why did the bee land on Carter? Was there a mutual curiosity? (p. 74)

Atkinson reminds us that, like us, insects learn about the world through sensory experiences and they are materially impacted by insect-human encounters encouraged in the name of educating humans. The following final vignette attempts to capture the experience of a walking stick living in captivity at the Insectarium when Elizabeth worked there:

> The walking stick is disturbed from her rest – they are nocturnal animals – when the museum interpreter removes her from the vivarium and places her on a plant on a cart. She takes a few bites of the newfound leaf then rests upside down, hanging from a branch in camouflage. Wheeled out to the museum floor for an opportunity to "meet" visitors, the educator gently coaxes the walking stick onto her fingers to demonstrate how harmless the creature is despite her spiky appearance. Disturbed once again, the insect starts to walk, searching for a branch and a chance to rest. As the fingers, hands, and arms of various humans are encountered, she senses different temperatures, scents, and textures, which takes energy to process. After walking for what seems like ages, she is finally placed back on a branch in the cart and wheeled back behind the scenes, gently placed back in her vivarium. Despite what her name might imply, she is not a stick, but a living creature with needs and preferences that she finds her captors sometimes ignore in their efforts to education humans about the plight of her kin. She returns to her rest until next time.

These walking sticks, like the other insects described in the preceding pages, have found themselves enrolled in educational activities of one sort or another. Let us not forget that they too are subjects of their own lives. And let us continue to seek ways to flourish together in this complex, messy world.

Abstract

This paper traces how animals have been and are reduced to mere objects for use in child development, examining historical and contemporary trends in developmental literature. We alternatively present scholarship that delves into children's and animals' subjective encounters and intersecting worldhoods as critical of more anthropocentric developmental psychology models. We utilize continuity as a model that emerges from our field work in order to make various suggestions about the ethics that emerge from children's embodied experiences with animals, including felt senses of vulnerability, death, and precarity. Finally, we finish the chapter by outlining potential pedagogical directions that encourage deeper reflections about the precariousness of childhood lives, lived differently and together on this planet. Key to this is the consideration of interspecies,

Introduction

While interviewing a 13-year-old girl named Sabrina, Joshua asked a question about the differences between the death of beloved companion animals and the deaths of animals in the wild or on farms. Sabrina thought for a moment before offering the following response:

> Um, well I feel like pets is different because you have like, a connection with them and like specific people will like, be sad about it and stuff, but I try not to think about like, the animals that are killed for food and stuff and then like the wild and stuff you don't really notice as much when they're killed because you don't really watch them die or anything and so then you kind of, its like not the same because you don't really think about it you don't really like notice, cuz I'm sure there's like lots of animals who have died like, really recently, like in the past hour or something but you just like don't, you don't know cuz you don't know specifically each animal.

As scholars working at the crossroads of environmental education, environmental philosophy, and human-animal relations, we are interested in the kinds of experiential curiosities that Sabrina outlines in her thoughtful response above. We wonder how children's lived experiences converge and diverge with wider sociocultural and political practices and discourses about multispecies cohabitation, and we believe that critical and caring research on child-animal relationships can provide insights that counter hegemonic practices and promote nonviolent coexistence. In this chapter, we outline a theoretical framework built on relational ontologies and ethics, as well as bodily experiences – ranging from felt desires to mutual vulnerabilities – that we argue illustrates the significance and implications of child-animal relationships. By using the phrase childhood animalness, we mean to reclaim the continuities and differences across animals from the tight anthropocentric hold that has existed in schooling. We use our framework to build a pedagogical vision of conviviality, albeit an interspecies living and learning together that embraces interdependence and ethical comingling.

Throughout our framing, we employ a range of phenomenological, evolutionary, and feminist materialist approaches as well as examples from our research with children, to identify the ethical, political implications of the intersubjective, bodily phenomena that are central to child-animal relationships. Drawing from an array of discourses, we turn our critical eyes toward the persistence of anthropocentric views of childhood (often Western, Eurocentric views too) and of animal life that encourage a hegemonic hyper-separation of "the adult human" as contra to "the animal" or

"the child." These are the same views that posit "culture" as dominant over nature, as outlined in the important work of Val Plumwood, Donna Haraway, and others. In place of these limiting and damaging human-centric models of child-animal-nature, we trace various ecological lines of thought that emphasize relationality, complexity, and material interconnections as foundational ontological realities.

In addition, we challenge both political and educational habits that emerge from ontologies of separation and human exceptionalism, which perpetuate existing violent and destructive human-animal relations driven by varieties of anthropocentrism. Such practices rely on speciesism and long-standing generalizations about (white, privileged) adulthood as the pinnacle of human development. We align with non-anthropocentric philosopher Matthew Calarco as we try to disrupt and "shrink the influence of the institutional and economic practices that limit animal potentiality and to create other ways of life that allow for both human beings and animals to flourish" (2015, p. 5). Our goal is to highlight bodily experiences that emerge from child-animal relations – in particular experiences of shared, bodily vulnerabilities across species lines – as a starting point for decentering privileged, anthropocentric visions of individual development. In its place, we offer our thoughts on a living and dynamic pedagogy of conviviality that aligns with the vision of childhoodnature that reminds us that human children, more-than-human animals, and human adults are all materially and ethically embedded in relational, naturalcultural spaces. We are using the linguistically awkward term more-than-human (Abram, 1996) to signal the enormous array of living beings other than human beings. We chose not to use the common term nonhuman as it reproduces a binary negation. Some Indigenous scholars, such as Haudenosaunee elder Paul Williams (1999), talk about animals and plant as our brothers and sisters, as our relatives (p. 2); we find this environmental philosophy much more suitable, especially given the lands we are on, but we do not wish to misappropriate it or use it disrespectfully, as we do not speak the language.

Tracing the Divisions of Childhood, Animality, and Adulthood

It is likely that anyone formally trained to work with children has at some point become familiar with the work of Swiss biologist Jean Piaget. Piaget was originally trained as a zoologist, and his particular interest in children actually arose from a deep curiosity about the development of rational, scientific cognition in humans. Piaget's work is described as establishing a "strong" model of human development (Damon, 1983). Piaget – along with Erik Erikson, Lawrence Kohlberg, and many others – portrays human development as a sequence of qualitatively distinct, holistic, and universal stages. Piaget notably outlined four stages of *cognitive* development:

1. The sensorimotor stage (newborns to infants of 2)
2. The preoperational stage (roughly ages 2–7)
3. The concrete operational stage (ages 7–12)
4. The formal operational stage (ages 12 and beyond)

These stages are part of Piaget's overall epigenetic theory of child cognition (Damon, 1983; Piaget and Inhelder, 2013). That is, Piaget held that children are born with a genetic disposition or map for cognitive development, social meaning making, and self-recognition. Included in any child's journey through these four stages and into adulthood are mastery over cognitive concepts like object permanence, intentionality, egocentrism, inductive reasoning, abstract thought, and rational problem-solving.

In his research, Piaget generally followed two categorical lines of growth in human beings: individuation, referring to a person's distinguishing of self from others, defining one's direction, and finding a position in society, and socialization, referring to the self's ability to integrate into society and dealing with others and the world at large (Damon, 1983). As a result of Piaget's foundational work, children, as research subjects, are often described in abstraction from their specific familial and social environments so as to maintain a dispassionate and universal view of their individuation and, ironically, their socialization (Damon, 1983; Burman, 1993). Piaget's empiricist approach not only abstracts children from their environment and universalizes this pattern of growth, but as Erica Burman (1993) notes, his actual tools of measurement work to produce children as both research objects and research subjects, thereby failing to theorize the contexts they inhabit. Of interest to us, Piaget conducted only limited research into child-animal relations, and much of that was focused upon children's categorical understanding of animals as animate and their cognitive ability to separate living from nonliving objects. For example, Piaget (2004) draws attention to the stage of development wherein children recognize that the moon, stars, and sun are objects separate from the free, self-motivated, and animate objects present in the animal kingdom, but this is the extent of his foray into children's interactions with animal others.

Research on childhood covers a significant amount of disciplinary ground, from developmental psychology and psychoanalysis to cultural, historical, and sociological research on childhood as a phenomenon (Jenks, 2005). Investigations of the roles and experiences of animals in childhood remain rooted mostly in critical and cultural studies of symbolic animals – especially those drawing on psychoanalysis – and in psychological research surrounding children's development in the presence of real animal others (Taylor, 2016). Gail Melson notes that child-animal relationships have rarely been given serious attention within research and scholarly literature, save for a few exemplary studies that tended toward an anthropocentric bias, studies which have "impeded both theory and research into the developmental significance of animals, especially companion animals, for children" (2003, p. 32). Given the disciplinary breadth of interest, however, researchers that do take up child-animal relationships vary widely in their scope and focus. What such work often shares, however, is an attentiveness to the ways in which animals play a key role in children's attainment of some contextually specific vision of "adulthood." At times, this emphasis on a predetermined achievement of adulthood diminishes children's knowledge and likewise erases other animals as subjects, agents, and active, meaningful participants in relational spaces alongside of children and adults. Still, it is useful to trace some of the ways in which researchers have sought to

explore children's relationships with animals as predominantly aligned with an anthropocentric, becoming-adult vision of development.

Several researchers have approached the study of child-animal relations as a way of understanding the development of empathy or morality. Lori Gruen (2009) outlines empathy's varied use within the psychological literature; it is typically described as knowing, feeling, or responding to another being's (typically a person's) own feelings. There is a historical precedent for thinking that relationships with companion animals contribute to children's empathic abilties (Grier, 1999). Several contemporary, developmental studies suggest that higher empathy "scores" are correlative to relationships with pets (Daly & Morton, 2006; Wynne, Dorey & Udell, 2011). What such scores *mean*, however, is debatable. As Gail Melson notes (2003), there is no indication that the presence or introduction of cats or dogs into the family home produces the effect of higher empathic understanding; it may be just as likely that sensitive, empathic children ask their parents for a pet. Still, when asked about the connections between children and animals, almost 70% of adults reported a belief that it is "good for a kid's development to grow up with pets" (Ipsos-Reid, 2001, p. 33). In a recent *Time* special edition on "The Science of Childhood," psychologist Michele Borba advocates teaching children empathy and how pets can assist with those teachings: "watch the puppy's tail, and you will know when she's happy" (2017, p. 63).

Another psychologist interested in what child-animal relationships reveals about children's affective and moral development, Frank Ascione similarly draws upon notions of empathy (see Ascione, 1992); although, his most prominent research tends to consider children's animal relationships as indicative of future affective capacities or psychopathologies. In *Children and Animals: Exploring the Roots of Kindness and Cruelty*, Ascione (2005) investigates various case studies and conducts new research into the correlations between domestic abuse, child abuse, and animal abuse. He argues that children who are abused by caretakers are more likely to abuse animals when young and spouses, family members, or other children when older. Ascione cites humane education programs as important steps toward improving children's empathic capabilities, not only toward companion animals but toward other human beings as well (1992, 2005). He also describes various social work programs and strategies as critical methods of intervention for an otherwise predictable turn from childhood animal abuse to future psychopathology and criminality.

Stephen Kellert's developmental research focuses upon the role of biophilia, as well as experiences with animals and nature, in children's "personality formation and character development" (2002, p. 117). Kellert distinguishes between three kinds of experiences children have in natural environments or with nonhuman beings: direct, indirect, and symbolic experience. Direct experiences involve physical contact "largely outside and independent of the human built environment," experiences that are unplanned or unstructured (Kellert, 2002, p. 118). Indirect experiences involve physical contact with "natural habitats and nonhuman creatures" that is the "result of regulated and contrived human activity" (Kellert, 2002, p. 119). Examples include visits to zoos or aquariums, animal visits to classrooms, and even experiences with pets in the home. Symbolic experiences, also referred to as "mediated"

experiences (Fawcett, 2002), occur outside of physical contact with nature, where children encounter "representations or depicted scenes of nature that sometimes are realistic but that also, depending on circumstance, can be highly symbolic, metaphorical, or stylized characterizations" (Kellert, 2002, p. 119). Children, for example, may have symbolic experiences while watching nature documentaries, YouTube videos, or reading books with animal characters. Each of these experiential modes, Kellert argues, enhances the development of various cognitive, affective, and moral abilities within childhood, a finding which Kellert describes as unfortunate, given the decline in natural spaces and species as a result of modern capitalist culture.

Recent developmental research builds upon the concept of biophilia in establishing young children and infants' tendency to "monitor the environment for the presence and location of animals and other humans," known as the "animate-monitoring hypothesis" (DeLoache, Pickard, & LoBue, 2011, p. 87). An overview of research in this area indicates that even in infancy, human beings are drawn to animate stimuli and in particular animals. Both dynamic and static features of animals are attended to, including facial features, body shapes, animal movement patterns, "self-initiation, and apparent agency and intentionality" (DeLoache et al., 2011, p. 94). Arguably, this perceptual attendance to animate and animal objects in an infant's lifeworld builds a foundation for children's future epistemic investigations, including categorization, names, identities, and typical behavior of animals. Furthermore, tracking the presence and location of individual and recognizable animals in early childhood figures to be key in establishing interspecies relationships, bonds, or even friendships (Fawcett, 2014).

Kahn and Kellert's (2002) exposition of biophilia overlooks the experience and meaning of child-pet relationships. Kellert suggests that direct experiences in nature are preferable to, and indeed more beneficial than, indirect and symbolic experiences. With this idea we largely concur. As a result, he puts studies of "pets" on a lower tier of interest. Ecological feminists have a lengthy history of critiquing the tendency to focus only on populations of wild animals and not include individual animals, such as pets. Erica Fudge notes similar trends within animal studies, citing a widely held belief that pets are "degraded animals," since the "truly animal qualities of wildness and self-sufficiency have been removed from – bred out of – the pet and replaced with tameness and dependency" (2008, p. 8). Fudge instead suggests that pets provide much to think about regarding globalization, the destruction of natural spaces, and the human-animal divide, particularly, she argues, within literary explorations of human-pet relationships. We would add that pets are good to think *with*, especially about the development of interdependence and empathy in childhood and throughout human lives.

What Ascione, Kellert, and the others have in common with Piaget and more traditional developmental thinkers is the anthropocentric and adult-centric framework they use in thinking through the process and endpoints of development. While there is more emphasis placed on relationships outside of the human realm, other animals are reduced to bystanders or passive participants in the nexus of childhood. In some extreme instances, animals become objects for contemplation, consideration, or moral and affective experimentation on children's journey to

fuller participation in a human-centered world, full of adults and their grown-up concerns.

Children, Adults, and Other Animals in Continuity

Challenging Western psychology's anthropocentric approach, a variety of other researchers have argued that children's relationships to animals and to the larger ecology of multispecies assemblages are important for nourishing development, not as an endpoint for human adults but as a continuous process of *becoming-with* (Fawcett, 2014; Livingston, 1994; Malone 2016; Myers, 2007; Russell, 2016; Shepard, 1982, 1997; Taylor & Pacini-Ketchawbaw, 2015; etc.). Gene Myers provides one of the earliest empirical studies of child-animal relations that embraces participation across species lines. Drawing on his year-long study of preschool children's interactions with animals in the classroom (2007), Myers' work is built around a belief that nonhuman animals are real, subjective, and vital figures in children's lives:

> Partly because we do not see animals as fundamentally important to human life, we have dispersed them to the official domains of child psychology – here in conceptual development, a bat that is not a bird; over there in psychoanalysis the horse that is the father. . . But in the actual lives of children, the animal is a whole and compelling presence. We can recover that animal by identifying the biases that have led us to marginalize other creatures and, most importantly, by going directly to the source – to children and their experience of animals. (2007, p. 2)

Myers firmly places humans within the sphere of animality, arguing that we are first and foremost relational selves within an ecology of subjects (Evernden, 1993). Such an expression of human embeddedness and creaturely existence echoes Donna Haraway's suggestion that "beings do not pre-exist their relatings" (2004, p. 6).

Myers' observations of children led to a wide range of findings regarding the significance of child-animal relationships and the self-other relations more broadly. While there is not enough room here to summarize each of his developmentally significant findings, a few stand out as particularly relevant for the project at hand. First, Myers presents several examples of child-animal interactions that display children's ability to recognize animals as possessing unique and significantly different minds, developing what is known as a "theory of mind." Theory of mind "holds that people have beliefs and desires, which can lead to intentions and actions, and which interact with situations in the real world and with emotions in the self" (Myers, 2007, p. 101). In essence, theory of mind is the ability to recognize subjective and affective states in other beings. Recent cognitive and consciousness studies indicate that theory of mind is present in varying degrees in humans, primates, and possibly other animals and may be attributed to the possession of mirror neurons. Mirror neurons are unique in that they "fire" as a result of both action *and* observation:

> They constitute, therefore, a specific neural system matching action observation and execution. The observed action produces in the observer's premotor cortex an activation pattern resembling that occurring when the observer actively executes the same action. (Gallese, 2001, p. 36)

We experience the effects of mirror neuron activation when we witness others being injured and reach for our own uninjured body part; the effect is similar when witnessing others act in ways that reveal a particular emotional response. It is possible that mirror neurons are actually at the root of some empathic understanding (Gallese, 2001). Children articulating a theory of mind regarding animals challenge the outdated Cartesian notion that animals are merely instinctual beings. Myers reveals that while children tended to attribute wants and desires to animals rather than more complex thoughts, the foundation for further development is laid in early childhood (2007).

Myers also emphasizes the interaction between theory of mind and children's development of language use. He describes several examples of children speaking to animals or speaking about animal language. One particularly interesting conclusion Myers makes is that children both make assumptions about animals' ability to recognize their intentions through verbal communication – typically through high-pitched, upward inflected questions – and that children can distinguish between their own use of language and the animals' modes of communication. Myers shares an interaction between the classroom teacher and the children during a visit with a dog as evidence:

> Mr. Grier: "If I'm up in my apartment and he's out in this park by himself, I've got to know when to go get him, right, when he's ready to come in. So you know what he does?" A child barks. Mr. Grier: "Exactly, who said that?" Ms. Tanner and Drew indicate it was Joe. Mr. Grier: "exactly, I'll be up in my apartment, maybe reading or something, and I'll hear from outside 'Woof, woof woof' just a couple of times, and that means he's waiting right by the door outside and he's ready to come on." (2007, p. 112)

Myers interprets 5-year-old Joe's barking as evidence that Joe recognizes the meaning conveyed by the dog's communicative action. Language use around animals shifts according to the contexts, moods, and desires of the children, revealing shifting experiences of self-awareness and relationality in a more-than-human. According to Myers, "language is essential in making us the creature that connects" (2007, p. 91). Myers' description of humans as *the* creature that connects belies a humanistic, psychological tendency to differentiate between humans and animals on the basis of some cognitive capacity, including language use (Calarco, 2008). David Abram, drawing on Merleau-Ponty's exploration of the embodiment of language, suggests that language is not just a matter of grammar or speech but is embodied:

> In the *Phenomenology of Perception,* Merleau-Ponty had begun to work out a notion of human language as a profoundly carnal phenomenon, rooted in our sensorial experience of each other and the world. (1996, p. 74)

Abram further suggests that language and meaning emerge within a sensory, affective world of embodied encounter with others and even with entire landscapes.

Understanding language in this way reveals that humans are one of the many social beings who make connections, both within and across species boundaries.

The highlight of Myers' study is perhaps his exploration of various intersubjective experiences and states. Intersubjectivity is multiply defined, but through outlining the phenomenological work of Edmund Husserl, David Abram concludes that intersubjectivity is, at heart, the experience of specific phenomena "by a multiplicity of sensing subjects" (1996, p. 38). Such shared experiences can be embodied, cognitive, imaginative, theoretical, and even affective or emotional. Myers outlines several modes of shared experience that he observed between children and animals to varying degrees, notably the sharing of affects (interaffectivity), shared attention, and shared intentionality. When different animals were brought into the classroom, Myers described the children's behaviors as often aligned with the vitality affects of the animal: a hyper monkey entered the classroom and the children became hyper, a turtle's presence made the children move slowly and even take the hunched over shape of a turtle in its shell, and so on. He notes that these "vitality affects" may have been unconscious on some level, but that children were often actively interpreting an animal's behavior as representative of her emotions and intentions (2007). While he warns that little evidence was found in his studies to suggest that animals aligned their own affects or intentions with the children's, Myers does acknowledge the possibility and suggests that children and adults may actually learn to interpret animal actions interaffectively. He provides the example of animals "liking" children:

> The turtle crawls toward Dawn, who declares: "He likes me." Mr. Lloyd: "He likes you? He's going to crawl right under you there, huh?" Dawn backs up, spreads her knees on floor, and laughs. (Myers, 2007, p. 93)

Myers' work reveals a promising foundation for a shift in developmental focus on child-animal relationships, one that takes animal agency and children's animality as a starting point. It is important to recognize the interplay of cognitive, linguistic, and embodied developments in the real and imagined relational spaces of childhood to obtain a larger picture of children's experiences, without predetermining what children "ought" to become as adults. Following in similar footsteps as Edith Cobb (1959) and John Livingston (1994), Myers draws attention to the ecological and intersubjective contexts of childhood. The rational, dispassionate, apex adult that epigenetic models of development portray as the endpoint of proper child development are so often removed from the more-than-human world. Models of development built on relational, ecological concepts offer new possibilities for thinking about not only childhood but the human animal's place in various contexts (Code, 2006).

As indicated in the previous section, many studies of child-animal relationships tend to focus on the impacts of those bonds on children's cognitive, emotional, and moral development, with little consideration to the agency, well-being, or subjective experiences of the animals themselves. This is a common trend within much academic literature, one that has become the focus of human-animal studies (HAS)

and anthrozoology. These interdisciplinary fields have risen in popularity among academics in fields as diverse as ethology, literary studies, science and technology studies, education, philosophy, political studies, and sociology (DeMello, 2010). We use the phrase human-animal studies broadly, to cover a wide range of scholars who may choose to label their work as "posthumanist," "post-Cartesian," "critical," or otherwise (see Castricano, 2009; DeMello, 2010; Wolfe, 2010).

Like others in human-animal studies, we espouse the post-Cartesian view that the oppressive dualisms of mind/body, human/animal, and culture/nature are both deeply embedded within Western culture (Plumwood, 2002) and also work to create unnecessary separations, suffering, and loss. Many of our colleagues in human-animal studies and environmental studies have developed strong research orientations toward what they see as a problematic and violent understanding of animals within their various research projects and publications (Castricano, 2009). Traci Warkentin, for example, articulates an approach that is rooted in phenomenological biology and ecological psychology for exploring human-whale interactions. Drawing in particular on the work of Jakob von Uexküll, Warkentin (2007) suggests that it is possible to imaginatively envision another being's sensory lifeworld – including the sights, sounds, scents, flavors, textures, and even their sense of time. Uexküll's famous concept of the *umwelt* – translated as "environment" or, more roughly, "surrounding world" – was radical in that it extended the possibility of worldhood and multiple realities to all living things. According to Uexküll, no singular being's reality is more truthful or accurate than another's; they are different yet complementary. This ontological coupling of animal being with environment is the foundation of an *umwelt*, the closed perceptual world of an individual organism. Uexküll's most famous example is that of the tick, an organism that can lie for years in an almost catatonic state until it perceives the scent of mammalian blood, when it will then drop down for a meal. Our perceptual worlds do not overlap; our reliance upon vision and sound is perhaps nonsensical to the tick. Its perceptual capacity for smelling blood and sensing body heat is largely unknown to humans. A tick's *umwelt* can be imagined, but never truly known or experienced, yet it is no less materially present in the world and "real" (Evernden, 1993; Warkentin, 2007).

Interspecies Ethics Within Children's Embodied Experiences

Recently, while watching a young seated child of 9 months exuberantly kicking his feet in every direction and simultaneously dancing his hands in the air as he made numerous sounds, Leesa was struck by the child's enthralled embodiment and the surrounding adults' enchantment. This was a scene of delight, especially when the child paused suddenly, looked down at his leaping feet, seemed surprised, stopped moving, and simply watched his feet as if to wonder whose they were. To be in awe about one's own bodily extensions and expressions into the world is part of childhood development. This child had dogs wandering underfoot, dogs with active legs and feet. For a child to discover their own feet and then see the feet

of a dog (or cat or squirrel, etc.) gives them the opportunity to witness the similarities and differences across physical forms and functions of legs, feet, and movement. Is it possible that children's discovery of their own bodies is abetted by seeing other animals' bodies?

Individuals are not alive alone. We are embedded in relationships with humans and a multitude of other species, daily. Searching for a nonviolent ethics (from a humanistic perspective), Judith Butler (2004) discusses a "common human vulnerability, one that emerges with life itself" (31) and that calls forth our collective responsibilities to each other. Butler carefully questions how some humans are made unhuman and their lives made unreal and how violence accompanies that unreality (2004, p. 33). To extend Butler's notion, for example, to the lives of animals in the animal-industrial complex is not unthinkable; indeed, Stanescu (2012) has done just that. The critical questioning of the wholly autonomous self is necessary to understand the circulation of recognition and reciprocity in social lives. As Butler acknowledges, "I am not fully known to myself, because part of what I am is the enigmatic traces of others" (46). These others need not be human others only. Although, her life's work is from a humanistic standpoint, Butler has recognized the importance of human-animal relationships (Stanescu, 2012). Butler asks us: "Is there a way that we might struggle for autonomy in many spheres, yet also consider the demands that are imposed upon us by living in a world of beings who are, by definition, physically dependent on one another, physically vulnerable to one another?" (2004, 27). When Leesa asked a 10-year-old about nature, they replied: "Nature is the same as people sort of. If people think they have the right to kill animals then they have the right to kill people, and it shouldn't be either one." In Butler's argument that all bodies are differently and inequitably vulnerable, we are reminded of children and animal's corporeal vulnerability and (inter)dependence, and we agree with both the 10-year-old child above and with Butler that we have a communal responsibility for the interdependence of our physical, emotional lives.

Key to Butler's response is her description of "recognizability," a Hegelian concept which she defines as "the more general conditions that prepare or shape a subject for recognition – the general terms, conventions, and norms "act" in their own way, crafting a living being into a recognizable subject, though not without errancy or, indeed, unanticipated results" (Butler, 2009, p. 5). Butler's descriptions align with a wider sense that others have meaningful lives, worthy of recognition. She provides an epistemic framework that echoes the animal rights philosopher Tom Regan's (1983) notion of moral subjects – including certain "higher" animals – as being "subjects of a life." Regan's metaphysical argument for animal rights suggests that beings capable of individual beliefs, desires, and a sense of self that extends both into the past and into the future are "subjects of a life" and hence deserve moral recognition. The children in our studies often recognize that this is the case and often express those observations while describing death, pain, and suffering of other creatures. Thirteen-year old Neville provides such a perspective, when asked about his thoughts about animals:

> Neville: . . . if we were just to call them [animals] like, an object, I don't think that would be um, too specific to them, I think they should be. . . all animals should be called like, uh, have feelings and, um, really to show you um, not to like, because yeah I have a microphone and a watch and, they're things (I: Yeah) I mean, a cat, I mean, living animals aren't (I: Yeah) if you know what I'm saying?

For Neville, this recognition of the vitality of other animals separates them from the world of "mere" objects. His description was particularly tied to various discussions about animal suffering and his experiences with the death of a cat.

Why might recognition of animals' lives and subjectivity coincide with the witnessing of their suffering or death? Butler (2004) claims that human beings' fundamental relationality and existential awareness of vulnerability leads to the possibility of recognizing others' lives as "precarious." Butler describes precariousness as built upon affective apprehension of life's fundamental relationality, the fact that we emerge from social conditions and attachments. This affective knowledge surfaces in the experience and expression of grief:

> It is not as if an "I" exists independently over here and then simply loses a "you" over there, especially if the *attachment* to "you" is part of what composes who "I" am. If I lose you, under these conditions, then I not only mourn the loss, but I become inscrutable to myself. Who "am" I, without you?. . . What grief displays. . . is the thrall in which our relations with others hold us, in ways that we cannot always recount or explain, in ways that often interrupt the self-conscious account of ourselves we might try to provide, in ways that challenge the very notion of ourselves as autonomous and in control. (Butler, 2004, pp. 22–23, emphasis ours)

Is it possible then to recognize precariousness in other kinds of beings? While Butler maintains an anthropocentric focus, concerned with how human lives are subject to the production of normative frames, she does acknowledge briefly that precariousness is "a condition that links human and non-human animals" (2009, p. 13). Butler has been criticized for establishing a line of inquiry and argument that maintains and reinforces the primacy of "humanness" (Iveson, 2012), but we suggest that Butler's arguments encourage a hermeneutic, phenomenological line of inquiry into the experience and meaning of interspecies relationality. In previous work, Joshua argues that mutuality and intersubjectivity between humans and more-than-human animals – and perhaps even landscapes – often leads to a sense of narrativity experienced in relational spaces between subjects (Russell, 2016). This phenomenon, referred to as "animal narrativity," acknowledges that other beings' lives are often perceived as stories both in and of themselves, but even more significantly, that other life stories converge and diverge with our own personal histories or those of our wider communities.

Children have provided us with various narratives, anecdotes, and descriptions highlighting the potential for recognizing other animals as having meaningful lives that are interdependent with human being(s) and subject to the same conditions of life. Building on Butler's descriptions of recognizability and precariousness, we argue that the children often recognize vulnerability in their

relationships with animals in several, mutually significant ways. During research interviews with Joshua, several children described euthanasia as a responsible choice made by members of the family out of care and concern for their pet's perceived suffering. One child even referred to prolonging a cat's perceived suffering as "animal cruelty." Extending Butler's terms, companion animal lives become "grievable" because of what is profoundly shared with others: space, time, bodily awareness and touch, and shared affects such as care, love, joy, and even sorrow. The children we have worked with throughout our studies seem to recognize precariousness as a shared state of existence among all living things and that personally significant relationships are the locus of the most deeply felt ethical and emotional connections. Children may recognize that part of the pain of losing a pet, for example, comes from a lost connection within a wider set of relations among family, friends, and other animals. As a result of one being's death, the structure of the community left behind can become significantly altered.

Yet ethical challenges persist, and through our conversations with children, we are often reminded about the complexities of sharing lives and worlds with other animals. Children have expressed difficulties in recognizing the vastness of loss, death, and suffering felt by other animals around the world. This was encapsulated in Sabrina's interview with Joshua about animal death:

> Sabrina: I feel like pets is different because you have like, a connection with them and like specific people will like, be sad about it and stuff, but I try not to think about like, the animals that are killed for food and stuff and then (p) then like the wild and stuff you don't really notice as much when they're killed because you don't really watch them die or anything and so then you kind of, its like not the same because you don't really think about it. You don't really like notice, cuz I'm sure there's like lots of animals who have died like, really recently, like in the past hour or something but you just like don't, you don't know cuz you don't know specifically each animal.

Sabrina's thoughts about all of the unseen, unknown animal deaths echo ecological feminist's concerns about the invisibility of individual animal suffering.

Conclusion: Toward an Interspecies Pedagogy of Conviviality

Charles Darwin (1936) understood the coextension of humans with other animals as a lineage of bodily and emotional similarities. Darwin was and is still reviled for suggesting the animality of human beings. Yet, many children are cognizant of their animalness. A grade five student told Leesa that they knew they were an animal because: "I'm alive. Because we live, eat, breath and grow and we're alive and if you do that you're either a plant or an animal and we're certainly not plants, so we're animals" (#111, 2002). In his nursery school research, Myers (2007) outlined how children felt vital and alive with other animals, and this was demonstrated in their actions. In a beautiful example, one young girl who enjoyed watching the classroom

doves and was intrigued by flight was videotaped gesturing, moving, and dancing silently in from of the doves (Myers, 2007). Myers believed that the animal's subjective qualities confirmed the child's own sense of self, deepened the child's self-other differentiation, and created special symbolism from the shared animacy. Myers identified four core traits of relatedness exhibited between children and animals: (1) agency, animals move on their own; (2) coherence, animals are each experienced as an organized whole; (3) affectivity, animals show emotions; and (4) continuity, animals exist over time. These traits of relatedness offer a stark contrast to human exceptionalism, reinforce Darwin's hunches, and give educators tangible teachable moments to work with.

Critical animal studies scholars, like Helena Pedersen (2010), have interrogated the lack of curricular attention to animal lives in public schools, despite student interest. Previously, philosopher Anthony Weston (2004) went so far as to call for deschooling environmental education, urging teachers to go against the patterns of the dominant culture and to examine the permeability of the human/other-than-human boundary beyond the classroom walls. Weston was drawing on Ivan Illich's ideas about how schools reproduce the established order of society and treat learning as a commodity to be produced for the benefit of an elite – instead of the learner's "inalienable right to learn what he likes rather than what is useful to someone else" (Illich,1973, p. 2). Illich railed against schools that "made teachers into administrators of programs of manpower *(sic)* capitalization through directed, planned, behavioural changes" while tying students into "unending consumption and dependence" (1973, p. 20). Illich believed in "the social structure necessary to facilitate learning, to encourage independence and interrelationship and to overcome alienation" (1973, p. 22). Despite, lively critiques of Illich's gender politics and his albeit humanist interests, we find his focus on capitalist systems of schooling and the importance of interrelationships vital to pedagogies of childhoodnature and animal relationality.

Conscious throughout his work of natural limits and scales, Illich envisioned: "A convivial society would be the result of social arrangements that guarantee for each member the most ample and free access to tools of the community" (1985, p. 12). Tools for Illich had a very broad meaning, as he maintained "schools were losing their claim to be effective tools to provide education" (1985, p. 8). Illich (1985) chose the term "*conviviality* to designate the opposite of industrial productivity" (people being much more than plain consumers) and for it "to mean autonomous and creative intercourse among persons, and the intercourse of persons with their environment," and he believed "conviviality was an individual freedom realized in personal interdependence and, as such, an intrinsic ethical value" (p. 11). Recognizing the agency and interconnectedness of emotional lives, one of Leesa's grade five students said: "If my Dad or Mom is in a bad mood he (the dog) runs away from them, jumps a fence." We would like to jump over the fence of anthropocentrism in childhood animal relations. To learn and teach from such an ethical, convivial standpoint – children in creative conversation with each other and their animal environments, realizing their interdependence – is a vision worth realizing on our collective pedagogical horizon.

Abstract

Within the United States, taken-for-granted curricular priorities and practices sanction child-animal relations within specific cognitive and socio-developmental perspectives. This chapter presents an onto-epistemological departure, drawing upon a yearlong post-qualitative classroom inquiry with 4- to 6-year-old children in order to map the various ways in which children were entangled within the process of becoming more-than-human animals. Adopting a materialist perspective on relationships, this work specifically highlights the ways in which children and everyday acts of becoming animal were mobilized within what the children referred to as "the beast" – an imbroglio of physical transformations,

environmental limitations, adult expectations, material affordances, and children's conceptions of and relationships to various animal actors. Through narrative and visual data (re)constructed with children, the chapter argues that (1) young child-animal hybrids (i.e., beasts) emerge within and through highly particular and dependent material-discursive circumstances and (2) attending to and honoring these "beasts" present opportunities for generative departures from the ways in which animals are typically conceptualized, valued, or otherwise recognized within early years curriculum.

Introduction

Within the early years context of the United States, taken-for-granted curricular priorities and practices generally wed the child-animal classroom relations to specific social and cognitive constructivist perspectives. For example, classroom pets have a long and favorable history within US education – to the point where they have become a commonsense avenue for supporting children's socio-emotional competencies, such as compassion and responsibility, as well as improving children's abilities to cope and reducing the occurrence of unwanted behaviors (see, e.g., Meadan & Jegatheesan, 2010). Beyond the use of classroom pets to support children's socio-emotional growth, animals also serve a variety of more traditionally "academic" roles within young children's classrooms. Both living and deceased/preserved animals are commonly utilized within early years science curricula as engaging physical specimens that can support "children's progressively more complex approaches to understanding the world" (Hamlin & Wisneski, 2012) by facilitating scientific skills, like questioning, observing, predicting, categorizing, and classifying, as well as the development of conceptual understandings of habitats, life cycles, and health (see, e.g., Cohen & Tunick, 1997; Harlan & Rivkin, 2012; Seefeldt, Galper, & Jones, 2012).

This chapter presents an onto-epistemological departure from these perspectives that position the presence of animals within classrooms as "objects for human utility, onto which humans project meaning or symbolic value" (Tipper, 2011, p. 149). Adopting a new materialist perspective on relationships, this work specifically highlights the ways in which children and their everyday acts of becoming animal were mobilized within what the children came to call "the beast" – an imbroglio of physical transformations, environmental limitations, adult expectations, material affordances, and children's conceptions of and relationships to various animal actors. It is worth noting that this research does partially align with Jane Bone's (2010) work on children's acts of becoming animal through play. Bone theorizes that a spiritual kind of intersubjectivity drives the metamorphoses of children into other animals.

That is, she interprets children's animal play as collapsing the human/nonhuman animal binary through children's spiritual, ethical, and emotional attunement to animals – what she calls "deep empathy" (Bone, 2010, p. 411). Her work and the relational becomings explored in this cartography are similar, as both give shape to the ways in which children were entangled in acts of becoming "more than one but less than two" (Haraway, 2008, p. 244). However, the chapter differs in that it attends to how "matter feels, converses, suffers, desires, yearns and remembers" (Barad, in Dolphijn & van der Tuin, 2012, p. 59) and how the children themselves articulate the material-discursive particulars of becoming (with) animals within everyday acts of classroom living.

Through narrative and visual data (re)constructed by and with young children, this chapter argues that (1) young child-animal hybrids (i.e., "beasts") emerge within and through highly particular and dependent material-discursive circumstances and (2) attending to and honoring these beasts present opportunities for generative departures from the ways in which animals are typically conceptualized, valued, or otherwise recognized within early years curriculum.

Methodological Context

From September 2013 to May 2014, I spent 3 days per week researching the material-discursive entanglements (Barad, 2003, 2007) of 16 kindergarten children, aged 4–6 years, at a university-affiliated laboratory early childcare and education center in the United States. I explicitly undertook this inquiry from/with a new materialist perspective, which seeks to highlight the ways in which humans and nonhumans engage each other and emerge differently from those engagements (Barad, 2003, 2007; Bennett, 2010; Lenz Taguchi, 2010, 2013). With relational intra-dependency, complexity, and nonlinearity as theoretical framings, my main focus throughout the inquiry was to recognize and map the ways in which the children, myself, and the multiple non-elements/actors of the classroom were bound together in the everyday events of classroom life and how these events were perceived, articulated, and re-presented by the children.

In keeping with my focus on the complexity of relationships, I employed a post-qualitative approach, attempting to reconfigure what Lather (2013, p. 642) calls the "settled places in our work." Not unlike many researchers who work with young children, this inquiry entailed a revision of adult researcher-child roles and data collection methods (e.g., Albon & Rosen, 2014; Clark, Kjørholt, & Moss, 2008). However, the ways in which the children and I "did" research focused less on finding out and representing what children already "knew" and more on mapping what emerged from our being together in the material-discursive flows of the classroom (see also Myers, 2014, 2017). To this end, I worked with the children to (re)shape the execution of more traditional visual ethnographic methods of observing, interviewing, and photographing. Within our *method assemblage*, "a tentative and hesitant unfolding, that is at most only very partially under any deliberate form of control" (Law, 2004, p. 41), we developed three interrelated processes – "being

with," "doing photos," and "becoming cameras." Within these movements of *being*, *doing*, and *becoming*, the children and I would spend our time together discussing, writing, drawing, and making photographs about the "important things" in their classroom. Within these processes, illustrations and photos were not treated as simply symbolic artifacts that might aid discussion. Instead, these assemblages of talking, writing, and imaging functioned as sites of productive entanglement (Lenz Taguchi, 2010), creating new layers of material-discursive action through which we attempted to re-present the complex relationships between children, adults, objects, things, materials, and animals.

Classroom Context

Like many early childhood classrooms, nonhuman animals populated this particular classroom landscape and were intended by adults to be subjects of study or tools for discovery (Bone, 2010). For example, live spiders or worms were temporarily held in glass and examined with magnifiers, several dried specimens (e.g., a mummified toad, a mouse carcass, a cicada shell) resided in small plastic jars in the "science area," and animals that were encountered on field trips or walks outdoors often became the subject of journal entries or classroom discussions. More abstractly, nonhuman animals were often present as plastic figurines meant for children to use as dramatic play props; in the illustrated pages of picture books, as line drawings on worksheets; or in photographs in the reference books in the science area.

In the data mappings the children and I constructed, however, the adult-sanctioned roles of classroom animals did not figure as "important things" of classroom life. What the children did highlight were the ways in which different more-than-human animals emerged *between* children and these more "official" nonhuman elements of curriculum. What follows are cartographies – presented in no particular order – in which I and several children attempt to visualize and narrate the complexities of the (im)proper classroom animal, the more-than-human *beast*, as it emerged within and through particular material-discursive circumstances of this classroom.

Child-Crab-as-Beast

The Crab Story originated when Paige meticulously chewed two pretzels into the shape of a turtle and a crab, respectively, one morning during snack time. As we sat in a small conference room – talking, drawing, and examining the photos we had taken in the classroom – Paige would tell the final version of the Crab Story, articulating what it meant to become a *beast* and how these beastly, more-than-human ways of knowing and being might emerge and retreat:

> Paige: *I think everyone should know the Crab Story. Put that in (the research). Once there was a turtle named Shelby. And he found a big island and he had it all to himself. But there*

was also a crab. And they fighted. And the crab said, "This is my island!" and Shelby said, "This is my island! I saw it with my own huge eyes before you were even a crab." Paige came and said, "I'm going to stop this argument right now!" So she chomped the crab and he went right into

her tummy. But then she had a spell on her and she turned into a little crab and walked all around the sand. And then a giant wave came and BOOM. . .washed away.

Casey: *Did you. . .I mean, the crab. . .get washed away?*

Paige: *I did, but. . .I'm not a real crab, like for real.*

Casey: *You were a crab in the story or. . .?*

Paige: *Because I just know. . .you can't turn into a whole animal. Like, when I was a crab, I was just being a crab with a spell. Not all the way.*

Casey: *So, just walking like a crab?*

Paige: *Well. . .you know Beauty and the Beast? Beast is a man inside and it's a spell.*

Casey: *Didn't a witch cast a spell on him or something?*

Paige: *Something. . . so he is a man and then a beast and then a man. But he was still a man while he was the Beast. . .because he would talk and wear clothes.*

Casey: *So he just looked like a beast?*

Paige: *I don't know. . .he did beast stuff. He was mean and I think he ate people. . .because he had really sharp teeth. He did some beast stuff and some man stuff at*

the same time because he remembered being a man. But he had to turn back into a whole man because the spell was broken. That's a beast.

Casey: *So. . .were you. . .a beast?*

Paige: *I'm pretty sure I was because I was still a girl, but I was moving like a crab after I ate him up. I was like a crab but not a WHOLE crab. Like. . .I knew how to be a crab and how to be a human. At the same time.*

When we returned to the classroom, the rest of the children were outside on the playground. With the classroom to herself, Paige took the opportunity to show me how she could become a beast – part crab, part girl. She sat down on the carpet and lifted herself off the ground with her hands and feet. As she "crab-walked" around the carpet, I took her photo and she asked me to come closer. As I approached her, she raised one arm like a pincer and reached for my ankle, grasping at me with her "claw" and making a chomping sound with her mouth. I let out a yelp and I jumped back; Paige giggled, collapsed out of her crab posture onto her back, and called to me. "Case-Case! Get over here!" She crawled over to me on all fours and pinched me playfully on my leg. At that moment two children arrived in the classroom and invited her outside to play chase. She got up quickly and followed them outside (on two legs).

Paige's explanation and demonstration of becoming crab indeed mirrored Disney's animated version of *Beauty and the Beast* (Trousdale & Wise, 1991) – the French fairytale in which an arrogant young man transformed into a human-animal hybrid until the spell is broken by true love. In Paige-Crab's case, when the specific material-discursive conditions are right for a *spell* – be it ingesting a crab-shaped pretzel or having an empty classroom in order to play rough on the

carpet – she was able to become a *beast*, doing both Paige stuff and crab stuff. As all of the children has some familiarity with the animated tale, the beast became the way in which we conceptualized the many lines of connection that emerged throughout children's animal becomings – the material-discursive entanglements from which these beastly spells emerge, what child and animal "stuff" makes itself known therein, and the conditions under which these hybrid beasts retreat.

Child-Butterfly-as-Beast

Rosa closely examined several series of photos I had taken of her engaged with plastic insect figures. I noticed she frequently chose to play with the basket of plastic insects during morning exploration time; I had taken several photos that (re)constructed her engagement with a particular blue and purple butterfly.

While examining these photos closely, she gave the following account:

Rosa: *That's my butterfly. . .my favorite one. There is another purple and blue (butterfly) that looks like mine, but it has little spots on it. I don't like that one as much.*

Casey: *Why not?*

Rosa: *Um. . .I just like this one better. I think I actually rubbed the spots off because I like to hold it and rub it. Purple and blue are my favorite colors. Do you know why? My blanket that I've had since I was a baby is purple and white and it smells like cotton candy. It is made with holes in every spot. Do you know that kind?*

Casey: Crochet? Is it made of yarn?

Rosa: Yes, I think. But it smells so good! I rub, rub, rub and then wait a little bit.

Casey: *What are you waiting for?*

Rosa: *I'm just thinking. . .about cotton candy, actually, and my blanket and my mom and dad. Then I jump! And fly over to the next thing I'm going to do. You didn't take a picture of that part. See how. . .I land in the plant for a while and rest. I put my butterfly in the branches and get inside. And do like. . .a butterfly rest*. [Zooming in to examine the leaves of the plant more closely in the photo] *I can't see my butterfly in there. . .I did put her in there though. Butterflies are really fragile so they need to rest*. [Laughing] *I look just like a butterfly in that plant! That's funny to me.*

Casey: *I remember that you asked me to take that photo.*

Rosa: *I wanted to see if I really looked like a butterfly.*

Casey*: Because you're resting?*

Rosa*: Yes, but. . .you know what? You didn't even notice me flying! I can flap really fast and go pretty far, actually.*

Casey: *I need to watch more carefully. Are you going to fly again sometime soon?*

Rosa: [Spreading her arms wide] *This is how butterflies say, "yes."*

After our first discussion about becoming a butterfly, I did notice instances of Rosa "flying" around the classroom, usually during the morning exploration period. Becoming butterfly began with a search for "her" purple and blue butterfly. If her butterfly was used for "decoration" on another child's structure, as many insect

figures often were, she would broker a trade or switch her butterfly out without notice. Once she had her butterfly in hand, she held it tight for a few minutes and then allowed it to rest in one of the sturdier leaves of the classroom plant. Next, she would step onto the building platform and launch herself into the air.

In an effort to document her flight patterns, Rosa-as-butterfly would tug gently on my shirt or tap my shoulder to let me know she was about to fly. I'd feel the familiar tap or tug and turn around to just in time to snap a photo of her in flight. When viewing these photographs, she delighted in the blurred image she imparted upon the screen and narrated the ways in which her flight patterns were influenced.

Rosa: *I'm so fast! I'm flying. . .you can barely see!*

Casey: *You're blurry. . .The camera has a hard time making a clear photo when you fly that fast.*

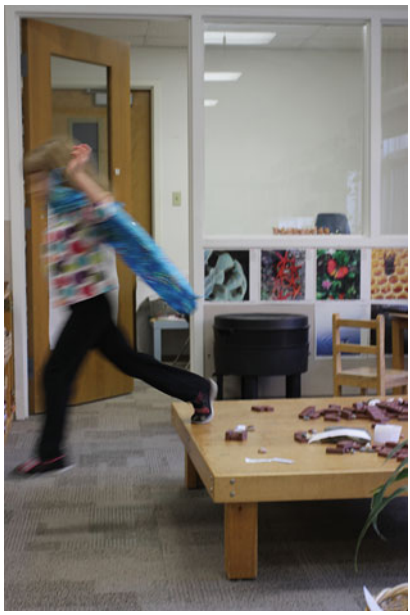
Rosa: *Well, the platform is the best spot. I like to take off from the platform mostly because it is just the right size. It's my. . .a butterfly surface. If I tried to fly from on top of the table or something it wouldn't be. . .you could get in trouble.*

Casey: *Why?*

Rosa: *I just try to fly really fast so no one sees me. You aren't allowed to run around the classroom, but I know how to fly so I won't get hurt. And I don't really want to touch the actual ground, so I fly from surface to surface if I can, but some blocks you can't land on or they will break. But I don't even think [other people] can see me. . .I'm so blurry.*

Rosa-as-butterfly's flight was entangled, not only with the plastic butterfly figure, the sense memories it imparted, and her knowledge of butterflies and the classroom plants but also with classroom spaces and materials, the rules for their use, and my camera's ability to reconstruct the flight visually. Her patterns of flight

were further complicated when a basket of fabrics was introduced to the classroom. These fabrics, particularly ones with blue and purple patterns, allowed Rosa to become more butterfly than before, thus presenting challenges to the human classroom space.



Rosa: *I like this one because I have butterfly wings on.*

Casey*: What do those do?*

Rosa: *Well, I usually try to get this blue one. . .or one with blue and purple when I am ready to do butterfly, um, flying.*

Casey*: And then what?*

Rosa: *I tie it around like this [motions around her neck with her hands] and, well, sometimes I need a teacher to help with that part and then I flutter. . .and that means move like. . .the wing part. It makes it like a fan almost. Like. . .*[fanning me with her hands]

Casey: *Oh, right. I can feel a little breeze from you right now. That's how your wings work?*

Rosa: *The wings make a breeze and that helps you to fly. My mom even told me.*

Casey: *So fabrics make your wings and that helps with your flying.*

Rosa: *It makes me faster, but sometimes I have to wait if someone else is using it. Or if someone wants what you have. . .your fabric. . .then it can be a disagreement because I just want these ones for the butterfly.*

Casey*: What happens if there is a disagreement?*

Rosa: *The fabrics get put away in the office and then no one gets to use them. Or if someone says, "You can jump off of there!" then I have to stop. . .just take off the fabric and make a good choice.*

Casey: *Being a butterfly isn't a good choice? Or flying isn't. . .*

Rosa: *Not really. It's fine for me, but that's why I have to be really fast. So no one can say, "stop!"*

The fabric wings not only allowed her to become more butterfly in color, but also in movement ("flutter") and effect ("breeze"). But there were instances that I observed in which Rosa was told to stop flying, either by other children or adults. As she said, having to stop flying was often the result of either a disagreement between children or when she wasn't fast enough to not be seen by adults who disapproved of her using the wooden platform as a launch pad/butterfly surface. In these instances, removing the fabric and, thus, becoming less butterfly were positioned as the better choice.

Given constraints of space, material resources, and adult idea(l)s about acceptable movement, Rosa would sometimes fly without the plastic figure, her plant resting place, the wooden platform, or the fabric wings. For example, several large boulders were partially buried in a small grassy slope on the playground. Rosa would often ask me watch her while she "flew" from rock to rock during the morning outdoors time. While engaged with these photos later, she commented on what was lost and gained when flying in this different way.

Rosa: *Going from rock to rock is. . .a better choice.*
You don't get in trouble for the flying part. But it's not really. . .it's less good.
Casey: *Why less good?*
Rosa: *I can't go high and land on the wood. See how my hands are wrapped up?*
Casey: *Inside your sleeves.*
Rosa: In case I fall on a rock. And you can't take the [plastic] butterflies outside or the fabrics! And there isn't a tree rest. But there are flowers for butterflies outside, but not for a long time. You can fly, but it's not so real, actually.

Jumping from rock to rock was a more proper way to become butterfly, at least according to adults. But this "better choice" for a human student was "less good" for a beastly butterfly. Rosa was a "less good" version of her butterfly-self without the smell of cotton candy, the press of the plastic figure in her hand, the flutter of fabric around her shoulders, and the wooden platform under her feet.

Child-Snake-as-Beast

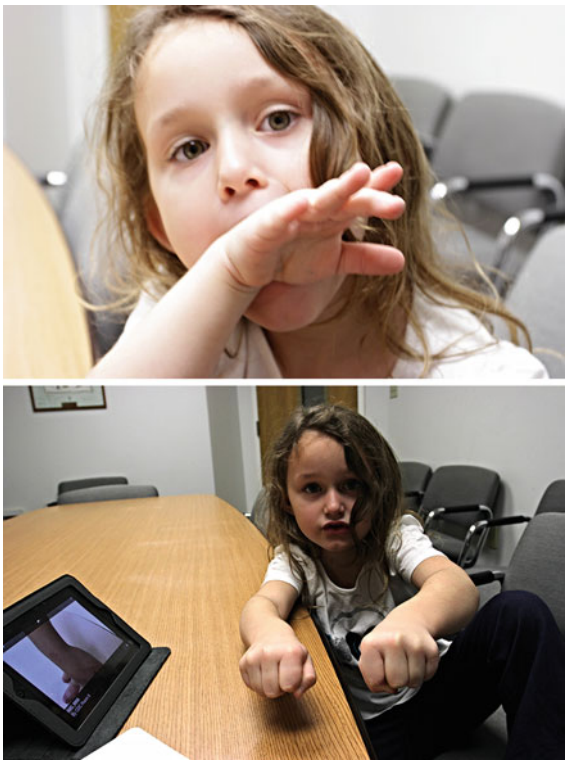
Two distinct ways of becoming snake emerged within the classroom. Although each of these child-snakes emerged through quite different material-discursive events, each would be understood through movements toward and enactments of inhabitation – of something or someone getting *inside*.

Nia Becomes Snake

I arrived in the classroom one morning in mid-September to news that a small snake had bitten Nia while the she played on the playground the day before. Nia was quick

to show me the oval pattern of marks the snake's jaws had left on her skin and allowed me to photograph her wrist with my camera. For several weeks afterward, many children engaged in various retellings of the events leading up to the moment of the snakebite and Nia often corrected their version of the story. Nia offered this retelling of what happened when she engaged with the snake:

> Nia: *This is how the story goes: I was on the Playground and I saw this baby snake. I picked him up and I wasn't even afraid. I've known how to hold a snake since I was three because I've done it before. And then some kids came over. I held the snake out for them to see they all started screaming. And I said, "Stop! Be quiet!" But they didn't stop. The snake put his head up in the air and opened his mouth three times. And then another time. He dove down and put his mouth right onto my wrist. I shook and shook and shook him off and everyone was still screaming and the snake crawled away. I don't know if I cried or not. I washed it and put a Band-Aid on it. And I don't know what's gotten into me, but I'm guessing it's snake germs. That snakebite. . .I am part snake.* Casey: *Part snake? Why?*
>
> Nia: *Because at night, when my parents think I'm sleeping I get down. . .lay one the floor. And then I* [makes a hissing sound] *all around until I'm done. Because, look* [holding out her arms]. . .*those two dots are scar dots. It, like, irritated my veins. See how they are green?*



Nia's transformation into a human-snake hybrid not only urged her to behave in a certain way but also imparted her with a certain fund of expertise – a kind of snake wisdom – that others would call upon for various purposes. For example, she was asked by the outdoor education teacher to talk with children from other classrooms

about "what happened with the snake." The purpose of these meetings was twofold: to give other children advice on keeping their distance from wild animals, both for their own safety and the safety of the animal, and to instruct children on how to properly hold a snake should the opportunity arise. During these meetings, Nia's expertise was framed as the result of her social history (e.g., the *choices* she made that allowed her to be bitten and the *lessons* she had since learned). In less structured human-snake engagements, such as when a small group of children encountered a small lifeless snake during an excursion just outside the playground fence, Nia's peers called upon her to be the *first* one to touch the snake because "she knew about snakes."

However, in our photo-doings, Nia noted that her previous social experiences as a child-among-snakes couldn't be separated from her current beastly self that was inhabited by snake germs. She also didn't simply see her expertise as a consequence of interacting with the snake incorrectly and, thus, learning important lessons about snake handling, nor did she view her familial relationship to snakes as uniformly positive.

> Nia: *You know what? This bite made me remember that when I was three, I found a snake egg on the playground and I carried it all over. And then I put a bunch of, like, sticks and grass on it to keep it warm and then I hid it. I think maybe (the snake that bit me) was that snake just as a grown up. And I think it remembered me. I didn't want him to bite me,*

but he didn't listen to me because I wasn't even a snake then. And he was afraid. And I was afraid because everyone was screaming. So it was both of us. This is making my wrist itch from the inside!

Casey: Where the snake bit you?

Nia: Oh, yeah...like you know when we found the little dead snake? I poked with the stick and flipped it over. And Matar and Petal were scared and I wasn't scared because it was dead and just laying there. But, like...my wrist was itching and itching and that can be a...little problem.

Casey: *The itching is the problem?*

Nia: *It does itch...but, like, I have snake on the inside, so whenever I see snakes, think about snakes, it keeps itching.*

According to Nia, becoming part snake endowed her with abilities, sensations, and memories, and both she and the snake were responsible for these things in various ways. While Nia was seen as some kind of snake expert, the snake continued to make itself known to Nia through physical sensations. To Nia, these sensations meant not that she was simply constructing knowledge from the outside in, but, since she now had "snake on the inside," she was becoming more snake from the inside out.

Elizabeth Becomes Snake

I often photographed the children engaging with baskets of fabrics during morning exploration time. A group of children would typically call me over, not only to allow me photograph their engagements with the fabrics but also to request my help in their efforts to tie fabrics around their waists or shoulders if their play necessitated it. With these particular animal-printed fabrics tied around their shoulders and waists or draped around their heads, Elizabeth, Lauren, Petal, Krissa, Clara, and Paige engaged in various animal enactments, such as growling, crawling on all fours, mooing, meowing, oinking, hissing, etc. Children who wanted to engage in this, but found themselves without a fabric to wear, would often take on roles of humans, specifically the "pet owners" of the various fabric-clad animals.

Elizabeth in particular created elaborate animal plays with these fabrics, often becoming more animal than kindergartener – spending the entire morning exploration period under spell of the fabric. When she examined images of these beastly events later, she remarked on the ways in which she emerged as a snake.

Elizabeth: *See what I'm doing with that fabric? Ssss! That's how they smell. They don't have a nose, so that's how they smell.*

Casey: *By hissing?*

Elizabeth: Yeah. I can do that really good. Really good because of these missing teeth... [She slides her tongue in and out of the space where her primary teeth used to be.]

Casey: *I've seen snakes do that with their tongue.*

Elizabeth: *And they...like, they have a tail that, like, shatters.*

Casey: *What's shatter?*

Elizabeth: *That means when they are scared they shatter their tail to say, "Get away from me!" They have a special shatter tail* [moving hand back and forth to simulate a rattling motion]. *And I could just do that.*

Casey: *Shatter like a snake tail?*

Elizabeth: *Well, we were playing a game and I became the pet with that fabric…* [Laughing] *and I was the worst pet they ever had! I shattered my tail all over…I was very scary. I would not like a pet snake or a pet alligator but being one is okay. I would not like to have a lake house, but I don't even do so it's not really a problem. But anyway, the fabric…it flattens out very easily and silky, so it's a…I love that it feels like a snake on my body. I could actually sleep with it.*

Casey: *Sleep with a snake?*

Elizabeth: *Not a sleep with a snake…be a snake and sleep IN it. Like, when stuff is so soft, I love it so much. And I could curl up, stay asleep…it's so cozy. But if you slept with a snake it would always be "Sss!" and it would be waking me up all the time. But if you were a snake it wouldn't even matter to you. Like, do you have a pet?*

Casey: *I have a dog and a cat.*

Elizabeth: *Well, then sometimes you know if you have a crack in your door your cat will come in, and just bother you? Or, like, scratching at the door?*

Casey: *Oh, yeah! My cat does that a lot at night.*

Elizabeth: *That's how pets can bother you. If you are a snake you don't care because you're just "Ssss!" all night long and you love it!*

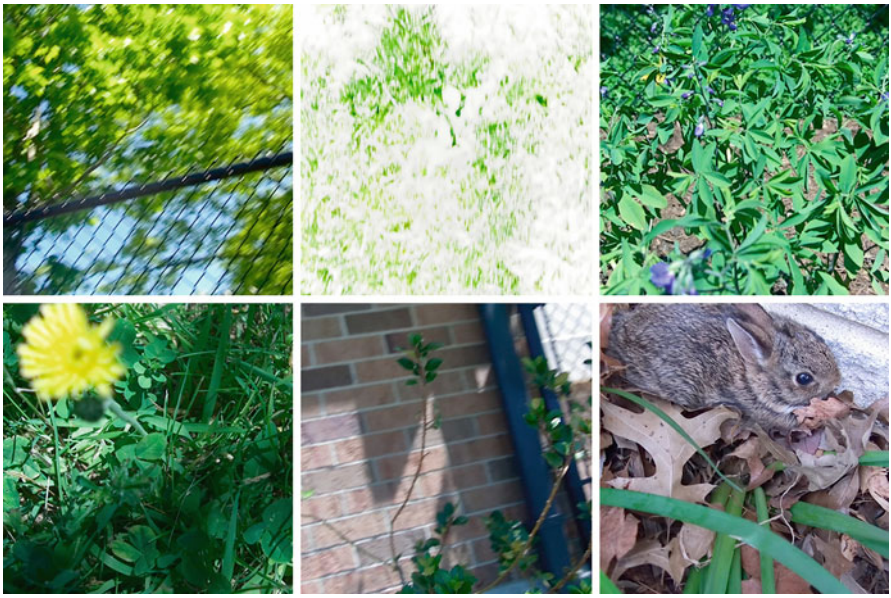
Casey: *You love being a snake…*

Elizabeth: *I do not! Just inside a fabric. A snake fabric is like being a snake inside a snakeskin that's a cozy feeling to a snake. I could shatter my tail and just get really cozy!*

For Elizabeth, becoming more snake than human was the key tolerating snake behavior. Elizabeth didn't particularly want to be in the company of a snake and recognized that Elizabeth-snake was the "worst" kind of pet, but she did enjoy *being* a snake in many ways. Becoming cozy inside the fabric snakeskin afforded a kind of comfort with snake behavior – hissing without feeling annoyed, shattering one's tail – that would otherwise be impossible. Just as Nia had become a snake "from the inside" due to "germs," Elizabeth also became a snake when the introduction of animal-print fabrics to the classroom allowed a kind of *interiority* to materialize. In this case, the properties of the fabric gave Elizabeth the opportunity to "get inside" and feel "cozy," which mobilized her beastly snake becomings.

Child-Bunny-As-Beast

One morning in April, I heard several shrieks and unintelligible, hurried talking coming from the small courtyard just outside the classroom. As Lauren rushed inside to grab the cameras, she told me there were two baby bunnies in the flowers. When I arrived in the courtyard, several children were in crouched positions near the beds, lifting the layers of dead leaves and carefully peeking to see if baby bunnies were hiding underneath, while others were talking loudly, either trying to tell others to come and see the bunnies or warning younger children to stay away. One tan bunny about the size of a teacup darted away through the courtyard, across the grassy area, and under the perimeter fence. A few children chased after, pointing their cameras wildly and clicking the shutters over and over again, trying to "catch" the bunny's image as it disappeared from sight. The other bunny remained – wide-eyed and still in the leaves of the flowerbed.



Teachers calmly convinced most children to keep their distance so as not to stress the animal any further. In spite of these warnings, Matar and Nia returned to the beds several times to take photos of the remaining bunny. Each time, they would squat low to the ground and approach the flowerbed as quietly as possible, shuffling on all fours; it struck me in that moment how much the tiny bunny impacted the girls' motion and how their movements. They had emerged somewhere in-between "child" and "bunny," and this had a dual effect. They were less likely to be noticed by teachers as they defied the orders that the other children had to obey and they were also less likely to scare the bunny into fleeing the flowerbed as the other children had done.

While other children were given warnings and chastised for getting too close or being too loud near the frightened animal, Matar and Nia moved stealthily in

and out of the bunny's territory – taking photos, avoiding adults' verbal corrections. I sketched them quickly in my notebook until the call of the morning bell began the official school day, breaking the spell.

A few days later, while Matar and I were examining the photos that had been taken during the bunny event, I showed her the drawings in my notebook.

Matar: *What? Is that me? Why?*

Casey: *Yes. . .I was really trying to notice how you moved toward the bunny. You're crouching . . .it seemed like that was a good way to move.*

Matar: *Move how?*

Casey: *Like, crouching. . .*

I try to make myself smaller in my seat, ducking my head and pulling my arms and legs to midline.

Matar: *Crouching. . .when you. . . crouching, you are more small to the ground, so the bunny is not so scared because you are not such a scary person to him. Like, so you won't kill him, you won't hurt him, he's not scared.*

Casey: *You were being very careful and quiet.*

Matar: *A bunny is so quiet, so you can be quiet.*

She giggles and pulls her hands up near her face, mimicking the ways bunnies clean their faces and ears with their paws.

Casey: *Ah! A little bunny! I've seen them move just like that.*

She takes a soft lead pencil and adds ears and paws to the drawing in my notebook and holds it up for me to see.

Matar: *You say, "Are you a little bunny now?" and I say* [putting her hands on her head, fingers up, mimicking the small ears of a bunny, laughing]. . .*okay, that's it.*

Just as Matar had done, Lauren and Nia explored this kind of beastly bunny movement as we assembled our data. During one particular event, Nia and Lauren

had created lists of important classroom events and were debating with each other whether or not those events were represented within the many photos that the children had taken with their cameras and how these might be arranged within the cartographies of the research "book." As they began to discuss the morning on the playground that the bunnies appeared and the images that were constructed of that event, they grappled with the ways in which bunny movement was constructed in/as images.

Nia: [Writing] *Okay, now, the most important thing to me lately is the baby bunny. I can't write that so I am just going to. . .*

She stops writing conventionally and draws a tiny bunny as an item on her list.

Casey: *That was important to Matar, too.*

Nia*: It was so cute. I think it was really scared of us, so it was just afraid to move even though we were trying to be quiet.*

Casey: *We talked about that. . .how it was important to stay very quiet around the bunny.*

Nia: *It was like. . .froze.*

Lauren: *But the cool thing is. . .it didn't even move. Bunnies never do that!*

Casey: *Do you think it was because you were moving so slowly and quietly?*

Lauren: *I think that the thing. . .what's important is that it was staying still and not hopping around so I could even take that photo. Because I tried to get a photo of the other one and all I got was like blurry. . .like grass.*

Nia: *Well, look at it now. . .it's going to hop all over our list!*

She draws some jagged lines at the top of the paper. Her hand bounces up and down wildly, mimicking the quick and unpredictable movements of the baby bunny.

Nia: *I'm making you, Lauren, and you're a little. . .little bunny.*

She draws Lauren and then continues the jagged lines into her body and down her legs. Both girls begin to laugh.

Lauren: *Ah! Why did you do that? That's weird!*

Nia: [Crossing her arms, smirking] *Well, if you're going to be a bunny, you are going to hop around on your legs!*

After we finished the list, the girls and I walked back to the classroom and arrived just in time for the daily patterning activity. Each morning, one or two children would assist the teacher in leading the class through a sequence of movements while counting up to the present day of the month. For example, if the date was the 15th, the children might choose a "two pattern" of "clap, jump" and then proceed to see if the pattern could fit evenly into the number 15. On this particular day, the child who was creating the pattern with the teacher was having trouble deciding on which movements to choose. Eager to begin, many children shouted suggestions.

Margaret: *Spin!*

Rosa: *Stomp!*

Nia: *Bunny hop! Bunny hop!*

Some of the children laugh and then join in her request, chanting until "bunny hop" is chosen as the third movement in the pattern. The children count aloud, bunny-hopping in unison.

Nia: [To me] *Make sure you take a picture of this.*

After the morning meeting had ended, Nia asked to view the photos I had taken of the bunny hop. As she viewed them on the camera's screen, we engaged in an

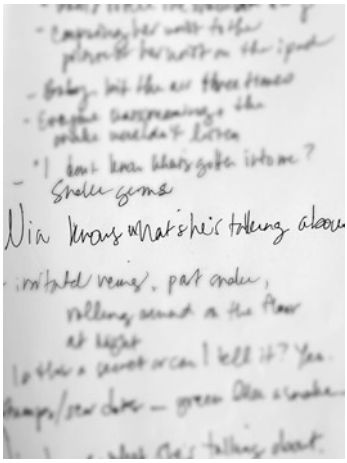
impromptu event of photo-doing, while the other children were busying themselves with transitioning to their morning work choices. While engaging with the images, Nia remarked on the limitations of our methods – the difficulties of constructing and critiquing static images of these kindergarten "beasts" when movement was a crucial way being-becoming – as well as the ways in which these more-than-human animals emerged within a variety of bodily desires, material forces, curricular constraints, and social expectations.

Nia: *It's blurry...this one, not so much.*
Casey: *You were moving pretty fast, so it's hard for the camera to make a clear photo.*
Nia: *I was trying to really hop like a bunny because never had a picture of that part.*
Casey: *Right – you said the bunny being able to hop was important, so...*
Nia: *But actually... if we wanted to really be a bunny, we shouldn't have been up so much*. [She crouches, pulling her arms and legs in] *But you can't crawl around in the classroom because that's not okay to do. That would be too...crazy. But it's more down.*
Casey: *It didn't feel like a bunny to do it that way? Up?*
Nia: [Popping up to a standing position] *It really felt like a bunny to hop like that...but it doesn't look like it. You can't really see it on there.*

Being-becoming bunnies – and all kindergarten beasts – was paradoxical in this way. Our means of rendering beasts visible was never adequate, as the kindergarten beast was always somewhere in-between, never still nor static, as classroom forces and the processes of our research, in various ways, caused beasts to emerge and retreat.

Conclusion (or Taking the Beast Seriously)

Imperative to inquiry grounded in a new materialist onto-epistemology is that children's ideas are not necessarily fantastical misunderstandings or egocentric projections, but articulations of classroom life that are tuned in to material-discursive entanglement. I found that entertaining this possibility required engaging with what children *said* seriously and affirmatively. This posthuman orientation toward their perspectives on relationships, events, bodies, and feelings of significance required an acceptance that children know what they're talking about. Despite positioning myself within a posthuman worldview, this was not a task that came easily, and the pull toward overinterpreting and analyzing what children "actually meant" during these moments was strong; All of these beastly emergences pulled me toward humanist interpretation. As a countermeasure to (and out of frustration with) my humanist interpretive tendencies, I began writing "(child) knows what he's/she's talking about" in my notebook whenever I noticed myself considering that a child's perspective might be borne out of their ignorance and inexperience rather than their expertise and astute awareness.



As simple as this tactic seems, materializing this affirmation on the page was generative in two important ways. First, it caused me to pause and literally do/become something different when I might have otherwise assumed, interrupted, or asked an unnecessary question. This practice pulled me onto the page. Second, it helped me to confront children's ways of knowing that were troubling and alerted me to the complex and confounding nature of their entanglements with animals. These would become touchstone moments of rupture – the very "patterns of differences that make a difference" (Barad, 2012, p. 49 in Dolphijn & van der Tuin). These very becomings ended up being the "important things" that children wanted included in the research. What they needed from me as a researcher was for me "to take seriously the things and actions with which they encounter their worlds. . ." (Rautio, 2013, p. 4).

How might engaging with classroom beasts as a complex, real-life event for young children allow us to consider alternatives to the traditional roles allocated for animals within early years curriculum? I argue that taking children at their word and engaging *seriously* and *affirmatively* with these child-animal hybrids – these *beasts* – may open generative spaces for animals within the early years curriculum. With regard to children's socio-emotional development, there are ways in which animals might be both included and reconsidered. For example, classroom beasts may afford a different perspective on the ways in which children work against, around, and within adult rules and expectations. In beastly events wherein Rosa-butterfly, Nia-bunny, and Matar-bunny emerged, their beastly movements and choices came up against the idea(l)s of teachers, though it was never clear if these adults understood the complex animal forces at work. From adults' perspective, it was the children alone who were either complying with the rules or not. Additionally, the commonsense understandings of the ways in which animals impact the socio-emotional landscape of classrooms might shift, allowing us consider that a uniformly positive view of animals in the classroom is an oversimplification of children's experiences. For both Nia and Elizabeth, the complex emotions, sensations, and identities around snakes were neither uniformly positive nor negative. With regard to

children's intellectual development, the popular use of animals as specimens within this classroom didn't figure into children's discussions, drawings, or photos of "important things." What mattered to children seemed to be the ways in which child-animal relations entered into their everyday academic practices, such as when a bunny upended the use of conventional writing to create a list or when a few children convinced the entire class to hop like bunnies during their patterning exercises. Moreover, just as Nia noted in the final movements of her bunny becomings, what emerges between children and animals in the classroom may not be available for neat capture – neither through taxonomies and hierarchies of scientific thinking nor through the static images of a digital camera.

Beyond animal's supposed utility for social and intellectual growth, children are living classroom lives intimately enmeshed with animals in delightful and disturbing ways. I acknowledge that is an impossible task to "to fully understand, organize or capture the essence of these material-discursive intra-activities" (Hultman & Lenz Taguchi, 2010, p. 540). Even so, it seems a worthwhile endeavor to allow the things that matter to children to move those of us who engage in early years work toward unthought-of possibilities and potentials. To this end, I can't conclude this beastly work with answers, only questions that might push our thinking-doing with young children in new and multiple directions. Does the notion of "child-animal relations" itself need rethinking, as the beasts that emerged through these research assemblages suggest a hybridity that overruns the stable categories of "child" and "animal"? Furthermore, how might saying "yes" to the complex ways in which children articulate their experiences, relationships, and everyday encounters in their classroom worlds reaffirm the agential force of children, and of all things in their midst – living, nonliving, human, animal, or whatever more-than-human beastly configuration that emerges in between?

intersections of childhood/animal/education seeking to circulate and disrupt the normalizing ideologies of speciesism that reinforce human exceptionalism and dominion. This chapter contributes to political and ethical conversations in early childhood education (ECE), as we argue that the commodification of nonhuman animals infiltrates educational praxis, in ways that contribute to our epistemological uncertainty as we search for possibilities of animal liberation and the desire to live without places of injustice and violence (White, 2015).

Research with children and their families in an Australian ECE context uncovered stories about life, love, and death. The impression given by these stories is that humanist thinking and anthropocentric viewpoints dominate what parents and teachers share with children and the way they talk about their children's experiences and retell their own childhood stories that concern relationships with animals. Redefining the human species as one among many offers the potential to not only challenge anthropocentric systems but also attempt to move beyond humanist principles and human-centered ways of relating ethically to the other (human or animal) (Kendall-Morwick, J Mod Lit 36:100–119, 2013; Lévinas, Entre-Nous: On thinking of the other. Columbia University Press, New York, 1997). Theoretical borders are also being tested here as we roam in and out of human, posthuman, and critical theoretical realms playing with old and new ontologies in our search for pedagogical resistance, anarchy, and places without violence. Specifically, we engage "post" methodologies and theories, to pay epistemological and theoretical attention to animal species (Hamilton, Taylor, Ethnography after humanism: Power, politics and method in multi-species research. Palgrave Macmillan, London, 2017).

Introduction

We the authors open the chapter by troubling the intersections of childhood, animals and education and continue with a description of our theoretical roaming's, before providing a brief overview of the territory where children and animals dwell in this Australian study. By exploring the everyday practices of animal and human bodies in an early childhood education space we test the boundaries that separate human and animal, seeking blueprints that uncover permeable spaces to roam through. A rescue dog called Kosi, a pedadog, helps to sniff out border crossings, revealing immanent possibilities for child/animal/educational roamings that (re)imagine relational ecologies of education. The chapter concludes with a conceptualistion of 'roaming pedagogy' that offers possibilities to disrupt the normalizing borders and boundaries that pervade the discourse of human and animal relations in early childhood.

The term 'Earth roamers' was prompted by an early childhood pre-service teacher Djycah Sarroza, as she explored notions of human interconnectedness and relationality with plants, animals, people and also elements of air, sunlight, life, water and soil in a university subject about environmental sustainability. The concept of roaming for Djycah articulates the movement and flow of material and ecological movement that travel in and out of material and ecological worlds with unseen, elusive and often unknown fluidity. The concept of 'roaming' has been put to work in this chapter wondering and wandering over unsettling and complex terrain, especially as prompted by restlessness and curiosity. We invite the reader to roam with us, as we walk the borders of human-animal as children do with uncertain configurations, through the restless and curious wonderings of childhood.

Troubling Childhood-Animal Relations

We question the position of the animal in early childhood. As researchers, early childhood educators, and animal activists, we notice the animal is everywhere but absent except in a certain way, as representation. The animal is materially and discursively embodied in children's books, emblazoned on the clothes and bedroom walls of the newborn human, softened and miniaturized as toys to play with, and sometimes found in their hearts as pets but not often as "kin animals" or the animals that secretly disappear on their plates. The inclusion of the nonhuman-animal in childhood has historic and pedagogical significance where animals are coopted into childhood projects (Cole & Stewart, 2014), and their bodies, habitats, and territorial spaces are enmeshed into narratives of violence, education, entertainment, and speciesism. Animal bodies are also commodified in the production of knowledge as cultural tools that teach children about life and death and what it means to be a good human. This representation in Western culture supports the objectification of the nonhuman-animal whose dead or alive body becomes a fetishized commodity and children and animals become "sentimentalized subjects" that validate a natural bond "as well as the fantasy of reconnecting with the primordial and the innocent" (Pedersen, 2011, p. 13).

Troubling Education-Animal Relations

We question the position of the animal in early childhood education. The cultural and pedagogical normalization of human-animal binaries is so entrenched in Western minority world childhoods and in early childhood pedagogy that speciesist practices are subverted through a naturalized order of experience and hegemonic structure that consistently reinforces human dominance. Although animals feature heavily in pedagogy and practice, they can become epistemologically erased as objects of study and not holders of knowledge. Bone (2013) notes how early childhood teachers stick to familiar scripts about pets, farm, and exotic animals with children's literature but not the violent and contained lives of farmed animals. Industrialized

animal production practices gloss over the violence inflicted on farmed/hunted animals, perpetuating human-animal separation through difference where they become invisible, and the human act of consuming such astonishing numbers of animals is hidden, subverted, and denied, especially with young children (Cole & Stewart, 2014; Stewart & Cole, 2009).

Birke asks "What's in it for the animals and how do we know they are being taken seriously and that the human viewpoint is not dominant" (Birke, 2009, p. 1)? We share unsettling narratives of animals in ECE who become expendable products appointed as pedagogical aids to teach children about biology, relationships, and how to care for a living creature and dispose of a dead one. Bone (2013) observed how educators make jokes about flushing dead goldfish in the toilet, and the following narratives recognize that the "condition of being tamed is not always a happy one for animals" (Bone, 2013, p. 60):

> A lamb is brought into the preschool, it is very small and spindly. The children do not treat it kindly. The lamb leaves pools of yellow runny shit. I ask the teacher what the point is and she says well it's fun for the children and he will probably die in the night.
>
> I look at a glass tank. There are black jellyfish shapes. The teacher looks and says oh no, the fish must have died ages ago. Well, yes!
>
> One of my friends say that the guinea pig was 'loved to death'. I ask her what she means and she says that one child just would not leave it alone and squeezed it so hard that it died. She said that they had to shield the child from being upset. Nothing was said about the right of the animal to be respected and cared for.

The material, discursive, and institutional practices that take place in early childhood education exploit animals while concurrently teaching discourses of speciesism. For example, the common practice of chicken incubation programs is heavily promoted by commercial businesses that provide fertile eggs and incubators for children to learn about the life cycle and embryonic development of chickens, with little awareness for the socialization process of young chicks when the mother hen is removed or responsibility taken for the chickens when they are returned to the hatching company or end up as unwanted roosters in family homes (Young, Clancy, & Ahern, 2015). Young (2010) also recalls seeing a live Siamese fighting fish in a decorative bowl as part of the design aesthetic of a low table setting in an ECE home corner and noticed the way hermit crabs were introduced as classroom animals in cold climates in the tiny flat, plastic prisons that slowly suffocate them, with little understanding of the care, nutrition, and habitats required to keep these sensitive and complex, tropical creatures alive. Hermit crabs can live for over 30 years and enjoy climbing and foraging in large colonies, where they often sleep piled up together and collaborate in teams to find food (Weis, 2012).

These brief examples of animal (dis)integration in ECE signify how education is always political as pedagogies, curricula, policy, and governance are formed by epistemologies of what we think we know, what is valued to pass onto future generations, and how this knowledge frames what is possible. MacCormack (2014) recognizes that human exceptionalism is reinforced through the dichotomy of thinking-through our ethical encounters with animals and the critique of our

violent treatment of them. Any consideration of animal others she insists must involve a radical deconstruction of what is meant to be human and animal. MacCormack (2013) describes how systems like education provide the institutional framework that foster relations with animal species as a war where the bifurcation of nature contributes to pervasive exploitation and exclusion and "language, discourse, pedagogy, and the will to know are 'acts of war' that the nonhuman other can neither win not participate in" (p. 13). This war can be thought of in different ways. Adams (2014) refers to this as a "war of compassion" where "conditions for violence flourish when the world is structured hierarchically, in a false Darwinian progression that places humans at the top" (p. 19). Wadiwel (2015) also adopts the terminology of battle, referring to the "war against animals" as a sovereign claim of superiority founded on violence where animals are the spoils of war. An example of warfare, as the mass slaughter of animals in education, can be observed in animal dissection practices. Dissection rarely takes place in early childhood education settings, although Bone (2013) recalls an occasion where young children were watching a parent armed with a knife, dissecting a dead animal, that was praised as an excellent "scientific" learning opportunity. Dissection as an educational practice is a reminder of the staggering markers of war that degrade and objectify animal life where "in the United States alone an estimated 20 million animals per year are killed for the purpose of dissection in biology class laboratories" (Wallin, 2014, p. 149).

The war on animals marginalizes species through categorization and regimes of truth by measuring perceived intelligence and an absence of mind. Murris (2016) identifies how children are also positioned through particular regimes of truth in early childhood as being ontologically and epistemically inferior, and Osgood (2017) describes how regimes of truth shape ECE and childhood. "Post" approaches offer possibilities to disrupt default thinking and practices; explore and expose power imbalances of class, gender, race, and ability; and position children as key actors with expert knowledge. We extend these ideas to nonhuman animals, particularly by exploring and exposing speciesist regimes of truth that shape "how knowledge and practice are produced by whom, for whom, for what interests and for what purposes" (Payne, 2017, p. 138). Foucault defines "regimes of truth" through the types of discourse that become dominant and sanctioned as practice, framing particular stories of what is said and unsaid and how we see and understand the world, by "those who are charged with saying what counts as true" (Foucault, 1980, p. 131). An example of widespread epistemology in Western ECE is the dominant discourse of nature as a teacher and font of knowledge for young children, where children and animals are described as having a "natural bond or affinity" with each other. These ideas can be traced to early childhood pedagogues like Froebel who created the concept of the kindergarten (child's garden) as both a garden of children and garden for children (Elliott & Young, 2015, p. 2) and philosophers like Rousseau who supported the "romantic coupling of childhood with nature" (Taylor, 2013, p. 4). Early childhood education is bound by dominant discursive and capitalist boundaries that reproduce factory models of children as consumers and workers, where academic knowledge, cultural values, and economic wants and desires are transferred to the next generation through humanist pedagogies and practices.

Intersections of Humanism and Speciesism

Humanist theories of learning emerged from the enlightenment period where the scientific movement appeared in Europe referred to as "the age of reason" (Pederson, 2010b) and also attends to human personhood, subjectivity, self-discovery, and the teaching of values and ethics that maintain civic unity. The human as a rational, knowing being is positioned center stage throughout childhood, and the scripted curricula of social and material histories form the humanist plot that is saturated by developmental, psychological, and sociological storylines. Fellow Earth dwellers are not the main story here as our relatives through evolution are estranged, violated, or relegated to environmental sidelines with designated bit parts and roles that never capture the vitality of their inner lives. In staging the ethical question of traditional concepts of humanizing education (Snaza, 2015a), we commence our roaming by prodding at the intersections of child-animal boundaries.

Intersections indicate crossing point place where two entities are caught in the act of crossing. The notion of intersectionality is a humanist concept that emerged out of a concern for social justice with an aim to understand the intersections of classed, raced, and gendered power relations (Crenshaw, 1989). Ecofeminist and critical human-animal studies extend these injustices to the more-than-human and ecological justice attributed to nature and animal species (Twine, 2010). These intersections of injustice are cultural, historical, and philosophical manifestations of relationships of dominion, largely based on processes of hierarchy and commodification, where the struggle to attain justice for animal species becomes confused by how the animal is categorized as pet, pest, or product. The intersections of humanist and posthumanist theory disclose aspects of speciesism where species difference is normalized and naturalized, to sustain human privilege, and where decentering the human can enable thinking with animality. For example, anthropocentric belief systems position human beings as ontologically superior and capable of making worlds based on human abilities of reasoning, self-determination, and self-worth (Weitzenfeld & Joy, 2014). Posthuman ontoepistemology enables the exploration of alternative worldviews and knowledges, and we wondered, for example, what this world-making might look like for bees. Would apoidea(bee)centric systems position bees as ontologically superior and capable of making worlds based on bee abilities of reasoning, advanced social division of labor, cohesive work ethic, and navigation and communication skills (Wohlleben, 2017).

Richard Ryder (1970) developed the term "speciesism" to describe the warfare against other species and to make comparisons with other prejudices like racism and sexism. In a video recording from this time, he emphasized the relational aspects of this ideology. "The point I was trying to make is that we are all related. All species are related biologically and through evolution. And instead of treating the other species like objects, we should be treating them like evolutionary cousins" (Ryder, 2013). Speciesist beliefs and practices construct, legitimize, and reproduce a desired social order in ECE that works to render "assumptions and values invisible, turn subjective perspectives and understandings into apparently objective truths, and determine that some things are self-evident and realistic while others are dubious

and impractical" (Dahlberg & Moss, 2005, p. 17). How we generate knowledge therefore aligns with what we see, where we are, and what is valued. Education embraces humanist and scientific animal-focused scholarship because of an entrenched belief that humans matter more. We turn our attention to theoretical roamings in the following section to wonder how animal species enter these ontoepistomogical spaces and consider how matterings of care, concern, and fact shift from studying human attitudes to animals to including the animals as stakeholders in learning (Taylor, 2017b).

Theoretical Roamings

Posthuman and critical animal studies analyze human relationship with animals, in an attempt to unhinge the ingrained human-centered view toward complex understandings of human-nonhuman-animal relationships. From an ethical perspective, it is important to consider the intersections of eating an animal to loving an animal and to using an animal as an educational tool. Critical posthuman theory offers insights for challenging culturally embedded anthropocentric attitudes and practices relating to the nonhuman-animal "other" in education. Critical animal studies and critical posthuman scholars (MacCormack, 2013; Pederson, 2010a, 2017; Rowe, 2012, 2016; Snaza, 2013; Snaza & Weaver, 2015) challenge and disrupt humanist principles of hierarchical dominion, contending that teachers can no longer remain silent, oblivious, or indifferent to the power structures of human-animal-nature relations, as they must become politicized, political, activist, or advocacy oriented (Taylor, 2017b):

> Delinking education from the structures of humanizing education, detaching it from the anthropological machine, requires radical educators to connect the dehumanizations enabled by state– administered compulsory educational institutions (segregated in so many, many ways) to the ways in which "we" humans pass over in silence the extraordinary violence "humans" do to animals, to ecosystems, to whole species, and, of course, to each other. These violences are inextricably linked. (Snaza, 2015b, p. 21)

Posthuman theory attempts to rethink and unhinge the privileged human in education, so the human child is no longer viewed within places of humanist privileged dominion. Posthuman relational approaches have helped us to think, sense, and feel how Earth roamers wander through the "ontological gap" as interspecies entanglements challenge the "places, times, matters and meanings" (Haraway, 2016, p. 1) of how humans engage with animals and animals with humans (Braidotti, 2013; Haraway, 2003, 2006, 2012; Latour, 2011). Relational approaches have also ventured into ECE research through common world perspectives that adopt multispecies ethnography (Nxumalo & Pacini-Ketchabaw, 2017; Pacini-Ketchabaw & Taylor, 2015, 2015b; Rooney, 2016; Taylor, 2014, 2017a; Taylor & Blaise, 2014). A critical posthuman ontology that we are proposing in this chapter has a point of difference to those described above, with the acknowledgment that human-animal relationships are formed with violence and the war on animals (Wadiwel, 2015) starts in early childhood.

Ecological feminist philosophies also provide critical scholarship and tools to challenge the hierarchical dualisms and binaries and expand complex ontologies of gender, race, culture, and ableism. Ecofeminists such as Valerie Plumwood (1993) exposed connections between different forms of oppression and exploitation of women and nature and how they are intimately connected and mutually reinforcing, specifically between patriarchy and environmental degradation. Ecofeminism and critical animal studies eventually aligned with other forms of injustice including animal exploitation to "connect the dots of oppression, and attack all of them simultaneously to liberate and protect, among other things, animals and our much-beleaguered earth" (Kemmerer, 2015, p. 1). It is these researchers and activists (Adams, 1990; Adams & Gruen, 2014; Donovon, 2006; Gruen, 2015; Kemmerer, 2011b; Warren, 1999) that reveal how forces and material effects have been purposefully obscured through everyday practices of what we eat, what we say, and what we do. Ecological degradation, sexism, speciesism, and homophobia are entwined, because all are connected within systems of patriarchal domination and oppression that overlap within each of the "isms." Kheel (2007) argues that an ecofeminist ethic must sever the connections that historically bind the environmental movement, including environmental education, to a practice of violence by finding ways to embrace contextualized ethics of concern and relationality. Kim (2015) eloquently theorizes multifaceted examples of dangerous borderlands between race and species where she adapts concepts of intersectionality, by renaming dualisms as taxonomies to appreciate multiple, complex, hierarchal ordering that are less didactic and more synergistic, rather than interlocking. This fits with our concept of roaming across multiple spaces in human-animal borders that we find are porous, fluid, and nonlinear. The following research study illustrates some of these multispecies roamings.

The Territory Where Children and Animals Dwell

An assemblage of teachers, families, children, animal species and researcher dwell within a doctoral study that takes place in a small independent school and early learning centre set on four hectares of land in the south-eastern region of Melbourne, Australia. The early childhood teacher suggests four families who live with pet animals, to engage with the research. The larger school community enables further inquiry with animal species including, wild animals such as water birds, rabbits, foxes, cows, sheep, birds and alpacas and stick insects, where chickens, yabbies, and turtles were some of the early childhood classroom animals. A dog named Kosi was also part of the school, community although as we will soon illustrate, Kosi sits outside the category of classroom animal. Post-qualitative methodologies were adopted to bring into question modernist assumptions about knowledge production, where practices of human rationalism order and reduce human and animal participants with categorical claims and meaning. Data was generated with a kindergarten group of children aged five-six years, through an assemblage of practices and entanglements with four focus families, in their homes and an education setting. Field studies took place over a six-month period with practices of walking, roaming, talking, observing,

sensing, taking part in daily curricula, and writing. Post methodologies and practices are important aspects of posthuman research as they seek to embrace messiness, complexity and boundary crossing. Rautio (2013) asks researchers to create space for spontaneity during field studies and to become grounded in the present. She urges "Join in. interrupt yourself as a researcher, stay on your toes, change methods in the middle of your data collecting phase if that is what it takes (Rautio, 2013 p. 404). Myers (2007) also identifies the need for new approaches with human-animal research that do not invisibly marginalise connections with animals:

> Research on human-animal interaction is fertile ground for new discoveries because animals present variations on the characteristics of a social interactant. To be open to these discoveries, we have to grant that unique phenomena may be present, and we have to be willing to assume, at least provisionally, that the animal contributes to the interactions in equal measure as the person or child. (p. 44)

The current eagerness to include animals in ethnography is part of the "species turn" in academia that "reflects posthumanism's claim that humans and animals inhabit the same social spaces with overlapping agencies and experiences, which challenges extant sociological ways of seeing culture and specifically the "affected ignorance" towards animals" (Hamilton & Taylor, 2017, p. 80). Multispecies ethnography practices illuminate how we live and learn together through multifarious, complex relations with other animals in ways that acknowledge the connections and disjunctions of these relatings. Children and animals were observed within their shared domestic and educational spaces, paying attention to how together they construct their world(s). In our search for cracks in the structural fault lines and intersections of the human-animal binary, the following narrative about Kosi the resident school dog offers an example of how mammals like humans and canines learn together.

Kosi the Pedadog

> We begin each day inside at the regular morning meeting place, seated cross-legged on the mat. The children gather in a circle as they centre their collective energies, to greet each other with the term for welcome, from the Indigenous Boonwurrung nation, the land of the two bays that surround Melbourne city (Briggs, 2015). "Womenjika" they say. It's Wednesday so Mr D, the outdoor education teacher arrives and sits on a chair next to the group and Kosi the resident dog who accompanies the children each week on their walks licks his face as he settles on the floor next to him. Kosi is restrained by a leash inside the early childhood classroom, where he knows he has to perform in a certain way and is not a part of this performance. As the discussion progresses however, Kosi makes his presence felt with a large howl and moves to a standing position, pointing towards the door with his snout leading the way. The children turn their heads in Kosi's direction and the teacher asks them "What do you think Kosi is saying to us"? Without hesitation, the children chant in unison. "He wants to go outside for the walk." We all nod and smile because we know this is exactly what he is communicating in his body and sound making (Fig. 1).
>
> The children and I get ready for the outdoor education walk within the large school landscape that offers unique opportunities for the children as they explore, trees, grasslands,

Fig. 1 Canine and human embodied shared learnings with water, weather and sticks

animal homes, a tall mounded earth hill, fruit trees, a lake and large puddles. As we pull on waterproof pants and gumboots in the midst of winter, Ruby tells the me that she loves Kosi and how she is not scared of him anymore. Kosi is eager to get going, letting us know his position of impatience, with occasional barks to hurry up. Today on the outdoor education walk Kosi is staying with us more than usual and not roaming away as he tends to do. I wonder about this shift of behaviour because he often wonders off in this unleashed space in the way of the wayfarer searching for interesting smells and the opportunity of finding a rabbit in the overgrown areas of blackberries and scrubby uneven bushland, where they have taken up residence. Perhaps it is because today we are venturing over flat terrain and he is less distracted or perhaps he is enjoying staying close with the children. He often mirrors their actions and the children pay close attention to him. As Taylor, one of the children strays from the group and is reminded by a teacher of the rules of staying together, Kosi also disappears and has to be called back.

Today Kosi is taking the lead and some of the children follow him through large muddy puddles as their animal bodies share the joy of unrestrained running and jumping in their gumboots with joy and delight. It is impossible not to share this feeling as Kosi runs through splashing everyone and then suddenly drops in the middle of a large puddle as he lies for a while to cool off. He runs back and forth out into the water puddles, not straying too far as he returns time and again to our group. He finds a stick and his joy is amplified as the children call out to him as he runs back to show us. "Look, look, Kosi has a stick" This stick is a large branch and we have to duck to avoid being scratched. I remind the children "Look Kosi likes to play with sticks like you do." The children start to collect sticks to give to Kosi and he takes them eagerly running off and throwing the smaller ones in the air in his own game of throw and catch.

Analytical Roamings

Kosi is a 2-year-old border collie who lives within the school grounds with Mr. D who has worked and lived at the school for over 20 years. This unique lived situation opens up rare border spaces in education settings where a dog is enabled a level of freedom and privilege that facilitates dog/child/stick/water entanglements. Kosi is free range

and allowed to roam. To roam is linked to being free in terms of domestic animals. To be free to roam is the domain of animals like horses and or chickens that range. The freedom is always implied as "given"; however there are limits to this freedom. Animals who are "free to roam" are usually on land that is owned or subject to roundups, cullings, and restrictions that usually end badly for the animal. The affective materiality of containment installs borders and boundaries between animal and child such as cages, dog and cat beds, aquariums, leashes, and fences that restrict and control animal leakage through the control of movement, mess, parasites, sexuality, "difficult behavior," and in turn animality. We wonder does the child-animal boundary also keep the peace in the war against animals and would there be chaos without it? Who might benefit from the chaos – would it be mutual? At the moment, Kosi is free, while he obeys Mr. D's commands, maintains his presence within the school boundaries, and brings delight to the children. He is young and energetic. If he gets old, incontinent, and snappy, it may well be a different story, but for now, Kosi is an Earth roamer whose position is valued and appreciated. This is unusual.

Kosi was named after an Australian rules footballer and abounds with the energy of this popular local sport. He loves to be in water and has an ability to take his human companions with and through water in ways that seep within relational boundaries in this territory where children and animals dwell. Kosi is an unpredictable roamer who takes every opportunity to swim across the school lake onto the island in the center, urged on by cheering children and parents who catch a glimpse of him. He breaks rules and walks off leash; he is uncaged, not abject; he makes decisions and works with the children and generally fulfills his role as pedadog. He has the starring role in the escapades of his life that proliferate in the school community. He is obviously not a child but an animal species accorded privilege who shows the children a different image of the animal. Foucault did not theorize directly about human-animal relations; however, his theory of biopower (Foucault, 1982) and analysis of power can be applied to this narrative, particularly as Kosi provides moments of resistance from institutional "pastoral power" that regulate and discipline the lives of humans and animals, enabling Kosi to act and resist relationships of domination (Palmer, 2001).

Kosi has always shared his life and school work as a pedadog with a human companion, and his photo at the top of the staff noticeboard is a testament to his position at the school. Kosi is privileged by the children who see him as a friend and playmate, and they relish in his energy and playfulness. He appears in their drawings and conversations with family members. The children take turns at being Kosi in their dramatic play, telling me that there can't be two Kosi's as they take turns asking, "Who is Kosi today?" During research interviews with Tracy, Kate the early childhood teacher identified many ways that Kosi is a pedadog, including helping a 3-year-old Ruby to move through her fear of dogs:

> Kosi has been coming to visit each week since he was a puppy for over a year now. We would be walking as we do each week and he would escape to join us. He was still quite big, but with puppy behaviours where he was "out there" and a bit ratty and would run wild. He would find us on the walks and the children loved it but of course Ruby was terrified and she

> would scream, even when he was on the lead. We noticed how this was a really important learning opportunity for Kosi and Ruby. We suggested to Mr D who is a secondary trained teacher that we trial bringing Kosi to the weekly outdoor education lessons. The surprising part of this practice was not how quickly Ruby got used to Kosi, but how he became a conduit for Mr D to build stronger relationships with the early childhood children who he was previously a little unsure of teaching. Kosi has been really important in developing tangible ways to show Mr D how to communicate with the children in his teachings, such as being more patient with their restlessness. Like he is with Kosi.

Kosi as an earth roamer emerges and is made and remade taking on multiple roles in the school. He challenges the usual hierarchical position of the animal in educational spaces. Despret (2016) attends to convergences and divergences between species demonstrating how human-nonhuman-animal collaborations can work against the oppressions of anthropomorphism, when the right questions are asked, and if positive relations are in place. Kosi shows the power of positive relations and brings delight to children, educators, and parents. What we draw from the closer interpretation of these narratives is the relationality of power afforded to Kosi by the school community who enable this practice to take place, as a being who responds and reacts. He is not trapped or contained all of the time as the object of study, for when animals are "denied the possibility of reaction, they pass from the category of the "reactive other" to being a "thing" over whom capacities are exerted rather than power relations exercised" (Palmer, 2001, p. 354).

Kosi demonstrates a very different integration of animals in early childhood education where the children are presented with an alternative image of the dog. Through his ability and the permission granted for him to roam Kosi reveals ambiguities and contradictions that are very different to the discomforting examples we presented earlier. How encouraging that one of us experienced the possibilities of a free animal in action. The stories we tell lead us to advocate for a pedagogy that unsettles anthropocentric imaginings and human superiority in the classroom. We are critical of the fact that the needs of the human child are always put first, even before the death of the animal. We ask ourselves, is there no limit to the suffering that humans will knowingly cause animals, even when the animal is supporting them, for instance, as a teacher, or as a companion?

Roaming Pedagogy

We conceptualize a critical posthumanist ecology of education as "roaming pedagogy" constantly in movement, becoming ethically unsettling and unsettled with guides who encourage us to wonder (Snaza & Weaver, 2015) and wander in the territory where children and animals dwell. Pederson provides insightful guidance as she asks how human-animal relations, posthumanism, and theories of education "can be reworked within a common realm of critical inquiry (Pederson, 2010b, p. 247). Dinker and Pederson (2016) outline an approach to 'unthink' the human in critical animal pedagogies as 'vegan education' with a shift from learning about animals, to learning with, from, and for them" (p. 420). MacCormack's (2013) abolitionist

stance to educational speciesism is conceptualized as "gracious pedagogy," where the concept of grace as a powerful act of humility enables something else to come in and transmutes a moment to something better, "teaching ways to unthink the self in order to open up the thought of the world" (p. 13). Gabardi (2017) describes this approach as part of the "next social contract" as one that structures "the ethical and political prioritization of animal life on par with that of humans' wellbeing" (p. 2). Despret (2013, 2016) describes these (re)makings of human-animal relations, with examples of mutual attunement, a passionate, bodily *with-ness* that depend on the availability of the bodies to each other, understanding how practices move through affect. Drawing on our theoretical and methodological roamings, we consider educational praxis to imagine multiple perspectives that embrace thoughtful radical departures from normalized ontologies of how we understand the world. Roaming pedagogy enables us to integrate the following three considerations: power relations, an ethical framework, and relational imagination.

Power relations are at the forefront of roaming pedagogies "that materialise in the intra-action between/with the material and discursive" (Jackson & Mazzei, 2012, p. 265). A focus on power relations and a relational (re)making of human-animal relations attempts to unshackle the logic of speciesism, seeking ethical, unknown possibilities of learning and living together. We draw parallels with Braidotti's (2015) nomadic theory that integrates critical theory to trace the landscape of the past, to analyze how practices in the present "adequately account for the brutality and the violence of our times as well as for their creative potential" (Braidotti, 2015, p. 18) in the future. These roamings are fluid and uncertain as we tread carefully through the speciesist minefield of conflicting ideas and actions. Power roamings shift the way the animal is currently represented in education trapped by humanist frames of mind as educational tools and subjects of inquiry, leaving us with uncertainties about favored childhood books or teaching practices we initiated such as inviting animals within the education context. We question if teachers should step aside from animals as an act of grace, where "if we are to encounter the nonhuman without being parasites, the grace can only come from leaving alone" (MacCormack, 2013, p. 15). We wax and wane about how the animal is included, never settling on a clear response to a common asked question "should teachers bring animals into education settings as classroom animals?" We are not proposing we have found a resolution, as neat solutions are not part of our roaming where precarious and slippery crossings abound.

We also become unsettled by notions of roaming in colonizing terms; settling into worlds that humans are taught from birth to conquer, consume, and dominate; acknowledging the difficulties of unsettling; and bringing into question dominant, normalized practices. Animal liberation is not just about the abstinence of animal consumption; it is about the ongoing struggle to identify epistemologies of consumption and take steps that lead to cultural and educational change to impede violence. Roaming pedagogies acknowledge that moving through affect in early childhood education is troubling because the loving and killing of animals take place concurrently and seamlessly, where families and teachers shield young children from the violent conundrum of loving and killing animals. We find Derrida's (1997) "double reading" helpful with the first reading of a dominant, stable practice and

secondly with a critical interpretation of this practice. For example, a tension exists in the common practice of children loving animals as companions in education and family homes where animals are coopted to teach children how to be good humans who care and nurture. Simultaneously animals are being harmed and sometimes killed in this process through disinterest and the lack of care we outlined earlier in the chapter; as being a companion, animal can also become their undoing. The double movement here is one of tracing and deconstructing this tension in the discourse of companion animals or animals under study while at the same time acknowledging the ways in which our understanding of the world is dependent on colonizing and enslaving animal species, even those we love as pets.

Haraway (2012, 2013) urges us to follow and "stay with the trouble of living and dying together on a damaged earth" (Haraway, 2016) in the pursuit of staying present to find new narratives of multispecies cosmopolitics as sympoiesis. Our roaming with pedadogs, like Kosi, analyzes the benefits of multispecies ethnography; however, we become uneasy by the quest for the "new" that rationalizes a familiar tale of privileged human-animal relations, rather than working toward possibilities to minimize the violence that prevails through speciesism. We move with caution as the conceptualization of mutual entanglements described by Dinker and Pederson (2016, p. 27) as "new euphemistic instantiations of human narcissism and desire for knowledge and meaning-making, rather than formations of genuinely ethical relation" between children and animals. Kemmerer (2011a) maintains there is always a problem with the vested interests of human theory and methodology when studying interspecies relationships, as they are never based on equitable relations. For example, posthuman paradigms that entangle the human, machine, and animal as hybrids or chimeras in techno-scientific representations are in danger of homogenizing difference in the metaphor of the "melting pot" that dehumanizes, deanimalizes, and devitalizes in ways that are not conducive to "liberating encounters" (Lorimar, 2010). The practice of imagining alternative shared worlds is helpful; however, there is doubt that they contribute to better worlds for animal species if they only sit as exercises in thinking.

Good intentions are not enough to advance ecological justice, unless an ethical framework is part of a critical process that exposes the connections, disjunctures, and intersections of loving, living, and killing of animals and does not lose animal bodies to theoretical abstraction. Our roaming with Kosi highlights power relations that "move from an ethics of sameness, through an ethics of difference, towards an ethics of relationality and responsivity" (Oliver, 2010, p. 269). Roaming pedagogy embraces multiple theoretical perspectives including an ecofeminist ethic of care as affect, connection, sensitivity, relationships, and nonviolence (Gilligan, 1982) that balance the prevalence of "matters of fact" with matters of concern described by (Latour, 2004). Gruen (2015) conceptualizes entangled empathy as a central skill of ethical relations as ways to "connect with a specific other in their particular circumstance, and to recognise and assess one's place in reference to the other" (p. 67). Roaming pedagogy is reliant on a contextualized ethical framework that embraces Earth roamers as citizens of the biosphere with individual and shared lifeworld experiences and desires while acknowledging the injustice that takes place in these shared communities. "Blended communities of humans and animals real and imagined – are both

the medium and means of posthumanist ethics" (Gabardi, 2017, p. 115), and roaming pedagogy requires imagination that posits animals and other earth entities as vital and vitalized members of a multispecies "community of knowers" (Fawcett, 2005, p. 276).

We suggest that grappling with the knowledge of diverse disciplines including education, human-animal studies, environmental education, ethology, philosophy, and creative writing helps us think with ecologies of knowledge that produce divergent thought. Ursula Le Guin (2009) proposes how "imagination is the instrument of ethics" (p. 7) that cannot be neatly organized or settled into moral tales for children, "because their imaginations are working full time to make sense out of reality, and imaginative story is the best tool for doing just that job" (p. 132). These imaginings are not new versions of moral truth making, as we want to think past the difficulties of imagination to depict such co-affectivity in ways that move beyond anthropocentric replication to envision a remaking of interspecies relations. Animality is therefore questioned even when we are not sure what this could be, by (re)imagining anthropomorphic stories that help to illuminate possibilities of humanlike characteristics of some animal species, like families, play, and attachment, and species-morphic examples highlight animallike characteristics of the human-animallike breathing, joy, pain, or memory. Critical posthuman interpretations of the role played by animal species in telling stories for children enable teachers to imagine animal lifeworlds with speculative and realist narratives, where animals interact with humans, make fun of each other's differences, face the tough unsettling questions about animal-human relations, identify how animal species have unique umwelt (Uexküll, 1934/2010), share lifeworlds with capabilities for flourishing, and depict how humans and animals could and do live in societies that do not artificially separate them. Learning how to cross boundaries helps us to trace the countless ways we relate with Earth roamers, our evolutionary cousins discovering who they are and what they may know and see and sense when they look at us.

Concluding Comments

We contend that the oppression and commodification of animal species in early childhood compel us to not just to (re)imagine common worlds pedagogy or to rethink the basic tenets of our interactions but to take steps to (re)imagine relational ecologies of education by (re)making ways of living together with ecological justice in both mind and action. Our intention is to move beyond the intersections of loving/living/dying where education works in specific ways to bring children, animals, and nature together through difference. Like others, we challenge this logic of separation and describe and suggest how we might learn to live together ecologically with fellow Earth roamers, in educational contexts that explore difference and recognize multifarious lifeworlds though relational imaginings.

Roaming pedagogy enables us to demarcate the borders of child-animal relations that colonize and commodify. It finds porous border spaces that ignite interspecies communication and ways of knowing as a profound political act (Wallin, 2014), where teachers can actively trouble the intersections of species boundaries with children as they co-construct action with and for ecological justice. This requires

more than observing entanglements of children and animals and teaching young humans how to ethically listen and attune with Earth roamers while at the same time seamlessly supporting and condoning speciesism. We know the complexities of the task at hand, and certainties or simple solutions do little to unshackle children, animals, or education from the dominant, humanist knowledges we have described. Such a remaking requires a radical rethinking of the purpose of education, requiring analysis as a process that continually questions humanity and animality. Despret (2016) poses the question "what would animals say if we asked the right questions," and Pederson and Pini (2017) are uncertain if we are capable of listening in this way, as they ask, "what conditions can compose a subject-assemblage capable of listening (p. 1052)? We conclude this chapter as we started with provocations for an alternative ethic for human-animal relations from pattrice jones:

> If we do this, we may hear that the priorities of nonhuman animals differ from our own preoccupations and also that the interests of various nonhuman animals differ from one another. When we listen to animals wellbeing and liberation, we don't get stuck in human-constructed deadlocks and are therefore more free to be their allies. (jones, 2015, p. 98)

Abstract

Nature-based experiences have gained increasing attention for their capacity to foster children's connectedness with nature, referred to here as childhoodnature. This chapter explores childhoodnature from a pedagogical perspective of place, beginning with an overview of the conceptual foundations of and distinctions between place-based education and place-responsive and place-conscious pedagogy. We then examine recently emergent posthuman and new materialist

ontologies and pedagogies for their contributions to new understandings of and approaches to childhoodnature connections. Besides providing a map of the childhoodnature pedagogies and place section of this handbook, we assess the extent to which the theoretical and empirical contributions of the section chapters lay the groundwork for developing the pedagogies of place literature. Despite marked differences in cultural contexts, a number of common themes emerged across the chapters, particularly in relation to the intent and focus of the pedagogies of place. All chapters expand and/or challenge current understandings and/or preconceptions of place, nature, childhoodnature relationships, and pedagogy. A number of chapters highlight the role of agency, embodied learning, and place relations in enabling children to build connectedness with nature. Finally, in considering the chapters as a whole, some implications are offered for future research.

Place-conscious pedagogy · Place-responsive pedagogy · Post-humanism · More-than-human · Connectedness with nature · New materialism

Introduction

The children of today will bear the brunt of the impact of the age of the Anthropocene and in particular of climate change (Cutter-Mackenzie, Edwards, Moore, & Boyd, 2014; Stevenson, Nichols & Whitehouse, 2016). At the same time, concerns have been expressed about children's increased physical and emotional distancing from nature (Louv, 2006; Soga & Gaston, 2016). Childhood is increasingly disconnected from nature with more time spent indoors drawing on technology-mediated play than outdoors with nature play activities. Critics emphasize that the growth of technology and the reduction of greenspace in many urban contexts resulting in limited nature-driven play poses a threat for children's wellbeing and development (Corraliza, Collado, & Bethelmy, 2012; Louv, 2016). One question that remains unknown is whether the childhoodnature disconnection will affect children's future capacity to mediate emergent anthropogenic impacts. This disconnection is viewed as an urgent priority to address, given the precariousness of the current state of natural ecosystems on which human survival is dependent.

Nature-based experiences have gained increasing attention for their capacity to foster children's connectedness with nature (Chawla & Derr, 2012; Ward-Smith et al. this volume). Writers over time have focused on the importance of these direct experiences in nature, through emphasizing, for example, the power of silence and solitude in connecting to nature (Knapp, 1996) or sensory immersion to cultivate an emotional attachment to the natural environment (Van Matre, 1990). More recently, the focus has been on these experiences being centered and bounded in the particular place(s) of where children's lives are lived irrespective of its spatial and cultural location. The importance of fostering children's emotional relationships with *place* has also been extended beyond the human environment to interactions with the more-than-human world, to all species and

nonliving things and to *place* itself. This raises the empirical question posed by Tooth and Renshaw in this section: Can children become emotionally interconnected with other living, as well as nonliving, entities?

Authors in this section of the Handbook grapple with the question of what kind of pedagogies of place facilitates the cultivation of children's connections with nature? They explore the theoretical underpinnings and value assumptions of a range of pedagogies of place enacted in diverse educational, cultural, and geographical contexts to enhance children's connections with nature; authors examine the outcomes and impacts of these pedagogies on this connectivity for learning, for individuals and human communities, and for the sustainability of eco-social communities. The chapters present current research and diverse ways of (re)thinking about place-centered pedagogy, supported by case studies and vignettes from these contexts. Contributors also explore the meaning of place in relation to children's interactions, connections, and other entanglements with "nature."

In this introductory Chapter, we first examine theoretical foundations of the broad concept of place-based education and then its limitations as revealed by the subsequent related but more critical or post-critical conceptualizations of place-responsive and place-conscious pedagogy. The relevance of emerging posthuman and new materialist ontologies and pedagogies is examined for their contributions to new understandings of and approaches to childhoodnature interactions and connections. Pedagogies of place that speak to politics and ethics (of Indigeneity and equity) are also briefly addressed. We then draw on selected literature that offers a praxis approach to pedagogies of place in teacher practice to begin to address the question of how might pedagogies of place research contribute to helping educators decide what to do next in a given place? Finally, we outline each of the seven contributing chapters in relation to the place-related frameworks presented and the more recent turns to new materialist and posthuman pedagogies before finally analyzing the theoretical and empirical contributions of these chapters to the pedagogies of place literature.

From Place-Based Education to Place-Conscious/Responsive Pedagogy

Place-based education has been defined as grounding learning in the local or the particular place of students' lived experience (Smith, 2002). Smith argued that place-based education was not a new phenomenon as its approach could be traced back to John Dewey who noted the "disconnection between school and the world and sought to overcome it in the University of Chicago Lab School that he and his colleagues created at the end of the 19th century" (p. 586). Dewey attributed the problem to "the fact that children possess minds that are primarily drawn to actual phenomena rather than to ideas about phenomena" (p. 586). The initial resurgence of interest in place-based education, as further described by Sobel, essentially focused on a pedagogical approach to enhancing student learning of traditional disciplinary concepts in the curriculum as well as connections to the community and the natural world:

> Place-based education is the process of using the local community and environment as a starting point to teach concepts in language arts, mathematics, social studies, science and other subjects across the curriculum. Emphasizing hands-on, real-world learning experiences, this approach to education increases academic achievement, helps students develop stronger ties to their community, enhances students' appreciation for the natural world, and creates a heightened commitment to serving as active, contributing citizens. (Sobel, 2004, p. 6)

The primary value of place-based education has been summarized as residing "in the way that it serves to strengthen children's connections to others and to the regions in which they live" (Smith, 2002, p. 594). Bonnett (2013) situates these connections in all human experience. Since we are all emplaced, "we dwell in a world . . .. . .of locales of intimately related things" (p. 264). He further describes:

> the anticipatory and ecstatic nature of emplacement, in which we are always beyond ourselves, with the emplaced things that we encounter. This constitutes a flow of involvements that sustains our sense of who we are and what we are doing . . . In this sense we are (literally) enlivened by encounters with emplaced things, sometimes quite explicitly, as say by the promise of the unknown encounters that are to come as we set off for a walk on a fine spring morning. (p. 266)

These notions of emplacement and presence have important implications for pedagogies of place in illuminating the potential development of enhanced awareness or consciousness. The latter is explicitly foregrounded by the concepts of place-responsive and place-conscious pedagogy. Although often used interchangeably in the literature with place-based, both place-responsive and place-conscious pedagogy represent important theoretical distinctions from the more widely used term and conceptualization. Place-responsive pedagogy has been defined as "explicit teaching by-means-of-an-environment with the aim of understanding and improving human-environment relations" (Mannion, Fenwick, & Lynch, 2013, p. 803). What is important, the authors argue, is that the core process of teaching and learning "is both pedagogically and ontologically linked," whereas "[m]ost conceptions of place-based education lack this ontological understanding and therefore can be distinguished from place-responsive education and pedagogy (Karrow & Fazio, 2010)."

Gruenewald (later Greenwood) (2003a, b) introduced the notion and discourse of critical place-based and place-conscious education by linking critical pedagogy and place-based education through the two important ontological relationships of decolonization and reinhabitation. Sometimes a heightened awareness of place:

> leads to a process of decolonization, that is, coming to understand and resist the ideas and forces that allow for the privileging of some people, and the oppression of others – human and more-than-human. At other times, place-consciousness means learning how to reinhabit our communities and regions in ways that allow for more sustainable relationships now and in the long run. (Gruenewald & Smith, 2008, p. vii)

In *A Critical Theory of Place-Conscious Education*, Greenwood (2013) argues the need for a decolonization of places by revealing "the often contestable nature of the dominant beliefs and motives" (p. 97) that shapes our perspectives of places. This

process of decolonization enables a reinhabitation of these places with "a more open and deeper consciousness" (p. 97).

The conceptualization of decolonization and reinhabitation not only emphasizes an ontological relationship but also "aims to enlist teachers and students in the firsthand experience of local life and in the political process of understanding and shaping what happens there" (Gruenewald, 2003, p. 620). In contrast, other forms of education that are attentive to place (e.g., geographical education or science education) may suffer from a tendency to ignore political dimensions because of a focus on a transmission approach to curriculum delivery and pedagogy designed to address individuals' development of knowledge and skills for self-awareness.

Emerging Poststructural, Posthuman, and New Materialist Pedagogies

In other areas of scholarship related to pedagogies of place, there are recent turns away from a focus on structural developmental views of the child in favor of understanding how children engage with a whole range of entities, relations (including with other species), forces, and materials found in their everyday worlds (for examples see Taylor & Pacini-Ketchabaw, 2015). Both the "material turn" and the "animal turn" are now posing challenges to the perceived limits of the linguistic "turn" and the anthropocentrism of poststructural thinking (Taylor, 2018). Ontological responses to (post)structuralisms and other anthropocentric philosophies have resulted in realist (re)turns in social theory, in particular speculative realism and matter-realism or new materialisms.

Although there are many forms of posthumanism (see Pederson, 2010), they share a perspective that dissolves the separation of nature and culture. Quinn (2013), for example, argues that "fixed distinctions between human and non-human spheres no longer hold . . ... [as] nature and culture are 'mangled' together at every point . . .. as 'the agency of matter is intertwined with human agency' (Hekman, 2010)" (Quinn, 2013, p. 738). Taylor and Pacini-Ketchabaw (2015) credit the boundary-blurring "natureculture" bio-philosophies of Haraway for illuminating "the ways that humans and other species share entangled, cascading and enmeshed pasts, presents and futures" (p. 6). Taylor and Pacini-Ketchabaw argue for moving away from the predominately individual child-centered pedagogies in early childhood education that focus on "learning within an exclusively socio/cultural (in other words, exclusively human) context (Rogoff, 2003)" (Taylor & Pacini-Ketchabaw, 2015, p. 6). Instead Taylor and Pacini-Ketchabaw (2015) argue for focusing:

> on the collective manners and means through which children learn from engaging with other species, entities and forces in their immediate common worlds. We call these collectively engaged modes of learning 'common world pedagogies' (p. 4).

Thus, new kinds of place-responsive pedagogies are emerging, such as multispecies pedagogies and more-than-human pedagogies (see http://common.worlds.net/).

Critics of the posthuman turn, such as Paul James (2017), suggest these kinds of pedagogies may be less well grounded, lack impact when it comes to politics and ethics, and fail to deliver their hope for getting beyond the dualism of nature and culture. James (p. 36) cites Snaza and Weaver's argument that "it is not even remotely possible at the present moment to conceptually or practically lay out a theory of posthumanist education or outline the contours of a posthumanist pedagogy." Perhaps because this field is emerging and nascent, an identifiable tendency in environmental and early childhood research has thus far been not to offer orientations for practice for nature-based posthuman educators but rather to use research to describe the ongoing flow of events for learners in natural settings. Hence one emerging gap in nature-based posthuman pedagogies appears to be a coherent research-based framework for educators to draw upon in the planning and enactment of place-related curricula. Another issue relates to how extant and emerging place-related pedagogies handle the political in their approaches. Without attempting to lay out a theory of posthumanist pedagogy, we briefly examine pedagogies of place that claim to take politics and ethics (of Indigeneity and equity) seriously.

The Political

In a recent study of experience-based place-responsive pedagogy in Environmental Education Centres (EECs) in Queensland, Australia (Renshaw & Tooth, 2018), a political dimension to teachers' work was identified. An analysis of center case studies revealed that the political varied across places from being explicitly articulated to more implicit with different aspects emphasized in different ways (Stevenson & Smith, 2018). For example, Stevenson and Smith (2018) observed that a conceptualization of "pedagogy as advocacy" reflected an explicitly political statement of the environmental goals of one EEC's work, while an "Inspiring Champions" approach at another center encouraged students to model their future behavior as adults on environmental champions of the past. At two other EECs, students are introduced to the work of local environmental activists who have played and are playing significant roles in protecting from development land with ecological and Indigenous cultural history values. Meanwhile, the pedagogy at several other centers is not explicitly political but implicitly addresses the political through not only exposing students to alternative (to the dominant anthropocentric) worldviews but also questioning and critiquing traditional understandings of economic growth, consumption economics, and related cultural values and the environment.

Yet a question that can be asked about the role of politics in pedagogies of place generally is are politics only aspirational at best in these and other educational endeavors? Certainly, the political needs to be more than aspirational while not advocating a particular position on a socio-ecological issue, despite the title of "pedagogy as advocacy" of one center's approach in Tooth and Renshaw's study.

We argue that the pedagogical focus should be on advocating the engagement of young people in first thinking critically about local socio-ecological issues, including unpacking and understanding the politics and ethics that are an inherent part of the different and conflicting interests and perspectives involved in socio-ecological issues. Second, active engagement should be encouraged in the political process in order to respond to such issues.

Others, such as Pederson (2010) and Quinn (2013), encourage a "re"human positioning in accepting that posthumanism works to decenter the human subject, and so the implications for learning are profound if we can develop an "understanding of what it means to learn *with* and *from* rather than *about* non-human animals" (Pederson, 2010, p. 20). Quinn reports on two studies, first referring back to her earlier study with colleagues of finding young people in jobs without training that "animals played a surprisingly large role in the lives of some young people" to the extent that "[i]n some cases, the emotional attachment to animals was far greater than that to humans and ease and comfort with animals contrasted to estrangement from family or peers" (p. 745). However, Quinn, while acknowledging the importance of Barad's (2003) foregrounding the non-human and the potential of such a perspective for liberation, appropriately cautions that:

> going too far down that road hides the fact that the intra-activity of human and nature is still shaped by social positions. We are all composed of matter shared with the non-human, but we are not all equally well placed to deal with any potential problems this may cause. (Quinn, 2013, p. 749)

Quinn's (2013) second study gives a greater sense of what role non-human animals play in young people's everyday outdoor learning:

> Animals teach the young people about the continuum of culture/nature and the necessity of balance and equilibrium. Of course this is very far from being an equal relationship; whilst Bennett might argue that animals have power and agency they do not have guns and traps with which to kill humans. Nevertheless, once the animal is given its due, a different form of knowledge emerges about factors which are key to the survival of humans, such as the chain of production and where our food comes from. (Quinn, 2013, p. 746)

Some poststructural and new materialist researchers take strong and distinctive political stances with respect to nature and place on the basis of new relational ontological framings. As we have seen, positioning animals as beings with whom we relate and learn repositions the natural world away from being something we save or steward as humans to being an entangled set of processes within which we need to interact and respond (see Taylor, 2017). Others take a strong feminist and decolonial stance (Nxumalo, 2015). These kinds of research agendas in effect try to combine critical ideological readings of place and nature while combining them with an ontological turn toward lived experience, process, and relationality. However, there is a tension between critical theory which situates politics and inequalities in social structures and feminist posthuman ontological focus on relational politics.

Pedagogies of Place in Teacher Practice

Posthuman research agendas seek to understand complexity and stay with the "trouble" of our damaged world with our commodified lives and the intricacies of educator-animal-child relations (Nxumalo & Pacini-Ketchabaw, 2017). Less common is practical advice for educators about how to help actualize pedagogies to realize these new relations or ecological and social justice. Quinn argues that the outdoor literature emphasizes practice, but theoretical positions are not very well developed, while "[c]onversely, in post-humanist feminist literature, there is much theoretical discussion about 'nature'. . .. . . Her paper seeks **"**to use post-human ideas to advance theoretical understanding of outdoor learning and to put post-human theory to work with empirical data from outdoor learning, in order to demonstrate post-humanism's analytic capacity. . ... to deepen understanding of outdoor learning" (p. 739).

Mannion et al.'s (2013) theory of place-responsive pedagogy draws on findings from a study they conducted of teachers devising interdisciplinary curricula while based in national parkland in Scotland. They explain:

> We see place-responsive pedagogy is one element in a wider process of curriculum making that emerges through the intra-activity (Barad, 2007) of: (i) educators' own experiences and dispositions to place, (ii) learners' dispositions and experiences of place and (iii) the ongoing contingent events in the place itself (including the presence and activities of other living things). (p. 803)

Five key aspects of an experience-based pedagogy in Queensland state-run EECs in Australia were identified by Ballantyne and Packer (2008, 2009) as learning by doing, being in the environment, addressing authentic tasks, cultivating sensory engagement, and exploring local problems and issues. In a follow-up in-depth study, conducted by Renshaw and Tooth (2018), place-conscious pedagogies were identified as requiring "that educators have an intimate knowledge of the ecology and history of the place, including an acute awareness of the pedagogical affordances of specific sites . . .... (forest or creek or tree or track)" (p. 10). One center educator describes blending the application of systems thinking to the complex patterns and connections among the parts of the forest, with a process of slow pedagogy and a (nonlinear) experience-reflection-representation cycle of engaging students in sharing, questioning, and inquiring into their discoveries of specific inhabitants of the forest (e.g., a leaf or insect). A view of place as a dynamic socially constructed site of "negotiation between related unfolding stories" (Renshaw & Tooth, p.3) underpins this pedagogical content knowledge that links together deep content and pedagogical knowledge (Stevenson & Smith, 2018).

Diverse pedagogies of place, as framed in Tooth and Renshaw's study, represent pedagogical content knowledge in nature-based experiential teaching (Stevenson & Smith, 2018). Specifically, that means knowledge and understanding of "the unique affordances of particular places for learning about, in and for the environment"

(Stevenson & Smith, 2018, p. 195). Such knowledge has been argued by Tooth and Renshaw as involving the intersection of three dimensions of place:

1. The materiality of place itself, its unpredictability, and its unique patterning of inanimate objects, natural features, and animate beings
2. The cultural meanings that have been storied into the place by Indigenous and non-Indigenous people, including the educators at each center
3. The agency of teachers, students, and parents, whose purposes and goals selectively foreground and background what can be experienced and learned in place (Renshaw & Tooth, 2018, p.4)

These illuminations of the pedagogies of place of experienced outdoor educators are consistent with evidence from Mannion et al.'s (2013) study suggesting first that, particularly for "novice outdoor" teachers, collaborative planning visits, extended time in natural settings, and opportunity for reflection were all useful ingredients in planning nature-based excursions. These approaches enabled teachers to find new scope to rework their own perspectives of themselves as educators such that place and material context were not backdrops to their actions but the new socio-material context was implicated in curriculum planning and later in teaching. For these teachers, spending time in the nature reserves involved getting to know the place and themselves better; through this reconnaissance, they looked again at what role the materiality of the world would play in their pedagogies and in their plans for the generation of new meanings with their learners. In part, this may be because of the design of the study in that it asked them to consider place as part of the curriculum design process, but this is expected to be a wider phenomenon common to more than this context. This strand of analysis provides empirical support for the potential of considering curriculum design as a socio-material and embodied practice in places.

A number of scholars have reported that curriculum planning with place in mind was easier for teachers who had spent time accruing a deeper relationship with the natural places visited (see Mannion et al., 2013; Martin, 2004; Renshaw & Tooth, 2018). More expert outdoor teachers were able to explain how they did this more comprehensively, while novice outdoor teachers found they needed to learn new dispositions or orientations to place. Drawing on the work of anthropologist Tim Ingold, evidence is emerging that supports the idea of curriculum making as a coming together of teachers, learners, generations, and places, and, through this coming together, relations are remade (see also Ross & Mannion, 2012). One might suggest that changing the place for education (in this case, from indoors to a natural setting) was a form of interruption in the ways in which the curriculum was normally socio-materially assembled. There is scope, therefore, for understanding curriculum making as requiring a form of interruption through new forms of attention and response to place.

Ross and Mannion conclude that their sense is that place-responsive teachers need to attend explicitly to the role of the places – the socio-material contingent events and relations between humans and other species – in their educational endeavors. In place-responsive pedagogy, teachers (in collaboration with students and others), as historically embodied subjects, explicitly set out to create new place-based practices and

place-based relations. We suggest that this involves learning to dwell or inhabit places differently while accepting our shared immersion in the world (see Ross & Mannion, 2012). In summary of the literature cited, given "the unique affordances of particular places for learning *in*, *about* and *for* the environment" (Renshaw & Tooth, 2018, p. 4) and the significance for teacher pedagogical practice of educators' own experiences and dispositions to place (Mannion et al., 2013), the first essential task for teachers is "being present in and with a place" (Wattchow & Brown, 2011, p. 800) through extended collaborative planning time in natural settings (Mannion et al., 2013). The purpose is for educators to get to know themselves and the materiality of place itself better through reconnaissance; this would include having the opportunity for reflection on what role the materiality, including living things, of place can play in their pedagogies and in creating plans for the generation of new meanings with their learners (Mannion et al., 2013; Renshaw & Tooth, 2018). A particular feature of teacher and student learning is the power of place-based stories and narratives (Wattchow & Brown, 2011) for identifying and creating "cultural meanings that have been storied into the place across time" (Renshaw & Tooth, 2018, p. 4). An enabling condition is for teachers, students, and parents to have the agency to enact the above curriculum and pedagogical planning (Renshaw & Tooth, 2018). This agency is relationally enacted with and through places in order it seems to maintain the necessary attentiveness to one's emplacement.

Introducing the Section Chapters

In any discussion of pedagogies of place, the ultimate important question is what can the educator do? How can research and theory contribute to helping educators decide what to do next in a given place? The authors in this section not only articulate their ontological positioning in relation to the theoretical perspectives outlined above but also generally identify pedagogical approaches that can be taken by educators. Thus, a strength of the following chapters is that they offer guidance or directions for practice that can make a difference. Furthermore, many authors in this Handbook section base their accounts on the empirical as well as the theoretical. As previously mentioned, it is important that the teaching and learning process is pedagogically and ontologically connected.

We now offer a brief overview of each of the seven chapters in this section of the Handbook. The culturally and geopolitically diverse studies that are reported were conducted in seven countries: Australia (2), Germany, Hong Kong, Qatar, South Africa, United Kingdom, and the United States.

Julia Truscott, in her chapter in this section ▶ Chap. 68, "Toward a Pedagogy for Nature-Based Play in Early Childhood Educational Settings," explores *how* young children experience nature through nature-based play and the influences on such experiences, particularly within an early childhood (EC) setting. Drawing on socio-cultural and Csikszentmihalyi's flow theory and qualitative data from preschool children and their educators, educator pedagogy emerged as the strongest and most critical component of Truscott's study of the interplay between children's

experiences and educator pedagogy. Truscott explores the facets of pedagogy – educators' values, beliefs, and behaviors – that appear to best afford children opportunities to become immersed in their nature-based play in EC settings.

Ron Tooth and Peter Renshaw, in ▶ Chap. 64, "Children Becoming Emotionally Attuned to "Nature" Through Diverse Place-Responsive Pedagogies," raise the interesting question, "can children situate themselves as not separated from "nature" but as part of "nature", emotionally interconnected with other living, as well as non-living, entities?" They analyzed children's representations of "nature" and themselves following an excursion to a forest in South East Queensland, Australia, where they were exposed to Ron Tooth's *storythread* designed program of a civic activist in the 1990s who was crucial for establishing the area as a protected reserve. Their connection to *place* is mediated throughout the excursion by an Aboriginal practice of attentiveness to and feeling in *place*. The children shifted toward an understanding of "nature" as agentic, knowledgeable, emotional, and bonded to them. The authors address the implications of this place-responsive pedagogy in the context of neoliberal times and accountability pressures for teachers.

In ▶ Chap. 69, "Toward Decolonizing Nature-Based Pedagogies: The Importance of Sociocultural History and Socio-materiality in Mediating Children's Connectedness-with-Nature" by Chesney Ward-Smith, Lausanne Olvitt, and Jacqui Akhurst, the authors explore children's "connectedness-with-nature" in a culturally diverse context in South Africa. They argue that nature-based pedagogies often project Eurocentric environmental values onto children in subtle ways, inadvertently colonizing natural spaces and children's experiences in them. Taking a sociocultural perspective, the chapter draws on a qualitative case study of 37 children from culturally diverse backgrounds at an outdoor education center. The Chapter explores the tensions and resonances between participants' value positions and those of the outdoor education center. Given that this interrelationship mediates the children's developing sense of *connectedness-with-nature*, integrating their values was found to be essential for designing appropriate nature-based pedagogies. Such pedagogies are seen as providing opportunities for more nuanced explorations of sociocultural and socio-material resonances and contradictions and for children to connect with nature in less colonizing ways.

Bob Coulter, in his ▶ Chap 67, "Developing Youth Agency Through Place-Based Education: Challenges and Opportunities," focuses on developing a greater understanding of the challenges and opportunities involved in fostering youth agency. He first examines critically conceptions of agency that are often implicit in descriptions of place-based education and emphasizes the need for better articulation of the ways in which meaningful agency among the participants can be supported. An analytic framework is derived building on both Greenwood's (2013) three questions for grounding place-conscious learning deeply within local ecological and cultural space and Fesmire's (2010, 2012) descriptions of ecological and moral imagination; Coulter argues that Fesmire offers tools through which thoughtful responses to Greenwood's questions can be developed. A series of vignettes are presented to embellish the framework, and a set of educational principles are derived in order to guide the support of children's agency within place-based education. The author

concludes with reflections on the power of a process of grounding our ecological and moral imaginations deeply in our local space when we consider the role of student (and teacher) agency in place-based education.

Sarah Urquhart and Oliver Picton's ▶ Chap. 70, "Third Culture Kids and Experiences of Places" begins by making a case that traditional assumptions and conceptualizations of a singular localized sense of place are incongruent with the experiences of, what they term, "third culture kids" (TCKs) who spend their developmental years in multiple and diverse physical, cultural, and social contexts. They reexamine the concept of sense of place through two case studies in international schools: (1) a quantitative examination in Hong Kong of differences in place attachment and relationships to nature between TCKs and local adolescents and how relocation has influenced TCKs' sense of place and (2) a qualitative exploration of how the "gatedness" of residential contexts in Qatar impacts adolescent TCKs' experiences of place and sense of place. The authors argue that immediate contexts are intrinsically linked to the diversity of places experienced by TCKs which presents both challenges and opportunities for place-based pedagogy in international schools that needs to be undergirded by relational conceptualizations of place and driven by an inclusive and globally minded sense of place for TCKs.

Elsa Lee, Nicola Walshe, Ruth Sapsed, and Joanna Holland in ▶ Chap 65, "Artists as Emplaced Pedagogues: How Does Thinking About Children's Nature Relations Influence Pedagogy?" take a more forthright approach to considering the role of teachers in linking learners to nature. The authors explore within the Chapter how female artists working with children are seen to follow young people's lead, yet also have input in taking children to new kinds of places. For the authors human exceptionalism sits uneasily yet catalytically alongside ecologically integrated views of the human-environment dialogue. Key to the pedagogy here is the link to an ontology that includes the actual and the virtual aspects of becoming – what we are and how we are becoming within nature are in constant dialectical conversation. Into this space, we have a worthy inquiry into what role teachers need to take in striving for new norms for human-environment relations. Part of this work involves imagination of the next generation.

Doerte Martens, Claudia Friede, and Heike Molitor, in ▶ Chap. 66, "Nature Experience Areas: Rediscovering the Potential of Nature for Children's Development", argue that healthy childhood spaces are under threat and "nature" offers a solution. Furthermore, according to the outcomes of their study, childhoods are seen as increasingly less autonomously managed by young people themselves. With urban dwelling on the rise and consequent less contact with nature, there is a decreased time spent in physical activity and more time with technology. In this context, local natural play areas can afford a safe, accessible action space for children's autonomous play wherein they benefit from greenspace experience – in terms of mental wellbeing, physical activity and literacy, social development, and learning through play. Of note is how the play value of natural settings is shown to be more diverse but also significant in the palpable sense that children really enjoyed the opportunities to play in hugely diverse ways; natural settings also provided affordances for fruit picking when in season and finding places for adventurous

activity as well as places to retreat at times from the busyness of the world. Rooted in a quite humanist concern for child development, nature as a key agent is not a lost figure in this chapter.

Advancing the Characteristics of Pedagogies of Place

The seven chapters encompass research studies conducted in seven countries in a diverse range of different kinds of nature-based places, including (declining) natural play areas in urban settings, a park or nature reserve on the outskirts of a major city, nature-based play in early childhood education, a gated residential complex, and an outdoor education center in a culturally diverse context. They share an emphasis on place as a prerequisite for experiencing the non-human world by treating place as a way to understand children's entanglements, connections with and care for the living and non-living world of nature. Table 1 summarizes the characteristics of pedagogies of place identified and discussed in the section chapters. The purpose of this table is to illuminate the materiality of particular places and their unique pedagogical affordances for learning about, in, and for nature (Renshaw & Tooth, 2018).

Despite these differences in context, as well as in age group of children involved (e.g., Coulter 7–12 years, Truscott 2.5–5 years), a number of common themes are evident across the chapters, particularly in regard to the intent and focus of the pedagogies of place. First, however, a not surprising recurring theme is that of the need for connecting (or reconnecting) children to nature (Coulter; Lee, Walshe, Sapsed, & Holland; Martens, Friede, & Molitor; Tooth & Renshaw; Truscott; Ward-Smith, Olvitt, & Akhurst). Notwithstanding the risk of continuing the nature child binary that this handbook sets out to disrupt, an assumption of most authors is that children are disconnected from nature, resulting from fairly recent modern phenomena (of, e.g., urban expansion, loss of community, heightened concerns about children's security) that should be addressed urgently in this time of the Anthropocene by reconnecting children to nature. The benefits for children of pedagogies of place, argue one group of authors (Martens et al.), include mental wellbeing, physical activity, literacy, social development, and cognitive learning.

All chapters expand and/or challenge current understandings and/or preconceptions of place, nature, childhoodnature relationships, and pedagogy. For example, rather than seeing pedagogy as a human-human endeavor, Martens and her co-authors conclude by implying that a more-than-human frame can be used to understand wider place pedagogies (beyond formal education). An example might be how we design public greenspace as a key part of the childhoodnature pedagogy "landscape" (a landscape both literally and metaphorically). The intent would be to harness the non-human into the affordances for play and learning – which fits a place-responsive pedagogy rubric or perspective at a material end of the continuum. Truscott identifies, from her study of nature-based play in early childhood education, children's positioning along a continuum of connections to nature, from immersion to (material) backdrop.

Table 1 Characteristics of pedagogies of place

Author	Tooth and Renshaw	Urquhart and Picton	Coulter	Truscott	Martens et al.	Lee et al.	Ward-Smith et al.
Name of pedagogy (as per author/s)	"Storythread" pedagogy	Global sense of place	Agency-supportive place-based education	Nature-based play	Nature experience as a form of place-responsive pedagogy	Place-responsive participatory pedagogy	Nature-based decolonized pedagogies
Intent of the pedagogy	To engage children's senses and emotions and to build their agency in a place-responsive pedagogy (not treating a natural place as simply a site to conduct nature inquiries)	To be inclusive by concurrently capturing inward/current (local) and outward/previous (global/international) childhoodnature experiences and perspectives of place	To build agency and develop childhoodnature connections	To build children's agency to become fully "immersed" in nature-based play leading to childhoodnature connections	To enhance young children's childhoodnature connections through daily contact with natural environments through play that is embedded in children's learning experiences	To build children's agency and connections to the outdoors and non-human nature	To create transformative nature-based learning processes that lead to the development of childhoodnature connections
Features or characteristics of the pedagogy	Pedagogical storying strategies, especially of emotionality and Indigeneity, to cultivate enduring interconnections with nature	Pedagogies that are inward and outward looking, including local and international perspectives that connect to students' lived experiences	Strategies to build childhoodnature agency and identity development through connection and imagination	Strategies to build childhoodnature connections through nature-based play in early childhood education everyday green spaces	Local natural play areas afford a safe, accessible action space for children's autonomous play wherein they benefit in terms of mental wellbeing, physical activity, literacy, social development, and learning	Posthumanism perspective leads to particular pedagogical strategies: e.g., One Minute Maps, Found Mapping	Pedagogies that are decolonizing, ethics-led, and embodied

What are the new contributions to pedagogies of place?	Storying pedagogies that treat children as having agency, being knowledgeable, and emotionally bonded in relation to nature	Lived experiences of "third culture kids" mean a pedagogical need for an inclusive and globally-minded concept or sense of place for these children	Enhanced understanding of ways to build childhoodnature agency: student (and teacher) agency should enable grounding ecological and moral imaginations deeply in local space	Educators' understanding of how children experience nature-based play and their related pedagogy influences children's positioning along a continuum of connections to nature (from immersion to backdrop)	Expansion of concept/ understanding of place-based pedagogies beyond formal human-human education, e.g., how we design public greenspace is a key part of the childhoodnature pedagogy "landscape" (literally and metaphorically)	Pedagogical role of striving for new norms of human-environment relations, including imagination of the next generation, with a constant dialectical conversation between what we are and how we are becoming within nature	Decolonizing, ethical, and embodied nature-based pedagogies should address potential tensions and resonances between participants' and educators' value positionings

An important reminder of starting from children's lived experience is provided by Urquhart and Picton. A singular localized sense of place is revealed as incongruent with the experiences of "third culture kids" (TCKs) who spend their developmental years in multiple and diverse physical and sociocultural contexts. The authors argue that immediate contexts are intrinsically linked to the diversity of places experienced by TCKs; this presents both challenges and opportunities for place-based pedagogy in international schools that needs to be undergirded by relational conceptualizations of place. More broadly, Urquhart and Picton draw on the work of Somerville and Green (2015) and argue as they do that "as a conceptual framework, place provides a bridge between the local and global, real and representational, indigenous and non-indigenous, and different disciplinary approaches" (p. 36). They also point out the need to move beyond a singular and conventional understanding of sense of place, acknowledging the work of Massey (1994), who has argued in the past that "the character of a place can only be constructed by linking that place to places beyond. . . .. . .What we need, it seems to me, is a global sense of the local, a global sense of place" (p. 156).

Part of lived experience for some children is a cultural history of colonial domination. In their Chapter in this section Ward-Smith, Olvitt and Akhurst propose "a potentially transformative triad of decolonising, ethics-led and embodied nature-based pedagogies to address calls for nature-reconnection in this context." They define *decolonizing pedagogies* as "approaches to teaching and learning that help learners to recognise and disrupt the structure and powers of colonial influences on their lives and in their communities." Drawing on McGregor (2012), Ward Smith et al. argue that the purpose of these pedagogies generally is "to re-centre indigenous ways of knowing, doing and relating, and support change-oriented, agentive responses in the world." Ethics-led pedagogies, the authors explain:

> engage explicitly and reflexively with the values and ethico-moral positions that people bring to each situation and seek to create challenging but safe spaces for learners to have ever-deepening conversations about what matters to them, why, and how that affects others, now and into the future. (Ward-Smith et al.)

One important theme emerging in four of the chapters including those of Tooth and Renshaw, Coulter, Truscott, and Lee et al. is that of agency. There is a consistent current across these four chapters of enabling children the agency to own and collaboratively lead (with teacher guidance) their own learning and that this is critical for building childhoodnature connections. When considering teacher agency, which is key to teachers having the kind of role envisaged in place-responsive pedagogy, Coulter emphasizes the power of a process of grounding students' ecological and moral imaginations deeply in local space. Lee et al. argue that the development of new norms of human-environment relations should include imagination of the next generation with a consistent dialectical conversation between where we are now and how we are becoming within nature.

This grounding in children's imaginations coheres with Somerville (2010) who argues that place exists in both a material and imaginative sense. The role and

importance of imagination can be traced back to Dewey who argued that it is the medium for realizing and appreciating values (Elliott, 2007). Renshaw and Tooth (2018, p. 12) propose that as well as imagining how a place was represented in the past by others, we can consider "how it might be re-inhabited and re-imagined in the present and future through emergent stories."

Embodied learning is identified by several authors as an important characteristic of pedagogies of place. Drawing on Somerville's (2010) notion of embodiment, Tooth and Renshaw argue that we come to know through the body by walking, touching, smelling, hearing, or sensing in place – but embodiment demands openness to the materiality of the landscape and its agency in shaping *what* we come to know. Urquhart and Picton acknowledge aligning with Massey (2005) in their understandings of place as relational and involving an unbounded and negotiated process. They add that the meaning of place to the TCKs they studied, drawing on the work of Cele (2006), revealed an emotional relationship dependent on the body, "an embodiment that is even more significant for children who often experience the landscape in more physical ways than adults through outdoor play and exploration."

In addition to embodiment, our relationship to place is constituted in stories (Somerville, 2010). Tooth and Renshaw, in their Chapter in this section, describe their experiences in using a pedagogical storying strategy, storythread, to evoke children's emotional attachment to non-human species and the materiality of a specific special local place. They emphasize the critical role of children engaging with animals (birds, insects) and landscape (the forest) as a pathway for children to recognize that the animal and non-animal material world has agency along with themselves. Yet the challenge of enabling children's agency, as Martens and her co-authors point out, is exacerbated by childhood being seen as increasingly less autonomously managed by young people themselves, while Ward-Smith and her colleagues argue that nature-based pedagogies often subtly project Eurocentric environmental values onto children. Lee et al. delineate the role of teachers in connecting students to nature from observing the work with children of female artists who "follow young people's lead" but also take initiatives in taking "children to new kinds of places." Expanding on Lee et al.'s approach, four pedagogical design principles to guide the support of children's agency are offered by Coulter: age-appropriate youth control, continuous development of skills and dispositions, nurturing interest and commitment through connection, and fostering depth through enhanced interest.

It could be argued that what is missing explicitly from the chapters is a coherent account of agency that, from a posthumanist perspective, captures a way of seeing agency as shared beyond the human to the other material living and nonliving objects. Further insights could be gained from exploring how such agency plays out when it comes to pedagogy with/in/or through the material/nature. Also omitted is much account of how collective agency might be exercised. Duhn (2012, p. 100), characterizing "pedagogy-of-place-as-assemblage," argues that a de-centered learner and distributed agency based on a posthuman or more-than-human perspective shift attention "from the individual child to the child's entanglement with forces and forms of all sorts, both human and more-than-human" (Duhn, 2012, p. 104). Mulcahy (2012, p. 21) adds that thinking of pedagogy as assemblage opens up a sense of collective responsibility:

> for developing and maintaining them [pedagogical relations] are similarly distributed and heterogeneous. This opens up a range of processes that form possibilities for a variety of elements to participate and create effects. The workings of bodies, technologies, texts and teaching desire come into view.

Bowden (2015) suggests a Deleuzian or "assemblage" conception of agency is compatible with a view that humans do have intentions and act in the world but that this world – we can read natural world – is full of forces and affective relations with nonhuman animals and other things. A cautionary note should be added that relational views of agency do not need to distribute agency to the extent that humans have not got an important pedagogical role to play.

The key point of the posthuman new materialism worldview is that the materiality of the landscape has agency which is intertwined with human agency (Hekman, 2010) and thereby shapes what children learn about/in/for nature. Simply stated, posthumanism brings matter to the forefront in a way that can deepen understanding of outdoor learning (Quinn, 2013). However, the ontological turn asks for something more than a "worldview." For educators, it is not about getting the ideology exposed (akin to critical place-based education/pedagogy of the last century) before you teach about nature experience per se (although materials are important), it is how materials and discourses are attuned to, in and through the pedagogy, in the planning, in the enactment, and in the outcomes of nature-based place learning. In other words, as Somerville (2010) argues, a thoroughly relational ontology is not a view from any "where" that is not a place. What is important, one pair of the contributors argues elsewhere, is that the core process of teaching and learning is both pedagogically and ontologically linked to create a praxis of pedagogies of place (Renshaw & Tooth, 2018).

Conclusion

Much literature over time has argued constructively for why place, especially natural place, is an important pedagogical site in which the child can explore nature, including their own positioning as part of nature. The chapters in this section represent an effort to explore how childhoodnature can be pedagogically enabled with a focus on new materialist approaches that offer a new ontological lens. Further, to some degree, the chapters explain what the outcomes or effects are in embodied ways for lived experiences through encounters with other species and the materiality's of place. In Quinn's (2013, p. 739) words, the contributors to this section have used "post-human ideas to advance theoretical understanding" of nature-based learning," while most have also used these ideas to work with empirical data on this learning, "in order to demonstrate post-humanism's analytic capacity" (op cit, p. 739).

The contributors portray place itself as (re)constructed and experienced by children and teachers in which pedagogies are perhaps best summarily captured by Urquhart and Picton's citation of Ruitenberg's (2005, p. 218) concept of a "radical pedagogy of place" which is "a pedagogy of 'place' under deconstruction, a pedagogy that understands experience as mediated, that understands the 'local' as

producing and being produced by the trans-local, and that understands 'community' as community-to-come." Further, according to Ruitenberg, students are encouraged to see the diversity of conflicts over interpretations of place for which there are no correct answers, as well as the meanings of the place in the past and the openness to future interpretations and constructions of meaning.

Based on our limited review of some of this literature and the contributions of the seven sets of authors, there may remain a need for future empirical research to understand the:

(a) Outcomes and effects for diverse groups of learners experiencing diverse kinds of pedagogies across different kinds of outdoor natural settings
(b) Inputs in particular contexts educators need to provide to facilitate desired outcomes (e.g., sustainable lifestyles, physically active citizens, knowledgeable conservationists)
(c) Planning and policies at a system level for nature-based places (parks, greening, school grounds, etc.) that are needed as the population lives more and more in cities
