Second Handbook of Information Technology in Primary and Secondary Education

 Springer

Springer International Handbooks of
Education

The *Springer International Handbooks of Education* series aims to provide easily accessible, practical, yet scholarly, sources of information about a broad range of topics and issues in education. Each *Handbook* follows the same pattern of examining in depth a field of educational theory, practice and applied scholarship, its scale and scope for its substantive contribution to our understanding of education and, in so doing, indicating the direction of future developments.

The volumes in this series form a coherent whole due to an insistence on the synthesis of theory and good practice. The accessible style and the consistent illumination of theory by practice make the series very valuable to a broad spectrum of users. The volume editors represent the world's leading educationalists. Their task has been to identify the key areas in their field that are internationally generalizable and, in times of rapid change, of permanent interest to the scholar and practitioner.

Preface

Major changes have taken place in the landscape of information technology in educational research, policy, and practice since the publication of the first edition of the *Handbook of Information Technology in Primary and Secondary Education* in 2008. The primary aim of the second edition of this *Handbook* is to update our knowledge of the field since 2008 and synthesize research about Information Technology in education from a broad international perspective. This second edition has 88 chapters written by 138 different authors. The authors come from 27 different countries and span five continents.

Consensus on the focus and structure of the *Handbook* was reached among the twenty (section) editors during a joint meeting at the headquarters of the United Nations Educational Scientific and Cultural Organization (UNESCO) in Paris in 2016. The editors decided to keep the same structure of the *Handbook* as in the first edition and organized the *Handbook* around two main themes: (1) the potential of information technology (IT) to improve teaching and learning in primary and secondary education; and (2) the support that is required to successfully implement IT in educational practice. These two themes are addressed in the 12 sections of the *Handbook*. Most of the sections in the first edition were kept (often with a slightly different titles) and three new sections were added. These new sections focused on the use of technology in assessment, mobile learning, and game- and simulation-based learning and teaching. The *Second Handbook of Information Technology in Primary and Secondary Education* provides an updated in-depth overview of research to date in the field of information technology in education.

In this introduction chapter of the *Handbook*, the editors-in-chief provide an overview of the main themes of this second edition and highlight the developments in the field since the publication of the first edition of the *Handbook* in 2008. Then in each section, there are between five and seven chapters addressing themes pertinent to a subfield of IT in education. After a brief summary of the chapters in the section, the section editor(s) provide an introduction of the research in their specific field in an overview chapter.

As editors-in-chief, we would like to express our gratitude to the section editors for their valuable contributions to the *Handbook* and their constructive collaboration throughout the editorial process. We also wish to thank all the authors for their efforts in contributing chapters to the *Handbook*, as well as the reviewers of these chapters. As our host at UNESCO, we wish to thank Mariana Patru for her generous hospitality.

Finally, we thank Springer, in particular Yoka Janssen, Audrey Wong-Hillmann, and Sindhu Ramachandran for their support and trust.

Contents

Volume 1

Section I Introduction	1
1 Developing an Understanding of the Impact of Digital Technologies on Teaching and Learning in an Ever-Changing Landscape	3
Joke Voogt, Gerald Knezek, Rhonda Christensen, and Kwok-Wing Lai	
Section II Curricular Challenges of the Twenty-First Century	13
2 Section Introduction: Curricular Challenges of the Twenty-First Century	15
Joke Voogt and Ola Erstad	
3 The Twenty-First Century Curriculum: Issues and Challenges ...	19
Ola Erstad and Joke Voogt	
4 New Literacies: Curricular Implications	37
Lotta Larson, Elena Forzani, and Donald J. Leu	
5 Digital Citizenship and Social Media: A Curriculum Perspective	53
Nancy Law, Siu-Lun Chow, and King-Wa Fu	
6 Students and Their Computer Literacy: Evidence and Curriculum Implications	69
John Ainley	
7 Computer Science and Computational Thinking in the Curriculum: Research and Practice	89
Aman Yadav, Phil Sands, Jon Good, and Alex Lishinki	

8	Dissolving the Digital Divide: Creating Coherence in Young People’s Social Ecologies of Learning and Identity Building	107
	Kristiina Kumpulainen, Anna Mikkola, and Antti Rajala	
Section III The Learner and the Learning Process		121
9	Section Introduction: The Learner and the Learning Process	123
	Kwok-Wing Lai and Keryn Pratt	
10	The Learner and the Learning Process: Research and Practice in Technology-Enhanced Learning	127
	Kwok-Wing Lai	
11	Information and Communication Technologies, and Learning Theories: Putting Pedagogy into Practice	143
	Vanessa P. Dennen, Kerry J. Burner, and Michelle L. Cates	
12	Developing Scientific Inquiry in Technology-Enhanced Learning Environments	161
	Carol K. K. Chan and Yuqin Yang	
13	Cultural and Social Issues in Using Social Media to Support Learning	181
	Royce Kimmons and Olga Belikov	
14	Bridging Formal and Informal Learning Through Technology in the Twenty-First Century: Issues and Challenges	199
	Cathy Lewin and Amina Charania	
15	Computer-Supported Collaborative Learning: Mediated and Co-Present Forms of Learning Together	217
	Lara Johanna Schmitt and Armin Weinberger	
Section IV Attitudes, Competencies, and Dispositions for Teaching and Learning with Information Technology		233
16	Section Introduction: Attitudes, Competencies, and Dispositions for Teaching and Learning with Information Technology	235
	Gerald Knezek and Rhonda Christensen	
17	The Evolving Role of Attitudes and Competencies in Information and Communication Technology in Education	239
	Gerald Knezek and Rhonda Christensen	
18	Information and Communication Competences for Students	255
	Koen Aesaert and Johan van Braak	

19	The Influence of Information and Communication Technology Use on Students’ Information Literacy	271
	Akira Sakamoto	
20	The Interaction of Psychological Constructs with Information Technology-Enhanced Teaching and Learning	293
	Yaacov J. Katz	
21	Information and Communication Technology Dispositional Factors and Relationship to Information and Communication Technology Practices	309
	Anne T. Ottenbreit-Leftwich, Theodore J. Kopcha, and Peggy A. Ertmer	
22	Instructional Technology Integration Models and Frameworks: Diffusion, Competencies, Attitudes, and Dispositions	335
	Dale S. Niederhauser and Denise L. Lindstrom	
23	Measuring Teacher Attitudes, Competencies, and Pedagogical Practices in Support of Student Learning and Classroom Technology Integration	357
	Rhonda Christensen and Gerald Knezek	
Section V	Professional Learning and Development of Teachers	375
24	Section Introduction: Professional Learning and Development of Teachers	377
	Peter R. Albion and Jo Tondeur	
25	Information and Communication Technology and Education: Meaningful Change Through Teacher Agency	381
	Peter R. Albion and Jo Tondeur	
26	Knowledge Base for Information and Communication Technology in Education	397
	Charoula Angeli and Nicos Valanides	
27	Preparing Preservice Teachers to Transform Education with Information and Communication Technologies	415
	Alona Forkosh-Baruch	
28	Teachers as Drivers of Their Professional Learning Through Design Teams, Communities, and Networks	433
	Sarah Prestridge and Katherine Main	
29	Connecting Research and Practice: Teacher Inquiry and Design-Based Research	449
	Susan McKenney and Natalie Pareja Roblin	

30	Professional Development for Online and Mobile Learning: Promoting Teachers' Pedagogical Inquiry	463
	Evrin Baran	
Section VI The Role of Leadership for Information Technology in Education		479
31	Section Introduction: The Role of Leadership for Information Technology in Education	481
	Sara Dexter	
32	The Role of Leadership for Information Technology in Education: Systems of Practices	483
	Sara Dexter	
33	A Distributed Leadership Perspective on Information Technologies for Teaching and Learning	499
	Richard Halverson	
34	Leaders Fostering Teachers' Learning Environments for Technology Integration	515
	Sarah K. Howard, Jen Scott Curwood, and Kelli McGraw	
35	Technology Integration, Leadership, and Organizational Support Frameworks for Instructional Improvement with Information Technology	535
	Scott McLeod	
36	Leading Information Technology via Design Thinking	543
	John B. Nash	
37	Appreciative Inquiry: Building on Strengths for Integrating Information Technology in Schools	549
	Megan Tschannen-Moran and Mark Hofer	
38	Teaching as a Design Science: Teachers Building, Testing, and Sharing Pedagogic Ideas	557
	Diana Laurillard	
39	Improvement Science Through Networked Improvement Communities: Leadership of Continuous Improvement with, of, and Through Information Technology	567
	David H. Eddy-Spicer	

Section VII Using Information Technology for Assessment: Issues and Opportunities 575

40 Section Introduction: Using Information Technology for Assessment: Issues and Opportunities 577
 Mary Webb and Dirk Ifenthaler

41 Assessment as, for, and of Twenty-First Century Learning Using Information Technology: An Overview 581
 Mary Webb and Dirk Ifenthaler

42 Formative Assessment and Feedback Using Information Technology 601
 Fabienne van der Kleij and Lenore Adie

43 Progress and Challenges for Automated Scoring and Feedback Systems for Large-Scale Assessments 617
 Denise Whitelock and Duygu Bektik

44 Assessing Problem-Solving Skills in Game-Based Immersive Environments 635
 Valerie J. Shute and Benjamin Emihovich

45 Making Use of Data for Assessments: Harnessing Analytics and Data Science 649
 Dirk Ifenthaler, Samuel Greiff, and David Gibson

46 A Futures Perspective on Information Technology and Assessment 665
 Jason M. Lodge

Volume 2

Section VIII Flexible, Distance, and Open Learning in the Twenty-First Century 679

47 Section Introduction: Flexible, Distance, and Open Learning in the Twenty-First Century 681
 Roumen Nikolov and Kwok-Wing Lai

48 Distance and Flexible Learning in the Twenty-First Century 685
 Roumen Nikolov, Kwok-Wing Lai, Evgenia Sendova, and Herma Jonker

49 Virtual Schools: A Global Perspective 701
 Niki E. Davis and Richard E. Ferdig

50	Open Education Resources, Massive Open Online Courses, and Online Platforms for Distance and Flexible Learning	719
	Jon Dron and Gerald Arditio	
51	Online Learning Communities in K-12 Settings	737
	Seng Chee Tan and Alwyn Vwen Yen Lee	
52	Designing Blended, Flexible, and Personalized Learning	759
	Keryn Pratt and Eugenia Petrova Kovatcheva	
Section IX	Mobile Learning	777
53	Section Introduction: Mobile Learning	779
	Elliot Soloway and Cathleen Norris	
54	From Engagement to Empowerment: The Evolution of Mobile Learning in the United States	785
	Julie A. Evans	
55	Barriers to Mobile Learning Advancements in the United Kingdom	807
	David Whyley	
56	The Implementation of Mobile Learning in Asia: Key Trends in Practices and Research	817
	Daniel Churchill, Mark Pegrum, and Natalia Churchill	
57	Mobile Learning in K-12: Roadblocks to Adoption	859
	Cathleen Norris and Elliot Soloway	
Section X	Game and Simulation-Based Learning and Teaching	877
58	Section Introduction: Games, Simulations, and Emerging Technologies	879
	David Gibson and Hiroaki Ogata	
59	Guiding Questions for Game-Based Learning	887
	Karen Schrier	
60	Evaluating Games for Classroom Use	907
	Katrin Becker	
61	Toward Creator-Based Learning: Designs That Help Student Makers Learn	921
	Chen-Chung Liu	
62	Trends and Opportunities in Online Learning, MOOCs, and Cloud-Based Tools	935
	Vanessa Chang, Christian Gütl, and Martin Ebner	

63	Educational Opportunities for Immersive Virtual Reality	955
	Richard E. Ferdig, Enrico Gandolfi, and Zachary Immel	
64	Educational Opportunities for Augmented Reality	967
	Enrico Gandolfi, Richard E. Ferdig, and Zachary Immel	
Section XI Issues and Challenges Related to Digital Equity		981
65	Section Introduction: Issues and Challenges Related to Digital Equity	983
	Thérèse Laferrière and Paul Resta	
66	Issues and Challenges Related to Digital Equity: An Overview ...	987
	Paul Resta, Thérèse Laferrière, Robert McLaughlin, and Assetou Kouraogo	
67	Information and Communication Technology Revitalizing Cultural Identity and Diversity	1005
	Paul Resta, Miri Shonfeld, Manal Yazbak Abu Ahmad, and Denelle L. Wallace	
68	A Sociocritical Perspective on the Integration of Digital Technology in Education	1015
	Jean Gabin Ntebutse and Simon Collin	
69	Learning Differences and Digital Equity in the Classroom	1025
	Jutta Treviranus	
70	Organizing Learning Environments for Relational Equity in New Digital Media	1047
	William R. Penuel and Daniela K. DiGiacomo	
71	Technology and Equity in Education	1063
	Mark Warschauer and Ying Xu	
72	Advancing Equity Through Educational Technology: Promising Practices for Adoption, Integration, and Use in K-12	1081
	Molly B. Zielezinski and Linda Darling-Hammond	
Section XII Paradigms for Researching Information Technology in Education		1099
73	Section Introduction: Paradigms for Researching Information Technology in Education	1101
	Margaret J. Cox and Joke Voogt	
74	Researching Information Technology in Education: Meeting the Challenges of an Ever-Changing Environment	1105
	Margaret J. Cox	

75	Meta-analyses of Large-Scale Datasets: A Tool for Assessing the Impact of Information and Communication Technology in Education	1125
	Yuen-Kuang Cliff Liao and Wan-Ching Lai	
76	Researching the Design and Evaluation of Information Technology Tools for Education	1143
	Eric Bruillard and Georges-Louis Baron	
77	International Large-Scale Computer-Based Studies on Information Technology Literacy in Education	1161
	Julian Fraillon	
78	Measuring the Impact of Emerging Technologies in Education: A Pragmatic Approach	1181
	Mutlu Cukurova and Rosemary Luckin	
79	Looking Back, Moving Forward: Impact and Measurability of the Use of Educational Technology	1201
	Norbert Pachler and Keith Turvey	
	Section XIII International Policies on Information and Communication Technology in Primary and Secondary Schools: Cross-National Policies	1221
80	Section Introduction: International Policies on Information and Communication Technology in Primary and Secondary Schools	1223
	Birgit Eickelmann	
81	Cross-National Policies on Information and Communication Technology in Primary and Secondary Schools: An International Perspective	1227
	Birgit Eickelmann	
82	Information and Communication Technology in Educational Policies in the Asian Region	1239
	Allan H. K. Yuen and Timothy K. F. Hew	
83	Information and Communication Technology in Educational Policies in Australia and New Zealand	1259
	Louise Starkey and Glenn Finger	
84	Information and Communication Technology and Educational Policies in the United States of America and Canada	1279
	Trina J. Davis, Joseph B. South, and Katrina D. Stevens	

85	Information and Communication Technology and Educational Policies in the Sub-Saharan African Region	1301
	Frank Tilya	
86	Information and Communication Technology and Educational Policies in Primary and Secondary Education in the Middle East and North African (MENA) Region	1321
	Ghaida M. Alayyar, Reham K. Aljeeran, and Abdullah A. Almodaires	
87	Information and Communication Technology Policy in Primary and Secondary Education in Europe	1343
	Geir Ottestad and Greta Björk Gudmundsdottir	
88	Information and Communications Technology and Educational Policies in Latin America and the Caribbean	1363
	Nancy Castillo-Valenzuela and José Miguel Garrido-Miranda	
Index	1381

About the Editors

Joke Voogt

University of Amsterdam
Amsterdam, The Netherlands

Windesheim University of Applied Sciences
Zwolle, The Netherlands

Dr. **Joke Voogt** is Professor of ICT and Curriculum at the Faculty of Behavioural and Social Sciences of the University of Amsterdam and Professor of Educational Innovation and ICT at Windesheim University of Applied Sciences. Since the 1980s, she has been investigating the integration of Information and Communication Technology in educational practice in national and international settings. She was part of the coordination team of Second Information Technology in Education Studies (1998–2008) of the International Association for the Evaluation of Educational Achievement and is currently involved as a curriculum specialist in the OECD Education 2030 study: The future of Education and Skills.

Dr. Voogt is Co-editor of the first edition of the *International Handbook of Information Technology in Primary and Secondary Education*. She is Co-founder and Chair of the EDUsummIT, the international Summit for research, policy, and practice that emerged from the first edition of the Handbook. Her areas of expertise are curriculum innovation, teacher learning and development, twenty-first century skills, in particular related to the integration of technology in education. Dr. Voogt has a master degree in Educational Science and Technology (with distinction) and a doctoral degree (Ph.D.) in Educational Sciences from the University of Twente, The Netherlands.

**Gerald Knezek**

University of North Texas
Denton, TX, USA

Dr. **Gerald Knezek** is Regents Professor of Learning Technologies at the University of North Texas (UNT), USA, and Co-director of the Institute for the Integration of Technology into Teaching and Learning (IITTL) at UNT. He was a Fulbright Scholar at the Tokyo Institute of Technology and Japan's National Center for University Entrance Examinations during 1993–1994 and completed Fulbright Senior Specialist appointments in Ecuador during 2006–2007 and in The Netherlands during 2011–2012. Dr. Knezek received his B.A. in Mathematics and the Social Sciences from Dartmouth College, USA, and his M.Ed. and Ph.D. degrees in Educational Psychology from the University of Hawaii. He was Co-editor on the first edition of the Handbook published in 2008.

**Rhonda Christensen**

University of North Texas
Denton, TX, USA

Dr. **Rhonda Christensen** is Research Professor in the Learning Technologies Department in the College of Information at the University of North Texas, USA. She is Co-director of the Institute for the Integration of Technology into Teaching and Learning at UNT and a Co-PI and Project Director for the Going Green! Middle Schoolers Out to Save the World (MSOSW) project funded by the US National Science Foundation (NSF) Innovative Technologies Program and the National Aeronautics and Space Administration (NASA) Space Science Education Consortium funded project. She serves as the Chair of the IT Council for the Society for Information Technology in Teacher Education (SITE). She is a Fulbright Senior Scholar recipient working in the Netherlands on a research teaching assignment. Dr. Christensen has participated as a leader and participant in four of the international EDUSumMIT meetings focused on ICT in education and was a section editor on the first edition of this *Handbook*.

Dr. Christensen has co-authored and taught a pre-service technology integration course for more than 15 years. She also teaches doctoral courses on research design and analysis. Her research interests are the impact of technology integration education, enhancing STEM education in middle schools and mobile learning in education.

Dr. Christensen received her Bachelors' of Science in Curriculum and Instruction from Texas A&M University, her Masters' of Science in Computer Education and Cognitive Systems and her Ph.D. in Information Science from the University of North Texas.

Kwok-Wing Lai

University of Otago
Dunedin, New Zealand

Dr. **Kwok-Wing Lai** is Professor of Education and Director, Centre for Distance Education and Learning Technologies, at the University of Otago College of Education, New Zealand. He was a high school teacher in Hong Kong prior to completing his graduate studies in educational technology in Canada, at Queen's University and the Ontario Institute for Studies in Education, University of Toronto. He is the founding editor of *Computers in New Zealand Schools* as well as the founding president of Knowledge Building New Zealand. He has been part of the leadership team of EDUsummIT (International Summit on ICT in Education) since its inception, and was its program Co-chair in 2015 and 2017. He was a section editor of the first edition of this Handbook.

Information technology · Teaching and learning · Leadership · Curriculum · Emerging technologies · Assessment · Research methodologies

Introduction

“There is a wealth of research on information technology (IT) in primary and secondary education. Yet most of it is scattered and a synthesis of the research from a broad international perspective is needed” (Voogt and Knezek 2008, p. xxix). This was the main rationale for the *International Handbook of Information Technology in Primary and Secondary Education*, which was published in 2008. At the dawn of the publication of the second edition of the *International Handbook of Information Technology in Primary and Secondary Education*, we realize that most sections of the *handbook* have substantially changed since the first edition.

The design and impact of technology-supported learning environments focusing on the student learner remain a major focus of the second edition. This line of research studies how learners, learning processes, and learning environments and their interactions change in a digitalized world. An equally important theme deals with the uptake of IT in educational practice. Research topics about the uptake of IT in education are considered from several perspectives: the curriculum, the teacher, the school leadership, the assessment, and the educational policy, while taking into account interdependencies. Equity is an important theme within research on IT in education and therefore deserves specific attention. Finally, valuing existing and evolving research paradigms and methodologies is needed to contribute to a better understanding of how technologies impact teaching and learning.

Since the publication of the first edition of the *handbook*, various terms on the use of digital technologies in education have been used, such as eLearning and mLearning. For pragmatic reasons we will stick with the term information technology (IT) as we did in the first *handbook*. In some chapters authors use the term information and communication technology (ICT) instead of information technology, because it better reflects the discourse in the addressed context.

In this introduction chapter, we reflect on the contributions of research in the field of digital technologies in education during the last decade (2008–2018). The guiding questions leading these reflections are (1) what progress in understanding digital technologies in education has been made? and (2) what emerging themes can be observed that warrant further study?

Overall, the progress made in the last decade is promising, and new research themes have emerged. This chapter highlights selected findings and issues that serve as exemplars for those addressed throughout the 2018 *handbook*, within the thematic strands that served as the blueprint for the reference work itself. Whenever possible, brief comparisons and contrasts are made to the evolutions over the past decade, since the first edition of the *handbook* was published.

Technology and Learners

Compared to the first edition of the *handbook*, there has been a stronger emphasis on the influence of digital technologies on learners instead of learning processes and learning outcomes in this second edition. Overall access to digital technologies by students, at least in the economically more advanced countries, is no longer a major barrier. We recognize that the importance of emotions, motivation, creativity, grit, and other non-cognitive variables related to attitudes toward teaching and learning with digital technologies has increased. Likewise, recognition of the importance of understanding the process of acquiring different kinds of competencies needed to be productive in a modern society (e.g., communication, confidence, collaboration) related to IT in education – rather than simply focusing on the end-goal performance of a mastered IT skill – has become universal.

By using networking technologies to support students working in learning communities, it is critical that students develop knowledge creating capabilities and the skills for knowledge innovation. Online learning communities should be designed not just for information sharing but should support an effective and student-centered way of learning.

Over the past decade, the use of digital technologies and applications has continued to increase, particularly the use of social media. However, research in social media is beginning to recognize that to be successfully engaged in this participatory culture, the learners need to acquire a new form of literacy and deal with cultural and social issues. Also, there is increasing recognition that how social media can be effectively used in the formal school context should be rigorously researched.

Research now clearly shows that digital technologies can support students to engage collaboratively to become innovative and creative learners. These technologies can support the creation of new knowledge and the development of new skills (Ito et al. 2013; Scardamalia and Bereiter 2015). It is still the case, however, that many young people use new technologies only to consume information.

With this focus on the learner, rather than simply the learning outcomes, there are also some alarming issues related to the use of technologies. Negative issues include privacy issues and the lack of attention to the overall well-being (psychological and emotional) of the learners. There are also health and safety issues due to the increase of cyberbullying.

Technology to Support the Learning Process

While the specific impact of digital technologies on students' learning is difficult to demonstrate, some recent meta-analyses of the literature show higher effect sizes for students' learning performance (cognitive, affective, and social skills) when students are learning with digital technologies than without digital technologies (► [Chap. 75, "Meta-analyses of Large Scale Datasets: A Tool for Assessing the Impact of Information and Communication Technology in Education"](#) by Liao and Lai). These meta-analyses include a broader variety of technologies (including games and mobile learning) than the earlier meta-analyses – and higher effect sizes were found. However, the mechanisms that account for these findings cannot easily be identified.

While technologies are constantly changing, the education field has been trying to choose those that will best support and enhance learning. Games, simulations, and immersive environments are able to provide a great deal of data that can be evaluated for learning but has only been harnessed for feedback in select environments. The next decade should see the large sets of data that are unobtrusively collected become useful for targeting learning needs in near real time.

Since the first edition of the *handbook*, mobile technologies have become ubiquitous. The education field has been working to find ways to harness the power of one-to-one learning with mobile devices. Over the past decade, the smartphone has become a pervasive device that is used by two-thirds of the world's population. Over the past 10 years, mobile devices have gone from supplemental to mainstream for twenty-first century learning in many classrooms.

Also in the last decade, we saw the emergence of new pedagogies such as flipped learning and the use of advanced digital technologies to support distance and flexible learning. There has been huge growth of virtual schools in the USA, but the growth in other countries was primarily in online learning, to support face-to-face learning. Since online learning has been widely practiced in schools, we see the beginning of a reconceptualization of distance learning, with a shift from being on the edge of the educational landscape to the center stage, and fast becoming mainstream, particularly in the USA (Naidu 2016). Supported by Open Education Resources and Massive Online Open Courses, in the last decade, open learning has advanced beyond higher education, into the primary and secondary sectors, and we see examples of learning environments being developed that facilitate open access to content with more open pedagogies. There is also recognition of the importance of designing flexible learning environments to support personalized learning.

There is modest advancement in pedagogy for how to support students to become innovative and creative. In terms of learning theories, social constructivism is still the dominant learning theory underpinning innovative use of technology-enhanced learning. Once considered promising, there has not been much development of connectivism in recent years.

Rapid advances in neuroscience research investigate how neural activities affect learning by using digital technologies such as functional magnetic resonance imaging (fMRI) and electroencephalography (EEG). A new discipline called educational

neuroscience (Bowers 2016) has been developed aiming to gain a better understanding of how the biology of learning can be used to support classroom practice and specifically in designing technology-enhanced learning (Howard-Jones et al. 2015). The advance of educational neuroscience has been slow, and there are many misconceptions as to how neuroscience research can illuminate learning sciences research. For example, it is not clear how and why immersing in digital technologies may reorganize and restructure the brain to enhance learning (Prensky 2009). There has also been increasing popularity of computer-based brain training software. However, to date it is not clear how or in what way these computer-based training programs can help the learner (Kroeger et al. 2012). Research in educational neuroscience has not advanced to the stage where research findings can be readily translated into practice (Howard-Jones et al. 2015).

Connecting In and Out of School Learning

The notion that learning is a lifelong process which extends beyond schooling and the school curriculum highlights the importance of informal learning and personalization of the curriculum. In the last decade, teachers began to recognize the importance of personal learning experiences taking place in everyday life and the involvement of other actors (e.g., the family and the wider community) in supporting students' informal learning. It is now considered pertinent to align students' experiences in school with their day-to-day digital practices in order to support identity and agency building. However, how formal and informal learning can be effectively connected remains a key research issue.

The maker movement is fast growing as an informal learning environment outside the school context (Pepler and Bender 2013), supporting participants to work on collaborative projects of personal interest but having connections to formal knowledge. Cultural clashes (► Chap. 14, “Bridging Formal and Informal Learning Through Technology in the Twenty-First Century: Issues and Challenges” by Lewin and Charania) between formal and informal learning are still unresolved. Mobile technologies provide affordances of informal learning and the opportunities to connect informal learning with formal learning. However, there has been slow advancement of how this can be effectively done. For now, it appears that learners will continue to advance most rapidly through mobile learning in the informal realm (► Chap. 53, “Section introduction: Mobile learning” by Norris and Soloway).

Teachers

We recognize that using digital technologies to foster twenty-first century skills such as critical analysis of information and collaboration with peers is often more important than using digital technologies to help students memorize facts. We have moved from standardized paper and pencil tests for teachers to show performance, in recognition that how much teacher knows must be equally important with how well they can

foster student learning. Instruments to measure teacher development can best be described as a battery of developmental appraisals rather than a single test.

There are issues of what teachers need to learn about digital technologies and the application of IT in supporting learning in the twenty-first century, since most teachers continue to use IT primarily to support content delivery rather than to engage students in creative activities. Recent research highlights the need for teachers to develop technological knowledge and technical skills, in addition to pedagogical and content knowledge.

However, research has shown that tacit qualities of the teacher (e.g., self-efficacy, positive attitudes, beliefs) are also important to develop, which are, beyond observed teaching performances and mastery of content knowledge or theories of teaching and learning. The instructional strategies teachers use in the classroom are evolving due to the influences and influx of digital technologies. In the case of technology integration, it is important to consider the level of confidence teachers have in the instructional use of technologies to enhance student learning.

How to support teachers in a technology-enhanced environment remains a key issue. This support involves a reconsideration of the role of the teacher, in terms of their agency, and their role in bridging formal and informal learning, with a growing importance of the latter. This is about empowering teachers to exercise agency. It has been suggested that a way of enhancing teacher agency is to engage them in collaborative pedagogical inquiry (► [Chap. 25, “Information and Communication Technology and Education: Meaningful Change Through Teacher Agency”](#) by Albion and Tondeur). Also, as one of the most important factors affecting student learning, there has been increasing recognition that research should be conducted to clarify the knowledge base of the teacher.

School Leadership

Teacher readiness for technology integration, although important, also depends on a school's readiness to support the use of digital technologies in teaching and learning (Petko et al. 2018). The role of school leadership therefore is important for fostering teachers' use of technology in daily teaching and learning processes.

We now know more about the benefits of a school-level perspective to technology integration, including leaders' roles in IT integration. Research has provided evidence that by adopting a distributed leadership perspective, the main functions of leading technology innovations, including developing vision, supporting integration, and ensuring the accountability of technology initiatives in terms of ownership and outcomes, can be framed.

The distributed leadership perspective and some key functions for IT leaders are still considered important to promote IT further in schools, but there is now a more fine-grained emphasis on practices – *how* leaders do their work. Research-based strategic interventions have been developed for leaders to coordinate actions across their schools so that multiple leaders' areas of expertise are used to facilitate and support teachers in using IT in classrooms. Thus, a shift can be observed from an

emphasis on instrumental actions of leaders from an accountability perspective, toward transformative and instructional leadership actions aiming to change the culture in schools regarding teachers' collaborative learning to fuel the design and enactment of IT in classrooms.

Curriculum and Assessment Challenges

In the first edition of the *handbook*, the focus of IT in the curriculum emphasized on the use of digital technologies to enhance the learning of traditional subjects as well as the use of digital technologies in cross-curricular themes. However in the last decade, we have witnessed a renewed discourse on the question of what should be taught in the twenty-first century society – which is the classical curriculum question (e.g., OECD 2018). Because of technological advancements and their implications for living, learning, and working, many countries and states worldwide are now redesigning their curricula. In the process of curriculum redesign, the need to pay attention to the knowledge, skills, attitudes, and values, often referred as the twenty-first century competencies, is recognized, as they are important in a global and digitalized society. Technology is seen as a driver of change as well as a tool to develop twenty-first century competencies. Emerging domains are important in the twenty-first century such as the development of new literacies, the notion of digital citizenship, and the importance of computational thinking as an integral part of digital literacy. These new domains are theoretically conceptualized and discussed in the *handbook*. However, empirical research evidence on these new domains is still scarce and further study is needed.

While curriculum deals with what needs to be learned, assessment is about what has been learned. Technology-based assessment is a dynamic field that has been advancing rapidly with growth set to accelerate with emerging opportunities for automatic data collection as well as increased possibilities of communication and interaction mediated by IT. In order to continue moving forward in a constructive manner for education, assessment discourse needs to involve designers, teachers, and learners working together to support twenty-first century curricula and pedagogies. This shared vision among stakeholders allows that data can be collected and represented to enable learners and teachers to identify achievements, collate evidence of achievements, diagnose needs – both cognitive and affective – and decide on suitable pedagogical approaches for enabling the next steps in learning.

IT Policies

Moonen (2008) concluded in the first edition of the *handbook*, in his review of IT policies of different regions of the world, that in the developed regions the emphasis had shifted from a concern about the IT infrastructure to the incorporation of IT into the teaching and learning process. As a result IT policies in education

were no longer explicit but had become implicit in the educational policy in many countries. However, a decade later the opposite seems to be true. Many countries are now renewing their IT policies in education. Current policy developments result in the inclusion of a computing (computer science) curriculum in schools (Fluck et al. 2016). However, in practice, there is little evidence to show that digital technologies have been used in a creative way globally.

Eickelmann (► Chap. 81, “Cross-National Policies on Information and Communication Technology in Primary and Secondary Schools: An International Perspective”) observes that in the last decade while variability of IT policies across regions was the norm, some commonalities as follows could be identified:

- Developing ICT infrastructures that reflect pedagogical aims, especially the fostering of one-to-one and BYOD (“bring your own device”) concepts, often in combination with personalized learning
- Focusing on access, equity, and participation
- Reaching all students and improving teacher training
- Bridging and linking formal and informal learning
- Integrating the aims of (subject-specific) learning with ICT with more general education goals such as creating a skilled workforce for the twenty-first century
- Introducing new topics (e.g., computational thinking) and modernizing curricula
- Pointing to new potentials such as those afforded by new forms of online learning and online assessment as well as to risks and more critical issues like data privacy

These common aspects in IT policy show that the high expectations at the turn of the century that IT would transform education seem to have now changed toward the more realistic opportunities IT may offer to solve some prominent challenges in the digital society. For IT in primary and secondary education, the challenge is to transfer the plans and core ideas of IT policies into practice, because realization of developing school systems in the digital age is still pending and not automatically assured by simply having policies. Having a vision and shared aims captured in IT policies is indispensable and especially valuable when they do not only outline goals but also give direction on how goals can be translated into practice and how supportive conditions can be facilitated.

The focus on access, equity, and participation is a common concern of IT policies globally. The evolving nature of digital equity is a complex topic, and depending on the point of view, there is both an increase and a decrease in digital equity. Regarding digital equity for learning with technology, there have been attempts to close the gap or bridge the divide regarding gender, race, social class, learning disabilities, etc. However, the focus is not on the amount of access that students have but on technology as a potential agent for social inclusion and strategies in moving toward digital equity for classroom teachers.

Research

From a superficial point of view, the time consuming and slow research process often do not seem to align with the rapid development of technologies and their potential for teaching and learning. However, research that helps to understand why specific technologies work and under which conditions might better predict the potential and issues of new technologies for improving student learning. For this reason we think it is important to review the history of educational IT research to better understand the issues at stake.

One important issue that remains essential in educational IT research is acknowledging the importance of context in which IT applications are used to foster teaching and learning. Unraveling the context is seen as a challenge for educational IT research. It requires researchers to think of research methods as being complementary to each other instead of hierarchical. Thus in addition to a clear theoretical basis guiding research on IT in education, deliberately making use of the diversity of research methods may help to better understand not only if specific technology interventions have impact but also why the outcome is realized. Even stronger than in the 2008 handbook, there is a call for further integration of research paradigms and of quantitative and qualitative research designs.

Since 2008, the technology landscape has tremendously changed. IT has now become a ubiquitous aspect of life. Many IT tools can be used for learning purposes, but they are typically not designed with student learning in mind. In addition, technology potentially can create learning environments everywhere, including outside the traditional education systems. However, how best to make use of technology to foster student development (including their well-being) yet mitigating its threats is a challenge for the design and evaluation of IT tools which requires close collaboration of researchers with key stakeholders. Much progress in understanding the evolving role of digital technologies in education has been made, but much that is unknown still remains regarding the impact of digital technologies on teaching and learning in an ever-changing landscape.

Section II

Curricular Challenges of the Twenty-First Century

Section Introduction: Curricular Challenges of the Twenty-First Century

2

Joke Voogt and Ola Erstad

Abstract

Rapid technological developments ask for so called 21st century skills or competences to prepare citizens for living, working and learning in our current society. Due to these changes many countries worldwide are in the process of redesigning their curricula. This section elaborates on the role of technology in 21st century curricula. First the notion of 21st century competences is elaborated upon. This is followed by research on emerging domains in 21st century curricula, such as new literacies, digital citizenship, digital literacy and computational thinking. The section finishes with pointing to the need to align school curricula with students' digital practices.

Keywords

21st century skills · Key competences · Curricular challenges

This section elaborates on the role of technology in twenty-first-century curricula. Recently international organizations such as OECD and the European Union as well as national policies in many countries are reconsidering curriculum frameworks

from the perspective of competences that are found relevant for living in and contributing to a global and digitalized society. These competences are generic and often referred to as twenty-first-century skills (North America), lifelong learning competences (OECD 2005), or key competences (EU 2007). According to Klieme, Hartig, and Rauch, competences are “context-specific cognitive dispositions that are acquired by learning and needed to successfully cope with certain situations or tasks in specific domains” (p. 9). They have cognitive, behavioral, and affective components. Twenty-first-century competences or skills are certainly not new (Voogt et al. 2013). For instance, already in 1910 Dewey (1910) mentions critical thinking as an important skill to be taught. What is different is that twenty-first-century competences should not be taught separately, but in conjunction with each other. Technology plays a specific role in the acquisition of twenty-first-century skills, not only because the ubiquitous use of technology in society also requires students to be digital literate but also because technology may facilitate the acquisition of twenty-first-century skills. A second important issue, related to the role of technology in twenty-first-century curricula, refers to the potential of technology to better align curricula with students’ needs. From the perspective of personalization of the curriculum, the curriculum is not bound to formal learning only but is considered a lifelong learning process, including informal learning experiences. It implies that curricula need to become more aligned with students’ out-of-school digital practices.

In this section we present research on some prominent twenty-first-century competences. We discuss conceptualizations of these twenty-first-century competences and the implications for schooling in the twenty-first century.

In ► [Chap. 3, “The Twenty-First Century Curriculum: Issues and Challenges,”](#) Erstad and Voogt introduce the concept of twenty-first-century competences. They present four meta-reviews that analyzed major conceptual frameworks that aim to provide an answer to the question of what should be taught and learned in the twenty-first century. The second part of the chapter focuses on the specific roles for new technologies to facilitate the implementation of twenty-first-century competences in the curriculum. The chapter finishes with recent research on barriers of and drivers for changing curricula in preparing students to live, learn, and work in the twenty-first-century society.

Based on the assumption that the nature of reading and writing is changing due to technological developments, Larson, Forzani, and Leu, in ► [Chap. 4, “New Literacies: Curricular Implications,”](#) elaborate on the implications of a new literacies perspective for literacy research and practice. They argue that schools today need to prepare students who can navigate and participate online in a global society. Two specific challenges are addressed: research on the need to be able to critically evaluate online texts and research on the potential of collaborative online learning across national and cultural borders. Research about implications for instruction and school curricula is presented.

Because of the pervasive use of social media and its global implications, the concept of citizenship is changing in the twenty-first century. Law, Chow, and Fu ► [Chap. 5, “Digital Citizenship and Social Media: A Curriculum Perspective,”](#)

conceptualize digital citizenship and discuss research on the implications for citizenship education, in terms of curriculum, and the challenges for implementation.

In ► [Chap. 6, “Students and Their Computer Literacy: Evidence and Curriculum Implications,”](#) Ainley conceptualizes computer literacy and related concepts such as ICT literacy. In his contribution he reports about large-scale assessment studies measuring computer literacy of students. Results show large differences between students. Ainley discusses how curriculum development can be informed by such assessment studies.

An important aspect of digital literacy is computational thinking. Computational thinking is rooted in computer science and considered an important twenty-first-century competence (The Royal Society 2012; Wing 2006). In ► [Chap. 7, “Computer Science and Computational Thinking in the Curriculum: Research and Practice,”](#) Yadav, Sands, Good, and Lishinki describe how computer science education in schools has developed in a number of countries. The chapter finishes with implications for the knowledge teachers need to have to be able to teach computing, and factors that influence students’ learning to program are discussed.

Finally, in ► [Chap. 8, “Dissolving the Digital Divide: Creating Coherence in Young People’s Social Ecologies of Learning and Identity Building,”](#) Kumpulainen, Mikkola, and Rajala discuss current research on the ways in which school can become a space in which students’ digital practices can be aligned with teaching and learning and how this can contribute to students’ identity building. They show promising findings on how digital technologies and media can be used to encourage engagement and learning across sites and contexts.

Abstract

In this chapter we review key conceptual frameworks that address the challenges of society in contemporary discussions about the curriculum. The central question

guiding the chapter is “What should be taught and learned in school curricula in the 21st century.” Four meta-reviews are presented that analyze the contribution of major conceptual frameworks to this discussion. After identifying the key competences important for the twenty-first century, the focus of the chapter shifts to roles for new technologies in the curriculum. Issues that hamper the curriculum to change in directions that are considered important for teaching and learning are identified. We finalize with new perspectives on curriculum and curriculum development in the twenty-first century society.

Keywords

21st century curriculum · Key competences · Information and communication technologies · Meta-reviews · Curriculum development

The Curriculum in Times of Change

A school curriculum usually refers to the content, objectives, and organization of learning (Walker 2003). In studying a curriculum, the classical question is about what should be learned by the students and taught by the teacher and why; it is a quest for the right balance of knowledge domains that are considered important for the development of the society as well as the students (Tyler 1949). Within societies the “curriculum therefore expresses simultaneously a legacy from the past and aspirations and anxieties about the future” (Williamson 2013, p. 2). As such, it is an important instrument for change and societal development.

A curriculum expresses the educational policies, strategies, priorities, and ideas of an education system. At its narrowest sense, it specifies the goals of learning. More broadly it describes the values, content, and aims used to justify the program of an education system or an institution and all of the educational processes and learning that go on within it (Williamson 2013). Curricula are defined at various levels, the state (macro) and school/classroom (meso/micro) level being the most well known. Because of this, curriculum is not only a concern of governments but also of schools and teachers. However, increasingly due to globalization, curriculum questions are also a concern of supranational organizations such as the Organisation of Economic Co-operation and Development (OECD) and the European Union (EU) and because of the attention to individualization in the postmodern society curriculum as a means to contribute to personal development are called for as well (van den Akker 2003).

Due to the rise of the knowledge society and in particular, the developments of information and communication technologies, there is a call for redefining the role and function of the curriculum as well as a means to facilitate the enactment of the curriculum in practice (cf. Voogt et al. 2013). Surprisingly however, not much has been written about what a curriculum should be in the digital age (Williamson 2013). Rather, the main focus for the last decades, across different countries and cultures, has been on the “core curriculum content standards” (Binkley et al. 2012) and ways that curricula as political documents define educational models and practices (Alexander 2001).

The important question for this chapter is “What might be (the future of) the curriculum in the digital age?” (cf. Williamson 2013, p. 2). In this chapter we will

explore this question by reviewing some of the key conceptual frameworks defining future competences that contemporary curricula may need to address and discuss some of the main issues and challenges of curriculum and curriculum implementation within broader perspectives of schooling and learning in the twenty-first century.

Rationales Guiding Curriculum Change in the Twenty-First Century

On a global scale, there are changes in labor markets and the competences needed for future working life. According to Trilling and Fadel (2009), the year 1991 marked a shift of the American economy since it was the first year when the United States spent more financial capital on infrastructures and initiatives needed for a knowledge society than on infrastructure and initiatives for an industrial society. Because of this they argue that changes are needed for the future workforce and thus the curriculum. Consequently, in many countries around the world, greater emphasis is put on education to teach socio-cognitive skills associated with knowledge work, with the production of ideas, knowledge, and information rather than material things (Williamson 2013).

Another important influence on the curriculum in the transition to the twenty-first century has been the growth of the learning sciences since the 1990s (Sawyer 2006). This field of research brought together key insights from research on “how people learn” (Bransford et al. 2000). An important point was that there seemed to be a mismatch between what research could document about the ways people learn and the ways schools and curricula were organized around core content, age-based classes, specific subject domains, and test-oriented assessment procedures. These tensions also raised issues about how prepared our education system is for the twenty-first century living and learning (Wells and Claxton 2002; Sawyer 2006; CERI 2008; Thomas and Brown 2011). Related to designing for twenty-first century learning, some key issues and principles are often emphasized based on the influence from the learning sciences. Some of the key issues are deep learning, collaborative problem-solving, personalized/adaptive learning, computational thinking, and critical thinking (Binkley et al. 2012; Pellegrino and Hilton 2012; Voogt et al. 2013).

Curricula for Twenty-First Century Learning: What Should Be Taught and Learned in School

One of the key issues in many countries around the world is about how to prepare children and young people for future societal challenges and the role of education to provide the skills and competences they need. Social transformations are rapid, while educational processes including curriculum development is slow. This tension of timescale for change is a major challenge since the needs for new skills and competencies are already existing in society, while the youngsters entering the school system now will be leaving this system and entering the labor market in 10–15 years. So how can we design for learning that is adjusted to the needs of societies in the twenty-first

century? This question led to various initiatives to develop frameworks, which aimed to guide curriculum development for the twenty-first century. In many of these frameworks, the concepts of “skills,” as in twenty-first century skills (Griffin et al. 2012), and “competences,” as in “key competences” (EU Commission 2006) or lifelong learning competences (OECD 2005), are being used predominantly and interchangeably. The following working definition related to both skills and competences will be used in this chapter: “context-specific cognitive dispositions that are acquired by learning and needed to successfully cope with certain situations or tasks in specific domains” (Klieme et al. 2008, p. 9). Thus, the notion of competencies encompasses cognitive but also motivational, ethical, social, and behavioral components. It combines stable traits, learning outcomes (e.g., knowledge and skills), belief-value systems, habits, and other psychological features (Rychen and Salganik 2001). Conceptually, however, the field of future competences is unclear, because frameworks describing twenty-first century competences use the same concepts in different ways and sometimes use different concepts for the same phenomena.

The conceptual discussions about what skills are needed in the twenty-first century, and why, point back to OECD’s work with DeSeCo (the Definition and Selection of Competencies) during the end of the 1990s and the beginning of the 2000s, which has become important for curriculum development including the role of technology during the last decade. DeSeCo’s work was linked to the PISA study by the OECD in 1997. The strategy was that the PISA study would test and compare students’ knowledges and skills within defined subject domains in schools across different countries, while DeSeCo would address a broader set of competences related to “What competencies do we need for a successful life and a well-functioning society?” (OECD 2005, p. 3) and “knowledge and skills related to outcomes of education in a broad sense” (Salganik et al. 1999, p. 13).

These questions are further elaborated in key curriculum documents during the 2000s. There are four key meta-reviews which are relevant to the discussion in this chapter. These meta-reviews are Dede (2010), Binkley et al. (2012), Voogt and Pareja Roblin (2012), and Kereluik et al. (2013). Together these meta-reviews provide a systematic overview of the key concepts and international initiatives within this field. All together they cover 28 different frameworks from different parts of the world, about future competence needs and curriculum changes and numerous research articles. We will give a short summary of each meta-review.

Dede (2010): Comparing Frameworks for Twenty-First Century Skills

This meta-review was initiated by the American organization “Partnership for 21st Century Skills” (P21). The aim of this meta-review was to discuss the concept “twenty-first century skills” and explore differences and similarities between different frameworks. This meta-review is based on eight frameworks, where four of them explicitly deal with twenty-first century skills, while the other four deal more with information and communication technologies specifically. The framework developed by the “Partnership for 21st Century Skills” is defined as the most detailed and broadest in scope.

Dede (2010) emphasizes collaboration, increasingly done through digital media, and the ability to rapidly filter huge amounts of incoming data, extracting information valuable for decision-making, what he describes as “contextual” capability, to be important aspects of twenty-first century skills. Based on his review, Dede (2010) defines five key competence areas. These are core subjects, twenty-first century content, learning and thinking skills, ICT literacy, and life skills. In comparison to other frameworks, Dede emphasizes that core subjects and knowledge orientation are very important, particularly in relation to the need for deep learning.

Dede (2010) discusses several important issues and challenges in the way major frameworks for twenty-first century skills around 2010 were addressed. One important challenge is that the lack of professional development is a reason why twenty-first century skills are underemphasized in contemporary schooling, which is still relevant today. Another matter he points out is the overcrowdedness of the curriculum and that a major political challenge is to articulate what to deemphasize in order to make room for students to deeply master core twenty-first century skills. As a way of summary, Dede (2010) argues that the twenty-first century skills frameworks are generally consistent with each other in terms of what should be added to the curriculum:

The stress on what may be underemphasized, because those skills are inconsistent with current classroom culture, highlights a substantial challenge to infusing these 21st century skills frameworks into educational practice and policy. At this point in history, the primary barriers to altering curricular, pedagogical, and assessment practices are not conceptual, technical or economic, but instead psychological, political, and cultural. We now have all the means necessary to move beyond teaching 20th century knowledge in order to prepare all students for a future quite different from the immediate past. Whether society has the professional commitment and public will to actualize such a vision remains to be seen. (p. 68)

Dede makes an important contribution in his meta-review that has been followed up in later meta-studies and frameworks.

Binkley et al. (2012): Defining Twenty-First Century Skills

The background for this meta-review is the international project “Assessment and Teaching of 21st Century Skills” (ATC21S). Twelve different frameworks, both international and national, on twenty-first century skills are presented and discussed. As an introductory part Binkley et al. (2012) outline some tensions in the transformations our societies are going through, especially the impact of new technologies. This relates partly to changes in working life, with increased automatization and robotics, and partly to changes in the everyday lives of young people growing up in a rapidly changing media culture. They write:

No longer can students look forward to middle class success in the conduct of manual labor or use of routine skills – work that can be accomplished by machines. Rather, whether a technician or a professional person, success lies in being able to communicate, share, and use information to solve complex problems, in being able to adapt and innovate in response to new demands and

changing circumstances, in being able to marshal and expand the power of technology to create new knowledge, and in expanding human capacity and productivity. (Binkley et al. 2012, p. 17)

The important input from this meta-review is the definition of key concepts and the operationalization of what each implies for pedagogical practice. They group and define the key concepts as:

- *Ways of Thinking*: (1) Creativity and innovation; (2) critical thinking, problem-solving, decision-making; (3) learning to learn, metacognition
- *Ways of Working*: (4) Communication; (5) collaboration (teamwork)
- *Tools for Working*: (6) Information literacy; (7) ICT literacy
- *Living in the World*: (8) Citizenship (local and global); (9) life and career; (10) personal and social responsibility – including cultural awareness and competence

Each of these concepts is then linked to specific knowledge, skills, attitudes, values, and ethics, in what has been defined as the KSAVE model. Since these competences are specified and operationalized, they provide a good foundation for measuring and evaluating these competence areas related to both research and practice. Based on this model the authors argue that:

New conceptions of educational standards and assessment ... are a key strategy for accomplishing the necessary transformation. Such standards and assessment can both focus attention on necessary capacities and provide data to leverage and evaluate system change. Technology too serves as both a driver and lever for the transformation. (Binkley et al. 2012, p. 18)

And the assessment system as a key part of the curriculum is considered the most important element in making the transformations needed.

Voogt and Pareja Roblin (2010, 2012): A Comparative Analysis of International Frameworks for Twenty-First Century Competences – Implications for National Curriculum Policies

This meta-review of conceptual frameworks about twenty-first century skills compared underlying rationales and goals, definitions of twenty-first century competences, and the recommended strategies for the implementation and assessment of these skills in educational practice. Voogt and Pareja Roblin included five frameworks, namely, Partnership for 21st Century Skills (P21), En Gauge, Assessment and Teaching of 21st Century Skills (ATC21S), National Educational Technology Standards (NETS/ISTE), and the National Assessment of Educational Progress (NAEP) in their review. In addition, three international studies were examined to analyze how supranational organizations (key competences, EU; DeSeCo, OECD and UNESCO) deal with twenty-first century competences.

In the review 32 documents were analyzed; they are mainly working papers, international standards for ICT competences, and reports from international studies.

The aim was to identify key issues across frameworks and come up with strategies and recommendations on how to support the implementation of twenty-first century skills (Voogt and Pareja Roblin 2010). Travers and Westbury's framework (1989) of the intended, implemented, and attained curriculum was used to identify differences between frameworks (horizontal consistency) and alignment between intentions and realizations (vertical consistency). The findings indicate a large extent of alignment between the frameworks about what twenty-first century competences are and why they are important (horizontal consistency), but intentions and practice seemed still far apart, indicating lack of vertical consistency. The study led to several recommendations to support the implementation of twenty-first century competences curricula:

- To be able to design learning trajectories that support the acquisition of twenty-first century competences, operational definitions – in terms of knowledge, skills, attitudes, and values – of twenty-first century skills are needed as well as indications of what can and should be attained by students of different ages and across educational levels.
- Opportunities for learning twenty-first century competencies in core subjects need to be identified. In addition interdisciplinary themes, to be addressed within and across subjects, may help to make the connections between the twenty-first century competencies stronger. Because the interdisciplinary themes are dynamic and in continuous change, they may reflect contemporary societal issues and can foster learning that is adjusted to the needs of the current society.
- To assure learning about and learning with information and communication technologies digital literacy competencies should be embedded in the curriculum.
- Twenty-first century competences are not only learned in schools but also at the workplace and in informal learning settings outside the school. To support the learning of twenty-first century competences, strategies to closely link what is learned in and outside the school should be developed.
- Simultaneously with the development of curricula that include twenty-first century competences, strategies need to be defined that facilitate the implementation and assessment of twenty-first century competences.

Kereluik et al. (2013): What Knowledge Is of Most Worth – Teacher Knowledge for Twenty-First Century Learning

The main objective of this meta-review is to identify important areas and recommendations across different twenty-first century learning frameworks that can say something about types of knowledge that are emphasized. The authors review 15 reports, books, and articles and look at methods used in the different frameworks. In comparison to other meta-reviews, this article offers a more critical review of the literature on twenty-first century knowledge frameworks, with a particular focus on what this means for teachers and teacher educators.

The title of the article alludes to the classical curriculum question of what knowledge is of greatest worth at a time of flux and change. The authors argue

that seemingly disparate frameworks converge on three types of knowledge, as necessary for the twenty-first century: foundational, meta, and humanistic. Although twenty-first century frameworks are thought to advocate new types of knowledge, little has actually changed in the new century with respect to the overall goals of education. Despite this sense of continuity, significant changes related to how technologies change all three types of knowledge need to be conveyed.

As a summary they argue that “though the manner in which we represent knowledge and act upon it may change, the core idea of what we do as educators has not” (Kereluik et al. 2013, p. 133).

Looking across these four meta-reviews, it is interesting that all emphasize three main categories of competences: foundational, meta, and life. Digital competence, as we will discuss in more detail below, is defined as key for all competencies as well as an important competence area in itself. The main competencies across different frameworks are collaboration, communication, ICT literacy, and social and/or cultural competencies including citizenship, as well as creativity, critical thinking, and problem-solving. The differences across frameworks are mainly about ways of categorizing these competencies and about the relationship between the more generic and transversal competencies and foundational knowledge and the core subjects.

A basic tension is the relation between twenty-first century competences and core knowledge domains, often related to the discussion whether “know-how” is nowadays more important than “know-what.” The argument put forward is that most knowledge that has to be learned at school – as prescribed in the curriculum – is likely to become outdated very quickly in today’s world (Williamson 2013). Young (2008) opposes to this argument and advocates the necessity to “bring knowledge back in” schools. He introduced the concept of powerful knowledge emphasizing the importance of disciplinary knowledge in the curriculum as opposed to everyday knowledge. He argues that powerful knowledge is needed to foster deep learning. At first sight these two positions seem incompatible, but McEneaney (2015), while showing how the Internet can be used for learning, offers a more subtle view when she argues that “in recognition of the existence, elaboration and wide accessibility of the Internet, curricula need to differentiate between comprehension and familiarity, with teacher-led support for querying and expert curation of virtual spaces as the surest connection to specialist communities and powerful knowledge for the next generation of learners” (p. 817).

New Technologies in the Curriculum

Moving from these broader meta-reviews of twenty-first century skills, we now turn to more specific issues of the role of new technologies in these recent curriculum developments. What is interesting is to look at the role of technology in the curriculum as learning with, through, and about new technologies. Technology is considered key for realizing twenty-first century curricula.

First, technology as a social factor is embedded in the preconditions and arguments for new curriculum developments, as mentioned earlier in this article, since our societies are becoming more and more digital in all facets of social life.

Second, technology is defined as a tool that can support the acquisition and assessment of twenty-first century skills (Voogt and Pareja Roblin 2010). What is important across the frameworks, referred to in the meta-studies above, is that technologies are not only linked to specific skills, but relate to all of them as an important skill in a technology-saturated society. For example, technological developments increase the need for skills in self-regulated learning (Kereluik et al. 2013). Also, this draws on research and development work on how different technologies can support knowledge work in different domains and strengthen different skills among students (e.g., Eseryel et al. 2014; Lee et al. 2010). In the “Assessment and Teaching of 21st Century Skills” initiative (Griffin et al. 2012), one of the main focus areas was about how technologies are linked to assessment of such skills. The argument is that technology holds the potential of changing educational assessment, especially toward formative assessment methods, and thereby supporting development of important skills for the twenty-first century. More recently there has been a movement in many countries toward including issues of “coding” and “computational thinking” as part of curricula for schools (see also ► Chap. 7, “Computer Science and Computational Thinking in the Curriculum: Research and Practice” by Yadav, Sands, Good, and Lishinki).

Third, a factor of growing importance for curriculum development is the growth of a new skills area presented as “digital literacy,” “ICT literacy,” or “digital competence.” In all the reviews referred to above, this has become part of curricula in different countries. As a skill it has moved from the periphery of the curriculum, as part of media education programs and skills in programming software for computers, to the core of the skills agenda addressing twenty-first century challenges (Erstad 2013). There are different definitions of such literacies or competencies, but most of them cover abilities to handle information in critical ways, to communicate/collaborate, and to create, as shown in this definition: “To be digitally literate is to have access to a broad range of practices and cultural resources that you are able to apply to digital tools. It is the ability to make and share meaning in different modes and formats; to create, collaborate and communicate effectively and to understand how and when digital technologies can best be used to support these processes” (Hague and Payton 2010, p. 1). Efforts have also been made to develop tests that could measure this skill and how it progresses among students, on both national and international levels, like the ICILS study (see also ► Chap. 6, “Students and Their Computer Literacy: Evidence and Curriculum Implications” by Ainley). In addition, digital citizenship, or what some countries term as “digital bildung” (Erstad 2013), has become increasingly important linked to democratic participation in social and cultural practices of importance for oneself and others, as well as ethical aspects of technology use (see also ► Chap. 5, “Digital Citizenship and Social Media: A Curriculum Perspective” by Law, Chow, and Fu).

In a meta-study of digital competence initiatives (Ferrari 2012; Ferrari 2013; Ferrari et al. 2014), covering 15 frameworks, the common elements of digital competences were defined as: “the set of knowledge, skills, attitudes (thus including abilities, strategies, values and awareness) that are required when using ICT and digital media to perform tasks; solve problems; communicate; manage information; collaborate;

create and share content; and build knowledge effectively, efficiently, appropriately, critically, creatively, autonomously, flexibly, ethically, reflectively for work, leisure, participation, learning, socialising, consuming, and empowerment” (Ferrari et al. 2014, p. 2). This study shows that the majority of frameworks on digital competence are based on skills development and on the ability to use a specific set of tools and/or applications. However, the recommendation is that the ability to use specific tools or applications is just one of the several competence areas that need to be developed by users in order to function in a digital environment. Further, this study concludes that:

It should, however, be said that the identification and description of competence areas is a first step towards the development of learning objectives. As the analysis in this report shows, different frameworks do not necessarily translate the same competence area into the same learning outcomes. As a matter of fact, a huge difference can be seen between cognitive approaches and application-oriented frameworks. Several frameworks of the latter type tend to apply operational skills to each area. We therefore suggest that, apart from the competence area “technical operations”, competences should not be centred on a tool-oriented perspective only. (Ferrari et al. 2014, p. 13)

Fourth, in order to better serve the diversity of students, technology can also be used to tailor the curriculum to individual learners’ personal learning trajectories. A tailor-made curriculum may refer to different aspects of curriculum such as place, pace, level, and goals of learning. Technology is seen as indispensable to realize such personal learning trajectories. Bray and McClaskey (2013) distinguish between three different forms of a tailor-made curriculum. Individualized learning trajectories refer to a curriculum in which learners can learn in their own pace using adaptive technology applications. Differentiated learning trajectories point to matching instruction to pupils’ learning needs. With technology it is easy to provide students with scaffolds that support the way students learn (e.g., Devolder et al. 2012). Personalized learning trajectories relate to a curriculum that is tailored to students’ preferences and interests. The virtual high school (Roblyer 2008) is an example as it offers students opportunities to choose their own curriculum components on top or instead of regular education. However, far-reaching forms of individualization of the curriculum may be contrary to another important function of curriculum, viz., the need to prepare all students for living and contributing to a democratic and coherent society (► Chap. 5, “Digital Citizenship and Social Media: A Curriculum Perspective” by Law et al. in this Handbook).

Implementation Issues and Change Forces

Only a few frameworks explicitly deal with more practical issues related to implementation and assessment. Those frameworks that do address such issues refer to three critical factors in the implementation of twenty-first century skills: (1) the integration of the skills in the curriculum, (2) the need for professional development, and (3) the involvement of stakeholders from various sectors. In addition, the adoption of new

assessment models in line with the cross-curricular and complex nature of twenty-first century skills is regarded as crucial to ensure the implementation of these skills.

A critical factor is how curricula get implemented within education systems and the implications they have on educational practices. In their meta-review, Voogt and Pareja Roblin (2012) emphasize that “most frameworks recommend integrating 21st century competences across the curriculum due to its complex and cross-disciplinary nature” (2012, p. 310). The point is that all frameworks demand changes in the curriculum, both in ways of restructuring the curriculum and new teaching methods to provide for the growth of such skills and assessment procedures.

Law (2009) found, in data from the international Second Information Technology in Education Study (SITES), that although many teachers reported to have curriculum goals that were in favor of twenty-first century competences, they did not apply them in classroom practice. This finding aligns with findings of Voogt and Pelgrum (2005) who studied international case studies of innovative pedagogical practices using technology in schools and found that only a minority of schools had adopted a curriculum that facilitated students’ acquisition of twenty-first century competences. These schools had restructured their school to realize the curriculum. Using technology was essential in the new structure and had become a routine for teachers and students. As we know from research on innovative practices using technologies in schools, there are challenges in most countries of scaling up from single schools and classes to whole education systems (Kozma 2003; Dede et al. 2005). The introduction of frameworks on twenty-first century skills and key competences might help to facilitate scaling of twenty-first learning in schools. Curricula that are developed now are more specific in the way technologies are embedded both in general ways as preconditions and levers for change and as new conditions for knowledge work among students and teachers. The challenges of implementing new frameworks and curricula in educational practices include:

- Access to and availability of different technologies in schools, which is still lacking in many countries
- Way to prevent curriculum overload to be able to give more space to the learning of twenty-first century competencies (Voogt et al. 2017)
- Ways in which the new frameworks are presented as new sets of skills, while many of them are also known from former curricula but redefined in the context of twenty-first century challenges (Dede 2010; Kereluik et al. 2013)

The second issue concerns the role of teachers and their professional development. The key role of teachers in the implementation of curriculum is widely documented in research (Fullan 2007; Liebermann and Pointer Mace 2008). In many ways the twenty-first century competences pose pedagogical challenges for teachers – in their own abilities in these skills, in using various methods with students, understandings of subject content and interdisciplinary content orientation develop technology-enhanced learning environments and ways of using a variety of assessment tools. There are similar challenges for teacher education institutions in developing professionalism around such skills and competences for pre-service teachers (Voogt and Pareja Roblin 2012).

The third issue is related to the involvement of stakeholders in the decision-making process of curricula for our current societies. This points to the complexity of the curriculum design process, or as Karseth and Sivesind (2010) state “curriculum is about meaning-making and negotiation among different actors in different positions” (p. 114). Stakeholders from the public, educational, and private sectors want to have a say about the curriculum and exert their influence on what is being taught in schools. In order to monitor the process of meaning making and negotiation, Davis, Eickelmann and Zaka (2013) advocate an ecological approach to guide change processes, including curriculum, in education systems in which actors in- and outside the system are recognized and codesign. Increasingly technology plays its role in the process of meaning making and negotiation about new curricula, either planned, with the intention to share, be transparent, and offer ample opportunities for active involvement (Nieveen et al. 2014), or unplanned in which proponents and opponents of change actively discuss and influence the decision-making process through applications such as Twitter (Supovitz et al. 2015).

Several studies have shown that assessment is still one of the weakest points in many country’s efforts to integrate twenty-first century competences in the school curricula (Ananiadou and Claro 2009; Gordon et al. 2009). For example, Gordon et al. (2009) identified four different approaches to the assessment of key competences across 27 Member States from the European Union: (a) assessment of cross-curricular competences explicitly, (b) assessment of cross-curricular competences implicitly, (c) assessment of subject-specific competences, and (d) assessment of knowledge rather than competence. While the first two approaches show some progress in the assessment of twenty-first century competences, the other two were more common across most countries participating in the study, revealing that the need to assess these competences is not yet fully acknowledged in many countries (Voogt and Pareja Roblin 2012).

Toward Twenty-First Century Curricula: Perspectives

In a recent project, called “KeyCoNet,” the implementation of the European eight key competences was studied. The “Key Competence Network on School Education” (KeyCoNet 2012–2014) (Ola Erstad was part of the research team of this project), organized by European Schoolnet, was a European policy network focusing on identifying and analyzing initiatives on the implementation of key competences in primary and secondary school education. It was a network of more than 100 members from 30 countries including Ministries of Education/related agencies, universities/research institutes, European organizations, and practice related partners. The aim was “to analyse and map emergent strategies in implementing key competences in education across Europe, and to develop recommendations to strengthen policy and practice in different country contexts” (Looney and Michel 2014, p. 4). This was done by different exercises such as case studies from different countries, transversal analysis of the KeyCoNet case studies, mapping of initiatives, several literature reviews, country overviews, and peer learning visit reports.

The conclusions from this project indicate that on the policy level “no country has made a complete shift toward competence-based education” (Looney and Michel 2014, p. 14) but that many countries had made significant progress. The strategies used were on different levels and targeting different factors for change such as legal frameworks for key competences, elaborating and operationalizing competence-based curricular frameworks, new and innovative partnerships, dedicated funding, capacity building, and monitoring and evaluation of new initiatives (Looney and Michel 2014). Further, the principles for effective school implementation and practice that emerged from the KeyCoNet case studies included a central focus on teaching, learning and assessment, effective communication with stakeholders, engagement with the broader community, school plans that incorporate key competences, and evaluation of progress. The theme of collaboration and engagement runs throughout these principles.

There are large differences between countries concerning the implementation of new frameworks within twenty-first century curricula and practices in schools. Concerning digital competencies specifically, there are a few countries where this has been addressed explicitly in national curricula. For example, in 2006, Norway was among the first countries in the world to define digital skills/competencies as one of five key competences traversing all subjects and levels of compulsory schooling (the other four being reading, writing, numeracy, and oral skills/competencies). This has been implemented in all schools through strategies and plans following up on the curriculum. In 2016 this was followed up with national strategies on the future of Norwegian schools emphasizing deep learning and a few competencies following different international frameworks on twenty-first century skills and key competencies. Similar developments have recently been implemented in Finland, where the European framework of key competencies has been the foundation of a new national curriculum. Of special interest for our discussion in this article is the emphasis on multiliteracies and coding as traversal skills/competencies that all Finnish students have to engage with, as related to technological developments and what is defined as new competences emphasized in the national curriculum.

Currently the OECD2030 Future of Education and Skills study is working on a follow-up of DeSeCo’s work (see <http://www.oecd.org/edu/school/education-2030.htm>), which involves more than 20 countries. The Learning Compass that is being developed has as its core mission that learners need to “Being able to navigate in time and social space, to manage their lives in meaningful and responsible ways by influencing their living and working conditions” (see link above). In addition data are collected with the aim to analyze how countries cope in their curricula with the challenges of twenty-first century societies. The results of the analysis are expected by the end of 2018.

As a way of concluding about the perspectives on new curricula on twenty-first century skills and competencies, the few studies that have been done show that many countries are in the process of changing their curricula to adapt to twenty-first century challenges. However, countries are nevertheless at very different stages in terms of integrating key competences and skills in curricula, engaging stakeholders, and in investing in teacher and school capacity.

The Future of the Curriculum in the Digital Age

In this chapter we have presented some perspectives on the curriculum in times of rapid change addressing twenty-first century challenges. On a fundamental level, such evolving perspectives on education and the curriculum in the twenty-first century raise questions about the models we have been using and whether they are appropriate to deal with the societal changes that we are experiencing. In order to explore this further we need to deal with questions and issues like:

- How the integration of twenty-first century skills/competences in the curriculum changes the what and the how of what is being taught at schools?
- What the implementation of twenty-first century skills demands from teachers, students, administrators, and educational leaders?
- How different educational contexts – beyond the formal education system – support the acquisition of twenty-first century skills?
- How ICT can contribute to bridge formal and informal educational contexts?
- What specific types of support teachers and schools need to facilitate the acquisition of twenty-first century skills?
- To what extent are teachers and students prepared to adopt the new forms of assessments demanded by twenty-first century skills?
- We propose that these questions should be addressed in a public debate about the implementation of twenty-first century skills.

It is important to remember that the novelty of twenty-first century competences is questionable. Competences such as problem-solving and critical thinking have always been associated with key objectives of education (Voogt and Pareja Roblin 2012: 316). This point might actually help in working with teachers and teacher education institutions in convincing that this is not a matter of replacing the old with something completely new. Teachers have for a long time been dealing with several of the key competencies mentioned in recent frameworks. What is new is the way they are contextualized and emphasized. For example, by stating that the way curricula have developed in most countries they have become overcrowded with content in all subject areas. Ways of deemphasizing and taking out content from the curriculum is a major political challenge. The same goes for changes in the assessment system that has to be done in order to assess these competences and skills that are not measurable by high-stakes tests the same way as regular cognitive skills of memorization and reproduction of content knowledge are. These aspects to the education system are important to reevaluate in order to make room for students to deeply master core twenty-first century understandings and performances. The demands are also related to the professional development of teachers to provide for the development of such competences in technology-enhanced learning environments.

Still, there are important issues and challenges in these developments that make us reflect on more fundamental transformations in moving from the twentieth to twenty-first centuries, especially when exploring the role of technological developments. As Dede (2010) has pointed out, “current approaches to using technology in schooling largely reflect applying information and communication technologies as a means of

increasing the effectiveness of traditional, 20th century instructional approaches” (pp. 8–9). The disruptive innovations that have happened in different sectors of society (see <http://www.claytonchristensen.com/key-concepts/>) have not manifested itself within the regular school systems, as manifested in the disruptive expectations with Massive Open Online Courses on higher education. This is still a major challenge in the ways ICT is implemented and used in most schools around the world.

Several of the recommendations stated in existing frameworks on twenty-first century competences express some of the decisions that need to be done, like: “defining goals and standards in national documents regulating the curriculum, embracing a powerful vision, encouraging collaboration between different sectors, building on already existing work and focusing on what is ‘do-able’, ensuring equitable access to education in present and future society, stimulating teacher collaboration, creating learning environments that enhance competence development, and aligning assessment methods and goals” (Voogt and Pareja Roblin 2012, p. 312).

Further, related to curriculum development, we might need to develop new metaphors to guide us in moving toward school systems framed by twenty-first century competencies. In his writing on this, Williamson (2013) has developed what he terms “centrifugal schooling” (2013, p. 7). By this he means:

Centrifugal schooling expresses a vision of the future of education and learning that is decentered, distributed, and dispersed rather than narrowly centered, channeled, and canalized. ... Recast as a response to these technological changes, the kind of prototypical curriculum of the future associated with centrifugal models of schooling may be imagined as a more “open source” process rather than a fixed product, as embodied in the “wiki” format of open authorship, collective editing, and collaborative production. Crudely caricatured, the traditional centered curriculum was a curriculum based on a standardized mass-production model of “reading” that positioned teachers as broadcasters and learners as receivers, as embodied by school textbooks. In comparison, the decentered curriculum is a post-standardized, mass-customizable “read-and-write” curriculum that repositions teachers and learners as peer-to-peer producers, participative authors, and active creators of curriculum content, processes, and outcomes in a distributed meshwork of joined-up learning. (pp. 7–8)

These metaphors of the curriculum as more open, network-based, and process-oriented are interesting as a way of creating new models directly adjusted to the needs of learning in the twenty-first century.

Abstract

This chapter explores the implications of a new literacies perspective for literacy research and practice, focusing on two specific challenges. First, it explores the challenges posed by the increased need to critically evaluate online information. With a diverse set of voices online, the absence of traditional gatekeepers requires an especially sophisticated level of critical evaluation by every reader and thus challenges each of us to read and think more critically. The new chapter addresses perspectives on critical evaluation in online environments, the importance of critically evaluating online texts, and the instructional implications of recent research in this area. Second, it explores challenges posed by the effective use

of collaborative online learning projects that cross national and cultural borders. Today, schools are challenged to prepare students who can navigate and participate in a global society. The chapter addresses recent initiatives in online learning, the need for new literacies for successful global communication and collaboration, and the instructional implications of global collaborations. Developing critical users of information who can also interact with others on a global scale requires a focused commitment of schools to ensure that online information is integrated into the literacy and learning curriculum in effective ways.

New Literacies: Curricular Implications

Today, new information and communication technologies continuously appear online, creating additional opportunities and challenges for the education of students in primary and secondary grades. In recent years, one response to these developments has been the “new literacies movement” with its focus on how the nature of reading and writing is changing due to technological developments and how we might integrate these changes into the curriculum in effective ways. This chapter will explore the implications of a new literacies perspective for a better understanding of literacy as well as literacy research and practice. It will begin with a brief theoretical definition of new literacies. It will then focus on two of the challenges that have become especially important to literacy and learning with online information: the critical evaluation of information and the effective use of collaborative online learning projects that cross national and cultural borders.

New Literacies and the Challenge of Change

We have entered a period in which the nature of literacy has become deictic (Leu 2000) as the Internet makes rapid, online distribution of new technologies for literacy possible. New technologies add additional dimension to literacy, requiring additional literacy practices, skills, strategies, and dispositions to fully benefit from online information (Lankshear and Knobel 2011). Moreover, these additional social practices, skills, strategies, and dispositions themselves change and initiate the development of additional online technologies for literacy. In short, continual change now defines literacy.

Continual change in the nature of literacy presents an especially problematic conundrum for research and theory. How do we study literacy when it continually changes? By the time we have a sufficient body of research in any set of new literacies, the nature of the technology on which the research is based has likely

changed, sometimes in subtle and sometimes in important ways. In short, the speed of change in technologies, and on the literacy practices they engender, is often faster than we can keep up through careful research.

To respond to the conduct of research during a time when literacy rapidly changes, a dual-level theory of new literacies has been proposed to include both lowercase new literacies and uppercase New Literacies (Leu et al. 2013). Lowercase theories explore a specific Internet technology, such as text messaging, or a focused disciplinary base, such as the semiotics of multimodality in online media or gaming. As such, research based on lowercase theories is able to stay more closely in touch with rapid changes taking place in specific technologies. Common findings across multiple lines of lowercase research may then be integrated into a broader, uppercase theory of New Literacies. This uppercase theory is likely to be more stable since it only includes those elements common across the landscape of many, continuously changing technologies.

Reciprocity defines the relationship between the two levels. The greater stability of New Literacies theory provides theoretical direction to inform the design of studies in rapidly changing contexts at lowercase levels, while the greater sensitivity to change at multiple, lowercase levels helps to identify those common, and more stable, elements for the uppercase level. One important aspect of all of these new literacies is that they enable us to read, communicate, and learn with the nearly unlimited information that is now available online.

One of these lowercase new literacies is used to frame this chapter, the new literacies of online research and comprehension. The new literacies of online research and comprehension seek to describe what happens when we read online to learn (Leu et al. 2013). It defines online reading as a process of problem-based inquiry using information on the Internet. It includes the skills, strategies, dispositions, and social practices that take place as we read online information to learn. During online research and comprehension, readers construct texts, meaning, and knowledge while engaged in several online reading practices: reading to identify important problems, reading to locate online information, reading to critically evaluate online information, reading to synthesize online information, and reading and writing to communicate online information. Online research and comprehension is not limited to lengthy and formal research projects. It also includes shorter tasks when one needs to know the answer to a question such as “When was Abraham Lincoln born?” or “What is the easiest way to get to central London from Heathrow?” Information queries, both large and small, initiate online research and require the use of new technologies to read, comprehend, and learn.

The ability to read and learn with online information is essential for full participation in today’s society (Organisation for Economic Co-operation and Development [OECD] 2011), but our students are not especially skilled at reading and learning from complex, online information (Kuiper and Volman 2008). Although today’s students live in an online world and are developing skills in gaming, social networking, video creation, and texting, research is showing how limited students’ skills are with online reading, especially with critically evaluating

online information (e.g., Forzani 2015; Walraven et al. 2008). Many students find it difficult to judge the accuracy, reliability, and bias of information that they encounter during online research (Kiili et al. 2008; Kuiper and Volman 2008; Leu et al. 2015). In fact, adolescents overgeneralize their ability to read and evaluate online information effectively, a perception informed by their ability to engage successfully with online social networking, texting, and video games (Kuiper and Volman 2008).

Online reading also presents special challenges in relation to income inequality, according to data from the United States. A separate achievement gap appears to exist for online reading, independent of the offline reading achievement gap (Leu et al. 2015). Yet, current assessments only measure offline reading ability. Since reading now takes place in both offline and online contexts, the reading achievement gap is likely to be greater than we currently recognize. If we are to address an achievement gap that is larger than national assessments suggest, it becomes essential to develop interventions that support proficiency with online reading so that we can provide teachers with the effective new tools they require.

There is also another important challenge. As online experiences push the world closer together, we must begin to consider how we can take advantage of this opportunity to prepare youth to learn from others around the world and benefit from the advantages that diversity provides. Online learning projects, between students and classrooms in different parts of the world, enable students to develop a more complete understanding of the differences that define our world as well as ways those differences may be used to enrich literacy and learning. Increasing students' global awareness, developing a richer understanding of global citizenship, and improving students' ability to work collaboratively with others, across national and cultural contexts, are beginning to become important new curricular objectives.

These issues are especially important because we have just reached a tipping point for literacy. As we write this chapter, 50% of the world's population has Internet access (Internet World Stats: Usage and Population Statistics 2017), a figure that continues to rapidly grow. This singular development carries profound implications for literacy and the literacy curriculum. If the Internet adoption rate continues to increase at the current rate, all, or nearly all, of the world's population will have access to online information within 10 years (UNESCO 2014). Thus, children who are just beginning formal schooling today will enter a ubiquitous world of online information when they graduate from secondary school. This makes it essential that they be prepared, at an early age, for online reading.

In every nation, the literacy and learning curriculum will have to radically change if we are to accomplish this preparation (Kervin et al. *in press*). We argue that two lowercase areas are particularly important: the critical evaluation of online information and the effective use of collaborative online projects that cross national and cultural borders. This chapter will explore both of these areas. Developing a better understanding of each will help us to respond to the challenges of the changing landscape of literacy in primary and secondary classrooms today.

The Critical Evaluation of Online Information

The first challenge we face with greater access to the Internet is developing the skills needed to evaluate online information. Reading online information requires an even greater degree of scrutiny, as recent events regarding “fake news” suggest (see Stanford History Education Group 2016). It is particularly essential, therefore, that students become skilled at evaluating online information to become better online readers. Students need these skills for personal and professional knowledge, decision-making, and problem-solving both while they are in school and throughout their lives. Without them, we risk students making decisions based on misinformation. This can have significant negative consequences both for individuals and for society.

Perspectives on critical evaluation in an online context. Critical thinking has long been an area of interest for teaching and learning. Critical thinking, for example, was a central aspect of Socrates’ instructional practice. In the “Socratic method,” a teacher questions a student to aid the student in deeply questioning the credibility of information, even when the information comes from an “authority.” Students are taught to identify underlying assumptions before accepting information as true. Later on, Aristotle also was interested in credibility. Metzger and Flanagin (2013) point out that Aristotle’s writings on rhetoric addressed three aspects of credibility: *ethos* (appealing to an audience using the character of the speaker), *pathos* (appealing to an audience using emotion), and *logos* (appealing to an audience using logic or reason). The author’s qualifications, the author’s emotions and biases, and the logic of an author’s argument are still the essential tools we use to investigate information credibility today.

Recently, policymakers have focused attention on teaching students to approach text critically (see, e.g., Australian Curriculum, Assessment and Reporting Authority n.d.), emphasizing critical thinking skills above simply learning facts. While there is some debate over whether critical thinking requires additional skills in an online environment or whether it requires the same skills used with greater frequency (Metzger and Flanagin 2013), the importance of critical thinking skills is heightened in an online environment, where credibility varies greatly.

Judd et al. (2006) define credibility as the expertise and trustworthiness of the source of information. This includes the accuracy, or reliability, of the information (Kiili et al. 2008). The more credible a source is, the more likely it is to contain accurate information. Here, we define the critical evaluation of online information as the process of evaluating the accuracy of online information. This includes evaluating two main aspects of credibility: knowledge claim credibility and source credibility (Forzani 2016). Knowledge claim credibility refers to the credibility of the information itself, including the logic of the argument and the quality of the evidence used to support that argument. Source credibility refers to the credibility of the source of the information, such as author or publisher, and includes questioning and assessing authors’ biases, assumptions, and points of view. Highly effective evaluation involves evaluating both aspects of credibility in order to fully evaluate the accuracy of information.

The importance and difficulty of critical evaluation in an online environment. The importance of critically evaluating texts is especially relevant in an online environment, where there are few vetting processes compared to an offline environment. In an offline environment, texts typically undergo scrutiny from editors, publishers, and even sellers before arriving in readers' hands. In an online environment, however, there are few checks such as these. Moreover, there are few uniform standards for publishing in an online environment (Metzger and Flanagin 2013), and many sources are commercially biased (Flanagin and Metzger 2010). This results in information of varying degrees of credibility. Thus, critical thinking skills are especially important in an online environment, where effective research hinges on a reader's ability to evaluate information accuracy and reliability (Goldman et al. 2012).

Unfortunately, today's youth are particularly challenged by the changes to literacy with respect to the critical evaluation of online information. In a recent study, fewer than 4% of students successfully completed all four tasks required to read and evaluate the source reliability of a single website (Forzani 2015). Another study showed that seventh-grade students performed successfully on only half of the items required to read and complete an online research task (Leu et al. 2015). A report from the Stanford History Education Group (2016) revealed that most middle school students in a study in the United States did not know when news was "fake" and that 82% of them could not tell the difference in an advertisement labeled with the words "sponsored content" and a legitimate news story. Finally, in a study by the eSeek Project at the University of Jyväskylä in Finland, fewer than 20% of 12- and 13-year-olds could recognize bias at a commercial website on energy drinks (Kiili et al. 2017).

Many students do not question the accuracy of online information (Zhang 2013) and do not critically evaluate websites when reading online (Kiili et al. 2008). When students do attempt to employ online critical evaluation skills, they often fail to do so effectively. Many students tend to use surface level cues alone to help them determine the accuracy of information or have misconceptions about how to evaluate sources (Coiro et al. 2015). Eastin et al. (2006), for example, found that third, fourth, and fifth graders were not skilled at judging the reliability of online sources and often based their evaluations on superficial or irrelevant cues. Students in this study viewed websites with more graphics as more credible than websites with fewer graphics. Moreover, younger adolescents often overestimate their abilities to critically evaluate online information (Flanagin and Metzger 2010). This may mean that students are less aware of the skills they need to obtain in order to read online effectively and thus may be less likely to acquire these skills.

Online critical evaluation in science and civics. Arguably, two of the most important areas today for the use of critical evaluation skills online are in the disciplines of science and civics. Science has become a priority for many nations (OECD 2016), and much scientific information is found online. It is also increasingly important for students to understand basic scientific concepts, so they can acquire information useful for a wide variety of personal issues, such as researching health issues on the Internet (Stadtler and Bromme 2014) or gathering

information about science-related controversies that impact their lives (Zeidler 2009). Students also need to understand basic scientific concepts if they plan to pursue a career in science.

Critical evaluation is a particularly important skill for learning during online inquiry in science (Goldman et al. 2012; Wiley et al. 2009). Scientific information is often inconsistent and conflicting (Longino 2002), a problem that is compounded by the Internet (Stadtler and Bromme 2014). Thus, in an online environment, the ability to evaluate the credibility of scientific information is even more important than in an offline environment. Without the ability to evaluate the credibility of information, students may develop misconceptions about science (Wiley et al. 2009), which may make it difficult for students to develop accurate understanding later on.

Several studies of secondary and college students have found that students are not especially skilled at critically evaluating online information in science, specifically. Halverson et al. (2010) found that students mostly used websites that were easily accessible and website evaluation criteria that were focused on superficial features rather than on website content. The researchers concluded that students did not engage in much evaluation of websites and, when they did, were not especially skilled at evaluating. Even when students know about evaluation strategies, they may not use this knowledge in practice (Hogan and Vernhagen 2012). Research on undergraduate students reading information in science has found that while students may be aware of source information, they may not use this when evaluating credibility (Strømsø et al. 2013).

In addition to understanding science, understanding civics is also a highly important educational area for many nations (see, e.g., U.S. Department of Education 2012). Students need to be able to understand social and political issues that affect them on personal, societal, and professional levels in order to be engaged citizens. Moreover, when people fail to evaluate the credibility of online information, it is easy for disinformation to spread, jeopardizing democracy (Stanford History Education Group 2016). In an online environment, readers are particularly susceptible to finding misleading information since there is a great deal of bias involved in reporting political issues and since these issues are often reported in news media, some of the most ubiquitous online information sources.

Instructional implications of research in online critical evaluation. The growing body of research in online critical evaluation has demonstrated the importance of online critical evaluation skills for comprehending information across multiple texts, as during Internet research (Braten et al. 2009). Unfortunately, many students are not especially competent in this area (Forzani 2016; Goldman et al. 2012; Stanford History Education Group 2016), highlighting the need for instruction aimed at teaching students effective critical evaluation skills. Importantly, students of varying ages lack the ability to judge the relevancy and credibility of search results (Brand-Gruwel and Gerjets 2008). This is problematic, since the ability to do so is a gatekeeping skill for evaluating the credibility of online texts, as students must first navigate to online texts by selecting them from a list of search results. Thus, instruction should begin with teaching students how to effectively evaluate the

potential relevancy and credibility of search results. However, it is important to keep in mind that students may learn evaluation strategies best when they have the opportunity to engage with these skills within the context of a larger research task (Walraven et al. 2008).

Research also has begun to identify particular areas of weakness for students on which teachers should focus during instruction. Students need to think beyond the “face” of the text. Rather than merely looking at surface level clues, such as the quantity of information (Wallace et al. 2000) or the design of a website, students need to investigate the quality of the information itself, including the logic of arguments and the quality of evidence (Forzani 2016), as well as the trustworthiness and credibility of the source of the information (Goldman et al. 2012). In doing so, it is important for students to assess multiple aspects of a website rather than using just one piece of evidence to evaluate information credibility (Coiro et al. 2015).

Lessons on critically evaluating information can be an integrated part of the science and social studies curricula, grounded in the needs of the discipline. Different disciplines, including science and civics, have different needs and values (Shanahan and Shanahan 2008). As a result, different disciplines use critical evaluation skills in different ways (Shanahan et al. 2011). Students need to learn ways of investigating credibility specifically for a given discipline and within an online context. For example, evaluating a news article reporting on federal laws and policies involves somewhat different skills and strategies than does evaluating an article reporting on a scientific study. Moreover, evaluating the credibility of an article reporting on federal laws and policies in an online environment is likely to include additional skills compared to evaluating an article found in an offline environment. Teaching students ways of evaluating information credibility within different disciplines and within online contexts can provide students with an arsenal of tools for engaging effectively with information for varying disciplinary purposes.

Finally, research indicates that students with different individual characteristics may perform differently when critically evaluating online information (Forzani 2016). It is especially important, therefore, that educators consider the ways in which certain teaching practices may be more or less effective with different ages and types of learners. For example, young children may need particular support evaluating online text, since online text may be above their reading ability. Teaching with students’ strengths and weaknesses in mind can help all students gain the skills they need to make decisions in their personal lives and be informed citizens.

Global, Online Collaborative Learning

New technologies and increased access to the Internet bring a second challenge to the curriculum. Today’s students face an unprecedented future in which they will navigate a global society. In a “flat” world (Friedman 2007), economies become increasingly interdependent, and global challenges – including migration, poverty, and natural disasters – grow in complexity. Regardless of future professions or place of residence, our students will interact and coexist with people of diverse cultures,

faiths, and perspectives. For example, 61 million immigrants and their US-born minor children (Camarota and Zeigler 2016) currently reside in the United States, and over one-fifth of the US population speak a language different than English at home (National Center for Education Statistics [NCES] 2016). Worldwide, the number of international migrants reached an all-time high in 2015, with 244 million people living in a country other than their birth nation (International Organization for Migration [IOM] 2016). Current migration trends indicate a drastic increase in the number of refugees, asylum seekers, and internally displaced people. In fact, by mid-2015, the world housed over 15 million refugees, the highest levels of forced global displacement since World War II (IOM 2016).

Instructional outcomes and initiatives in global, online learning. Undoubtedly, we can no longer debate if global awareness is essential. We do, however, need to carefully consider how to prepare students to thrive in a malleable world that will continue to evolve. To successfully live, flourish, and compete in an interconnected world, students must develop aptitudes beyond reading, writing, and arithmetic and learn how to embrace tolerance, value cultural and linguistic differences, and communicate across cultures and languages (Mansilla and Jackson 2014). Raising globally aware students who can thrive in an interconnected world is a common component reflected in current initiatives and curricular outcomes. For example, the Partnership for 21st Century Learning (P21) argues that high school graduates must be “prepared for twenty-first century citizenship” and should “develop the attitudes, skills, and knowledge to understand and participate in a globally connected world” (2014, p. 1). To successfully navigate a global society, students will need skills and competencies required to cope with disparate values and attitudes, along with a deluge of new scientific and technological knowledge. In fact, to help define requisites for global competence, OECD (2016) recently proposed adding a global competence assessment to the 2018 Program for International Student Assessment, commonly known as the PISA. The proposed assessment of global competence would provide an essential overview of education systems’ progress in cultivating students’ global competence for an interconnected world.

Online communication tools (e.g., blogs, message boards, social media apps, Skype, Google Classroom) provide a viable, and often free, gateway for global collective dialogue and collaboration. Hence, curricular objectives relating to technology and digital competencies are also relevant. The International Society for Technology in Education (ISTE 2016) recently revised their student standards to promote “future-ready learning” where students assume roles as global collaborators who “use digital tools to broaden their perspectives and enrich their learning by collaborating with others and working effectively in teams locally and globally” (n.p.). Similarly, the National Council of Teachers of English (NCTE 2008/2013) emphasizes that to become successful members in a global society, students need to be fluent users of technology tools, “build intentional cross-cultural connections and relationships with others so to pose and solve problems collaboratively and strengthen independent thought” and “design and share information for global communities to meet a variety of purposes.” (n.p.).

Global, online learning demands new literacies. As traditional literacy practices are combined with new literacies of the Internet and other ICTs in complex and sophisticated ways, students need supplementary skills, strategies, dispositions, and social practices to fully benefit from the affordances of these technologies (Dalton and Proctor 2008; Leu et al. 2013). In the past, teachers thought of the Internet as something students learned *from*; today, forward-thinking teachers explore how students can learn *with* the Internet. Lindsay (2016/2017) explains that since its inception, global online collaboration has evolved from a simple exchange of information (Global Collaboration 1.0) to co-creation of artifacts and shared knowledge. Twenty years ago, as the possibilities of the Internet emerged, Global Collaboration 1.0 began as forward-thinking educators explored possibilities for collaboration. Using low-level technology (e.g., e-mail) tools to primarily exchange information, interaction between students were limited. With advanced technology tools and enhanced Internet availability and speeds, educators engage students in Global Collaboration 2.0, which involves both information and artifact exchange using common Web 2.0 tools. Today, as both connectivity and communication tools improve, the focus shifts to student-centered learning in Global Collaboration 3.0. Here, students exchange information and co-create multimedia-rich products. They use a wide array of social media tools to communicate and collaborate with peers, educators, and experts from around the world (Lindsay 2016).

Given that online experiences are already pushing the world closer together, we must focus on providing students connected learning opportunities across space, time, and diverse cultures. Connected learning occurs when teachers and students use new literacies and common online tools that afford them abilities to connect, collaborate, and communicate on a global scale (Lindsay 2016). Digital tools offer students access to a wealth of information, along with the ability to be active participants and creators in self-directed inquiry and socially constructed learning (Dwyer and Larson 2014; Leu et al. 2013). Connected learning projects may cultivate students' understanding of both differences and commonalities that define our world while building critical literacy skills through the exposure of diverse (and often contradictory) perspectives and ideas. In early 2017, there were over 1.86 billion monthly active Facebook users worldwide; the *like* and *share* buttons were viewed across almost ten million websites daily (Facebook 2017). As youths are constantly bombarded with both facts and fiction from around the world, it is no longer enough to critically evaluate information from a local, or even national, perspective.

As discussed earlier in this chapter, students are particularly susceptible to encountering misleading or biased information in online environments. They need to understand global viewpoints in order to make sense of online information and negotiate shared meaning through cultural differences, rather than allowing online media to propagate divisions and dislikes (Kist 2013). More than ever, students need the ability to select sources that provide accurate information and, in turn, create and contribute to those channels (Richardson 2016/2017). Farmer (2015) argues that ICTs have "collapsed time and space" as people have more access to global knowledge, can exchange ideas instantly and spontaneously, and can respond to

one another more easily than ever before (p. 6). In other words, while recent digital advancements have opened doors for global collaborations and communications, technology prowess alone is not enough. For ICTs to become effective in the context of global learning, global literacy is critical. Students need to effortlessly toggle between local and global perspectives while having a firm grasp of global competencies, including the capacity to communicate ideas effectively with diverse audiences as they bridge linguistic and cultural barriers and recognize and communicate multiple viewpoints (Mansilla and Jackson 2014; Tolisano 2014).

Instructional implications of global collaborations. Raising global-ready students is unarguably a conspicuous goal. Fortunately, new mobile technologies and social networking tools offer teachers and students broadened opportunities to engage in authentic, borderless learning experiences in which students can learn *with* the world, rather than *about* the world (Lindsay 2016/2017). Global learning should not be viewed as an additional subject to be taught, but rather as an integrated approach to pedagogy where students encounter daily opportunities to engage in global collaborations, consider diverse perspectives, and inquire about the world (Dwyer 2016). Advancements in digital tools and Internet speed afford new ways of constructing, sharing, and accessing ideas and content with others across the globe (Knobel and Lankshear 2014). The creation of ideas and products call for habitual coordination, contribution, and shared conception, within the context of shared ownership of co-created outcomes (Laurillard 2012). Hence, moving toward online collaborations means recognizing changes in social practices and learning strategies, along with an increased need for teachers who can orchestrate global learning opportunities and assist students who need support in developing social learning abilities in online environments (Larson 2009; Leu et al. 2013). Many educators use the Internet to globalize their classroom through collaborations among students across the world. Often, these collaborations involve reading common texts and using digital tools to communicate and socially construct knowledge (Kist 2013; Larson and Dwyer 2015). For example, when teachers move traditional literature discussions, or book clubs, into online learning spaces, opportunities for global collaboration occur.

Recently, sixth-grade students in the United States and Ireland engaged in online literature circles while reading award-winning literature for young adults (Dwyer and Larson 2014; Larson and Dwyer 2015). The two groups wrote blog posts in response to readings, created discussion prompts, and engaged in online conversations about the books. Findings from these collaborations suggested socially constructed understanding of the texts, in addition to heightened levels of global awareness and diverse perspectives. While the sixth graders engaged in literature discussions, they interminably constructed community identity and affinity space (Alvermann et al. 2012). In a current study, preservice teachers in the United States engage in online book discussions with ninth-grade students in Sweden who are studying English as a foreign language. In addition to reading and responding to quality literature, the Swedish students improve verbal and written communication skills in English. The American preservice teachers learn how to instruct students whose native language is not English while gaining important experience in online

teaching. Both groups cultivate global awareness and learn how to use digital tools to communicate and socially construct knowledge (Larson and Brown 2017). Configurations of online global literature circles vary, as do the digital tools used to collaborate. To form a suitable partnership, teachers can use services such as ePals (www.epals.com), a global community where teachers can form connections from all over the world. Alternatively, the *Global Read Aloud* project (<https://theglobalreadaloud.com>) has engaged over a million students in a worldwide book club since its inception in 2010. According to Pernille Ripp (n.d.), teacher and project founder, “. . . we pick a book to read aloud to our students during a set 6-week period and during that time we try to make as many global connections as possible” (n.p.). Participants use a wide variety of tools, including Skype, Edmodo, and Twitter, to engage in a global reading experience with others from around the world. Each year, there are several book choices, allowing teachers to match literature to students’ needs and abilities. Furthermore, using social media or audio/video apps, students can “meet” authors or experts in the field that can help them make sense of texts and gain multiple perspectives (Kist 2013; Larson and Brown 2017).

There is no doubt that today’s students are exposed to rich cultural and linguistic diversity, both in and out of school. While diverse classrooms are worth celebrating, they pose tremendous challenges for teachers aiming to differentiate instruction, promote language learning, and honor divergent viewpoints. Tolisano (2014) cautions that the process of moving from a traditional educator, who primarily operates within the confines of her own classroom, to a globally connected educator occurs in small steps of raising awareness, making a commitment, developing digital competence, building a learning network, and amplifying the curriculum. Educators at all levels must gain proficiency with online technologies and find opportunities for connecting with others beyond classroom borders (Larson and Brown 2017; Lindsay 2016/2017).

The Journey Forward

New literacies that are important to learning and emerge with the Internet and other technologies continually challenge us with changes. We have explored two lowercase areas that are increasingly important for curriculum in both primary and secondary education: the critical evaluation of online information and global online collaborative learning. From a research and theory perspective, this suggests that other lowercase perspectives should begin to determine if the kinds of patterns we find in the two lowercase areas explored here are also found in other lowercase contexts, with other technologies. If they are, it would call for their inclusion in the common elements included in the uppercase theory of New Literacies and call for even greater attention into studying these elements.

From a practice and curricular perspective, it is important to recognize that these elements already require attention. Recent fake news episodes (Wallace 2017) tell us that important threats to national sovereignty can appear through online disinformation campaigns. In addition, rapid access to global information makes it easier to

encounter people who are substantially different from us, and this may make us open to political campaigns that drive us apart rather than bring us together. Both outcomes lead to a more troubled and threatened planet.

We cannot legislate solutions to either challenge, nor can we avoid them. Everyone, or nearly everyone, will have access to online information within the next decade (UNESCO 2014). Our only hope, and the only solution, is to prepare a new generation of citizens who are better prepared for the challenge of changes in the nature of literacy and learning in an online world.

This will require greater effort and focus in our schools, in every nation, to integrate online information into the literacy and learning curriculum, developing more critical users of information and, at the same time, engaging students in collaborative online learning experiences with students in other nations. In this way, we make it more likely that the next generation can resolve the many, seemingly intractable, problems that our planet faces today.

Abstract

The escalating speed of technological development, particularly the pervasive accessibility of the Internet and the rise of social media in the twenty-first century, creates unprecedented opportunities for empowerment and connectedness to individuals and communities. It has also brought challenges and changes to the concept of citizenship and how it is enacted. Especially, the phenomenal growth

of the Internet revolutionizes people's sociopolitical and civic engagement, engendering a more self-actualized form of citizenship (Bennett 2008), and directly influencing the process of democratization (Ferdinand 2000) and the processes of social and political decision-making. This chapter provides a brief overview on how the concept of "citizenship," which has traditionally been inextricably tied to the geopolitical realities of specific nation states, is changing in the twenty-first century due to the pervasive impact of technology, particularly that of globalization and ubiquitous connectedness through social media. We further discuss the implications of these changes on citizenship education, in terms of the conceptualization of digital citizenship, what constitutes a digital citizenship curriculum, and the challenges in its implementation.

Keywords

Digital citizenship · Global citizenship · Social media · Citizenship education

Technology Development, Citizenship, and Digital Citizenship

Citizenship refers to the process, right, and intellectual capacities of the members of a society to participate fully according to the prevailing standards and to share in that society's social and cultural heritage. According to T.H. Marshall's oft-cited definition (1992), citizenship consists of multiple domains, namely, the civil, political, and social rights of membership, and includes "the right to share to the full in the social heritage and to live the life of a civilized being according to the standards prevailing in the society." It can further be expressed as a sense of identity, interest, and involvement in public affairs, and the acceptance of basic social values. However, digital technologies have empowered people to participate in a broader range of societal activities through various devices and media. Therefore, contemporary definitions of citizenship need be extended to include digital entitlement and participation to truly reflect the range of activities in which the members of a society have the right to participate.

Citizenship engagement entails not only the right of access, but also the capacity (cognitive, social, and emotional) to participate, as well as the values and perspectives that underpin the motivation to participate. The latter two aspects are critically influenced by increased connectivity, extending the potential for augmented performance capacity and globalization. In fact, globalization is challenging the concept of citizenship, which has traditionally been associated with membership of geopolitical entities such as nation states. Citizenship in the twenty-first century is multileveled (personal, group, local, and global) (Kubow et al. 2000) and each of us has multiple citizenship identities, reflecting our participation in different communities: family, friends, workplace, religion, hobbies, etc. Hence, digital citizenship should also include the motivation and capacity to recognize these multiple identities and make use of digital technology to participate at these multiple levels.

Before we go into a deeper discussion of digital citizenship and its implications for education and the curriculum, it is important that we first review briefly

citizenship and citizenship education to understand how digital technology and social media impacts on both these two areas.

Citizenship and Citizenship Education

Citizenship is traditionally defined by geopolitical membership, comprising responsibility, rights, and privileges (Sherrod et al. 2010). People possessing such membership are supposed to share the same set of social norms and expectations as citizens (Dalton 2008), and since the nineteenth century such membership is usually based on nationality and/or civic involvement in nation states (Flanagan and Faison 2001). As this form of citizenship is granted by the nation state one belongs to, the set of responsibility, rights, privileges, and even identity as a citizen is also defined by one's nation state membership. Duty and responsibility may include pragmatic contributions to one's nation state such as tax and insurance payment, and work (Marshall 1992). In some nation states such as the USA, where citizenship emphasizes more on shared values than race or geographical boundary, the responsibility of citizens also includes supporting the Constitution and participation in the country's democratic processes (From U.S. Citizenship and Immigration Services: <https://www.uscis.gov/citizenship/learners/citizenship-rights-and-responsibilities>). Concerning rights in relation to national citizenship, Marshall (1992) puts forward a multifaceted model of civic, political, and social rights, which aligns with the aspiration to achieve social equity within the framework of universal democratic values, such as giving citizens the opportunity to live at or above a basic minimum standard, to vote for their social administrators, to receive a certain level of education, to have freedom of speech, to have fair trial by jury, etc. These are fundamental human rights under Western democratic ideologies. In contrast, privilege is more associated with resources and strategies allocated to specific citizenship sectors (Kuisma 2008), such as social benefit and tax allowance for eligible citizens, which do not apply to "foreigners."

Civic or citizenship education is a mandatory component in the basic education curriculum in many countries, and is generally bound by within-nation requirements related to the rights, duties, and privileges of the respective political systems. As the meaning of citizenship is socially constructed, and differs across countries and societies, there are inherent differences in competence requirements for the individual to exercise their rights and responsibilities as a citizen (Turner 1993). The goals of civic or citizenship education in the traditional curriculum comprises two basic dimensions. The first is about the inculcation of values and norms, including national, political, cultural, and religious requirements imposed by the nation state on those vested with membership and identity as a citizen in the country (Abowitz and Harnish 2006). A major goal of this dimension of citizenship education is to ensure that all groups in the nation state share one dominant mainstream culture and value system. Schools, in serving as an agent for the delivery of citizenship education, also take on the role of promoting assimilation into the mainstream culture for building citizenship and national belonging (Banks 2007). The second dimension is on developing the competence (knowledge and skills) needed to understand the citizen roles and

identity, and to exercise the associated rights and responsibilities, including participation in civic and political action. Schools are often the first institutions to introduce an elementary idea of citizenship to children, as well as to offer a societal and institutional context for understanding the concepts of rights and responsibilities (Astuto and Ruck 2010). It is thus fair to say that the role of citizenship education in the school curriculum has primarily been one of promoting homogenization in cultural norms, social values, and practices, and giving priority to national interests.

The Challenge of Globalization to Citizenship and Citizenship Education

The concept of citizenship has become less monolithic and more complex since the late twentieth century under the influence of globalization and postmodernism. Globalization can be regarded as a process that “encompasses the causes, course, and consequences of transnational and transcultural integration of human and non-human activities” (Al-Rodhan 2006), which is accompanied by changes in transnational economy, capitalism, consumption and cultural patterns, as well as political infrastructures such as global governance and authority structures (Robinson 2007). Advances in transportation and communication technologies have greatly accelerated interactions among countries, with impacts on economic cooperation and integration, policy assimilation, knowledge transmission, cultural stabilization across nations, and the redistribution of global powers. It has also led to the spread of capitalism worldwide through facilitating globally more liberal systems and free markets, as an extension of modernity and industrialization (Giddens 2013). The process of globalization is further escalated through international labor immigration and frequent economic interaction among nation states. However, economic integration across nations and changes in political ideologies may not always align, leading to political and ideological clashes at the state level. In some countries, economic liberalization stimulated changes in political ideology, demands for policy choices and reprioritization of democratization, leading to the erosion of state sovereignty by global markets (Woods 1998), and clashes with nationalism ideals.

While the globalization process challenges the concept of national and cultural citizenship, the influence of population flow, economic and social collaboration has also led to the emergence of “global citizenship” (Falk 1993) within collaborative regions, such as the transnational citizenship within member states of the European Union. In this circumstance, the rights and privilege of citizenship extend to a more macro-level, for example, the grant of freedom of movement to individuals with member states of the regional community as in the case of the European Union, and the sharing of knowledge and expertise among members of supranational organizations as in the case of sharing medical information and knowledge through WHO. Global citizens are responsible not only to their own nation states, but to the larger collaborative community.

The concept of rights is also moving beyond the confines of the nation state as a result of globalization. A two-dimensional framework of primary (or basic) rights

and enabling rights has been proposed (Dahrendorf 1994). The former comprises human rights, civil rights, and democratic political corollaries, and the latter comprises social rights such as social services and welfare required to empower people with the capacity to exercise their basic rights. This originates from an ideology that strives for a world civil society and world citizenship premised upon equality not only within a society, but also across societies.

The adverse effects of globalization, such as international crimes, illegal immigration, and environmental destruction, have also generated demands on the coordination, regulation, and arbitration roles of international agencies and regulatory bodies that operate at a multilateral level, which to some extent undermine individual state sovereignty, and move citizenship from a solely national realm to a more global level. One typical example is the global “ecological imperative” to combat climate change, which requires states to abide by global ecological regulations. Citizens in the regulated nations have the responsibility to take actions for the protection of the environment, including challenging their government’s decision if deemed to be against the international environmental regulations. In summary, through the process of globalization, some elements in the sovereignty of nation states is relegated upward to the regional community, international institutions, or supranational agencies, or downward to the open market economy (Delanty 2000).

Under the influence of globalizing forces, people and countries are getting irrevocably more interdependent. In addition to knowing their responsibility, rights, and privilege as citizens in their own countries, people need to understand the same as members of collaborative transnational communities, and to equip themselves with a basic level of proficiency in and acceptance of the languages and social norms of collaborating partners. Those with nontransferable skills and linear thinking styles would find it difficult to cope with the globalization process and are likely to be marginalized (Woods 1998). Hence, there is a strong move toward emphasizing transferable skills such as critical thinking, creativity, and the ability to take on multiple perspectives in recent system level curriculum reforms (Brown et al. 2001). Other emerging goals in citizenship education include the development of identity and attachment to more global communities, and the capacity to connect to people around the world, under the broad umbrella of cosmopolitanism. To function as global citizens, people have to take responsibility for actions and decisions to solve problems at the global level, which may involve giving priority to one’s responsibilities as a human being to every other instead of loyalty to the local community and the state.

Social Media and the Emergence of the Netizen

Ongoing globalization processes and the development of the Internet, particularly the rapid expansion of social media, contribute to the emergence of the network society (Castells 2000). The technology underpinning social media is the read-write web, popularly referred to as Web 2.0. Technologically, Web 2.0 was not a novel leap. However, in going from a broadcast mode of communication in Web 1.0 to supporting bidirectional and interactive communications, it creates an unprecedented

social novelty through supporting online communication, community-formation, collaboration, and the crowdsourcing of collective intelligence (Aghaei et al. 2012).

“Space” for public sphere and “membership” for civil engagement are the two core components constituting citizenship. Transnational cooperation brought about new concepts of citizenship through creating concrete world-regional systems of rights, civil societies, and public spaces, such that citizenship becomes definable in terms of political community, civil society, and the public sphere rather than being coterminous with the nation state, race, or culture (Habermas 2003). Similarly, social media have contributed to new forms of citizenship. The Internet provides the “space” for public sphere, and the online social networks/communities established through Web 2.0 technology provide the civil engagement contexts for “membership.”

Another impact of technology on citizenship is the development of a DIY (do-it-yourself) or self-actualizing culture. This results largely from the empowerment potentials unleashed by the increasing accessibility of sophisticated technologies such as powerful search engines, 3D printers, and multimedia production software suites. DIY means taking personal charge of matters rather than leaving them to others. Engaging in DIY activities implies simultaneously becoming a producer and a consumer. DIY activities, even in the context of everyday transactions, challenge existing hierarchies of authorities and the status quo. Ratto and Boler (2014) coined the term “DIY citizens” to refer to individuals and groups who engage in politically transformative activities such as video productions, civic rituals, or political protests organized on- and offline. They also refer to large-scale networked protests such as Occupy Wall Street as a form of DIY democracy, characterized by horizontal processes of leadership and consensus, and the blatant rejection of traditional forms of government-centered democratic participation.

Public participation in politics is considered a defining feature of democratic citizenship in Western culture. Advances in digital communication platforms and social media have given rise to unprecedented levels of production and distribution of ideas, public deliberation, and network organization. Social media provide the technological infrastructure for the development of DIY organizational processes, values, and norms, and in the process extend and transform citizenship from what Bennett (2008) coined as dutiful citizenship subordinated to the government to more self-actualizing forms of citizenship. This includes the preference for more self-determined political decisions and perspectives.

The role of established civic organizations and political parties has been undermined by online communities and loose, instant networks of collective actions orchestrated through interactive technologies and social media. The burgeoning occurrence of mass civic and political movements orchestrated through digital technology and social media has brought fundamental changes to the processes of civic participation and political decision-making. These new forms of social participation and political engagement pose significant challenges to citizenship and citizenship education.

Another fundamental shift in the concept of citizenship relates to the process and authority in granting citizenship. Individuals can now form and/or select their own online “citizenship,” which is very different from the citizenship granted by nation states. People can now take responsibility for defining their own identities in the “network society.” Social software and digital network technology accelerate the pace

of globalization, creating a parallel borderless society connected through the Internet. They also provide a network of platforms to build social and personal identities. Collaborative online networks, virtual and actual communities, together generate more fragmented, fickle but multiple identities of individuals in the digital world, where national boundary is ephemeral. The term “netizen” (members of the network society) implies a form of online citizenship that coexists with other offline citizenships.

Challenges to the Well-Being of Netizens

Digital technology has provided unprecedented empowerment and connectedness opportunities to individuals and communities, thereby extending the concept of citizenship beyond the confines of nation states and created new and innovative forms of sociopolitical participation and decision-making. Social media have played particularly significant roles in giving voice to individuals, and supported new forms of democratic participation. These changes also mean that the development of the necessary competence, particularly in the critical and socially responsible consumption and production of media, is important for ensuring the well-being of citizens. Further, there are social phenomena and behavior, both online and in real life, that are mediated or orchestrated through social media, and observed to pose new challenges to the well-being of digital citizens (or netizens). These include cyberbullying and identity thefts, as well as phenomena such as echo chambers that are setbacks to the ideals of equity in basic human rights and global citizenship. Social media have also provided opportunities for large corporates and political magnates to manipulate mass social participation through social media platforms and big data analytics of personal and behavioral data. These challenges and the implications for digital citizenship education are discussed briefly in this section.

Cyberbullying

Cyberbullying, similar to bullying, is an act of aggression with the intention to cause harm or distress to the victim, characterized by a power-imbalance (Whittaker and Kowalski 2015). In the case of bullying, the imbalance often reflects more directly observable differences such as social status or physical strength, while the imbalance in the case of cyberbullying may be differences in technological expertise. Cyberbullying occurs through digital communication technologies such as instant messages, emails, or social media, often involving sending distressing messages repeatedly and/or to hundreds of recipients for the purpose of public shaming. Social media platforms have become prominent venues for cyberbullying because of their wide and instant accessibility to the public. There are, however, important differences between traditional forms of bullying and cyberbullying. In the case of the former, the perpetrator and the victim as well as their relationship are generally identifiable, while the victim and the perpetrator may not know each other in the case of cyberbullying. Pyżalski (2012) classified cyberbullying among students into six

categories: against peers, against the vulnerable, against groups who are different (such as religion or ethnicity), against celebrities, against school staff, and random cyber aggression. Whittaker and Kowalski (2015) found that reactions toward cyberbullying depend on the victims targeted, and cyber aggression targeting peers is perceived to be least acceptable. Although cyberbullying does not directly cause physical harm to the victim, it may cause serious social, emotional, and/or behavioral damages and should not be ignored.

Echo Chambers

It has been hypothesized that the Internet presents an open platform for borderless information access and expression of alternative viewpoints, fostering ideological pluralism and the creation of a more globalized and integrated society that accommodates diversity (Bimber 1998). However, it has been shown that people tend to expose themselves to information that reinforces rather than challenge their own views. Hence the abundant availability of diverse information online may simply provide more opportunities for selective attention to those that are similar to their own viewpoints, favoring the emergence of echo chambers, which may further lead to social extremism and political polarization. In a study of political homophily using Twitter data, Colleoni et al. (2014) differentiated cases when Twitter served as a social medium from when it served as a news medium, and found higher levels of homophily and echo-chamber like communication patterns in the former situation involving interpersonal networks, but not in cases when social ties are eliminated.

Influence and Manipulation of Social Participation through Social Media

The Brexit decision through referendum by UK citizens and the election of Trump as the 45th US President in 2016 not only came as unexpected political outcomes, but also stimulated a lot of debates about whether social media serve as a public sphere for democratic debates and participation or as platforms for political manipulation at an unprecedented fine level of granularity. The use of social media for political campaigning has become a reality in many countries since the turn of the millennium. Obama's 2012 election campaign has been credited as having made spectacular advances in the use of large-scale data analytics and behavioral modeling on a wide range of data beyond the general voter database, common demographic records, and commercial databases, to include data from social networks and canvassing, for the design and implementation of sophisticated micro-targeting of campaign messages (Bimber 2014). Easily accessible records of behavior on social media platforms such as Facebook likes can also be used to predict with relatively high accuracy sensitive personal attributes such as ethnicity, personality traits, and religious and political views.

Advances in data science to make accurate inferences based on digitally recorded behavior pose serious threats to privacy concerns. The lack of transparency in data

collection, data processing and use by unknown actors for purposes outside of our control as data owners, and without an “opt-out” mechanism, undermines important democratic norms. Furthermore, in making use of data analytics to construct political appeals on narrow issues to appease targeted receptive electorates, campaigners are segmenting the population, thereby restricting the opportunities for wide participation in debates on important issues of public interest.

Limits to DIY Citizenship

As mentioned earlier, digital technology, especially social media, has fostered the development of a DIY culture, which is manifested as DIY democracy, such as the Arab Spring and Occupy Wall Street in the realm of civic and social participation. These mass political actions demonstrate how digital technologies can support grassroots democracy and direct action in challenging the status quo and traditional authority hierarchies, without going through the standard democratic processes of voting and advocating for policy changes (Ratto and Boler 2014). In Europe, it has been observed that this form of political participation is particularly preferred by young people, who have become increasingly disillusioned with electoral politics, and took to the streets to vent their anger and frustration with the political and economic situations.

Meta-analysis of findings from studies of social media shows that social media use is positively correlated with the three subcategories of citizen engagement: social capital, civic engagement, and political participation (Skoric et al. 2016). This indicates the tendency for political participation using digital technology to be skewed toward those who are technology savvy and well educated, particularly in countries where there are still significant gaps in digital access and use. Hence the Internet has become an instrument of inequality in political voice, which is counter to the democratic ideal of equal access to information and participation. Another challenge is that the very social media that the public depends upon for their sociopolitical participation are mostly operated by US-based corporations, with compliance to unaccountable US intelligence agencies.

Digital Citizenship Curriculum in the Literature

In the foregoing sections, we have reviewed how the concept of citizenship has been challenged and extended by the spectacular advances in connectivity and the augmentation of human performance brought about by digitally integrated technology. Given the pervasive impact of digital technology on the well-being of citizens, it is not surprising that the concept of digital citizenship started to appear in the literature related to school curricula soon after the transition into the twenty-first century. However, a careful examination reveals that the term “digital citizenship” does not carry a clearly defined meaning in the current curriculum literature.

Digital Citizenship as Digital Competence

Until now, the staunchest proponents of digital citizenship in the school curriculum have been educational professionals concerned with the development of computer literacy and information literacy in students. Among the most well-known curriculum frameworks for digital citizenship is the nine element model (Bailey and Ribble 2007; Ribble 2015) published by the International Society for Technology in Education (ISTE). This model conceptualizes digital citizenship as the behavioral norms with regard to technology use for living and learning in the twenty-first century. The nine elements are grouped into three areas:

1. Digital access, digital learning, and digital communication for *student learning and academic performance*
2. Digital rights and responsibilities, digital etiquette, and digital security as norms for *school environment and student behaviors*
3. Digital health and wellness, digital law, and digital commerce as necessary knowledge and skills for *life beyond the school environment*

Despite the popularity of Ribble's (2015) nine element model of digital citizenship within the school community, there is no common agreement on the scope of digital citizenship even within the education technology community. For example, in the third edition of the National Educational Technology Standards (NETS) for Students (ISTE 2016), digital citizenship includes the rights and responsibilities of living and learning in a networked society as well as how to act in a safe, ethical, and legal manner, which only addresses one out of the three areas of concern in Ribble's (2015) model as described above.

Digital Citizenship as an Integral Part of Information Literacy

School librarians is another educational professional sector that have been actively promoting digital citizenship education in the curriculum as an extension of the role they have been playing in students' information literacy development, focusing on helping students to use and create information responsibly, safely, and ethically (Maughan 2017). The American Library Association (ALA) plays an active role in supporting the professional development of school librarians with regard to digital citizenship education, in alignment with Ribble's nine element model.

Given the increasing complexity and sophistication of technology one encounters on a day-to-day basis, some argue that school librarians' role in digital citizenship education should include data literacy (Fontichiaro and Oehrli 2016), and critical civic literacy (Levin 2016). Data literacy focuses on developing students' statistical literacy, the ability to create and comprehend data visualization, use data in argument, participate in citizen science by contributing to big data, manage personal data, and to use data ethically. Critical civic literacy focuses on critical consumption of media, and the capacity to analyse and act on social and political issues.

Another important information literacy issue that has become more acute because of the ease of replication and transmission of information is the need to respect and protect the intellectual rights and copyrights of online materials. The Office for Harmonisation in the Internal Market (OHIM), an agency of the European Community, defines intellectual property (IP) education as “the skills and competences that young people can be expected to acquire in the classroom that enable them to become familiar with intellectual property, understand its potential to generate income and economic growth and lead them to respect intellectual property rights, whether their own or those of others” (OHIM 2015, p. 7). This report finds that a cross-curricula approach for teaching intellectual property rights, such as through the ICT, STEM, and citizenship curricula, is more feasible and effective than teaching it as a separate subject. A more in-depth understanding of IP should include more nuanced interrelationship between creative productions and their protection, especially in the case of derivative creations, and the industry structure of online digital content markets.

Digital Citizenship as Preparation for Civic and Political Participation

This digital competence focus does not address directly issues related to national belonging, cultural norms, social values/practices, and political participation, which are found in traditional citizenship education. Moyle (2014) points out that in the case of Australia, school education does not connect ICT use with the development of democratic values so as to be in alignment with the country’s political system, or with civics and citizenship in the curriculum.

In an empirical study using concept analysis method on published literature related to digital citizenship in a wide range of disciplines, including political science, journalism, and communication, Choi (2016) identified four themes: ethics, multimedia and information literacy, participation and engagement (P&E), and critical resistance (CR). The first two themes are generally addressed in the school curriculum, either under the banner of digital citizenship or digital competence/information literacy as discussed earlier. However, digital modes of P&E and CR are generally not included in the school curriculum. Like Moyle (2014), Choi (2016) argued for the importance of these social/political-participation-related aspects of digital citizenship in the curriculum. He further highlighted the multidimensional nature of digital citizenship and the need for it to be connected to citizenship education.

Digital Citizenship Education Should Proactively Foster Positive Attitudes toward Diversity

Shaming is the use of defamatory language, imagery, or other media to devalue others. Shaming is often observed in social media, and is one common form of cyberbullying. Armfield et al. (2016) link shaming to the creation of a stigma, which occurs when there is a perceived discrepancy between what someone is supposed to be and what the individual actually is. Shaming thrives on the dominance of a social

norm, or the construction of an “in-group” that sets the boundary to the exclusion of others, who could then become targets to be bullied. Armfield et al. (2016) further argue that social media as is normally presented fosters homogeneity and shaming behavior, as it encourages people to connect with those similar to themselves. Students will naturally socialize with those who are similar to themselves, whether online or offline. Hence, they propose that digital citizenship can be “reinforced as a way to think about others the students are not physically connected with” (ibid., p. 278). As such, teachers and schools should encourage students to make positive connections even with those who are unlike themselves as part of digital citizenship education.

Online bullying and hate speech are more severe forms of negative behavior harmful to the victims’ psychological well-being, which may result in depression and other mental issues (Wang et al. 2011). Some students consider online bullying as more serious than real-life bullying because of the apparent anonymity, even though cyberbullying usually comes from within the victim’s own social circle and relationships (Mishna et al. 2009). These issues need to be addressed at both school policy and curriculum levels. At the curriculum level, students need to learn how to identify and react to online bullying behavior, including reporting online bullying through appropriate channels, submitting relevant evidences, and knowing the measures to seek help.

Digital Citizenship Education in Policy and Practice

While there may be differences in emphasis or scope, the core constituent of digital citizenship is widely taken as having the digital competence and disposition for safe, responsible, and ethical use of digital technology. In the USA, Ribble’s (2015) nine element framework has been integrated into the ISTE National Educational Technology Standards for students and teachers, and the information literacy framework of the American Library Association. Hence, this has been adopted in the school curriculum in many US states. It has also been incorporated in the school curriculum in some other education systems, such as in Ontario and Alberta in Canada.

UNESCO (2016) formulated a definition of digital citizenship that is somewhat narrower in scope on the basis of a wide-ranging policy review involving countries from the Asia-Pacific region: “being able to find, access, use and create information effectively; engage with other users and with content in an active, critical, sensitive and ethical manner; and navigate the online and ICT environment safely and responsibly, being aware of one’s own rights” (p. 15).

Netsafe, a New Zealand-based nonprofit organization providing the community with support on online safety, put forward in a white paper (Netsafe 2016) on digital citizenship that is similarly focusing on knowledge, skills, attitudes, and values to be able to participate actively as a lifelong learner in a connected world. However, it also proposes a three-stage model of digital citizenship development. At the lowest level of development is a set of *digital literacy* skills. This should further develop

into *digital fluency*, which expands the digital competence to include knowledge and understanding of digital environments and contexts and their integration with offline spaces, as well as the dispositions for positive connections and personal integrity online through the development of appropriate attitudes and values. Digital citizenship, according to this model, is a high-level outcome in being able to demonstrate digital fluency through their participation in multiple contexts. It further puts forward a *Learn-Guide-Protect* framework to support digital citizenship development, beginning with a primary focus on *protecting* children at a young age through the provision of a safe digital learning environment; to *guiding* students to develop online safety skills and engage in positive digital technology use through programs and resources; and finally to support students' *learning* to contribute as self-managing members of the community through active participation in different meaningful contexts.

Instead of focusing on the competence and behavior of the individual as is often the case in digital citizenship literature and policy documents, Cassells et al. (2016) focus on what it means to the individual to be a digital citizen. This publication is an edited volume introducing more than 30 eTwinning projects related to the theme "Digital Citizens." The authors describe three "pillars" of digital citizenship: these citizens belong to, engage in, and are protected in the networked world. More importantly, they put forward a four-level model of digital participation: through consumption and observation; through sharing information/ideas and connecting people; through creating new content, practices, and tools; and through harnessing digital technology to shape the society for a better future. This is promoting a perspective of the learner as a more active and self-directed agent, which is more aligned with the concept of the twenty-first-century learner. The projects presented in this publication demonstrate how students, with support from their teachers, take an active role in using technology to explore different forms of participation and engagement with peers in other countries.

The Future of Digital Citizenship and Digital Citizenship Curriculum

In the first part of this chapter, we traced how the concept of citizenship evolved from being closely connected to the rights, privileges, and responsibilities of the individual as a member of the nation state, through the emergence of multiple and global citizenship that goes beyond politically defined national boundaries, to the much more nuanced and complex concept of digital citizenship due to the pervasive access to the Internet, particularly the impact of social media on all aspects of our personal, social, and work lives. A fundamental difference between traditional citizenship and digital citizenship lies in the dramatic changes in participation rights, power structures, and forms of social participation and organization that have taken place because of the unprecedented ease of access to information, networks, and institutions. Cost of access is no longer a major obstacle in many countries, but the digital divide is largely one of digital competence and online social capital. The Internet and

social media have influenced deeply the socioeconomic, civic, and political changes in many parts of the world. The scale and pace of such changes will only escalate in the foreseeable future, bringing deeper changes to the contexts and realities of the digital citizen.

While the concept of digital citizenship is getting increasingly fluid and dynamic, digital citizenship education is by and large staying within a competence and dispositions framework for safe, ethical, and legal participation online. As such, digital citizenship education has generally been unconnected with the social/political concerns normally addressed in citizenship education (Moyle 2014; Choi 2016). Digital technology is empowering and challenging individuals and societies in fundamental ways, and hence is also challenging long-standing concepts of citizenship. However, digital citizenship education has generally not brought these fundamental issues and changes in citizenship into the curriculum.

One important feature of contemporary citizenship concepts is the “coexistence of bipolar perspectives including universalism and particularism, heterogeneity and homogeneity” (Lee 2015, p. 94). The universal value of human rights promotes a respect for particularities and differences, and in turn diversity and heterogeneity. This echoes with Armfield et al.’s (2016) argument that digital citizenship must cultivate a respect for diversity and positive attitudes toward heterogeneity. Lee (2015) raised the question of what would be the essential features of citizenship education that can prepare students to be citizens of the future, one that focuses on becoming rather than being. The current emphasis in digital citizenship education on digital competence and disposition for safe, ethical, and legal participation provides a necessary baseline for a digital citizen of today. What would be an appropriate curriculum model for a future-oriented digital citizenship? Would Lee’s (2015) model of citizenship education centering around how one relates harmoniously to oneself, to others, to nature, and to become a good citizen through self-cultivation to be a good person the appropriate direction to go?

Abstract

For a number of years, education authorities have responded to the importance of school students developing computer literacy by including it as part of the school curriculum, directly as a cross-curriculum capability, and by assessing the extent

to which students are computer literate. Computer literacy and related concepts, such as ICT literacy, are defined so as to include both technological expertise and information literacy. Assessments of computer literacy, even though they vary, indicate that there are substantial variations in levels of computer literacy among students in the lower years of secondary school. In technologically developed countries, approximately one half of Year 8 students demonstrate proficiency, or advanced proficiency, in computer literacy, but up to 10% have very limited computer literacy. Assessments of computer literacy can also provide the basis for progression maps that could be used to inform curriculum development. Those progression maps will be more valuable if the frameworks on which they are based become more strongly integrated with each other. In addition, computer literacy appears to be influenced by student background, including familiarity with computers, as well as the emphases placed on it in classrooms and schools and the support provided by ICT in education systems. At present, there is less information about school and classroom influences on computer literacy than there is about student background influences. In the immediate future, the construct of computer literacy may need to accommodate increasingly to changes in software and hardware contexts in which it is manifested.

Keywords

Computer literacy · ICT literacy · Assessment · Curriculum

Introduction

Computer literacy has been recognized for some time as important for life in modern society (Kozma 2003), and many countries have officially recognized the importance of developing computer literacy through schools. During the first decade of the twenty-first century, policy statements from many national education authorities asserted the importance of school students developing capabilities in information and communication technology (ICT) to support learning in other domains and to provide a foundation for their productive future participation in work and society (Qualifications and Curriculum Authority 2007; E-learning Nordic 2006; Hinostroza et al. 2008; MCEETYA 2008; Sanchez and Salinas 2008; Office of Educational Technology, US Department of Education 2010).

Computer literacy also features as a focus of cross-national organizations. Interest in capabilities related to digital technologies is evident in the assertion by the European Commission that digital literacy is “increasingly becoming an essential life competence and the inability to access or use ICT has effectively become a barrier to social integration and personal development” (European Commission 2008, p. 4). The United Nations Educational, Scientific and Cultural Organization (UNESCO) has canvassed the possibility of a global measure of digital and ICT literacy skills in a paper commissioned for the 2016 Global Education Monitoring Report (ACER 2016). Projects such as the IEA International Computer and Information Literacy Study (Fraillon et al. 2014) and the Assessment and Teaching of

21st Century Skills (Griffin et al. 2012) indicate a quickened interest in defining and assessing appropriate capabilities for modern societies. An assessment of digital reading was included as an international option implemented by 19 countries in the PISA 2009 cycle (OECD 2011).

One view of student use of digital technologies was that students in the modern age were “digital natives” (Prensky 2001) who had grown up to be expert users of these technologies and who had developed “sophisticated knowledge of and skills with information technologies” and even different learning styles from older generations (Bennett et al. 2008, p. 777). Others have challenged this view pointing to wide variations among young people in their use of ICT, the lack of a clear distinction between young users and older users, and the predominance of relatively mundane usage (Helsper and Eynon 2010; Koutropoulos 2011; Selwyn 2009). Selwyn (2009) characterizes young people’s Internet use as “passive consumption of knowledge rather than the active creation of content” (p. 372). For this reason, and other reasons, many school systems provide teaching of computer literacy to develop students’ capabilities in that domain (Sturman and Sizmur 2011) sometimes outlining a learning progression (e.g., ACARA 2017), and the assessment of computer literacy has become a component of monitoring student achievement. In many countries, and internationally, assessment programs have been designed to determine the extent to which students are developing appropriate levels of computer or ICT literacy. This paper draws on the evidence that has been assembled by those assessment programs to address the question: To what extent are students computer literate?

Conceptualizing Computer Literacy

The terms computer literacy, ICT literacy, and digital literacy have slightly different meanings but in practice are used interchangeably (Markauskaite 2006; Siddiq et al. 2016). This chapter refers to computer literacy but recognizes that the concept overlaps with other terms. Conceptualizations of computer and ICT literacy have been greatly influenced by work of an international panel convened by the Educational Testing Service (ETS) to develop a framework for ICT literacy (ETS 2002). The panel proposed that “ICT literacy is using digital technology, communications tools, and/or networks to access, manage, integrate, evaluate, and create information in order to function in a knowledge society” (ETS 2002). Since that initial work, conceptualizations have combined aspects of technological expertise with information literacy and extended to include ways in which digital information can be transformed and used to communicate ideas (Catts and Lau 2008). The conceptualizations of computer literacy that have emerged involve both the use of digital tools and the ideas of information literacy. Studies of computer literacy assume that there is an underlying construct that can be measured in different contexts. This assumption is consistent with the view that computer literacy is more than operating hardware and software and includes the information literacy skills associated with

accessing and evaluating information as well as the creative competencies of transforming and creating new digital information.

Binkley et al. (2012) synthesized the operational definitions of ICT literacy that had been developed around the knowledge, skills, and attitudes concerned with being able to access and evaluate information (e.g., search, collect, and process), use and manage information (e.g., process information accurately and creatively, manage the flow of information from various sources, understand the reliability and validity of information), and apply technology effectively (e.g., applications and devices). Similarly, the European Commission proposed a digital competence framework (DIGCOMP) based on a review of ICT literacy frameworks (European Commission 2010). It invokes five main competence areas: information management, collaboration, communication and sharing, creation of content, and problem-solving (European Commission Joint Research Center-IPTS 2013; Ferrari 2012). At a more detailed level, DIGCOMP specifies particular skills that make up these five competence areas and proficiency levels for each competence area.

ICILS adopted the definition of computer and information literacy as referring to “an individual’s ability to use computers to investigate, create and communicate in order to participate effectively at home, at school, in the workplace and in society” (Fraillon et al. 2013, p. 17). It envisaged two strands. The first was a receptive strand involving collecting, managing, and processing information. It incorporated knowing about and understanding computer use (the generic characteristics and functions of computers and basic technical knowledge and skills that underpin the use of computers), accessing and evaluating information (the processes that enable a person to find, retrieve, and make judgments about the relevance, integrity, and usefulness of computer-based information), and managing information (the capacity to work with computer-based information to adopt and adapt information-classification and information-organization schemes in order to arrange and store information so that it can be used or reused efficiently). The second strand focused on producing and exchanging information and using computers as tools for thinking, creating, and communicating. This included transforming information (change how information is presented so that it is clearer for specified purposes), creating information (using computers to design and generate information products), sharing information (understanding of how to use computers to communicate and exchange information with others), and using information safely and securely (understanding legal and ethical issues of computer-based communication).

The definition of ICT literacy adopted in Australia for use in its National Assessment Program was similar to, and preceded, that used in ICILS. It was elaborated through a set of six key processes and a broad description of progress according to three strands (MCEETYA 2005). The six key processes were accessing information, managing information (organizing and storing information), evaluating and making judgments, developing new understandings (e.g., creating information and knowledge), communicating (i.e., exchanging information and creating information products), and using ICT appropriately. The three strands of progress were working with information, creating and sharing information, and using ICT responsibly.

In 2014, the US National Assessment of Educational Progress included an assessment of technology and engineering literacy (NAEP-TEL) which has ICT as one of its three areas. Information and Communication Technology was one of three content areas (the other two were Technology and Society and Design and Systems) (Institute of Education Sciences, National Center for Education Statistics 2012). Information and Communication Technology covered “computers and software learning tools, networking systems and protocols, hand-held digital devices, and other technologies for accessing, creating, and communicating information and for facilitating creative expression” (NCES 2016a, p. 8). This involved proficiency in using computers and software learning tools, networking systems and protocols, handheld digital devices, and other technologies that enable users to access, create, and communicate information and engage in creative expression. It also identified five subareas of competence: construction and exchange of ideas and solutions, information research, investigation of problems, acknowledgement of ideas and information, and selection and use of digital tools (NCES 2016b).

In Chile, the ICT Skills for Learning Test thus defines ICT literacy as “the capacity to solve problems of information, communication and knowledge in digital environments” (Claro et al. 2012, p. 1043). Claro et al. (2012) elaborate that this requires the mastery of ICT applications in order to “solve cognitive tasks in a digital environment” but that the skills are not themselves technology-driven in that they reference “information, communication and knowledge tasks in an ICT context” rather than particular software. They also incorporate higher-order thinking processes and related to continuous learning. ICT literacy is envisaged as involving using ICT with regard to information skills (sourcing for information, processing information), communication skills (effective communication, collaboration and virtual interactions), and appreciating ethical issues and social impact (evaluating responsible use and social impact) (Claro et al. 2012).

Assessing Computer Literacy

Over the past two decades, there has been a number of approaches to the assessment of computer literacy including self-reports, traditional assessments based on multiple-choice and constructed response items, and performance assessments. Each of these provides different perspectives.

Self-Reports of Computer Literacy

Siddiq et al. (2016) note that there have been numerous examples of self-reports as measures of students’ ICT literacy. They caution that, although these measure self-confidence or self-efficacy, they do not provide sound measures of ICT literacy. Therefore, Siddiq et al. (2016) excluded studies based on self-reports from their

review of instruments measuring ICT literacy. They noted the low correlations of self-reports with measured competence. Rohatgi et al. (2016), based on analyses of Norwegian data, note that ICT self-efficacy may not be a unidimensional construct and distinguish basic ICT self-efficacy from advanced ICT self-efficacy. Basic ICT self-efficacy was positively related to computer literacy ($r = 0.22$), whereas advanced ICT self-efficacy was negatively but minimally associated with computer literacy ($r = -0.06$) (Rohatgi et al. 2016). A similar correlation between ICT self-efficacy and measured computer literacy was reported among students in Years 6 and 10 in Australia (ACARA 2017). There is also evidence from Australia that measures of ICT self-efficacy may not be equivalent for boys and girls: Boys were more confident than girls about using ICT, but this confidence was not matched in measured computer literacy (ACARA 2017). It has been widely concluded that self-report measures do not provide a basis for inferring the extent to which students are computer literate even though these measures may be important for understanding student learning in computer-based learning environments (Moos and Azevedo 2009).

Assessments Based on Traditional Item Formats

Siddiq et al. (2016) have provided a comprehensive review of the instruments used to assess students' ICT literacy. They observe that many of the instruments are directed to lower secondary-school students, involve multiple-choice items, and measure aspects such as searching, retrieving, and evaluating information as well as technical skills. Siddiq et al. (2016, p. 63) identify four item categories in assessments of ICT literacy: multiple-choice items based on static information, multiple-choice items based on dynamic information, items that require the respondent to interact with the test material, and the performance of tasks that require responses in an authentic situation. Some assessments of computer literacy use print formats to assess computer literacy (Senkbeil et al. 2013). Critiques of approaches using standard item formats have been that they do not reflect the ways in which people use these technologies in practice and that they do not capture the range of computer literacy competencies (Siddiq et al. 2016).

Most assessments of computer literacy and related constructs have used computer-based assessments (Siddiq et al. 2016). Computer-based assessments typically take advantage of the medium to provide richer stimulus material (e.g., video and other dynamic graphic material) on which to base items and enable better targeting of item difficulty to respondent ability (e.g., assigning items based on responses to previous items). However, an essential consideration for computer-based assessments, which is not such an issue for print-based assessments, is to ensure a uniform assessment environment. Computer-based assessments delivered through software and resources loaded on devices such as laptop computers are able to achieve this, but when materials are located on demountable media such as USB devices and accessed by local computers or accessed through the Internet, uniformity is harder to achieve.

Performance Assessment

Many approaches to assessing computer literacy incorporate performance assessment in which students are required to perform tasks on a computer rather than simply answer questions about computers and computing (Aesaert et al. 2014; Ainley et al. 2016; Claro et al. 2012; NCES 2016b; Van Deursen and Van Dijk 2016). Performance assessments provide opportunities to collect different types of responses (e.g., information products) and enable interaction between the respondent and an assessment system (e.g., dialogue between a respondent and the system). Performance assessments have been used in a number of learning domains and require a demonstration of mastery by performing a task or producing an information product that is subsequently evaluated using an assessment rubric (Madaus and O'Dwyer 1999). There are also examples of recording direct observations of people completing a task (Katz 2007).

Aesaert et al. (2014) developed a performance-based direct measure of ICT competence with a focus on primary-school students' competence in digital information processing and communication. They developed and trialed 56 items around a matrix of 19 higher-order competences and 15 technical skills, and the data from the trial were examined to investigate dimensionality, fit, local item dependence, and monotonicity. The items were "simulation-based assessment tasks" which reflected "real-life information searching, processing and communication activities" (p. 171). The tasks were embedded in a narrative theme of "a journey through time" (p. 171). Twenty-seven items that required retrieving and processing digital information as well as communication with a computer were included in the final instrument.

Van Deursen and Van Dijk (2016) used a measure of Internet skills based on the performance of 21 discrete tasks in a survey of just over 1000 adults. The survey was administered as part of an online survey and also included measures of traditional literacy and Internet usage. The reliability of the measures of formal Internet skills, information Internet skills, and strategic Internet skills was high ($\alpha > 0.80$), but that of observed Internet skills was a little lower than ideal ($\alpha = 0.72$). They concluded that the level of operational skills, as well as traditional literacy, had a positive effect on formal, information, and strategic Internet skills. However, traditional literacy was not related to operational Internet skills.

ICILS employed four modules of which each student was randomly assigned two. Each module involved a number of discrete tasks and a large task (Fraillon et al. 2014, p. 18). One of the modules required students to create an advertising poster for an after-school exercise program (Available for viewing at: <http://www.iea.nl/icils-past-cycles>). To do this, they needed to set up an online collaborative workspace through which to share information which was then selected and adapted for the purpose. A second module required the creation of a webpage about a school band competition. Students needed to plan the webpage and use a simple website builder. The third module asked students to prepare a presentation about breathing for 8- or 9-year-old students. It involved file management and the collection and evaluation of relevant information. The fourth module required students to produce an information sheet about a school trip for their peers. They needed to use online database tools and to

assemble relevant information. They could create a map using an online mapping tool. Each large task resulted in an information product that was assessed by scorers against a set of criteria (each criterion with its own unique set of scores) relating to the properties of the task. In ICILS 2013, large tasks constituted around 60% of the assessment.

In Chile, the ICT Skills for Learning Test also made use of purpose-designed software that simulated ICT applications and tasks that were embedded in realist contexts (school and work) (Claro et al. 2012). The software included commonly used applications (email, Internet browser, text processor, spreadsheet, and presentation software). In addition, there was a chat window through which a virtual conversation among three participants was simulated. Each student was assigned tasks to perform. The tasks were incorporated in a story (ecology), and in each task the student was faced with different situations, which were designed to test ICT skills. The first task required the student to participate in a campaign for the protection of species under threat of extinction. The second task required the student to prepare a working document about global warming. The third task required students to recognize risky behaviors in virtual environments and evaluate the impact of the Internet in different dimensions of life. Students were expected to use scientific evidence presented in graphs, text, and images to analyze and contextualize the evidence (Claro et al. 2012, p. 1045).

The NAEP-TEL assessment in the United States was also computer-based and included interactive, “multimedia scenario-based tasks (SBTs)” (NCES 2016b). Students were required to solve technology and engineering problems in real-world contexts that were designed to allow students to demonstrate the range of knowledge and skills detailed in the three content areas (Technology and Society, Design and Systems, and Information and Communication Technology) across three practices (Understanding Technological Principles, Developing Solutions and Achieving Goals, and Communicating and Collaborating). Some tasks related to one content area and practice, while others were concerned with more than one content area or practice. In one SBT, a local fruit juice company had offered to build a new recreation center for teenagers. Students were required to create content for a website promoting the benefits of building the recreation center (NCES 2016a). Another involved a group project examining the advantages and disadvantages of a cold medication. Students searched a relevant website and used evidence from that site to develop an evaluation. A third involved planning the building of a tree house using information from a website about tree houses and searching for information about the strength of different types of tree. The complete TEL assessment included 20 SBTs and 97 discrete questions within a rotated design so that individual students responded to only a portion of the entire assessment.

Computer Literacy of Students

In order to estimate the extent to which students are computer literate, it is necessary to focus on those studies that involve representative samples of defined student populations in one or more education systems. In practice, most of these studies focus on lower secondary schools (Years 7–10).

Perspectives from ICILS

In 2013, ICILS investigated the computer literacy of Year 8 students and established four described levels of its computer and information literacy (CIL) scale. In addition, there were a small number of items that had difficulties below Level 1 which represented the most basic skills and did not warrant description (Fraillon et al. 2014). The levels are outlined in Table 1 together with the percentages of students in the ICILS countries whose computer literacy score would place them in each of the levels.

In addition to recording the percentage distribution across levels for the 14 countries, Table 1 also shows the distribution for 12 countries with Thailand and Turkey omitted because the distributions for those 2 countries were very different from the other 12 countries. The discussion focuses on the 12-country distribution.

The ICILS scale is hierarchical in the sense that computer literacy becomes more sophisticated as student achievement progresses up the scale. Table 1 records the percentages of students “in each level” as well the percentages “up to and in each level” (in other words, the cumulative percentage). Students working below Level 1 are unlikely to be able to create digital information products.

At Level 1, students show familiarity with basic software commands enabling them to access files, complete routine text and layout editing, recognize basic software conventions, and recognize the potential for misuse of computers by unauthorized users. At Level 2 (which could be considered computer literate – see later) and beyond, students are familiar with and can use a broader range of software commands. They can format text and images in information products. At Level 3, they can edit and create information products with attention to layout and design, and at Level 4 they show an awareness of audience and purpose when formatting information products that they create including using layout and formatting features appropriately. At Level 2, students can use computers as information resources to locate information in digital sources as well as select and add content to information products. At Level 3, students independently search for information and select relevant information from digital resources being aware that information may be biased, inaccurate, or unreliable. Key factors differentiating Level 4 from Level 3 are the extent to which students can work autonomously with a critical perspective when accessing information and the precision with which they search for and locate information.

The data in Table 1 show that across the 12 countries, just over two thirds (69%) of Year 8 students recorded scores in Levels 2, 3, or 4. There was some variation across these countries with the eight middle countries in the distribution having percentages ranging from 64% to 75%. Across the 12 countries, just over one quarter (26%) of Year 8 students recorded scores that corresponded to a Level 3 or Level 4 attainment.

Links to the Australian National Assessment of ICT Literacy

ICILS 2013 was administered in Australia to a sample of 5326 students from 320 schools (de Bortoli et al. 2014). In addition to the ICILS assessment, students

Table 1 Percentages of Year 8 students at each proficiency level in ICILS 2013

Level description	Average % students (14 countries)		Average % students (12 countries)	
	In level	Up to and in level	In level	Up to and in level
Level 4:	2	2	2	2
Select the most relevant information to use for communicative purposes				
Evaluate usefulness of information based on criteria associated with need and evaluate the reliability of information based on its content and probable origin				
Create information products that demonstrate a consideration of audience and communicative purpose				
Use appropriate software features to restructure and present information in a manner that is consistent with presentation conventions, and adapt that information to suit the needs of an audience				
Demonstrate awareness of problems that can arise with respect to the use of proprietary information on the Internet				
Level 3:	21	23	24	26
Demonstrate the capacity to work independently when using computers as information-gathering and information-management tools				
Select the most appropriate information source to meet a specified purpose, retrieve information from given electronic sources to answer concrete questions, and follow instructions to use conventionally recognized software commands to edit, add content to, and reformat information products				
Recognize that the credibility of web-based information can be influenced by the identity, expertise, and motives of the creators of that information				
Level 2:	38	60	42	68
Use computers to complete basic and explicit information-gathering and information-management tasks				
Locate explicit information from within given electronic sources. These students make basic edits and add content to existing information products in response to specific instructions				
Create simple information products that show consistency of design and adherence to layout conventions				
Demonstrate awareness of mechanisms for protecting personal information				
Demonstrate awareness of some of the consequences of public access to personal information				

(continued)

Table 1 (continued)

Level description	Average % students (14 countries)		Average % students (12 countries)	
	In level	Up to and in level	In level	Up to and in level
Level 1: Demonstrate a functional working knowledge of computers as tools and a basic understanding of the consequences of computers being accessed by multiple users Apply conventional software commands to perform basic communication tasks and add simple content to information products Demonstrate familiarity with the basic layout conventions of electronic documents	23	83	23	91
Below Level 1: Execute only the most basic skills (e.g., clicking on a hyperlink)	17	100	9	100

Adapted from data provided in Table 3.6 in Fraillon et al. (2013, p. 98). The data refer to the 14 countries that satisfied the IEA response rate criteria: Australia, Chile, Croatia, Czech Republic, Germany, Korea, Lithuania, Norway, Poland, Russia, Slovak Republic, Slovenia, Thailand, and Turkey

also completed a module from the National Assessment Program Information and Communication Technology Literacy (NAP-ICTL) assessment (ACARA 2012). The purpose was to benchmark the NAP-ICTL scale against the international ICILS scale (ACARA 2012). It found that ICILS Level 1 was equivalent to NAP-ICTL Level 2, ICILS Level 2 was similar to NAP-ICTL Level 3, ICILS Level 3 to NAP-ICTL Level 4, and ICILS Level 4 was equivalent to NAP-ICTL Levels 5 and 6.

The NAP-ICTL surveys involved a standards-setting exercise (MCEETYA 2007). Consultations were held with panels of practicing teachers, ICT curriculum experts, and educational assessment experts. They examined test items and results from the assessments to agree on proficient standards for each year level (MCEETYA 2007, pp. 46–47). The proficient standard for Year 6 was defined as the boundary between NAP-ICT Levels 2 and 3 (ICILS Levels 1 and 2), and the proficient standard for Year 10 was defined as the boundary between NAP-ICT Levels 3 and 4 (ICILS Levels 2 and 3). Based on this standard setting, it can be concluded that across 12 developed countries, two thirds (68%) of Year 8 students had attained a standard of proficiency that would be recognized for a Year 6 as computer literate and one quarter (26%) had attained the standard of proficiency for a Year 10 student.

Perspectives from the NAEP-TEL Assessment

In the US Technological and Engineering Literacy Assessment (TEL), results were reported in terms of the percentages of Year 8 students in three performance bands

and a fourth band that was lower than basic (NCS 2016b). The descriptors of these bands incorporate the related content areas of Technology and Society, Design and Systems, and Information and Communication Technology. Table 2 records the descriptors that refer to the Information and Communication Technology content area.

Perspectives from the ICT Skills for Learning Test in Chile

Results from the ICT Skills for Learning Test in Chile referred to the percentages of 15-year-old students who would be expected to successfully complete eight major tasks or levels. The analyses resulted in a set of tasks empirically ordered from most difficult to least difficult. The tasks are listed in Table 3 along with the percentages in each level and at or above each level (Claro et al. 2012).

Claro and colleagues (2012, p. 1050) concluded that approximately three quarters of Chilean students were able to search for information, half were also

Table 2 Descriptors of performance bands in the US Technological and Engineering Literacy Assessment with percentages of Year 8 students in each band: 2014

Proficiency band and descriptors	% students at level	% students up to and in level
Advanced	3	3
“Draw upon multiple tools and media to address complex problems and goals, and demonstrate their understanding of the potential impacts on society”		
“Integrate the use of multiple tools and media, evaluate and use data and information, communicate with a range of audiences, and accomplish complex tasks”		
“Explain the ethical and appropriate methods for citing use of multimedia sources and the ideas and work of others”		
Proficient	40	43
“Select and use an appropriate range of tools and media for a variety of purposes, tasks, and audiences”		
“Contribute to the work of collaborators”		
“Find, evaluate, organize, and display data and information to answer research questions”		
Basic	40	83
“Use common tools and media to achieve specified goals and identify major impacts”		
“Select common information and communications technology tools and media for specified purposes, tasks, and audiences”		
“Find and evaluate sources and organize and display data and other information to address simple research tasks”		
“Appropriately acknowledge the work of others and use feedback from colleagues”		
Below basic	17	100

Adapted from data provided in NCES (2016b)

Table 3 Percentages of 15-year-old students able to successfully complete each type of task in the ICT Skills for Learning Test in Chile: 2009

Task type or level	% students at level	% students up to and in level
Successfully perform all eight tasks including being able to “refine digital information and create a representation in a digital environment (e.g., synthesize, interpret, and represent information using worksheet tools and functions)”	17	17
Able “to develop their own ideas in a digital environment (e.g., publish a post or write an email adequate in content”	13	30
Evaluate “digital information using specific criteria related to quality (e.g., authorship, relevance, edition)” and “analyze digital information (e.g., integrate and compare information presented in a digital representation)”	10	40
“Transmit information effectively by selecting the most appropriate media (e.g., blog, social network, email, etc.) and information to communicate in a digital environment and collaborate and interact in virtual networks (e.g., solve a problem in virtual interaction with others)” as well as being able to search for, select, and organize digital information	11	51
Organize and manage digital information (e.g., search for files and arrange folders in the computer) as well as search for and select digital information	12	73
Not able to demonstrate mastery in any of the tasks	27	100

Adapted from data provided in Claro et al. (2012, p. 1050)

able to organize and manage digital information, but only one third of the students are able to develop their own ideas in a digital environment, and less than one fifth could refine digital information and create a representation in a digital environment.

Perspectives from the ICT Literacy Assessment in Korea

Kim and Lee (2013) report the results of an Internet-based test of ICT literacy that incorporated 36 multiple-choice and performance items and was administered to a representative sample of 15,558 middle-school students in Korea in 2011. A set of performance levels was defined through a standard-setting exercise with expert judges. According to Kim and Lee (2013, p. 85), “excellent” represented an ability “to use or create information using existing ICT most effectively for solving problems”; “average” indicated “an understanding of the operating principles of computer and IT equipment” as well as “essential concepts and principles of computer science” and being able to use ICT for solving problems somewhat effectively; and “basic” signifies the ability to use IT skills “without having an understanding of the principles behind the skills.” The percentage distribution of student scores for Grade 3 was categorized as excellent (8%), average (34%), basic (53%), and below basic (4%).

Factors Associated with Computer Literacy

From a number of studies, it is evident that student computer literacy varies across countries, across schools within countries, and across students within schools. To begin with the variation across countries, average computer literacy varies greatly across countries and is positively associated with the *ICT Development Index* and negatively associated with the average ratio of students to computers in schools (Fraillon et al. 2014). Aesaert et al. (2015) point out that national ICT policies influence school and classroom practice through the curriculum, professional development for teachers, and the provision of resources. In terms of variation within countries, Aesaert et al. (2015) proposed a multilevel model based on factors from the student, classroom, and school level to explain differences in computer literacy within countries.

Individual Influences

Student-level influences on the development of computer literacy can be considered in terms of attitudinal or dispositional characteristics, familiarity with ICT, and background characteristics. In terms of attitudinal factors, Hatlevik et al. (2015) report that higher levels of mastery orientation and self-efficacy were associated with the development of digital competence in Year 7 students in Norway. ACARA (2015) reports that ICT literacy and ICT self-efficacy were both associated with interest and enjoyment in using computer technology. Greater interest in and enjoyment of ICT use were associated with higher CIL scores in 9 of the 14 countries that met the ICILS sampling requirements (Fraillon et al. 2014). The direction of the relationship between ICT or computer literacy and ICT self-efficacy is not clear from these studies and may involve reciprocal links. It also appears that measured computer literacy is positively associated with basic ICT self-efficacy but not with advanced ICT self-efficacy (Fraillon et al. 2014; Rohatgi et al. 2016). This is consistent with measures of computer literacy being focused on information and communication rather than advanced computer skills such as programming or database management.

Familiarity with computer technology is taken to include frequency of use and experience of using the technology. These factors appear to be consistently associated with computer literacy and self-efficacy in many countries (ACARA 2015; Fraillon et al. 2014; Kim et al. 2014; Rohatgi et al. 2016). Interestingly, it appears that ICT use for recreation may be a stronger predictor of computer literacy than ICT use for study or school purposes (Rohatgi et al. 2016). Among background characteristics, greater access to ICT resources (e.g., access to a home Internet connection and the number of computers at home) and higher socioeconomic status in general (e.g., as measured by parental occupation and educational attainment, the number of books in the home, or access to subsidized meals) are consistently associated with higher levels of computer literacy (ACARA 2015; Fraillon et al. 2014; Claro et al. 2012; Kim et al. 2014; Hatlevik et al. 2015). Aesaert et al. (2015) argue that, in

addition to the socioeconomic characteristics of homes, consideration needs to be given to parental attitudes to, and practices with, information technology.

A number of studies report that girls have higher levels of computer literacy than boys (ACARA 2015; Fraillon et al. 2014; Kim et al. 2014) but this is not universally the case with some studies reporting the reverse and others finding no difference (Rohatgi et al. 2016). It seems possible that an explanation for this mixed pattern could lie in the nature of the assessments with those assessments that emphasize information literacy favoring girls and those that emphasize technical aspects favoring boys.

There is also evidence that computer literacy is higher for students in more advanced school years than those in earlier school years. The Australian National Assessment of ICT Literacy used a linked scale covering Year 6 and Year 10 so that it was possible to compare the performance of students 4 years apart (ACARA 2015). It found that students in Year 10 exhibited higher levels of computer literacy than students in Year 6. The differences were between one and one and a half standard deviations but becoming smaller over time from 2005 to 2014. Kim and Lee (2013, p. 87) also report higher levels of computer literacy among students in the third year of secondary school than among students in the first year of secondary school.

Classroom and Teacher Influences

The model proposed by Aesaert et al. (2015) includes among potential classroom- and teacher-level influences teachers' ICT competence, attitudes to ICT, professional development, logistic appropriateness, ICT use, and ICT experience. However, there are few reported studies that relate teacher attributes and classroom practices using ICT to the development of student computer literacy. There is evidence that the emphasis on developing computer literacy is related to teachers' ICT self-efficacy and positive views of ICT in education (Fraillon et al. p. 218). It also appears that the emphasis placed on developing computer literacy varies across learning areas being much higher in computer studies than in other learning areas and relatively higher in science and human sciences or humanities than in mathematics (Fraillon et al. 2014, p. 220). Kim et al. (2014) suggest that satisfaction level of students in classes using ICT was related to students' ICT literacy levels. Again, the direction of causality is not clear.

School Influences

There are several studies that explore school-level influences on student computer literacy. It does generally appear, across most countries, that the average level of socioeconomic background of the students attending a school is associated with student computer literacy (Fraillon et al. 2014). Hatlevik et al. (2015) found that commitment among teachers in a school toward professional development was

associated with students' computer literacy. Dexter (2008) argued that managing teachers' professional development in the use of ICT for teaching and learning was an important school-level influence on the use of ICT in schools. Fraillon et al. (2014) found that collaboration among teachers about the use of ICT was positively associated with the emphasis placed on developing computer literacy. ICILS also reported that in several countries student reports of having learned about ICT at school were associated with higher levels of computer literacy (after controlling for other measured influences).

Emerging Issues

The Challenge of Change

Changes in hardware and software technologies have meant that the contexts in which computer literacy can be demonstrated have also changed. An important question is whether the nature of the computer literacy construct has remained consistent even though advances in hardware and software technologies have meant that the contexts in which computer or ICT literacy can be demonstrated have changed. Studies that have attempted to measure changes in computer literacy over time have used anchor tasks between adjacent cycles and new tasks to accommodate new developments in software and hardware contexts (ACARA 2015). It is important to establish that the construct has remained the same if the proportions of students who are computer literate are to be compared.

Computer Science and Computational Thinking

There has emerged a challenge to the idea that computer literacy as currently conceptualized is an adequate element of understanding computing and computers. This challenge proposes that learning to use and apply computer technology is not an adequate representation of computer literacy and that understanding some principles of computing has educational benefits (Peyton Jones 2011). In other words, this view sees the sort of thinking used when programming a computer as being part of computer literacy (Grover and Pea 2013; Lye and Koh 2014). Computational thinking includes activities such as formulating, representing, analyzing, and executing a solution. This can involve developing or implementing an algorithm with computer code. The principles of teaching computational thinking resonate with work from five decades ago using "logo" and "turtle graphics" (McDougall et al. 2014). A number of countries have school computer science courses that contain computational thinking. The take-up of the ideas of computational thinking represents a challenge to the ways in which computer literacy has been envisaged since 2002. There remains a debate as to whether this provides a basis for general education (Barr et al. 2011) and how computational thinking relates empirically to computer literacy as currently conceptualized.

Conclusion

Since 2002, computer literacy has been accepted as referring to being capable of accessing, evaluating, using, managing, processing, and communicating information with digital technology. On the basis of international and national studies of computer literacy, it appears that there are substantial variations in levels of computer literacy among students in the lower and middle grades of secondary school. Therefore, there is no simple unambiguous answer to the question are students computer literate? In most countries, there is a group of students whose computer literacy is very limited. In most technologically developed countries, this appears to be fewer than 10% of students, but it is more than that in many countries. In general, approximately one half of lower secondary students demonstrate proficiency, or advanced proficiency, in computer literacy, and approximately one quarter demonstrate advanced proficiency in computer literacy. However, the field could benefit from investigations of how the various measures of computer literacy relate to each other from standards-setting exercises that could inform judgments about the scores on these scales that represent computer literacy.

Computer literacy is higher in countries with higher levels of ICT development and within countries is higher among students whose families are socioeconomically advantaged, who are more familiar and experienced with computer technology, and who have greater confidence in using computer technology. Girls tend to have slightly higher levels of computer literacy than boys. It is sometimes assumed that young people who have grown up with computers as a ubiquitous part of their lives will have high levels of computer literacy. However, there remain wide variations in computer literacy, and there is a challenge to ensure all young people are capable of productively using a range of digital technologies. Part of that challenge is to build a larger base of empirical studies of school and classroom influences on the development of computer literacy. Longitudinal studies of these influences on changes in computer literacy would be especially informative.

If we are to ensure that the widest possible range of young people becomes computer literate, greater attention needs to be given to the inclusion of education about computer technologies in the school curriculum. Designated courses about computer technology currently appear to provide the greatest emphasis on developing computer literacy, and the prospect for developing computational thinking, but what happens in other subjects is also important. Computer literacy is best seen as a cross-curricular capability and needs to be underpinned by progression maps (such as those reviewed in this chapter) that are linked to curricula in other learning areas. A progression map could provide a focus for collaboration among teachers and for professional learning activities for teachers.

Abstract

Computer science education, including computational thinking, has received considerable attention over the last few years as more and more countries are expanding or starting efforts in the primary and secondary schools. In this chapter, we provide examples of computer science efforts in a number of countries, including the United States, and discuss how these efforts to increase the role of computing in schools gives us a unique opportunity to expand computing education research, which

has significantly lagged the rapid growth of computer science. We have laid out directions for future research under two broad areas of teaching training and student learning. Specifically, we discuss potential research areas around knowledge teachers need to teach computing ideas and factors that influence students learning to program.

“The child programs the computer and, in doing so, both acquires a sense of mastery over a piece of the most modern and powerful technology and establishes an intimate contact with some of the deepest ideas from science, from mathematics, and from the art of intellectual model building” – Seymour Papert

Introduction

The above quote by Papert in *Mindstorms* highlights the power of computing to enhance how students think and learn by changing mental processes even when they are removed from the physical presence of a computer (Papert 1993). This is even more true today as computing has significantly changed how we interact with our world. From how we consume information to simulating scientific processes, the pervasiveness of computing technologies touches all aspects of our lives. Furthermore, computing tools and ideas provide individuals with opportunities to extend their creative expression to solve problems, create computational artifacts, and even develop new knowledge (Yadav and Cooper 2017). Computing promotes innovation by allowing individuals to explore and create digital artifacts and “extend traditional forms of human expression and experience” (College Board, p. 8). For example, Mishra and Yadav (2013) highlighted two examples of how individual creative expression in partnership with the power of computing can lead to new forms of artifacts. One of the examples included David Cope, a noted musician, who used programming as an extension of his brain to compose music (with the computer program as a co-composer). The deep knowledge of music and an understanding of computer programming allowed David to combine the power to develop creative insights into composing music. This example highlights the ever-increasing use of computation across multiple fields, which makes it imperative to prepare students for their future studies and careers.

At the same time, demand for professionals with computing experience, the interest of undergraduates in computer science (CS) as a major, and the overall drive to expand computer science course offerings in K-12 have increased considerably in the last few years (Strickland 2014; Taylor and Miller 2015). Hence, there is a push for students across the elementary, secondary, and postsecondary education spectrum to understand computing ideas and how they influence our lives. Computational thinking has been suggested as one way to introduce students to concepts fundamental to computer science and expose students to a “range of mental tools that reflect the breadth of computer science” (Wing 2006).

In this chapter, we discuss computational thinking, its applicability across the curriculum, and how it could instantiate across the primary and secondary classrooms. Next, we provide an overview of computer science education initiatives across the globe, including the United States, United Kingdom, the Netherlands, Australia, and Mexico. Finally, we argue that these initiatives provide computer science education researchers with opportunities to develop an empirical base on factors that influence how students learn computing ideas, how to train teachers in computing, and how to support diverse learners in computing.

Computational Thinking: A Problem Solving Approach for Digital Age

Computational Thinking (CT) has been defined as a set of mental skills that were historically developed through the study and practice of computer science, yet can be found and used across multiple contexts (Barr and Stephenson 2011; Wing 2008). Wing (2006) stated that CT involved “solving problems, designing systems, and understanding human behavior, by drawing on the concepts fundamental to computer science” (p. 33). Denning (2017) argued that computational thinking came into wide use during the 1980s when it was referred to as computational science. During this era, scientists started using computational science as the term for emerging branches of science that used computation as their primary method of inquiry. Physicist Kenneth Wilson, who developed “computational models that produced startling new discoveries about phase changes in materials,” was instrumental in lending credence to the field. Denning also suggested that some of the scientists “used the term computational thinking for the thought processes in doing computational science – designing, testing, and using computational models.” He went on to define computational thinking as “the mental skills that facilitate the design of automated processes” and asserted that CT became popular after 2006 when educators started using computation as a part of STEM education in order to draw more young learners to science. While there have been a number of CT definitions, Wing (2006, 2008) identified three A’s of computational thinking as being central to the practice of computer science and as being the most critical skills for students to develop – abstraction, algorithms, and automation.

Abstraction

Wing (2008) described abstraction as “the essence of computational thinking” in which “deciding what details we need to highlight and what details we can ignore – underlies computational thinking” (pp. 3717–3718). Abstraction allows us to deal with complexity by focusing on the essence of an object/problem and ignoring unimportant details. Using abstraction, individuals must choose “the right detail to hide so that the problem becomes easier, without losing anything that is important” (Csizmadia et al. 2015, p. 7). Throughout the process of enacting possible solutions to problems, individuals must repeatedly

revisit their previous abstractions to refine them, test them, and refine again. Abstraction is used to craft algorithms, decide upon test cases, identify needs of the stakeholders, and a myriad of other tasks related to problem-solving.

Algorithms

Algorithms in their most basic form are a series of step-by-step instructions for how to complete a task. Wing (2008) stated that algorithm is an “abstraction of a step-by-step procedure for taking input and producing some desired output” (p. 3718). As algorithms become more complex they allow for decision points, request data from other sources, and may branch into simultaneous processes. The development, refinement, and repeated use of these algorithms is another central component of computational thinking (Wing 2006, 2008; Barr and Stephenson 2011; Yadav et al. 2016b). Within the context of computer science, algorithms are represented through lines of code, whereas within the noncomputing environment algorithms could be employed via flowcharts and similar planning tools to ensure that tasks are completed in a complete and timely manner. We use algorithms daily in our lives to accomplish simplistic tasks, such as brushing our teeth, to solving more complex problems, such as the traveling salesman problem. For students, refining the skill of developing algorithms allows them to employ their existing abstractions to develop solutions to problems. The visual or textual representations of those algorithms provide a guide to their planned steps, which they can refer to when interpreting unexpected results.

Automation

Wing (2008) argued that while abstraction is the mental tool of computing, computing itself is the automation of our abstractions. Automation, the act of mechanizing an algorithm, gets to the heart of what makes computation so powerful in multiple fields. In its most common form, automation is enacted through the use of computing hardware and software. However, Wing also argued that this could also be done within the human “hardware,” as there are tasks that humans still execute more efficiently than computers, such as visual interpretation of objects. For students, this is not simply learning how to translate instructions into code, or a set of steps for their classmates to enact. For automation to be powerful, students must consider the strengths and weaknesses that their “hardware” provides. Crafting an algorithm with these characteristics in mind will result in a more effective and efficient solution.

CT in Primary and Secondary Education

Building on Wing’s work, researchers have expanded on these central computational thinking concepts to allow educators to embed them in elementary and secondary classrooms. For example, Barr and Stephenson (2011) envisioned computational

thinking in the classroom through a collection of nine CT concepts and capabilities. Specifically, they suggested that data collection, data analysis, data representation, problem decomposition, abstraction, algorithms/procedures, automation, parallelization, and simulation have applicability across multiple subject areas in elementary and secondary classrooms contexts. Grover and Pea (2013) also offered elements of computational thinking that could form the basis of curricula, including pattern generalizations, processing of information, problem decomposition, and conditional logic. While programming is one of the key tools for supporting the development of computational thinking, researchers have also suggested that unplugged activities (i.e., not using a computer) are equally valuable in introducing computing ideas and the nature of computer science to students (Grover and Pea 2013; Yadav et al. 2014, 2017).

To introduce CT concepts to a primary and secondary audience, it is critical to keep in mind that these skills are already being used to some degree in the classroom (Weintrop et al. 2016). What computational thinking provides is a framework for naming, organizing, and developing these abilities into a complementary skillset (Voogt et al. 2015). Students use abstraction when deciding what belongs on a chart of plant growth, categorizing numbers in a mathematics lesson, or writing a report on their summer vacation. Algorithms are developed and employed in science experiments, developing strategy in sports in gym, and developing daily study habits. Automation can be found in simulations and models that are enacted with software in the classroom, such as viewing animations of the effects of global warming models on coastlines, how altering the shape of a catapulted object affects its velocity and flight path, or how different preferences may affect how students arrange themselves on a school bus.

We believe that computational thinking provides a framework for educators and students to become familiar with how computing ideas influence and transform other disciplines. This has multiple benefits as students develop an understanding of computational thinking. First, it opens pathways for students into computing fields and even prepares students for a future in computer science. Those entering a programming course for the first time will be aided by the familiar terminology such as algorithms, data, and logic. Second, it allows students to understand how computation shapes their lives in an increasingly digital and computerized world. A knowledge of CT concepts and practices provides students with opportunities to see its applicability and use to solve complex problems in other domains. For example, a scientist may be able to use CT skills to automate lab tests and analyze results; an artist could use it to design computational artifacts; and a historian could discover patterns in documents and maps as a result of having an understanding of CT.

Another argument for embedding CT ideas in primary and secondary schooling is to prepare students to become critical consumers of information in a digital age. The knowledge of computing would give students a skillset to be critical of how and why they receive particular news stories and know how advertisers target their needs. Gretter and Yadav (2016) argued that computational thinking is complementary to media and information literacy to provide students with not only useful tools for their further studies and careers but also a critical lens through which to approach their

personal and professional lives. Majority of the efforts to expose students to CT has been lead under the umbrella of computer science education efforts. In the following section, we discuss how these efforts are shaping up across the globe.

Curriculum for Computer Science Education: A Global Perspective

Across the globe, a number of governments and organizations have ramped up efforts to expand access to computer science in primary and secondary classrooms. For example, in the United States, the CS for All consortium is a culmination of years of hard work of computer science education community to expand computing education in K-12 schools in the United States. Similar efforts are underway in other countries, such as Computing at School in the United Kingdom (Peyton-Jones et al. 2013) and Digital Literacy in the Netherlands (Voogt and ten Brummelhuis 2014). The common thread across all of these initiatives is the need to prepare students for the jobs of the future in a twenty-first-century digital economy. The jobs argument is valid and strong as computing jobs are one of the highest job growth areas over the next decade (Bureau of Labor Statistics 2016). However, just using the jobs as the reasoning for computing education sells short the power of computer science to influence students' thinking and creativity. A stronger argument could be made regarding how computing allows an expression of creative ideas and develop students' problem-solving abilities (Yadav and Cooper 2017). The emphasis on creativity in computing has appeared in many places in newly developed curriculum, including its appearance as one of the seven big ideas in the new Advanced Placement Computer Science Principles Course.

Current State of Affairs: The United States

The current push towards increased access to computer science in American elementary and secondary schools has been based on a number of efforts over the last decade led by National Science Foundation (NSF) and Computer Science Teachers Association (CSTA). With support from NSF, the College Board launched a new course entitled Advanced Placement Computer Science Principles (CSP) in 2016–2017 to help increase student participation in computing. The CSP course, which focuses on a selected subset of seven big ideas in computer science (Abstraction, Algorithms, Creativity, Data and Information, the Internet, Global Impact, and Programming), covers concepts from a broader perspective than traditional programming-centered courses (College Board 2016). One of the chief aims of this course is to attract a more diverse set of learners given the large gender and racial imbalance in computer science courses.

Both the CSP course and increase in computer science education advocacy led by NSF, CSTA, and [Code.org](https://code.org) has driven a significant increase in demand of computer science courses in US schools. For example, the number of overall students taking the AP CS A exam increased by 17.3% in 2016 (Ericson 2016). While this growth has been significant in terms of overall participation, the number of women and underrepresented

minority student participation is still far below the expected rates. Additionally, pass rates for students of color remain abysmal. Given the focus of CS principles on big ideas of computing, it is hoped that it would open pathways for all students to pursue computing and reduce the disparities in numbers of minority students in computer science.

While there is an increase in enthusiasm and enrollment of students into computer science, there are several barriers that exist that could derail these efforts. One of the biggest challenges to meet the critical needs in computing education in the United States is the training of new teachers (CSTA 2013). A report on teacher certification in the United States stated that “teachers, administrators, and policymakers must work together to create requirements that are grounded in the discipline of Computer Science and these requirements must be supported by teacher preparation programs for pre-service teachers and professional development for current teachers that enable all teachers to become exemplary teachers” (CSTA, p. 26). With various entities pushing for every student to have access to computing education in the curriculum, the need for qualified educators is the major bottleneck for reaching equity and accessibility goals. While a number of efforts have focused on providing professional development and training for inservice teachers, there is an urgent need to develop pathways at the teacher preparation level to provide certification for pre-service teachers to teach computer science (Flatland et al. 2015). Once the issue of how to recruit, train, and retain computer science educators has been addressed, future steps to examine best teaching practices will move to the forefront in CS teacher preparation.

Current State of Affairs: United Kingdom

Similar to the efforts in the United States, Computing at School (CAS) effort in the United Kingdom has spearheaded computer science in elementary and secondary classrooms. The working group for CAS had its inception at Microsoft Research Cambridge in 2008, and blossomed as part of a partnership with the British Computer Society (Peyton-Jones et al. 2013). The collaboration between these groups was the start of the development of a full computing program for primary and secondary schools in schools in Scotland, Wales, Northern Ireland, and England. In 2012, following the publication of the report “Shutdown or Restart” from the Royal Society, the government made the necessary legislative changes to include computing in the curriculum (Furber 2012). To change the computing opportunities for learners in the United Kingdom, a General Certificate of Secondary Education for Computer Science was henceforth offered to students at age 16. This was the replacement to an existing curriculum for an Information and Computing Technology course which allowed students to focus on computer science concepts in their program of study. Additionally, computer science was added to the English Baccalaureate science section. This effort has seen a rise in the number of students participating in the General certificate of Secondary Education (GCSE) for computer science to 62,945 students in 2015–2016 (from 15,557 in 2013–2014), with 12,700 of those students being female (from 2300 in 2013–2014) (United Kingdom Department for Education 2016).

In order to meet the growing need for CS teachers in the United Kingdom, the government has primarily focused on recruiting new educators in computer science with the launch of a program to provide scholarships of £20,000 for computer scientists that intend to train to become teachers. To support beginning teachers, CAS has also led the effort to provide professional development of computer science teachers through local communities of practice. Sentance et al. (2014) discussed the CAS professional development model, which uses master teachers to support beginning computer science teachers in a community of practice. Master teachers are experienced computer science teachers with “excellent subject pedagogy and outstanding classroom practice” (p. 81), but also have “experience in mentoring colleagues, running training sessions, and credibility in their communities” (p. 82). Other parts of the United Kingdom have experienced different challenges in their CS education efforts, mostly around issues of teacher preparation. A report by CAS Scotland found that there is a greater outflow of retiring teachers as compared to influx of new CS teachers, which has led to a 25% drop in CS teachers (CAS Scotland 2016).

Current State of Affairs: Examples from Other Countries

A number of other nations have focused their attention on CS education at the primary and secondary levels. Of particular interest are regions and nations that have seen investment from advocacy groups, and the curriculum changes that seek to engage all students in the conversation about computing.

In Netherlands, a dramatic shift towards computer science education happened in 2013 with the publication of a report on digital literacies by the Royal Netherlands Academy of Arts and Sciences (See Lenstra et al. 2012). The report forced Dutch educators to assess the role of computational thinking in their preexisting digital literacy courses (Voogt and ten Brummelhuis 2014) and how it fits “as part of the digital literacy skills along with critical thinking skills when using Information and Communication Technologies (ICT), and applying (ethical) rules when using ICT, including notions of privacy and security” (Yadav et al. 2017, p. 1055). In addition to the computing specific change, Netherlands has also embraced a larger national movement known as “Onderwijs 2032,” with a goal to create a dialogue on skills needed by students that will graduate in 2032.

Australia made a commitment to invest \$12 million to revamp the national curriculum, aiming to replace components of history and geography at the primary level with coding (Sarabia 2015). As a part of this effort, the Victorian Certificate of Education (VCE) includes a new study on algorithmic thinking to provide students with the foundation to study computer science and software engineering. In New Zealand, there are digital technology guidelines now in place for schools based on a listing of “Technological Context Knowledge and Skills,” including a segment focused solely on computer science (Bell et al. 2010). This includes higher level questions regarding tractability, coding complexity, and implementation of the software development lifecycle.

Israel has a long history of attention to computer science education dating back to influential changes in the mid-1990s. In the early 2010s, a renewed emphasis was placed on the sciences, which included a revamp of the computer science curriculum in secondary schools. In addition, students in Israel may take an entire computer science track in high school, which involves five additional units including topics such as, cybersecurity, graphics, and mobile development (Gal-Ezer and Stephenson 2014). Other supporting elements in Israel include the Machshava, which is the Israel National Center for Computer Science Teachers. The center focuses the work of Israeli CS educators through conferences, courses, meetings, publications, and learning material development.

Finally, in Mexico we have an example of a nation that is taking some preliminary steps towards engaging the population with computing curriculum. Student enrollment is up overall (94% of 6–14-year-olds in 2010), but the nation still deals with high dropout rates. A majority of schools do not have computers at all, and only 18% have access to the Internet. In conjunction with CS Ed Week 2014, Mexico adopted the Scalable Game Design approach, and implemented CS Ed Week activities in a small number of schools focused on this curriculum (Escherle et al. 2016). The impact of this approach has yet to be measured fully, and there is much work to do to provide opportunities to explore computing across the curriculum.

Research Agenda for Computing Education

The growing demand to increase the role of computing in schools also provides a unique opportunity to expand computing education research, which has significantly lagged the rapid growth of computer science. We have decided to use computing education research rather than computer science education intentionally because we do not want this productive research area to be limited to just learning to program. Instead, we view computing education research broadly, which includes questions like how to embed computational thinking concepts and practices in other subject areas; how do computing activities influence learners creative thinking; what knowledge teachers need to effectively teach computing concepts; how to train CS teachers through professional development and teacher preparation programs; how to assess student learning and understanding of computing ideas; and how to engage a diverse group of learners in computing. Computing Community Consortium recently released a white paper (Cooper et al. 2016) on the importance of computing education research and called the field to answer some fundamental research questions in the field:

- “How should we teach computer science, from programming to advanced principles, to a broader and more diverse audience?”
- How can we ensure that we retain this more diverse audience through inclusive pedagogy and generally more effective teaching?
- How can teaching approaches and their assessment (regarding student learning) scale effectively?

- What training should K-12 teachers receive? What methods have been shown to be effective?
- How can computer science teaching adapt to how different people learn and build on age-related learning progressions?
- How should computing be taught and integrated into other disciplines?” (p. 1–2)

These broad questions serve as a good starting point for computing education researchers to expand the empirical basis for what works. However, in order to answer these questions, computer education research needs to move beyond experimental design as the standard for methodological rigor and value other theoretical perspectives and approaches. While there are a number of research studies that could be developed under these questions, we focus remainder of the chapter on a discussion around computer science teacher development and factors that influence student learning in computer science.

Research on Teacher Training and Development

As discussed previously, training and development of teachers remains one of the biggest obstacles to meet the growing demand of computing courses. The challenge is not only to train new teachers to teach computer science but also prepare teachers to embed computational thinking within core subject areas. The challenge of recruiting, training, and retaining CS teachers becomes even more problematic given that we know little about what knowledge teachers need to effectively teach computing concepts and how to support CS teachers given that they are typically the lone teacher in schools (Yadav et al. 2016). A recent study by Yadav and colleagues (2016) found that CS teachers report a number of challenges related to teaching computer science, including limited content and pedagogical knowledge related to computer science. Specifically, the study found that teaching computer science presents a unique set of challenges outlined below.

- *Isolation.* There are few computer science teachers (often at most one per school), and they typically work independently from one another. They rely on email lists and online discussion groups to stay in touch, rather than informal collaborations and opportunities to team teach.
- *Professional Development.* With the combined difficulties of a rapidly changing computing field, lack of training opportunities, and busy workday schedules, teachers are finding it increasingly difficult to stay current in the field.
- *Lack of Support.* Teachers face a lack of support for and interest in computer science from administrators and IT staff.

Other researchers have also reported similar barriers teachers face in the classroom and types of support they need to be successful (Sentance and Csizmadia 2016). Prior research on teacher retention has suggested that 40–50% of teachers leave the profession in the first 5 years as a result of a number of factors, including

isolation (Fantilli and McDougall 2009). Within the STEM disciplines, teacher retention is even more dire as teachers in these fields are twice as likely to leave the profession than any other subject area (Ingersoll 2001). Furthermore, teacher turnover in urban areas is significantly greater than suburban areas as highlighted by Guarino et al. (2006) who found that “28% of teachers in the New York City region were still in the same school 5 years later, as compared with 46% in suburban schools” (p. 189). Given that the recent efforts to expand computer science have mainly involved large urban school districts in the United States, such as New York City and Chicago, so it is important for computer science educators to examine potential pitfalls in teacher retention and develop mechanisms to support beginning CS teachers.

While there is considerable work being done to provide professional development to teachers, we know little about the impact of this training with regard to addressing the following questions for the CS education community. How can we train and showcase effective instructional practices to inservice teachers, where they can learn to use the knowledge in the context of classroom practice? How do teachers acquire knowledge, including the knowledge of subject matter, pedagogy, and pedagogical content knowledge? The number of inservice teacher professional development providers, such as Project Lead the Way and Exploring Computer Science, provides an opportunity for researchers to better understand how different professional development models (face-to-face vs. online, short intensive summer programs vs. longer academic year programs, etc.) can support computer science teachers and develop their knowledge to teach computer science to all students.

In order to examine the effectiveness of the professional development efforts to train computer science teachers, researchers need to develop measures that examine teachers’ knowledge to teach computing (i.e., pedagogical content knowledge). Shulman (1986) argued that in addition to the knowledge of subject matter and knowledge about methods of teaching, ability to teach also requires pedagogical content knowledge (PCK), which includes “the ways of representing and formulating the subject that makes it comprehensible to others” (p. 9). We know very little about what computer science pedagogical content knowledge (CS-PCK) looks like and how teachers come to develop CS-PCK. In an analysis of teaching vignettes designed to measure CS-PCK, Yadav and colleagues (2016) found that computer science teachers are able to address observable issues of teaching; however, they struggle to see students’ thinking during teaching. Other researchers have also argued that measuring CS-PCK should include teachers’ ability to recognize and address student thinking (Margaritis et al. 2015). While there is some research beginning to emerge on CS-PCK, we need to measures that transfer across teacher training efforts to assess what models are successful in developing knowledge teachers need to effectively teaching computer science.

The computer science education community also needs to address teacher pipeline issues in order to ensure that there will be enough teachers to meet the increased demand of computing courses. A natural place to address this issue is at the pre-service teacher preparation level through colleges of education. Yadav and colleagues (2016) argued that the dearth of CS teacher preparation programs in

conjunction with teacher attrition rates should cause alarms for CS education stakeholders, including policy-makers. A CSTA (2013) report highlighted that teacher certification in the United States is deeply flawed as there are few pathways for undergraduates to become certified to teach computer science. A Computing at School report in Scotland also called attention to similar challenge of recruiting high quality applicants to teacher education program in computer science (CAS 2016). So how do we prepare next generation of teachers to not only be able to teach computer science but also become computationally literate teachers. An initial starting point might be for teacher education programs to embed computational thinking ideas in the core courses for pre-service teachers. This could start with educational technology courses forming the core, and then incorporating CT ideas into content area methods courses (Yadav et al. 2017).

Yadav et al. (2017) provided a framework to prepare preservice teachers to teach computational thinking and provide recommendations on approaches to do so within the constraints of teacher education curricula. Prior research has suggested that once preservice teachers are exposed to computing ideas, they are more confident in their ability to integrate those ideas in their own practice (Yadav et al. 2011, 2014). We also believe that once teacher education students are exposed to these ideas, they are more likely to pursue computer science teaching licensure programs. Future research needs to examine these pathways for preservice teachers and how they come to understand computing ideas. For example, research need to understand how varying levels of exposure to computational thinking from small modules to integration in the teacher education curricula influences preservice teachers' knowledge of CT as well as confidence in pursuing computing courses.

Research on Student Learning in Computer Science

Research on student factors that play a role in learning has been one of the most productive areas within computer science education. A number of studies have examined how cognitive (e.g., Barker and Unger 1983), noncognitive (e.g., Wiedenbeck 2005), and background (e.g., Wilson and Shrock 2001) variables influence students' academic outcomes in computer science. Cognitive factors have mainly involved mental ability constructs, generally surrounding problem solving, critical thinking, analytical reasoning, and mathematical ability. Non-cognitive factors, on the other hand, have included motivational constructs, self-efficacy, and metacognitive strategies. Researchers have also examined how students' prior programming experience (e.g., Hagan and Markham 2000), anxiety and comfort level (e.g., Bergin and Reilly 2005; Wilson and Shrock 2001) influence their performance.

Prior research has examined a number of different cognitive factors (such as, problem solving and abstract reasoning) in relation to student outcomes in computer science, focusing primarily on programming courses (e.g., Barker and Unger 1983). Various skills related to problem solving are also related to student success in programming, including the ability to translate a problem statement into abstract

formal notation, the ability to choose the correct sequence of steps needed to solve a problem (Hostetler 1983), and the ability to predict the outcome of a procedure stated in plain language (Mayer 1985). Furthermore, training in problem solving strategies may contribute to success in programming courses (Evans 1988). Other cognitive variable that predict students' performance in programming include abstract reasoning development (Barker and Unger 1983a) and mathematical ability (Wilson and Shrock 2001; Bergin and Reilly 2005).

A number of studies have also examined how noncognitive variables, such as motivation and self-efficacy, relate to student outcomes in computer science. For example, Wiedenbeck (2005) found that self-efficacy is positively associated with overall course grades and students debugging abilities. Similarly, Ramalingam et al. (2004) found that CS1 (introductory programming course) students' self-efficacy increased over time and was positively associated with course grades and previous programming experience. Goal orientation is another noncognitive variable that influences success in CS. Intrinsic goal orientations have been found to be associated with higher exam scores in a CS1 course (Bergin and Reilly 2005). The use of metacognitive strategies is associated with higher course grades in CS1 (Bergin et al. 2005).

In order to ascertain a fine-grained picture of how motivation and learning strategies affect student performance, Lishinski et al. (2016) used the Motivated Strategies for Learning Questionnaire (MSLQ) to measure students' self-efficacy, metacognitive self-regulation, intrinsic goal orientation, and extrinsic goal orientation. Through multiple measures of self-efficacy, programming projects, and two multiple exams throughout the semester, the authors were able to develop the most comprehensive picture to date on the role of noncognitive variable on student programming performance. Results suggested that self-efficacy was significantly related to students' multiple different types of programming course outcomes, including both multiple choice exams and programming projects. However, one of the most important findings was that "metacognitive strategies and goal orientation impact self-efficacy, which impacts performance, and then performance impacts self-efficacy, which then impacts performance again" (Lishinski et al. 2016, p. 218). The authors also found that male and female students modified their self-efficacy beliefs differently with females responding to performance feedback and revising their self-efficacy beliefs earlier than males.

Another noncognitive factor that appears to be important for success in programming is learner's comfort level. Comfort level refers to the general levels of feelings of ease and confidence that students experience in class and while doing course assignments. This factor has a strong impact on student success in programming courses (Wilson and Shrock 2001; Bergin and Reilly 2005). Not surprisingly, prior work has suggested that previous programming experience contributes to student success in programming courses with even one programming language increasing success in introductory programming courses (Hagan and Markham 2000). However, formal programming course experience may have more of an impact on student success than independent study of programming (Wilson and Shrock 2001). Previous programming experience may also have an indirect effect on students' programming course outcomes by virtue of having a positive effect on self-efficacy (Wiedenbeck et al. 2004).

Although many individual student factors have been examined in the literature on learning to program, there are many aspects of how and why students succeed or fail at programming that we do not yet know. The broadest issue with the existing literature on student factors in learning programming is that the majority of the research has only examined simple correlations between single and small groups of factors with the easiest to measure course outcomes, such as exam scores or overall grades. Despite the fact that researchers have created detailed models for the developmental process involved in learning to program (e.g. Robins 2010), researchers have by and large not investigated student success factors in the context of an ongoing learning process. Future research should examine how students respond to feedback as they learn to program, as it would allow CS education researchers to redesign instructional practices that are inclusive for all learners. Future research should also examine a number of other factors that have not yet been studied, such as the way students' affective states during programming influence their learning; how cognitive and affective factors interact to predict student success; and how dispositional characteristics during the process of learn to program differ across various student demographics.

Future research also needs to understand how these factors play a role in success for all students at the elementary and secondary level. Specifically, we need to examine the influence of computer science efforts (e.g., Computing at School, CSforAll, etc.) on students' understanding of computer science. Research needs to focus not only on how K-12 students learn programming but also how they come to understand computational thinking ideas (e.g., conditionals, data, etc.) and use computational thinking practices (e.g., problem-decomposition, abstraction, etc.). We also need to study how problem-solving skills developed as a result of engaging in computing activities transfer to other academic disciplines. Calao et al. (2015) found that students' understanding of mathematical processes increased significantly after embedding computational thinking ideas in sixth grade mathematics lessons. Future research needs to also study processes students engage with during computational thinking activities using qualitative methods, such as think-aloud interviews.

Valentine (2004) argued that computing education research needs to move beyond what he called "Marco Polo" research where a researcher describes "how their institution has tried a new curriculum, adopted a new language or put up a new course" and conclusions are drawn simply based on anecdotal evidence. Such research does not contribute to developing an empirical basis for what works in computing education. Computer science education researchers, however, should also be cautious as they try to study what works in computing education based on prior work in other social science fields, including education and psychology. The contextual nature of educational research means that findings do not transfer from one situation to another, which led Berliner to call education "the hardest science of them all." This is highlighted by Morrison (2015), who found that even rigorous experimental research studies from educational psychology do not replicate well in computing education. It is quite possible that the uniqueness of computing education makes it difficult to translate results from other educational domains.

Conclusion

This chapter focused on current computer science efforts across the globe to develop elementary and secondary students' abilities to think computationally, including how computation can help solve problems across disciplines. We believe that while computational thinking provides students with opportunities to engage in practices central to computer science, it also shows them how those ideas are applicable to other disciplines. However, as we have argued above, computer science education research is still in its infancy and there is considerable work that needs to be done in order to develop an empirical basis for what works in computing education. We have laid out directions for future research under two broad areas of teaching training and student learning. We understand a lot more about factors that influence student learning than how to develop computer science teacher knowledge. Given that the success of computing education efforts described in this chapter largely depends on training thousands of teachers, there is an urgent need to examine mechanisms to support teachers to effectively teach CS both at the preservice and the inservice teacher level. At the same time, we need to develop a more complete picture of how various cognitive and noncognitive factors interact to influence students' success in computing. While our discussion on directions for future research in computing is not exhaustive, we hope that it provides computer science education researchers a starting point to begin to address some of the research questions raised above.

Abstract

This chapter discusses current research on educational efforts to connect school learning with young people’s digital practices in- and out-of-school. Instead of focusing on divides between in-school and out-of-school learning or between the “digital generation” and other age groups, in this chapter we discuss what recent research says about the ways in which school can become a space in which young people’s digital practices can transformatively converge with schooling, and how this convergence is related to their learning and identity building. We begin our narrative reflection of current research by focusing on the myth of digital natives. Next, we will conceptualize recent efforts to researching and understanding young

people's engagement, learning and identity building across sites and contexts. We will then turn to illuminating some key rationales of current educational research on creating convergence in young people's social ecologies via the use of digital technologies and media. We conclude our reflections by pointing out that although there are some promising findings on how digital technologies and media can create convergence in young people's engagement and learning across sites and contexts, less research attention is given to young people's personal sense-making and self-making mediated by their digital practices, and how formal education could build on those practices for academic, vocational and/or civic ends.

Keywords

Young people · Digital Learning · Identity building · Social ecologies · In-school learning · Out-of-school learning

Introduction

Today's children increasingly grow up in media-rich homes and are in daily contact with a wide range of digital tools (e.g., Chaudron 2015). Digital practices and contents are becoming an important source of many young people's "cultural curriculum" not necessarily in the sense of preferable but in the sense of pervasive (Wineburg et al. 2007). At the same time, recent educational efforts motivated by the need to make the school curriculum more relevant for young people and to support their readiness for the twenty-first century including digital literacy have begun to explore the ways in which to meaningfully bridge the informal digital practices of contemporary youth with formal schooling (Hung et al. 2012; Ito et al. 2013). These developments stem from an accumulating body of research that points to a need to create coherence between formal and informal learning (Rajala et al. 2016; Bronkhorst and Akkerman 2016, see also ► Chap. 14, "Bridging Formal and Informal Learning Through Technology in the Twenty-First Century: Issues and Challenges" by Lewin and Charania). For example, emerging research suggests that disengaged students could become more engaged at school if sociodigital technologies they use in their informal lives were also made available to them at school (e.g., Salmela-Aro et al. 2016). There are also concerns for social equity and inclusion; for some students constructing coherence between school and other spheres of their lives is much easier than for others, with serious consequences for their success in school (Ito et al. 2013; Phelan et al. 1991). Furthermore, creating coherence between school instruction and students' everyday reasoning and cultural practices can support robust conceptual learning and engagement in authentic disciplinary practices in studies of different school subjects (e.g., Rosebery et al. 2010; Wong et al. 2010).

Curriculum reforms and pedagogies enriched by the use of digital technologies and media are being developed to connect with young people's everyday lives aligned with their experiential worlds and personal aspirations, including informal digital practices (Loveless and Williamson 2013). For instance, in Finland the new

national core curriculum calls for learning environments and pedagogies that draw upon students' life worlds in and out of school (FNBE 2014). The rationale for this approach is to relate with, critically examine, and further extend young people's learning experiences in- and out-of-school, and in general to make learning at school more interesting and relevant to students encouraging their lifewide and lifelong learning (Kumpulainen and Sefton-Green 2014). Furthermore, as young people's informal lives and peer cultures are widely reported to be strongly related to their academic engagement and learning (e.g., Bempechat and Shernoff 2012; Berndt and Murphy 2002), attention in education is increasingly directed to the social ecologies of young people's learning, defined as a set of interacting sites in young people's lives that mediate their engagement, learning, and identity building (Barron 2006).

In this chapter, we will direct our attention to the rationales of recent research on educational efforts to connect school learning with young people's digital practices in- and out-of-school. By drawing on recent research studies in the field, we will reflect on the conditions and implications of such efforts and what is currently known about how these mediate and position young people's learning and identity building. Instead of directing our attention to divides between in-school and out-of-school learning or between the "digital generation" and other age groups, in this chapter we discuss what recent research says about the ways in which school can become a space in which young people's digital practices can transformatively converge with schooling, and how this convergence is related to their learning and identity building.

We begin our narrative reflection of current research by focusing on the myth of digital natives. In doing so, we demonstrate the important role of educational institutions in fostering every young people's technological fluency, digital literacy, and other twenty-first-century knowledge and competencies. Next, we will conceptualize recent efforts to researching and understanding young people's engagement, learning, and identity building across sites and contexts. We will then turn to illuminating some key rationales of current educational research on creating convergence in young people's social ecologies via the use of digital technologies and media. We conclude our reflections by pointing out that although there are some promising findings on how digital technologies and media can create convergence across sites and contexts of young people's engagement and learning, too often young people are positioned authoritatively to standardized expectations of the school. Less research attention is given to young people's personal sense-making and self-making mediated by their use of digital technologies and media across contexts, and how formal education could build on these practices for academic, vocational, and/or civic ends.

"Digital Natives": A Problematic Category

For the last two decades or so, young people have oftentimes been characterized by notions such as "digital natives" (e.g., Prensky 2001), "digital generation" (e.g., Tapscott 1998), or in terms of other portrayals of expert technology users. Proponents of such categorizations have argued for the highly active, engaged, and resourceful kinds of learning young people are gaining, for example, with digital

games and online activities (Ito et al. 2013). However, there is very little research evidence to support the claims that all young people are digitally savvy and that they have radically different patterns of knowledge creation and sharing in comparison with older generations. In fact, the level of digital competencies among children in Finland and throughout Europe is found inadequate (European Commission 2013). Young people are reported to be adept in using technologies for operational purposes but they generally lack more advanced competencies, such as critical literacy (Ala-Mutka 2011). Overall, research indicates that mere exposure to technology does not equate with the development of more advanced digital competencies. The picture of young people as being information-savvy digital natives is more of a myth than an evidence-based claim (Kirschner and De Bruyckere 2017).

Also labeling youth under a unified label of “digital natives” or alike category based solely on generational differences is argued to be flawed and misleading (Bennett et al. 2008). Not all young people have equal opportunities to use digital technologies fully due to various social and cultural factors, lack of interest and confidence, or social support (Ala-Mutka 2011). Altogether, the digital native paradigm discounts technical skill disparities that result from developmental, socio-economic, gender, and cultural differences, effectively erasing the educational needs of the individual and privileging the technically adept (Bennett et al. 2008).

Although physical access to digital media is becoming less of an issue, there are stark differences among young people in access to learning opportunities that will help position them to use media in ways that can promote their own development and career paths (Barron 2006). It is generally educationally privileged youth with productive learning supports at home who are able to take full advantage of the new learning opportunities that the online world has to offer and to translate these opportunities to their academic and/or career success (Li et al. 2017; Ito et al. 2009). Hence, the role of educational institutions in supporting every young people’s learning and identity building in and for the digital age deserves attention.

Learning in School and out: From Dichotomies to Convergence

The uptake of digital technologies and media in various spheres of life has changed the ways in which young people can access information; create and consume, use, and produce meaning and knowledge; how they can interact with others; how they can engage in learning; and how they see themselves and their futures (e.g., Li et al. 2017). The growing diversity and fragmentation of today’s media ecology means that young people have a greater range and choices in their participation, learning, and identity building (e.g., Erstad and Sefton-Green 2013). It is evident that the sites and contexts of learning of many young people, at least in the Western world, have expanded and transformed from the time when Lauren L. Resnick (1987) wrote her seminal paper on the discrepancies of in-school and out-of-school learning. For her, school learning is typically based on individual performance, symbolic thought, and general skills and knowledge. Out-of-school learning, on the other hand, is mostly socially shared, tool-aided, and embedded in mediating objects, resources, and

situations, resulting in contextualized competencies, skills, and knowledge practices (Resnick 1987).

While contrasts between the dominant features of learning in-school and out are valuable in extending our understanding of the contextuality of learning, this limited view of in-school and out-of-school learning easily leads to oversimplifications on the nature of young people's engagement, learning, and identity building in the digital age. Most importantly, this kind of conceptualization is unable to explain the convergences and inter-relationships between various sites and contexts in young people's social ecologies. For example, to date we have little knowledge how young people's informal digital literacy practice mediate their engagement and learning at school. We also know little how learning at school travels to and impacts young people's informal lives. Yet, the questions of how, when, and why young people learn are particularly salient now, as there has been a rapid increase in access to information and to novel kinds of technologically mediated learning environments. Understanding how engagement, learning, and identity are distributed among multiple settings and resources is hence an increasingly important goal.

Today, educational researchers are increasingly directing their attention to researching young people's learning and identity building across sites and contexts (e.g., Erstad and Sefton-Green 2013). For the most part, these studies have been guided by sociocultural theorization on human learning and development (e.g., Cole 1996) where learning is conceived as ontological and ideological as much as it is epistemological. This intertwined and holistic understanding allows researchers to approach young people as actors who participate not only in school but other contexts which dynamically interact with one another and contribute to their meaning-making (i.e. learning) and self-making (i.e., identity building) (McLay et al. 2017).

The sociocultural framing defines learning as a social construct that emerges in interaction, while people participate in and contribute to various activities mediated by different communities, participants, rules, instruments, and artifacts. Here, learning is understood as a holistic experience of participation situated across multiple sociocultural contexts, not as something that takes place exclusively in one setting, such as in formal education (Ludvigsen et al. 2010). Hence, rather than seeing technology use in schools merely in terms of "digital divides" or inequalities of access, many of these studies have turned their attention to the broader social contexts and symbolic resources that structure diverse educational uses of new media that lead to certain forms of engagement, learning, and identity formation among young people.

Creating Convergence in Young People's Social Ecologies

We can identify a variety of rationales for the use of digital technologies and media in education to promote young people's learning and identity building across sites and contexts, also captured in the notions of "seamless" or "anywhere anytime" learning (Wong 2013). As McLay et al. (2017) point out, many of these approaches

direct their attention to mobilizing young people's learning across physical and social space (Kearney et al. 2012), interest (or "conceptual mobility"), and time (Kumpulainen et al. 2013). In a recent review of research literature, Rajala et al. (2016) further explicated efforts to these approaches by identifying three, often overlapping, rationales that have guided educational efforts to build convergence in young people's learning across sites and contexts. These rationales are dealing with efforts to promote: (a) equity and educational inclusiveness, (b) learning requirements and competences of the twenty-first century, and (c) learner agency and identity. Our narrative review of empirical research in the field has been inspired by this distinction in rationales, and we use these rationales as heuristics to guide our work. However, in the context of our work, we have adjusted these rationales in order to better address the role and meaning of digital media and technologies in mediating young people's learning and identity building across sites and contexts.

Opening up and Valuing Diverse Opportunities for Educational Engagement

The rationale of educational inclusiveness stems from efforts for opening up diverse opportunities for young people's educational engagement in which they can harness various cultural resources stemming from their social ecologies to make meaning of their learning and becoming. An example of such an effort is a study by De Lange (2011) on vocational media studies course in a Norwegian upper secondary school. In this study inclusiveness was tied with efforts to promote young people's twenty-first-century competencies as the students were invited to address curricular goals on the basis of their informal media experiences. In the course, media teachers and their students worked together to collaboratively plan, execute, and evaluate classroom-based media projects. The findings of the study showed that the participative procedure of the course created a transactive space for students to bring in their informally developed expertise in using digital tools and to challenge the structuring of the classroom work. However, the author cautions that the students' experiences in using digital tools did not guarantee a reflective or knowledgeable perspective on their own digital practice. Instead for developing productive strategies of digital production, it was found essential that the teachers also confronted and challenged the students' perspectives.

Some other studies have also documented the creation of online learning spaces that resembled those that young people are commonly known to use in their leisure time in order to support young people's educational engagement (Lantz-Andersson et al. 2013; Kumpulainen and Mikkola 2014; Vigmo and Lantz-Andersson, 2014). The aim has been to let the students take these digital spaces as theirs and to enable them to use the advanced and creative media practices they have developed in their leisure time for academic learning. The digital spaces have included commercially available digital tools such as blogging (Vigmo and Lantz-Andersson 2014), Facebook groups (Lantz-Andersson et al. 2013), and various online collaborative learning spaces (Kumpulainen and Mikkola 2014).

Building Competencies for Active Participation in the Twenty-First-Century Society

The educational rationale of twenty-first-century learning requirements addresses young people's competences for active participation in the academic, working, and/or civic life. Such rationales are evidenced, for example, by studies that document young people's creative competencies across school and out-of-school sites, and which have positioned young people in the role of active producers instead of mere consumers of digital technologies and media (see e.g., de Lange 2011). In these studies, the expertises that students developed outside of school, such as in digital production, were not seen as self-sufficient but complementary to what they developed in school.

Other studies addressing the promotion of young people's twenty-first-century competencies, including civic engagement and citizenship have examined educational activities that deal with complex problems with social significance (Rajala et al. 2013). For example, Fauville et al. (2016) studied how a digital tool for calculating carbon footprint was used by high school students around the world. The carbon footprint calculator measures the quantity of a person's carbon dioxide emissions associated with their lifestyle and visualizes this otherwise invisible aspect of the person's environmental impact. The students used the calculator to determine how different activities of their everyday life contributed to their carbon footprint and compared the results to the local and global averages. Students were also prompted to reflect on how to reduce their carbon footprint. The averages of each of the participating classes worldwide were then displayed on a digital map and the students took part in international online discussions about the topics of climate change and its mitigation. Finally, students completed a questionnaire regarding the pedagogical activity. The study showed that involvement in the activity triggered emotionally and morally charged reactions, such as pride and guilt, among the students. The pedagogical activity also allowed the students to shift their focus between local and global perspectives in ways that challenged and expanded their views about the topic. The focus on a local perspective was found important because reflections at this level enabled students to feel responsible for the environment and take action. Yet, the possibility to shift to a global perspective fostered the students' awareness of the issues at a general level enabled them to make sense of their local life styles in the global context.

In some other educational efforts, the focus has been on young people's "abilities to self-direct" learning while engaging in learning activities across contexts. Here, self-directed learning has been considered as a valued learning outcome in itself. This argument is visible in the so-called seamless learning approach (Wong 2013). Wong (2013) presented two design experiments in Singapore in which seamless learning was fostered by giving primary school students smart phones that featured a digital camera and a mobile learning environment software. The smart phones functioned as "learning hubs" that the students carried with them all the time enabling them to manage their seamless learning across contexts and activities. The pedagogical design involved a cyclical model consisting of four types of

activities: learning engagement, personalized learning, online social learning, and in-class consolidation. Some of these activities took place in formal and some in informal settings. The first design experiment involved learning of idioms in Chinese, and the second one involved a series of inquiry-based science learning projects. Among other things, in both of the projects the students made observations and took photos in their daily encounters outside of school and associated these photos with the knowledge learned in the class. The students' photos and other learning products that they created were then discussed in virtual learning environment among peers and in class facilitated by the teacher.

While in both of the projects the seamless learning design contributed to the conceptual learning of the students, indications of the emergence of limited but growing self-directed seamless learning were documented. In the first design experiment, the students started to take photos illustrating given idioms in their homes and in other locations of their everyday life on their own initiative. Thus, the formal artifact creation activities "spilled into" the students' informal settings. In the second design experiment, the students started to sustain informal inquiries on topics of their own interest with the aid of the smart phones. The researchers interpreted these as indications of their success in "planting a seed of seamless learning in the children."

Identity Building across Sites and Contexts

Educational rationales addressing young people's identities across sites and contexts focus on young people's identity negotiations in relation to others, digital technologies and media, and the contexts of their activities (Erstad and Sefton-Green 2013). For instance, in their research, McLay et al. (2017) explored the fluid shifts and transformations of learner identities in response to the mediating influence of the iPad taken up in an Australian high school to enable students to move fluidly between in-school and out-of-school contexts. Following Bakhtinian perspectives, these researchers attempted to illuminate young people's identity building by making visible the ways the students negotiated their identities in relation to social resources and material resources, sometimes taking up and at other times resisting and rejecting various possible selves.

Altogether, a review of existing research reveals that there is fairly little documented research on young people's identity building processes in relation to educational efforts that aimed at building coherence in young people's learning across sites and context via the use of digital technologies and media. Furthermore, many of the reported educational activities have been framed authoritatively with expected ways of working, learning, and being with little attention to young people's self-making processes. These reported educational activities have positioned young people with somewhat predefined identities to which they are assumed to aspire and which are to promote particular kinds of desired futures for the youth. Such forms of identities often entail being active, creative, connected, autonomous, and self-responsible (Loveless and Williamson 2013).

Efforts that recognize and build on young people's own aspirations and motives are typically situated in other contexts than schools, such as, in after-school clubs,

libraries, science centers, and other cultural communities (e.g. Ito et al. 2013). Here, young people are supported to pursue their personal interests with the support of peers and adults with the goal of linking these initial interests to academic achievement, career success, and/or civic engagement. In doing so, such connected learning efforts aim to harness “digital technologies and media to more easily link home, school, community and peer contexts of learning; support peer and intergenerational connections based on shared interests; and create more connections with non-dominant youth, drawing from capacities of diverse communities” (Ito et al. 2013, p. 4). It remains to be seen how such “connected learning” efforts will travel to schools and how they manage to embody the values of students’ equity, social belonging, and participation, as advocated by such approaches.

Conditions and Challenges

While there are some promising findings how digital technologies and media can mediate convergence across sites and contexts in young people’s digital engagement, learning, and identity building, existing research has also pointed out challenges and critical conditions that are worthy of attention to guide future research and educational practice.

Extending Official Classroom Space to Incorporate Students’ Everyday Ways of Being

The study by Lantz-Andersson et al. (2013) which focused on the pedagogical use of a Facebook group in English-learning classes, with 60 students aged between 13 and 16 from Colombia, Finland, Sweden, and Taiwan, showed that the ways in which these spaces were framed in formal instruction created tensions with those of the students’ peer culture and everyday interactions. The study showed that the conventional educational activity was resistant to being extended to incorporate nonschool language use and that the conventional framing of the activity was sustained both by the teacher and the students. However, an expansion of the activity took place through students’ playful, everyday interactions that challenged the formal language use in the group. A posting by one of the students that made fun of the assignment generated a lively interactional exchange of comments that diverged from a formal language use at school and resembled young people’s everyday interactions in social media. The results of the study highlight that extending the official classroom space to incorporate students’ everyday ways of engaging in digital media was not trivial. Despite the seemingly unproductive nature of these exchanges, at times, they were found to mark a shift in the interaction pattern after which the students more frequently commented on each other’s postings. Also Kumpulainen and Mikkola (2014) in their study of primary school students’ chat interaction during collaborative writing of a school musical script both inside and outside school found out that seemingly “useless” everyday interactions of the students played an important role in building trust and social relationships. The study also reports that boundary crossing

in the students' chat interactions gave rise to hybrid spaces where the discourses of schooling and everyday life intersected.

As these studies show, the values and identities young people themselves wish to pursue can sometimes be at odds with what is considered appropriate in a school setting or teachers could find it risky to allow students to bring some aspects of their lives to school. Nevertheless, attending to more difficult aspects of students' lives can connect instruction to vital personal meanings in the students' lives and foster deep engagement in school learning (Zipin 2009; Thomson and Hall 2008). Conversely, the avoidance of topics that are of central importance in some of the students' lives may alienate these students from instruction. It is also important that the "cultural curriculum" of students' informal lives is brought under joint reflection, critical analysis, and elaboration in the schools, as to guide students' learning and identity building towards enriched directions promoting their academic, vocational and civic engagement, and learning.

Altogether, existing research points out how it is important to acknowledge that educational efforts that aim at building coherence across young people's digital learning lives across school and out can lead to meaningful and transformative engagement, learning and identity building can only emerge through sustained collective efforts. Without an appropriate curriculum and pedagogical working culture that transform traditional learning practices, digital media and the knowledge funds of contemporary youth are initially likely to represent a mere additional layer to schooling with a likelihood of even counter-productive consequences. Furthermore, while creating education extends across young people's social ecologies, it is thus not just a matter of implementing and putting into use alternative pedagogical ideas and technologies, but in many cases, it is also a matter of transforming simultaneously existing social practices. Co-evolution of the social and technological infrastructures of education should be the starting point for expanded and hybrid learning opportunities (Kumpulainen et al. 2013).

Authentic, Current, and Complex Real-Life Problems

Facilitating learning across sites and contexts also demands educational activities that are authentic, current, and complex real-life problems (Hakkarainen 2010). These learning activities can have the potential to transform the forms of students' engagement by expanding the requirements for engagement and bringing in new audiences with whom students pose questions; share and discuss their observations, opinions, reflections; as well as co-develop new knowledge and understanding. In these situations, students are likely to see the meaningfulness and applicability of their learning within and beyond the school. When doing so, new audiences respond, thus providing students with feedback about the feasibility of their ideas and work. In essence, the culture of learning mediated by hybrid approach leaves room for creativity, renegotiations, and surprises. Addressing authentic problems and tasks requires the teacher and students to work with open, flexible, and tentative plans and goals that might not be clear from the outset and need reconfiguring also along the way (Rajala et al. 2013).

Enacting educational opportunities that stretch across sites and contexts also require transformative actions on the part of the teachers (Lipponen and Kumpulainen 2011). In particular, pursuing a transformative stance to traditional pedagogical practice that is typically limited in space and time and dominated by narrow and authoritative stance can result in conflicts and contradictions (Brown and Renshaw 2000). However, questioning current practices and seeing alternative futures are pivotal prerequisites in transforming social practices (Engeström and Sannino 2010). Also, in order to connect learning and teaching to expert communities outside school, teachers and schools need to build partnerships and networks. Building networks and partnerships also requires new competences from teachers, such as being able to engage in multiprofessional collaboration (Kumpulainen et al. 2010). In sum, to build education that is responsive to young people's learning and identity building across sites and contexts requires transformation at many levels that create the systemic whole.

Conclusions

Existing research among youth has revealed that in contrast with the view of dissatisfied "Net Generation" people who do not value school, there is evidence that are a number of young people who regard school as a valuable learning environment (Bennett et al. 2008). Yet, it is the object and nature of learning that makes schoolwork easily irrelevant and meaningless. It is unwise to assume that the interest, motivation, or affinity of all young people will be automatically enhanced by the simple inclusion of digital media technologies in educational contexts. In fact, without a meaningful pedagogical agenda, students can react negatively to the use of technologies and media in formal education, what they may perceive as teachers' attempts to colonize their free-time domains (Sharples 2006). Indeed, a number of researchers warn against attempts to motivate and engage students simply through the introduction of consciously trendy forms of media technology into educational processes. Young people are unlikely to be automatically enthused and motivated by the use of digital technologies, social media, and gaming for educational purpose, if these technologies are not meaningfully integrated into learning practices and pedagogies that support their authentic and transformative engagement (Kumpulainen et al. 2013).

Education that is responsive to young people's social ecologies is part of a long-standing tradition in progressive education that has stressed the importance of civic engagement, connecting schools with the wider world, and the value of hands-on and social learning (Dewey 1916). Today's digital technologies and media offer us the ability to pursue these progressive goals in new ways through purposeful integration of tools for social connection, knowledge co-creation, and linking the classroom, community, and home. From this perspective, the role and position of the school in the digital age needs to be seen not in opposition to youth cultures nor as "digital enrichment" of traditional schooling but rather conceptualizing school as an important element of all young people's social ecologies for engagement, learning, and identity building in and for the digital age.

Education that stretches across sites and contexts has implications for schools, including curriculum, pedagogies, and the design of learning environments. Conceiving the school as a meeting place for different identities, interests, and discourses reveals the potential of formal education to become a site where no cultural ways of being and acting are secondary but important focuses of joint attention, analysis, and reflection (Gutiérrez et al. 2011). At best, it can provide teachers with a more holistic way of thinking about their students, directing attention to epistemic and ontological dimensions of young people's learning and becoming. Yet, as our narrative review reveals, little attention has been paid into educational activities that position children as active, creative, and critical investigators of and with digital technologies. Moreover, at present there is a dearth of knowledge for creating learning opportunities for digital competencies that are inclusive for diverse learners with different capabilities and interests, and that are able to accommodate their different personal situations and objectives and combine, for example, formal and informal learning (Kumpulainen and Mikkola 2014). In sum, these realities point out the urgent need for research and development of innovative pedagogies as to ensure meaningful learning experiences that enhance every child's digital competencies already early on.

It is clear that further research is necessary in order to better understand young people's learning and identity building in education that aims to build convergence in young people's social ecologies via the mediating influence of digital technologies and media. In specific, there is a need for research studies that look into the dynamics of young people's learning (sense-making) and becoming (self-making) at the intersection of multiple sites and contexts mediated by digital technologies and media. This seems as a serious deficiency that should be overcome as to gain a better understanding about the values and learning identities young people themselves wish to pursue in the moment and in their futures.

Section III

The Learner and the Learning Process

Section Introduction: The Learner and the Learning Process

9

Kwok-Wing Lai and Keryn Pratt

Abstract

This introduction provides an overview of the main focus of the chapters in Section III “The Learner and the Learning Process”, in the *Second Handbook of Information Technology in Primary and Secondary Education*.

Keywords

Technology-enhanced learning · Informal learning · Learning theories · Computer-supported collaborative learning · Inquiry learning · Social media

The landscape of technology-enhanced learning (TEL) in primary and secondary education has changed tremendously in the last decade due, at least in part, to the proliferation of mobile technologies and social networking applications as well as the availability of learning resources such as MOOCs and OERs. This change has led to a reconceptualization of how learning should be conducted and where, when, and how it should take place. The chapters included in this *Handbook* section have reviewed the most significant new developments of TEL in primary and secondary education and, in particular, discussed the pertinent learning issues and challenges related to technology use in education in the twenty-first century, with a key focus on the learner and the learning process. Since one of the objectives of this *Handbook* is to review the relationship between research and educational practice, the chapters in this section have paid close attention to pedagogical designs and highlighted exemplar practices in a variety of technology-supported learning environments, both in formal and informal contexts.

The first chapter of this section, (► [Chap. 10, “The Learner and the Learning Process: Research and Practice in Technology-Enhanced Learning”](#) by Lai), is an overview chapter, which reviews a range of promising and effective ICT tools used in the learning process focusing on their pedagogical design. New developments in neuroscience research and innovative pedagogical practices, such as flipped learning, one-to-one computing, and online learning, are also reviewed in this chapter. The author argues that while in the last 10 years there has been an increasing focus on the learner rather than on the technology, mainstream research is still primarily looking for technological impacts or effects on learning outcomes and adopts a rather deterministic view on the use of digital technologies in education.

In ► [Chap. 11, “Information and Communication Technologies, and Learning Theories: Putting Pedagogy into Practice,”](#) Dennen et al. discuss how learning theories, including behaviorism, cognitivist, and constructivism, underpin the use of digital technologies in the K-12 classroom. An emerging theory, connectivism, is also explored. The authors argue in this chapter that learning theories are important in guiding the development of pedagogical knowledge and instructional strategies, but there are challenges and implications of using them to successfully integrate information and communication technologies to the learning process to facilitate effective student learning experiences.

In ► [Chap. 12, “Developing Scientific Inquiry in Technology-Enhanced Learning Environments,”](#) Chan and Yang adopt a learning sciences framework to examine some key theoretical issues affecting the design of learning environments in supporting inquiry-based learning. Four technology-enhanced learning environments designed to support inquiry-based learning are reviewed. The learner and the learning process, nature of collaboration, pedagogical design, and assessment of these inquiry-based learning environments are compared to highlight the theoretical and educational implications of designing technology-enhanced inquiry-based learning environments.

Kimmons and Belikov argue, in ► [Chap. 13, “Cultural and Social Issues in Using Social Media to Support Learning,”](#) that while social media certainly have benefits to the learners, there are also cultural and social challenges related to their use in the learning process that practitioners need to understand. The authors of this chapter tease out these issues under four themes, namely, literacy, privacy, civility, and identity. Under each of these themes, they discuss the key problems in the use of social media and recommend how teachers can effectively tackle these problems.

In ► [Chap. 14, “Bridging Formal and Informal Learning Through Technology in the Twenty-First Century: Issues and Challenges,”](#) Lewin and Charania review how formal and informal learning are defined and how they can be connected by using technologies to support pedagogical practices. The authors argue for the importance of changing the school culture to support the shifting from transmissive to collaborative pedagogical strategies in order to enhance the learner’s agency and collaboration and provide opportunities for authentic learning.

Information and communication technology affords new learning opportunities for learners to learn together. The sixth and final chapter in this part, ► [Chap. 15, “Computer-Supported Collaborative Learning: Mediated and Co-Present Forms of Learning Together,”](#) by Schmitt and Weinberger, reviews the potentials and problems of different forms of computer-supported collaborative learning (CSCL) and discusses how current pedagogical approaches deal with these problems and afford the sharing of knowledge and co-creating solutions.

These six chapters in this section present a coherent theme, that is, we should not lose sight of the centrality of the learner when designing technology-enhanced learning environments. It is pertinent that when harnessing technology affordances, we focus on how well technology can afford the development of learner agency, in both personalized and collaborative learning and in formal and informal environments. This presents a challenge for practitioners and researchers to consider as we move forward in the twenty-first century.

has been increasing focus on the learner rather than on the technology, mainstream research is still looking for technological impacts or effects on learning outcomes, and many adopt a rather deterministic view on the use of digital technologies in education. It is also noted that how innovative technology-supported learning environments can be scaled up and sustained is a major issue. Also, more attention needed be put on the psychological and emotional effects of TEL, as well as health and safety issues of digital technology use on the young learners.

Technology-enhanced learning · Learning process and characteristics · ICT in education

Introduction

Since the publication of the overview chapter on the learner and the learning process in the first edition of this *Handbook* (Lai 2008) some 10 years ago, new digital technologies and applications have emerged and some of them (e.g., *Facebook and Twitter*) have become extremely popular with students. Children and young people now spend a significant amount of time using digital and mobile devices to access the Internet and the Web to engage in cognitive as well as social tasks. A survey undertaken by the Pew Research Center in 2015 reported that over 92% of the teenagers (aged 13–17) in the USA accessed the Internet on a daily basis, and close to a quarter of them (24%) used the Internet almost constantly, with 91% of them accessing the Internet at least occasionally using a mobile device (Lenhart 2015). Findings from PISA (Programme for International Student Assessment) also showed that students in the OECD (Organization for Economic Cooperation and Development) countries on average spent over 2 hours online during school days in 2012 (OECD 2015). Taking advantages of the new affordances of digital and mobile technologies, innovative pedagogical designs and models of technology-enhanced learning (TEL) have also emerged in the last decade. With the prevalence of digital and mobile devices and social media which undoubtedly has affected how children and young people communicate and learn, we note that in the last decade this increasing accessibility and connectivity of digital technologies have not only provided new learning opportunities but also created new issues and challenges.

With technologies being increasingly ubiquitous, it is pertinent for policy makers, practitioners, and researchers to understand their implications to learning, and in particular, how new digital technologies can help support the development of the twenty-first-century skills. In the last decade we have amassed a large number of case studies investigating technology use in different curriculum areas and levels. Review studies (e.g., Clark et al. 2016; Lawless 2016; Warschauer and Matuchniak 2010) have also been undertaken to synthesize research conducted in the field. We find that increasingly TEL research has attended to the contextual factors of learning, such as student learning characteristics and styles, demographic and socioeconomic contexts, subject content, school and class cultures, and a wider context at the system

level when investigating the relationship between technology and learning. Also, a realist perspective (Pawson et al. 2005) has often been adopted to understand the digital technology phenomenon. Instead of seeking a blanket answer to the question of what works, the question of what works for whom and under what conditions is now being asked and investigated by many TEL researchers.

The purpose of this overview chapter is not to add another review to the literature, but to screen the most significant developments of TEL in primary and secondary education in the last 10 years to highlight some significant learning issues and challenges related to digital technology use in the twenty-first century. This chapter thus surveys the landscape of how the field of technology-enhanced learning has advanced in the last 10 years, and also discusses its implications to the learner and how it affects the learning process.

In the other five chapters in this section of the *Handbook*, issues and challenges of the key pedagogical strategies related to TEL will be reviewed and discussed in more detail. These chapters will review and discuss several key technology-enhanced learning environments, including inquiry-based learning, computer-supported collaborative learning (CSCL), learning supported by social media, and learning facilitated in informal contexts. Key learning theories underpinning the use of technologies in the learning process will also be reviewed in one of the chapters.

We begin this chapter by focusing on the learner, and reviewing how digital technologies have influenced the learning behaviors based on research findings from cognitive science and educational neuroscience. Then we will discuss the relationship between technologies and twenty-first-century skills. In the subsequent section we will discuss some new technology-enhanced learning models and strategies, and finally key issues and challenges in TEL will be reviewed in the last section.

The Digital Learner

The Myth of the Digital Native

With the prevalence of digital and mobile technologies, a pertinent question is whether and how students would learn differently. Some researchers argue that since students increasingly spend a large amount of time immersing in technologies both in and out of school, the current generation of learners has developed a set of learning characteristics and styles which are fundamentally different from previous generations (e.g., refer Prensky 2001; Rosen 2010). The term digital natives has often been used to describe the young digital learners who prefer images than text, multitask, are constantly connected with their peers, have needs for immediacy, and prefer experiential learning (Bullen et al. 2011). Due to these new learner characteristics, the digital natives advocates further argue that new pedagogical strategies should be designed to meet their “more technology-driven, spontaneous, and multi-sensory” learning needs (Prensky 2001). While the concept digital natives is intuitively appealing, it is noted that very little empirical research has been conducted at the primary or secondary levels to show that there is in fact a distinctive set of digital

learning styles characterizing children and adolescents of the digital age. On the contrary, research conducted in higher education (e.g., Bullen et al. 2011; Lai and Hong 2014) suggests that the way younger tertiary students (who would be considered as digital natives) use digital technologies does not fundamentally differ from older students (who would be considered as digital immigrants) and it will be an oversimplification to use terms such as digital natives to categorize young learners as a homogeneous group. However, while the validity of the digital natives concept is questionable, with the widespread use of digital technologies, undoubtedly children and young people have now developed certain expectations of how technologies should be used in formal and informal learning settings. These expectations have created pressure for teachers to change their pedagogical practices and policy makers to invest in digital technologies as well as develop guidelines for their use.

Advances in Neuroscience Research

There is a high expectation that recent advances in neuroscience research using technologies such as functional magnetic resonance imaging (fMRI) and electroencephalography (EEG) to identify changes in neural activities can increase our understanding of how the brain works and how neural activities affect the learner in the learning process. A new discipline called educational neuroscience has been rapidly developing in the past decade focusing on how cognitive neuroscience research can inform educational practice. It is expected that a better understanding of the biology of learning will provide guidelines to classroom practice and specifically for TEL (Howard-Jones et al. 2015). For example, neuroscience research findings relating to the plasticity of the brain have already led to the conjecture that frequent interaction with digital technologies may reorganize and restructure the brain (Prensky 2009). This conjecture has resulted in the flourishing of computer-based brain training software aiming to improve the working memory for retention and transfer of skills, arithmetic and reading performance, as well as literacy skills (Howard-Jones 2014). However, it is not yet clear what and how these computer-based training programs can help achieve. A review of 20 computer-based math intervention programs by Kroeger et al. (2012) concluded that “[A]lthough much has been learned about how the brain develops and functions, and program development has begun to be influenced by neuroscience, claims that bear a direct impact on individual student learning may be immature” (pp. 52–53). Researchers have also begun to apply neuroscientific principles to technology-enhanced learning. For example, Howard-Jones et al. (2015) have investigated the relationship between digital gaming and the brain’s reward system to seek explanations as to why game-based learning is effective. However, it is acknowledged that at present the connection between educational neuroscience research and technology-enhanced teaching practice is not straightforward and it is difficult to translate educational neuroscience research findings into technology-enhanced practices. As observed by

Howard-Jones et al. (2015), “what we do know about the learning brain must be combined with educational research and expertise, and also some common sense, if we are to develop pedagogy that draws on authentic science and is educationally valuable” (p. 133). Research on educational neuroscience so far has not been able to provide concrete guidelines to improve the design of technology-enhanced learning environments.

Twenty-First-Century Skills and Technologies

With the emergence of globalization and the knowledge economy in the late twentieth century, it is now recognized that knowledge is the primary driver of growth and development in the twenty-first century, and thus learners need to develop new skills and competencies to adapt to technological innovations and become knowledge-based workers in order to tackle many unprecedented complex socio-economic-political problems. There is a call to equip young learners with new knowledge and twenty-first-century skills to enhance “problem solving, critical thinking, communication, collaboration, and self-management” (Pellegrino and Hilton 2012, p. 14) and to increase their innovative and knowledge creating capability (Scardamalia 2001). Many pedagogical guidelines (e.g., Partnership for 21st Century Skills 2007) have been developed nationally and internationally to support this development. After an extensive review of the literature, Pellegrino and Hilton (2012) suggest that these so-called twenty-first-century skills can be categorized under three domains: “the cognitive domain, including competencies such as critical thinking, information literacy, reasoning and argumentation, and innovation; . . . the intrapersonal domain, including competencies such as flexibility, initiative, appreciation for diversity, and metacognition; . . . [and] the interpersonal domain, including competencies such as communication, collaboration, responsibility, and conflict resolution” (p. Sum-3). As pointed out by Warschauer and Matuchniak (2010), many of these so-called twenty-first-century skills or competencies are technology-related. In fact, the use of technology to enhance thinking skills has a long history. For example, in the early 1980s, Papert (1980) has developed the Logo programming language to support the development of problem solving and metacognitive skills of young learners. More recently, advances in computational thinking research (Grover and Pea 2013) suggest the need to include computational thinking as a required domain in the school curriculum. However, we are reminded by Scardamalia (2001) that in supporting students to develop twenty-first-century skills, educators should not start by focusing on the technology, but instead need to first ask what kind of education and learning experience children and young people should acquire in a knowledge-based society, and then consider in what way can technology be used to enhance such a process and experience. Scardamalia (2001) suggests that we should encourage students to use digital technology to enhance pursue of deep understanding, develop knowledge creating capability and epistemic agency, rather than simply acquiring technological skills for its own sake.

Technology-Enhanced Learning

In evaluating the use of new digital technologies in learning, we thus must be mindful of how they can add value to the learning process. While digital technologies can certainly help increase the efficiency of learning, for example, they can be used to support students to access and present information, facilitate word processing, manage spreadsheets and databases, and enhance communication and collaboration, Wellington (2004) points out that there may be a trade-off in using technologies to perform these tasks since some important cognitive skills may be lost in the process because students are no longer required to practice them. We are reminded to distinguish between the inauthentic experience from using digital technologies, which is only labor saving, and the authentic learning experience which can lead to further learning (Wellington 2004). A unique contribution of digital technologies, which adds value to the learning process, is their affordances in supporting the development of innovative and creative skills. In the following subsections some recent advances of pedagogical models of technology-enhanced learning which may add value to the learning process are briefly discussed.

Flipped Learning

The flipped learning model has become a popular pedagogical model in the last decade. As defined by the Flipped Learning Network (FLN) (2014):

Flipped learning is a pedagogical approach in which direct instruction moves from the group learning space to the individual learning space, and the resulting group space is transformed into a dynamic, interactive learning environment where the educator guides students as they apply concepts and engage creatively in the subject matter.

The flipped learning model has become popular in primary and secondary education in the economically more advanced countries in the last decade. For example, in the Speak Up survey (Project Tomorrow 2015) on flipped learning conducted across the USA in 2014, almost half (48%) of the school technology leaders reported that flipped learning had positive results in their schools. In a flipped classroom, students are given more control of the learning process since they are asked to be an active learner in charge of what, when, and how they study the subject content. As a learner-centered approach, the flipped learning model can help develop learner agency, which is essential for lifelong learning. The use of digital technologies is integral to this model to facilitate students to take part in whole class and small group online discussions, access content from the Internet in and out of class time, and also for teachers to create learning materials. Flipped classrooms are benefited from cloud computing. For example, by using the freely available Google Apps for Education such as *Gmail*, *Docs*, and *Calendar*, collaborative learning and group projects can be supported where students can share and develop their ideas. The *Google plus community* can be used to support asynchronous text-based discussion and *Google Hangouts* can support synchronous video conferencing for students to collaborate in

formal and informal settings. Technology has always been closely associated with social constructivism, and flipped learning is yet another example of how technology can be used to support a pedagogy which is underpinned by constructivist principles such as active, self-regulated, and collaborative learning.

Informal Learning Augmenting Formal Learning

Increasingly, it is now being recognized that technologies have huge potential to augment formal learning with informal learning since students are now no longer constrained by a lack of access to information. The affordances of mobile devices such as smartphones and tablets, which are distinctive from previous technologies in terms of portability and connectivity, can provide anywhere, anytime, on-demand, on-the-fly learning opportunities for students (So et al. 2009). Since children and young people use mobile devices primarily in out-of-school settings, they are able to gain knowledge and skills as well as computing experience in these informal settings. For example, there is evidence that informal learning in computer classes in community centers help young people develop twenty-first-century learning skills and lifelong learning skills (Warschauer and Matuchniak 2010). It is well documented that the way young people use technologies in informal settings is often different from how they use them in formal school settings (Khaddage et al. 2015), and this is challenging for teachers since they need to develop pedagogical practices to bridge in and out-of-school learning in order to harness what students have learned informally to support what they learn in the school. The key issue is for teachers to reconceptualize learning as a continuum and understand that there should be no distinction between formal and informal learning in terms of its value to the learners. In fact, students spend more time engaging in informal rather than formal learning but their efforts are seldom recognized in formal education since assessments are primarily focused on formal course content (Khaddage et al. 2015). It should be noted that while it is pertinent to study the relationship between formal and informal learning, there are pedagogical (e.g., instructional strategies, assessment), policy (e.g., Bring Your Own Device, BYOD), technical (e.g., infrastructural support and connectivity), and research (e.g., evaluation) challenges that researchers, policy makers, and practitioners need to tackle if digital technologies and in particular mobile devices are to be successfully employed to support school learning and augment it with informal learning (Khaddage et al. 2015). For a more detailed discussion of the connection between formal and informal learning using digital technologies refer Lewin and Charania, ► [Chap. 14, “Bridging Formal and Informal Learning Through Technology in the Twenty-First Century: Issues and Challenges”](#) in this *Handbook*.

Gaming

There has always been huge interest for children and young people to engage in computer games (Lenhart et al. 2008). With the rapid increase in Internet connectivity

and accessibility of mobile devices, interest in digital video games has greatly increased in the last 10 years and playing multiplayer digital games has become one of the most popular leisure activities of teenagers (Young et al. 2012). According to Lenhart et al. (2008), about 97% of the teenagers in the USA already regularly played some form of video games about a decade ago. Research on gaming is primarily conducted as case studies to document the use of digital games in different learning settings. Reviews surveying the field have also been undertaken. For example, in a recent media comparison review, Clark et al. (2016) have identified 69 media studies conducted between 2000 and 2012 and concluded that digital games could significantly enhance student learning as compared to nongame conditions. However, as will be discussed later in this chapter, there are issues in using media comparison studies to support the efficacy of TEL. More detailed discussion of games and simulation-based learning can also be found in Section X “Game and Simulation-Based Learning and Teaching” of this *Handbook*.

One-to-One Computing

The improved access to computing hardware and software by primary and secondary students in the last decade has greatly facilitated one-to-one computing. For example, in the USA, it is estimated that one-third of the middle and high school students use school-owned mobile devices (Nagel 2014). Mobile technologies also provide new learning opportunities in the economically less advanced countries and Africa countries in particular are the fastest growing countries in the world in terms of mobile phone penetration, with an increase from 200 million connected mobile devices in 2006 to 735 million in 2012 (UNESCO 2012). While in the economically less advanced countries mobile devices are primarily used to provide informal learning opportunities, in the economically more advanced countries it is now commonly expected that students in schools will work in a one-to-one computing environment. In these countries, students are either provided with a laptop or tablet computer by the school, or they are required to provide their own mobile devices. In a one-to-one computing environment, there are funding issues for schools to provide fast Internet connectivity and software access. There are also issues of technical support, Internet privacy, and protection of intellectual property that schools need to tackle (Alberta Education 2012). If students are required to provide their own digital devices (i.e., BYOD) for school learning, there is an equity issue of justifying the shift of provision of learning tools from the school to the parents. The limited research available on one-to-one computing does provide some evidence to show that it is beneficial to teaching and learning, with teachers and students using technologies more often in the class, and there is also an improvement in student engagement, research skills, achievement, and collaboration (Bebell and Kay 2010; New South Wales Department of Education and Training 2009).

Social Media and Formal Learning

It is quite clear that in the last 10 years social media have become the most popular digital applications for young people (Lawless 2016), and social media apps have drastically changed how young people communicate and learn. The use of social media can have huge implications on formal learning. However, the majority of research on social media has been conducted in informal settings and so far very little is known about how social media can be used to support learning in formal settings (Khaddage et al. 2015). While there is some positive evidence on the use of social media in schools (e.g., refer review by Gao et al. 2012 on *Twitter*), there are questions of how they can be used productively in class without causing distraction to other students, and issues such as privacy and identity have also been raised (Crook 2012). In this *Handbook*, Kimmon and Belikov, ► [Chap. 13, “Cultural and Social Issues in Using Social Media to Support Learning”](#) have reviewed the cultural and social issues of using social media in supporting learning.

Online Learning

Online learning in primary and secondary education is growing and in particular, in the USA where virtual schools have become increasingly common and high school students can now complete their diploma totally online. According to one estimate (Wicks 2010), over 1.5 million US K-12 students enrolled in online learning in 2010. In the UK, one source reported that there were over 300 virtual schools with over 200,000 students enrolled in 2014 (UK Department for Education 2014). Online learning can facilitate personalized learning as it provides additional choices to the student. It also reduces inequity since students who previously had no access to face-to-face education can now have the opportunity to complete schooling without having to attend a brick-and-mortar school. Online learning is now supported by the proliferation of open education resources (OER) available on the Internet, and there are also open educational courses that students can enroll. Massive open online courses (MOOCs) have become popular at the tertiary level in recent years, and now there are MOOCs specifically designed for primary and secondary students. For example, in 2014, 5% of the 3 million students enrolled in MOOCs developed by the edX platform were high school students (Atkeson 2014). In the UK, the Department of Education (2014) has listed 24 MOOCs specifically designed for students. There are MOOCs on specialized or supplementary courses that are not normally available in formal education, and they give students choice and facilitate personalized learning. However, the effectiveness of MOOCs is not known since so far there is a paucity of research on learning outcomes of MOOCs in primary or secondary education. A more detailed discussion of MOOCs and open learning can be found in Dron and Ardito, ► [Chap. 50, “Open Education Resources, Massive Open Online Courses, and Online Platforms for Distance and Flexible Learning”](#) in this *Handbook*.

“Effects” of Using Technologies in the Learning Process

In the last 10 years, governments globally have continued to invest heavily on ICT equipment and software, and also to fund professional learning and development of teachers of how to use digital technologies in their classrooms. For example, in the USA, in 2014, K-12 schools have reportedly spent nearly US\$10 billion on learning technologies (Lawless 2016). Similarly, in the UK, schools spent around £880 million on ICT in 2008/9 (Livingstone 2012). Digital literacy has also been included as a required component in the national curriculum in many countries. For example, in Norway, in its national curriculum, digital competence has been listed as a basic skill (Erstad 2009). Advocates have continued to expect that digital technologies can be used effectively to transform teaching and learning. However, even though numerous studies have been conducted in the last 30 years to investigate the relationship between digital technology and learning, there is little conclusive evidence to justify what Kozma (2008) has called the “strategic educational ICT policy rationales” (p. 1085) for its use, and there is little evidence to confirm that the use of ICT in education has supported economic growth, promoted social development, advanced educational reform, or enhanced education management. In terms of learning outcomes, as pointed out by Lawless (2016) in a recent review, “taken as a whole, research on the effectiveness of general contemporary technologies does not yield enough decisive evidence to support conclusive proof of their effectiveness in improving educational outcomes” (p.5). The most recent large-scale review was published by OECD (2015), titled *Students, computers, and learning: Making the connection*, based on data from two PISA studies (2009 and 2012). This report concludes that “the connections among students, computers and learning are neither simple nor hard-wired; and the real contributions ICT can make to teaching and learning have yet to be fully realised and exploited” (p. 4). The OECD (2015) report verifies the mixed results of the effects of ICT on student performances frequently reported in previous reviews, with a conclusion that there is a lack of evidence to show “appreciable improvements in student achievement in reading, mathematics or science in the countries that had invested heavily in ICT for education” (p. 15).

Various reasons have been suggested to explain why the use of digital technologies in schools has not resulted in measureable positive effects. For example, when reviewing the benefits of games, Young et al. (2012) argue that the wrong question may have been asked because there is no such thing as “the effects of technology,” and their advice is to “stop seeking simple answers that address the wrong question” (p. 84), as there are both methodological and substantive issues which make measuring technology effects or impacts very difficult if impossible. The “media effects debate” back in the 1980s and 1990s has highlighted the controversy of measuring the impact of digital technology on learning. In this debate R. E. Clark (1983) argued that since the instructional medium (i.e., a technology) could not be teased out from the instructional design (i.e., a pedagogy), trying to measure the effect of the medium was a futile exercise. Taking an opposing stance, Kozma (1994) stressed that a technology might have certain attributes, which would provide specific affordances without which the instructional strategy could not be carried

out. Thus research could focus on these affordances. Commenting on this debate using digital gaming as an example, Clark et al. (2016) response was that while technological applications/software provided new affordances, it was how they were used, and how the learning environment was designed which “leverage those affordances” (p. 116). This debate highlights the problem of using media comparison data to support technology use in the classroom. (Media comparison studies compare the outcomes of using a technology (medium) in a class with another class not using the technology or using another medium of instruction.) The media comparison approach has been criticized (e.g., Selwyn 2011) for not able to measure the true effect of technology use. Salomon (2002) also criticizes the media comparison approach by arguing that while technology rich learning environments can change education in a profound way, for example, in supporting the development of knowledge and skills needed for the twenty-first century, it may not necessarily enhance achievement, and thus it is pointless to measure it in media comparison research.

As a cultural tool, digital technology is not a “disembedded tool” (Wellington 2004) since it cannot be used in a vacuum, but to be embedded in and influenced by a complex sociopolitical and cultural system with each of its constituent components interacting with one another simultaneously. Thus, trying to achieve any “degree of confidence or certainty over a discernible ‘case-and-effect’ relationship between technology and learning is nigh on impossible” (Selwyn 2011, p. 84). To better understand the design and implementation of TEL, as well as its benefits, some researchers argue that design-based research is a more fruitful methodology to employ because it is classroom-based, it involves a partnership between the researcher and practitioner, is more holistic in approach, and it generates knowledge in both theory and practice (Amiel and Reeves 2008).

While there is little generalizable evidence to document how technology can support learning (but a wealth of case study findings), some researchers argue that there are “soft” effects that technologies bring to the learning process (Livingstone 2012). One of the most cited “soft” effects is the motivational effect to engage students to learn. Indeed, there is evidence that positive motivational effects are found in technology-enhanced classes (e.g., Passey et al. 2014). However, we should be cautioned about these effects. Are they simply the novelty effects of digital technologies which help create the short-term interest in the learning tasks? Hidi and Renninger (2006) distinguish two forms of interest: situational and mature or deeper interest. As argued by Philip and Garcia (2013), the motivational effects of digital technologies are by and large situational. Using technologies in class may provide situational interest, but it may not lead to sustained interest, which will be required to engage students in deep learning. It is the contexts of learning and in particular the pedagogy employed in a learning context which will be crucial for supporting students to sustain their interest, rather than simply by using technologies (which are often used as a reward system).

Furthermore, it seems that the negative effects of using digital technologies in learning are seldom reported in the literature (Selwyn 2011). We should be mindful that there are cognitive as well as social costs in using digital technology. Taking

multitasking as an example, multitasking has been widely endorsed by digital technology advocates as a positive learning outcome of technology use, and a skill that students should acquire, to the extent that teachers in some countries, e.g., Germany, are required to teach their students the skill of how to multitask (Spitzer 2014). However, as pointed out by Lee et al. (2012), multitasking as a learning strategy contradicts with what we have learned from cognitive science (the cognitive load theory) and neuroscience research, which suggests that undivided attention is needed in intentional learning. Multitasking may not be an effective learning strategy in academic learning and thus should not be encouraged. Also, how intense and frequent should students use digital technologies are contestable. For example, Fuchs and Woessmann (2004) argue that while some students may benefit from using digital technologies in class, their frequent use at home may “distract students from effective learning” (p. 1). As pointed out by Philip and Garcia (2013), seeing technology as a quick fix for educational issues is at best problematic and at worst dangerous. Taking a techno-centric view in evaluating the use of ICT in learning and education may create a biased view of what is actually happening in the classroom. Thus, in reviewing the literature, it is important to differentiate what are the expected or potential benefits of digital technologies, as proposed by digital technology advocates, from their actual benefits as classroom practices as documented in empirical research studies (Selwyn 2011).

We should also note that while there has been significant increase in technology-related activities in schools in the last 10 years, for example, technology hardware such as interactive whiteboards and tablets are now more widely used in schools, there is a digital divide in technology access, and digital technologies are frequently used only by a minority of students, and in certain school subjects. (A more detailed discussion of equity issues can be found in Section XI “Issues and Challenges Related to Digital Equity” of this *Handbook*.) For example, the recent OECD (2015) report showed that even in countries such as China and South Korea where the computer and mobile device penetration rates topped the world, only 42% and 38% of the students in these countries, respectively, used computers in schools in 2011. It seems what Cuban (1986) has argued some 30 years ago about the cycles of technology use in education still holds today. Cuban (1986) maintains that there is a cycle of technology use whenever a new technology is introduced to the education sector. At first there is great expectation for its benefits; then it is supported by some initial research confirming its effectiveness; subsequently policy makers will invest on it; but at the end of this cycle there is limited use in the classroom and no conclusive outcome is reported. Then it comes the next cycle when a new technology is advocated.

Issues and Challenges for Researchers and Practitioners

With the increasing ubiquity of digital and mobile technologies, it is a challenging time to be a technology-using teacher or a TEL researcher. For practitioners, they now face even greater institutional pressure than a decade ago to use digital technologies in their teaching, even though they may not be conversant with the pedagogies associated with TEL and their educational benefits. Almost 15 years ago

Maddux (2003) used the term Everest syndrome to describe how policy makers and teachers viewed the use of technology in learning, and his observation is still valid today. The Everest syndrome refers to a general conception that “computers should be brought into educational settings simply because they are there” (p. 5). As a quick add-on to the classroom, the use of digital technologies is often driven by a technology-centered approach where technological innovations are adopted in the classroom to drive pedagogy without adequate research validation (Maddux 2003). This techno-centric ethos still largely dominates the thinking of many educators, even though they may not be aware of it. It is hoped that through professional learning and development this techno-centric mindset can be erased or at least minimized. As for researchers, with the proliferation of TEL journals and conferences, and increased work pressure in a knowledge-driven society, there is a temptation to publish speedily from small exploratory case studies. As pointed out by Selwyn (2011), the challenge for researchers is to spend sufficient amount of time in the classroom with students and teachers so as to understand what is actually going on when digital technology is used to support teaching and learning, since TEL research is not just about the technology, or for that matter even just about learning, but how and why learning happens within a complex sociopolitical system, with technology being only one of the components of the system. While in the last 10 years there has been increasing focus on the learner rather than on the technology, mainstream research is still looking for technological impacts or effects on learning outcomes, and many researchers and policy adopt a rather deterministic view on the use of digital technologies in education. A more ecological view should be encouraged in the future, and the learner should be seen as organically interacting with technologies embedded in a sociocultural environment.

While digital technologies have primarily been seen as cognitive tools, increasingly practitioners, researchers, and policy makers have become aware of their psychological and emotional effects on the young learners. Attention is drawn to the health and safety issues related to digital technology use. With the ease of creating anonymity and identity on the Internet, cyber bullying is on the rise (Navarro et al. 2016). Easy accessibility and fast connectivity to the Internet also mean a higher risk of students being exposed to inappropriate materials, and the possibility of developing addictive behaviors. While the issue of Internet privacy has always been a concern, with the increasingly use of analytics tools by schools, there is an urgent need to develop policy guidelines to protect the access and use of personal data and to prevent unnecessary intrusions of personal learning space (Livingstone et al. 2012). Using a more holistic view in examining the use of technologies in the learning process, researchers, policy makers, and practitioners should be mindful of how to protect the learners and look after their overall well-being. This concern should not exclusively be cognitive, but also emotional, as well as the general health and safety of the children and young people.

How practitioners use technologies to support the learning process is a big challenge. Teachers should not underestimate their key influences on how technologies are used by their students in formal settings, as well as in informal settings outside the school context. If students are to be encouraged to use digital technologies to support deep learning, develop twenty-first-century skills, and be innovative

in creating knowledge (Scardamalia 2001), the roles of the teachers and their professional identities have to be changed. Teachers have to model the attitudes and dispositions of being a lifelong learner and knowledge creator in order to support their students to develop these attributes. The goal is to harness technology's affordances to support learner agency in a holistic way.

Conclusion

This chapter has provided a general overview of how digital technologies have been used to support the learner and the learning process. It should be noted that while in the last 10 years there has been an increase in the use of digital technologies in the learning process, on the whole their use has not been as widespread as expected. There is also a major difference between the anticipated use of digital technology, as advocated by some technology enthusiasts, and its actual use. While there are pockets of innovative designs of TEL, how these technology-supported learning environments can be scaled up and sustained is a major issue. Also, after more than 30 years of using digital technologies in the school system, and a wealth of research has been amassed on TEL, we need to admit that we do not know very much about what actually happens to the learner during the learning process when digital technologies are used to support such a process. The effects of digital technology use are inconclusive, since it is not clear whether and how they can be measured. We are reminded by Cuban (1986) that since digital technologies are advancing so rapidly, it is easy to fall into the trap of the endless "pursuit of the new" and keep reinventing ourselves without truly understanding the promises and benefits of technology-enhanced learning.

Abstract

This chapter explores how learning theory relates to the use of information and communication technologies (ICT) in the K-12 classroom. Teachers need both pedagogical knowledge and technological knowledge, along with content knowledge, in order to support effective learning experiences for their students. Learning theories guide this pedagogical knowledge, providing support for which instructional strategies teachers might use. The three historically dominant learning theories – behaviorism, cognitivism, and constructivism – are briefly presented

through vignettes that explore student and teacher ICT use. Basic tenets of each theory are briefly discussed along with examples of instructional strategies that reflect each theoretical approach to ICT use. A fourth theory, connectivism, which has yet to be fully accepted or embraced as a major learning theory but nonetheless represents a theoretical approach to learning via ICT-based networks, also is explored. With these theories in mind, this chapter notes that ICT are not always used in a manner that reflects sound or thoughtful pedagogical decisions; a teacher's pedagogical choices may also be system-driven or technology-driven. As the chapter concludes, we share implications both for using ICT in a manner that is consistent with and fully supports learner development and for supporting teacher development of knowledge about learning theory along with the intersection of pedagogy and technology.

Keywords

Behaviorism · Cognitivism · Constructivism · Connectivism · Learning theory · Pedagogy · ICT

Information and communication technologies (ICT) can be integrated in K-12 education in myriad ways, reflecting diverse approaches to learning, communication, and behavior management among teachers and institutions as well as differences in disciplinary areas. Some ICT have been developed with specific learning theories and related instructional strategies in mind. Additionally, instructors may choose specific ICT for classroom use and develop learning activities that reflect and support a specific epistemological perspective. Regardless of the approach taken, the greater point is that ICT are not theory-neutral technologies. Instead, their design and classroom integration both reflect specific orientations toward knowing and learning.

In this chapter, we explore how theoretical perspectives – particularly pedagogical theories – shape how ICT are used in K-12 settings. We start with brief discussions of how teacher pedagogical beliefs and knowledge influence the ways learning theory is used to support K-12 ICT adoption and integration. Next, we summarize theoretical approaches, focusing primarily on how the three dominant learning theories – behaviorism, cognitivism, and constructivism – and a newer theory (connectivism) provide instructional implications for ICT use. As we conclude, we discuss specific challenges and implications related to taking a theory-oriented approach to ICT use in K-12 learning contexts.

ICT Integration and Teacher Pedagogical Orientation

Learning and related ICT use cannot easily be disambiguated from the context in which it occurs. To that end, technology integration is a systemic endeavor that integrates technology, pedagogy, and content in the service of achieving learning goals. The Technological Pedagogical Content Knowledge (TPACK) Framework explores how these three constructs relate to each other and overlap in the service of

technology integration (Mishra and Koehler 2006). One dimension of TPACK is Technological Pedagogical Knowledge (TPK), or knowledge of how to use technologies in support of learning. Teachers with strong TPK can effectively use technology in ways that enhance learning and make decisions about technology integration that are responsive to different types of teaching activities and learning outcomes (Schmidt et al. 2009). With the addition of content knowledge, teachers can make these technology integration decisions in a manner that is discipline-appropriate.

Pedagogical beliefs have great influence over if and how teachers choose to integrate technologies into their classrooms. Teachers tend to choose technologies that both support their beliefs and their prior experiences (Tondeur et al. 2016). They can be supported in their technology integration endeavors by the provision of examples, support, and professional development that are aligned with their existing beliefs (Ertmer and Ottenbreit-Leftwich 2010). In the classroom, pedagogical knowledge is closely intertwined with both technological and content knowledge (Archambault and Barnett 2010). It is difficult to clearly specify the boundaries between each of these constructs, but doing so is necessary to help better guide practitioners on technology integration issues (Graham 2011). By isolating pedagogical beliefs, it is possible both to challenge teachers to try new technologies and to support teachers in finding technologies and technology integration strategies that are likely to succeed in their classrooms.

Theoretical Approaches

Various means have been suggested for examining theoretical – especially pedagogical – approaches to ICT use in education. Taylor (1980) classified approaches to computer-supported learning in terms of how the learner interacts with the ICT, whether as a tutor, a tool, or a tutee. Koschmann and colleagues later explored these classifications in the context of ICT research, seeking a way to understand how newer technologies were being used to support interpersonal collaboration (Koschmann 2001; Koschmann et al. 1996). This initial work demonstrated how ICT use and research paradigms aligned with learning theories, with the most recent paradigm – computer-supported collaborative learning (CSCL) – having a social constructivist foundation (Koschmann et al. 1996). Others have also drawn direct parallels between ICT use and learning theories. Bottino (2004) described three models of ICT-based learning, a transmission model, a learner-centered model, and a participative model; these models parallel the dominant three learning theories. Naismith et al. (2004) similarly remain close to learning theories when describing approaches to mobile learning use. They classified mobile learning activities in six ways. The first three activity classifications directly reflect the learning theories that are embodied in the design and use of the technology (behaviorist, constructivist, situated), whereas the last three reflect the purpose and conditions of use (collaborative, informal and lifelong, and learning and teaching support). What all these

approaches to ICT classification share is a focus on the underlying epistemological beliefs and their corresponding learning theories.

This section discusses ICT use within the context of behaviorist, cognitivist, and constructivist learning theories. Each theory is introduced with a vignette that introduces classroom scenarios in which ICT are used in accordance with that theory. Then the core tenets of the theories are presented along with an overview of ICT use related to that theoretical approach. It is only possible to scratch the surface of these theories and related ICT use in a single chapter, but the key ideas and cited literature pave a path for deeper inquiry in these areas.

Behaviorism

Julia picks up an iPad from the cart in the corner of her third grade classroom and returns to her desk. Swiping the device on, she opens an app called Multiplication Circus. After logging in, Julia is given a series of multiplication problems to solve. Each time she solves a problem correctly, the clown in the corner of the screen gets an extra ball to juggle. Each time she solves one incorrectly, the clown drops the balls. When the next question is answered correctly, the clown begins to juggle again. Every time she solves five consecutive problems correctly, she is rewarded with an animation of acrobats. While Julia is engrossed in the app, her teacher takes note. Using her iPad, the teacher opens Class Dojo and marks down that Julia is “on task.” That evening, her parents will be able to log on to the system and see that Julia had good behavior in school today and how far she progressed with her multiplication practice. Julia is motivated – if she gets all good reports on her behavior and class progress this week – she will be able to have her best friend sleep over on Saturday.

Across town, in a high school classroom, Julia’s older brother Jacob is using a student response system, or clicker, in his chemistry class. His instructor is doing a quick review of the material from the previous unit and the review is punctuated with slides that have multiple choice questions. When a question screen pops up, Jacob and his classmates select a response. The teacher then shows the answers, allowing the students to see whether they were right or wrong. Later, the teacher will review the students’ responses to determine the areas where more practice is needed. Additionally, students who answer all the practice questions correctly will not be required to turn in homework the next day.

That afternoon, in Julia’s music class, the iPads are being used again. This time the students are using simulated keyboards and learning how to play a simple song within a one octave range. Each time the student repeats a measure from the song satisfactorily three times, the student is prompted to practice the entire song as learned thus far, and moves on to learning the next measure. Students are moving at their own pace, and the teacher circulates the room to see if anyone needs additional help.

Major Tenets of Behaviorism. Behaviorism is a theory focused on learning as a persistent change in observable behavior. In other words, in the behaviorist approach

we know that someone has learned something when they are able to perform a new behavior visibly and consistently. Behaviors can be strengthened or weakened by using a reinforcing stimulus (Skinner 1958). This stimulus may be satisfying or aversive, and it may be presented to the learner or removed (see Driscoll 2005, for a fuller description of the principles of behavior management). It is not limited to physical actions but also includes verbal behavior (Skinner 1957).

Behaviorism and ICT. The roots of behaviorism and technology use date back to Skinner's work in the 1950s with programmed instruction and teaching machines. Skinner (1958) proposed that individual students could engage in self-paced mastery learning, responding to prompts, checking answers, and only advancing when the correct answer is supplied. Skinner suggested that this practice and feedback was a form of shaping the correct behavior as the learner received incremental feedback with each bit of learning progress. Skinner and his early colleagues were technological determinists, believing that the technology, along with its precisely designed learning materials, was the key to the promoting efficient instruction. Programmed instruction saw its decline as a primary means of education as researchers identified other elements (e.g., teacher attitude, student motivation) that were critical to learning success and as the rigidity of the intervention led to limited and oversimplified learning interactions (McDonald et al. 2005). Still, behaviorism lives on in current uses of ICT, although in many instances they are developed with more flexibility in mind. For example, student response systems (SRS) can be used to foster the same type of interactions, with students responding individually to a question and receiving immediate feedback on their response (Edens 2008). Today's SRS differ from programmed instruction, however, in that they are typically used in a group situation, with questions asked of an entire class. Although SRS may be used in support of other learning theories, their use is frequently embedded in lectures for the purposes of attendance and individual formative learning assessment, and students may receive points for their participation (Liu et al. 2016). Additionally, the teacher plays an integral role in both determining the questions and setting the overall pace of the instruction based on the responses of the whole group (Scott 2014).

Behaviorism also remains alive and well in the classroom through the many applications designed to promote drill-and-practice style interactions, allowing students to answer practice questions focused on simple skills and concepts (see Kuiper and de Pater-Sneep 2014 for an example), as well as classroom management tools. Behaviorist practice activities may be embedded in a game-like context to help engage the learner (Kebritchi and Hirumi 2008). This form of ICT-based learning became popular in the 1990s as CD-ROM technology rose to prominence and has again found a strong user base through mobile applications and learning systems. Today, most mobile learning activities for PK-12 children are designed from a behaviorist perspective (Crompton et al. 2017). Computer-based learning systems that address mathematics and reading skills, often purchased from educational publishers, typically support objective-style practice activities and generate learner performance analytics that can later be used to monitor learner progress and to guide subsequent learning activities. Typically aligned with standardized tests,

use of this software may be associated with increased test performance (Martindale et al. 2005).

Finally, teachers are adopting technology-based behavior management systems that allow them to keep digital records of student behaviors, reward students for their behaviors, and share student behavior information with parents. Through digital token economies, these systems may support behavioral goal setting and, ultimately, change (Krach and McCreery 2015). Although not yet heavily researched, early indicators suggest that these behavioral ICT interventions help improve student behavior when used for positive reinforcement (MacLean-Blevins 2013).

In the above vignette, Julia's teacher is using Class Dojo as a behavior management tool. Reporting Julia's on task performance to her parents is a reward, a form of positive reinforcement. The multiplication game that she plays similarly provides positive reinforcement when she answers questions correctly (e.g., the clown juggles an extra ball, or an animation appears) and punishment for incorrect answers (e.g., the clown drops the balls). Her brother Jacob is similarly answering questions and receiving feedback about the correctness of his answer. His teacher is using negative reinforcement (e.g., removing homework) to encourage students to perform well on the practice activities. Finally, Julia's music teacher has students learning via an app that teaches the complex behavior of playing an entire song via chaining, or connecting smaller behaviors.

Cognitivism

Malcolm's seventh grade civics class is visiting the computer lab today. Once seated, Malcolm opens *Webspiration* and begins concept mapping roles of the US government. His task requires him to synthesize information from his teacher's lectures, his textbook, and cursory web searches. Malcolm chooses the three branches of federal government as his top organization categories and then includes key responsibilities which further branch into landmark decisions. Next to him, Chloe has chosen to make governmental roles as the main categories and then branches into the various levels of government that fulfill these roles. When complete, Malcolm and Chloe share their concept maps with their teacher, who will provide feedback through comments directly in the web-based program.

In a classroom across campus, eighth grader Anna pulls a laptop from a cart and opens her digital textbook. Class begins with a short lecture during which the teacher projects a Venn Diagram on the screen. The teacher proceeds to compare viruses, today's topic, to bacteria, which students studied last week. Anna then reads the assigned portion of her textbook on the laptop, the content of which is chunked into three sections. Each page utilizes bold headings and vocabulary words so Anna is focused on the key concepts. The concepts are summarized and elaborated in frequent tables and diagrams. When Anna completes each section, she checks her comprehension in an embedded three-question multiple choice quiz. To her delight, Anna is directed to pull out her smart phones and slip it into a Google Cardboard. Anna is now immersed in a 3-D virtual reality scene showing a virus attacking a cell

and spreading throughout the body. Finally, she works with two students to demonstrate their new learning in a digital worksheet accessed through the online textbook software.

In the nearby elementary school, first-grader Aidan is choosing a research topic for his contribution to an ocean unit. He opens *Pebble Go*, a K-2 research database, and is greeted by a picture-based browsing window. Aidan browses through the following categories in increasing specificity: animals, mammals, whales and other water mammals, killer whales. Having chosen the topic “killer whales,” Aidan’s task is to print the two activity sheets included in the software, and then to use those sheets for recording information. One sheet is a color diagram of a killer whale on which Aidan will identify body parts from a word bank. The other sheet is a notetaking page on which he will record facts about the killer whale’s body, habitat, food, and life cycle. Aidan now has a purpose for reading. The *Pebble Go* information is divided into five tabs aligned with the activity sheets. Each tab has three sentences and a picture. Since Aidan is a beginning reader, he clicks the speaker icon so the text is read aloud to him in a natural voice, highlighting each word as it is read. He then chooses the media icons to see video of killer whales in the wild, hear their songs, and see a range map of their habitat. Finally, Aidan returns to the tabs that align with his activity sheet and reads independently for information to complete the research questions.

Major Tenets of Cognitivism. Malcolm, Anna, and Aidan are learning through ICT activities entrenched in cognitivist learning theory. This theory emerged around the mid-twentieth century as an outgrowth of behaviorism. Like behaviorism, cognitivists believe in an objective reality that can be known and taught. Unlike behaviorists, cognitivists focus on the internal processes within the brain through which new information is stored in long-term memory and then retrieved for use in the short-term memory.

Cognitivists support a three-component memory system akin to a computer: sensory memory \rightarrow short-term memory \leftrightarrow long-term memory. Students are surrounded by environmental stimuli, some of which is attended to by their sensory memory. From there, the information then moves to the short-term memory (STM). It is in the STM that active thinking occurs. If students rehearse the information in their STM, it may be encoded and stored in the long-term memory (LTM). When students need that information again, they retrieve it from the LTM and transfer it to the STM. Cognitive scientists focus on ways of helping students attend to, encode, and retrieve information so it may effectively transition between the three memories. Frequent and diverse practice coupled with elaborative feedback is the means by which learning occurs in the memory system.

Cognitivism and ICT. Cognitive theorists have proposed many approaches to supporting student learning that are now familiar in classrooms. These well-established approaches are often utilized in ICT to help students effectively learn and remember information. Below are a few fundamental approaches that were apparent in the above vignette. This list is representative rather than exhaustive.

Advance Organizers. Advance organizers structure learning material for use prior to mastering the content. Anna’s teacher uses the Venn diagram to connect new

knowledge to previous learning. Aidan printed his activity sheet prior to learning so that he knew where to focus his reading. ICT often include an overview and objectives as advance organizers. Advance organizers alert students to the important concepts or elicit prior knowledge, preparing students to organize new information into existing mental structures (Ausubel 1978).

Chunking. Chunking occurs when pieces of content are grouped together, or chunked, to assist short-term memory. Short-term memory is finite; it is thought to hold seven bits of information, plus or minus two, for 15–30 sec (Miller 1956). When many discrete facts are chunked into topics, the STM can utilize the chunks of facts as needed, rather than attempting to recall discrete bits of information at once. In the vignette, Anna's text was divided into sections followed by short quizzes and Aidan's killer whale text was presented in topical tabs. These design decisions increased STM capacity through chunking.

Cognitive Load and Encoding. Cognitive load is the amount of effort expended by the STM to complete a task. Heavy cognitive load may impede learning. Sweller (2010) states that the intrinsic cognitive load of information can only be minimized by instructional design, not by changing the nature of the information itself. ICT-based learning environments make use of multiple channels of information (e.g., text, visual, audio); depending on their design, they may reduce or increase cognitive load. Sweller's research shows that dual-encoding, using both visual and verbal inputs, reduces cognitive load and thereby increases STM capacity. Similarly, Mayer's (2009) theory of multimedia learning provides guidance for designing multimedia-based ICT that will reduce cognitive load and support effective encoding. In the vignette, Aidan used the narration feature in *Pebble Go* to manage his cognitive load, ensuring that reading struggles did not impede his comprehension, while Anna used typographic and graphic supports for semantic encoding when reading her digital textbooks.

Practice, Feedback, and Schema Development. To encode information, students need to practice or rehearse it. The simplest encoding strategy would be tireless repetition for rote facts such as multiplication tables. Here, cognitivism is like behaviorism, using drill-and-practice coupled with feedback. However, where behaviorism relied on reinforcement as feedback, cognitivism supports specific and elaborative feedback to shape encoding, breaking misconceptions, and building better relationships. But cognitivism expands knowledge beyond rote learning to include conceptual learning, the relationship of information to other information. Gagné (1985) claims learning through relationships rather than simple reinforcement is a defining improvement of cognitivism over behaviorism. These relationships, called schema, are a hallmark of cognitivism; information is organized into hierarchical models in the brain, interrelated through examples and nonexamples, categories, and attributes (Anderson 1984).

Malcolm explored and solidified his schema of the US government through his concept mapping, a common cognitivist strategy wherein students explore information relationships in a manner that is logical to their existing schema. Anna and Aidan's content was preorganized into relationships for them, which is less effective for meaningful encoding and therefore less able to be retrieved unless coupled with

other types of practice. In terms of feedback, Malcolm only shared his project with this teacher, but he could have used ICT to share a copy with classmates, too. Anna will also receive feedback on her team effort synthesizing the reading with the tables, charts, and simulation; however, this feedback will be supplied by the online textbook. What differentiates Anna's feedback from behavioral feedback is elaboration on why responses were right or wrong.

Constructivism

As the web-conference started, Demetria noticed Margarit was sitting low, with her shoulders drooping. As the two began to talk, Demetria learned that her mentee was having difficulty differentiating instruction in her ESOL immersion class. Margarit was concerned that her students were not learning as effectively as they could. Her students in this class were a mixed grade, mixed proficiency group of nonnative speakers, most quite new to the country. Excluding English, five languages were represented in her classroom. She explained that she was having classroom management problems, possible due to the challenge of keeping everyone engaged in the same lesson.

Demetria asked how the hands-on project-based learning unit was going. Margarit explained to Demetria that she had believed the building block robotics project would be a way to bring the students together in a hands-on task that did not depend on common language or having demonstrated proficiency at a state standard. The students had access to the Internet to search for resources in their own languages and could translate material for them by the tool loaded onto the four computers in her classroom. She had hoped that as the students interacted and shared the success of building their project, they would all be motivated to communicate and write in their classroom translation journals, which they used for their weekly oral updates, so they could share in English their excitement about the project. Instead, the students were angry and nonparticipative. They did not stop to use the computers; they argued, and one afternoon a part was broken.

Demetria pointed out that the project contained an unfamiliar set of objects requiring specialized knowledge and handling. The students did not know how to do the project or how to research then translate the information they needed. Demetria suggested this project was evoking the opposite of Margarit's intentions. Demetria challenged Margarit to keep the idea of collaborative problem-based learning but to pick an enterprise already common or at least familiar to all or most of the children and build on what they knew. She asked Margarit to think of an experience that would be familiar to all the students in her class and one for which she would be able to provide learner support for each of her students. Then she asked Margarit to describe what worked best about the buddy-reading program that paired lower grade students with upper-grade students at the elementary school three times a week to read to each other. Margarit shared that her ESOL students especially benefited because they were usually paired with the other ESOL students and then it hit her. She sat straight up and looked at Demetria with a smile and shared her idea.

Margarit explained that she was going to develop a seed-to-table bake-a-birthday cake unit in collaboration with the local middle school ESOL teacher. She continued that she had an established relationship and that her class had previously interacted with the local middle school ESOL pull-out class using the school's learning management system's conferencing tool for a version of the buddy-reading program. The two groups of students worked hard to communicate in English. She had gotten special permission to let her students use their phones or mobile devices, if they had one, to translate as they all typically had a preferred tool already loaded and the one provided by the school was limited in scope of languages and unfamiliar to all of them. Margarit wondered if she could get that permission for mobile use all the time. She also hoped that by working with the middle school teacher, his students would be working a week ahead of hers, making the weekly conference calls an opportunity for the older kids to practice their new English skills by sharing their expertise on the content. The more she talked about it, the more excited she was. Demetria recalled the slump-shouldered first-year teacher she saw on her screen an hour ago and made sure to point out to Margarit how she turned what she thought was a failure into an opportunity. Both women logged off their mentoring meeting satisfied and were looking forward to the next one.

Major Tenets of Constructivism. Constructivism holds that people create their own unique meaning based on their sensory-based experiences and the subsequent integration of and reflection on those experiences. As a pedagogical framework, constructivism in the classroom requires reinforcing the individual's independent involvement in what is commonly found in K12: a structured group setting. Differentiating instruction requires that teachers have a sense of their students' ranges. In addition to the formal assessment of learning outcomes that is a standard feature in K12 settings, constructivist approaches require constant assessment during the learning process, which is, according to Green and Gredler (2002), consistent with the types of problem-solving approaches educational psychologists believe are most efficacious for learning. Teaching from a constructivist perspective does not mean that there are not attainable, common learning outcomes, but it does mean that our larger, inner knowledge bases are different because of our own unique historical trajectories and of our resulting standpoints. Constructivism relies on the constituted nature of human experience: the context in which we learn and the context that has shaped our at-this-moment selves is integral to the nature of constructivism. There are various forms of constructivism, the most common being social and cognitive constructivism. Both support the key tenet that meaning is constructed through human experiences, but the locus of knowledge construction differs.

Social Constructivism. Social constructivism centers around the notion that people create individual meaning by way of social interaction. Berger and Luckmann (1967) introduced the idea of socially constructed reality at the level of the individual, arguing that individuals use language and experiences to uniquely interpret then internalize these interpretations as their reality. Vygotsky (1978) also considered the role of social interaction, culture, and language in the meaning making of children, identifying the zone of proximal development (ZPD), "the distance between the actual developmental level as determined by the independent

problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers” (p. 86). Learning experiences should be scaffolded by the provision of support that is just enough to help the learner accomplish new tasks within the ZPD.

Cognitive Constructivism. Cognitive constructivism focuses on the internal processes of an individual’s learning more than on the context, culture, or social setting in which that learning happens. Cognitive constructivism relies heavily on schema theory as well; learners are constructing knowledge by adding it to the old in an ongoing process of refining individual knowledge. Bartlett (1932) first introduced the term schema to refer to an individual’s internal understanding and perspective on a given topic. It is to this internal schema, all newly learned information is added, according to educational psychologists and learning theorists. The activation of that knowledge is key to the process of adding to it. From a cognitive constructivist teaching perspective, the onus is on the instructor to stimulate and build upon what the learner already knows and do so in a developmentally appropriate way (Piaget 1960; Bruner 1964).

Constructivism and ICT. In the mentoring example above, ICT were used both by the teachers and students. The ability to mentor a teacher via web conferencing is an example of Demetria using a common ICT in a socially constructivist way. Modeling this manner of connecting at a distance for the sake of learning demonstrates both social cognitivism and cognitive constructivism. The cognitive apprenticeship between Demetria and Margarit centers around their co-construction of meaning in relation to Margarit’s first-year teaching experiences. Cognitive constructivists would argue that the mental model of connecting at a distance with a more experienced peer influenced the eventual lesson design Margarit settled: connecting her Grade 4/5 students with middle school ones via web conferencing is using an ICT in support of promoting learning in her students’ zones of proximal development. Teaching from a constructivist perspective in a classroom with speakers of many languages adds a level of complication as constructivist theories and language are entwined. The first iteration of her lesson failed because she was relying on novelty to outweigh the need for extant knowledge on which to build. Her students had limited schema in place for building block robotics projects; coupled with the lack of common language, this created a frustrating not fruitful learning experience for her students. By tapping into something they all likely have some experience with, and learning what the level of experience is by assessing their current mental models, Margarit has developed a lesson from a constructivist perspective that incorporates ICT in a way consistent with that perspective.

The collaboration evidenced in the vignette is a type of computer supported collaborative learning (CSCL). CSCL involves fostering collaboration among students with a computer as a key partner in that interaction and should not be confused with e-learning efforts that emphasize computer-based dissemination of learning materials (Stahl et al. 2006). CSCL theory has been the focus of robust research and development during the twenty-first century, as researchers seek ways to best support learning collaborations and enculturate learners in the practice of shared knowledge activities (Roschelle 2013). Metacognition, social factors, guiding scripts, and scaffolded interactions all play important roles in this theory (Kirschner and Erkens 2013).

Beyond Behaviorism, Cognitivism, and Constructivism: Connectivism

Lou is fascinated by hurricanes and is interested in being a meteorologist someday. Her interests have led her to explore the topic online. When she first started researching hurricanes on the Internet, she immediately came across several great resources. They ranged from the websites of official meteorology organizations to regular citizens who shared her interests and who also wanted to learn more about meteorology in general and hurricanes more specifically. Lou reached out and made connections with these people; she followed them on Twitter, joined listservs and discussion forums, and even began to host her own blog where she documented her personal learning journey about hurricanes, including her experiences as a child growing up in Florida, where hurricanes are an annual threat. When Hurricane Harvey bore down on the United States, Lou was very active online. With her online network, she was sharing and discussing the latest hurricane tracking data. She in turn blogged a twice-daily hurricane update, which was read by both people in her social networks (e.g., family and friends, her fellow hurricane followers) and others who stumbled upon her blog. People asked her questions in the comments, which she answered to the best of her ability. She helped connect her blog followers to other online hurricane resources, as well, because she knew the value of her network for learning about hurricanes.

Major Tenets of Connectivism

One criticism of the major three learning theories has been that they reflect learning in a different era (Siemens 2005). All three theories – behaviorism, cognitivism, and constructivism – have their roots and major development situated firmly in the nineteenth century, a time when learning involved either face-to-face interaction or interaction with static learning materials. Siemens (2005) suggests that we need a new way of looking at learning, one that reflects current technologies and trends such as informal learning, lifelong learning, a rising need for information access skills, and a growing dependence on technology to handle formerly memory-intensive tasks. Siemens (2005) asserts that “technology is altering (rewiring) our brains. The tools we use define and shape our thinking” (para. 4). Not everyone will agree with technological determinism as an approach to learning theory, but technological determinism nonetheless has been a common theme of distance learning scholars and ideally technology and pedagogy work in a symbiotic manner to foster effective learning (Anderson and Dron 2011). Based on this idea that contemporary life is shaped by technology, connectivism has been recommended by Siemens (2005) as a fourth theoretical approach to learning, one that is inextricably interwoven with ICT and focuses on networked learning. Although connectivism’s status as a theory has been questioned (Kop and Hill 2008), even its critics believe it is at a minimum complementary to existing learning theories (Bell 2011), and the technological shift that has prompted researchers and theorists to renew the discussion of the adequacy of existing learning theories has been termed “seismic” in its effect on how people think and learn in their everyday lives (Dede 2008).

Connectivism and K-12 Education

The connectivist approach supposes that learners can act autonomously within their networks to set and achieve their goals, which may not be realistic for all learners and in all contexts (Anderson and Dron 2011). Within the K-12 curriculum, the idea of preparing students to engage in lifelong and informal learning via connectivist means fits well with the current efforts to support ICT literacy skills, although engaging elementary students in this form of learning may be a bit of a stretch developmentally. As can be seen in Lou's vignette, the connectivist approach puts the learner in the position of building and interacting in a personal online learning network, which requires not only sufficient literacy skills but also a degree of maturity.

Learner development is not the only challenge facing connectivist learning in K-12 settings; even at the high school level, there are few examples of connectivism in practice. Schools are rife with structure and rely on teachers to lead and assess learning activities. Connectivism – which leaves no clear role for a teacher other than that of network member (Anderson and Dron 2011) – is somewhat at odds with formal educational systems. A shift in the teacher's role has been suggested, blending instructivism and constructivism in the service of developing connections (Siemens 2008). For example, perhaps Lou could have been guided by a science teacher to explore meteorology online, and her classmates might have been encouraged to explore their own relevant science interests in online networks. However, we currently lack guidelines and examples to work this approach into existing K-12 educational systems.

Additionally, Internet use policies in K-12 schools may prohibit or restrict learners' freedom to form meaningful online networks and connect to the full range of people and information that may be useful to support their learning goals. These limiting actions are done in the name of student safety but may mean that true connectivist approaches to K-12 learning are not feasible. It is possible that via a social constructivist approach to ICT-based learning – or perhaps a modified connectivist approach (e.g., mixing restricted networks and limited autonomy with flexible, learner-driven goals, and decision-making processes in a resource-dense online environment) – K-12 students could develop the information and networking skills that will allow them to engage effectively in connectivist learning outside of the school setting and throughout their lives.

Challenges

System-Driven Pedagogy

One challenge that limits learning theory-driven ICT integration within K-12 settings is the competing forces at play in educational systems. For example, the growing accountability culture in the United States (Rice 2014) has resulted in the increased use of software designed to prepare students for standardized tests, which themselves have increasingly been administered via computer. These tests, as currently designed, are focused primarily on assessing preset content and convergent thinking (Schoen and

Fusarelli 2008). At the same time, competing messages about the aims of education and ICT use are being sent at the national level. A content analysis of US Department of Education (USDOE) reports focused on elucidating the key components of contemporary ICT movements in K-12 education showed a heavy interest in technology use to support twenty-first century skills such as critical thinking and problem solving (Roberts-Mahoney et al. 2016). However, until student-centered instruction becomes the norm in classrooms and assessments and accountability measures that focus on the complexity and creativity underlying these skills are developed and adopted (Rotherham and Willingham 2010), efforts in this area are likely to be diffuse.

Additionally, ICT literacy skills are among the fuller list of twenty-first century skills supported by organizations such as Partnership for twenty-first Century Learning and the International Society for Technology in Education (refs). However, in terms of concrete ICT-based classroom activities, the USDOE mostly discusses student use of contemporary personal learning systems to practice and receive feedback in a manner reminiscent of Skinner's learning machines that leads to the standardized assessment of preset content discussed by Schoen and Fusarelli (2008). These learning systems continuously generate learning analytics data that are used for formative assessment in preparation for high-stakes testing. As Swan (2016) notes, this use of learning analytics influences epistemology, "privileg[ing] knowledge that can be quantified and tested" (p. 6). Theoretically, this approach to ICT-based learning represents an objectivist epistemology with largely behavioral and cognitivist undertones. Social learning is not heavily represented in this vision of K-12 ICT use (Roberts-Mahoney et al. 2016) even though social learning activities are consistent with addressing the complexities of twenty-first century skills (Rotherham and Willingham 2010). Although this example is from the United States, the larger point could apply anywhere: forces within the system such as legislation and policy may hinder a pedagogy-first approach.

Technology-Driven Pedagogy

Pedagogical choices may be led by technology adoption in some instances, rather than vice versa. Teachers may feel pressured to make use of technologies that the school has purchased, and these purchases may reflect a desire to follow trends or appease a group of stakeholders rather than a thoughtful choice about supporting a particular pedagogical strategy. ICT use also may be driven by an individual teacher's desire to be innovative and try something new in the classroom, and the novelty factor may encourage a tool-first approach in which technology adoption overshadows pedagogical concerns and strategies.

Further complicating matters, in many instances technologies are developed for other purposes and then co-opted by education, and technology-based learning materials may be developed by people whose programming expertise is stronger than their pedagogical knowledge. This means that the pedagogy is not necessarily designed into the ICT, but rather that the ICT are in search of a pedagogically sound use. While these atheoretical approaches may have their successes, ideally ICT will be designed and used in a manner that is pedagogically grounded.

Implications

Implications for Developing Learners

Each learning theory brings with it different implications for learners. Many of these are discussed above, but it also is worth considering the intersection of ICT, learning theory, and cognitive development. As children develop, they attain new psychomotor and cognitive skills. During grades K-2, many children are new readers and they benefit from graphical and auditory-based ICT interfaces. They may not yet read or understand text, and they are still learning the interface conventions that guide many programs. As they develop, these learners will engage in several cognitive transitions through which they will acquire increasingly complex cognitive abilities, such as those involved in abstract and hypothetical thought (Flavell 1992; Piaget 1960). Different ICT will be developmentally appropriate for different groups of learners. This does not mean that most learners will outgrow some ICT, but rather that some learners will need to grow into those ICT.

Bruner's (1964) work on modes of knowledge representation also has implications for how ICT literacy skills are developed. Novice learners likely need direct, manipulative experiences with both hardware and software. Learners with limited experience will still benefit from these action-based forms of instruction but may also be able to learn new ICT skills by watching someone else or watching a video. Advanced learners are the ones who are most likely to succeed when this instruction is delivered solely through written or spoken words.

Implications for Teacher Preparation and Professional Development

Teachers need theory to help them select the appropriate ICT integrated learning activities to achieve their instructional goals. For example, if the instructional objective is remembering and understanding, then ICT activities based in behaviorism are appropriate. Students receive information, practice repeatedly and at increasing levels of complexity, and then can demonstrate their learning. If applying and analyzing are the objectives, then cognitivist ICT activities, in which learning is based on connections, may be used. If critical thinking is the objective, then constructivist ICT activities in which students collaboratively address ill-structured problems are well suited. Teacher preparation and professional development programs can support teachers in developing this dual-view of ICT in which learning objectives and theoretical influence are intertwined.

What teachers do in their classrooms can reveal their epistemological beliefs, which may be tied to a single theory or more likely a pragmatic combination of behaviorism, cognitivism, constructivism, and connectivism. At the same time, teachers may be unaware of the nuanced theory underpinning their decisions and instead articulate their ICT-related choices as a reflection on what will be effective or has been successful in the past. Alternately, they may not know how to effectively match ICT use to their beliefs about learning and may limit classroom ICT experiences to academic software

that presents knowledge and provides practice, either through drills, tutorials, or multimedia information sources. Teacher preparation and professional development programs can help develop and improve teachers' TPK, helping them better understand how to select and apply theoretically-based learning strategies in conjunction with ICT.

Conclusion

Learning theory plays a critical role in the success of K-12 ICT integration. As can be seen in this general overview of learning theories and their manifestation in ICT design and use, learning theory, although very important, is not the only factor that influences how ICT are used in schools. ICT integration occurs within a larger system; Fu's (2013) conclusion, that ICT integration takes effort from students, teachers, and administration, is one that we echo. We would add that teacher preparation and professional development that focuses on technical knowledge and pedagogical knowledge in addition to content knowledge is necessary to help teachers select appropriate ICT and make effective use of those already at hand.

Abstract

This chapter discusses theory, pedagogy, and design of technology-enhanced learning environments in promoting inquiry in science classrooms. Inquiry refers to both the diverse ways in which scientists study the natural world and the means of engaging students actively in developing an understanding about science

content, science process, and how science develops. Supported by technology, students can be scaffolded to engage in inquiry practices, like those used by scientists, to help them deepen their understanding of science and to develop twenty-first-century educational competencies.

This chapter employs the Learning Sciences research paradigm that emphasizes social-constructivist frameworks and design-based research methodology. We first outline changing theories and frameworks of learning, pedagogy, and assessment, and discuss how they influence the design of technology-based learning environments. We then examine several major research programs, including Knowledge Integration, Project-Based Science, Virtual Environments, and Knowledge Building, all of which focus on the alignment of technology, theory, and pedagogy, and emphasize iterative implementation and design principles. Analysis and comparison of these different programs help illuminate theoretical issues and educational implications and identify challenges to designing technology-enhanced inquiry-based environments. We conclude that theory, pedagogy, and technology need to be integrated, and design-based research can illuminate and support learner processes synergizing theory and practice in real-world classrooms.

Keywords

Technology-enhanced learning environments · Inquiry · Collaboration · Knowledge creation · Design-based research

Introduction

Information and network technology-enhanced learning environments (TELEs) are receiving increasing attention for their potential to support new educational goals, including collaborative inquiry, problem solving, and knowledge creation (Edelson et al. 1999; Jeong and Hmelo-Silver 2016). The changing needs of knowledge-based societies have spawned new educational demands and opportunities; in particular, students need to develop new capacities as inquiry learners, collaborative problem solvers, and knowledge workers. The possibilities and challenges of technology-enhanced inquiry environments in scaffolding inquiry and transforming classroom practices are important questions for education and school improvement.

Helping students to engage in inquiry is a major educational goal in the knowledge era, and inquiry is of particular importance in science education – major policy documents and science curricula have specified the goal of teaching students scientific inquiry (e.g., National Research Council 1996; 2007). Inquiry has diverse meanings and we follow the framework adopted by the National Science Council documents – Inquiry refers to *both* the diverse ways in which scientists study the natural world and the means of engaging students actively in developing an understanding about science content, science process, and how science develops. Scientific inquiry in classroom, similar to how scientists study the world, involves several interrelated processes: (a) core inquiry processes, such as initiating and generating

questions, inquiring into problems, using data, testing hypotheses, constructing explanation, and manipulating and coordinating scientific representations in problem solving; (b) process management and regulation, such as deciding what to do next, and planning, reflecting on, and regulating inquiry processes deploying metacognition; and (c) synthesizing, such as communicating and articulating how knowledge has been developed, and sustaining inquiry for knowledge creation (Edelson et al. 1999; Eslinger et al. 2008; Quintana and Zhang 2004). When engaging in inquiry learning, students have the opportunities to behave like what scientists do and inquiry is the main way of how knowledge is generated.

Inquiry plays a crucial role in science education: Participation in inquiry-based learning contributes to students' development of scientific practice such as posing and refining questions, planning and managing investigations, analyzing and communicating results, and also developing understanding of scientific principles. Inquiry can also help develop key twenty-first-century competencies and higher order thinking including problem solving, metacognition, and collaboration. Different from traditional approaches, inquiry learning is open-ended and entails cognitively complex tasks. In pursuing inquiry, students become problem solvers, and since inquiry is often implemented in social situations where discussion, argumentation, and negotiation are involved, students must interact and collaborate with others. Specifically, inquiry learning requires and provides opportunities to promote students' metacognitive skills, as they must engage in planning, monitoring, and regulating complex processes, and work collaboratively to solve complex problems; collaboration is now considered key to knowledge advance and creation (Scardamalia and Bereiter 2014).

Inquiry learning has many benefits, but it is also a complex process in which technology can support. Research has shown that technology-enhanced inquiry-based learning promotes such high-order thinking skills as questioning and explanation, problem-solving, critical thinking, reflection, self-directedness, collaboration, and knowledge creation (Ketelhut et al. 2010; Geier et al. 2008; White and Frederiksen 1998; Yang et al. 2016), and develops students' high-level epistemic agency (Damsa 2014; Scardamalia and Bereiter 2014). Technological affordances can support inquiry-based learning by promoting student motivation and interests, making information and digital libraries accessible, helping students manipulate real-world modeling processes, visualizing and investigating scientific process, enabling and tracking records, and supporting reflection and discourse (Jeong and Hmelo-Silver 2016).

Despite the enthusiasm surrounding technology, its educational benefits are unconvincing (Kim and Hannafin 2011). Integrating technology with classroom practices requires substantial pedagogical changes and sociocultural support (Jeong and Hmelo-Silver 2016). Rather than using short-term experimental approaches or applied classroom research, we propose the use of design-based research commonly used in Learning Sciences for research-practice synergy.

In this chapter, we adopt a *Learning Sciences* paradigm that focuses on the alignment of theory, pedagogy, and technology, and emphasizes design, iteration, and design principles. Design-based research (DBR) addresses the dialectical

relationships between theory and practice, supporting researchers and teachers to design productive learning environments while allowing researchers to study such phenomena as learner processes. Design-based research that consists of iterations of classroom implementation and evaluation is an important methodology for studying the interaction between technology, contexts, and learning theories (Collins et al. 2004); one that often involves teacher-researcher and multidisciplinary teams as codesigners.

This chapter examines theory, pedagogy, tools as integrated designs of technology-enhanced learning environments (TELEs) in scaffolding learning and inquiry in science classrooms. We first outline changes in theories of learning, pedagogy, and assessment (section “[Contemporary Theories of Learning Underlying Design of Learning Environments](#)”), and then review several major research programs of technology-enhanced inquiry-based learning environments (section “[Technology-Enhanced Classroom Innovations on Inquiry-Based Learning](#)”), followed by a comparative analysis of these programs and discussion of theoretical and pedagogical issues and implications for future research (section “[Implications and Further Issues](#)”).

Contemporary Theories of Learning Underlying Design of Learning Environments

This section introduces contemporary themes in learning, pedagogy, and assessment to provide theoretical perspectives for examining technology-enhanced inquiry-based learning.

From Behavioral Learning to Knowledge Construction to Knowledge Creation

Traditionally, learning has been considered from a behaviorist perspective and situated in school settings emphasizing information transmission and students’ acquisition of well-established content knowledge and skills. Early computer-assisted learning reflects and amplifies this approach through drill, practice, reinforcement, and rewards designed to make students’ acquisition of predefined knowledge and skills more efficient and effective.

Since the early 1980s, learning has been reconceptualized from a constructivist perspective. Bransford et al. (1999), in their seminal book, *How People Learn*, maintained that learners adopt a constructive role in the learning process – relating new information to prior knowledge to restructure the latter, and use metacognitive strategies to reflect on their learning. In the 1990s, cognitive constructivism evolved into social constructivism, which conceptualized knowledge as coconstructed via interaction and sociocultural processes, and viewed learning as situated cognition, acculturation of practice, and participation via interaction and discourse. Since the 2000s, metaphors of learning have been expanded beyond “knowledge acquisition”

and “acculturation,” and researchers conceptualize learning as “knowledge creation,” examining the emergence of new ideas and knowledge mediated by artifacts (Paavola et al. 2004; Scardamalia and Bereiter 2014). Aligned with these theoretical shifts, technologies have been designed to elicit and support students’ learning and inquiry, including constructive processing and knowledge integration (Linn et al. 2004); metacognitive inquiry and regulation (Azevedo 2005); interaction and group cognition (Stahl 2006); and collaborative knowledge-building (Scardamalia and Bereiter 2014).

From Individual Learning to Group Learning to Knowledge Communities

Early learning theories and psychological studies predominately focused on *individual* learning and emphasized *individual* performance; thus, technology was developed to support individual learning. Recent approaches, however, depict learning as a social process. Related to learning theories emphasizing situated cognition (Lave and Wenger 1991), distributed cognition (Salomon 1993), activity theory (Greeno 2006), and collective cognitive responsibility (Scardamalia and Bereiter 2014), the unit of analysis has shifted toward group cognition and collective accomplishment; learning is distributed within group and emerges collectively in group and community contexts.

Such shifts underpin the development of new computer technologies that support students’ collaborative, rather than individual, problem-solving, and inquiry. Specifically, computer-supported collaborative learning (CSCL) has emerged as a field focusing on examining the analysis of collaborative processes and how learning emerges through small group inquiry and interaction. The unit of analysis has changed from individuals to groups and communities, extending to students’ interactions with agents (Leelawong and Biswas 2008), collaborative inquiry among community members (Zhang et al. 2009), and technology-supported mass collaboration (Halatchliyski et al. 2014).

From Instructionism to Guided Instruction to Emergent Design

Sawyer (2014) critiqued traditional schooling’s emphasis on instructionism, a transmission teaching approach in which students receive information from the teacher, process it superficially, without constructing their own knowledge. Learning science designs highlight the importance of pedagogy that fosters deep learning and understanding; research has indicated students learn and retain materials better, and can better generalize it to other contexts, when they solve problems and act as professionals do in the field. *Authentic* problems and practices are thus key in pedagogical design. Accordingly, computer-supported environments must support deep learning and understanding (Sawyer 2014). Classroom implementation and design of technology learning environments must enable learners to manipulate and revise

their developing knowledge by working with different scientific models and representations and engaging in inquiry-based activities for deep learning, much as scientists ask driving questions, propose hypotheses, and find evidence to support their conclusions (Linn et al. 2004; Krajcik and Shin 2014; Scardamalia and Bereiter 2014).

In learning sciences research, technologies are designed to guide and scaffold different kinds of learner and inquiry processes integrating with different pedagogy. For example, when structured inquiry is used to help students develop conceptual understanding of difficult science concepts, web-based libraries are developed; different tools are designed in alignment with different instructional patterns to support the knowledge integration processes (Linn et al. 2004; Slotta and Linn 2009). Knowledge building emphasizes emergent inquiry and advocates principle-based pedagogy not scripted activities; Knowledge Forum[®] is designed in ways to realize these principles and facilitate the development of knowledge-creation processes (Scardamalia and Bereiter 2014). Primarily, changing and emerging pedagogy influences the design of technology-enhanced environments in supporting learner processes.

From Assessment of Learning to Assessment as Learning and Collective Assessment

A fourth theme pertains to changing *assessment* theories and practices. Traditionally, assessment has focused on the objective measurement of such constructs as intelligence and ability (Shepard 2000); constructivism has shown knowledge domains to be more complex, and has informed a progression from evaluating student performance (*assessment of learning*), to using assessment to promote learning (*assessment for learning*), to students taking agency to monitor and reflect on and improve their learning progress (*assessment as learning*) (Shepard 2000; Black and Wiliam 1998). Researchers have urged better alignment among theory, practice, and assessment, spawning additional research on formative assessment (Carless 2010).

Changing assessment theories and practices have influenced technology design for computer-supported learning and peer assessment. Researchers in the recently emerged learning analytics field have used data stored in digital learning environments to examine and evaluate interaction patterns contributing to learning (Shum and Ferguson 2012), and use this data to facilitate *formative assessment* – that is, providing feedback to improve ongoing teaching and learning processes (Black and Wiliam 1998; Evans 2013). Assessment approaches also emphasize *reflective assessment* (learners reflecting on assessment data to improve their scientific inquiry) (White and Frederiksen 1998) and concurrent and transformative assessment (Scardamalia and Bereiter 2014). Most current learning analytics assess pre-defined learning objectives and learners' acquisition of static-state knowledge and skills (Schwartz and Arena 2013), rather than higher order thinking skills essential for innovation (Chen and Zhang 2016). Aligning assessment with pedagogy, and learning for promoting students' inquiry in technology-enhanced learning environments, are important research areas.

Technology-Enhanced Classroom Innovations on Inquiry-Based Learning

This section discusses four major research traditions of technology-enhanced learning environments, spanning over two decades, that support student inquiry, and make problem-solving, metacognition, and collaboration more prominent in classrooms. All these programs employ design-based research, involving iterative classroom implementation and evaluation for improving designs, and integrate theory, pedagogy, and technology in classrooms.

Knowledge Integration and the Web-Based Inquiry Science Environment (WISE)

The knowledge integration framework and WISE (<http://wise.berkeley.edu>) support science learning through technology-enhanced and web-based inquiry in the science classroom. Building on such earlier projects as the Computer as Learning Partner Project (1980s) and the Knowledge-Integration Environment (1990s), WISE is a free, open-source curriculum platform that provides inquiry-based units on a wide range of science topics for middle- and high-school students; it also provides authoring tools for creating new inquiry units. The goal is to bridge the science taught in schools with students' everyday life (Linn et al. 2004), engage students in inquiry, and help them improve their scientific understanding in becoming lifelong learners (Linn and Eylon 2011).

WISE was designed based on the Knowledge Integration (KI) framework, which is “a dynamic process where students connect their conceptual ideas, link ideas to explain phenomena, add more experiences from the world to their mix of ideas and, restructure ideas with a more coherent view” (Bell and Linn 2000, p. 797). Students often come to the classrooms with fragmentary ideas, and the KI framework aims at *eliciting* students' ideas and *adding* new normative ideas by engaging students with scientific visualization, experiments, and hands-on activities, and scaffolds students' processes of organizing, *distinguishing* between, and connecting these ideas, emphasizing students' continual reflection as they construct and articulate their *integrated* understanding (Linn and Eylon 2011).

In a typical WISE inquiry project (e.g., the deformed frog mystery), most of which lasts 5–10 days, student dyads work on a shared computer and navigate through a sequence of inquiry activities. A WISE project involves students completing different activities in set sequence, by clicking on successive steps in the WISE inquiry map, one at a time. Students respond to online inquiry activities such as using visualization to explore simulations, design experiments, and interact with media, supported by technology-enhanced scaffolds that guide students to visualize the inquiry process and emphasize the use of evidence and scientific argumentation.

Over the years, different WISE instructional patterns and inquiry tools have been developed to help students work on diverse problems and projects, use complex scientific models, and track their learning process in complex projects (Slotta and

Linn 2009). For example, *Idea Manager*, a web-based, curriculum-integrated tool suite, was designed to help students construct evidence-based explanations from dynamic scientific visualization as they generate, distinguish between, and reconcile their ideas, to facilitate students' reflecting on and sharing of ideas, and to record students' understanding. Other examples include *Data Visualizer*, which presents tables and graphs; *Sensemaker*, wherein students sort out scientific evidence; and *Causal Map*, where students arrange causal factors in interactive maps (Slotta and Linn 2009). Continuing efforts are given to the development of different WISE tools to support different instructional patterns and KI processes. This research program also investigates its impact on student learning: for example, Linn et al. (2006) showed the WISE cohort (N = 4520) scored significantly higher than the regular cohort (N = 3712) on complex science items (not regular multiple choice), while Linn and Eylon (2011) used learning trajectory studies and found students' improvements from pre- and posttests to delayed posttests across different units.

This tradition of work provides an important example of design-based research (DBR) for the sequence of design, formative evaluations guiding iterative revisions to the designs, and sets of design principles. This program comprises four meta-principles: (a) make science accessible by connecting it to what students know; (b) make science visible by explaining scientific processes and illustrating connections; (c) help students learn from each other through respectful in-classroom collaborations; and (d) promote autonomous lifelong learning by supporting project work, and reflecting on scientific ideas (Linn et al. 2004). These key principles (and numerous subordinate principles) were developed from numerous studies in complex classrooms. Linn and colleagues worked with multidisciplinary teams of researchers, scientists, teachers, and technology experts – Participants exchanged insights relevant to design, learning, and teaching, including the development of curricula materials and professional development strategies including teachers' participation in the design of technology to support their practice.

Project-Based Science and Inquiry Model in Science

Technology-enhanced project-based science. In the last two decades, Krajcik and colleagues have developed project-based science curricula, supported by learner-centered technologies that allow students to learn by doing, inquiring, applying ideas, and solving problems (Blumenfeld et al. 2000; Krajcik and Shin 2014). In project-based science, students engage in meaningful problems and carry out activities that mirror what scientist do. Project-based science emphasizes constructing knowledge through problem-solving by “asking and refining questions, designing, and conducting investigations, gathering, analyzing, and interpreting information and data, drawing conclusions, and reporting findings” (Blumenfeld et al. 2000, p. 150).

Based on extensive classroom implementation of project-based science curricula (Beyer et al. 2009), several key principles and features for the design of the inquiry environments are identified: (1) starting with a meaningful, driving question, a

problem that needs to be solved; (2) setting learning goals that align with science standards and assessments; (3) engaging students in inquiring into the question by participating in scientific practice; (4) involving different actors, including teachers, students, and the community, in tackling the problem; (5) scaffolding student inquiry with learning technology; and (6) supporting students in creating a set of tangible product and artifacts as representations of their learning (Krajcik and Shin 2014).

These project-based learning contexts consist of authentic, challenging, and open-ended problems that require deep disciplinary knowledge and metacognitive skills. Frameworks for scaffolding and technological tools have been developed to support students' metacognition and inquiry. For example, *Model It* supports the development of qualitative model building (Jackson, Stratford, Krajcik, and Soloway 1994), *Artemis* helps students search a digital library, organize information, and share questions (Wallace et al. 2000), and *Digital IdeaKeeper* (Quintana and Zhang 2004) provides students with tools to plan their inquiry, search digital libraries, read information, and address questions. Quintana et al. (2005) have developed four guiding principles for tool design/use to scaffold learners' metacognition in online inquiry: (1) facilitate learners' understanding of inquiry task structures through explicit visual representations, (2) incorporate tools to encourage learners to plan their tasks and online inquiry, (3) make the inquiry process, working history, and information common to multiple activities explicit, to support learners' self-monitoring and –regulation, and (4) use prompts to help learners understand what they should reflect on and articulate throughout their inquiry.

In Project-Based Science, development of project inquiry curricula materials for teachers, professional development, and school reform are key themes with collaboration among universities and schools (Krajcik and Shin 2014). Assessment of the impact of this research program indicates that students in project-based classrooms show better domain understanding and processing skills than do students in traditional classrooms (Geier et al. 2008) using state-wide national assessments. Recent developments involve the design of project-based learning materials to support the scaling up of reform efforts and making innovation possible in a wider range of classrooms (Kolodner et al. 2009-2013).

ThinkerTools Inquiry Model and Curriculum. Researchers have considered metacognition to be crucial in facilitating students to engage in complex inquiry (White et al. 2009). *ThinkerTools* curriculum incorporates an inquiry cycle and reflective assessment in pedagogical and technology design to support students' metacognition (White and Frederiksen 1998). The inquiry cycle – question, hypothesize, investigate, analyze, model, and evaluate – is developed as a general model of the inquiry process. Student groups design science projects guided by the cycle, constructing and applying increasing complex causal models of Newtonian principles, asking questions, testing hypotheses, conducting research through computer simulation, and revising theories via investigation. As well, students engage in self- and peer-assessment as they monitor and reflect on their metacognitive inquiry process. Evaluation of the interventions show that inquiry supported by reflective assessments are particularly beneficial for students with low academic achievement (White and Frederiksen 1998).

Eslinger et al. (2008) extended their earlier work in designing an interactive learning environment, *Inquiry Island*, in which students conducted scientific inquiry projects on genetics curriculum topics, supported by a framework of inquiry and self-assessment tools. Students in the intervention showed significant gains in inquiry skills, and the software also helped to gather and analyze qualitative data about students' learning process. Herrenkohl et al. (2011) created the web-based system called *Web of Inquiry*, which aimed at scaffolding students to develop and/or test theories; learn language of science and scientific tools, and take up a scientific worldview about the social nature of science. These research programs demonstrate the importance of addressing students' cognitive and metacognitive processes and developing pedagogical principles when designing technology-enhanced environments, technology in turns illuminates and makes complex processes more accessible to different learners.

Virtual World Environments

The Multiuser virtual environment (MUVE). Another major research program is the design of multiuser virtual environments to help students develop both science content and science process skills (Dawley and Dede 2014). Virtual worlds are highly motivating and can engage students in scientific practice, working on socio-scientific issues. In the River City MUVE, a nineteenth-century historical city, students immerse themselves in the virtual world and interact with computer-based agents and other digital objects. They behave like scientists and collaborate in teams of three/four to figure out why people in River City are getting sick (<http://muve.gse.harvard.edu/rivercityproject/>). They communicate, navigate, and share experience through chat and virtual gestures using different digital tools and artifacts. Students engage in different inquiry practices, including observing the city, posing questions to agents, finding different sources of information (e.g., River City library), hypothesizing and collecting/analyzing data, reviewing experimental evidence, developing explanations, and communicating results. Compared with a similar, paper-based curriculum, students in MUVE were shown to be more able to engage in inquiry, were more motivated, and learned as much or more science content (Ketelhut et al. 2010).

More recently, the EcoMUVE curriculum (<http://ecomuve.gse.harvard.edu>) employs immersive authentic simulation to help students develop a deeper understanding of inquiry, experimentation, and content in ecosystem science. EcoMUVE consists of two virtual worlds that simulate ponds and forest ecosystem; students investigate the research questions and collaborate, analyze, and share data, working as ecosystem scientists engaged in scientific inquiry into the causal relationships of ecosystems (Dede et al. 2017). Virtual worlds also open up opportunities for assessment using analysis of log data addressing aspects of assessment of inquiry.

Dede and colleagues, working with networks of teachers, researchers, and technologists, adopted DBR in implementing MUVE curriculum in networks of schools and examined scaling issues to increase the sustainability and spread of this technological innovation (Clarke-Midura and Dede 2009). MUVE curriculum helps

students increase their motivation, learn biology content, and inquiry skills, develop twenty-first-century skills, and engage in scientific practice (Ketelhut et al. 2010).

Virtual Singapura and Omosa. Similar to River City MUVE, Virtual Singapura and Omosa are virtual worlds and the aim is to help students learn scientific inquiry skills in systematic ways (Jacobson et al. 2010). Following up the work on Virtual Singapura when they started exploring instructional sequence of inquiry, Jacobson and colleagues developed *Omosa*, a collaborative virtual planet wherein students inquire into ecosystems and food web, aligned with secondary science curricula. In the scenario-based immersive 3D virtual world, student scientists worked in teams to find out the causes of and possible solutions to declining food source and decrease of animals, and they reported their findings to the Environmental Agency. Students are scaffold to engage in different kinds of inquiry practice; they also conduct computational experiments using *NetLogo* to formulate and test their hypotheses. A special feature is the use of a “productive failure,” a pedagogical design that first involves students in low-structure open inquiry, followed by high-structure and consolidation (Jacobson et al. 2016). Ongoing research to examine the effects of these different pedagogical approaches would enrich the design of technology-enhanced inquiry-based learning.

Virtual worlds are highly engaging for students from diverse backgrounds made possible with technological supports. All different MUVES featured problem scenarios that elicit and support scientific inquiry; students navigated the MUVES as scientists – questioning, hypothesizing, experimenting, collecting data, communicating with virtual agents; processing and interpreting data. While River City and EcoMUVE involve large-scale professional development and *Singapura* and *Omosa* are small-scale researches, all are closely linked to schools and emphasize classroom practice.

Knowledge Building and Knowledge Forum

Knowledge Building (KB), supported by Knowledge Forum[®] (Scardamalia and Bereiter 2014), is one of the pioneering models in computer-supported collaborative learning (Sawyer 2006). Knowledge building/creation can be understood as a community’s efforts to advance the state of knowledge in that community (Scardamalia and Bereiter 1994, 2014). Knowledge building/creation, as an educational goal, emphasizes students’ creative use of ideas and the sustained pursuit of inquiry as innovative capacities in the knowledge era. Scardamalia and Bereiter (2014) argued that even school-aged students can contribute to and engage in knowledge-creation processes similar to those practiced by communities of scientists.

Knowledge forum (KF) is specifically designed to support students’ knowledge creation and sustained inquiry (Scardamalia and Bereiter 2006, 2014). KF provides a digital space in which students can contribute, build-on, reflect, synthesize, and “rise-above” as they collectively work toward knowledge advancement. The basic unit in a KF database is a *view*, which is essentially a canvass upon which student-

generated notes are placed; different views can be interconnected to facilitate the emergence and synthesis of ideas. Within a specific “view,” students write computer notes and create networks of notes expressing their questions and ideas, and collectively build upon them to develop theories. When writing a *note*, students can use modifiable *scaffolds* (e.g., “my theory,” “I need to understand,” “new information”), which mirrors the inquiry processes of theory building. KF provide different tools that allow students to link ideas, synthesize different lines of inquiry, and make their learning trajectories visible. Design efforts aimed at KF’s further development are ongoing (see Scardamalia and Bereiter 2014).

KB inquiry environments focus on emergent inquiry, with no specific end goal or predesigned curriculum materials. In a KB classroom, each KB inquiry initiative (e.g., How does the body work?) spans several months. While the inquiry is situated within a specific curriculum area; it is the students who take cognitive responsibility for identifying their driving questions and inquiries into core concepts. Typically, students start with face-to-face discussions, in which diverse student ideas are elicited and made public for improvement. Through both online KF and classroom KB talk, they identify problems of understanding, advance theories, build on each other’s ideas, construct explanations, compare different models, and revise their theories. In this process, new questions arise in emergent inquiry. KB classroom inquiry design is informed by a set of principles, key among them being students taking agency (epistemic agency); all ideas are improvable (idea improvement); and the centrality of collective inquiry (community knowledge) (Scardamalia 2002).

Recent developments in KB have emphasized the development of technology-enhanced assessment and tools (Scardamalia and Bereiter 2014). To engage in complex and sustained scientific inquiry, students need to track their learning trajectory and discourse on KF, examining what the community has accomplished and setting new goals. Researchers have designed KB portfolios, with which students take agency in assessing their own knowledge building discourse (van Aalst and Chan 2007). van Aalst et al. (2012) developed the *Knowledge Connection Analyzer* (KCA) to facilitate students’ reflection on their KF online discourse, and their findings showed that low-achieving students can benefit from using these approaches (Yang et al. 2016). Zhang et al. (2016) created the Idea Thread Mapper (ITM), a time-based collective discourse mapping tool that helps students visualize their collective online discourse journey to facilitate their inquiry practices. Chen et al. (2015) developed the *Promising Ideas Tool* (PIT) to support young students’ selection of promising ideas from their online KF discourse and charting of directions for deepening inquiry. While learning analytics are generally used by researchers, the KB approach involves students using these analytic tools themselves and use evidence to assess the process of inquiry and community progress.

Chen and Hong (2016) reviewed 30-years of design-based research in KB with iterative classroom implementation that informs changes in theory, pedagogy, and leading to new KF designs. Research on the instructional impacts of KB – including different analyses encompassing research measures as well as standardized tests have shown positive results related to students’ understanding of science and the nature of science, and their scientific literacy development (see review, Chan 2013;

Chen and Hong 2016). Knowledge building extends beyond the confines of classrooms, and includes networks of researchers, teachers, policy makers, scientists, and technologists from different countries working collectively in knowledge-building communities. In design-based research, researchers and teachers are codesigners, and work with multidisciplinary teams to pursue synergistic advances for theoretical progress and professional development.

Implications and Further Issues

This section considers the theoretical and educational implications of designing technology-enhanced inquiry learning environments by comparing the different programs based on four key themes – learning and learner processes, the nature of collaboration, pedagogical design, and assessment (see section “[Contemporary Theories of Learning Underlying Design of Learning Environments](#)”). Challenges and future directions in designing and implementing technology-enhanced learning environments are also discussed.

Theoretical and Pedagogical Implications

Learning and learner processes. These different technology-enhanced learning programs illustrate how learning theories underpin the design of the environments, and how these environments illuminate the learning processes to enrich the diverse meanings of learning. All these learning sciences inquiry programs are primarily informed by constructivist and social-constructivist theories, which view knowledge as actively constructed, distributed, and socially situated. Nevertheless, these programs vary in their meanings of inquiry and emphases on the learning process. KI emphasizes students’ *constructive processes* and how technology can make scientific processes visible; inquiry involves students’ *connecting* prior knowledge using technology and curriculum materials to support students’ learning of science concepts. Project-based Science and ThinkerTools curriculum highlight *problem solving* and *metacognition*; inquiry is student-designed and more open-ended, technology elicits and supports metacognition, and students are to reflect on their inquiry processes and monitor their knowledge gaps. Virtual Environments (VE) emphasize situated aspects of cognition and authentic practice; inquiry emphasizes creating learning scenarios and students developing an *understanding of scientific inquiry processes*. KB emphasizes the *sustained pursuit of inquiry* in community; new knowledge emerges from ever-deepening explanations and theory revision. Examining these traditions reveals the different *learner processes* they elicit and cultivate, and how these varied approaches mirror and enrich meanings of learning and inquiry. Educators can consider the different possibilities of inquiry for enriching learner processes when designing the learning environments.

Nature of collaboration. Comparison of these programs illuminates different perspectives and designs on collaboration. KI and VEs include designs wherein

students can engage in scientific inquiry, individually or as *dyads*; teamwork is seen to facilitate inquiry, but not key design or analytic goals. Project-based environments typically involve *small groups* carrying out scientific inquiry; student groups also engage in self- and peer assessments. KB is *community-based*, and focuses on collective inquiry and examines the progress of collective knowledge; individual learning is a by-product.

Technology provides an important medium for theorizing and designing collaboration. For example, metacognition is traditionally investigated as an individual learner process; these technological-inquiry environments require students to develop social metacognition and coregulation when they engage in complex collaborative inquiry, that is, students need to regulate own learning as well as group inquiry. Technology design brings about new opportunities for theories of learning and collaboration – there need to be reconceptualization of what metacognition and regulation involves in a social context. There are also educational implications for considering how to support students to develop social metacognition and collective regulation. Recent development in large community-based environments (e.g., knowledge building, wiki) illustrates how participants collaborate in new, different ways, and how new technology can enrich our understanding of the nature of collaboration needs to be investigated.

Pedagogical design. In designing inquiry-based environments, there have been controversies regarding the levels of support provided to learners and how much scripting should be given (Kirschner et al. 2006). Review of these research traditions reflect differences in underlying theories, and highlight different pedagogical approaches ranging from structured to emergent approaches. KI generally uses high-structure, providing guided and sequenced approaches using rich curriculum materials. Project-based learning involves open-ended inquiry, with student groups designing their projects, and driving questions may be provided. VEs use open inquiry – *Omosa* uses a mixed pedagogy approach called “productive failure,” involving low-structured inquiry followed by high-structured inquiry. KB, the least-structured inquiry approach, emphasizes opportunistic principle-based approach rather than prescribed activities or tasks – KB pedagogy focuses on students initiating and directing their own inquiry, rather than relying on guidance from teachers.

While all programs emphasize inquiry, these varying pedagogical approaches reflect different epistemologies and goals. For example, if the focus is to teach students difficult science concepts, guided inquiry in KI may be more relevant. Alternatively, when the goal is to develop knowledge-creation innovative capacities, students need to take up epistemic agency and more open-ended principle-based pedagogy would be more appropriate. Primarily, the controversies and choice of pedagogical design in inquiry-supported learning environments, whether structured or emergent, scripted or unscripted, need to be considered in relation to the epistemology and learning goals of the programs.

The different ways in which scaffolds are used further illuminate different aspects of learner processes and inquiry-based learning designs. These programs employ different kinds of scaffolds including cognitive, metacognitive, conceptual, and

epistemic ones. For example, the inquiry map in KI/WISE scaffolds students' conceptual understanding of science and cognitive processes; the Cycle of Inquiry provide scaffolds to help students with metacognitive understanding; and knowledge building engages students in the epistemic scaffolds of theory building. Scaffolds may make inquiry learning meaningful and productive, or superficial or complex. Reiser (2004) considered scaffolds' purpose was not only to *structure* but also to *problematize* learning. Different kinds of scaffolds need to be considered when designing and implementing inquiry-based environments supporting students' cognitive, metacognitive, conceptual, and epistemic processes.

Assessment for inquiry-based learning. Research on technology-enhanced learning environments illuminates different perspectives on assessment. Assessment in KI generally focuses on evaluating students' knowledge and skills; *formative assessment* emphasizes examining students' performance and providing feedback to guide their inquiry. Project-based learning (e.g., *ThinkerTools*) focuses on reflective *assessments* for metacognition; students actively monitor and reflect on how their inquiry processes align with scientific inquiry models for making changes. VEs use online data to gauge students' inquiry processes, and such information is used to diagnose students' learning processes. KB emphasizes collective reflective assessment; students are engaged in *transformative* assessment and have agency in using analytics and assessment tools, using evidence to chart their collective knowledge advance.

These examples illustrate the different ways assessment can be undertaken in TELEs. They all highlight the importance of using assessment to promote learning and inquiry, and how technology now opens up new opportunities for tracking student growth. These approaches also vary in terms of students' role in assessing their own learning; use of assessment tools for summative, formative, and transformative purposes; and whether assessments are for individual or collective growth. These examples provide possibilities for integrating assessment with student inquiry when designing inquiry-based learning environments.

In sum, all the above programs consider sociocognitive and technological dynamics in promoting inquiry and embed assessment tools/learning analytics to track students' inquiry process; they all employ design-based approaches to improving theory and design. While these programs have different emphases on inquiry in relation to theory, pedagogy, and assessment, comparisons and analyses of these various designs and learning goals and contexts can enrich theory, design, and classroom practice.

Issues and Further Research

Scaffolding inquiry. Inquiry-based learning environments provide rich opportunities for inquiry, problem-solving, and metacognition to meet twenty-first-century education goals. However, questions exist as to how well students can collaborate in constructivist-based and open-inquiry environments. Inquiry-based learning environments are primarily rich and complex, yet students may not know how to work to

realize these affordances; typically, students may lack the epistemology needed for engaging in inquiry, metacognition, and knowledge creation. How technology and pedagogy can shift students' epistemic understanding need to be investigated.

A related question is the use of scaffolds. Different technology-enhanced learning environments (TELEs) focus on developing different forms of scaffolds to support inquiry. However, how to develop and employ scaffolds so that students do not become reliant on them, and how scaffolds can be faded in or out to help students internalize the inquiry processes are important questions for further investigation.

Assessment of inquiry. It is also important to examine how to develop assessment in TELEs to serve both functions of scaffolding and measuring inquiry. In view of the increasing popularity of learning analytics, how teachers and students can use learning analytics for assessment merits investigation. Many programs include assessment of conceptual knowledge, performance, and science knowledge, but assessment of inquiry and related twenty-first-century skills remains complex. In line with the current review, it is important that assessment be student-driven and transformative to facilitate progress. How technology-enhanced environments can support students' assessment of inquiry, and how learning and teaching analytics can be effectively used in classrooms to support learner processes are now major research areas.

Teachers' beliefs and knowledge. All these inquiry-based environments emphasize understanding and promoting such learner processes as examining students' knowledge models and cognitive-collaborative strategies, rather than focusing on technology or tools *per se*. In relation to these demands, teachers face many challenges and their belief in and capacity for the productive use of these environments need to be considered. To implement these designs and models, teachers need to view students as knowledge contributors, not information receivers, and to become colearners with students in inquiry and knowledge-building communities, rather than information providers. In inquiry-based teaching, teachers must also develop inquiry-based learning epistemology and become inquiry teachers to support student learning. How pedagogy, technology, and teacher epistemology are intertwined are critical issues to explore.

Classroom implementation and scaling issues. Many challenges exist regarding how technology innovation and practice can be implemented, sustained and scaled up. Research on computer-supported learning often focuses on technological affordances and features in a bound setting (Kim and Hannafin 2011), rather than on the dynamic nature of classroom interactions, and accompanying social and cultural factors (Jeong and Hmelo-Silver 2016). Technologies *per se*, even with these sophisticated environments cannot generate positive effects on student learning and learner processes; the positive influence is based on the ways of integrating pedagogy with technology – developing teacher expertise in relation to social context and supporting teacher professional communities to meet these challenging goals are fruitful research areas (Chan 2011).

Scaling up is another complex issue and often technology innovation cannot be implemented as intended. This chapter has emphasized employing design-based methodology and there are both benefits and challenges. Studies using design-

based research are complex and efforts to document changes and improvements over iterations of designs are often unsystematic. Design-based research is most suitable for studying and tuning designs in classrooms; however, examining scalability would require refining DBR or developing new methodology to study changes in classroom systems and networks.

Conclusion

In this chapter, we have discussed the theory, pedagogy, and design of technology-enhanced inquiry-based environments, focusing on how technology-enhanced inquiry-based environments can be designed and implemented in classrooms, and how they can foster student inquiry and related twenty-first-century competencies. We have also discussed theoretical issues and changing views of learning and assessment and how they impinge on technology designs. Four examples of major research programs on technology-enhanced inquiry-based environments were provided, and all of them have developed design principles from iterative studies, that would have classroom implications for designing inquiry. All programs focus on developing students' scientific inquiry; students are scaffolded by technology, to develop a deeper understanding of science and to engage in scientific practice, like what scientists do, with the development of a range of inquiry processes elicited and enriched in these environments. These programs have been evolving over two to three decades and continuing with current development in new assessments and technology in support of student learning and learner processes in the knowledge era.

Our analysis of these technology-enhanced inquiry-based environments shows that there are different ways of theorizing and scaffolding inquiry, which highlights the intertwined relationships among theories, pedagogy, and technology. This chapter has emphasized design-based research as a promising methodology for synergistic improvement of theory and design in classrooms, and to support technology integration in classroom contexts through a partnership of teachers and researchers, and multidisciplinary teams of technologists and scientists. The key implications are that theory, pedagogy, and technology need to be integral to each other – The design of technology-enhanced inquiry-based environments needs to be informed by theories and principles of learning; reciprocally, their implementation can help elicit and scaffold the learning process, and thus enrich our theoretical understanding of how students learn.

Abstract

The widespread use of social media (e.g., Facebook, Twitter, YouTube) has led many researchers and practitioners to explore their benefits for education, including their ability to connect people together in ways that value diverse perspectives, creativity, and individual expression. However, there are some complex cultural and social aspects of these tools that deserve attention and that educators and students should be aware of. In this chapter, we explore a variety of issues through the themes of (1) literacy, (2) privacy, (3) civility, and (4) identity. Literacy issues include digital participation divides and the ways that differences in abilities among students to use these tools lead to inequities in educational and social opportunities. Privacy issues include those involving the sharing of personal information via ubiquitous, persistent technologies and the subsequent

hierarchical and lateral surveillance that this enables. Civility issues include cyberbullying and other utilizations of these media to manipulate the emotional states and social standing of others through dehumanization, decontextualization, and persistent abuse. And identity issues include those arising from the incomplete, skewed, or performative expression of identity via social media and subsequent tensions that arise between the use of acceptable identity fragments and the reductionism that occurs as authentic identity is translated into online spaces. With each of these themes, we explore pertinent problems that arise in social media (e.g., echo chambers, incivility, identity collapse) and also provide suggestions for educators to alleviate their severity.

Cultural and Social Issues in Using Social Media to Support Learning

Social media include a rich variety of technologies and platforms that are now used on a daily basis to connect people together. Among these media, features, functions, and goals are very diverse, and various social media are therefore quite distinct from one another even though they have some common characteristics. Today, some of the most prominent social media platforms include juggernauts like Facebook, Twitter, Pinterest, LinkedIn, Snapchat, Wordpress, YouTube, Wikipedia, and many others. Facebook alone boasts 1.7 billion monthly active users, or roughly one-quarter of the earth's population (Statista 2016), and YouTube serves almost 5 billion videos per day through its video sharing service (Statistics Brain 2016). Social media have successfully permeated everyday life for people throughout the world, and educators have understandably considered how to use such ubiquitous tools to improve teaching and learning and to address educational problems. Though there are some clear potential benefits to using such media to support learning, there are also many social and cultural issues to consider for safely and effectively guiding their use.

Social media are defined as web-based services that allow users to create a profile, to friend others, and to view the profiles and friends of others (boyd and Ellison 2008) or, more inclusively, as “anything that uses the Internet to facilitate conversations” (Solis and Breakenridge 2009, p. xvii). This broad group of services may provide a diverse range of functions including the following examples:

- Profile creation (e.g., LinkedIn)
- Status updating (e.g., tweets, posts)
- Instant messaging (e.g., direct messages)

- Linking (e.g., URL inclusion, mentioning)
- Media sharing (e.g., images, videos)
- Tagging (e.g., hashtags)
- Social networking (e.g., Facebook, MySpace)
- Image sharing (e.g., Instagram)
- Video sharing (e.g., YouTube, Snapchat)
- Microblogging (e.g., Twitter)
- Blogging (e.g., Tumblr, Wordpress)
- Synchronous discussion (e.g., Skype, Google Hangouts)
- Asynchronous discussion (e.g., 4Chan, Reddit)
- Social bookmarking (e.g., Reddit, Pinterest)
- News aggregation (e.g., Buzzfeed)
- Social gaming (e.g., FarmVille, Mafia Wars)
- Collaborative editing and creation (e.g., Wikipedia, Google Docs)

By allowing for new methods of communication, expression, and sharing, such services empower students and teachers to share and engage with one another in new and more efficient ways. With microblogging and status updates, for instance, learners can share their commentary on social issues and provide links to pertinent news stories with private circles or the public. With social networking, students and teachers can connect with one another, with professionals, or with their communities either from inside or outside of class and can cultivate learning networks that extend beyond the confines of the brick-and-mortar classroom. And with social bookmarking, learners can aggregate, evaluate, and share resources in a structured way, both to support individual and collaborative research efforts. In each of these cases, social media serve as nexuses for bringing people and resources together in ways that permit people to create meaning, artifacts, relationships, and experiences together.

Many of the greatest benefits of social media for education are based in how they connect people together in ways that value diverse perspectives, creativity, and individual expression (West and Kimmons 2017). By removing traditional communication barriers and empowering new forms of connection and expression, such tools can lead us to rethink the purposes of educational systems, the goals of learning, and how learning can be supported throughout life (Siemens 2005). However, there are some complex social aspects of these tools, and their use that deserves attention and that educators and students should be aware of when using them for personal, professional, and educational purposes. Due to their ubiquitous nature, many of these issues have been partially explored in popular books and magazines, while others have been given treatment in research journals and have warranted empirical study. Moving forward, we will organize our conversation on these issues around four main categories: literacy, privacy, civility, and identity. We will explore each of these categories in turn and provide suggestions for how educators can address relevant concerns and exhibit exemplary social media practice in both their own lives and the lives of their students.

Literacy

Just as the advent of written language gave rise to new literacies (in the form of reading and writing), new digital media create a need for new forms of literacy regarding sharing, creating, and communicating (Kimmons 2014). Social media are designed to foster participation and the development of a participatory culture around multiple forms of media insofar as these tools: (1) provide low barriers to artistic expression and civic engagement, (2) support sharing and creation, (3) enable informal mentorship, (4) engender a belief from the community that contribution is important, and (5) provide a degree of social connection between participants (Jenkins et al. 2009). This means that just because learners can read or write, it does not follow that they can meaningfully engage in social media to support learning. Rather, to engage with participatory culture, social media users must develop concomitant literacies that may be unnatural or unexpected in traditional social and classroom settings. In fact, learners of all ages may have difficulty in developing the skills and dispositions needed to meaningfully engage with participatory culture, may not be able to reflectively utilize online experiences to enhance learning, and may not be able to develop the ethical and behavioral norms required to navigate complex online environments. While educators might find the promises of participatory culture appealing for supporting learning, they must recognize that there are a variety of challenges involved in helping learners to develop the literacies necessary to meaningfully and fully engage with that culture, and until those challenges are addressed, the potential benefits of social media will not be realized.

Educators have long recognized that a digital divide may exist between learners, in that learners from poorer families might have less access to digital resources than their more affluent peers, but in the current age of technology ubiquity, children in the USA and many other nations have “at least minimal access to networked computers at school or in public libraries” (Jenkins et al. 2009, p. 17). Most teens in the USA use social media, spending over 2 h per day on sites like Facebook and Snapchat (Common Sense Media 2015), and 92% of US teenagers go online daily, with most having access to a laptop, desktop, or smartphone (Lenhart et al. 2015). Although this may vary by country dependent upon cultural practices or access to technology and internet, similar patterns of use exist throughout the world as teenagers are spending hours of their time online. However, differences exist between teen use of media based upon race/ethnicity and family income. For example, in the USA, black and Hispanic learners spend considerably more time watching television, listening to music, and using social media than their white counterparts, while white learners are more likely to use computers and to read (Common Sense Media 2015). Socioeconomic differences exist worldwide and these patterns are likely reflected in various regions throughout the world, with different members of the community having different access to and prioritizing of technologies. When economic differences are considered, higher income learners are more likely to use social media, but when they do use social media, lower income learners spend about 1.5 h more per day with these tools (Common Sense Media 2015). Such differences in patterns of participation may

suggest differences in literacies necessary to benefit from participatory culture and its associated learning potentials.

That is, if learners use digital technologies primarily for passive media consumption (e.g., watching television, listening to music, following celebrities, skimming feeds), then such practices may not provide the same benefits as more participatory activities (e.g., creating content, engaging in discourse, sharing resources, networking, building civility). As one set of researchers explained:

No longer are children and young people only or even mainly divided by those with or without [digital] access. . . . Increasingly, children and young people are divided into those for whom the Internet is an increasingly rich, diverse, engaging and stimulating resource of growing importance in their lives and those for whom it remains a narrow, unengaging, if occasionally useful, resource of rather less significance. Hence, a new divide is opening up, one centred on the quality of use (Livingstone and Bober 2005, p. 34).

Just as social media can empower learners to engage in participatory culture, differences in quality of use may arise as many may use these media in distracting or educationally unbeneficial ways (Andersson et al. 2014).

For instance, though social media can help to expose learners to a diversity of perspectives on culturally significant issues or to encourage critical thinking about social issues, unexamined use can contrarily become a vehicle for promoting narrowness of thought, misinformation, and groupthink. In fact, many technologies naturally lend themselves to the development of online echo chambers as people gravitate toward or intentionally structure their accounts to only interact with those with similar ideological beliefs (Colleoni et al. 2014; John and Dvir-Gvirzman 2015), and similar phenomena may be mimicked in the form of search engine results and news feeds wherein the content that users access is algorithmically determined by previous behaviors and demographic data (e.g., filter bubbles). Learning to determine information accuracy, to recognize biases, and to understand issue complexity and diversity in opinions are essential skills in an information society. Without explicit guidance on how to think critically about their online participation, learners will continually find themselves at the mercy of these technologies' distractive, controlling influences rather than their empowering potentials.

To counteract this problem, educators and educational institutions should (1) recognize that learners are already using these media in their personal lives, (2) enact policies that value and encourage beneficial personal participation, (3) help learners develop critical thinking skills related to their media use, and (4) seek to connect classroom practices to the most beneficial aspects of these media (e.g., diversity, connectedness, expression, creation). Exemplary practice, then, involves explicit classroom learning opportunities that help students to navigate these media and to develop beneficial personal habits related to their use. Students should be taught to critically analyze the information they encounter online, its source, and its merits. They should be encouraged to identify and analyze the biases in a manner that values diversity of backgrounds and democratic pluralism (Goodlad et al. 2004). And they should be challenged to create, express, and share through these media rather than to remain passive consumers of others' content (Jenkins et al. 2009).

Privacy

Democratic societies have always looked upon institutions of power with some degree of skepticism and distrust, as the ideological anthem of such societies has been to ensure and safeguard the rights and privileges of individual citizens by guarding against totalitarian overreach into their personal lives. One popular image used in this regard has been that of the panopticon or a circular prison surrounding an observation tower in which guards have constant vision of the incarcerated, but the prisoners have no contact with one another. According to Foucault (1977), the panopticon was an “enclosed, segmented space, observed at every point, . . . in which all events are recorded, . . . in which power is exercised without division, according to a continuous hierarchical figure, in which each individual is constantly located” (p. 197). Using the panopticon as an image of the police state, Foucault and others have argued that totalitarian power structures are established and maintained by segmenting the population and establishing a constant expectation of recorded observation, and such imagery has regularly been invoked with the advent of new technologies, such as closed-circuit television, geotagging, and other recording technologies, to warn against potential hierarchical incursions into the privacy of individuals’ lives.

In addition to enabling additional methods of hierarchical surveillance, such as Facebook’s collection of data on users that might be shared with governmental agencies, social media also introduce surveillance in a new form: citizen-to-citizen. According to Andrejevic (2005), this *lateral surveillance* consists in “the use of surveillance tools by individuals, rather than by agents of institutions public or private, to keep track of one another” (p. 488) and represents “the redoubling of the panoptic model whereby the subjects of the panoptic gaze come to take on some of the responsibilities not just of monitoring themselves, but of keeping track of one another” (p. 485). Social media empower lateral surveillance by giving users deep access to the lives of one another (e.g., the Facebook timeline) and allowing the sharing of vast amounts of private data with little consent and expectation of observation. In this way, individual privacy in the digital age is threatened both by hierarchical attempts at surveillance and by lateral attempts, in which users of social media engage in constant forms of surveillance upon one another to decide whom to hire, date, befriend, and elect.

When it comes to learning, educators must recognize that data that are shared via social media are different than data that exist in a school database or a sanctioned learning management system, which are generally more secure, transitory, and impersonal in nature. Social media data are persistent, are typically not owned by the individual (but by the service provider), and could include private information that, if improperly shared, might have life-changing impacts on students and educators alike. Despite their sensitive nature, these data are often shared publicly and are available to family, friends, future employers, and the general public, and if students use social media as part of their classroom learning experiences, then the data associated with this use could follow them for the rest of their lives and be used by those engaged in hierarchical or lateral surveillance to make high-stakes judgements about them.

For this reason, requiring a student to create a Twitter account to complete an assignment is very different from requiring a student to post to a private discussion

forum within a school-sanctioned system. By forcing students to use social media, educators may be requiring them to provide information about themselves, their online activities, their habits, their social circles, their identifying information, and their personal lives with others without fully considering the potential long-term ramifications of such sharing. Similarly, by requiring students to connect with one another or the teacher in a popular platform (e.g., friending on Facebook), the teacher might inadvertently require the student to self-disclose private information to others in a way that ignores the student's right to privacy and collapses the student's complex social interactions into something more simplistic and potentially volatile.

Thus, educators should consider the privacy of their students as they engage in social media learning activities and recognize the power that these media have to enable both hierarchical and lateral surveillance. To help ensure privacy, educators should (1) help students to draw clear lines between personal and classroom use of social media, (2) teach students not to post content to these media that could be personally harmful or misconstrued if taken out of context, (3) guide students in self-evaluation and self-critique of the digital footprints they are creating online, and (4) train students to realize that content shared via social media are never truly private (Zheleva and Getoor 2009).

Civility

Many people have discussed civility in recent years in relation to politics, education, social media, and a variety of other topics (Mower and Robison 2011), and students and teachers need to grapple with this issue, because incivility is generally considered to be a rampant problem in social media that has serious implications for students and teachers alike. In social media, incivility is evidenced through verbal and written abuse, such as vulgar, threatening, prejudicial, stereotypical, or aggressive statements often used in a harassing manner, which may be used to bully or intimidate others. At its heart, incivility is intended to have a dehumanizing effect on the target and has been evidenced most clearly among K-12 students in the forms of cyberbullying, trolling, flaming, shaming, and stalking. In this manner, incivility is a form of dehumanizing abuse that invites conflict and seeks to control others through manipulation and the fostering of misunderstandings (Phillips and Smith 2004). As an illustration, many logical fallacies and sophistry techniques, such as ad hominem attacks or vulgar language use, could be said to be uncivil in nature, because they seek to manipulate others by relying upon argumentative approaches that demonize or trivialize the humanity of opponents. Thus, a YouTube personality might engage in a vulgar tirade on a topic they are passionate about for the purpose of intimidating others and preventing critique. Similarly, a Facebook bully may mock or disparage a person in order to manipulate their emotional state or social status. In its most severe forms, extensive cyberbullying may lead victims to disengage socially or to harm themselves, and many high-profile cases of teenage suicide in recent years have led communities to recognize the seriousness of this issue and to seek remedy (Hinduja and Patchin 2010, 2012; Rice et al. 2015).

In contrast, civility is expressed through humanizing activities that invite interaction in order to seek understanding or to respectfully persuade others. In this way, civility is much more than mere manners or etiquette (though these can be guidelines for promoting civility), and the heart of civility is empowerment of people and interactions through a process of valuing one another's perspectives, experiences, agency, and inherent value as people (Mower and Robison 2013). Thus, civility counteracts abuse in all forms – physical, emotional, intellectual, and social – by emphasizing respectful, humanizing interaction as a precursor for sharing, argument, and critique.

Since incivility is a means to the intended end of dehumanizing and manipulating others, perhaps the reason that incivility has received so much interest in recent years in relation to social media is that these tools may empower us to dehumanize others in new, more persistent, and more effective ways. For instance, a traditional bully in a K-12 schoolyard might effectively dehumanize their victim through physical violence, verbal aggression, or social shaming, but that victim could anticipate some reprieve from such behaviors when class bells ring, when the school day ends, or when the weekend or summer comes around. With social media, however, a cyberbully has a persistent, instant connection to the intended victim that can be manipulated at any time and at any place and that permits for a wider audience to witness the abuse. Even if the victim disconnects from the medium in order to create a buffer with the bully, the bully would still be able to use the medium to socially shame the target in front of peers by sharing photos, memes, or abusive language that would then influence the victim's daily interactions with peers. In such ways, social media may not be the cause of incivility, but they provide mechanisms for more effectively enacting uncivil behaviors across time and locations.

Beyond improving the effectiveness and persistence of uncivil behaviors, there are at least three ways in which social media tools actually invite incivility due to the nature of their designs. These include pithiness, social distance, and ad hominem. First, most social media are designed to provide users with the ability to send very short, focused messages to each other and to attach some other piece of audio, video, or animated media (e.g., emoji) as a supplement. Twitter and text messages, for instance, enforce a limit on the number of characters that can be sent in a single message, and even more text-generous platforms like Facebook are nonetheless designed to encourage just-in-time, quick interactions between users. These design decisions allow such media to facilitate quick, sustained conversations, but the trade-off is that users are not encouraged or expected to put much time into crafting (or reading) lengthy messages to one another, and this means that they will generally be more pithy than what might be expressed through a formal letter or even verbal interaction. If civility requires us to respectfully consider and respond to the perspectives and experiences of others, then media that favor fast, limited responses will lose contextual richness and will focus upon aspects of disagreements that are most divisive, flagrant, and emotive. Any argument expressed in 140 characters or less will by its nature be a strawman argument.

Second, anonymity and perceived distance can lead users to indulge in uncivil behaviors that they might otherwise eschew. In one study of online news comment boards, anonymous users were shown to be three-times more likely to exhibit

incivility when talking about a controversial topic than those whose comments were connected to their authentic identities in some manner (Santana 2014). Social distance is not a strict binary between anonymous and nonanonymous, however, since different methods of communication are more intimate and connected than others. A person might say something to another through a letter or group message that they might not say face-to-face or one-on-one, because the added layer of the medium gives the person a feeling of distance from the intended recipient and makes the communication less intimate. In politics, it has been shown that incivility can be effective for persuading voters, even though politicians do not want to be labeled as uncivil (Carraro et al. 2012). It is for this reason that politicians are notorious for allowing or encouraging others to make uncivil attacks against their opponents in a vicarious or distanced manner, thereby reaping the perceived benefits of incivility without any of the social repercussions. Similarly, social media users who feel distanced from their targets may feel free to engage in incivility for its effectiveness at manipulating others without fear of accumulating stigma for such incivility. Thus, this social distance helps users to feel more secure in uncivil practices, because they do not anticipate that such behaviors will elicit the social criticism and dismay that would arise in a traditional setting.

And third, because interactions in social media are generally organized around profiles of users, this means that any type of disagreement in the platform will be directly connected to the people involved, thereby making any disagreement feel like an ad hominem attack. If a student posts a political stance on a controversial topic to their Facebook feed and another student disagrees with that stance by providing a comment, the author must grapple with the fact that they are publically being denounced for their stance directly upon their profile feed, which will persistently serve as a means of identifying themselves to the public, in front of their entire social circle, which might include friends, family, parents, and teachers. This makes it difficult for the author to separate the argument from themselves, because in order to save face, they must react decisively both to safeguard the integrity of their profile and to protect their social standing with their connections. There tends to be little neutral space for disagreement or debate in such media, because every interaction is connected directly to the performance of a user's profile, which represents them as a person. Thus, the dispassionate and leveled discussion necessary for civil disagreement to occur is supplanted by attempts to save face and to perform before a social audience, and failure to win a disagreement may be viewed as a mark on the author's profile for the community to see in perpetuity.

Against this backdrop, it is essential for teachers to engage students in addressing instances of incivility and to model exemplary civility in their own practice. By having classroom discussions and lessons specifically focused on addressing cyberbullying, for instance, teachers can help students to understand the effects of their actions and give them strategies for coping with incivility and abuse when they occur. However, in this process, teachers need to be careful not to employ incivility as a means to punish or ridicule the perceived incivility of others. In many high-profile cases, for instance, social media users have resorted to public shaming or vulgar tirades of others whose behaviors they considered to be uncivil without holding themselves to the same standards of

civility. In such cases, the message of civility is lost in a milieu of anger, disgust, and self-righteous indignation that is unaware of its own hypocritical stance and that often is not based upon reality, such as data-supported evidence of others' participation (cf. Kimmons et al. 2017). Incivility is often easy to perceive in others but is difficult to identify in ourselves, but if civility and the resulting humanizing of people is our goal, then we should ensure that civility permeates both how we engage with those who we believe are behaving civilly and those who are behaving uncivilly alike.

That having been said, civility is contextual, and norms of civil participation in one setting may not transfer to another setting in a one-to-one fashion. For instance, whether or not a particular word is vulgar, inappropriate, or offensive might vary based upon the community where it is used, who the speaker is, and how the word is used. Thus, when exploring civility with students, teachers should be willing to critically examine the contexts of interactions surrounding actual language use and behaviors in social media with the goal of determining the intent of the behavior and not as an attempt to justify incivility. Anyone can be civil, and anyone can be uncivil, but teachers need to work with students to decipher the anticipated effect of behaviors within social media and to determine if the goals are uncivil (dehumanization, manipulation, misunderstanding, abuse) or civil (humanization, understanding, empowerment) and to engage in practices that continually exemplify civility.

Identity

Perhaps the most problematic category of issues related to social media use for learning deals with identity. Identity is a complicated construct that various researchers and philosophers have grappled with for a very long time, but at its heart, identity deals with who we are as people, how we see ourselves, and how we present ourselves to others. When using different social media, people may be said to express their identities through the intentional creation of acceptable identity fragments or AIFs (Kimmons and Veletsianos 2014), as we explain elsewhere:

The notion of an AIF grows out of the premises that educators [and students] (a) consider relationships with others to belong to different types (e.g., friends, family, colleagues) and (b) act differently when they are interacting with others of different relationship types or when relationship types in a given context are mixed. . . . [Thus,] the AIF suggests that participants in a given social context may limit their participation or expression of identity in a way that is appropriate to that specific context or is acceptable to the specific relationships they have with others in that context (p. 295).

Unlike other theories of identity expression in social situations that rely upon dramaturgical metaphors to explain a person's acting in a fake or exaggerated manner (Goffman 1959), AIFs represent authentic images of the self that present pieces of a person's identity to different groups in a fragmented manner (Kimmons and Veletsianos 2014).

The actual self, then, may be said to represent a multifaceted crystal constructed by various AIFs or as a "highly adaptable constellation" (Lemke and Van Helden

2009) of AIFs, thereby transcending any singular social situation and encompassing all of the AIFs that an individual might construct (encompassing, for example, relationships with family, friends, colleagues, etc.):

If we consider each social context that a person expresses an AIF within to be a single point in space (i.e., stars in the sky), then authentic identity is the plotted representation of the self (i.e., constellation) that a person utilizes to create a meaningful self-concept (Kimmons and Veletsianos 2014, p. 299).

This construction of the self may change over time as a person matures and goes through transitional stages in life (e.g., child to teenager, university student to professional, young adult to parent), thereby interacting with different groups of people with different norms of participation (e.g., language patterns, civil norms) and different goals (e.g., exploration, dating, professional growth). Furthermore, each AIF is responsive to the social interactions around it, changing the behaviors of the individual to accommodate the norms of groups, thereby further complicating the identity constellation into a transitional phenomenon that changes and adjusts shape as each AIF's point in space adjusts to its environment. Thus, identity through the AIF lens is something that is authentic but that is also complex, intentional, transitional, socially-responsive, and necessarily incomplete.

This last point deserves additional attention, because it suggests that a person's identity cannot be readily perceived by observing a single AIF any more than the constellation of Orion can be perceived by viewing one star on the hunter's belt. When drawing conclusions about others' identities, then we should be thoughtful about the social structures and other considerations that have elicited the specific AIFs that we can perceive. In the case of social media, however, identities are typically essentialized, simplified, or trivialized as technologies attempt to structure and represent these very complex constructs in a manner that can be readily consumed via a profile page or smartphone interface. That is, rather than presenting a complex, shifting constellation, popular social media sites may present a view of the self that is monolithic (i.e., everything is presented in one place and is shared the same way with all groups), historically persistent (i.e., all behaviors remain connected to the user's identity via a timeline or history), or disfigured (e.g., emphasizing particular aspects of identity, like sexual interests or geographic location, over others, like ideology). For instance, according to the Facebook terms of service, users of that service are not allowed to "create more than one personal account" and are required to use their "real names and information" and to "keep [their] contact information accurate and up-to-date" (Facebook 2015). Furthermore, each user's personal timeline represents a chronological, persistent record of their Facebook posts and interactions, which suggests linearity and singularity in identity rather than multifacetedness and transition. According to this model of identity, a person's name, contact information, friends, and timeline cumulatively represent their identity, but it ignores the possibility that this identity might be incomplete, decontextualized, hyperbolic, or transitional.

This tension between the complex notion of the self as presented by AIFs and the essentialized representation of identity as constructed in social media presents a

conundrum that educators must grapple with (Kimmons 2014). Because the self is complicated and multifaceted, it resists essentialist attempts at classification, and people will understandably reject misrepresentations and misjudgments about their identities that arise through the representation and interpretation of a single AIF, even though social media platforms are generally only designed for and equipped to handle a single AIF. As people participate via a social media platform, they will construct their AIF in accordance with their imagined audience for the platform (Kimmons and Veletsianos 2014; Litt 2012; Marwick 2011; Vitak 2012). Thus, if a student is interacting with peers through the platform, then the AIF will be different than if the student were interacting with their parents or their teachers. However, since such platforms only allow for a single AIF, contexts and imagined audiences quickly become collapsed as students begin connecting with a variety of groups including other students, teachers, parents, siblings, extended relatives, and even strangers, thereby reducing the student's ability to maintain a useful AIF for self-disclosure and expression (Kimmons and Veletsianos 2014; Marwick 2011; Vitak 2012). The representation of the self, then, is essentially colonized within the medium by those who connect with the student, dictating an ever-decreasing set of appropriate behaviors that are deemed suitable for an ever-increasing collapse of social contexts.

A critic of this argument might counter that such colonization is beneficial in education, because by connecting with a student, the teacher can help to counteract the problems of incivility and abuse discussed above, having a civilizing influence on the medium. But such a stance should give us reason for concern, because it smacks of colonial-era arguments for colonization of indigenous peoples by assuming cultural superiority of the teacher and ignoring (or actively seeking to counteract) student agency in the change process. There are undoubtedly a host of appropriate and meaningful behaviors that students engage in that would be lost if teachers sought to insert themselves and classroom-style norms of participation into existing social media, and this seems to especially be true of cultural minority students who may use the space as an alternate means of participation than that afforded by their everyday school contexts. For instance, an ethnic minority student might not feel comfortable posting information about her quinceañera or bat mitzvah for teachers and students to see, because this might elicit unwanted attention, questions, or misunderstandings or require her to become an unwilling spokesperson for her ethnic group to her classmates. Similarly, a religious student might no longer feel safe sharing Christian Bible videos or Muslim Koran verses for fear that teachers or classmates will misinterpret a genuine act of sharing as a form of proselytization or bigotry or operate on the expectation that such behaviors are not acceptable for public discourse (Bobkowski and Pearce 2011; Davidson and Farquhar 2014; Kimmons and Veletsianos 2015). A student whose home language is not English might find herself posting less in her native tongue, because the teacher and other students might not be able to understand her and look upon such expression as excluding and rude. Or a student with unpopular political or ideological beliefs may not feel able to support her candidate or to voice her opinion on a contested issue for fear that her stance might not be shared by the class or that since classroom standards of behavior are being imposed that such forms of expression are better suited

elsewhere (Kimmons and Veletsianos 2015). By colonizing and reshaping students' existing social media AIFs, teachers run the risk of eradicating valid and important forms of expression and potentially destroying the only opportunity that those students had for sharing those aspects of their identities.

Such practices may lead to disfigured digital identities for students, wherein they feel compelled to restructure their behaviors in a manner that no longer feels authentic or meaningful. Thus, educational practices with social media that embrace the complex, transitional, and negotiated nature of identity are preferable to those that take an essentialist view; those that rely upon tools that imply monolithic identity constructs or elicit persistent data to create a stagnant vision of the self; or those that seek to impose classroom-like standards of participation upon all social media interactions. As a negative example, consider one colonization approach to using social media to support learning in a monolithic-identity manner. Seeing that students love using Facebook to interact with one another socially, a teacher might consider using a Facebook group to facilitate class discussion. She friends her students and requires them to friend one another. She then begins to connect classroom discussions to the likes and interests of her students expressed in the platform and encourage her students to extend classroom discussions beyond the group to their family and friends in the platform. The problem with such an approach is that by forcing connections with students and enforcing certain behavior expectations, the teacher requires all students to renegotiate their Facebook AIFs in a manner that focuses on schoolwork and appropriate, classroom-like, student-teacher interactions. The resulting AIF is shaped to reflect the power structure between teacher and student and may not be suitable for other interactions. Though the teacher might believe that such a result would effect a positive policing or etiquette benefit among students by improving civility or professionalism, it seems that such activities might rather serve a colonizing influence in the medium and have a subtractive influence on cultural identity expression (Valenzuela 2010). Such students might change their language norms or cease to share sensitive, unpopular, or potentially misunderstood experiences and beliefs through the medium, and peers with whom these students had previously been connected might now see that they are behaving differently or are participating less in the medium (for fear of being observed by their teacher) and may therefore disconnect from or become dismissive of those whose AIFs have now become school-like. Also, sensing that they can no longer participate with their peers in their desired ways on Facebook, students in the class may begin to resist this colonizing influence by seeking out alternative methods for connection that are unknown to the teacher where they may once again express AIFs that they deem to be more suitable and socially useful (e.g., Snapchat).

In contrast, a teacher who recognizes and values the complexity of their students' identities might resist inserting themselves and classroom norms into their students' negotiated lives and might therefore seek to structure social media learning experiences with their students in a manner that focuses upon the creation of an isolated AIF (1) that is not collapsed with other AIFs and (2) that would not extend beyond the temporal and structural confines of the classroom. For example, using a closed, Facebook-like platform like Edmodo, Schoology, Ning, or Elgg, the teacher could construct a classroom-oriented social networking experience with their students

wherein each student's AIF would only be constructed by interactions with the teacher and peers in the class. This would allow the teacher to establish norms of participation in the medium without forcing these norms to have a subtractive influence on students' other AIFs, because only one AIF would be expressed in the platform, and it would be specifically geared toward learning. This would also ensure that the AIF constructed in the medium would be transitional (i.e., not going into a persistent timeline for future employers and colleagues to see). However, the drawback of such a structured and isolated approach would be that it subverts many of the potential benefits of social media for learning that are identified in literature on sociocultural learning (Selwyn 2012; Vygotsky 1978), connectivism (Siemens 2005), open pedagogy (Hegarty 2015), and lifelong learning (Blaschke 2012). Such structured social media practice ignores the preexisting socially constructed lives of students by not valuing or incorporating their existing social connections; reinforces traditional educational barriers that separate the classroom experience from the outside world; ignores student agency by not allowing students to incorporate the learning experience and its artifacts into their larger social media practices; and establishes a temporal end to learning activities, wherein all student learning and sharing ceases with the end of the semester's class. These tradeoffs may counteract the greatest benefits for using social media for learning and suggest that exemplary practice may require a discerning teacher to counterbalance identity and cultural participation concerns with pedagogical benefits.

Exemplary practice in this regard, then, will take into consideration the age and maturity level of students and their ability to make informed choices about their AIF construction and sharing choices. For instance, using a closed platform like Edmodo might be very useful for teaching primary students about civility in online interactions and for facilitating class-confined sharing, but it would be less useful for more mature students who could more thoughtfully negotiate their AIFs and would benefit from connecting learning activities with learners or professionals outside the classroom. In contrast, secondary students might be encouraged to create a Twitter account for class where they microblog about social topics and connect these conversations with larger social movements and leaders, but recognizing the importance of identity transition and privacy, the teacher might encourage students to use pseudonyms for Twitter handles and to keep the class-constructed Twitter AIF disconnected from the students' other social media accounts.

In this vein, anonymous and pseudonymous participation can be a useful method for encouraging social media learning activities without resorting to identity colonization. Students might be encouraged to create individual accounts using pseudonyms, or they might participate as a group through a single, shared classroom student account, representing the co-constructed AIF of all students in the class. Rather than being purely arbitrary, pseudonym use can also have clear connections to learning objectives, as students might be encouraged to create a Twitter account for a prominent historical figure and to tweet as if they were that person, thereby engaging in roleplay and exploring the perspectives of different historical figures in a manner that cannot be connected to their identities. Such activities allow students to benefit from the connected, social, and exploratory aspects of these media without having to restructure their AIFs and to do so in a manner that defies the problems associated with persistent data.

Not all participation need be anonymous, however, because students should be encouraged to think about their AIFs and to thoughtfully structure their participation in social media in a manner that aligns with their interests, values, and cultural norms. The key with using identifiable social media with students, however, is to ensure that they are able to construct their own AIFs in an agentic manner with minimal compulsive oversight or surveillance from their teachers or classroom peers. For instance, students might be given a task to complete in social media (like having a civil conversation with a friend on a controversial topic) and then to selectively report out on the experience without being forced to give their teacher or classmates full access to their social media profiles. Such reporting might take the form of an essay, screenshots, or oral report and allows the student to maintain an AIF that will not be scrutinized according to classroom expectations while at the same time using their social connections within the medium to construct meaning and explore important topics in a culturally appropriate manner, thereby paving the way for lifelong learning.

Similarly, not all social media participation needs to be expressive or creative in nature, because one can participate through observation or analysis. That is, there is great value in observing the social interactions, perspectives, and artifacts of others without being compelled to interact or to take a stance on a controversial topic oneself. Thus, social media can be a tool for studying the behaviors of others or for aggregating subject-area content (as in following a Twitter hashtag), and this is a form of legitimate peripheral participation that students can be required to engage in without forcing identity colonization (Lave and Wenger 1991). As they observe the interactions of others, students might begin to feel comfortable to create or share themselves, but such sharing should be natural and student-driven (rather than teacher-driven) in order to prevent identity colonization.

In short, identity is a complex construct that is intertwined with social media participation in important and unpredictable ways. For this reason, teachers should be thoughtful in how they require students to use social media for learning and should favor activities (1) that allow for student agency, (2) that do not unduly compel AIF reconstruction or colonization, (3) that allow for culturally valuable forms of expression that may not fit classroom norms, and (4) that capitalize upon the social, connected, open, and lifelong pedagogical benefits of social media.

Conclusion

This chapter has explored some of the primary cultural and social issues that students and teachers must consider when using social media to support learning. Major takeaways from this chapter include the following: (1) teachers should guide students in the development of critical thinking skills in relation to online information and social media content; (2) teachers should carefully consider the privacy needs of their students when requiring them to participate via social media; (3) teachers and students should thoughtfully exemplify civility in their interactions; (4) teachers should be mindful of the colonizing influence that classroom-driven social media use

can have on student identities, favoring activities that allow for more complex, transitional, and authentic forms of identity expression; and (4) pedagogical benefits should be counterbalanced against other considerations to ensure that students have safe, meaningful learning experiences through social media. These technologies are new and ever-changing, and they hold great potential for improving educational opportunities and experiences for our students. Yet, they are also fraught with dangers and considerations that teachers must thoughtfully and proactively address if they are going to positively impact lives and improve learning.

Abstract

This chapter presents a comprehensive review of the current debates surrounding bridging informal and formal learning, from the perspective of improving the learner's experience in formal educational provision. Firstly, the chapter reviews the literature defining informal and formal learning, noting the complexity and the lack of consensus. Secondly, it discusses how technology can be used to bridge learning through harnessing the digital practices that young people engage with informally such as social networking, game-based learning, and digital making.

The authors then outline some pedagogical issues which need to be considered to maximize the potential of bridging formal and informal learning. Next, the pedagogical strategies needed to enhance learners' opportunities for autonomy, collaboration, and authentic learning are discussed. The chapter also explores the divides, cultural tensions, and ethical concerns that shape practices such as the constraints of a performativity culture and the invasion of young people's private space. A vignette of a project in India is presented as an illustration of good practice. Here, despite limited access to technology, young people have been supported to engage in authentic learning projects involving the creation of digital artifacts, both in- and out-of-school. The chapter concludes by arguing that there must be a shift from transmissive to collaborative pedagogical strategies; school cultures need to change. In order to do so, teachers need professional development and support to take risks and experiment. More research is needed so that the interrelationship between technology-enabled formal and informal learning can be better understood but also because good models of practice need to be identified and shared.

Bridging Formal and Informal Learning Through Technology in the Twenty-First Century: Issues and Challenges

Formal learning (education and training), broadly conceived as organized through educational institutions and leading to recognized qualifications, is considered by many to be the tip of the iceberg (see Rajala et al. 2016; Rogers 2014; Yang 2015; Werquin 2010). That is, learning can and does take place in many different contexts beyond formalized schooling including after school clubs, homes, peer cultures, museums, galleries, and other community settings.

Technology, such as social media and mobile devices, offers many benefits for informal learning. Many argue that technology changes the way people learn through enabling new and more immediate ways of accessing and creating knowledge shaped through social interaction, increased ability to cross time and space, and new modes of representation (Banks et al. 2007; Cox 2013; Davies and Eynon 2013; Erstad and Sefton-Green 2013). Technology enables young people to engage in participatory and collaborative models of knowledge production that are interest-driven and authentic, with increased agency and opportunities to develop new skills (Ito et al. 2013). However, many young people only engage in passive interaction such as communicating with their friends and posting photographs in social networks rather than creating, editing, or remixing digital artifacts (Clark et al. 2009).

Technology can disrupt the boundaries between types and sites of learning (Greenhow and Lewin 2016) (see also ► Chap. 8, "Dissolving the Digital Divide: Creating Coherence in Young People's Social Ecologies of Learning and Identity Building" by Kumpulainen et al. in this Handbook). Formal educational institutions

are increasingly trying to harness the potential of technology for making connections to the different types of learning that take place (Ito et al. 2013; Rajala et al. 2016). This is often driven by political demands to improve outcomes and address issues such as student retention by making learning more engaging and relevant (Kumpulainen and Mikkola 2016). However, this shift in school culture is not without its tensions as outlined below.

This chapter reviews the current debates surrounding the conceptualization of informal, nonformal, and formal learning. It then considers recent attempts to bridge young people's formal and in/nonformal learning through the adoption of technology. In the light of this shift in focus, the chapter discusses some of the pedagogical issues arising as educationalists attempt to realize this vision. In an attempt to avoid a biased Western view, it then presents an exemplar of a project in India designed to connect learning across sites. Finally, it concludes by highlighting future challenges and considering the implications for life-long learning.

Conceptualizing Informal Learning

As noted by many, there is a lack of consensus regarding the complex, slippery concepts of in/nonformal learning (Colley et al. 2003; Sefton-Green 2004, 2013; Rogers 2014; Werquin 2010). Policy makers, alongside others, have presented discrete definitions of the concepts and avoided discussion of the difficulties in doing so (Eshach 2007; The World Bank 2003; UNESCO 2012). However, as Sefton-Green (2013, p. 18) notes, "it is easy to think of exceptions and challenges" to discrete definitions. In response, many have argued that instead of viewing these terms as discrete they should be viewed as on a continuum (Lai et al. 2013; Werquin 2010; Yang 2015). That is, definitions should be relative rather than absolute as conceptualizing each term as distinct and bounded is impossible (Sefton-Green 2013). In acknowledging the struggles of many who have focused on this area, Colley et al. (2003) argue that "It is more sensible to see *attributes of formality and informality* (emphasis as in original) as present in all learning situations" (p. 29). This conceptualization is becoming increasingly more important as pedagogical practices combining formal and informal attributes to varying degrees become more commonplace in educational contexts (Weigel et al. 2009).

It is insufficient to define formal and informal learning according to where it takes place (Sefton-Green 2004); instead, it is more important to consider the purpose and structure of the learning (Sefton-Green 2004). Informal learning can thus be broadly conceived as "what happens outside the structures and boundaries of formal education, the topic or focus of which is determined by the person doing the learning, on their own or with others" (Davies and Eynon 2013, p. 330). Informal learning is concrete, interest and practice-driven, open-ended, and highly contextualized (Arnesen et al. 2016; Lemke et al. 2015) as compared to the relatively abstract and decontextualized knowledge delivered through formal education. Informal learning may not always be planned; rather it may be reactive and spontaneous (Eshach 2007). It may also include incidental learning, described as "the everyday

experiences through which we learn a great deal without ever being conscious of ‘learning’” (Rogers 2014, p. 18).

A distinction is also often made between nonformal learning and informal learning. Nonformal learning is commonly used to describe planned but flexible learning that takes place in after-school programs and other activities held outside school hours, in- and out-of-school (Eshach 2007). These activities are organized to some degree around purposeful activities (e.g., football training) but the learner has more agency and choice than in formal settings and more opportunities for social engagement (Lemke et al. 2015; Sefton-Green 2013).

More recently, some researchers have avoided the regular use of the terms in/nonformal learning (and thus the need to conceptualize them), instead referring to sites of learning across space and time including in-school and out-of-school (Erstad 2012; Rajala et al. 2016). In their “learning lives,” young people are conceptualized “as learners [moving] between different contexts of learning, both offline and online, in a constant flow of activities” (Erstad 2012, p. 26). This conceptualization focuses on boundaries and boundary crossings between different learning practices, which demand ongoing complex negotiations (Erstad et al. 2013).

Bridging Formal and In/Nonformal Learning: The Role of Technology

The benefits of connecting to informal learning practices include authenticity, greater engagement, development of social capital, opportunities to develop twenty-first century skills, and the potential to enhance learning (Banks et al. 2007; Hung et al. 2012; Ito et al. 2013; Lemke et al. 2015). Many recent initiatives have tried to capture informal learning and “institutionalize” it (Erstad and Sefton-Green 2013). Everyday experiences are important learning opportunities that can support many different curriculum areas. Schools can draw on everyday knowledge and skills held not only by young people but also their families and the wider community, thus involving a wider range of “teachers” (including the students themselves) (Banks et al. 2007; Erstad et al. 2013; Kumpulainen and Mikkola 2016). Life-long learning policies are also being developed to formally recognize, validate, and accredit the in/nonformal learning that occurs outside formal education (e.g., home, community, workplace) for young people and adults (see Werquin 2010; Yang 2015).

The rapid uptake of technology in many societies and the developing digital youth culture has generated greater interest from policy makers, educators, and academics in bridging formal and in/nonformal learning (Erstad and Sefton-Green 2013; Sefton-Green and Erstad 2016). Technology has created new possibilities for connecting learning taking place in different sites, connecting people with shared interests and expertise, and for integrating informal attributes within formal learning practices (Laru and Järvelä 2015). Concerns have been repeatedly raised about the mismatch between young people’s digital practices in- and out-of-school, often described as a “disconnect” (e.g., Clark et al. 2009; Erstad and Sefton-Green 2013; Ito et al. 2013). School needs to be viewed not in opposition to youth culture but

as “an important part of a network of learning contexts that optimally create a supportive ecosystem for engagement and learning for a diverse range of students” (Kumpulainen and Mikkola 2016, p. 32).

Nonformal learning is perhaps a special case in relation to bridging formal and informal learning. After-school clubs can connect academic and everyday knowledge, enabling students to focus on interest-driven activities with more flexibility and without high-stakes testing but still with recognizable benefits for academic learning outcomes (Deng et al. 2016; NRC 2015). However, schools do not provide enough opportunities for nonformal learning as part of their standard offer to students although most teachers recognize its academic value (Birdwell et al. 2015).

Many argue that schools should take account of young people’s uses of technology outside formal education although Crook (2012) cautions that digital practices are shaped by context leading to tensions if they are imported from one to another. Young people’s everyday digital practices can complement formal education but may require what counts as knowledge to be reconceptualized (Sefton-Green 2004). Additionally, the informal skills and practices developed through social media, gaming, mobile learning, engaging in online communities, and digital making can be appropriated in the classroom to support schoolwork when it seems beneficial to do so (Erstad et al. 2013).

Social media can readily be used to support discussion and collaboration (Chen and Bryer 2012) and a participatory culture (Mao 2014) both within the classroom and beyond, including with experts and community members when appropriate. However, uptake in the classroom remains low, lacks purpose, or is tightly structured (Mao 2014) despite interest in its potential for over 10 years (Crook 2012). Young people may utilize such technology informally to gain peer support outside the classroom (Schuck et al. 2017) but little is known about the extent of such use. Alternatively, personal learning environments have been proposed as formal mechanisms for harnessing social media and other digital tools to support self-regulated learning through access to informal networks and peers, access to additional content, and sharing and cocreating knowledge (Dabbagh and Kitsantas 2012). However, young people are not making the most of the opportunities that social media offers for supporting formal learning, partly because they do not possess the skills to do so effectively (Clark et al. 2009; Dabbagh and Kitsantas 2012).

Game-based learning is another popular youth pastime which has been proposed as a means of supporting learning in classrooms for decades. Kluge (2016) concludes that teacher support and scaffolding is required in order to make connections between game playing and academic learning as the transfer of learning from games does not always take place, even with games designed to explicitly support learning and used in classroom contexts. He suggests that young people engaging in trial-and-error gaming strategies as a means of improving game results can undermine the learning aims built into educational games. Therefore, even though game-based learning can be very engaging for students, it may not facilitate productive learning. From a different perspective, Brevik (2016) suggests that gaming outside school can have a positive impact on language development. However, the students involved in this study did not make connections between their development of English outside

school and their language use in school, supporting the argument for teacher support to maximize learning opportunities.

Seamless learning, facilitated by mobile technologies, enables “a continuity of the learning experience across different scenarios or contexts” (Chan et al. 2006, p. 23) enabling collaboration, personalization, and authentic learning to take place (Schuck et al. 2017). Seamless learners are viewed as being on a spectrum from those who self-direct their learning to those requiring more structure and support (Sharples 2015); that is, as with formal and informal learning, self-directed and facilitated learning are not discrete polar opposites. Boticki et al. (2015) developed a mobile learning platform for primary-aged children enabling them to spontaneously capture media, comment, and share. Students also received prompts, either periodically or triggered by location, to scaffold learning. The intention was that young people would use the technology for both teacher-directed and self-initiated activities linked to school learning. However, students mainly undertook teacher-directed activities; the authors conclude that self-initiated activities still require teachers’ pedagogical support and structure.

In developing nations like India where access to education remains difficult in the rural and remote areas, mobile technology offers tremendous potential (Adhikari 2014; Brewer et al. 2005). Where other basic infrastructure and technology has failed, mobile technology use has grown even in the remotest areas of India, which now has the second largest user base in the world (Raman 2014). However, while its potential to support learning has been explored at the higher education level through platforms such as MOOCs, its adoption in school education has yet to take place. Reasons could include the lack of pedagogical knowledge for connecting formal and in/nonformal education and too much emphasis on content creation, which is difficult to customize for the many local languages and culture. A similar trend of low uptake occurs in adult learning: 80% Indian employees find mobile learning useful, but only 27% of the companies have adopted this approach for capacity building of their employees (Srivastava 2015).

Online communities enable people with shared interests to come together. Connected learning “is that which is socially embedded, interest-driven, and oriented toward educational, economic, or political opportunity” (Ito et al. 2013, p. 6). Drawing on learners’ interests can beneficially connect learning across sites (Weigel et al. 2009) developing skills such as resilience and adaptability, and a positive disposition to academic learning (Ito et al. 2013). Technology is central to this approach, facilitating greater opportunities for access to knowledge, information, and supportive communities, and the means to produce multimodal digital artifacts (Kumpulainen and Sefton-Green 2014). Ito et al. (2013) suggest that connected learning can be facilitated through creating opportunities for students to engage in creative and collaborative project work strongly linked to their own interests, with an emphasis on production and performance.

The maker movement is growing in after-school settings (Peppler and Bender 2013), one aspect of which is digital making (Quinlan 2015) while much maker activity draws on technology in some way. Making generally involves the collaborative pursuit of technical projects related to personal interest and include

3D printing, programming, and e-textiles. Making can develop skills in creativity, computational thinking, evaluation, reflection, collaboration, communication, problem solving, and resilience, and contribute to learning outcomes (McKay and Pepler 2013). It provides strong connections to both everyday practices and academic knowledge. It is already being appropriated in school contexts for open-ended and interest-driven activities where institutional structures allow (McKay and Pepler 2013).

Technology can also be used to bring informal resources into the classroom. Stocklmayer et al. (2010) describe how students in Australia accessed presentations given by staff at a science center through video-conferencing; here technology acts as a technical bridge connecting to learning resources outside the classroom. Virtual reality is another such example, providing opportunities for learners to experience “authentic” contexts such as geographical and historical sites that they might not otherwise be able to do (Freina and Ott 2015). This can also be achieved through simpler technologies; for example, lower socioeconomic children at a learning center in Kolkata, India were able to explore the Taj Mahal and its history through videos, and London through google searching.

Pedagogical Issues in Using Digital Technologies to Integrate Informal Learning Practices in Formal Education

As discussed above, bridging formal and informal learning through technology fosters connected authentic and seamless learning across settings. However, this bridging remains a major pedagogical challenge, with limited uptake to date, despite the growing interest from policy makers and practitioners in doing so (Khaddage et al. 2016; Lai et al. 2013; Rajala et al. 2016). The ubiquitous nature of technology has made the learning landscape more complex, thus increasing the “transfer problems” (the difficulties of applying knowledge in new contexts) that occur in transitions between spaces (Illeris 2009). Bridging learning through technology demands pedagogical change to ensure that everyday practices and knowledge are integrated and assessed in meaningful ways (Kumpulainen and Mikkola 2016; Lai et al. 2013). The need for teacher professional development in digital pedagogical practices has always remained an important factor to integrate technology in school classrooms (Chen and Bryer 2012). However, teachers also need specific professional development in nonformal pedagogies (Birdwell et al. 2015; Quinlan 2015). Without pedagogical change, technology may be used to replicate rather than enhance existing practices (Erstad and Sefton-Green 2013; Khaddage et al. 2016).

Pedagogical Strategies for Bridging Formal and Informal

It is suggested that traditional formal pedagogies focus on the individual rather than the sociocollective more commonly found in informal learning (Deng et al. 2016; Hung et al. 2012). A variety of pedagogical strategies commonly found in

out-of-school contexts could, however, be incorporated into formal learning, using technology, to ensure that learning in the classroom is more social, participatory, experiential, and experimental (Deng et al. 2016; Hung et al. 2012).

Informal learning strategies can be introduced through project, inquiry, and problem-based learning approaches facilitating authentic and experiential tasks (Banks et al. 2007; Erstad 2012; Illeris 2009). The adoption of informal learning practices (concrete, interest and practice-driven, open-ended, and highly contextualized) can require a shift in roles as teachers become knowledge managers and students become self-directed learners (Schuck et al. 2017). This shift in control from teacher to learner can readily be facilitated through technology (Cox 2013). In addition, integrating informal learning practices in the formal classroom, drawing on the personal and social contexts of the students for knowledge construction, often remains challenging due to timetabling restrictions, mismatch with assessment practices, and lack of technology infrastructure.

Bridging formal and informal learning needs teachers' guidance to enable learning to take place across contexts (Boticki et al. 2015). This is particularly important given that generic digital tools rarely offer pedagogical support (Laru and Järvelä 2015). Teachers must be more flexible and creative in order to integrate informal learning practices and exploit the resources available outside the classroom (Deng et al. 2016; Sharples 2015; Stocklmayer et al. 2010) or to build learning activities around students' personal interests (Deng et al. 2016). For example, Sharples (2015) notes that teachers can use learning undertaken outside the classroom, such as science inquiry activities, as a starting point for a lesson but that this requires them to improvise and actively make connections to the curriculum. Providing support to learners to help them make connections across sites can ensure that learning experiences are recontextualized and that students pursue their interests and develop them further (Hung et al. 2012; Lopez and Caspe 2014). Family support is also an important enabler of bridging learning across sites (Lopez and Caspe 2014). Technologies, such as social media and mobile devices, can enable a variety of stakeholders to support students.

Students' interest-driven learning out of school is also connected to their extracurricular activities in school (Deng et al. 2016). After-school extracurricular activities run by teachers can provide further opportunities for learners' personal interests to be leveraged and linked to formal learning (Deng et al. 2016). In addition, teachers can extend support to other after-school providers through participating in their events, planning, and designing lessons collaboratively with informal educators to ensure the topics taught in both the settings connect enabling knowledge to be deepened for students.

Divides, Cultural Tensions, and Ethical Concerns

Students need to have ubiquitous access to technologies including mobile devices to harness the potential benefits of bridging learning across sites (Lai et al. 2013), and as noted above, this is often not the case in developing countries (Davies and Eynon

2013). Limited finances can constrain access to out-of-school resources such as technology and Internet access leading to inequalities in relation to informal learning opportunities (Lopez and Caspe 2014). After-school clubs and informal learning centers (as provided in India) can bridge this digital/cultural divide. When ubiquitous access is a possibility, young people's everyday practices with smartphones, such as texting and checking social media accounts, can be perceived by educationists as disruptive (Hsi 2007) with some arguing that their adoption in formal education has a negative impact on learning outcomes (Beland and Murphy 2015).

Although it is commonly reported that young people's uptake of technology is high, levels of engagement vary from none at all to sophisticated practices. Children can be "passive recipients" of online content rather than active producers of it (Ito et al. 2013); that is, they may not engage fully in sociocollective and rich learning activities through technology. Students do not always have the skills or interest in using technology such as social media to support learning (Erstad 2012; Chen and Bryer 2012).

Young people can associate technology use outside school with play and everyday activities, whereas acceptable school use is typically linked to work and academic learning (Hsi 2007). They do not feel that their everyday uses of technology are valued by their teachers nor recognize the ways in which they could be appropriated to support formal learning (Chen and Bryer 2012). Indeed, some students consider accessing social media in the classroom inappropriate and a distraction suggesting that pedagogical scaffolding is required to maximize its impact in classrooms (Mao 2014). Even when the learning activity is orchestrated by a teacher across multiple contexts, students can find it difficult to apply the knowledge from outside the classroom to the learning that takes place inside it (Sharples 2015).

From an institutional perspective, increasing accountability, high-stakes testing, and a curriculum based on declarative knowledge constrain opportunities to integrate informal learning practices (Erstad and Sefton-Green 2013; Ito et al. 2013). This leads to a culture clash between in- and out-of-school learning (Ito et al. 2013). Furthermore, assessment practices can be challenged by the adoption of informal learning practices (Birdwell et al. 2015). Formal assessment structures do not always value and/or recognize knowledge acquired from everyday informal experiences and social learning (Chen and Bryer 2012; Lemke et al. 2015). School structures inhibit recognition and accreditation of learning that takes place outside established systems and curricula. Yet, learning arising from informal practices needs to be valued and the knowledge legitimized (Hsi 2007; Rajala et al. 2016). Authentic and ongoing strategies such as rubrics, portfolios, and badges can support the assessment of informal learning (Boticki et al. 2015; Chen and Bryer 2012).

Teachers may resist the changes required to integrate the seemingly contradictory informal learning practices in their pedagogies (Chen and Bryer 2012; Weigel et al. 2009); they need to be open to change, recognize the value of everyday learning, and make connections to students' interests (Eshach 2007; Schuck et al. 2017). Time constraints may also be an issue (Birdwell et al. 2015; Chen and Bryer 2012). In some cases, nonformal educators may have different levels of experience and

qualifications from formal educators; this difference could lead to tensions if these educators from different backgrounds work together to support learning across sites.

Tools and Internet sites commonly used outside school (e.g., YouTube, MSN) are often restricted inside school for safe-guarding reasons (Chen and Bryer 2012; Davies and Eynon 2013; Merchant 2012); in particular, collaboration and communication through technology is prevented or minimized. In comparison, access to technology outside schools is more open and sometimes not controlled in any way whatsoever. Controlled access in schools can be partially addressed by encouraging the use of digital tools and resources to support homework (Davies and Eynon 2013) although of course not all young people have access to technology outside school.

It is also argued that incorporating informal learning practices in formal education can be viewed as an invasion of private spaces and a “pedagogization of everyday life” (Sefton-Green and Erstad 2016) with the possibility that students may resist such endeavors (Weigel et al. 2009). From an alternative perspective, the ubiquity of technology meaning that learning can take place anytime and anywhere can have negative implications for the work–life balance (Chan et al. 2006).

Bridging Formal and Informal Learning Through Technology Without Ubiquitous Access

Of course, in many developing countries, access to the Internet and technology is not ubiquitous (Davies and Eynon 2013). The uptake of technology in developing countries is constrained by insufficient access to electricity, Internet connectivity, and bandwidth, particularly in rural areas (Brewer et al. 2005). In many parts of India, the digital divide is all too apparent and is mediated by the variables of gender, age, and socioeconomic status (Kumar et al. 2010). In many developing countries like Brazil and India, informal learning can enhance formal education by fostering learning centered on life skills, cultural identity, and respect for diversity (Hoppers 2006). In addition to classroom use, research shows that mobile phones can increase access to and support learning beyond the classroom walls and lifelong learning (Kumar et al. 2010).

A vignette of an after-school learning context in a rural- and tribal-dominated region in Bengal, East India, drawing on coauthor Charania’s work, is now presented. Inhabited by Santhal and Kora tribes, some villages are underdeveloped in socioeconomic terms. Most of the tribal children attend the government-funded schools, but they struggle with the official language of instruction, Bengali, which is different to their native language. Similarly, teachers and parents face communication challenges. Standardized state textbooks dominate the instruction at schools and have no relevance to their immediate culture; teaching practices tend to be teacher-centered. Suchana, a local non-government organization (NGO), established an after-school learning center for the tribal children, providing academic support, bridging the language barriers, and welcoming parents as active participants.

In 2013, Suchana adopted and implemented the Tata Trusts initiative, “Integrated approach to Technology in Education” (ITE) (Charania 2015). ITE is a pedagogical

framework designed to foster authentic and project-based learning for young people who live in some of the most underprivileged locations in India. Students, mostly first-time computer users, create learning artifacts to deepen their learning of content, for example, graphical representations of jute production in India. Through Suchana, all the projects assigned to students are carefully selected by the informal educators and match the local school curriculum. Suchana also engaged with local school teachers, inviting them to exhibitions at which students showcased their projects, providing opportunities for educators to meet parents. These events served as platforms of exchange and boundary crossing between formal (school) and nonformal (learning center) sites. Three remote-learning centers were subsequently opened by Suchana with funding from Tata Trusts; a mobile van carried charged-up laptops, solar lights, Internet dongles, and also books between them.

ITE projects multiplied at these learning centers and many authentic projects connected to school curricula were created. For example, students used video and spreadsheets to measure speed, distance, and time in cycling and athletics. The adoption of ITE at the learning centers improved: student attendance and interest in school subjects; digital skills including showcasing work; collaboration skills; authentic learning experiences; and improved teaching processes.

In 2014, Suchana introduced community projects during vacation periods using project-based learning and authentic activities to focus on social issues, rather than school curricula. In one example, adolescents created a video about their local river, interviewing community members to understand its changing flow over time and how it affected the community's lifestyle. This project also raised awareness about cultural and environmental change. Students seemed more engaged in community projects compared to those focusing on school subjects. Vacation periods offered more and flexible time; the community projects were relevant to their immediate lives, providing opportunities to change their own social realities.

In 2015, Suchana strengthened their interaction with the government schools and extended ITE to formal education, directly implementing ITE in four government schools. They trained school teachers and administrators, negotiated space in the school timetable, and supported teachers implementing ITE projects in the schools. These schools had no computers or Internet connectivity and had irregular power supply. Suchana provided charged-up laptops and dongles to facilitate connectivity. Through this initiative, the schools have realized the potential of digital technologies to facilitate learning and student interest, both very difficult goals to achieve in a lower socioeconomic context where even the benefits of completing formal education are unclear.

Thus, the initiative that was developed initially at the learning centers was subsequently integrated within the mainstream schooling system shifting informal learning practices into the formal context of school. Suchana continued to run its learning centers before and after school serving as resource points for schools taking up ITE: creating lesson plans, organizing events for showcasing students work, and bringing teachers and the community together. They also provided technical support, charged the laptops, and prepared dongles for delivery to schools.

The learning centers are not bound by timetabling and language of instruction at schools; they have access to community space and culture to explore subjects in real-life situations, and greater flexibility when working on community projects. They provide deep authentic learning experiences and a sense of agency for young people, developing life-long learning skills, supporting social and personal transformation in young people's lives and their communities. The adolescents cross contextual boundaries using their newly developed digital skills and basic technologies (i.e., laptops), working toward similar goals, using the framework of ITE. The deep and authentic learning experiences undertaken outside the school context intersect with formal education while utilizing a flexible and open environment. Given the tribal and school culture which is largely compliant with members accustomed to being directed by those in authority, this learning was not self-directed. ITE uses technology, links to school subjects, and develops skills such as collaboration, problem solving and critical thinking, and creativity. These being lifelong learning skills, it is likely that in the long run, these adolescents will become more self-directed in creating such learning opportunities for themselves.

Conclusion

A comprehensive review of recent literature on how informal learning, including everyday knowledge and informal practices, could help to reshape formal education has been presented. To harness the potential benefits of informal learning in formal contexts, there is a need to shift formal pedagogical practices from transmissive approaches to collaborative, student-centered and self-directed approaches to create opportunities for young people to draw on everyday knowledge and practices (Khaddage et al. 2016). Indeed, a recent Horizon report for K-12 (Adams Becker et al. 2016) predicts greater uptake of problem-based learning, collaborative, self-directed, and active learning, with the growth of remote interaction, all facilitated by technology.

However, while there are strong arguments for bridging formal and in/nonformal learning, there is still limited understanding of the interrelationship between using technology in school for learning and using technology outside school for a wide range of learning activities (Cox 2013; Hung et al. 2012). It is also clear that there remain many challenges in relation to pedagogy, technology, policy, and research (Khaddage et al. 2016; Kumpulainen and Sefton-Green 2014; Schuck et al. 2017). Indeed, there are broader cultural tensions, and moral and ethical concerns relating to bridging learning, as discussed above. Khaddage et al. (2016) argue that the difficulty of developing a shared understanding of informal learning is one barrier to the development of pedagogies that bridge different types of learning. However, it is better to accept informal learning as a slippery and complex concept, and to focus instead on the formal and informal attributes of learning (Colley et al. 2003; Greenhow and Lewin 2016). Khaddage et al. (2016) also note that it is difficult to capture informal learning as it happens and assess its outcomes. In addition, there are relatively few models of good practice for bridging formal and in/nonformal learning

(Merchant 2012). From an ethical perspective, the danger of blurring boundaries and attempting to capitalize on learning that takes place outside the school is that people's personal spaces are invaded potentially having negative impact on learners' engagement and outcomes (Sefton-Green and Erstad 2016).

In the past, a lack of infrastructure has been noted as a significant barrier to integrating technology in formal education. This is not necessarily the case any longer in developed countries although further investment is still required to support increased use of mobile technologies in classrooms. Infrastructure capabilities are also being improved in many developing countries. For example, the Digital India initiative funded through the Indian Government aims to provide universal mobile connectivity. In the future, this should ensure better access to digital educational resources particularly in rural areas of India. Formal institutions like the National Institute of Open Schooling in India which allows nontraditional learners to pursue secondary-level education in a nonformal context, should harness the growth in mobile connectivity to increase their outreach and quality of delivery.

In order to maximize the potential of bridging formal and in/nonformal learning, school cultures need to change. The boundaries between in- and out-of-school need to be recontextualized to create "possibilities for participation, interaction, and collaboration across a diversity of sites and contexts, both within and across institutions" (Kumpulainen and Sefton-Green 2014, p. 13). It would be beneficial to view learning as an ecosystem, considering a community's rich assets such as designed settings (e.g., after-school clubs, museums), natural settings (e.g., geographical areas, historical sites), people and networks of people (enthusiasts, experts), and everyday encounters (at home, online) (NRC 2015). It would also be beneficial to reconsider "what constitutes appropriate kinds of knowledge, ways of learning and pedagogic relationships" (Sefton-Green and Erstad 2016, p. 3). Strong collaboration between all stakeholders including learners, teachers, parents, and policy makers is necessary to ensure that all knowledge is valued and recognized (Banks et al. 2007). However, it is unlikely that such cultural shifts will take place while curriculum constraints, timetabling, high-stakes testing, subject silos, and risk aversion continue to act as barriers to innovation and change (Adams Becker et al. 2016; Schuck et al. 2017).

Professional development for teachers and out-of-school educators is one means of addressing current challenges (Khaddage et al. 2016; NRC 2015), both in developed and developing countries. Teachers need to understand the possible benefits of harnessing both informal learning practices and the knowledge and skills developed through everyday practices to support the achievement of formal learning outcomes (Banks et al. 2007). Teachers also need to be prepared to take more risks and experiment with their classroom pedagogies. This requires support and encouragement from school leaders. In addition, more work around assessment is required. There is a need for mechanisms to recognize the complex and varied outcomes that arise in out-of-school learning and to develop ways of comparing data from in- and out-of-school learning (NRC 2015).

Students also need to be offered more support and guidance from their teachers in order to make more connections between learning in and outside school. It would be

beneficial to ensure that they have the skills required to harness the full potential of technology to support all forms of learning, particularly in relation to the development of supportive networks and identifying relevant online communities. This is essential if students are to be equipped with the means to continue using technology to support lifelong learning.

Abstract

Computer support offers versatile opportunities for learning together at a distance as well as for collocated scenarios of collaborative learning, in which learners construct arguments, share knowledge, and jointly produce task solutions themselves. In this chapter, we explore different computer-mediated and co-present forms of computer-supported collaborative learning (CSCL). We will discuss both the potential and the problems of CSCL. Finally, we will show how current instructional approaches aim to overcome CSCL problems to realize its full potential.

A straightforward and concise way of defining computer-supported collaborative learning (CSCL) is to state that it involves some form of learning together with peers and computer-based support for learning. Starting from there, however, multiple approaches to collaborative learning can be distinguished, and computer support can vary considerably and is rapidly progressing along with information and communication technologies (ICT).

Collaborative learning. One of the most widely disseminated and intuitive distinctions of learning together with peers is the one between collaborative and cooperative learning. A well-established definition of collaboration is “Collaboration is a coordinated, synchronous activity that is the result of a continued attempt to construct and maintain a shared conception of a problem” (Roschelle and Teasley 1995, p. 70); thus, collaborative learning is different from cooperative learning, in which a group of learners splits the work into individual, additive sub-tasks. While per definition being a “synchronous activity” (Roschelle and Teasley 1995, p. 70), asynchronous CSCL can still host collaboration with learners’ reasoning processes being not temporally but transactively intertwined (Roschelle and Teasley 1995), i.e., learners address and build on the reasoning of their peers. Respectively, the “interactions among peers” (Dillenbourg et al. 2009, p. 3) were termed as the main feature of collaborative learning. Furthermore, learners can convergence in collaboration and share knowledge as a result (Weinberger et al. 2007). One of the foci in investigating collaborative learning is to analyze how learners acquire knowledge by engaging in specific argumentative discourse activities, which have been classified along different epistemic, argumentative, and social dimensions (Weinberger and Fischer 2006).

- Regarding the *epistemic quality* of discourse, learners may be more or less on-task, may demonstrate a more or less correct understanding of concepts, and may more or less adequately link and apply concepts when solving a problem case.
- *Argumentative quality* refers to how learners elaborate their line of reasoning in formal argumentative structures, including the extent learners warrant their claims, produce evidence, and anticipate and include counterarguments in their line of reasoning.
- The *social modes of interaction* regard how learners refer to and build on each other’s reasoning, which has been termed the degree of transactivity (Stahl 2013). Here, learners could use peers as additional resource and elicit knowledge from each other or agree and disagree with each other’s stances.

Past research has shown that transactivity is a core quality of learners’ discourse, strongly related to individual and group learning outcomes (e.g., Noroozi et al. 2013). A highly transactive act is, for instance, to relate to peer contributions in a critical way with the goal to sort out differences of perspectives by subsequent negotiation, integration, and modification of understanding. Transactivity also builds on the establishment of a common ground among collaborative learners (Beers et al. 2006). Common ground refers to the externalization and transformation or re-contextualization of the group members’ knowledge or “grounding,” to reach

mutual understanding (Bechky 2003, p. 534), the base for all further interactions and knowledge construction processes (Bechky 2003).

Specifically, in the context of early school education, the success of collaborative learning largely depends on a sense of intimacy and mutuality through sharing experiences and common goals (Crook 1998). The concept of common ground relates to the question of how learners co-develop more or less similar knowledge structures when learning together and converge on knowledge. Knowledge convergence has been conceptualized and investigated as an important quality of collaborative learning (Weinberger et al. 2007). Through processes of establishing common ground and transactive discourse, learners may acquire equivalent amounts of knowledge and share knowledge as a result of learning together. This group-level perspective on collaborative learning underlines the importance of epistemic, argumentative, and transactive qualities of discourse. While successful groups of learners spontaneously display elaborated and critical forms of consensus building, there are robust findings that collaborative learners typically benefit from additional scaffolding promoting these discourse qualities and facilitating knowledge convergence (Kreijns et al. 2013; Noroozi et al. 2013). Hence, scaffolding learners to engage in productive interactions is a major focus in CSCL.

Computer support for collaborative learning. Computers can be used to support remote learning as well as face-to-face learning settings (colocated CSCL); they enable asynchronous discussions, e.g., discussion boards, and synchronous learning and working, e.g., simultaneously drafting documents in shared workspaces together. Computers are tools for representing and sharing ideas and knowledge. Externalized knowledge that is being developed jointly, e.g., as a mind map, can help learners to focus on important concepts and foster the quality of learner products as well as learning outcomes (Janssen et al. 2010).

The following two sections introduce and discuss two main branches of CSCL, mediated and colocated computer-supported collaborative learning. We will give insights into exemplary learning environments and research done in this field, drawing on seminal work, constitutional to the research area of CSCL, as well as recent developments.

Computer-Mediated Collaborative Learning

Building on the “communication” function of ICT, computer-mediated learning entails all forms of learning together at a distance. Computer-mediated communication (CMC) can be relatively synchronous or asynchronous, that is, participants in online interaction may use platforms, in which an immediate response is expected, such as in chats or videoconferences, or may expect any kind of delay on platforms such as discussion boards or email. Moreover, communication may be more or less enriched by media formats building on platforms that support sharing of, for example, videos or text only.

Computer-mediated learning scenarios are often designed for online learning groups of adult learners but can enable learning across schools (Ligorio and Van

der Meijden 2008), in blended scenarios of learning in and out of schools and combining online and face-to-face dialogue. Computer-mediated learning scenarios mainly address secondary school students and adults, which we will outline in the following paragraphs.

Typical Scenarios of Computer-Mediated Collaborative Learning

Computer media for communication span from asynchronous, text-based emails and discussion boards to synchronous multimedia environments like videoconferencing and virtual worlds. Video is playing a major role in transmitting lectures or providing one-on-one tutorials, but only few CSCL studies have been focusing on videoconferencing (e.g., Ertl et al. 2006). In these scenarios, learners are communicating by video chat and simultaneously work in a shared workspace, e.g., creating a concept map together or co-constructing arguments.

Asynchronous and text-based scenarios of CSCL, in contrast, have been widely investigated and applied in different platforms and contexts (Tsovaltzi et al. 2015). Learners in asynchronous environments have equal opportunities for participating in argumentative discourse by constructing arguments at their own time without being interrupted with the ability to search for and include additional resources. Small groups of online learners can be composed to jointly inquire scientific problems and phenomena, but also larger online courses and MOOCs (massive open online courses) do partly build on collaborative scenarios and typically provide a platform for social interaction. Likewise, CSCL in social networks is moving beyond small group interaction and is supporting collaboration among larger communities. Here, learners provide personal profiles and share information across different groups of friends and larger communities fostering social interaction (Kreijns et al. 2013). A recent study found how learning in social networks strongly builds on knowledge sharing and co-construction to the extent that individual preparation can lead to premature knowledge consolidation and impede learning gains in argumentative online learning scenarios (Tsovaltzi et al. 2015).

In other advanced, but under-investigated computer-mediated scenarios of CSCL, learners direct avatars through virtual landscapes, where they meet and interact with avatars of peers. These scenarios are strongly influenced by massive multiplayer online games and often build on the respective game environments. For instance, *Second Life* is a game environment in which, for instance, foreign language learning is being investigated utilizing the virtual context as a visual and linguistic support (Hsiao et al. 2015).

Platforms sometimes support different types of communication media. For instance, *Euroland* offers both asynchronous discussion boards and a virtual world, in which learners need to be carefully introduced to the tools and possible courses of action for expanding a local classroom into a larger online community (Ligorio and Van der Meijden 2008). The seminal *Virtual Math Teams* project (Stahl 2006) connects people over the Internet to collaboratively discuss and solve math problems using a shared whiteboard and a chat tool. This project shifted from a local

intervention to building an online math community connecting students from different classrooms all over the world to participate in discourse for a deep understanding of mathematical principles (Stahl 2006).

Issues of Computer-Mediated Collaborative Learning

Regardless of the communication media, there are indications that computer-mediated communication requires learners to more explicitly coordinate themselves than in face-to-face (FTF) environments (Van Der Meijden and Veenman 2005). The “poorer” the medium is, the less socially present peers are and the more pronounced are effects of the medium on different qualities of communication. So, for instance, the effect of an increased need for coordination is more pronounced in text-based communication and mitigated but still observable in “richer” videoconferences (Ertl et al. 2006). Social context cues are what seem to be lost in poorer scenarios, such as discussion boards, in comparison to rich communication scenarios like FTF or videoconferencing. At the dawn of CMC in the late last century, lack of social context cues has been related to problems of deindividuation, i.e., submergence in an anonymous group with a loss of identity and individual responsibility leading to violation of social norms online; however, later CMC models indicated how lack of social context cues may also increase group identity and foster social attraction (for an overview, see Walther 2011).

Walther’s hyperpersonal model of CMC exceeding face-to-face interaction in allowing to control, edit, and optimize presentation of one’s self (Walther 1996, 2011) appears to be particularly relevant for communication in social networking sites (SNS) like *Facebook*, in which users can cultivate a profile and intentionally disclose their personality to a high degree. In this way, Facebook and other SNS may foster social aspects of academic life including actual friendships (e.g., Selwyn 2009), which can contribute to study-related knowledge sharing (Wodzicki et al. 2012). SNS can also greatly support active information seeking and building social capital that increases the connectedness with people for future support and cooperation (Lampe et al. 2012). Interestingly, media effects may not necessarily impede learning, because learners can compensate media effects over time or can be additionally supported to overcome media limitations. Hence, advantages of asynchronous CMC for learning – independent of place and time – also factor into how learners can harness CMC for higher levels of CSCL. In online discussion boards, learners have the time they individually need to inquire additional resources, construct elaborate arguments, and transactively build on the reasoning of their peers.

Another issue of computer-mediated collaborative learning is, however, how motivational problems, well-known in collaborative learning research, translate and potentially aggravate in computer-mediated scenarios. Online learning seems to particularly suffer from attrition and lack of participation. Up to half of learners drop out of regular online courses, a rate that can go up to 90% in MOOCs learners take by free choice (Jordan 2015). Moreover, participation within online courses drops rapidly after the first week and often precedes dropout (Nistor and Neubauer

2010). Reasons for dropping out are numerous and include personal motivational problems as well as technical difficulties (Park and Choi 2009; Sitzmann et al. 2010). Registration to online courses can be easy enough for learners to have a peek at the learning material but participation hard enough to quickly reconsider and refocus on alternative courses, or learners do not intend to complete the course in the first place. Within dedicated CSCL scenarios that build on student agency and engagement, lack of and heterogeneity of participation have been discussed as particularly harmful to motivation and learning (Weinberger and Fischer 2006). Motivationally detrimental effects in CSCL work on the group level, i.e., peers influence each other's motivation, and can be enhanced as learners may have difficulties to contact each other online, i.e., online learning partners can be more elusive than FTF learners. One well-known problem is free riding, which refers to a team member not investing the required effort assuming that other team members will do (Kerr and Bruun 1983) and vice versa the so-called sucker-effect of one learner covering major parts of the task and hence losing motivation. This suboptimal distribution of group work can tremendously reduce the potential of collaborative learning for equal participation in argumentative elaboration activities (Cohen and Lotan 1995). While collaborative learning aims to establish equal participation and access to opportunities for argumentation and active learning, there are robust findings that collaborative learning often produces the exact opposite (e.g., Nihalani et al. 2010). Advanced learners benefit, in particular, from complex, collaborative learning scenarios, whereas participants with suboptimal preconditions for learning are left behind. Finally, it has been found that a sensible argumentation culture in online scenarios cannot be expected as a short-term goal but needs time, even weeks or months, to develop (Puhl et al. 2015).

Co-Present Computer-Supported Collaborative Learning

Contrary to computer-mediated collaborative learning discussed above, in co-present CSCL scenarios, learners are physically together, interacting with each other face-to-face and with one or several technologies in order to construct knowledge. Devices to support co-present collaborative learning are interactive whiteboards, desktop computers, handhelds, tablets, or tabletops. The “social situation” positively affects learners' motivation and communication (Roschelle and Teasley 1995, p. 69). In early co-present CSCL scenarios, e.g., Logo programming, learners typically had to share the access to the input devices (mouse, keyboard). Only one learner at a time could manipulate the representations on the screen, while the learning partner was cast back to a more passive role or the role of ‘thinker’. Roles and actions had to be negotiated. With the advent of multi-touch interfaces (tabletops, tablets), several learners of all age groups can simultaneously access and directly manipulate a shared representation. Thus, new ways of interacting with each other and with the learning environment emerged, which may be conducive to embodied cognition (Schneps et al. 2014). In the context of learning, embodiment refers to the role of the body in interacting with the (learning) environment to construct knowledge and is gaining more and more attention in the learning sciences (Abrahamson 2017).

Typical Scenarios of Co-Present Collaborative Learning

Primary Education

Taking the role of embodiment into account, researchers have been designing for *collective* embodied learning experiences. For example, in the *STEP* (Science Through Technology Enhanced Play) project (Danish et al. 2015), 7- to 8-year-old children playfully learn about chemical concepts by acting out particles. A projection on the wall depicts a chemical element that changes its matter of state depending on the children's (the particles') movements through the classroom.

CSSL among primary school children can also be realized around a multi-touch table, in which, for instance, students in groups of four can be encouraged to discuss complex tasks and organize and distribute responsibilities and roles within their groups (Mercier et al. 2014). In another project utilizing iPads as mini-tabletops, fourth graders (on average 10 years old) collaborated in dyads on one shared tablet to work out proportional reasoning tasks with the *Proportion* app (Rick et al. 2015). Though tablets are personal devices, usually not used by several people at once, this scenario intentionally brings learners together. The pedagogical idea is to combine an embodied and immersive way of learning (moving two bars on the tablet to map volumes with numbers) with the benefits of collaboration (reasoning together). Peculiar interaction patterns can emerge in such a scenario: a case analysis of "Tarzan and Jane" (Rick et al. 2015), who were notably heterogeneous in their approach to learning, showed remarkable learning gains. Tarzan and Jane started with under-average pretest results but ended up being exceedingly successful in solving the Proportion tasks and acquiring knowledge. Beyond this specific case, significant learning gains were found in a sample of $n = 162$ primary school children that collaboratively used Proportion (Schmitt and Weinberger 2017), pointing at the benefits of embodied collaborative learning.

For a scenario to be classified as co-present collaborative learning, learners do not necessarily need to share one device. In the *TechPALS* (Technology-mediated, Peer-Assisted Learning) learning environment (Roschelle et al. 2010), fourth graders were working in groups of three solving math problems with everyone using their own handheld device. However, the students had to work closely together, agree on solutions, and share resources in order to make progress, and feedback was only provided on the group level. The collaboratively working students gained significantly more domain knowledge compared to a control group working individually (Roschelle et al. 2010).

That said, collaborative and individual learning approaches are not mutually exclusive, but can be effectively orchestrated as parts of a larger learning unit. For example, in a study by Gijlers et al. (2013), children aged 10–11 years first created representations of a scientific phenomenon (photosynthesis) on separate tablets. Individually creating a first version of the drawing was then followed up by sharing and comparing drawings with a peer and finding a joint solution. The orchestration of individual and collaborative learning phases showed to enhance the quality of dialogue and knowledge outcomes compared to a collaborative-only control group (Gijlers et al. 2013).

Secondary Education

Shifting the focus to older students, the next paragraphs will focus on exemplary studies of co-present collaboration at the secondary education level.

Quite common are learning environments that enable simulating phenomena of natural sciences. In their seminal paper, Roschelle and Teasley (1995) delineate the learning processes of two 15-year-old collaborative learners who are acquiring an understanding of Newtonian physics with the *Envisioning Machine* that served as a joint problem space. *Co-Lab* is a scientific inquiry-learning environment that students use either individually or collaboratively (via the Internet using a chat tool or face-to-face sharing a computer). It was found that providing high school students (16–18 years) with a regulation tool (i.e., supporting the processes of planning, monitoring, and evaluating) has positive effects on planning and evaluating activities, supposedly because of the complex and novel task the students had to carry out (Manlove et al. 2009).

The learning environment *WISE* (web-based inquiry science environment) was employed to help 16-year-old students in web-based inquiry learning (Raes et al. 2016). Groups of two shared one computer to search the Internet and collect information about the topics global warming and climate change. Central to the activity was critically assessing the quality of the information found on the Internet. To facilitate advantageous interactions, like equal participation between the students, a collaboration script was added.

Issues of Co-Present Collaborative Learning

Despite the advantage of interacting directly with each other, there are also issues of co-present collaborative learning. The challenges addressed in the following paragraphs add to the general requirements, like transactivity, regulation of learning, and task focus that need to be met for effective collaborative learning.

One issue is the question of access to the environment and territoriality, i.e., the subdivision of available workspace in a jointly used device. The available space might either be open and accessible for everyone, so that learners would need to negotiate and co-regulate their input activities and times, or the instructions might steer toward specific interaction patterns (Dillenbourg and Evans 2011). Designing for productive territorial interaction in the context of young learners may be difficult. For example, in the Tarzan and Jane case study (Rick et al. 2015), peers could reach over and interfere with the partner's virtual objects. In spacious tabletop environments, each participant may have their own territory and input devices at their disposal. After having worked on a tabletop and produced input, e.g., when jointly constructing a mind map, learners may, however, at times move altogether to one side of the tabletop, rotate all concepts to be read upright, and look at and reference their map when discussing their work. Hence, usability issues are to be taken into account when designing co-present learning environments: How should learners share the workspace? To what extent does the workspace enable equal sharing of activities? Where should learners be positioned? Does everyone get their own input opportunity or working space?

Closely related to questions of territoriality are dominant interaction patterns in co-present CSCL. Especially in desktop computer settings, one learner might dominate the other(s) by controlling the mouse and not sharing access to the input device. Solutions proposed to address this issue are, for example, encouraging turn-taking and providing a split-screen (Moed et al. 2009) or providing several mice (Stanton et al. 2002), so that every learner would have the chance to interact with the learning environment, which may, however, render the learning scenario cooperative rather than collaborative. Providing several mice, albeit beneficial for student engagement and participation overall, fosters co-operative and parallel interactions (Stanton et al. 2002). Also, dominant behavior does not necessarily disappear when every learner has access to his/her own mouse (Moed et al. 2009). When multiple input opportunities via multi-touch vs. multiple mice on a tabletop were directly compared, multi-touch was found to support fluid interactions and reduce coordination effort compared to the multiple mice condition (Hornecker et al. 2008).

There are also concerns that playful, embodied learning environments might be overly hands-on, neglect verbalization and elaboration of concepts and thus do not support abstraction to the underlying concepts. For example, in Danish et al.'s (2015) study where children acted out particles, the situation sometimes got a bit out of hand, and children would run around the classroom and even play tag. To prevent learners from being "lost in action," sensibly combining hands-on environments with phases of reflection is needed (Danish et al. 2015), in order to improve the quality of learners' epistemic and social activities. However, reflection phases need to be introduced and intertwined carefully with the hands-on activities, to not interrupt learners' flow and disengage them (Schmitt and Weinberger 2017).

Finally, the practical-technical and pedagogical issues of integrating computer-based tools into everyday classroom practices are a not to be underestimated challenge for teachers, calling for systematic professional development measures (Vanderlinde et al. 2014).

Solutions/Facilitating CSCL Environments

The following paragraphs will discuss two fundamental strategies to support effective collaborative learning: structuring vs. regulating interactions (Dillenbourg 2002).

Structuring Interactions

One well-investigated method to structure social interactions in CSCL is collaboration scripts. These scripts assign learning activities and roles to the learners and reduce time spent on organizational issues and generally show a positive impact on learning (Scheuer et al. 2010). Encouraging high schoolers to develop joint group norms regarding their communication and task solving positively affected their collaborative interactions and learning outcomes (Zahn et al. 2012). The Guided Reciprocal Peer Questioning script successfully fostered primary school children's

collaborative discussions and quality of the learning product (Gelmini-Hornsby et al. 2011). The beneficial effects of scripting seem to be rather consistent, bearing in mind that too much scripting might lead to “over-scripting,” meaning that an overly tight specification of interactions would ruin the nature of collaboration, negatively influencing interactions and acceptance of the script (Dillenbourg 2002). Consequently, the question of amount, content, timing, and general presentation of scripts is a complex one (see also Fischer et al. 2013). One of the future directions is seen in the development of adaptive scripts (Fischer et al. 2013).

Supporting learners’ behavior in computer-supported learning environments is needed for both reducing disadvantageous behavior (for instance, gaming the system) and fostering advantageous behavior, like reflecting, abstracting, and elaborating. The goals of scaffolding are helping the learner to solve the task at hand but also to increase the understanding to support future task solving (Reiser 2004). Scaffolding can come in two forms (Reiser 2004): making the task easier (structuring) and making the task harder (problematizing concepts). Fourth graders working in dyads with a tablet app benefitted from prompts that problematized concepts by requesting explanations in that they had a higher discussion quality, but they also displayed more negative emotions and more off-task behavior (Schmitt and Weinberger 2017). Seventh graders were found to perform better in a physics game running on tablets when they worked with peers compared to working alone (Chen and Law 2016). This positive effect was even strengthened when question prompts were provided. However, there are also indications that both collaborative condition and question prompts had a negative impact on self-reported motivation (Chen and Law 2016), pointing again at the need of challenging learners to increase their opportunities to learn while keeping their motivation flow high (see also Deater-Deckard et al. 2014).

Fostering Regulation of Interactions

While structuring methods are usually set before the learning activities start, fostering learners’ regulation can occur during the ongoing learning activities. One prominent way of regulation is awareness tools that visualize qualities of learners’ interactions while they take place, e.g., showing how much learners are participating (Gijlers et al. 2013). On one hand, raising awareness showed to positively influence variables like transactivity and shared task focus (Gijlers et al. 2013), cohesion, positive attitude toward collaborative learning, and reduced conflicts (Phielix et al. 2010) or fostered coordination of the collaborative learning situation (Janssen et al. 2007). On the other hand, the overall influence of awareness tools remains limited as the aforementioned studies could not find a general effect of an awareness tool on the quality of the group product (Phielix et al. 2010) or equality of participation (Janssen et al. 2007). It appears to be a crucial factor to what extent learners are motivated and able to effectively use an awareness tool to alter their behavior patterns in order to foster positive group interactions and learning (Janssen et al. 2011). This goal may be achieved by scripting the use of the awareness tool (Janssen et al. 2011; Tsovaltzi et al. 2015).

Conclusion

In this chapter, two major branches of computer-supported collaborative learning, namely, computer-mediated vs. co-present collaborative learning, were discussed. Computer-mediated collaborative learning scenarios encompass asynchronous as well as synchronous learning activities. The learning scenario might be reduced to a text-based forum or simulate a richer social situation, like in virtual worlds or videoconferences. The scenario might foresee one-to-one communication or address large amounts of users at the same time, as in the case of MOOCs. Learning anywhere and anytime at one's own pace is one of the benefits of such learning environments. Typical issues in computer-mediated collaborative learning are the lack of social context cues, free riding, a greater need for explicit coordination, higher attrition, and large dropout rates. In co-present collaborative learning scenarios, learners are physically together and engage in synchronous learning activities. The scenario might foresee to share one device, which is particularly suited for tabletops and tablets, or to provide every learner with an own device, for example, a handheld. Co-present scenarios can take into account the growing recognition of the role of the body in learning and afford hands-on embodied learning experiences. Typical issues in co-present collaborative learning are how learners divide the available working space when the device is shared, how to prevent individual members of exclusively controlling input and dominating the group, and how to sensibly combine embodied learning experiences with phases of reflection (Danish et al. 2015; Schmitt and Weinberger 2017).

Scripting interactions or providing awareness tools showed to be promising means in supporting CSCL. Next to the positive effects, scripts can come with negative side effects, such as over-scripting or demotivation (see, e.g., Chen and Law 2016; Dillenbourg 2002; Schmitt and Weinberger 2017), and awareness tools' effects might fall short of expectations. Hence, more research is needed in refining instructional means to further develop CSCL practices in primary and secondary education. Another emerging topic concerns the question on how to increase salience of feedback through awareness tools and leverage their effectiveness in CSCL environments. To that end, for example, scripting the use of awareness tools has been proposed (Janssen et al. 2011; Tsovaltzi et al. 2015).

Beyond designing for productive but isolated CSCL scenarios, orchestration of collaborative with individual learning scenarios, enriched with various types of computer support, will allow learners to encounter diversified challenges, finally leading to progressively expanding knowledge and skills. While CSCL practice typically is embedded in larger learning arrangements, research on how to productively coordinate scaffolding across learning experiences occurring at different social levels is still scarce (Prieto et al. 2015). Future research will need to focus on the conditions of productive orchestration of learning scenarios and their support, for example, awareness tools and scaffolding, with the ultimate goal of fully developing CSCLs potential for acquiring both domain knowledge and key competencies. Beyond sequencing learning arrangements, the question

expands to how learners use different devices and link and document their learning activities in a larger learning landscape. Such a learning landscape bridges formal and informal learning in schools, social networks, and any other place and time using mobile devices.

Gerald Knezek and Rhonda Christensen

Abstract

Key developments in attitudes, competencies, and dispositions for teaching and learning with information technology are presented through seven chapters in this section and described in this overview. The perspective of the teacher is the focus of several chapters, with the understanding that enhanced learning by the student is the end goal. Developments that have evolved since the printing of the first edition of this handbook are the focus of the section. These developments are featured in the write-ups for each chapter provided in this overview.

Keywords

Attitudes · Competencies · Dispositions · Teaching and learning · Information technology

In this section of the handbook, attitudes, competencies, and dispositions that are important for the effective integration of information technology are presented for both teaching (for educators) and learning (for students).

In the opening chapter by Knezek and Christensen, ► [Chap. 17, “The Evolving Role of Attitudes and Competencies in Information and Communication Technology in Education,”](#) a discussion of how the field has changed over the past decade, since the publication of the first edition of the handbook, is pursued. Attitudes and competencies were previously viewed as related but independent entities. Now they are typically contextualized as part of an integrated whole. The authors discuss how mediating variables have emerged to a status of their own. Learning sciences is proposed as one interdisciplinary field holding promise for integrating knowledge

and wisdom to chart the best paths forward, contributing to the continual refinement of best pedagogical practices for teaching and learning with technology.

In ► [Chap. 18, “Information and Communication Competences for Students,”](#) Aesaert and van Braak present the problems associated with discrepancies between theoretical and empirical dimensionality of Information and Communication Technology competences with the assessment of mastery not matching the objectives of the curriculum intended to be measured. These authors argue for the delineation of ICT competences as a necessary condition not only for creating ICT curricula that reflects the dimensionality of ICT competences but also for creating ICT curricula that will be measureable in a valid and reliable way. The authors propose that research should focus on the development of user-friendly assessment instruments that enable teachers to identify for each student the ICT competences of the ICT curriculum that need attention.

In ► [Chap. 19, “The Influence of Information and Communication Technology Use on Students’ Information Literacy,”](#) Sakamoto presents the different ways in which information literacy is defined in both Japan and other nations. The chapter includes findings of empirical research on the impact of children’s ICT use on information literacy. Different research method techniques that support the inference of causal relations among variables are discussed including specific examples of research findings that use these methods.

► [Chapter 20, “The Interaction of Psychological Constructs with Information Technology-Enhanced Teaching and Learning,”](#) by Katz, presents research that indicates that the effective use of IT-based tools by teachers leads to the enhancement of elementary and secondary school students’ learning achievement and all-round educational performance. Constructs that characterize teachers such as teacher change, teacher knowledge, and pedagogical beliefs as well as affective constructs that typify both teachers and students such as autonomy, creativity, flexibility, motivation, satisfaction, and self-efficacy are presented as vital tools to maximize the positive effect of IT-based tools in the classroom. The author implores educational administrators to formulate teacher professional development programs that include the enhancement of those constructs needed to successfully mediate the efficient use of IT-based tools that will conceivably lead to the promotion of student achievement.

Ottenbreit-Leftwich, Kopcha, and Ertmer’s, ► [Chap. 21, “Information and Communication Technology Dispositional Factors and Relationship to Information and Communication Technology Practices,”](#) reviewed a variety of research that addresses an important question regarding the specific dispositions teachers need to use ICT in the classroom. Research suggests that a teacher’s self-efficacy, attitudes, openness to change, and pedagogical beliefs each have a relationship with a teacher’s use of ICT for teaching and learning. The chapter includes the importance of exploring the practical strategies that best support teachers in articulating and addressing their dispositions that may interfere with their efforts to use ICT for teaching and learning.

In ► [Chap. 22, “Instructional Technology Integration Models and Frameworks: Diffusion, Competencies, Attitudes, and Dispositions,”](#) Niederhauser and Lindstrom

provide an overview of current models and frameworks that inform teacher adoption of technologies that support the integration of technology into student learning experiences in K-12 school settings and to link them to theories of diffusion, adoption, and change that underpin them. Relative to classroom technology integration, models can be useful in helping us understand and explain how technology integration occurs, allow us to better make decisions about how to effectively utilize technology resources, and provide insights that support development of strategies to more effectively and efficiently promote the kinds of pedagogical reforms that reformers hope to see in schools.

Christensen and Knezek's, ► [Chap. 23, "Measuring Teacher Attitudes, Competencies, and Pedagogical Practices in Support of Student Learning and Classroom Technology Integration,"](#) features instruments to measure teacher attitudes, competencies, and pedagogical practices judged to be important for effectively integrating technology into the classroom learning environment. Specific instruments that serve as exemplars for teacher appraisal are introduced and discussed in the chapter.

Abstract

Attitudes and competencies related to ICT in education have evolved over the past decade from being viewed as separate but related entities to now being viewed as part of an integrated whole. As of 2018 the prevailing view of competencies relevant to teaching and learning with technology is that they often span the cognitive, affective, and psychomotor domains of psychology and are best appraised by concepts such as self-efficacy that lie at the intersection of two or more of these domains. New developments in social media technologies stretch the limits of relevance of psychology as pertaining to the behavior of an individual and move into the realm of sociology, or behaviors of groups of individuals. Noncognitive

variables beyond attitudes have assumed a more prominent role in ICT in education, as of the second decade of the twenty-first century. Learning sciences is proposed as one interdisciplinary field holding promise for integrating knowledge and wisdom to chart the best paths forward, contributing to the continual refinement of best pedagogical practices for teaching and learning with technology.

Introduction

Since the publication of *The Importance of Information Technology Attitudes and Competencies in Primary and Secondary Education* (Knezek and Christensen 2008), much has changed. In general the recognition of the importance of emotions, motivation, creativity, grit, and other noncognitive variables related to attitudes toward teaching and learning with technology has increased. Likewise recognition of the importance of understanding the process of acquiring many kinds of competencies needed to be productive in a modern society (e.g., communication, confidence, collaboration) related to ICT in education – rather than simply focusing on the end-goal performance of a mastered ICT skill – has become universal. This chapter focuses on new perspectives emerging and especially the evolving definitions and roles of attitudes and competencies regarding ICT in education. The chapter will begin with a description of the evolution from technology as an affordance for better mastery of knowledge and skills, toward technology as a catalyst aiding potential positive teaching and learning outcomes in the complex field of learning sciences.

Three Domains of Psychology Relevant to ICT in Education

Psychology can be defined as the science of human behavior at the individual level (Henriques 2004). The portion of psychology most directly relevant to ICT in education is focused on learning. More than 60 years ago Benjamin Bloom and colleagues described three domains of psychology focused on learning: cognitive, affective, and psychomotor. The group published their framework in 1956, in *Taxonomy of Educational Objectives, Handbook I: The Cognitive Domain* (Bloom et al. 1956). How technology can contribute to teaching and learning in each of these domains is the focus of this section.

The Cognitive Domain

Bloom and his colleagues completed a detailed taxonomy for only the cognitive domain in the original taxonomical work in the 1950s (Bloom et al. 1956). The

Table 1 Original and revised categories of Bloom’s taxonomy for the cognitive domain from lowest to highest cognitive level

Comprehension	Understanding
Application	Applying
Analysis	Analyzing
Synthesis	Evaluating
Evaluation	Creating

cognitive domain is generally defined as pertaining to mental skills or knowledge. Forty-five years after the original publication, Anderson et al. (2001), including Krathwohl who was an author of the original taxonomy, developed a revision of the taxonomy of educational objectives for the cognitive domain. The revision changed the names of the lower and higher order thinking skill levels from nouns to action verbs and placed “creating” at the highest level of the cognitive domain (Anderson et al. 2001). Category names for the original and revised taxonomies are shown in Table 1.

Alignments have been developed to illustrate how interactions between the user and the technology can contribute to learning at each of the cognitive domain levels. The technology examples in Table 2 illustrate ways in which current technologies can be used for learning activities in the cognitive domain. One instructional designer (Carranza 2016) has created a visual representation of the how various technologies can be affordances in the development of lower and higher order skills in the cognitive domain (see Fig. 1). This graphic has been used to aid instructors in planning for technology-enhanced curricula in university courses (Boston College Libraries 2017; Sneed 2016).

The Affective Domain

Approximately 20 years after Bloom and colleagues published a taxonomy for the cognitive domain, Krathwohl et al. (1973) also published a taxonomy for the affective domain, which includes “the manner in which we deal with things emotionally, such as feelings, values, appreciation, enthusiasms, motivations, and attitudes (Clark 2015, np).” Jones and Issroff (2005), when writing about affective and social issues in learning technologies, observed:

Traditionally in learning there has been a division between cognition and affect: where cognition is concerned with skills and processes such as thinking and problem-solving and affect with emotional areas such as motivation, attitudes, feelings. Affective issues have been viewed as somewhat problematic in studying learning, so although it is well known that learner attitude, motivation, and emotional state are very important, they have often been excluded from the frame of research, or studied separately from cognitive learning. This position is gradually changing [. . .]. (Jones and Issroff 2005, p. 395)

Table 2 Revised cognitive domain categories with learning verbs and illustrative technology affordances

Revised Bloom category	Related action verbs	Sample technology applications by category
Remembering	Recall, list, retrieve, find, name, recognize, identify, locate, describe	Searching for topics in a browser; bookmarking topics in browser for retrieval; identify and download apps
Understanding	Interpret, summarize, rephrase, explain, classify, compare	Creating a comparison table in a word document; playing a 360 degree video of the solar system from YouTube using virtual reality glasses
Applying	Produce, implement, practice, illustrate, demonstrate	Creating a Powerpoint presentation on a topic; producing a 360 degree video using an iPad and camera
Analyzing	Compare, organize, question, research, deconstruct, outline	Creating a budget in an electronic spreadsheet; searching the Internet for two points of view on a current event topic
Evaluating	Check, judge, critique, experiment, hypothesize, test, detect	Collaborating online with colleagues; responding to topics in a blog; retweeting related information to colleagues
Creating	Design, build, construct, plan, produce, devise	Creating a podcast; creating an avatar; designing a web presence; creating a digital story; designing a 3D object to print

Affective domain attributes in recent decades have been gradually added as co-variables in the prediction equation shown in Fig. 2. In the twenty-first century, promoting more positive affect such as more positive attitudes toward information technology is sometimes recognized as an outcome measure (end goal) on its own. The assumption is typically that more positive affect leads to better performance, as shown in Fig. 2. Professional development workshops for elementary and secondary teachers aimed at removing computer anxieties or increasing comfort level are based on this assumption.

Variables used for studies with ICT are generally classified in the affective domain when they have emotional (as opposed to logic or reasoning) components in their foundations. One of the most important human attributes in the affective domain is that of attitude. Many studies conducted in the late twentieth and early twenty-first century cite Fishbein and Ajzen (1975) who defined attitude as “a learned predisposition to respond in a consistently favorable or unfavorable manner with respect to a given object” (p. 6).

While the definition of attitude has stayed intact, the term disposition, which is generally regarded as longer persisting, has also assumed a prominent role. ICT in education trends over the past decade align well with the general definition of dispositions published by Allen et al. (2014): “We call these human qualities dispositions—a person’s core attitudes, values, and beliefs demonstrated through both verbal and non-verbal behaviors as one interacts with oneself, others, one’s

Bloom's Digital Taxonomy

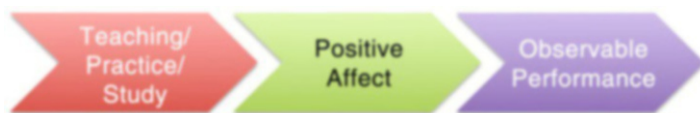

Fig. 2 Affect as an outcome variable, or mediating variable en route to performance

purpose, and frames of reference” (p. 2). This definition of dispositions appears to align well with the original taxonomy of learning in the affective domain (Krathwohl et al. 1973) as shown in Table 3. In the words of Morshead (1965), “This classification scheme, or taxonomy, is made up of five hierarchically arranged categories which provide individual descriptions of different changes that occur in behavior as values or attitudes are learned” (p. 165). Illustrative technology affordances appropriate for human development in areas such as core values and beliefs, respect

Table 3 Affective domain categories with learning verbs and illustrative technology affordances

Bloom's taxonomy of affective domain	Learning objectives and related action verbs	Sample technology applications by category
Receiving phenomena	Become aware: Accept, listen, notice, acknowledge	Watching a TED talk and viewing a contrasting YouTube video on a topic, respecting the different points of view; following a peer on Twitter
Responds to phenomenon	React: Answer, greet, aid, consent, follow, cooperate, conform	Responding to a blog in an appropriate manner; giving proper credit for sources used in a paper or digital presentation
Valuing	Understand and act: Adopt, assume, choose, cherish, exhibit, express, respect	Respecting the privacy of others when tagging them in social media; being aware of the digital footprint left when posting information about yourself or others
Organization (of values)	Develop value system: Compare, relate, discriminate, synthesize, prioritize	Creating a wikispace for a group project that includes multiple points of view; determining the most useful media sources for current event paper
Internalizes values	Become proactive: Advocate, defend, exemplify, influence, justify, serve, support	Creating an online community that is positive and respects others; recognizing your role in protecting others who may be victims of online cruelty

for others, and personal, social, and emotional adjustment were added by the authors of this chapter to form Table 3.

Although ICT in the form of computer programs and user interfaces has traditionally been considered to be void of emotions or other affective components, Table 3 illustrates that the broad expansion of social media systems has created the need to focus on teaching and refining affective competences. Examples referred to in Table 3 include respect for the views of others expressed in online environments, giving proper credit for use of resources available in digital form and having compassion for and protecting victims of online bullying and other forms of social media disrespect. Proficiency in these human social skills would likely be considered important as twenty-first century skills in almost all societies of the world. ICT in general, and especially new information technologies incorporated into social media systems, would appear to increase the complexity of contributions to human development in this realm.

The Psychomotor Domain

The psychomotor domain pertains to physical movement, coordination, and motor skills, all of which include both fine and gross motor movement. The committee

Table 4 Psychomotor domain taxonomy for simple to complex abilities with example technology affordances

Psychomotor categories	Related action verbs	Sample technology applications by category
Observe	Hear, taste, touch, observe, identify	Observe the teacher showing how to use a touchscreen tablet; watch a how-to video online to learn how to use VR glasses
Model (attempt to replicate)	Copy, imitate, repeat, try, reproduce	Touch the screen on an iPad; imitate the proper pronunciation of a foreign language word generated by a technology-based language drill system
Recognize standards (recognize and follow accepted standards)	Detect, distinguish, recognize, notice	Determine which app to touch to launch the instructed application; touch the app to make it open; avoid clicking on off-topic web sites during an academic subject internet research exercise in school
Correct (self-evaluate performance and make corrections)	Adapt, adjust, alter, correct, improve, practice, revise	Close the app and re-open it independently; review YouTube video of ballet performance to improve one's own dance routine
Apply (apply skills to real life situations)	Create, design, originate, produce	Choose an app that is of learning value and manipulate the software; produce a video illustrating ideal back stroke swimming techniques
Coach (instruct others to perform skill in generalized situations)	Demonstrate, exhibit, instruct	Teach another student how to use an iPad; analyze slow motion images of a sprinter's start of a race to suggest a better positioning in the starting blocks

headed by Bloom in the 1950s did not produce detailed psychomotor domain specifications, but others have since that time. Modern professional development guides for instructors writing student learning objectives related to the psychomotor domain often include categories such as the ones created by Scherr (2006), with six categories from simplest to complex. Table 4 includes examples of uses of technology that are centered in the psychomotor domain, including using a mouse, trackpad, voice recognition software, and so forth. The psychomotor domain is somewhat different from the cognitive and affective domains in that most of the activities are visibly measurable and typically will include the development of a skill from simplest to most complex.

For learners with physical disabilities, technology can often be an accommodation tool to enable expression of cognitive processes, or measurement of activities in the cognitive domain. For example, a student who may be unable to write his or her thoughts on paper or a keyboard can use voice recognition technology to dictate thoughts and have them printed in a word document for others to read. Often traditional mechanisms (test formats) for measuring cognitive ability are not adequate, and therefore not accurate, for a student with a physical disability and

therefore a students' abilities may be more accurately assessed through the use of technology.

Technology is also often used to track physical movement and vital signs and give feedback to the user. For example, a physical activity monitoring device can track user's activity, sleep cycles, and heart rate, to provide ongoing performance improvement. Recent developments in learning analytics and big data have led to great interest in the capabilities of technology-based systems for tracking the process of and recording milestones of acquiring expertise in abilities while showing incremental levels of progress from beginning to end.

Learning Sciences: Integrating the Three Domains of Psychology with Technology

Other conceptualizations useful for ICT in education have evolved that are broader than the three domains of psychology previously described. Learning Sciences is an interdisciplinary/multidisciplinary field that extends beyond the psychology of learning and includes computational, sociological, and anthropological approaches to the study of learning. The field draws on theoretical frameworks from diverse fields such as cognitive science, sociocultural theory, educational psychology, computer science, and anthropology (Sawyer 2005) with the main focus on understanding the processes, tools, and contexts, as well as outcomes, of learning regarding learners and their needs.

While much educational research is focused on the institution of education – including practices, organizational structures, and policies – learning sciences focuses on how people learn and what is needed to enable and support learning (Roschelle et al. 2014). Learning scientists are often concerned with learning that is not yet measured well nor currently considered to be an important knowledge, skill, or ability. Because learning science includes multiple disciplines such as psychology, they are also focused on social and emotional outcomes (Roschelle et al. 2014).

Noncognitive Variables and Psychosocial Behaviors

Learning scientists often study human characteristics that do not exclusively belong to one of the domains of psychology previously described. For example, psychosocial behavior involves both psychological and social aspects, at the intersection of psychology and sociology. As ICT in education has moved beyond the simplest case of a human interacting with a program running on a machine – in the case of drill and practice or tutorials, for example – and into the realm of ICT serving as a communication conduit for two or more humans interacting with each other, the learning and behavior of persons using such systems moves into the realm of the study of the behavior of groups of individuals. Social media systems such as Facebook, Twitter, Instagram, Snapchat, and even email would all appear to fall into this realm. Texting and especially group texting would be in this category as well. Much of the study of

ICT in education in the near future might be focused on psychosocial attitudes and competencies.

Human attributes that learning scientists study outside the realm of cognitive psychology have evolved to have a designation of their own, called noncognitive variables. Attitudes are one human attribute that have been studied extensively related to technology (Knezek and Christensen 2008), but there are many others that are now recognized as important as well. The emerging importance of other noncognitive variables as they relate to teaching and learning with technology is illustrated by the trend toward studies including many intervening factors that influence whether or not a teacher well trained in technology skills is able to foster the enhancement of twenty-first century skills in students. “Noncognitive is used here to refer to variables relating to adjustment, motivation, and student perceptions, rather than the traditional verbal and quantitative (often called cognitive) areas” (Sedlacek 2011, p. 191). Noncognitive skills may include self-concept, leadership abilities, creativity, motivation, accurate self-appraisal, empathy, and persistence. Creativity is one example that is spotlighted by others such as Liu (► Chap. 61, “[Toward Creator-Based Learning: Designs That Help Student Makers Learn](#)”) related to creative designers with technology, and Schrier (► Chap. 59, “[Guiding Questions for Game-Based Learning](#)”) related to desirable outcomes of game-based learning. Grit (Duckworth and Yeager 2015; Shechtman et al. 2013) is another noncognitive variable that has come to be accepted as very important as an intermediary variable influencing under which conditions technology is effective in enhancing learning. Noncognitive variables are becoming more valued in the twenty-first century because they can function in research designs as important intervening or mediating variables that “. . . stand between the independent and dependent variables, and [. . .] mediate the effects of the independent variable on the dependent variable” (Creswell 2002, p. 50).

Many noncognitive variables are traits deemed desirable in both teachers and students, such as enthusiasm, excitement, and sustained interest. There is some empirical evidence that for these kinds of attributes related to ICT in education, positive or negative valences are transmitted from teacher to student (Christensen 2002). Such findings have implications for preferred pedagogical style to transmit the motivation to learn from teachers to students, among the alternatives for technological pedagogical approaches to be described in the sections that follow.

Evolution of Competencies for Teaching with Technology

Competencies have evolved over the past decade from a focus on being able to demonstrate technology skills to being able to (a) solve a problem with technology in collaboration with others and communicate the solution (for students) or (b) being able to integrate technology into the teaching and learning process (for teachers) with confidence and appropriate pedagogical expertise. Technology integration has become the primary goal of technology initiatives for teachers as of 2018, and many proven models have emerged. For example, early work by Shulman (1986) on pedagogical content knowledge paved the way for Technology, Pedagogy, and

Content Knowledge (TPACK) (Mishra and Koehler 2006), and several other prominent models that feature the combination of many attributes to profile a high-integrating teacher are described in further detail by Niederhauser and Lindstrom (► Chap. 22, “Instructional Technology Integration Models and Frameworks: Diffusion, Competencies, Attitudes, and Dispositions”). Research over the past two decades has demonstrated that teachers who are competent also need to be confident in their competence in order to perform well, and this has led to a strong focus on self-efficacy as an important attribute for technology-using teachers. Katz (► Chap. 20, “The Interaction of Psychological Constructs with Information Technology-Enhanced Teaching and Learning”) discusses how the integration of will (affect or attitude) and cognitive skill are both important in modern conceptions of competence.

A new kind of competence verification has taken on increasing importance over the past decade. This involves verification of completion of steps along the way and tracing the path by which desired technology-infused performance comes to fruition (► Chap. 46, “A Futures Perspective on Information Technology and Assessment” by Lodge). This new kind of tracking could enable detailed formative evaluation of the type that has come to be called assessment for learning (► Chap. 41, “Assessment as, for, and of Twenty-First Century Learning Using Information Technology: An Overview” by Webb and Ifenthaler). The emerging ways of viewing development of competencies would appear to align with Vygotsky’s (1978) ideas of scaffolding learning.

In the competency-based testing environment that surrounds twenty-first century education, proficiency in technology itself has also assumed an important role, whether it is used to enhance instruction, for communication between teachers, students, and parents, or to assess student learning. The ability to integrate twenty-first century technology for learning in schools is an expectation for teachers in most parts of the world today. Because technologies are constantly changing and the most productive use of technology is dependent on content, it is now considered more important to develop more general competencies focused on how technology can be used for teaching and learning. In particular, rather than focusing on how to use technology in the classroom, educators should start with the content or topic that is being taught and look for the ways to enhance learning outcomes through the use of technology (Keengwe et al. 2008; Richardson 2013). Technology should not drive the learning, but using the benefits and strengths of technologies can enhance student learning (Jonassen 2000).

Proficiency in technology integration is a goal that is beginning to supersede concepts such as mastery of skills or acquisition of competencies, regarding expectations for a teacher’s level of performance in the integration of technology into teaching and learning. Here we define technology integration as the meaningful and effective use of technology to enhance learning in students (Christensen 2002). Acquisition of foundation skills is still necessary, but may not be sufficient without acquisition of other essential components such as effective pedagogical practices, teaching self-efficacy, and positive attitudes and dispositions toward information and communication technology.

Attributes That Contribute to Competency in Integrating Teaching and Technology

Teachers need to feel comfortable using the new technologies that are rapidly permeating education, and they also need to understand the pedagogical strategies for effectively integrating technology into learning. Teachers are the key players in the success or lack of success of any technology initiative in the classroom (Ertmer et al. 2012). While it is important to develop confidence and skills, the knowledge and ability to use technology for personal use does not necessarily translate into the integration of technology into the classroom. Ertmer (1999) categorized barriers to technology integration in the classrooms into two types. First order barriers were those considered to be external regarding ability to integrate technology. These external barriers included tools, training, and support. The second type of barriers are second order or internal and include attitudes, confidence, and beliefs in the need for technology (Ertmer 1999). While many of the external barriers have been reduced over recent decades, the internal barriers still exist and are more complicated to overcome (Ertmer et al. 2012). Researchers suggest that it is the internal barriers that are the gatekeepers to successful technology integration and these barriers should be acknowledged and addressed (Ertmer et al. 2012; Rogers 2000).

Demonstrating Competencies in Pedagogical Practices

One commonly used dichotomy related to pedagogy focuses on two opposing ideologies – teacher-centered versus student-centered teaching (Meirink et al. 2009). The teacher-centered approach is considered to be the more traditional teaching method and is related to the transmission of knowledge from teacher to student. The student-centered method emphasizes student agency in learning and is focused on knowledge construction and a more social learning environment among peers (Liu 2011). Teachers who teach with technology tend to practice the pedagogical approach with which they feel more affinity. Researchers have found that there is a positive correlation between teachers who hold more constructivist (student-centered) beliefs and the extent of their use of technology in the classroom; conversely, holding more traditional beliefs tends to be negatively correlated with extent of technology use in the classroom (Kim et al. 2013). Niederhauser and Stoddart (2001) found that the pedagogical style teachers practiced influenced the type of software they chose to use in the classroom. Sang et al. (2010) confirmed that teachers with the strongest constructivist beliefs were more likely to integrate technology into instruction compared to those teachers who did not hold constructivist beliefs.

Opportunities made possible through the maturation and wide scale dissemination of new information technologies may be making the adoption of constructivist practices regarding ICT in education more practical. Evans (► Chap. 54, “From Engagement to Empowerment: The Evolution of Mobile Learning in the United States”) argues that new information technologies, and in particular mobile devices,

have transitioned into the realm of empowerment for self-directed learning that organically aligns better with student-centered pedagogical approaches. Initially it was thought because students were using mobile devices they were engaged, but it was difficult to assess whether they were truly engaged in learning. However, with an increase in the number of students who have access to mobile technologies, a shift has occurred that allows teachers the opportunity to create more self-directed learning options with mobile technologies that are aimed at empowering students to use technology for more meaningful, problem-based learning. This type of learning environment typically has built-in assessment in that finding a solution is evidence of learning. This type of affordance of ICT would appear to align best with a student-centered pedagogical approach based on constructivist beliefs. It would also appear to be relevant to learning inside as well as outside the classroom, with motivations, incentives, and options for creative approaches to solutions designed into the learning exercise, based on research-grounded design principles and knowledge of the influences of attitudes, dispositions, and other noncognitive variables.

The End Goal: Competencies in Support of Student Learning

Most countries of the world agree that technology competencies are important for twenty-first century teachers and students. Reviewers of the 2016 US National Educational Technology Standards (NETS) have stated the issue succinctly as “Technology is a reality but students and teachers need new ways to envision its purpose and possibilities” (Stoeckl 2016, np). Therefore, technology integration proficiency for teachers involves more than just technology skills; it includes being able to envision technology’s purpose and possibilities and having confidence in the path chosen. Several kinds of competencies to support learning with technology integration are addressed in this section.

Self-efficacy is well established as a factor that influences the effectiveness of teaching (Hoy et al. 2009). Self-efficacy is one of several important components required for successful technology integration in the classroom. Self-efficacy is based on Bandura’s (1986) Social Development Theory and is sometimes defined as the expression of beliefs of individuals related to their own capacity to perform a certain behavior (Gencturk et al. 2010). The authors of this chapter have proposed an operational definition of self-efficacy as *confidence in one’s competence* (Christensen and Knezek 2017).

Research has shown a strong relationship between perceived self-efficacy and technology usage (Albion 2001; Cassidy and Eachus 2002) and between perceived self-efficacy and technological abilities (Anderson and Maninger 2007). These relationships are consistent with Social Cognitive Theory which supports the idea that confident individuals believe their actions will produce successful results (Pajares 2002). As established by Bandura (1993), self-efficacy is a good predictor of behavior. As reported by Gencturk et al. (2010), teachers with higher self-efficacy are more ambitious and passionate in their teaching. Koh and Frick (2009) found teachers’ self-efficacy beliefs to be indicators of success for technology integration.

Teachers must have confidence in their skill and ability to use technology with their students before they are willing to use it (Ward and Parr 2010).

Competencies in fundamental technology skills can also be a problem for teachers – even for new teachers entering the field. An emerging problem among preservice teachers appears to be a decline in the level of fundamental IT skills among students entering teacher preparation programs. In particular, preservice candidates typically know how to text, surf the web, and use social networking tools, but frequently have little or no experience with using blogs, wikis, or other applications appropriate for teaching tools and lack the preparation to use these technologies in the classroom (Lei 2009; Schrum and Levin 2016). If prospective teachers lack fundamental knowledge of respected learning technology tools, then who will convey them to the next generation of students?

Summary and Conclusions

Attitudes and competencies related to ICT in education have evolved over the past decade from being viewed as separate but related entities to the current status of their being viewed as parts of an integrated whole. Competencies relevant to teaching and learning with technology are now frequently recognized as spanning the cognitive, affective, and psychomotor domains of psychology and are often best appraised by constructs such as self-efficacy that lie at the intersection of two or more of these domains. New developments in social media technologies involve concepts from psychology and sociology and appear to have found a home in the interdisciplinary field of learning sciences. Learning sciences is suggested as holding promise for integrating knowledge and wisdom to chart the best paths forward, contributing to the continual refinement of best pedagogical practices for teaching and learning with technology. Bloom's Taxonomies and their extensions are time-honored frameworks that can aid in the identification of specific technology affordances having the greatest potential for facilitating a targeted type of learning among the multifaceted goals of twenty-first century education systems and societies. Technology affordances, including specific technologies' purposes and possibilities, must be familiar to teachers if we expect teachers to foster quality technology-enhanced learning in students.

Abstract

The general aim of this chapter is to provide an overview of the main results of educational research studying 1) the concept of ICT competence; 2) the assessment of ICT competences and 3) characteristics related to differences in ICT competences. More specifically, the relationship between student, teacher and school level characteristics and primary school students' ICT competences is described in the context of direct, performance-based assessment. At the end of the chapter, three underlying topics that are important for future research are discussed, that is, 1) the difference between the theoretical and empirical dimensionality of ICT competences; 2) the development of user-friendly assessment instruments; and 3) the need for research focusing on alternative ICT competences.

Introduction

In the last four decades, information and communication technologies (ICT) have permeated virtually all aspects of our daily lives by contributing to the economic, social, and educational transformations that characterize the present knowledge society (Jara et al. 2015; Kozma 2008). These transformations and challenges ask for the acquisition of specific ICT competences individuals – and particularly children – need in order to develop skills for social interaction, information retrieval and processing, civic participation, and professional success and advancement (Voogt and Pareja Roblin 2012). This significance of being ICT competent is reflected in several international policies on educational ICT use. In Europe, for example, the DIGCOMP framework describes ICT competence as a necessary transversal key competence for lifelong learning that is defined as the confident, critical, and creative use of ICT to achieve goals related to work, employability, learning, leisure, inclusion, and/or participation in society. In this context, ICT competences are categorized into five ICT competence areas, that is, information, communication, content creation, safety, and problem-solving. For example, the ICT competence area “information” contains the ICT competences browsing, searching, and filtering digital information, evaluating digital information, and storing and retrieving digital information (Ferrari 2013). On a national level, recently more and more governments are administering formal expectations to schools in terms of ICT competence standards and curricula (Aesaert and van Braak 2015). As ICT competence standards and attainment targets define the achievement expectations for students, these ICT curricula formalize the status of ICT competences as official educational outcomes in their own right (Thomas and Knezek 2008). Consequently, the teaching of ICT competences no longer depends on the individual willingness and competence of the teacher. Instead, all teachers have the responsibility of providing all their students with equal possibilities to develop ICT competences.

In general, educational research on students’ ICT competences can be divided into three main categories (Litt 2013). The first category of researchers tries to define what comprise ICT competences that students need to deal with the challenges in their everyday life. These researchers are occupied with describing and defining the concept of ICT competence and also with the operationalization of the construct in ICT competence frameworks. The second group of researchers focuses on the assessment of ICT competences and tries to measure students’ proficiency in handling ICT-related tasks and problems. In this category, different assessment methods are used to capture students’ level of ICT competences such as self-perceived measures of ICT competence or ICT self-efficacy (Siddiq et al. 2016) or more direct assessment methods such as observations (Hargittai 2002) and, more recently, performance-based assessment (Aesaert et al. 2014; Christoph et al. 2015; Huggins et al. 2014; Scherer et al. 2017). The third category of researchers tries to explain the measured differences in students’ ICT competences by linking their level of ICT competence to other characteristics such as gender, socioeconomic status, and ICT experience or classroom use

of ICT (Aesaert et al. 2015; Claro et al. 2012; Fraillon et al. 2014; Siddiq et al. 2017). This chapter provides an overview of the main results on these three research categories.

Students' ICT Competences

Various concepts and terms are used to describe the range of students' abilities to use ICT. The terms most commonly used in national and international frameworks and research literature are computer and information literacy (Fraillon et al. 2014), Internet skills (van Deursen and van Diepen 2013), digital competence (Ferrari 2013), and ICT competence (Aesaert and van Braak 2015). Although these terms have specific meanings and refer to various set of ICT-related capabilities, they are mostly interchangeably used. For convenience, only the term ICT competence will be further used in this chapter.

Although the formalization of ICT competences into official attainment targets and ICT curricula is only a recent phenomenon, the need for schools and teachers to deliver ICT-competent students has existed since the 1960s. In sum, the different types of ICT competences schools focus on have gone through a three-stage evolution of *mastery (1960s to mid-1980s)*, *application (mid-1980s to late 1990s)*, and *reflection (late 1990s until present)* (Aesaert et al. 2014; Martin 2006). In the *mastery stage* schools emphasized learning about information technology rather than learning with or through computers. ICT competences were perceived as basic knowledge of how the computer works (simple computer science) and rudiments of computer programming, i.e., a fundamental understanding of the components of the machine, of its history, and its principal application, and as acquiring hands-on skill in programming language (Tannenbaum and Rahn 1984).

In the mid-1980s, the potential of ICT for learning was recognized by several authors. As software and operating systems became easier to use, user-friendly, and more powerful, the focus in schools shifted from learning about information technology to using information technology to learn. ICT competences shifted into an *application-oriented* stage and were perceived as practical basic skills to apply common software in education, leisure, and work, rather than on specialist knowledge and technical skills (Martin 2006).

In the third and present *reflective* stage, the technical- and application-oriented ICT competences of the previous stages are considered important, but insufficient to deal with the challenges of the present knowledge society. The focus of ICT competences has shifted from basic skills and the application of basic software to a more reflective, evaluative, and critical approach to computers, the Internet, and digital information (Anderson 2008). As such, ICT competences are perceived as twenty-first-century skills or skills for lifelong learning that are concerned with – among others – problem-solving, information processing, creativity and innovation, critical thinking, digital citizenship, communication and collaboration, and technology operations and concepts (Ferrari 2013; Voogt et al. 2013). Within the context of the reflective stage, several authors have stressed the complexity and hierarchical

structure of ICT competences. ICT competences are described as the interactive use of general cognitive capabilities that are underpinned by technical- and application-oriented ICT knowledge and skills in order to successfully complete cognitive information and ICT-based tasks (Aesaert et al. 2015; Markauskaite 2007). For example, in order to find information on the Internet, one needs not only to be able to operate the search engine but also to distinguish between relevant and irrelevant information. This description illustrates that the technical- and application-oriented ICT skills are still considered to be important. The technical- and application-oriented ICT skills are considered to be instrumental to the general cognitive capabilities, and one needs to master the basic technical and application skills to even come to performing the general cognitive ICT competence, i.e., the mastery of basic ICT skills and ICT applications is a condition to solve cognitive tasks in a digital environment (Claro et al. 2012). van Deursen and van Dijk (2016) stress this hierarchical structure in which the skills of the mastery and application stage are subordinate to the reflective stage for the particular case of Internet competences (a subdomain of ICT competences). They make a distinction between two types of higher cognitive ICT competences (i.e., information Internet competences and strategic Internet competences) and two types of application- or medium-related types of ICT skills (i.e., operational or navigation Internet skills and formal or orientation Internet skills). The authors stress that the content-related ICT competences depend on the medium-related ICT skills, i.e., a person without the medium-related skills will not even come to perform the content-related skills.

Measuring ICT Competences

Research on the assessment of students' ICT competences can be divided into studies using direct measures and studies using indirect measures to assess students' level in successfully completing computer- and Internet-related tasks. At present, the research interest is mainly oriented toward indirect measures such as self-efficacy, self-evaluation, and self-reported measures of ICT competences (Litt 2013; Siddiq et al. 2016). In the studies using indirect measures, a student's ICT competence level is based on the analysis of the student's own judgment of his/her ability to successfully complete ICT-related tasks. As these indirect measures are not resource-consuming and easily deployed on large samples for data collection and analysis, several surveys and self-report instruments have been developed to measure students' ICT competences (Litt 2013; Livingstone and Helsper 2010). In general, these self-report instruments are divided into instruments measuring students' computer competences, Internet competences, or both (Fraillon et al. 2014; Rohatgi et al. 2016). Whereas some instruments measure ICT competences in general, others focus on specific aspects of ICT competences. With regard to general ICT competence, Compeau and Higgins (1995) developed the general computer self-efficacy scale, which is used to measure students' perceptions of their ability to apply computer skills to broader tasks in the future. Liang and Tsai (2008) developed the General Internet Self-Efficacy Scale, which refers to students' self-perceived competence in

using the Internet in general. Tsai and Tsai (2010) focused on specific aspects of ICT competence and use an Internet self-efficacy scale that measures students' perceived ability in online exploration (navigate and search for information on the Internet) and online communication (communicate via the Internet). Similarly, Aesaert and van Braak (2014) used an ICT self-efficacy instrument to investigate students' judgment of their own competence in communicating, retrieving, and processing information with a computer and the Internet, as well as their underlying technical- and application-oriented skills.

Although these indirect measures are easily administered to large samples, self-reported results often offer a less accurate representation of students' actual proficiency or performance level (van Deursen and van Dijk 2011). Students can over- or underestimate their own ICT competences which makes these indirect measures vulnerable to validity problems of self-report bias (Merritt et al. 2005). For example, results of Ballantine et al. (2007) indicate that students significantly overestimate their ICT competence with regard to general ICT awareness, spreadsheets, word processing, databases and presentation software, and e-mail/Internet. Moreover, the majority of studies that compared students' self-reported levels of ICT competence with their actual ICT competences show low correlations between both measures. This research reinforces the statement that self-report measures of ICT competences are not reliable (Siddiq et al. 2016).

In order to tackle these shortcomings of self-reported measurements, recently researchers have started to assess students' ICT competences in a more direct way. This means that students' levels of ICT competences are based on the analysis of directly performed and observed actions, i.e., students perform hands-on actions on a computer which are then observed and analyzed by the researcher. Being a pioneer in direct assessment of ICT competences, Hargittai (2002) used observations and thinking-aloud protocols to identify differences in adults' ability in retrieving online information. These performance- and simulation-based tasks that come close to reality are valuable because they are a more authentic appraisal of complex competences and therefore more valid than conventional item designs such as survey measures (Wirth 2008).

Although these direct measures based on observations offer a suitable alternative, allowing for more valid measurement of ICT competences, they suffer from practical issues such as being expensive, time-consuming, difficult to replicate, and difficult to conduct on large samples. In order to deal with these practical disadvantages, researchers recently have started setting up large-scale assessment initiatives to measure students' ICT competences in a direct and standardized way using computer software. From an international perspective, for example, ICILS 2013 (International Information and Computer Literacy Study 2013) used a computer-based test in order to measure secondary students' ICT competences (Fraillon et al. 2014). More specifically, the results indicate that on average 78% of 14–15-year-old students have a basic to lower mastery level in collecting, managing, producing, and exchanging digital information. Furthermore, it seems that the evaluation of the reliability, usefulness, and relevance of digital information requires a higher level of ICT competence (Fraillon et al. 2014). A study

of van Deursen and van Diepen (2013) produced similar results, i.e., the data of their performance-based test showed that the levels of searching and processing online information of secondary school students still have much room for improvement. More specifically, their results suggest that students still have difficulties defining proper search queries and evaluating the reliability of the information in the results of these search queries. The study of Aesaert and van Braak (2015) confirmed these results for the context of primary school students. It seems that these students are having trouble with assessing and judging the relevance of digital information, with delivering requested digital content in a socially acceptable and understandable way and with information searches that require more complex searching behavior. With regard to the latter finding, students can easily find digital information using a search index, the menu of a website, or a search engine as long as the number of keywords is limited, i.e., students experience more problems with search queries that require more keywords to obtain a correct result. According to Kuiper et al. (2005), students find it very difficult to choose appropriate keywords in a structured and systematic way. In this context, van Deursen and van Diepen (2013) state that students' search queries are often too long and not specific enough. Furthermore, results of Claro et al. (2012) showed that communicative ICT activities, such as writing an e-mail or publishing a post that is adequate in content, require even a higher level of ICT competence compared to other activities such as searching for digital information. Similarly, Aesaert et al. (2014) found that the most difficult ICT activities are those for which students have to formulate a message in which the content is socially acceptable and understandable. According to some authors (Aesaert et al. 2014; Kuiper et al. 2005), these communicative activities often take place in less pre-structured software applications such as an e-mail program or a blog, requiring a more developed ability from students.

The results presented above clearly call into question the widely accepted claims that a generation of digital natives exists. The results suggest that not all students possess sophisticated ICT competences and that students are perhaps not as computer and Internet savvy as it is often assumed. Primary and secondary school students still encounter problems with higher-order cognitive ICT competences such as finding, using, and evaluating the right digital information (Calvani et al. 2012; Kuiper et al. 2005). It is possible that the complexity of these ICT competences will even increase in the future and require even more from students, as the number of websites and the information available on the Internet is growing at lightning speed and everybody can act as an author. Consequently, the results of performance-based ICT competence tests illustrate that the assumption of digital natives has a weak empirical foundation and that it should be studied within the diversity of ICT competences (Bennett et al. 2008). This also means that the popular claim that education must make fundamental adaptations to cope with the needs of the net generation must not be taken for granted. On the contrary, education should especially provide students with opportunities to acquire those competences of the ICT curriculum that are less developed. As students still develop their ICT competences mainly in out-of-school settings (Hatlevik et al. 2015b; Rohatgi et al. 2016), they enter the classroom with different and differently

developed ICT competences. The identification of these competences by teachers and schools is an essential condition for providing all students with equal possibilities to become ICT competent.

Characteristics Related to ICT Competences

In general, research exploring characteristics related to students' ICT competences is mostly conducted from the perspective of student characteristics such as socioeconomic status (SES) or gender (Aesaert and van Braak 2015; Litt 2013; Meelissen 2008). However, it is well known that students' educational outcomes – which ICT competences are since they are incorporated in official ICT curricula and attainment targets – are attributed to characteristics at different levels (e.g., student level, teacher level, school level) (Creemers and Kyriakides 2012). Consequently, recent research has elaborated on these traditional student characteristics and focused on the impact of students' cognitive abilities and teachers' and schools' practices that might foster ICT competences (Claro et al. 2012; Fraillon et al. 2014).

Student Level

Most research directed toward ICT competences has tried to explain differences in ICT competences from the perspective of gender. At present however, research still reports inconsistent results (Rohatgi et al. 2016). Whereas some researchers have found a significant relationship between gender and ICT competences in favor of boys (Kuhlemeier and Hemker 2007; van Deursen 2012), others identified a positive association favoring girls. For example, Hohlfeld et al. (2013) found that secondary school female students performed better on the Student Tool for Technology Literacy than their male counterparts. Similarly, the results of the ICILS 2013 study indicate that female students on average outperform their male counterparts in digital information retrieving, processing, and communication (Fraillon et al. 2014). What has become clear out of these studies is that more nuanced measures that focus on specific types of ICT competences are more appropriate than general measures for identifying gender-related differences. For example, Jones et al. (2010) found a significant relationship between gender and certain ICT activities such as using graphics, audio/video, computer maintenance, and spreadsheets, in favor of males. However, this relationship was not found for activities that require digital communication and information processing such as writing on blogs and using online library resources. Results of Aesaert and van Braak (2015) show that girls are particularly better in delivering digital information in a socially acceptable and understandable way, in reacting on a forum, in judging the relevance of digital information, and in using e-mail for communication. The results of these studies clearly tackle the traditional assumption that using computers and the Internet is a male activity. A possible explanation that female students are better in digital communication than male students is that social online activities such as

e-mailing, blogging, and using social network sites are more popular activities for girls than for boys (Volman et al. 2005). Similar, Drabowicz (2014) states that boys tend to use the Internet as an entertainment tool (e.g., playing games), whereas girls use it as a communication tool to get something done. Investigating students' ICT use profiles, Scherer et al. (2017) found that girls use ICT more frequently for social communication and exchanging information than boys. As girls participate more in social online activities, they have more opportunities that the results of their conducted communication activities are interpreted as successful experiences than their male counterparts. Within the context of social cognitive theory (Bandura 1986), these successful experiences can increase girls' ICT self-efficacy more than that of boys, which in turn can raise girls' motivation to engage in more challenging and difficult social online activities, and eventually develop better competences in digital communication (Tsai and Tsai 2010).

Although SES has often been linked to ICT competences, this relationship has mostly been studied from self-reported measures. However, the little research that has been conducted on the relationship between SES and students' ICT competences has produced similar results so far. For example, Claro et al. (2012) were some of the first to investigate the relationship between SES and students' actual ICT competences. These authors found that the higher the students' socioeconomic status, the better they score on digital communication, digital information retrieving and processing, and interacting and collaborating in digital environments. A similar positive relationship was found by Aesaert and van Braak (2015) and Siddiq et al. (2017) who operationalized SES as the highest educational degree of the parents. The results of both studies indicate that the higher the educational degree of the mother or father, the better the technical-procedural ICT skills (e.g., adding attachments to e-mails) and higher cognitive digital competences (e.g., integrate digital information into existing information products) of the students. At the international level, the ICILS 2013 study produced similar results, i.e., in more than 50% of the participating countries, a significant positive effect of parental educational level on students' ICT competences was found. These findings are reinforced by the fact that other indicators of SES such as parental occupational status and home literacy are positively associated with students' ICT competences in all participating countries (Fraillon et al. 2014). This finding is problematic as SES is a structural student characteristic that cannot easily be altered (Creemers and Kyriakides 2012). However, it emphasizes the need for the identification of teacher, classroom, and school characteristics that can foster the development of ICT competences of students of specific socioeconomic groups.

Besides these student background characteristics, research on ICT competences has also focused on some cognitive and motivational student characteristics, of which ICT self-efficacy is probably the most frequently studied one. ICT self-efficacy is rooted in Bandura's broader concept of self-efficacy (Marakas et al. 1998). ICT self-efficacy comprises the two domains of computer and Internet self-efficacy. Consequently it refers to a person's belief in his capability to successfully perform computer- and Internet-related tasks (Papastergiou 2010). In general, most studies report a positive relationship between ICT self-efficacy and students' ICT

competences, i.e., the higher students judge their own ability for solving computer- and Internet-related problems, the better their actual ICT competences (Rohatgi et al. 2016). Results of Hargittai and Shafer (2006) show that self-assessed net skills are positively related to actual net skills. More recently, Aesaert et al. (2015) found that the higher primary school students' ICT self-efficacy, the better they score on performance-based ICT competence tests. These results clearly illustrate that ICT self-efficacy is not only important for developing ICT competences but also for being able to use technology in learning (Hatlevik et al. 2015a).

Finally, we discuss some important student characteristics of which the relationship with students' ICT competences has been less studied. More specifically, we focus on ICT experience and ICT use at home. Students' ICT experience and ICT use at home are two important student characteristics of which the relationship with ICT competences has been studied in numerous investigations. ICT experience refers to the total number of years a child has been using the computer and the Internet or the time a child daily/weekly spends on computer and Internet use outside the school context (Tsai and Tsai 2010). Although Ballantine et al. (2007) did not find a significant relationship between ICT experience and students' ICT competences, recent studies are more positive. For example, Jara et al. (2015) identified ICT experience as one of the most important characteristics for developing students' ICT competences. Similarly, Aesaert et al. (2015) found that the more hours per week a student on average uses a computer and the Internet at home, the better he or she is in successfully completing tasks that are related to finding, processing, and communicating digital information. ICT use at home refers to students' use of specific types of computer and online application use in an out of school context. Livingstone and Helsper (2007) found that primary and secondary school students who use the Internet in a more conservative way have less developed online competences. Jara et al. (2015) elaborated on this matter. Their results show that students who daily use and communicate through social network sites have better ICT competences than students who do not take up these activities. Moreover, it seems that students who use the Internet mainly for downloading music, games, or programs have less developed ICT competences than students who never do these activities. It is important to stress that the relationship between ICT use and ICT competences is a reciprocal one. van Deursen and van Dijk (2016) found that different types of Internet usage are directly determined by specific Internet skills. More specifically, it seems that higher levels of strategic Internet skills result in more information-directed online use.

To conclude the discussion on the relationship between ICT competences and students' ICT use, we refer to Jara et al. (2015) who stress that rather the way in which students use specific applications than the frequency in which they use them is important for developing ICT competences. It seems that students with high ICT competences use a set of academic skills, i.e., a mix of cognitive skills and organizational skills, that allow them to make more appropriate use of the opportunities provided by computers and the Internet in order to meet their personal objectives. More specifically, these students not only keep focused on their goal when they use ICT, but they also make use of higher-end information processing strategies such as

judging the quality of websites, comparing multiple sources, and making summaries. Within this context of the relationship between academic skills and ICT competences, Aesaert et al. (2015) found a significant and positive relationship between “control” learning style and students’ ICT competences. This means that the more students plan, monitor, and regulate their learning process while learning, the higher their ability in digital information processing and communication. This relationship can be explained from the perspective of metacognitive skills. Different aspects of digital information processing such as judging information and comparing multiple online sources require metacognitive skills (Eisenberg 2005), which are typical for students using a “control” learning style. Aesaert et al. (2015) also identified analytic intelligence or students’ ability to adapt their thinking to new cognitive problems without relying on declarative knowledge derived from previous experience in or outside the classroom, as one of the most important characteristics affecting students’ ICT competences. These studies emphasize the importance of training specific general cognitive abilities for the development of ICT competences rather than just increasing the frequency of ICT use.

Teacher and School Level

Although the importance of schools for the development of students’ ICT competences has been widely recognized, only a few studies have investigated which teacher and school characteristics might affect students’ ICT competences. With regard to educational ICT use, the results are rather negative. For example, Aesaert et al. (2015) investigated whether differences in primary school students’ ICT competences could be explained by teachers’ ICT competences, ICT attitudes, ICT professional development, educational ICT use, ICT experience (teacher level), roles of the ICT coordinator, ICT policy planning, ICT support, and ICT infrastructure (school level). Of all these characteristics, only a positive but weak effect was found between the use of ICT as an information tool in the classroom and students’ ICT competences. Similarly, the results of the ICILS 2013 study show that learning about ICT at school has a statistically significant positive effect in only 4 out of 15 countries (Fraillon et al. 2014). Moreover, Appel (2012) did not find a significant relationship between the use of computers at school and students’ ICT competences, and Hatlevik et al. (2015b) even found a negative impact of ICT use at school on students’ ICT competences. These results provide weak evidence that the specific ICT activities that teachers organize in their classroom pay off in terms of ICT competence development.

However, results of Fraillon et al. (2014) illustrate that among countries 11–53% of the variance in students’ ICT competences is located at the teacher/school level. These results suggest that there exist differences in ICT competences between students’ from different schools. Taken into account that (1) there exist differences in students’ ICT competences between schools, that (2) the proof of the effect of educational ICT use on students’ ICT competences is limited, and that (3) research has not yet conclusively identified other teacher and school characteristics related to

directly assessed students' ICT competences (as far as we know), the question rises if other teacher and school characteristics such as access to technology, teacher beliefs, and teaching style do explain differences in students' ICT competences.

Conclusions

Our limited review clearly points out that research on ICT competences is still in its infancy. Instead of summarizing the results, we focus on three underlying topics that are important for future research. The concept of ICT competences represents an interesting but fast-evolving and complex construct. In its present state, it is perceived as a multidimensional and hierarchical construct, in which higher-order cognitive skills are underpinned by more technical-procedural ICT skills. None of the studies above were able to empirically validate the theoretical dimensionality of ICT competences. We believe this difference between the theoretical and empirical dimensionality of ICT competences is quite problematic. One can question the validity and reliability of assessing students' mastery of an ICT curriculum if the structure of the empirical data used to assess the specific ICT competences does not match the structure of the objectives of the ICT curriculum intended to be measured. Consequently, we believe that a combination of theory- and data-driven approaches for curriculum evaluation is necessary to develop high-quality ICT curricula. Together with theoretical arguments, empirical data on the dimensions that underlie students' ICT competences should be used to adapt and create more delineated and mutually independent ICT attainment targets. Although some authors plea for a more holistic approach to ICT literacy, the delineation of ICT competences can be seen as a necessary condition for creating ICT curricula that not only reflect the dimensionality of ICT competences but also for creating ICT curricula that will be measurable in a valid and reliable way.

The results indicated that some important and sophisticated ICT competences such as searching, evaluating, and communicating digital information are not always well developed and that students are perhaps not as computer and Internet savvy as it is often assumed. As the information available on the Internet is growing at lightning speed, most likely, the complexity of ICT competences required to handle this unstructured amount of data and information will increase. Further, it seems that these ICT competences are far from universal among young people (Bennett et al. 2008). For example, girls are particularly better in delivering digital information in a socially acceptable and understandable way than boys. Consequently, gender preferences still need to be studied. Moreover, the impact of teachers and schools is limited as almost no teacher and school characteristics seem to contribute to students' ICT competences. Consequently, it can be assumed that students still develop these competences especially in informal, out-of-school settings. This means that students enter schools with different and differently developed ICT competences. If we want to create equal opportunities for all students to develop ICT competences, it is important that teachers and schools can compensate for those specific ICT competences that students do not yet possess. However, teachers themselves are

often not fully equipped with ICT competences, which makes it hard for them to identify and assess their students' level of ICT competences. Research should therefore focus on the development of user-friendly assessment instruments that enable teachers to identify for each student the ICT competences of the ICT curriculum that need attention.

To conclude, we believe that future research that tries to explain differences in students' ICT competences should focus on different types of dependent and independent variables. With regard to the dependent variable ICT competences, our results indicate that most studies focus on digital information processing and communication. Research should elaborate and focus on other ICT competences such as collaboration by means of ICT, presenting information by means of ICT, digital media production, or even socio-emotional skills that students need in social networking. This will not only deliver a more comprehensive, construct, and content valid picture of students' ICT competences, but it would also be an important step in the investigation of the dimensionality of ICT competences. With regard to the independent variables, we believe that the relationship between ICT use in the classroom and students' ICT competences should be further investigated. More specifically, research should focus on the mediating role of the instruction of teachers, e.g., to which degree do the teaching style and teaching beliefs of the teacher mediate between using ICT in the classroom and the development of ICT competences.

Research on the development of ICT competences should remain a highly addressed topic for educational researchers, because those competences – among others – that offer children the possibility to engage in a world immersed in digital information and applications.

Abstract

In this chapter, the concept of information literacy and research findings on the impact of children's use of ICT (information and communication technology) on information literacy are introduced, with a focus on Japan and including comparisons to other parts of the world. A general explanation of information literacy is first provided; then the concept, history, measurement, and other issues of information literacy are described. The findings of Japanese empirical research on the impact of children's ICT use on information literacy are detailed and aligned with major international research findings and orientations on the issues of impact of ICT use. Major findings are as follows: (a) ICT use can improve information competencies, in particular abilities to collect and evaluate information; and (b) it

appears that ICT use at school could be more effective than ICT use at home, but even the use at home has effects which cannot be ignored. Findings contribute additional evidence of causality to the current body of literature based primarily on large international studies addressing the issues of the educational impact of ICT use through data gathered across many educational systems but from each subject just one time.

Information literacy · ICT use · Quasi-experiment · Panel study · Japanese research

Introduction

This chapter introduces studies on the influence of ICT use on information literacy among elementary, junior high, and senior high school students. Although many references are made to studies from other parts of the world, detailed examples are provided from research studies in Japan.

What Is Information Literacy?

Information literacy has been regarded as being a skill necessary to live well in the information society. According to Virkus (2003), increasing attention to information literacy in recent years is partly due to the result of information overload especially related to the growth of digital information and the new focus on student learning in a lifelong learning context. Although such notice of information literacy has been taken, its concrete concept is not quite clear. In the glossary section of the first edition of the *International Handbook* (Voogt and Knezek 2008), the term information literacy was defined as:

Computer literacy, digital literacy, e-literacy, e-skills, technological literacy, new literacy – all knowledge and skills that are necessary to participate in an information society; . . . [and] more narrowly defined as skills that are necessary to effectively use technology, e.g., finding and evaluating information on the Internet. (p. 1185)

Based on the explanation provided in the previous paragraph, it is possible to recognize that the term information literacy can have many meanings from narrow to wide definitions. Virkus (2003) described its various concepts and definitions. Some researchers have been engaging in work to overcome such confusing situations. For example, Anderson (2008) presented the term *knowledge-related skills* as inclusive abilities necessary for life in the information society. Knowledge-related skills consist of seven subskills, and Anderson described the subskill *to access, assemble, and reorganize knowledge*, as being the original information literacy.

Anderson (2008) also discussed relationships between information literacy and its similar concept, that is, ICT literacy. According to Anderson, information literacy

is usually defined based on information functions, while ICT literacy is defined based on information skills. From this perspective, he made and presented a comprehensive model to describe the relationships of the two concepts. Anderson's work can also be regarded as an effort to resolve long-standing confusion related to the meaning of the term information literacy.

One reason the concept of information literacy is ambiguous could be that abilities which are regarded as important have changed depending upon the time period (Martin 2006; Voogt 2008). Actually, it seems that skills to operate ICT tools were important before, while the skills of high-order thinking for ICT are important now. It is conceivable that the concept of information literacy which focuses on important skills particular to each time period has so far been presented, and this time period transition has led to the currently existing variety of information literacy concepts.

Since the important abilities are still continuing to change, concepts are also continuing to be presented. For example, Mioduser et al. (2008) presented a new literacy, which consisted of multimodal information processing, navigating the infospace, communication literacy, visual literacy, hyperacy (the ability to deal with nonlinear knowledge representations), personal information management literacy, and coping with complexity.

Researchers have taken notice of such issues regarding the concept of information literacy, but the issue of whether ICT use can enhance information literacy has also gathered their attention, and consequently some studies have been being conducted. As far as the results of these studies are concerned, it seems that they have produced mixed findings as to effects on information literacy (Scherer et al. 2017), although they have in general indicated positive effects on subject learning (Tamim et al. 2011).

In particular, according to Scherer et al. (2017), a mixture of results have been found for research on ICT use at school, and as for the use of ICT at home, its positive effects are more clear. The use of ICT at home was not previously regarded as effective to obtain information literacy, and so the importance of school education was argued, but there is now a view that the home use could be effective (Rohatgi et al. 2016). This is supported by the fact that home use has now become sophisticated (Biagi and Loi 2012; Steinkuehler and Duncan 2008). As for the effects of ICT use on information literacy, it seems that researchers' attention has recently been focused not only on school technology access but also on home technology access. Home use was much more frequently found than school use (Fraillon et al. 2013a), also making issues related to the impact of home use important to study.

Information Literacy Study in Japan

In Japan, the term information literacy has a unique and broad definition in the field of primary and secondary education, This chapter first introduces the Japanese concept of information literacy, its characteristics, measurement methods, and the influence of ICT use on information literacy. The outline and characteristics of quasi-experiments and panel studies in media influence research are briefly described. These methods have often been used for Japanese research regarding the influence of

ICT use on information literacy. While many Japanese studies have addressed some aspect of the influence of electronic media tools use (e.g., Sakamoto 2013; Takahira et al. 2012), this chapter focuses on the relationship between ICT use and information literacy and describes the background and trends in this area.

Historical Development of Information Literacy in Japan

In 1986, the Japanese concept of information literacy (*jouhou katsuyou nouryoku*) was presented by the Japanese government for the first time. Information literacy was defined as the “basic qualities of individuals necessary for independently selecting and using information and information tools” (Ad Hoc Council on Education 1986, p. 101), and the Ministry of Education, Culture, Sports, Science and Technology of Japan (MEXT) established development of these qualities as the goal of information education in primary and secondary schools (MEXT 2010).

MEXT first described and defined information literacy in 1987 (Curriculum Council 1987) and then refined its description in 1998 in terms of the following three components that remain as of 2018: (1) information competencies, (2) the ability to understand information scientifically, and (3) the ability to contribute to a desirable information society (MEXT 2010).

The first component, information competencies (*jouhou katsuyou no jissenryoku*), is defined as “the ability to independently collect, evaluate, organize, process, and create necessary information, and to send out or communicate information while taking into consideration the state of the recipient, including appropriately using information tools in accordance with issues or objectives” (MEXT 2010, p. 72). Information competencies defined for Japan seem to be similar to *information literacy* as it is widely used in other countries. Collection, evaluation, organization, processing, creation, and communication of information represent a series of activities from acquisition of information to outputting results in problem solving or research, and the abilities required for these activities are defined as shown in Table 1.

Table 1 Six components of information competencies in Japan

1. Ability to collect information (<i>syuusyu ryoku</i>): the ability to actively collect all information necessary to the objective in an appropriate way
2. Ability to evaluate information (<i>handan ryoku</i>): the ability to select necessary information from among a vast amount and evaluate it in order to draw out appropriate information
3. Ability to organize information (<i>hyougen ryoku</i>): the ability to organize information in an appropriate way with attention to how it should be expressed
4. Ability to process information (<i>syori ryoku</i>): the ability to appropriately process collected information in order to understand key information
5. Ability to create information (<i>souzou ryoku</i>): the ability to formulate and produce based on one’s own ideas and opinions
6. Ability to communicate information appropriately (<i>hassin dentatsu ryoku</i>): the ability to send out or communicate information while taking into consideration the recipient’s perspective or ability to process information

Table 2 Examples of scientific understanding of information

Understanding of:
A method to effectively, efficiently, and accurately process written character, numerical, and image data
Statistical approaches to correctly collect and analyze experimental, observational, and study data and a method of developing a model necessary to allow such statistical approaches
An effective simulation method to predict future results or to learn how different conditions can lead to different results
Human cognitive characteristics that support effective and accurate communication of information and prevention of incorrect judgment of information
The mechanism of information technology widely used in home appliances
Functional categories and characteristics of typical information tools for communicating, processing, and recording information

The second component, the ability to understand information scientifically (*jouhou no kagakuteki rikai*), is defined as “the ability to understand the characteristics of information tools, which are the basic building blocks of information use, and the ability to understand the basic theories and methods in order to not only handle information appropriately but also to evaluate and improve one’s information skills” (MEXT 2010, p. 72). It could also include knowledge and skills of information science and computer science. Table 2 lists detailed examples of scientific understanding. While information competencies focus on the ability to achieve good results through information processing activities, the ability to understand information scientifically focuses on the basic knowledge and skills that support such achievement.

The third component, the ability to contribute to a desirable information society (*jouhou syakai ni sankakusuru taido*), could be rephrased as having the knowledge and attitudes of a desirable digital citizen. It is defined as “the ability to understand the roles and influences of information and information technology in society, to consider the necessity of information morals and responsibilities for information, and to demonstrate a willingness to take part in the creation of a desirable information society” (MEXT 2010, p. 72). Note that the Japanese term *information morals* (*jouhou moraru*) covers both information ethics, such as prevention of harming others and spending unnecessary time and money with the use of ICT, and online safety, such as avoiding being harmed by others. In summary, this third component of information literacy focuses on the ability to understand the positive and negative aspects of digitization of society and to pay the necessary attention or give appropriate consideration in order to overcome the negative aspects.

This Japanese version of information literacy seems to have a unique structure and concept. First, the Japanese version emphasizes the independence of information users. This is particularly explicit for information competencies. In Japan, it has been frequently argued that Japanese lack independence and assertiveness, holding them back from playing an important role internationally. Accordingly, in the field of education, the importance of helping children and students develop independence has been frequently emphasized. The focus on independence in information literacy seems to reflect these values.

Second, the Japanese version of information literacy gives particular weight to the ability to contribute to a desirable information society or demonstration of knowledge and attitudes of a digital citizen. As mentioned earlier, this ability is one of the three components of information literacy. By way of comparison, in the new 2016 National Education Technology Standards for Students by the International Society for Technology in Education (ISTE) (2016), *digital citizenship* is one of seven standards. Japanese school education places importance on teaching students how to avoid problems caused by ICT use, and this is reflected in the weight given to the ability to contribute to a desirable information society.

Third, the Japanese version of information literacy also gives weight to the ability to understand information scientifically or to the acquisition of knowledge and skills of computer science and information science. Similarly, in the 2007 ISTE National Education Technology Standards for Students, one of the six standards called *technology operations and concepts* corresponds to the ability to understand information scientifically. However the 2016 ISTE standards no longer include this technology standard. It appears that recent situations where technological operations and concepts have been deemphasized have often also led to the use of the concept of computer and information literacy (CIL). This is defined as “an individual’s ability to use computers to investigate, create, and communicate in order to participate effectively at home, at school, in the workplace, and in society” (Frailon et al. 2013b, p. 17) and is often used in research and discussion on educational ICT use. It seems that this discussion of terminology has become necessary because researchers often want to deal with the issues of abilities including technical operations and concepts. The Japanese version of information literacy gives relatively greater weight to technical issues, and therefore it might be that Japanese information literacy and CIL can be regarded as being reasonably overlapping concepts but they are not exactly the same.

Recently, UNESCO (2017) presented an ICT Competency Framework which was jointly developed by many nations of the world. The framework addresses three different areas of competencies. The first is technology literacy, enabling students to use ICT in order to learn more efficiently. The second is knowledge deepening, enabling students to acquire in-depth knowledge of their school subjects and apply it to complex, real-world problems. The third is knowledge creation, enabling students, citizens, and the workforce they become to create the new knowledge required for more harmonious, fulfilling, and prosperous societies. Although this framework is based on viewpoints different from those of the Japanese version of information literacy, it seems that topics covered by each overlap to some extent. However, knowledge creation is one of three categories in UNESCO’s framework, which is not emphasized in the Japanese version of information literacy. The ability to contribute to a desirable information society in the Japanese version of information literacy includes some parts of this in knowledge creation, but the other two components (information competencies and the ability to understand information scientifically) do not include knowledge creation to a significant degree. The Japanese version of information literacy has concepts in common with the UNESCO framework but is not exactly the same.

Measurement and Structure of Information Literacy in Japan

Abilities can be measured through tests, observations, and self-evaluation (Christensen and Knezek 2008; Schulz-Zander et al. 2008). Measurement by tests and observations has strength in that it guarantees objectivity, but it seems that self-evaluation can also be useful for measurement of Japanese information literacy. Information competencies focus not only on the abilities to produce good results using information but also on independent information use, the latter of which can often be represented by attitudes. The ability to contribute to a desirable information society is also related to attitudes. Generally speaking, the importance of self-evaluation is high in attitude measurements (Christensen and Knezek 2008), and therefore, self-evaluation can be a useful option when researchers wish to measure a construct which has both aspects of skills and attitudes, like Japanese information literacy.

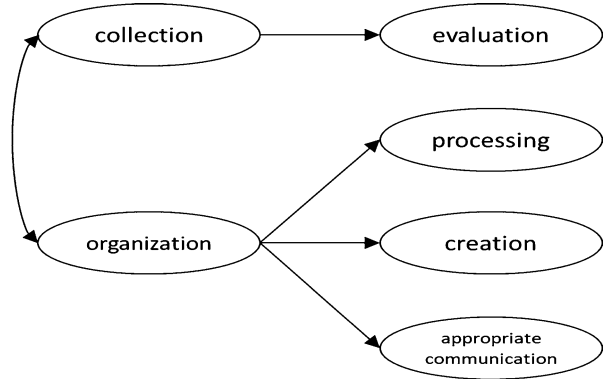

Scales for self-evaluating components of information literacy have been studied and developed. For example, Takahira et al. (2001) developed a 56-item information competency self-reporting scale. This scale covered all six components of information competencies, which include the abilities to collect, evaluate, organize, process, and create information as well as the ability to communicate information appropriately. The researchers administered the survey to 1649 junior and senior high school students and confirmed that the scale had sufficient reliability and validity. Table 3 shows example questionnaire items.

Table 3 Example statements in the scale measuring information competencies

Ability to collect information: ten items	
I ask my friends for information materials when I need them more often than collecting the materials by myself [R]	
I make myself use dictionaries when I encounter information that I do not understand	
Ability to evaluate information: eight items	
When there are opposing opinions, I always listen to both sides to understand pros and cons of each opinion	
I am not very good at finding necessary information from a large volume of materials [R]	
Ability to organize information: eight items	
After I have collected a lot of information, I make myself categorize it by content	
When I read sentences, I never underline important points [R]	
Ability to process information: eight items	
When I solve problems, I tend to draw a conclusion more instinctively than logically [R]	
I am good at identifying a common feature or a rule in information organized in charts and tables	
Ability to create information: ten items	
I am not good at coming up with opinions different from others [R]	
Once I solve a problem using a particular method, I will not try to find a better method	
Ability to communicate information appropriately: ten items	
When I have a message for someone, I try to make the message eye-catching by, for example, underlining important points	
When I talk with someone, I usually do not wonder what the other person wants to know [R]	

Note: Statements marked with [R] are reverse scoring items

Fig. 1 The structure of the information competencies

Using the scale developed by Takahira et al. (2001), Ichihara et al. (2008) examined the structure of information competencies. Ichihara et al. (2008) administered the survey to 714 junior high school students and performed confirmatory factor analysis using the obtained data. As a result, the model shown in Fig. 1 was selected due to its goodness of fit. Based on the results of this study along with others, the researchers argued that it was possible to assume two effective learning activities: (1) acquisition of the ability to collect information followed by acquisition of the ability to evaluate information and (2) acquisition of the ability to organize information followed by acquisition of the ability to process and create information as well to communicate information appropriately. They also emphasized the importance of the former activity for younger students and the latter activity for older students. Note that information competency scales have also been developed by other researchers in Japan (e.g., Okugi and Furuta 2005).

Kobayashi et al. (2000) created a 50-item scale to measure the ability to contribute to a desirable information society. This scale covered all components of the ability to contribute to a desirable information society. These researchers administered the survey to 1639 junior high, senior high, and university students and concluded that the scale had sufficient reliability and validity. They performed confirmatory factor analysis on the obtained data. Figure 2 displays the structure of the ability to contribute to a desirable information society. Table 4 lists example questionnaire items. Note that other researchers have also developed scales to measure this ability (Miyagawa and Moriyama 2011; Miyake 2005).

A wide variety of studies have been conducted using the scales previously described. For example, Mori et al. (2004) used these scales to examine the correlation between individuals' self-teaching ability, information competencies, and the ability to contribute to a desirable information society, finding high correlations. Also, Omi et al. (2004) conducted a survey of elementary school students to examine the correlation between their information competencies and intelligence. The study showed that the magnitude of correlation between information competencies and numerical intelligence was approximately $r = 0.30$, moderate in magnitude according to guidelines provided by Cohen (1988). Finally, Ando and Ikeda

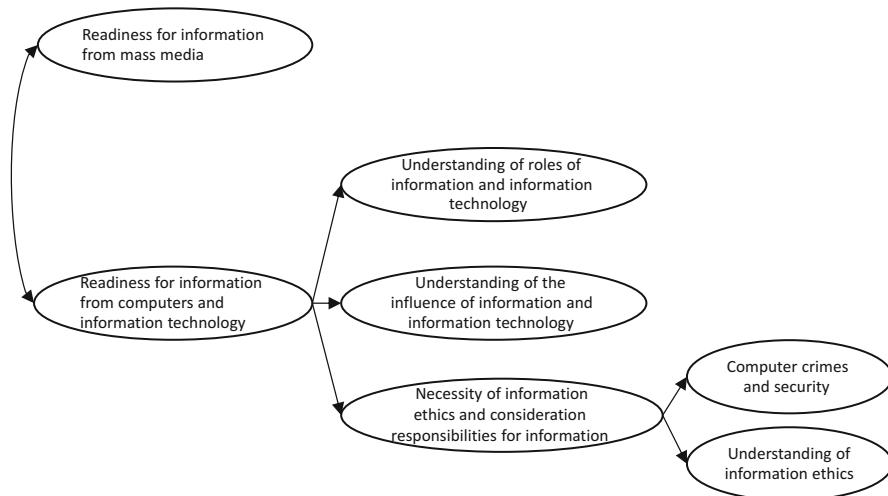

Fig. 2 The structure of the ability to contribute to a desirable information society

(2012) found that high information competencies predicted higher critical thinking skills in follow-up assessments 5 months later.

Empirical Research on the Influence of ICT Use on Information Literacy in Japan

Japanese junior high schools have a technology and home economics class, which includes an information education module. Japanese senior high schools have a class dedicated to information education. These classes are designed to develop students' ability to understand information scientifically, which is a component of information literacy. Meanwhile, students cannot acquire the other two components of information literacy, which are information competencies and the ability to contribute to a desirable information society, through these classes alone; they need hands-on experience with ICT while studying a wide variety of school subjects and engaging in school activities. MEXT has provided detailed examples of activities using ICT, which should be provided in each school subject in order to improve students' information literacy (MEXT 2002). Table 5 shows examples of activities for a science class.

As previously described, the use of ICT is considered important for the development of information literacy. The Japanese government therefore has promoted the introduction and use of ICT in schools, and whether or not ICT use actually improves students' information literacy, information competencies, and the ability to contribute to a desirable information society in particular has become an important research area. The following sections introduce quasi-experiments and panel studies conducted on this theme.

Table 4 Example statements in the scale measuring the ability to contribute to a desirable information society

1. Understanding of roles of information and information technology
I am not interested in studying computer programming [R]
I want to actively use computers to make my daily living more convenient
2. Understanding of the influence of information and information technology
(a) Issues regarding a computer-dependent society
I want to understand issues regarding a computer-dependent society
I am not interested in the influence of computers on the human body [R]
(b) Influence of mass media on society
I try not to let commercials influence my purchasing decisions
I am easily influenced by opinions introduced on TV, in newspapers, and in magazines [R]
3. Necessity of information ethics and consideration of responsibilities for information
(a) Understanding of information ethics
1. Information ethics and manners
I often give information to others even though I am not sure of its correctness [R]
I do not want to post information on the internet that may make viewers uncomfortable
2. Privacy
I disclose my friends' street addresses and phone numbers without their permission [R]
I do not want to view websites containing content that violates someone's privacy
3. Copyrights
If I can copy game software such as video games, I will do so without hesitation [R]
I want to understand the Copyright Act properly
(b) Computer crimes and security
I hope technology that allows safe online information exchanges will develop further
I admire hackers (people who infiltrate others' computers via networks) [R]

Note: Statements marked with [R] are reverse scoring items

Table 5 Examples of science class activities that improve students' information literacy

Tabulation, processing, and drawing graphs of observational or experimental data using a computer and discovering a new rule in the processed data
Quantification of natural events and changes and performance of experiments, including measurement and control, using a computer
Consideration of a causal relationship within an event through simulation
Searching for information on natural events and objects using a computer or the internet
Exchanging information on nature or the environment via the internet

Quasi-experiments

A randomized experiment is a powerful method to determine a causal relationship between independent and dependent variables by controlling extraneous variables. It is however not realistic to implement a randomized experiment to examine the educational effect of ICT use on Japanese primary and secondary school students. In a randomized experiment, participating students are first divided into groups, and

each group is subject to a different educational intervention. Should a randomized experiment be conducted, it usually involves a short-term intervention or a small number of participants. It has been pointed out that many studies on the effect of ICT use face this experimental limitation (Pérez-Sanagustín et al. 2016).

A quasi-experiment is an experimental method that overcomes the issues of randomized experiments by sacrificing some control of extraneous variables. Studies on the influence of ICT use on information literacy should examine long-term effects, and their results need to be generalizable to a wide range of student categories. These criteria provide a strong rationale for selecting a quasi-experimental approach. Extraneous variables are not fully controlled in a quasi-experiment, and it is therefore important to discuss and nullify an alternative interpretation that interferes with the determination of a causal relationship between independent and dependent variables.

For example, a quasi-experiment to examine the influence of a use is viable when (a) changes in participants between before and after the diffusion of the subject media tool in one area (treatment condition) are compared to (b) changes in participants in areas where the same media tool has already been or does not take place (control condition) within the same period of time. One of the well-known quasi-experiments is by Harrison and Williams (1986) where researchers measured creative thinking skills, spatial perception skills, and the vocabulary size of children at two different time points in a town with no television (Notel condition), a town with only a single TV channel available (Unitel condition), and a town where all TV channels were available (Multitel condition). TV was introduced to the Notel town between the first and second measurements. Analysis of the obtained data indicated that, although children in the Notel condition had higher creative thinking skills than their counterparts at the first measurement, such skill difference was no longer observed at the second measurement. The study suggested that TV viewing may have been responsible for the decline of creative thinking skills.

In the field of information literacy, Naito et al. (2003) conducted a quasi-experiment to examine whether or not the use of high-speed internet improved students' information competencies. In one region of Japan, high-speed internet was introduced to three schools (treatment condition) and was not introduced to two schools (control condition). These five schools existed in very similar environments, and Naito et al. (2003) compared the changes in students' information competencies between treatment and control schools. The pre-post change score was computed by subtracting the students' information competency score measured before the high-speed internet was introduced from the score after it was introduced. The interval between measurements was 6 months. The data analysis indicated that the change score was significantly more positive for the treatment schools than for the control schools. This result suggests that internet use at school may contribute to improvement of information competency. The result also supports the study by Underwood et al. (2005) on the effectiveness of high-speed internet.

Naito et al. (2003) also compared the six components of information competencies – the ability to collect, evaluate, organize, process, and create information as well as the ability to communicate information appropriately – between schools with

and without high-speed internet. Except for the ability to create information, the scores of pre-post change were more positive at the schools with the high-speed internet than those without it.

In a quasi-experiment by Naito et al. (2003), students' information competencies were measured twice, before the high-speed internet was introduced and once after the introduction. The interval between the two pre-introduction measurements was 6 months. These two measurements allowed controlling for the baseline changes between the two conditions (Shadish et al. 2002). As a result of analysis, the information competency score between the two conditions showed no changes in the two pre-introduction measurements. The difference score changed rapidly after the introduction, however, and this difference could not be explained by any changes observed prior to the introduction of high-speed internet. Such nullification of alternative explanations strengthens the argument that the introduction of high-speed internet influenced information competencies in students.

Kashibuchi et al. (2003) conducted a quasi-experiment on the ability to contribute to a desirable information society, one component of information literacy. Similar to the study by Naito et al. (2003), Kashibuchi et al. (2003) measured students' ability to contribute to a desirable information society. These students were from junior high schools with or without high-speed internet. Changes in the ability score difference between the two conditions were compared before and after the introduction of high-speed internet. The result of the analyses indicated no differences between the two groups in their changes over time. Therefore, high-speed internet use was deemed unlikely to have influenced students' ability to contribute to a desirable information society in the Kashibuchi et al. (2003) study.

Panel Studies

In addition to quasi-experiments, panel studies have been used to examine the influence of ICT use on information competencies and the ability to contribute to a desirable information society. A panel study is a type of longitudinal study in which the same set of participants is measured in the same way multiple times with a certain time interval. For example, to examine the influence of media tool use, participants are measured multiple times for their exposure to the subject media tool and the outcome variables, such as cognitive skills or aggressiveness, which may be influenced by the use of the media tool. As with quasi-experiments, panel studies allow estimation of a causal relationship to some degree (Markus 1979; Finkel 1995).

Markus (1979) popularized panel studies by using the technique to address questions such as whether political party membership in the USA tends to influence positions on issues or whether positions on issues tend to influence party membership. As for the research of media impact, the application of similar methodology has been found in earlier periods in research such as the Sesame Street evaluation study which confirmed a positive impact of viewing this young children's television program on school readiness skills (Bogatz and Ball 1971; Searcy and Chapman

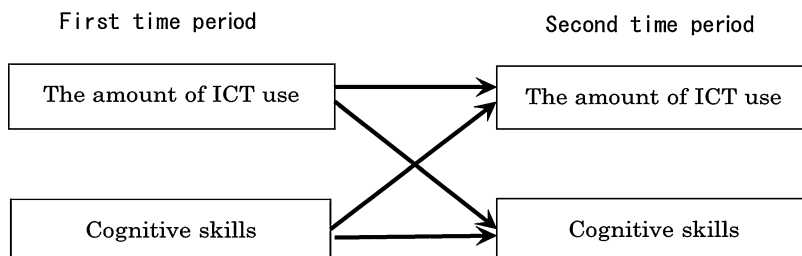

Fig. 3 The cross-lagged effects model of ICT use and cognitive skills

1972). Christensen (2002) gathered and analyzed panel study data to show that needs-based professional development for technology integration in teachers fosters more positive attitudes toward computers in their students. One major advantage of the panel study method is that it allows causal inference without a laboratory-type experimental design. In the field of educational science concerning ICT use, it seems so far that there have been only a small number of studies that examined causal relationships using panel study data.

Figure 3 shows a typical analysis model created for examining the causal relationships between the amount of ICT use and cognitive skills at two different time points. This model is called a cross-lagged effects model. If analysis using this model indicates that the path from the amount of ICT use measured at the first time point to cognitive skills measured at the second time point is significant, a causal relationship of ICT use influencing the cognitive skills is regarded as being supported. Unlike panel studies, on the other hand, cross-sectional correlation studies that require only a single measurement cannot fundamentally determine causal relationships (Prot and Anderson 2013).

Some Japanese panel studies examined the influence of ICT use on information literacy. For example, Takahira et al. (2007) examined the influence of ICT use on information competencies. They measured the amount of daily internet use at school and home and information competencies of 702 students from eight elementary schools. Measurement was performed twice with a 2-month interval, and the two sets of data obtained at different time points were analyzed using the cross-lagged effects model. The result indicated that internet use had a significant effect on improving information competencies of elementary school students, and among the components of information competencies, the ability to collect information improved the most. Internet use also had a positive effect, although weak, on the abilities to evaluate and organize information. The study further indicated that information competencies as a whole and the ability to collect information promoted internet use. The researchers developed and used a scale appropriate for elementary school students based on the scale developed by Takahira et al. (2001) for use by junior and senior high school students.

Another example is a panel study by Takahira et al. (2003) of 675 students from nine junior high schools. This was a two-wave study with a 5-month interval, and researchers measured the amount of internet use at home. Analysis of data indicated

that home internet use had a significant effect on improving the ability to collect information but no other information competency components. In addition, as with the case of elementary school students, the researchers found that the ability to process information promoted internet use and the ability to communicate information appropriately promoted email use. Takahira et al. (2002) also conducted another study of 201 senior high school students. Again, they measured the amount of internet use at home. The result of data analysis indicated that home internet use only had a significant effect on improving the ability to evaluate information while it weakened the ability to create information. No significant effect was observed regarding the ability to collect information.

Mouri et al. (2002) conducted a panel study to examine the effect of computer use at school. From 34 senior high schools, 2304 students participated in the study. Measurements were performed with a 6-month interval. The study showed that, while computer use influenced the ability to operate a computer, it had almost no effect on information competencies. The researchers then conducted a survey of teachers of the participating schools. They examined the level of effort that each school put into information education and reanalyzed measurement data for the schools that actively implemented information education and for those that did not. As a result, the students of the schools that actively implemented information education showed the effect of computer use as improving their ability to operate a computer and also the ability to evaluate information.

In the paper reporting the influence of internet use on information competencies of junior high school students described above, Takahira et al. (2003) also reported the influence of internet use on the ability to contribute to a desirable information society. The result indicated almost no significant effect due to internet use. It even had a significant negative effect on readiness for information from mass media. In the study of senior high school students by Takahira et al. (2002) described above,, internet use also showed almost no significant effect on their ability to contribute to a desirable information society.

The Causal Relationship Between ICT Use and Information Literacy

Only a few extensive evaluation studies have recently been conducted to analyze the causal relationship between ICT use and information literacy. This maintains the relevance of earlier evaluation studies. There are some possible reasons for the decline in the number of evaluation studies. First, current educational science thinking places importance on practicability of studies. This may deter researchers from conducting scientific evaluation studies. Second, it has become difficult to obtain the permission of schools to conduct evaluation studies with students due to human rights concerns. However, some studies in other regions of the world have produced findings with causal inference, and at least one large-scale study has been conducted across nations that tends to provide correlational evidence relevant to findings with causal inferences previously reported. For example, the European

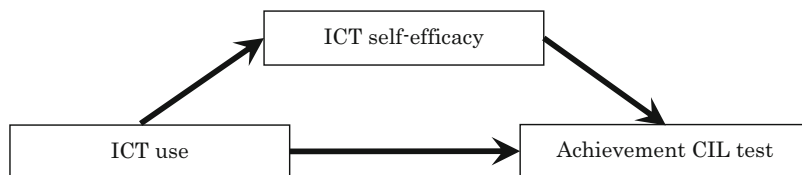

Fig. 4 Indirect effect of ICT use on computer and information literacy (CIL) achievement via ICT self-efficacy (Source: Adapted from Rohatgi et al. 2016, p. 107)

Commission's ET2020 strategy framework identified the innovative use of ICT as a priority and catalyst for achieving transformation in education (Brecko et al. 2014).

In another large-scale analysis, Rohatgi et al. (2016) analyzed Norwegian data obtained from the International Computer and Information Literacy Study (ICILS) in 2013 ($N = 2410$ students in grade level 9) and found through structural equation modeling that there is an indirect effect of ICT use on computer and information literacy (CIL) achievement via ICT self-efficacy (Fig. 4). The indirect effect was significant and positive for students' ICT use for task learning via basic ICT self-efficacy ($\beta = 0.03$, $p < 0.001$), with similar but stronger effects for recreational uses of ICT and basic ICT self-efficacy ($\beta = 0.07$). For students' ICT use for study purposes, the indirect effects were not significant. By way of contrast, none of the direct effects of ICT use on CIL achievement were significant at the $p < 0.05$ level. Rohatgi et al. (2016) viewed these findings as strong support for the indirect effect of ICT use on computer and information literacy achievement, via ICT self-efficacy.

Brecko et al. (2014) polled 149 educational stakeholders to evaluate a set of 60 policy recommendations developed during the "Up-Scaling Creative Classrooms in Europe" (SCALE CCR) project of the European Commission, in order to produce seven clusters of recommendations and a top ten list. Under the infrastructure cluster was the third recommendation, to "ensure that all learners have equal and ubiquitous ICT access, in and out of school" (p. 5). These recommendations by EC educational stakeholders reinforce the implications of the research by Rohatgi et al. (2016) that access to information technology outside of school appears to be critical for fostering high computer and information literacy in many parts of the world.

Summary of Insights Regarding ICT Use and Information Literacy

The results of quasi-experiments and panel studies introduced in this chapter, in the context of relational studies or expert opinion compendiums from other regions of the world, lead to the following insights.

First, both quasi-experiments and panel studies indicate that ICT use can improve information competencies. In particular, the abilities to collect and evaluate information can be improved by even daily internet use, as suggested by the panel study results. To heighten information competencies, therefore, promotion of ICT use should be effective. This could support such recent international frameworks and

orientations on information education and recent findings of major research on educational ICT use as previously mentioned. This can also be regarded as providing evidence of causality underlying those frameworks and orientations.

Second, unlike for information competencies, ICT use was not found to improve the ability to contribute to a desirable information society. More frequent ICT use of course tends to cause more information ethics issues and online safety problems. As far as the study results are concerned, however, it is quite unlikely that individuals can naturally acquire high-level information ethics and online safety just because they use ICT. This means that students who start or increase the use of ICT must be provided with education designed to improve their ability to contribute to a desirable information society, with a special emphasis on information ethics and online safety.

Third, quasi-experiments and panel studies produce different results. While the quasi-experiments indicated that ICT use could promote the majority of components of information competencies, the panel studies suggested that ICT had a limited effect. This may be explained by the fact that ICT use measured in the quasi-experiments was a part of class or school activities with an educational purpose. In fact, it has been suggested that giving educational meaning to ICT use is important to heighten its effect (Condie and Munro 2006). On the other hand, positive effects detected by the panel studies existed, even if they were limited. As mentioned in the first section of this chapter, it seems that researchers have documented the positive effects of ICT use not only at school but also at home (Scherer et al. 2017). Actually, the sophistication of ICT use at home has been observed (Biagi and Loi 2012; Steinkuehler and Duncan 2008), and additionally some research results which suggest the importance of home use have been presented (Brecko et al. 2014; Rohatgi et al. 2016). It therefore seems that the results of panel studies do not contradict international expectations and findings on ICT home use. Fraillon et al. (2013b) showed that (a) ICT use was much more frequent at home than any other place, (b) the amount of ICT use at home was positively correlated with CIL, and (c) the amount of ICT use at school was also correlated with CIL. This suggests that if children learn the appropriate use of ICT at school, it could lead to the appropriate use at home, and consequently CIL would be improved. Future studies should examine the types of usage of ICT at home that have positive educational effects and how the effects of home use can be enhanced through school education,

Fourth, according to the results of the panel studies presented in this chapter, the effect of ICT use on information competencies may vary with user age. More specifically, it seems to be the most effective on elementary school students and the least effective on senior high school students. The effect on junior high school students is in the middle. These study results match the traditional argument that the effect of ICT use is strong on elementary school students and weak on secondary school students (Balanskat et al. 2006). Components of information literacy that are influenced by ICT use may also vary with user age. In the panel studies of elementary and junior high school students, ICT use improved their ability to collect information. In similar studies of senior high school students, on the other hand, ICT use improved their ability to evaluate rather than collect information. Generally

speaking, if individuals are unable to collect much information, they will have only limited opportunities to evaluate the quality of information, and this may prohibit improvement of the ability to evaluate information. The elementary and junior high school students participating in the panel studies may have shown the effect of ICT use on only the ability to collect information because they had little experience with ICT at the time of study, while the senior high school students may no longer have shown the effect on the ability to collect information but, instead, the ability to evaluate information, which is supported by the ability to collect information, because they already had it established through their earlier experiences.

Fifth, among information competencies, the ability to create information was found unlikely to improve through ICT use. Both the quasi-experiments and panel studies failed to show any improvement. Different studies that measured the ability to create information through tests also failed to find any effect of ICT use (Sakamoto and Sakamoto 1993; Sakamoto et al. 1998). Whether or not ICT use improves the creativity of users has been discussed for a very long time. While optimistic opinions have been presented frequently (Clements 1995; Loveless 2002), some still argue that sufficient testing is necessary (Scherer 2016). As far as the Japanese study results are concerned, it seems to be difficult to have an optimistic view toward the effect of ICT use on creativity. Given that it is not easy to improve creativity, it would seem particularly important to consider educational approaches to improving it.

Finally, the panel studies often indicated a reverse causal relationship in which information competencies promoted ICT use. Students' attitudes toward using ICT and their ICT skills have been found to be important in promotion of ICT use (Knezek and Christensen 2008). The result of Japanese studies suggests that like attitudes toward ICT skills and ICT skills themselves, information competencies could be included in the set of student variables that promote ICT use.

Conclusion

Researchers' interest in the educational impact of ICT use has a long history, and this issue has been studied in Japan as well as other countries. Quasi-experiments and panel studies have often been used in Japan, and these methodologies have strength in the identification of causality. This chapter reported the findings of Japanese research on the impact of ICT use on children's information literacy, while aligning the concept of information literacy in Japan with its major concepts in other countries. Japanese researchers have presented many research results which indicate positive effects of ICT use on information literacy. In particular, positive effects on the ability to collect information from a lot of resources and to appropriately evaluate the authenticity and value of each piece of information have often been identified. Japanese research has also indicated that not only ICT use at school but also the use at home could have positive effects, and therefore home use cannot be ignored. These findings are consistent with current international orientations on the issue of the educational impact of ICT use and also provide strengthened evidence of

causality. It seems that research on the impact of home use becomes necessary to be continued worldwide. If so, quasi-experiments and panel studies would be options for the research, and Japanese research studies could also be referred to as a sample of these methodologies.

Abstract

Information Technology (IT) has developed into an effective teaching media available to educators. Research evidence clearly indicates that the effective use of IT-based tools by teachers leads to the enhancement of elementary and secondary school students' learning achievement and all-round educational performance.

However, effective utilization of IT-based tools by teachers for the benefit of their students is almost totally dependent on the existence of relevant constructs in teachers' and students' affective arsenals. Constructs that characterize teachers such as teacher change, teacher knowledge, and pedagogical beliefs as well as

affective constructs that typify both teachers and students such as autonomy, creativity, flexibility, motivation, satisfaction, and self-efficacy (that includes technological self-confidence) are vital tools in the repertoire of teachers and students needed to maximize the positive effect of IT-based tools in the classroom.

Educational administrators need to formulate pre-service as well in-service teacher training programs that include the enhancement of those constructs needed to successfully mediate the efficient use of IT-based tools that will conceivably lead to the promotion of student achievement and all-round performance in the educational process.

Keywords

IT enhanced teaching · IT enhanced learning · Psychological constructs of teachers · Psychological constructs of learners

Introduction

Information Technology (IT) has gradually become an indispensable educational medium. Since the 1960s when the first attempts were made to implement mass IT-based instruction in the educational system, teachers have accumulated valuable experience that has increased the potent use of IT-based tools as a teaching and learning medium. Achievement levels attained by students have gradually and moderately improved as a result of the use of IT-based tools in the teaching and learning processes, and there is increasing evidence that the efficient use of IT-based tools by teachers is related to teaching variables such as teacher change, teacher knowledge, and pedagogical beliefs of teachers as well as to affective variables, such as autonomy, creativity, flexibility, motivation, and self-efficacy (including technological self-confidence) of both teachers and students (Katz 2014a).

This chapter will address the relationship between IT-based tools used in teaching and learning and enhanced educational achievement as well as the mediating contribution of key variables demonstrated in numerous studies to contribute significantly to the effective use of IT-based tools in teaching and learning. The key variables related to effective teaching with IT-based tools include teacher learning and knowledge about educational technology (Riel and Becker 2008) as well as teacher change, teacher self-efficacy, and pedagogical beliefs of teachers (Ertmer and Ottenbreit-Leftwich 2010). In addition, research evidence has indicated the existence of key affective variables associated with effective teaching and learning, such as autonomy, creativity, flexibility, motivation, satisfaction, and self-efficacy (including technological self-confidence) of both teachers and students (Katz 2014a). The different uses of IT-based tools will be addressed as they relate to the development and implementation in the educational system. One needs to bear in mind that teachers utilizing IT-based tools for their teaching usually use a number of IT-based tools, depending on the specific characteristics of the content being taught as well as the specific needs of the students. Thus the evolution of the different types and levels of IT-based tools generally used by teachers will be described in the first

section of the chapter. Thereafter the relationship of the aforementioned variables, such as teacher change, teacher knowledge, pedagogical beliefs of teachers, as well as autonomy, creativity, flexibility, motivation, satisfaction, self-efficacy (that includes technological self-confidence), of both teachers and students regarding the use of IT-based tools and the mediating power of these variables and their contribution to the enhancement of students' performance and their positive feelings towards their studies will be examined in the second section of the chapter.

IT-Based Tools

IT-based tools can be divided into two distinct categories. The first category consists of those tools that are confined to predefined and inflexible teaching that is based on offline software packages uploaded onto computers and used by teachers and students in the classroom. These tools deliver subject matter and are based on the software present on the computers at the disposal of teachers and on the ability of teachers to efficiently use the software for their teaching. The second category is characterized by the use of flexible IT-based tools mainly imported via online Internet access where the teachers' role is to facilitate students' use of the Internet delivered content rather than to directly instruct the students. Following are overviews of the two categories of IT-based tools.

Evolution of IT Teaching and Learning Tools

The evolution from inflexible or preset ("closed") or flexible ("open") IT-based tools ran parallel to the introduction of different learning approaches in the educational system (van Rooij 2009). Beginning with the behavioristic approach associated with the use of totally inflexible "closed" IT-based tools, through the introduction of more flexible "open" IT-based tools explained by the constructivist approach to learning, culminating with advanced and totally "open" IT-based tools backed by cognitivist and social learning approaches, the centrality of IT in the educational system was entrenched.

Skinner (1958) was among the first researchers to address the implementation of IT-based tools in education and published a study in which he described teaching machines and cautiously predicted that these machines would make teaching dramatically more efficient. The first computers introduced into the educational systems in the developed world in the 1960s and 1970s were minicomputers with individual terminals available for use by students. These minicomputers utilized software used by teachers in order to assist their students to perform drill and practice as well as for evaluation of students' progress and achievement in language and mathematics (Kuiper and de Pater-Sneep 2014). These systems were totally inflexible, i.e., closed, with teachers unable to effect any changes in the computer software and served as teaching aids that complemented traditional classroom lessons. Teachers diligently followed students' progress in language and mathematics as mapped out by the computer software and planned their traditional language and mathematics lessons

accordingly. The minicomputer system with terminals was widely used and popularized the initial use of IT in the educational systems in the developed world.

Drill and Practice

When the first generation of personal computers became commercially available in the developed world, Apple IIs, Ataris, and Commodore CBMs personal computers connected in rudimentary networks, began replacing the minicomputers and terminals in the school systems. Teachers closely followed inflexible computerized syllabi in a limited number of subjects, among them languages, mathematics, and science. This generation of PCs also drew on behavioral theory (Bryant and Hunton 2000) and the software packages offered to the educational systems were used to complement traditional teaching and were considered to be especially advantageous in providing students with a robust platform for revision after learning via traditional teacher-student face-to-face instruction.

Spreadsheets

Educational researchers began questioning the validity of totally behaviorist learning (such as drill and practice) as a valid theoretical source and inspiration for IT use in the educational system. Additional questions were raised that addressed the relative advantages, effectiveness, and cost-efficiency of inflexible “closed” IT-based tools used in drill and practice. Heated debates characterized the educational establishment regarding the direction to be taken in the use of IT-based tools in the educational system and as a result of these debates other theoretical approaches were suggested. Thus, constructivist theory came to the forefront in the developed world, albeit alongside the behaviorist approach (Salomon 1996), and led to the gradual development and adoption of more flexible use of “open” IT-based tools and learning programs that were introduced into the educational systems. For example, in Israel the use of electronic spreadsheets (Dreyfus et al. 1997) was introduced using IT-based tools that, to a certain extent, enhanced students’ autonomy and creativity and provided them with sophisticated graphic assistance that contributed to added understanding of complicated subject matter. Databases, which were also developed and incorporated in this stage of development of IT-based tools (Appelberg 1997), provided students with the opportunity of enriching their knowledge and comprehension of subject matter by facilitating the search for sources hitherto available only in libraries and museums. Aydin (2005) noted that the introduction of the use of spreadsheets and databases in the educational process contributed to the introduction of improved IT-based tools in education leading to enhanced teaching and learning.

Simulation

As time passed and IT became more developed and sophisticated, the constructivist learning model almost totally replaced the behaviorist approach and motivated the introduction of simulation software into developed educational systems. For example, Kaufman and Ireland (2016) described simulation technology as a sophisticated and enhanced methodology that utilizes IT-based tools designed to generate situations similar to those that exist in reality and to introduce these situations into the

instructional and learning processes. They noted that educational technology simulations are based on dynamic interaction between the learner and the instructional computer program and may be defined as part of a modeling process that involves the execution of the model by the learner. Through the methodology of simulation, teachers were able to provide their students with realistic models of subject matter thereby facilitating students' understanding and mastery of learning. Wang et al. (2014) cited simulation as especially effective for the science and technology subjects where experiments can be conducted using IT-based tools instead of having to prepare and use materials in the traditional science or technology laboratory.

Delialioğlu and Yildirim (2007) indicated how the use of IT-based tools contributed to enhanced cognitivist learning and to students' use of higher order thinking skills in the learning process. Baran and Maskan (2013) confirmed that the achievement of students who experienced instruction and learning via simulation with IT-based tools was usually on a par with or even outstripped achievement of students exposed solely to teaching and learning situations that did not simulate reality.

Virtual and Augmented Reality

Additional IT development in educational systems focused on virtual reality and augmented reality technologies, closely associated with cognitivist learning (Lúcia and Rubens 2004). Tiala (2007) defined virtual reality technology as a highly interactive IT-based environment in which the user becomes a fully-fledged partner in a virtual world. When experiencing virtual reality, the user becomes an immersed participant in the technology generated virtual reality program. Psotka (2013) confirmed that upon entry into the virtual world students feel physically immersed in that world and undergo physical, cognitive, and emotional experiences very similar to those that exist in the real world in which they live. He added that the use of virtual reality technology in instruction positively contributes to enhanced cognitive performance of learners. Thus virtual reality with advanced IT-based tools provides both cognitivist learning and understanding that surpass achievement characterized by more traditional approaches (Zinchenko et al. 2010).

Augmented reality was developed as an offshoot of virtual reality (Bacca et al. 2014) and even further enhances cognitivist learning. An augmented reality system allows for combining or supplementing real world objects with virtual objects or superimposed information. As a result virtual objects seem to coexist in the same space with the real world (Azuma et al. 2011). However, augmented reality is not restricted only to the sense of sight; it can be applied to all senses such as hearing, touch, and smell. Augmented reality allows for combining virtual content with the real world, thereby differing from the notion of a virtual reality environment where the user is completely immersed inside a synthetic environment (Azuma et al. 2011). In this sense, augmented reality supplements reality, rather than completely replacing it and is better equipped to enhance constructivist learning where the learners are able to utilize all their physical and cognitive faculties in their thinking processes. According to Azuma et al. (2011), augmented reality has been shown to enhance students' learning and achievement.

Internet-Based Learning

A further breakthrough in the use of IT in educational settings occurred with the development of IT-based tools delivered via the Internet as well as distance learning. Internet-based distance learning provides students in the educational system with new opportunities to study efficiently when the location where teaching originates may be separated by geographical distances from the learning centers. Instructional activity through the medium of Internet-based learning systems was redefined to include and focus on teaching and learning based on teacher-student interaction (Johnson 2006). Interaction through the medium of Internet or Intranet offers one-to-one or one-to-many interaction in which teachers and students are able to communicate synchronously or asynchronously thereby solving key instructional and learning problems.

Tsai (2004) proposed that Internet-based learning provides an adequate context that facilitates the development of evaluative standards by learners. The standards are used to judge the information and knowledge acquired from online environments. Tsai found that students who were exposed to sophisticated Internet-based teaching and learning perceived an increase in their learning potential and an enhancement of their ability to process content and to access valuable learning resources. Abdallah (2009) indicated that the latest Internet-based teaching and learning strategies contribute to improved quality of students' learning and provide students with content and resources that are easily accessible. In summary, research evidence indicates that creating, sharing, and knowledge capitalization are all efficiently and effectively facilitated by Internet-based student-centered teaching and learning packages.

Mobile Learning

Mobile learning, a specific development of Internet-based learning, offers a learning environment that is especially characterized by flexibility offered to the learner as it is not bound by space or time (Katz 2014a). It should be noted that the use of mobile learning provides enhanced technological possibilities on small hand-held devices such as Ipads, tablets, and smartphones which include among other features, text, voice, still-camera, video, paging, and geo-positioning capabilities. These tools provide a rich variety of IT-based delivery strategies that enhance teaching and flexible student-centered learning. Rui-Ting et al. (2014) indicated that mobile learning contributes significantly towards a more comprehensive cognitive educational environment for learning and confirmed that mobile learning has become an appropriate and key student-centered and self-regulatory learning channel in the educational system.

Mobile learning particularly provides opportunities to teach and learn through social networks (Kapuler 2011). Recent studies have indicated the increasing effectiveness of the contribution of social networks to the learning process. Alvarez and Olivera-Smith (2013) concluded that learning via social networking is positively received by students and contributes to an enhancement of student cognitive performance in the learning process. They added that social networks afford ample and potentially effective opportunities to improve student self-regulated learning at both

school and university levels. Katz (2014a) indicated the relative efficiency of SMS, Facebook and WhatsApp delivery of learning as well as students' relative preferences regarding the different social network learning delivery platforms.

A number of research studies have indicated that students' academic achievement is positively related to the use of delivery platforms suited to mobile learning. Ituma (2011) confirmed that students who were enrolled in courses where learning was delivered by mobile applications had positive perceptions of the learning process and Chandra and Watters (2012) confirmed that learning physics through the medium of mobile learning delivery enhanced students' understanding of the content matter as well as learning outcomes.

It appears that the different types of IT-based tools that were developed over the years and described above lend themselves to enhance learning processes. As these tools developed and the learning platforms became more sophisticated, learning became more student-centered and led to student self-regulation, which in turn promoted student achievement and learning outcomes.

Interaction of Constructs with IT-Based Learning

After reviewing the literature dealing with evolving aspects of IT-based tools as presented in the previous section of this chapter, this section addresses the relationship between constructs characterizing teachers, on the one hand, and efficient and effective utilization of the IT-based tools mentioned in the previous section on the other. Evidence from research studies that examined the relationships of general and affective constructs and their contribution to the promotion of positive and effective IT-based teaching will be presented. Emphasis will be placed on constructs scientifically known to have significant relationships with the use of IT-based tools. General constructs are defined as those that are related to teaching and pedagogy and affective constructs may be defined as those variables that lend themselves to the enhancement of student cognitive activity and learning (Katz 2014b). Motivation is a typical example of an affective variable that is significantly related to the enhancement of learning. Thus the relationship between constructs and the use of IT in learning will be discussed in this section of the chapter.

Constructs and Learning with IT-Based Tools

Katz (2014a), among others, testified to the existence of constructs characterizing teachers at elementary and secondary school levels that contribute to the efficient utilization of IT for educational purposes. Teachers willing to use IT are typified by quite a large number of general constructs, most especially teacher change, teacher knowledge and pedagogical beliefs (Riel and Becker 2008; Ertmer and Ottenbreit-Leftwich 2010). In addition, Katz (2014a) indicated both teachers and students are characterized by affective constructs such as autonomy, creativity, flexibility, motivation, satisfaction, and self-efficacy (including technological self-confidence). Teachers characterized by positive attitudes toward some or all of these constructs have been more effective and efficient in their use of different IT-based tools than teachers not characterized by affective variables

and students typified by the some or all of the affective constructs have reached enhanced learning and achievement levels. A sample of these research studies are presented below.

Teacher Change, Teacher Knowledge and Teacher Pedagogical Beliefs

Drent and Meelissen (2008) confirmed that teachers in elementary and secondary schools, who are characterized by certain constructs, are favorable towards the use of IT-based tools in the teaching process and that positive integration of IT in classroom teaching and learning is highly dependent on the existence of these constructs. Riel and Becker (2008) indicated that teacher knowledge about the use of IT in their teaching as well as ongoing teacher collaboration in developing IT knowledge and skills for effective teaching are necessary preconditions for the efficient utilization of technology in teaching. Ertmer and Ottenbreit-Leftwich (2010) described how teachers' positive attitudinal change towards the use of IT-based tools in their teaching as well as teachers' pedagogical beliefs about the added value of the use of IT in their teaching are essential prerequisites for effective use of IT in the educational process. They added that it is critically important that teachers believe in their own abilities to implement these changes within their classrooms. Teachers who positively strengthen their pedagogical beliefs and adopt the notion that effective teaching includes the use of IT-based tools also need to be reinforced with evidence that student thinking and learning processes as well as achievement are significantly enhanced by the use of IT-based tools in teaching and learning.

Additional research studies have indicated that teachers and students who hold positive perceptions of their autonomy, creativity, flexibility, motivation, satisfaction, self-efficacy (including technological self-confidence) are significantly more positive towards the utilization of IT-based tools in their teaching and learning than those who do not hold similar affective constructs.

Autonomy

Webb and Cox (2004) contended that the move from teacher centered to student centered pedagogy depends significantly on the level of autonomy of the teacher and the ability of the teacher to adapt teaching to the use of IT-based tools. Tijdens and Steijn (2005) found that autonomy of both teachers and learners is one of the key factors contributing to the ability of the learner to master learning material when using IT-based tools. Granic et al. (2009) added that teacher and learner autonomy is a significant factor that contributes to effective use of technology-based mobile learning. Katz (2014a) confirmed the relationship between teacher autonomy and learner autonomy and effective utilization of technology in the teaching and learning processes. Thus autonomy characterizing both teachers and students can be

considered as an important construct that serves as a prerequisite for effective and enhanced teaching and learning with IT-based tools.

Creativity

According to Henriksen and Mishra (2015), creative teachers show a willingness to try new things and use innovative educational approaches such as the harnessing of IT-based tools in their teaching. As a result of teachers' creative use of IT, students tend to be enthusiastic in their studies and are able to acquire the skills necessary for success in problem solving and applying knowledge (Zhao 2012). Henriksen et al. (2016) contended that the use of creative approaches by teachers fosters new methods of utilizing IT for pedagogical purposes, and in a reciprocal way, IT in teaching can stimulate and expand teacher and student creativity.

Peterson and Harrison (2005) postulated that the ability of the teacher to foster a creative atmosphere in the classroom contributes significantly to the creativity of students and enhances their effective use of IT-based tools in learning. Hosseini (2014) confirmed that teachers, characterized by their ability to promote a creative atmosphere among their students in their classrooms, contributed significantly to the enhanced and effective use of IT by students in their learning processes.

Thus the use of IT-based instruction and learning in the classroom is highly dependent on the creativity of both teachers and students as well as on the ability of the teacher to foster a creative atmosphere in the classroom. Creativity is a focal affective construct positively related to effective use of IT-based tools in the classroom.

Flexibility

Ravitz and Becker (2000) indicated that teachers who embrace flexible teaching philosophies are more positive towards the use of IT-based tools in their teaching. Himsworth (2007) studied the relationship between the use of IT by teachers in their teaching practices and their pedagogical beliefs. Results of the study indicated that teachers whose pedagogical beliefs were more flexible and democratic in nature use IT-based tools in their teaching more frequently than teachers who have more traditional pedagogical and authoritative beliefs. These results were later confirmed by Ertmer and Ottenbreit-Leftwich (2010). Ying-Shao et al. (2007) reaffirmed that flexibility is a defining factor in teachers' ability to more readily use IT-based tools in their teaching and classroom practice and to enhance the flexibility of their students in the cognitive and learning processes. Malik (2009) described the twenty-first century teacher as one who flexibly imparts education and helps students to adopt flexible learning strategies, especially when using IT-based tools. Hsu (2016) confirmed that teachers who hold flexible pedagogical beliefs as well as positive attitudes toward flexible innovation in students' thinking and learning are highly disposed towards the use

of IT-based tools in their teaching and more significantly stimulate the cognitive and learning processes of their students.

Thus the affective flexibility construct is significantly related to teaching with IT and to the enhancement of students' flexibility in the learning process.

Motivation

Katz (2014a) confirmed that the use of IT-based tools by teachers provides them, as well as their students, with teaching and learning opportunities that motivate them to more effectively address the study material than traditional instruction that does not utilize IT-based tools. Both teachers and students involved in teaching and learning via IT-based educational packages indicated higher levels of motivation when involved in the educational process and also felt that they were more in control of the teaching and learning processes than teachers and students who used less IT in their teaching. In addition, the teachers and students exposed to IT-based tools perceived teacher-student interactions to be more positive and intense than in classrooms where teaching did not include significant use of IT.

Ying-Shao et al. (2007) declared that teachers' and students' motivation, beliefs, and attitudes toward IT use in teaching and learning as well as readily available technological resources are major factors that enhanced their efficient use of IT-based tools in teaching and learning. They emphasized that teachers' motivation and beliefs regarding IT are the major predictors of teacher IT preferences as well as enhanced teacher-student interactions and student achievement. Conversely, a lack of motivation or strong beliefs and attitudes toward the use of IT-based tools in teaching contributes significantly to teacher's hesitation to use IT in their teaching as well as to reduced teacher-student classroom interactions.

Katz (2014a) presented a number of studies that indicated that student motivation to utilize IT-based tools in the learning process significantly contributes to the enhancement of learning skills and academic achievement. Thus it appears that motivation is a central affective construct that spurs both teachers and students on to utilize IT-based tools in their teaching and learning and promotes efficient and enhanced learning and achievement.

Satisfaction

In a comprehensive research study, Katz (2014a) found that one of the key constructs that positively affects teacher and student performance is the satisfaction of both teachers and students with the introduction of IT-based tools into the teaching and learning processes. When teachers and students utilize IT-based tools in teaching and learning, the level of their satisfaction with the educational process increases as does student performance. Small et al. (2012), who also addressed the issue of teacher satisfaction with the use of IT-based tools in their teaching, found that teachers who utilize IT in their teaching are more satisfied with their teaching and are better liked

and respected by their students. Tsai (2012) confirmed that teacher satisfaction with the use of IT-based tools in the teaching process enhances teaching effectiveness.

Sahin and Mack (2008) demonstrated how student satisfaction with the use of IT in the learning process ultimately leads to higher levels of student engagement, learning, and success. Goyal et al. (2011) confirmed that satisfaction with the use of IT-based tools in the learning process significantly explains the enhancement of students' learning performance. Mayer et al. (2017) confirmed that a student-centered IT-based learning environment fosters student satisfaction with the learning process. The above evidence emphasizes the key relationship between satisfaction of both teachers and students resulting from the use of IT in the teaching and learning processes.

Self-Efficacy (That Includes Technological Self-Confidence)

According to Kumar and Kumar (2003), the positive attitude of science teachers toward the use of IT-based tools in their teaching may be attributed to their positive experiences with the use of IT in teaching and the resulting feelings of self-efficacy and technological self-confidence in their use of IT-based tools in the classroom. Watson (2006) concurred that a feeling of self-efficacy and technological self-efficacy of teachers leads them to permanently use IT-based tools in their classroom teaching, and Anderson and Maninger (2007) found that pre-service teachers' self-efficacy was the best predictor of technology use in the training classroom. Ertmer and Ottenbreit-Leftwich (2010) described how positive teacher change towards the adoption of IT-based tools in their teaching contributes to their feeling of teacher self-efficacy which is of paramount importance in the effective use of IT in teaching. Jarvis et al. (2011) confirmed that self-efficacy and technological self-confidence in the use of student-centered IT-based tools in the teaching of science is a major factor that contributes to the enhancement of learning. Yaprak (2014) observed a significant relationship between teachers' feelings of IT self-efficacy and their willingness to use flexible IT-based tools in their teaching. Hsu (2016) indicated that personal dispositions of teachers, such as openness to change and innovation towards the use of educational technology, lead to an increase in their feelings of self-efficacy and technological self-confidence towards the use of IT-based tools in their teaching.

The results and conclusions of the research studies described above lead to a clear understanding that teachers' perceptions of their self-efficacy is significantly related to their willingness to use IT-based tools in their teaching. Varol (2013) confirmed the existence of a reciprocal relationship between self-efficacy and technological self-confidence of teachers and their use of IT in their teaching. The higher the teachers' level of self-efficacy and technological self-confidence, the more they tend to use IT-based tools in their classrooms.

In summary it may be concluded that self-efficacy that includes technological self-confidence is a key factor motivating teachers to use IT-based tools in their teaching. When teachers perceive themselves to be in command and control of technology then the way is clear for them to employ IT-based tools for the benefit and enhancement of their students' cognitive performance as well as their learning and achievement.

Conclusions

This chapter described the different IT-based tools that have been developed and introduced into elementary and secondary school classrooms since the 1960s. The penetration of IT-based tools began with the use of initial inflexible and closed technologies such as drill and practice software; continued with the use of more flexible and open electronic spreadsheets, student-centered simulation, and virtual and augmented reality technologies; and is now characterized by different facets of Internet-based technologies that allow for the use of totally flexible IT-based tools in their teaching. IT-based tools have contributed to a major change in the art of teaching and have significantly contributed to a situation where teachers have progressed and evolved from classroom managers who directly teach their frequently passive and accepting students into mentors and facilitators who teach indirectly by assisting and prodding their typically active and investigative students into student-centered meaningful cognitive learning experiences.

However, the teaching potential and educational advantages presented by IT can be maximized only by teachers who possess suitable and relevant constructs that over the years have been shown to facilitate and enhance effective and efficient utilization of IT-based tools in school classrooms. Research over the years has clearly indicated that teachers characterized by the positive teacher change, teacher knowledge, and pedagogical beliefs about IT use in the classroom as well teachers and students typified by affective constructs such as creativity, flexibility, motivation, and self-efficacy (that includes technological self-confidence) have a special ability to maximize the use of IT in their teaching in their quest to enhance student learning and all-round performance. Thus it is essential that during both pre-service and in-service teacher training, the relevant constructs that enhance the effective use of IT-based instructional strategies are intensively addressed and strengthened (Katz 2014b).

In light of the evidence pervading the research findings presented in this chapter, IT in general as an educational medium and the use of IT-based tools in particular have the potential to bring about a dramatic and continuous positive change in teaching and learning. However education policy makers as well as teachers and teacher trainers need to be acutely aware of the different constructs needed by teachers to utilize IT-based tools in their teaching. It is imperative that educational authorities allocate the necessary resources to enhance the development, adoption, and intensification of the necessary constructs by teachers so as to ensure effective and efficient use of IT-based tools in teaching and learning.

Abstract

Teacher dispositions reflect multiple internal factors that contribute to a teacher's decisions/behaviors in any given situation. There have been many studies focused on which dispositional factors lead to teachers' use of information and communications technology (ICT). Teachers' integration of ICT has been assessed in a variety of different ways – as a teacher's intention to use ICT, as the frequency of ICT use in the classroom, and/or as student-centered teaching practices with ICT. If a teacher's dispositions (i.e., attitudes, perceptions, values) are reflected through his or her behaviors, then we need to ask an important question about ICT practices: What specific dispositions do teachers need to use ICT in their classrooms? This chapter reviewed empirical studies that examined four primary dispositions associated with teachers' uses of ICT: self-efficacy, attitudes, pedagogical beliefs, and openness to change. This knowledge provides a robust starting point for answering more challenging and complex questions in the near future, such as: Why does a teacher hold certain dispositions, and how can we capitalize on that information to better support teachers in their actual use of ICT?

ICT · Beliefs · Knowledge · Attitudes · Self-efficacy · Teacher practices · Technology integration

Introduction

What makes a good teacher? This is a difficult question to answer. Oftentimes, it's a gut feeling – “He/she is just a natural teacher.” Or it's offering a cliché – “you know it when you see it.” Many have referred to this innate quality as a teacher's disposition, which typically encompasses his/her values, attitudes, beliefs, and

personality characteristics. Ritchhart (2002) provided the common example of a “friendly disposition” to explain: “we tend to understand a disposition as a tendency toward a general type of action. When we talk about someone having a friendly disposition, we understand that to mean that the person tends to approach situations in a certain way and to display a general set of actions we associate with friendliness. No one action is specified, but rather a whole range of related actions and responses may be evident” (p. 20). Freeman (2007) further asserted that dispositions are closely associated with actual behavior, not just intentions or beliefs, which is why many accrediting institutions are now incorporating dispositions into their assessments of preservice teachers.

According to Wasicsko (2007), teacher dispositions encompass three main constructs: teacher perceptions (e.g., core values and beliefs), teacher characteristics (e.g., attitudes or tendencies consistently demonstrated), and teacher behaviors (e.g., observable activities). In general, these behaviors represent a teacher’s internal characteristics and values. For instance, the 2006 standards published by the National Council for Accreditation of Teacher Education (NCATE) defined dispositions as “the values, commitments, and professional ethics that influence behaviors. . .” (p. 53). These values and commitments have been linked to the reasons teachers initially pursue the teaching profession. Studies have shown that college education majors assigned more importance to altruistic values that aligned with “a world at peace” and “being honest” than business students who selected values related to a “comfortable life” and “social recognition” (Feather and Collins 1974). In a more recent study of 99 student teachers and 125 in-service mentor teachers, Welch and Pitts (2010) found that both populations assigned primary importance to happiness, being loving, earning self-respect, responsibility, and honesty. Furthermore, Welch and Pitts found that the eight NCATE dispositions were promoted by their teacher education program positively with these values. The general idea is that teacher dispositions reflect multiple internal factors that contribute to a teacher’s decisions/behaviors in any given situation.

Teachers’ Uses of ICT

In the field of educational Information and Communications Technology (ICT), our main goal has been to support one specific behavior – teachers’ integration of ICT. In reviewing the literature, we found that teachers’ integration of ICT has been assessed in a variety of different ways – as a teacher’s intention to use ICT, as the frequency of ICT use in the classroom, and/or as student-centered teaching practices with ICT.

Intention to Use ICT

Intentions to use ICT are often the easiest outcome to measure, but intentions do not always translate into practices (Ertmer et al. 2012). In one example, Teo (2009) surveyed 592 teachers in Singapore. Teo incorporated factors from several models

(technology acceptance model, theory of planned behavior, and unified theory of acceptance and use of technology) to measure teachers' self-reported intentions to use ICT. Teachers' perceived usefulness of technology, positive attitudes toward ICT use, and facilitating conditions all directly influenced their intentions to use ICT. Measures of intentions to use ICT are often used with preservice teachers and determined through surveys or interviews (all self-reported). However, despite teachers' good intentions, barriers and other factors can significantly impact teachers' actual technology practices (Ertmer et al. 2012; Sadaf et al. 2012).

Frequency of ICT Use

Frequency of ICT use is another common outcome that can be assessed using surveys, interviews, or observations. Many researchers have examined the impact of different dispositional factors on the frequency of teachers' ICT use. For example, Inan and Lowther (2010a) surveyed 1,382 US teachers to examine which factors were related to self-reported frequency of ICT use. They reported that as a teacher's age and years of teaching experience increased, computer proficiency and self-reported frequency of ICT use tended to decrease.

However, Inan and Lowther (2010a) found that school-level factors (e.g., ICT resources, support) positively influenced computer proficiency. Teacher beliefs, readiness, and computer availability also were positively related to the frequency of teachers' uses of ICT. Still, as Rakes et al. (2006) found, frequency of ICT use, although positively associated with the number of times teachers used ICT, did not predict the use of student-centered ICT practices. The difficulty with this outcome (i.e., frequency of use) is that it is specifically focused on the dispositional factors needed to use ICT frequently. Is our goal to support teachers' *frequent* use of ICT, or is it to promote teachers' student-centered uses of ICT?

Student-Centered ICT Practices

Student-centered ICT practices are often the most difficult outcome to measure. Although this is the outcome posited by researchers and stakeholders (e.g., U.S. Department of Education 2016) as the eventual goal for teachers' ICT use, it is the least commonly measured. The dispositional factors necessary to support student-centered ICT practices may be different than those used to predict the previous two outcomes. For example, Chen (2010) constructed a SEM to examine the outcome of student-centered ICT uses for 206 preservice teachers during their student teaching experiences. Chen found that self-efficacy was the strongest total effect on use among the four factors (value, training, context, self-efficacy). ICT use was measured by survey responses to frequency of uses for students using ICT to (1) gather information or collect data, (2) conduct in-depth projects, and (3) communicate ideas via classroom presentations.

In other examples, researchers have examined the processes by which teachers design ICT lessons and implement them. However, these studies have often focused on the relationship between pedagogical beliefs and practices (Chiu and Churchill 2016; Ertmer et al. 2012; Prestridge 2014). Ertmer et al. (2012) found that teachers who implemented student-centered practices also self-reported high knowledge and attitudes toward ICT. However, the other teachers in the study, who did not implement student-centered practices, self-reported similarly high levels of knowledge and attitudes toward ICT. In Prestridge's (2012) study of eight teachers, she implemented a survey, followed by interviews and document analysis. Of the two teachers who described higher amounts of student-centered practices, Prestridge indicated they possessed "a high level of ICT competence and confidence to try new software and approaches" (p. 457). She suggested that the ICT competency-confidence relationship was important to consider when examining teachers' uses of ICT.

Teacher ICT Dispositions

If a teacher's dispositions (i.e., attitudes, perceptions, values) are reflected through his or her behaviors, then we need to ask an important question about ICT practices: What specific dispositions do teachers need in order to use ICT in their classrooms? Overall, the literature suggests that there are four primary dispositional factors associated with teachers' uses of ICT: self-efficacy, or a belief in one's own capability to use ICT to support teaching/learning; attitudes, or the extent to which teachers value ICT use or find it beneficial; pedagogical beliefs, or beliefs about teaching and learning and the role of technology in the teaching-learning process; and openness to change, or a willingness to incorporate new technologies or try new approaches to teaching with technology. In the sections that follow, we define each disposition and delineate the relationship between the disposition and teachers' ICT practices (i.e., intentions to use, frequency of use, and student centeredness). For each disposition, we also describe how others have successfully increased the factor to lead to more/better ICT practices.

Self-Efficacy

What Is Self-Efficacy?

Self-efficacy has often been referred to as one's belief in his/her capability to do a certain task. Thus, a teacher's self-efficacy refers to his/her belief in his/her capacity to complete teaching tasks. One literature analysis of 165 articles, focused on teacher self-efficacy, found that it has positive relationships with students' academic achievements, classroom quality, and even teachers' feelings of accomplishment, job satisfaction, and commitment (Zee and Koomen 2016). In the case of ICT use with teachers, self-efficacy is often referred to as teachers' belief in their capacity

to use ICT for teaching and learning. Sometimes, scholars will also discuss computer self-efficacy, which is basically teachers' belief in their capacity to use computers in general.

Studies have also investigated a similar construct, perceived ease of use (e.g., Holden and Rada 2011), which we have also included within this dispositional factor. With regard to teachers' adoption of ICT, perceived ease of use encompasses how easy the teacher perceives it to be to use a particular ICT tool. Venkatesh and Davis (1996) stated that "an individual's perception of a particular system's ease of use is anchored to her or his general computer self-efficacy at all times" (p. 451). Therefore, although these terms are often mentioned separately, we consider them to be under the same conceptual disposition factor.

Finally, there is an abundance of studies examining teachers' TPACK (or technological pedagogical content knowledge) (Koehler et al. 2014). However, several scholars have suggested that TPACK is a construct that is difficult to measure (Kopcha et al. 2014). The measures typically used to examine TPACK are surveys, such as the Schmidt et al. (2009) survey, which ask teachers to self-report on their perception of their knowledge and/or abilities. When we measure self-efficacy for teachers, we typically use statements asking teachers to assess their capabilities with ICT (e.g., Schmidt et al. 2009). Therefore, scholars have begun to use TPACK surveys as measurements of self-efficacy (e.g., Abbitt 2011; Banas and York 2014; Kazu and Erten 2014) rather than knowledge.

How Does Self-Efficacy Relate to ICT Practices?

Teachers' self-efficacy is important to consider because teachers will tend to avoid activities for which they lack confidence, such as ICT use, and engage instead in activities that lead to success (Pajares and Schunk 2002). Researchers have found that preservice teachers' ICT self-efficacy is positively correlated to their intentions to use ICT in their future classrooms (Banas and York 2014; Celik and Yesilyurt 2013; Lee and Lee 2014; Sang et al. 2010). In addition, studies have found that in-service teachers' ICT self-efficacy can impact teachers' frequency of ICT use (Inan and Lowther 2010a; Pan and Franklin 2011; Turel 2014).

How Does Self-Efficacy Relate to Student-Centered ICT Practices?

While researchers have often measured the link between self-efficacy and intentions to use ICT and/or frequency of ICT use in the classroom, few have investigated the link between self-efficacy and teachers' use of ICT to support student-centered ICT practices. However, Chen (2010) asked 206 preservice teachers to self-report how often they used student-centered ICT practices during their student teaching experiences. Student-centered ICT practices included opportunities for students to use ICT to (1) gather information and/or collect data, (2) conduct in-depth projects, and (3) communicate ideas through classroom presentations. Chen (2010) also asked the

preservice teachers to report on the training they had received in their teacher education programs, their skills, teaching beliefs, learning beliefs, computer self-efficacy, ICT integration efficacy, and contextual factors (support, time, access). Based on the results of Chen's survey, measures of preservice teachers' ICT self-efficacy had the strongest relationship to student-centered ICT use. However, this relationship was mediated by their perceived value of teaching and learning with ICT.

Limited research has been conducted on this factor with in-service teachers. However, Minshew and Anderson (2015) examined the 1:1 classroom practices of two middle school science and math teachers to determine how their dispositional factors (knowledge, self-efficacy) impacted those practices. Even when teachers had strong ICT self-efficacy, they still did not use ICT to support student-centered practices: "While Jake exhibited strong self-efficacy with respect to his science knowledge it was not observed in either his technological knowledge or in his pedagogical knowledge with respect to constructivist, inquiry-based practices of science" (p. 357). Dunn and Rakes (2010) also found a significant relationship between in-service teachers' learner-centered beliefs and ICT self-efficacy, but they did not examine teachers' actual practices.

How Can We Increase Self-Efficacy to Lead to More/Better ICT Practices?

Studies have shown that completing educational ICT courses tends to positively impact the ICT self-efficacy of preservice teachers (Albion 2001; Lee and Lee 2014). In addition, when preservice teachers participate in authentic learning experiences with ICT, their ICT self-efficacy has been shown to increase. For example, Lee and Lee (2014) found, in their study of 136 preservice teachers, that ICT self-efficacy was increased via lesson planning practice. Banas and York (2014) also found that authentic learning experiences (such as lesson design and microteaching) increased ICT self-efficacy and intentions to use ICT for 104 preservice teachers. Therefore, in order to increase preservice teachers' intentions to use ICT, teacher education programs should consider incorporating more authentic experiences related to planning lessons with ICT.

Student-teaching experiences may also impact preservice teachers' self-efficacy (Al-Awidi and Alghazo 2012; Flores 2015). Al-Awidi and Alghazo (2012) surveyed 62 preservice teachers before and after their student teaching experiences. The survey results showed an increase in ICT self-efficacy. They also conducted follow-up interviews with 16 of the preservice teachers who rated themselves highest in ICT self-efficacy. These preservice teachers reported that during their teacher education programs, the most influential experiences toward building their ICT self-efficacy were mastery experiences (e.g., self-exploration of tools and resources) and vicarious experiences (e.g., tips from supervisors or peers).

In general, many of the same approaches have been used to positively impact ICT self-efficacy of in-service teachers. Pan and Franklin (2011) found that professional

development experiences were critical to increasing teachers' ICT self-efficacy. However, this recommendation is rather vague, stating that merely increasing the amount of time spent in PD will result in stronger self-efficacy, whereas others have suggested that specific approaches to PD (e.g., sustained, contextual, personalized) are needed in order to impact teachers' ICT use (DeSantis 2013; Lawless and Pellegrino 2007). DeSantis (2013) found that by providing ICT professional development experiences that were sustained, collaborative, and scaffolded, he was able to increase teachers' ICT self-efficacy with regard to interactive whiteboards. In order to create change in teachers' self-efficacy and learner-centered beliefs, Dunn and Rakes (2010) recommended that professional development begin by explaining the benefits and relevance of student-centered ICT use, including actual stories of real teachers and students. In addition, they suggested the use of observations and modeling as additional ways to increase in-service teachers' ICT self-efficacy.

Attitudes, Value Beliefs, and Subjective Norms About ICT

What Are Attitudes, Perceived Usefulness, Value Beliefs, and Subjective Norms?

One dispositional factor that researchers indicate influences a teacher's adoption or use of ICT is the extent to which the teacher values ICT. This factor has been defined using many different terms: attitudes (Christensen 2002), perceived usefulness (Teo 2009), value beliefs (Ottenbreit-Leftwich et al. 2010), and even subjective norm beliefs (Hazzan 2003). While all these terms have slight nuances in how they are measured or even conceptualized, we believe they all address the same question: Does the teacher find ICT useful and important for his/her teaching and learning?

How Do Attitudes Relate to ICT Practices?

Some studies have shown a strong relationship between teachers' attitudes (or perceived usefulness) and teachers' ICT practices. At the preservice level, attitudes are commonly tied to intentions to use ICT (e.g., Sadaf et al. 2012). For example, Sadaf et al. surveyed 286 preservice teachers in the United States to examine which factors predicted their intentions to use Web 2.0 tools in their future classrooms. They triangulated the survey findings with seven interviews. The two most significant predictors of preservice teachers' intentions to use Web 2.0 technologies were positive attitudes and perceptions of perceived usefulness. Furthermore, in their interviews, preservice teachers indicated that their intentions to use Web 2.0 technologies depended on the subjects and grade levels being taught. In another study, Yusop (2015) surveyed 100 preservice teachers to examine their intentions to use Web 2.0 technologies and to determine which factors predicted

those intentions. Similar to Sadaf et al., Yusop found that attitudes were the most influential factor in determining preservice teachers' intentions to use Web 2.0 in their future classrooms. In another survey of 727 Chinese preservice teachers, Sang et al. (2010) also found that computer attitudes correlated with intentions to use ICT in their future classrooms.

Studies at the in-service level have also identified a relationship between teachers' attitudes and their ICT practices. In one survey of 242 Taiwanese secondary science teachers, Shiue (2007) found that teachers' attitudes and perceived usefulness impacted teachers' intentions and self-reported frequency of ICT use. Another survey of 460 Jordanian secondary teachers (Al-Zaidiyen et al. 2010) found a significant correlation between teachers' attitudes about ICT for educational purposes and their self-reported frequency of ICT use. In another example, Chiu and Churchill (2016) examined how beliefs, attitudes, and anxiety levels of 62 secondary in-service teachers changed during the implementation of mobile devices in teaching. Half of the teachers were math and science teachers, while the other half taught language and humanities. Chiu and Churchill found that the mathematics and science teacher group significantly improved their views on the usefulness of ICT, but the language and humanities group did not experience similar changes. The authors suggested: "These changes appear to be influenced by subject matter culture and learning objectives in different subject areas. The mathematics and science group in this study found that the adoption of mobile technologies can help them achieve their teaching goals; the language and humanities group in this study found that mobile devices were not especially appropriate teaching and learning tools although they managed to make use of those devices" (p. 324).

How Do Attitudes Relate to Student-Centered ICT Practices?

How do teachers' attitudes relate to student-centered ICT practices? In other words, what do teachers' attitudes need to look like in order to support student-centered ICT practices? There are few studies that examine how teachers' attitudes influence, or are related to, student-centered ICT practices. Yagci (2016) surveyed 186 preservice Turkish teachers and found that their attitudes about ICT were related to their pedagogical beliefs. In other words, if a preservice teacher had positive attitudes toward ICT, they were more likely to have student-centered pedagogical beliefs (Yagci 2016). In another preservice survey of 727 Chinese teachers, Sang et al. (2010) found that computer attitudes were correlated with student-centered teaching beliefs.

In an example with in-service teachers, McKnight et al. (2016) examined a team of four teachers who reported strongly valuing ICT and using it in student-centered ways. However, the principal described being surprised that the ideals and attitudes shared by this small group of teachers had not spread to the rest of the school. Although it is plausible that teachers need positive attitudes about ICT to support student-centered ICT practices, the exact nature of those attitudes, as well as teachers' perceptions about what's valuable, still need to be investigated.

How Can We Increase Attitudes to Lead to More/Better ICT Practices?

In order to facilitate more positive teacher attitudes toward ICT, scholars have recommended ongoing PD support and collaboration with other teachers. For example, Christensen (2002) found that her ICT professional development impacted teachers' attitudes. Christensen (2002) examined three sites and the impact of ICT PD on teachers' attitudes and ICT practices: two sites provided district-determined ICT PD, while one site received needs-based ICT PD. The needs-based ICT PD included 2 intensive training days at the beginning of the school year with follow-up training every 6 weeks for the remainder of the year. Christensen found that the needs-based ICT PD had a "rapid, positive effect on teacher attitudes, such as computer anxiety, perceived importance of computers, and computer enjoyment" (p. 411), as well as increased self-reported frequency of computer use. Christensen recommended that ongoing and customized PD was critical to improving teachers' attitudes toward ICT, as well as frequency of use.

Context, such as school support and policies, can also influence teachers' attitudes (Blackwell et al. 2014; Teo 2009). Chiu and Churchill (2016) suggested that teachers may be worried about how ICT will impact their workload or evaluation. In another study of novice high school mathematics teachers' attitudes toward integrating ICT into their instruction, Hazzan (2003) found that perceptions of a negative undercurrent from veteran teachers discouraged novices from using ICT in their lessons. Therefore, schools and teacher education programs might consider creating communities that support the development of positive attitudes toward ICT use in education.

Drent and Meelissen (2008) found that one of the most critical factors for ICT use was "personal entrepreneurship," which directly influenced ICT attitude. The authors operationalized personal entrepreneurship as the number of contacts teachers have available for their own ICT professional growth. Schools and teacher education programs can support the development of personal entrepreneurship through learning communities and reflection activities (Drent and Meelissen 2008). In addition, Sang et al. (2010) recommended that in order to increase preservice teachers' positive attitudes toward ICT, teacher education programs should incorporate more real-life experiences within actual classroom settings.

Openness to Change

What Is Openness to Change?

A teacher's openness to change plays a key role in his/her decision to integrate technology. The characteristics of this disposition have been described in several ways – as a willingness to "try new instructional innovations" and "take risks in teaching" (Baylor and Ritchie 2002, p. 399) as well as "a willingness to commit one's time 'above and beyond the call of duty' and a risk-taking attitude" (Vanatta and Fordham 2004, p. 261). Of course, many teachers are apprehensive of

integrating new technologies and practices in the classroom. This has led researchers to examine a teacher's lack of openness, often described as their resistance to change (Mathipa and Mukhari 2014) or anxieties (Chiu and Churchill 2016) over integrating technology. These characteristics of openness are highly related between and among each other and, overall, address the same overarching question: *Is the teacher willing to incorporate new technologies and new approaches to teaching with that technology in the classroom?*

What Evidence Supports the Relationship Between Openness to Change and Technology Practices?

The relationship between a teacher's openness to change and use of technology in the classroom was established over a decade ago. Overall, teachers who are more open to change tend to use ICT more frequently. In a study of 94 classrooms across four states, Baylor and Ritchie (2002) examined the relationships among 15 different predictors of technology use in the classroom (e.g., openness to change, level of planning, instructional use) and technology-related outcomes (e.g., frequency of use, qualities of use). The authors found that a teacher's openness to change was a statistically significant predictor of his/her ability to integrate technology in the classroom, as well as his/her plans to use technology to address higher-order thinking skills. Openness to change, when combined with strong technology leadership, was also a strong predictor of teachers' perceptions of, and plans to use, technology for students' acquisition of content. Vanatta and Fordham (2004) surveyed 170 teachers from 4 schools who were involved in a 3-year professional development project as part of a Preparing Tomorrow's Teachers to Use Technology (PT3) grant. Similar to Baylor and Ritchie, the authors found that openness to change and a willingness to invest additional time predicted teachers' uses of technology (e.g., presentations, email, Internet) when coupled with training. In both studies, openness to change was found to make a unique contribution to the predictive model when compared with related factors such as overall competency and ICT self-efficacy.

More recently, Blau and Peled (2012) surveyed 97 Israeli middle school teachers and found that both their openness to change and overall attitudes toward ICT implementation were significant predictors of teachers' uses of the Internet for professional purposes. In that same study, there was a strong relationship between teachers who volunteered to participate in a one-to-one laptop program and their openness to change. Among 527 teachers from 68 primary schools in Belgium, Tondeur et al. (2008) found that a school's willingness to be innovative was positively related with teachers' uses of technology for learning. Although the presence and capacity of classroom technology has changed dramatically over the past decade, these studies suggest that the relationship between a teacher's openness to change and his/her decision to integrate technology into teaching and learning has not.

Related to openness to change is the concept of resistance to change – that is, an attitude whereby teachers are resistant or unwilling to try new technologies or to use

technology in their existing practices (Mathipa and Mukhari 2014). This resistance often stems from a teacher's perception that technology is not useful for teaching and learning and may represent a risk to his/her ability to teach successfully (Howard 2013; Mathipa and Mukhari 2014). Among 157 pre- and in-service teachers, Kimmons and Hall (2016) found that a teacher's decision to integrate technology is based largely on whether he/she thinks that technology will improve what he/she does as a teacher. The authors concluded that teachers who are resistant to change may not be reacting to the technology itself but rather to their perceptions of whether that technology is useful to them and their goals for student learning. This position on resistance to change is not new – other scholars have noted how teachers who resist technology often struggle to see how it improves teaching and learning (Becta 2004; Levin and Wadmany 2008).

What Evidence Supports the Relationship Between Openness to Change and Student-Centered Technology Practices?

The relationship between openness to change and student-centered technology practices is complex, demanding openness both epistemologically and technologically. While many studies have examined teachers' openness to change and overall technology use, far fewer have examined how openness to change impacts student-centered teaching practices. Those that have, however, suggest that an openness to change may be related to a teacher's use of student-centered practices with technology. For example, Baylor and Ritchie (2002) found that openness to change predicted both overall technology use as well as teachers' uses of technology for higher-order thinking, which included activities commonly associated with student-centered practices (e.g., analyze, compare, contrast, or evaluate resources). Tondeur et al. (2008) found that teachers were more likely to use technology for student-centered learning when their school was more willing to support innovative approaches to instruction. Likewise, Aldunate and Nussbaum (2013) found that teachers who were less willing to integrate technology were more likely to abandon their integration efforts when the technology became too complex to use. These studies suggest that the relationship between openness to change and teachers' uses of technology for student-centered learning is likely to be consistent with, if not more pronounced than, their uses of technology more broadly.

What Studies Show How We Can Increase Openness to Change to Lead to More/Better Technology Practices?

One way to improve a teacher's openness to change may be through professional development. In a detailed account of three teachers learning to integrate technology, Levin and Wadmany (2008) found that a teacher's openness to changes varied over time. In particular, they found that a teacher's level of openness increased as they adopt student-centered approaches and that these were associated with overall

attitudes and beliefs about technology. The authors suggested that openness and centeredness represent a spectrum that teachers move through as they learn to integrate technology. Howard and Gigliotti (2016) detailed how one teacher developed specific coping strategies (e.g., relying on students to resolve technology issues, reverting to non-digital approaches as needed, developing a core set of teaching activities) over a 3-year one-to-one laptop initiative. The coping strategies addressed more complex uses of technology over time and played a key role in alleviating anxiety and improving the teacher's willingness to take risks and try new practices with technology. Other studies suggest that there is a relationship between a teacher's knowledge of integrating technology and willingness or interest in integrating technology into classroom practices (see Baylor and Ritchie 2002; Bingimlas 2009; Sang et al. 2010).

Another way to improve a teacher's openness to change may be through school culture. Recent studies suggest that teachers are more likely to integrate technology when the school offers a supportive environment. In a study of 1,030 Turkish teachers, Karaca et al. (2013) found that both principal and peer support are important factors that contribute to a teacher's overall attitude toward technology and, in turn, his/her decision to integrate technology in the classroom. Similarly, Tondeur et al. (2008) found that teachers who used technology in student-centered ways more often came from schools that supported innovative approaches to learning. Others have similarly found that school-related factors and support can contribute positively to a teacher's decision to integrate ICT in the classroom (Inan and Lowther 2010a, b; Tondeur et al. 2009).

Pedagogical Beliefs

What Are Pedagogical Beliefs?

Pedagogical beliefs, as they relate to ICT, typically include "teachers' educational beliefs about teaching and learning (referred to here as pedagogical beliefs)" (Ertmer 2005, p. 28). Many have often described pedagogical beliefs on a continuum, from teacher-centered to student-centered (Levin and Wadmany 2008). Teacher-centered beliefs with ICT typically support lower-level uses (e.g., drill and practice, lecturing, information presentation, etc.), while student-centered pedagogical beliefs typically support higher-order thinking skills (Dwyer et al. 1994). Others have suggested that a teacher may possess multiple beliefs with regard to ICT (Ertmer et al. 2015; Hsu 2016; Tondeur et al. 2016). Dwyer et al. (1994) described these pedagogical beliefs as "beliefs about classroom management, curriculum, collaborative learning, and other such issues" (p. 1).

Although most researchers have categorized beliefs on a continuum from teacher-centered/traditional to student-centered/constructivist, some researchers have attempted to create other categories to classify pedagogical beliefs. For example, based on her survey of 48 Australian teachers, Prestridge (2012) identified 4 categories of ICT beliefs and practices: foundational (general statements about using ICT in

all subjects), developing (curriculum implications of ICT), skill-based (students need to develop ICT skills), and digital pedagogical practices (ICT promotes student-centered learning). Ertmer et al. (2012) also suggested terms focused on the role of technology in teachers' ICT practices: ICT to deliver content and reinforce skills, ICT to complement or enrich the curriculum, or ICT to transform teaching and learning.

What Evidence Supports the Relationship Between Pedagogical Beliefs and ICT Practices?

Some researchers have shown that teachers' espoused pedagogical beliefs do not align with their ICT practices (e.g., Liu 2011; Shifflet and Weilbacher 2015). For example, Liu (2011) surveyed 1,120 Taiwanese elementary teachers about their pedagogical beliefs and reported practices. Although most teachers ($n = 888$) reported constructivist beliefs, only 28.2% of these teachers reported implementing constructivist activities with ICT. However, of the teachers who reported traditional beliefs ($n = 232$), 80.2% of these teachers reported implementing traditional or lecture-based activities with ICT. Liu concluded that although most of the Taiwanese teachers expressed constructivist beliefs, their reported practices with ICT were typically traditional. However, these results were based on self-reported data.

Other studies have shown mixed results. In one survey with 1,230 Singaporean preservice teachers, Chai (2010) found that although those with traditional beliefs intended to use ICT in traditional ways, those with constructivist beliefs had broader intentions. Teachers who reported constructivist beliefs also reported intentions to use ICT to support both constructivist and traditional practices. In another survey of 152 US elementary teachers, Hsu (2016) compared teachers' self-reported pedagogical beliefs with their self-reported ICT practices. Among the teachers who participated, most identified their pedagogical beliefs as constructivist ($n = 120$), while some identified as traditional ($n = 32$). Of those teachers with constructivist pedagogical beliefs, 85% self-reported technology integration practices that contained eclectic instances (McCrorry's (2006) framework of ICT's affordances for students to engage in high-level learning. McCrorry classified these affordances as representation (illustrating ideas and processes that were difficult to represent without ICT), information (providing access to data or content), transformation (changing the tasks students engage in), and collaboration (ICT helps students communicate with peers/experts). For those teachers with traditional pedagogical beliefs, 68% reported using only information practices (e.g., Google searches) with ICT. Hsu then conducted follow-up interviews and observations with eight teachers representing a maximum range of grade levels, locations, and years of teaching experience. Similar results were found when actual practices were observed. Those teachers with constructivist pedagogical beliefs used two or more practices of high-level learning in their lessons, while those with traditional pedagogical beliefs utilized high-level learning practices.

Many researchers examining pedagogical beliefs and technology practices have used interviews and observations. These studies have typically found that pedagogical beliefs and technology practices did align (Kim et al. 2013; Prestridge 2012). In one example, Ertmer et al. (2012) examined the beliefs and practices of 12 US award-winning ICT-using teachers. Ertmer and colleagues found that in most instances, teachers' beliefs aligned with their actual practices. For those that expressed more traditional pedagogical beliefs in their interviews, their implementation of ICT usually supported the achievement of skills. For the teachers who held more constructivist beliefs, their implementation of ICT tended to support higher-order thinking skills. For the remaining two teachers who showed differences in their beliefs and practices, Ertmer and colleagues suggested this might have been due, in part, to contextual barriers (e.g., lack of resources). In another survey of 474 US teachers involved in a pilot study using technology, Overbay et al. (2010) found that those with constructivist beliefs were more likely to use technology and that there was a relationship between their beliefs and practices. Teachers who identified ICT as a useful tool to support student-centered learning were more likely to use technology.

What Studies Show How We Can Increase Pedagogical Beliefs to Lead to More/Better Technology Practices?

Lim and Chan (2007) implemented ICT experiences for 19 Singaporean preservice teachers, with the intent of changing their pedagogical beliefs to be more constructivist. After 8 weeks in a local school practicum, preservice teachers were asked to design an individualized ICT lesson. For the remaining 5 weeks of the course, preservice teachers were introduced to constructivist-based learning experiences with ICT and asked to design a collaborative lesson with others in the course. Lim and Chan collected the two lesson plans, conducted weekly beliefs surveys, and conducted three interviews (the preservice teacher with the largest increase in belief survey scores, smallest change, and largest decrease). Holistically, all individual ICT lessons used traditional instructional practices, whereas the collaborative lessons all used constructivist instructional practices. Lim and Chan suggest that this change indicates a change in preservice teachers' pedagogical beliefs. However, they concluded that merely providing exposure to constructivist theories was insufficient to change preservice teachers' pedagogical beliefs. In addition, they suggest that asking preservice teachers to reflect on their dissatisfaction with traditional instructional approaches, as well as helping preservice teachers to identify their perceived barriers to implementing constructivist instruction, may help change beliefs and practices.

Prestridge (2014) followed 16 teachers through an action research professional development program with ICT, wherein teachers were asked to reflectively blog. For the one teacher who consistently blogged, Prestridge was able to observe strong pedagogical changes. Prestridge suggests that the reasons the other teachers did not blog as often was because they did not find value in the reflection activity. However, she reasoned that if teachers received more guidance and support, they might see the

value and reflective blogging has the potential to be more transformational for teachers' ICT pedagogical beliefs.

One of the earliest transformative stories emerged from the Apple Classrooms of Tomorrow (ACOT) research. In ACOT, Apple provided 32 US teachers with resources and support to integrate ICT in the late 1980s. Results showed that all 32 teachers moved through 5 stages of ICT integration, toward more constructivist learning experiences. After 4 years, Dwyer et al. (1994) described how teachers' beliefs need to be confronted: "Before teachers can reflect on their beliefs, then, they must somehow bring them to a conscious level, and they must see and understand the connection between their beliefs and their actions. They must also be aware of alternative belief systems and have experienced the consequences of those beliefs" (p. 37).

Connecting Dispositions to Knowledge

Knowledge in and of itself is not a teacher disposition. Dispositions are typically the attitudes and values that a person holds that help explain his/her behaviors. However, knowledge plays an important role in shaping a teacher's dispositions as well as predicting a teacher's use of ICT technologies. For example, teachers' pedagogical beliefs may grow as that they become more knowledgeable about using ICT to support student-centered approaches to learning (Ertmer and Ottenbreit-Leftwich 2010). This may, in turn, improve their attitudes about the value of ICT in the classroom (Ottenbreit-Leftwich et al. 2010). Similarly, teachers' pedagogical beliefs and attitudes toward ICT may grow more positive as they become more knowledgeable about using ICT to support student-centered approaches to learning (Howard and Gigliotti 2016; Levin and Wadmany 2008; Vanatta and Fordham 2004). Both self-efficacy and openness to change play a role in a teacher's decision to integrate ICT in the classroom, and this relationship is stronger when teachers receive professional development that addresses their knowledge of ICT integration (Baylor and Ritchie 2002; van Braak et al. 2004). Thus, a teacher's knowledge is an important piece of a teacher's dispositions, even if it is not a disposition itself.

Several recent studies suggest that knowledge and dispositions each play a unique role in a teacher's decision to use ICT in the classroom. Inan and Lowther (2010a, b) used path analysis to evaluate the influence of both primary (e.g., teacher readiness with and attitudes toward ICT) and secondary (e.g., professional development, school support) factors. In both papers, a teacher's readiness to use computers and beliefs about integrating ICT were significant predictors of their ICT use; readiness was strongly influenced by a teacher's knowledge of and proficiency with computers, whereas beliefs were strongly influenced by overall support from the school. Agyei and Voogt (2011) explored how knowledge and dispositions influenced the ICT use of 120 math teachers in Ghana. Teacher attitudes were measured on several dimensions, including anxiety/willingness to integrate, perceived benefit and enjoyment, and professional enhancement. The authors found that teacher attitudes toward computers and teacher

competence with computers together accounted for the largest percent of variance when predicting teachers' level of ICT use. In a study of 357 Swedish teachers, Petko (2012) similarly found that teachers more often incorporated computers and Internet for learning when they felt more competent, expressed constructivist beliefs about learning, and perceived ICT as a benefit in the classroom. Karaca et al. (2013) similarly found that computer competence and teacher attitudes were significant predictors of a teacher's ICT use. Overall, these studies suggest that both knowledge and dispositions work together to influence a teacher's use of ICT in the classroom.

Current Issues in ICT Dispositions Research

Based on the current research, it is difficult to determine how dispositions independently influence a teacher's ICT use. One reason for this difficulty is that the outcome variable differs across studies. For example, many studies examine a teacher's ICT use in terms of both instructional and noninstructional uses. When ICT is examined broadly, computer competency or proficiency (i.e., knowledge) is more strongly associated with ICT use than dispositions such as attitudes and beliefs (e.g., Inan and Lowther 2010a; Karaca et al. 2013; van Braak et al. 2004). However, when Inan and Lowther (2010b) assessed teachers' uses of laptops with students, specifically, knowledge and dispositions were similarly strong predictors. Tondeur et al. (2008) found that a teacher's use of ICT for learning was strongly influenced by his/her level of constructivist beliefs about learning; this was additionally influenced by school-related factors (e.g., levels and types of support, willingness to innovate, availability of ICT). Thus, the influence of knowledge and dispositions on a teacher's ICT use is likely to differ depending on the ICT practice that is assessed.

Another challenge concerns the nature of our current measures. Current predictive models typically rely on teachers' self-reports of dispositions (e.g., attitudes, self-efficacy, beliefs), knowledge, and ICT use (see Baylor and Ritchie 2002; Inan and Lowther 2010a, b; Karaca et al. 2013; Sang et al. 2011; Tondeur et al. 2008). While self-reports are valuable tools for measuring beliefs and attitudes, they become more problematic with regard to knowledge and actual ICT use. Scholars have argued that self-reported knowledge may actually reflect one's self-efficacy (Banas and York 2014). This is particularly a concern when the items ask a teacher to report on his or her perceived ability as a reflection of that knowledge (e.g., "I can do *this*" or "I know how to do *that*"). Similarly, teachers' self-reports of their practices are susceptible to bias and may reflect what is socially desirable more than what is actually happening in the classroom (Desimone 2009; Kopcha and Sullivan 2007). The problem that self-reports create concerns the manner in which the results are discussed, often as if a teacher's *actual* knowledge predicts his/her *actual* ICT use. A more accurate portrayal would be that a teacher's *perception* of his/her knowledge predicts his/her *perception* of ICT use in the classroom. The gap between perceived and actual ICT use makes it difficult to see what practices best to support teachers' actual ICT use in the classroom.

A third challenge concerns the manner in which dispositions are defined and measured. In some studies, beliefs reflect one's value beliefs (see Ottenbreit-Leftwich et al. 2010), while in other studies beliefs represent pedagogical beliefs about teacher- and/or student-centered instruction (see Ertmer et al. 1999; Sang et al. 2010). Further complicating this issue is that value beliefs and attitudes are often conflated. This conflation stems from the nature of the items used to assess those construct. Scholars have drawn on the technology acceptance model (TAM; e.g., Davis 1989) to assess a teacher's perception of the usefulness of ICT in the classroom or ease of use with ICT. In some studies, those perceptions are taken to reflect beliefs (Baylor and Ritchie 2002; Kimmons and Hall 2016), while in other studies they are defined as attitudes (Agyei and Voogt 2011); still other studies combine multiple components into the single construct of "attitudes and beliefs" (e.g., Karaca et al. 2013). Similarly, teacher knowledge is often conflated with computer competency or proficiency (see Baylor and Ritchie 2002; Karaca et al. 2013), while other studies focus on competency but not a broader perspective on the knowledge associated with ICT integration (e.g., Inan and Lowther 2010a, b). Computer competency inherently reflects knowledge – however, other forms of knowledge are important when integrating ICT in the classroom (e.g., knowledge of pedagogy with ICT, classroom management; Ertmer 1999). Likewise, a teacher's willingness to integrate ICT is sometimes measured in a positive light (i.e., openness to change; see Baylor and Ritchie 2002), while in other cases it is measured in a negative light (i.e., resistance to change or anxiety; see Agyei and Voogt 2011). These issues make it difficult to look across studies and generate research-based recommendations regarding how best to support teachers as they adopt ICT for teaching and learning.

Dispositions: Proceed with Caution

In the past decade, research on the relationship between teachers' dispositions and ICT use in the classroom has risen dramatically. Much of that research is detailed in this chapter and suggests that dispositions play an important role in a teacher's decision to integrate ICT (see also Knezek and Christensen 2008). However, making sense of that relationship is anything but straightforward. Much of the current research uses predictive models to explore teachers' uses of ICT. Predictive models are effective for determining *if* a relationship exists between ICT use and dispositions but do little to reveal what the relationship is or why it exists (Christensen and Knezek 2008; Inan and Lowther 2010a, b). An important caution about that research, then, is to avoid treating any correlative results as causal. For example, several models suggest that computer competency and self-efficacy are related to ICT use. However, this does not mean that ICT use will improve just because teachers participate in stand-alone workshops that aim to improve competency – in fact, such workshops are often least likely to promote ICT use in the classroom (Mouza 2009; Wells 2007). Integrating ICT in the classroom is complex and multifaceted

(Ertmer et al. 2012; Kopcha 2010); knowing *if* dispositions and ICT use are related is far different than knowing *why* they are related and *how* to capitalize on those relationships to better support teachers.

With that in mind, there are several possibilities for future research on dispositions in the context of ICT that would help establish the *why* and *how*. One suggestion is to refine the manner in which dispositions are defined and measured. At this point in time, there are a number of validated instruments for measuring each dispositional factor. These measures, however, differ in subtle but critical ways. For example, the disposition of openness to change has also been studied as a willingness to integrate ICT or even a resistance to ICT. Beliefs and attitudes are often interchanged. While each aspect of these dispositions is undoubtedly related, it is not clear that they reflect the same internal state or construct. Rather than creating new instruments for measuring these potentially related aspects of dispositions, it may be more beneficial to establish if and how these measures converge to reflect the larger construct they seek to represent. Such research would not only help to solidify our definitions of these dispositions but also improve the conclusions that can be drawn across studies (Trochim and Donnelly 2008).

It is also important to note that no single dispositional factor can fully account for a teacher's use of ICT in the classroom – nor should it be the goal of dispositions research to isolate and account for each dispositional factor. Dispositions reflect a complex set of interrelated internal constructs that work together, with knowledge, to form and manifest specific behaviors. Our current measures and models have provided ample evidence of *if* those dispositions influence ICT use. In looking forward, then, research in ICT could build on prior studies to ask more complex questions about dispositions, such as how they form, how they influence actual ICT use, and how they can help scholars and educators support teachers as they learn to integrate ICT into student learning. In other words, how can scholars and educators better understand *why* a teacher holds certain dispositions, and *how* can we capitalize on that information to better support teachers in their actual use of ICT?

This focus on *why* and *how* would help move us past the current issues with ICT dispositions research in several ways. To begin, it would focus less on the specific nature of the disposition as it is measured (e.g., openness/willingness to change vs. resistance) and more on how each disposition reflects the teacher, more holistically. From a holistic point of view, it would be far less important to accurately measure a specific disposition (e.g., resistance) than understand it as it relates to his/her use (or disuse) of ICT due to the disposition. The latter would help determine *how* to capitalize on teacher dispositions as they learn to integrate ICT.

Additionally, a focus on *why* and *how* has the potential to focus more on teachers' actual use of ICT in the classroom. While some argue that existing self-report surveys are valid and reliable measures of a teacher's dispositions and ICT use (Christensen and Knezek 2008), others have shown how triangulating self-reports with observations adds richness and detail to the complex relationships involved in a teacher's decision to integrate ICT (Shulz-Zander et al. 2008). Surveys are

undoubtedly useful in collecting large quantities of data, which can improve the generalizability of the findings. However, the focus on generalizability risks losing the specificity needed to better understand how scholars and educators can better support teachers in their use of ICT in the classroom. The relationship between dispositions and ICT use is personal and contextual, often changing over time – teachers may hold similar attitudes and beliefs about computers and learning yet arrive at different levels of ICT use over time (Levin and Wadmany 2008). Triangulating multiple sources (i.e., self-report with objective measures) would better account for the complex relationships between a teacher's dispositions and ICT use and the contextual factors that influence those dispositions.

Conclusion

In this chapter, we reviewed a variety of research that answers an important question: *What specific dispositions do teachers need in order to use ICT in their classrooms?* Overall, that research suggests that a teacher's self-efficacy, attitudes, openness to change, and pedagogical beliefs each have a relationship with a teacher's use of ICT for teaching and learning. This knowledge provides a robust starting point for answering more challenging and complex questions in the near future, such as: *Why does a teacher hold certain dispositions, and how can we capitalize on that information to better support teachers in their actual use of ICT?* If the goal of ICT research is to support teachers in adopting a range of teacher- and student-centered ICT practices, then knowing *why* a teacher holds a disposition may be as, or more, important than measuring the disposition factor in and of itself. As the quantity and capacity of ICT in schools continues to increase, it will be important to explore the practical strategies that best support teachers in articulating their dispositions and addressing them when they interfere with their efforts to use ICT for teaching and learning.

Introduction

Despite a massive 30-year infusion of technology into school systems across the USA, current reports on levels of schoolteachers' technology integration indicate that instructional uses of technology with students remain relatively low and that traditional transmission-oriented pedagogical approaches continue to dominate teachers' practice. For example, in a recent Pew Research Center survey, less than half (40%) of teachers allowed students to develop, share, or post work on a website, wiki, or blog. Only 39% of teachers allowed students to participate in online discussions, and only 22% of teachers allowed students to post projects online where someone other than their teachers or classmates could see it (Purcell et al. 2013). These findings are disappointing given early claims about the transformational potential of instructional technologies (c.f., Sandholtz et al. 1992; Sheingold 1991).

According to Webb and Cox (2004), integrating technology into classroom learning requires teachers to engage in complex pedagogical reasoning. However, numerous studies and reports have demonstrated the difficulties involved in prompting teachers to adapt their pedagogical reasoning in ways that take advantage of the learning opportunities provided by digital technologies (Bauer and Kenton 2005; Hutchinson and Reinking 2011). In the 1980s, efforts to infuse technology into schools largely ignored the teacher factor and embraced a "build it and they will come" mentality. Millions of dollars were spent under the assumption that simply installing computers and related technologies and infrastructure in schools would transform education and support the use of constructivist approaches to teaching and learning advocated by the pedagogical reform movement of the day (Niederhauser and Stoddart 2001). Success was measured by counting the ever-increasing numbers of computers, printers, and network connections available in schools. Major issues under discussion at the time included whether computers should be installed in labs or classrooms and whether students should be allowed to access the Internet or be confined to a safer within-school intranet.

While reaching a critical mass of hardware, software, and infrastructure was necessary to provide a fertile environment for technology integration to occur, the lack of teacher behavioral change made it clear that simply providing access was not sufficient to address the kinds of transformational pedagogical change hoped for by

reformers. Over time, educators, researchers, and policy-makers began to recognize that the integration of technology was an extremely complex process with multiple interacting factors including environmental, technological, individual, organizational, and pedagogical considerations (Sherry 1998). With the realization that the teacher factor was to play a critical role in the process, new models that addressed teacher knowledge and developmental change were needed to improve instructional integration of technology into the classroom environment.

Models and frameworks help us better understand complex ideas and processes by providing a simplified explication of a concept, phenomenon, relationship, structure, system, or aspect of the real-world that allows us to focus on essential aspects of that which is being modeled. Relative to classroom technology integration, models can be useful in helping us understand and explain how technology integration occurs, allow us to better make decisions about how to effectively utilize technology resources, and provide insights that support development of strategies to more effectively and efficiently promote the kinds of pedagogical practices identified as essential to transforming learning in schools. The purpose of this chapter is to provide an overview of current models and frameworks that inform teacher adoption of technologies that support the integration of technology into student learning experiences in K-12 school settings and to link them to theories of diffusion, adoption, and change that underpin them.

Theories of Innovation Diffusion and Adoption

Diffusion theories help explain how an innovation spreads through a population; while adoption theories help us understand the intrapersonal factors and social processes that lead individuals to accept or reject a particular innovation (Straub 2009). The result of engaging in diffusion and adoption processes is change; however, there is no unified model for understanding the processes teachers go through when adopting instructional technologies. Three theoretical orientations underpin models of how and why teachers come to integrate information technology into their pedagogy.

The broadly applicable *Diffusion of Innovations* (DOI) theory (Rogers 2003) helps explain factors that influence individuals' uptake of new technological tools and innovative practices and the developmental stages that adopters pass through, within a community of practice – or within the larger society. Two sociopsychological theories, the *Theory of Planned Behavior* (TPB; Ajzen and Fishbein 1980; Ajzen 2012) and *Social Cognitive Theory* (SCT; Bandura 1986), have been useful in helping us understand the intrapersonal factors that govern developmental change in human behavior.

Diffusion of Innovations

DoI was developed to explain how new ideas and technologies spread within a society and addresses *attributes of the innovation* (relative advantage, compatibility, complexity, trialability, and observability; Rogers 2003, pp. 15–16) and *characteristics of adopters* relative to their stage in the adoption process:

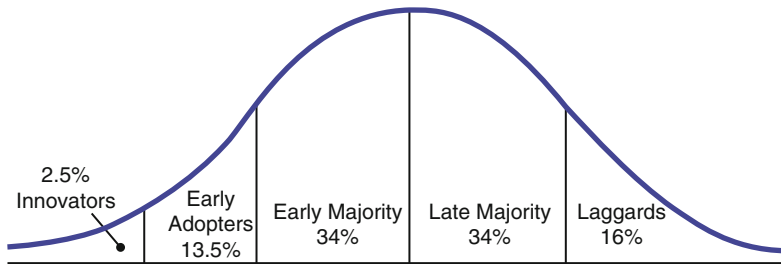

Fig. 1 Characteristics of adopters (Rogers 2003)

Innovators: Interest and initiative drive them to seek new ideas and ways of doing things. Tend to be viewed as risk-takers by the peer group.

Early adopters: Respected by peers. Known for judicious, successful, and discrete use of new ideas and technologies. Often serve as opinion leaders and innovation champions.

Early Majority: Tend to be more deliberate in their adoption. Follow innovators and early adopters willingly but seldom lead.

Late Majority: Innovations are approached with skepticism and caution. Peer pressure and norms drive the innovation-decision process.

Laggards: The last group to adopt an innovation. Tend to be suspicious and delay adoption decisions to see whether the innovation is successfully adopted by others.

As can be seen in Fig. 1, Rogers portrays these adoption categories as arrayed across a bell-shaped distribution.

Also addressed are the stages individuals typically go through when engaged in the *innovation-decision process*:

Knowledge: Becoming aware of the innovation

Persuasion: Becoming knowledgeable about the characteristics of the innovation

Decision: Deciding to adopt or reject the innovation

Implementation: Putting the new idea or technology into practice

Confirmation: Reflecting on the decision and implementation experience to decide whether to continue or discontinue adoption of the innovation

Finally, *diffusion networks* (Rogers 2003, p. 300) help explain how interpersonal connections among community of practice members drive the innovation diffusion process. Diffusion networks provide insights into social norms, capital, and relationships which play a central role in the innovation diffusion process. The literature on diffusion of instructional technology use within the P-12 teacher community of practice provides insights into factors that may influence an educator's likelihood of utilizing a new technology for instructional purposes. Foulger and her colleagues (2013) used DoI as a theoretical framework for examining university faculty use of mobile technologies and found that communication channels within and among

institutions of higher education were not substantial enough to initiate widespread use. While DoI may provide a good foundation for understanding how innovations diffuse within a society, it is not easily applied in complex and interconnected processes associated with teacher adoption of technology, which includes numerous variables like characteristics of adopters, characteristics of the innovation, and characteristics of the context, making it difficult to determine the causes of the eventual adoption of an innovation (Damanpour 1996).

Theory of Planned Behavior

The theory of planned behavior (PPB) is useful for explaining, predicting, and guiding change in human social behavior. According to the theory, intention is the immediate antecedent of behavior and is itself a function of attitude toward the behavior, subjective norms, and perceived behavioral control. These determinants follow, respectively, from beliefs about the behavior's likely consequences, from normative expectations of important others, and the presence of factors that control behavioral performance (Ajzen 2012). TPB is grounded in expectancy-value theory. Expectancy-value theory posits that:

1. An individual holds many beliefs about any given object, that is many different characteristics, attributes, values, goals, and concepts are positively or negatively associated with any given object;
2. Associated with each of these "related objects" is a mediating evaluative response – an attitude.
3. These evaluative responses summate;
4. Through the mediation process, the summated evaluative response is associated with the attitude object, and thus;
5. On future occasions the attitude object will elicit this summated evaluative response – this attitude (Fishbein 1965, p. 117).

Thus, an individual's attitude toward any object is a function of the strength of his/her beliefs about the object and the evaluative aspect of those beliefs.

These principles were extended into the TPB, in which performance of a behavior is a joint function of intentions and perceived behavioral control. Specific attitudes toward a behavior, coupled with an individual's beliefs about how people he or she cares about will view the behavior in question, can be expected to predict the individual's intent to engage in that behavior. Further, perceived behavioral control, or people's perceptions of their ability to perform a given behavior, influences intentions (see Fig. 2). In general, more favorable attitudes and subjective norms promote greater perceived control, positively influencing the person's intention to perform the behavior in question (Ajzen 2012).

Research that draws on the TPB tends to focus on the relationships among teachers' beliefs, expectations, intended use, and use of technology in the classroom. For example, in a longitudinal study, researchers found a connection between

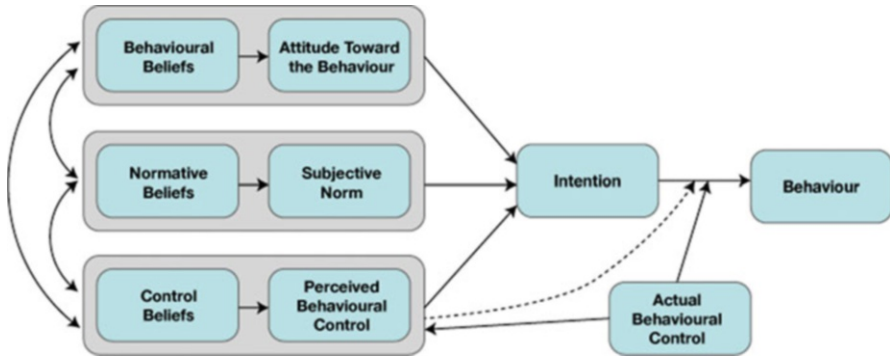

Fig. 2 Graphic representation of the theory of planned behavior (Ajzen 2006)

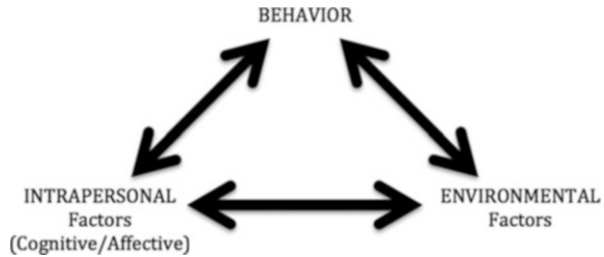

perceived relevance, perceived usefulness, and technology acceptance for teachers who participated in professional development for using a presentation technology in the classroom (Hu et al. 2003). Teo and his colleagues then showed that perceived usefulness, perceived ease of use, and subjective norms were strong predictors of preservice teachers' computer attitudes (Teo et al. 2008). However, other researchers suggested that only perceived usefulness had a direct significant effect on a group of preservice teachers' intentions to use computer technologies with their future students (Ma et al. 2005). This research has demonstrated that intrapersonal beliefs have a powerful influence on teachers' technology acceptance and intentions.

Social Cognitive Theory

In developing social cognitive theory, Bandura (1986) acknowledged that observation and vicarious reinforcement play key roles in human learning and behavior; however, breaking with the pervasive behavioral paradigm of the time, he also recognized that cognitive, self-regulatory, and self-reflective processes were essential in explaining human adaptation and change. According to Pajares (2002), Bandura viewed people as self-organizing, proactive, self-reflecting, and self-regulating rather than as reactive organisms shaped by environmental forces or driven by concealed inner impulses. He viewed human functioning as the product of a dynamic interplay of personal, behavioral, and environmental influences, with the results of one's own behavior informing and altering their environments and intrapersonal factors which, in turn, inform and alter subsequent behavior. This *reciprocal determinism* is grounded in the idea that (a) cognitive factors in the form of cognition, affect, and biological events; (b) behavior; and (c) environmental influences create interactions that result in a *triadic reciprocity* (see Fig. 3).

Environmental factors clearly play an important role in the technology integration process. Both the social environment and physical environment shape, and are shaped by, teachers' decisions to use technology with their students. As mentioned

Fig. 3 Graphic representation of social cognitive theory (Adapted from Pajares 2002)

previously, access to technology is a necessary, but not sufficient, condition for technology integration to occur. Thus, access to technology (coupled with the nature of the technology and nature of the access) influences a teacher’s ability and willingness to integrate technology into his or her pedagogy, and a teacher’s willingness to use technology with students shapes the technology that is available in the environment as he or she requests access to certain technologies and develops pedagogical reasoning to take advantage of the affordances of the available technologies.

In a body of research which examined the Apple Classrooms of Tomorrow initiative – an early attempt to bring the reforming power of computers into K-12 classrooms during the 1980s and 1990s – the initial focus of the project was on providing a technology-rich environment for students and teachers (see Sandholtz et al. 1997). However, “. . .ACOT researchers learned soon enough that a *saturation strategy* failed to alter how teachers taught. . .” [emphasis added] (p. xiii). Noticing that teachers in ACOT classrooms appeared to be moving through developmental stages, they shifted their attention to focus more directly on teachers and identified three stages that teachers moved through as they became increasingly sophisticated in their use of technology for teaching and learning in their classrooms:

1. *Survival*: Feelings of being overwhelmed by an inability to anticipate problems, and make necessary changes;
2. *Mastery*: Beginning to anticipate problems and develop strategies for solving and avoiding problems related to teaching and learning with computers;
3. *Impact*: The ability to use technology to enhance student motivation, interest, and learning (Sandholtz et al. 1992).

The realization that we needed to look beyond student access to technology and examine teachers’ feelings, beliefs and attitudes played a central role in shaping the technology integration effort that became widespread during the 1990s and prompted increased attention to professional development efforts and the conceptualization and application of models that focused more directly on intrapersonal factors that shaped teacher behavior. Thus, given that technology has become more available to teachers within a particular *environment* (classroom computers, computer labs, media centers, 1-1 device initiatives, etc.), *intrapersonal factors* have increasingly been recognized as playing a central role in teachers’ integration of technology into their practice and the nature of that integration (*behavior*).

Key intrapersonal factors from social cognitive theory include self-efficacy (SE), outcome expectations (OE), and knowledge. Social cognitive career theory (SCCT; Lent et al. 1994, 2002) is an application of social cognitive theory that seeks to explain and predict academic and career-related behaviors. SCCT has been used to examine the role of SE and OE across a variety of career options – particularly in areas of information management and in information technology-related fields (Niederhauser and Perkmén 2008). Of these, self-efficacy has captured the most attention in the literature and is considered the critical factor in the SCCT model (Lent et al. 1994).

Self-efficacy is essentially an individual's level of confidence that he or she can accomplish a given goal. SE addresses “. . . people's judgments of their capabilities to organize and execute courses of action required to attain designated types of performances. It is concerned not with the skills one has but with judgments of what one can do with whatever skills one possesses” (Bandura 1986, p. 391). SE is the belief that one can successfully produce a desired outcome and appears to be an important determinant of human behavior because it influences motivation. Those who judge themselves inefficacious may avoid engaging in certain tasks, whereas those with higher SE may participate more enthusiastically (Schunk 2001).

Outcome expectations address one's motivation to complete a task. OE involves the anticipated outcomes of an action (“If I do X, Y will happen”) (Lent et al. 1994). According to Bandura (1986), OE rewards take three major forms: *physical* (external rewards like money or grades), *self-evaluative* (self-satisfaction), and *social* (respect from others). Schunk (2001) addressed the importance of OE in human behavior: “Expectancies are important because they help people form cognitive maps, or internal plans comprising expectancies of which actions are needed to attain goals. People follow signs to a goal; they learn meanings rather than discrete responses. People use their cognitive maps to determine the best course of action to attain a goal.” (p. 106) Like SE, OE also plays an important role in motivation: “Unless people believe that their actions will have the desired consequences, they have little incentive to engage in those actions” (Pajares 2002, p. 6). Further, outcome expectations may drive individuals to sustain behaviors over long periods of time if they believe their actions will eventually generate the desired outcome.

Teachers' self-efficacy has been widely addressed in the instructional technology integration literature. When computers were first introduced as an instructional tool for classroom teachers in the 1980s, most teachers had little or no experience with these technologies in their personal or professional lives. Teachers' self-efficacy, with regard to using these new technologies with students, played an important role in determining whether they were willing to integrate the new tools into their teaching repertoires (Brinkerhoff 2006; Ertmer et al. 1994).

Aside from the fact that access was limited, hardware and software was rudimentary, and pedagogical awareness of what was available and possible was minimal; many teachers lacked confidence in their ability to use technology with students (Rosen and Weil 1995). As time has passed, and new technology-savvy teachers have joined the workforce, their knowledge of (and facility with) technology has steadily increased – prompting commensurate improvement in self-efficacy. These

developments have brought outcome expectations to the forefront (see Niederhauser and Perkmen 2010). Since access to technology has improved dramatically, hardware and software has become much more sophisticated, and teachers becoming increasingly knowledgeable and confident in their ability to use technology (Wang et al. 2014), outcome expectations will likely be a fruitful research area in the future.

Instructional Technology Adoption Models

The theories of innovation, diffusion, and adoption presented above underpin the instructional technology adoption models that are addressed in the remainder of this chapter. These models and frameworks help us better understand the complex ideas and processes that are in play when teachers integrate technology into their pedagogical practices.

The first model, *The Concerns-Based Adoption Model (CBAM)*, is a developmental model that addresses concerns teachers progress through when adopting an innovation and the increasingly sophisticated ways that teachers use technology with their students. Next, we address the *Technological, Pedagogical, and Content Knowledge (TPACK)* framework and *Substitution, Augmentation, Modification, Redefinition (SAMR)* model, which address overlapping areas of knowledge that frame teachers' technology using decision-making and behavior, and the ways that technology can be used to enhance and transform instructional practices, respectively. The *technology acceptance model (TAM)* and *unified theory of acceptance and use of technology (UTAUT)* draw on the psychosocial theories presented earlier. The TAM speaks to technology adoption in the general population, while UTAUT applies TAM in educational settings with teachers and learners. *Will, Skill, Tool, Pedagogy (WSTP)* is the most comprehensive model to date for examining instructional technology integration. In this model the Will construct addresses attitudes and motivation; Skill addresses ability, experience, knowledge, and confidence; Tool addresses availability, accessibility, and environment; and Pedagogy addresses teaching style, knowledge, and practices. Together, these models provide a multifaceted view of the complex processes involved in the integration of technology into teachers' practices and the culture of classrooms and schools.

The Concerns-Based Adoption Model

Grounded in educational change theories and conceptual work on the influence of teachers' concerns in their willingness and likelihood to change (Fuller 1969), CBAM was developed to model teacher change as an individual process undergone by those seeking to – or required to – change their teaching behaviors (Hall 1974). Although it was originally designed for the study of the adoption of any new educational innovation, the Stages of Concern (SoC) and Level of Use (LoU) constructs have been extensively used to directly address adoption of information technology innovations, serving as a theoretical lens for researchers worldwide over

the past four decades (Hancock et al. 2007). CBAM proposes a predictable order of the emergence and progression of concerns about innovations that are developmental in nature. In general, initial teacher concerns will subside in intensity before later, higher-stage concerns are internalized and expressed (Wesley and Franks 1996). However, if the lower stages of concern are not resolved or addressed, then higher stages of concern are not likely to emerge. The Stages of Concern dimension provides a sequence of stages that teachers pass through based on their level of concerns about the innovation:

Unconcerned: Little concern or involvement;

Informational: General awareness of, and interest in, the innovation. No worry about the innovation;

Personal: Uncertain about demands of the innovation. Worried about his or her adequacy and role in implementation. Analyzing potential rewards, role, conflicts and commitment;

Management: Focus on process and tasks of using the innovation. Concerns are about efficiency, organizing, managing and scheduling;

Consequence: Focus on the innovation's impact on his or her students. Concerns are about relevance, for students, evaluation of student outcomes, and changes needed to improve those outcomes;

Collaboration: Focuses on coordinating and cooperating with others regarding use of the innovation;

Refocusing: focuses on exploring ways to reap more universal benefits from the innovation, including the possibility of making major changes to it or replacing it with a more powerful alternative (George et al. 2006).

The second dimension of the CBAM, Levels of Use, focuses on how performance and activities change as the individual becomes more familiar with the innovation and more skillful at using it (Loucks and Hall 1979). Like Stages of Concern, LoUs are developmental in nature. The general LoU model includes eight phases: Nonuse, Orientation, Preparation, Mechanical Use, Routine Use, Refinement, Integration, and Renewal (Hall et al. 2006); however, a Level of Technology Integration framework (LoTI) was developed to specifically address teachers' instructional technology integration levels:

Nonuse: Perceived or actual lack of access to technology-based tools, or a lack of time to pursue electronic technology implementation;

Awareness: The use of computers is generally one step removed from the classroom teacher (e.g., integrated learning system labs). Computer-based applications have little or no relevance to the individual teacher's instructional program;

Exploration: Technology-based tools serve as a supplement to existing instructional program (e.g., tutorials, educational games, simulations). The electronic technology is employed either as extension activities or as enrichment exercises;

Infusion: Technology-based tools (e.g., databases, spreadsheets, calculators, and desktop publishing applications) are used to augment isolated instructional events (e.g., a science-kit experiment that utilizes spreadsheets to analyze results or desktop publishing to produce a school newsletter);

Integration: Technology-based tools are integrated in a manner that provides a rich context for students' understanding of concepts, themes, and processes. These tools enhance students' opportunities to identify and solve authentic problems relating to an overall theme/concept;

Expansion: Technology access is extended beyond the classroom. Classroom teachers actively elicit technology applications and networking from business enterprises, governmental agencies and other sources (e.g., contacting NASA to establish a link to an orbiting space shuttle via the Internet) to provide expanded student problem solving, issue resolution, and activism experiences;

Refinement: Technology is perceived as a process, product (e.g., invention, patent, new software design), and tool to help students solve authentic problems related to an identified real-world problem or issue. (Moersch 1995)

Lower levels in the taxonomy are representative of issues like access and ease of use; while higher levels tend to reflect higher-order reform-oriented instructional practices.

Research grounded in CBAM indicates that higher CBAM levels are linked to enhanced pedagogical change and increased positive attitudes for teachers (Hao and Lee 2015), as well as collaborative classrooms and more effective instructional strategy-use by teachers (Hall et al. 1975). A strength of the CBAM model is that change is addressed through a developmental perspective – that individual's progress through the stages involves increased sophistication in the use of the innovation (Straub 2009); however, there are some limitations when applying the CBAM model to examine technology integration.

Because CBAM primarily deals with top-down imposed change, it presupposes that teachers will resist change and have negative perceptions (concerns) about the innovation. Therefore, it is not as effective in explaining the role of teacher leaders who tend to embrace change and favor a more bottom-up adoption process. Some teachers may be resistant to change – but may also have positive attitudes toward a particular innovation that may coincide with the existence of the concerns. Straub (2009) cautions against ignoring teachers who may have positive dispositions toward an innovation, as CBAM may sell teachers short by portraying them as resistant luddites.

Technological, Pedagogical, and Content Knowledge

TPACK provides a framework for capturing the dynamic and complex relationships among content, technology, pedagogy, and context (see Fig. 4). The framework highlights what teachers need to know to teach in an information age and supports the design of faculty-based professional development that pushes them to change the

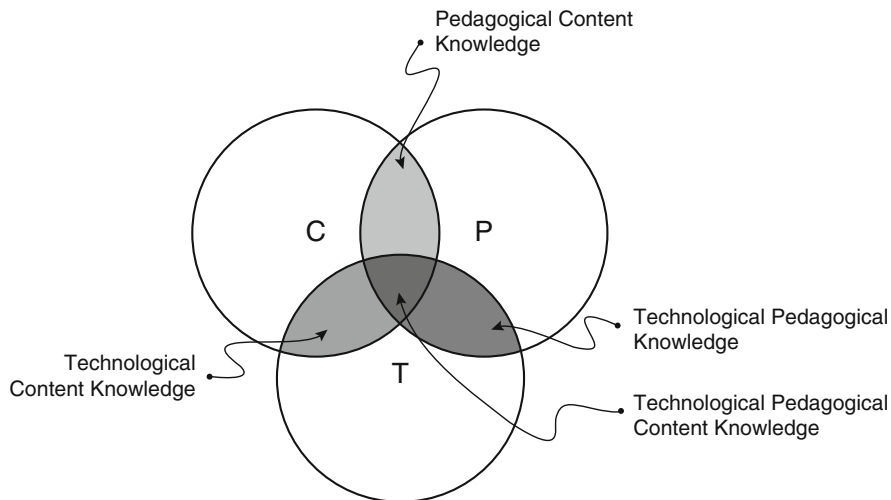

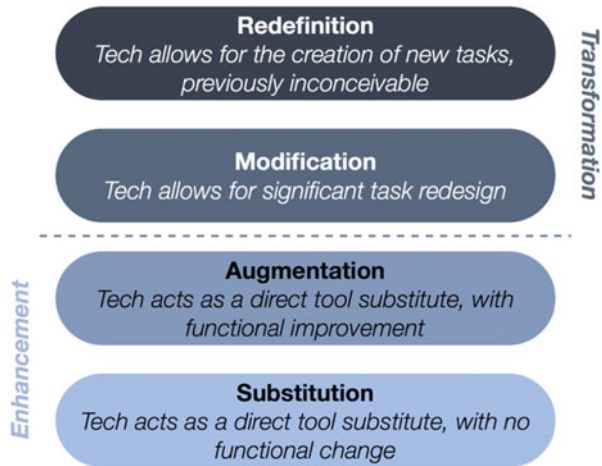

Fig. 4 Graphic representation of the TPACK framework (Mishra and Koehler 2006)

way they teach. The intersection of these three knowledge types represents the interplay among teaching content, pedagogical methods, and use of technologies (Mishra and Koehler 2006). Seven components comprise the framework:

1. Technological knowledge (TK): Knowledge about various technologies, ranging from low-tech technologies like pencil and paper to digital technologies like computers, the Internet, and interactive whiteboards
2. Pedagogical knowledge (PK): Knowledge about methods and processes of teaching including instructional strategies, sequencing instructional events, assessment, classroom management, etc.
3. Content knowledge (CK): Knowledge about the subject matter that is to be taught
4. Technological Pedagogical Knowledge (TPK): Knowledge about how technologies can be used to enhance teaching
5. Technological content knowledge (TCK): Knowledge about using appropriate technologies to teach a specific content area (e.g., the Internet can be used to find original sources when teaching history)
6. Pedagogical content knowledge (PCK): Knowledge of appropriate pedagogy in a given content area (e.g., knowing how to teach literature analysis versus knowing how to teach students to solve differential equations)
7. Technological pedagogical content knowledge (TPACK): Knowing how to effectively integrate technology into one's teaching within a particular content area

The TPACK framework is an important tool for helping teachers reflect on how their technological, pedagogical, and content knowledge shapes their practice and offers teacher educators and professional development providers ways to assess teachers' knowledge and strategically target their knowledge-building efforts.

Fig. 5 Graphic representation of the *Substitution, Augmentation, Modification, Redefinition* model (Puentedura 2012)

Substitution, Augmentation, Modification, Redefinition

Focused on promoting the potential for technology to transform instructional practice, the Substitution, Augmentation, Modification, Redefinition model provides a scale for examining the degree to which teachers' technology use enhances and/or transforms the instructional context (see Fig. 5). The goal is to transform learning experiences so they result in higher achievement levels for students.

While the TPACK framework has had a major influence on the technology-using teacher preparation field, the pragmatic focus of the SAMR model has made it particularly appealing to the professional development community.

Technology Acceptance Model

The TAM was developed to help us understand all forms of technology adoption in the general population. TAM is grounded theoretically in the theory of planned behavior (Ajzen and Fishbein 1980; Ajzen 2012) and was among the first models to include social-psychological factors to examine technology acceptance. TAM specifies the relationships between perceived usefulness, perceived ease of use, attitude toward computer use, and behavioral intention to use technology. TAM proposes that perceived ease of use and perceived usefulness of a technology are fundamental determinants in computer use. Perceived usefulness is the degree to which a person believes that using a particular technology will enhance his or her job performance (Davis et al. 1989), while perceived ease of use refers to the degree to which a person believes that using a particular technology will require little effort. As can be seen in see Fig. 6, these two mediating factors significantly influence attitude toward computer use, which in turns affects the behavioral intention to use technology (Liaw and Huang 2003).

Results from research using TAM in educational settings suggest that teachers tended to consider the limitations and effectiveness of technology tools in the

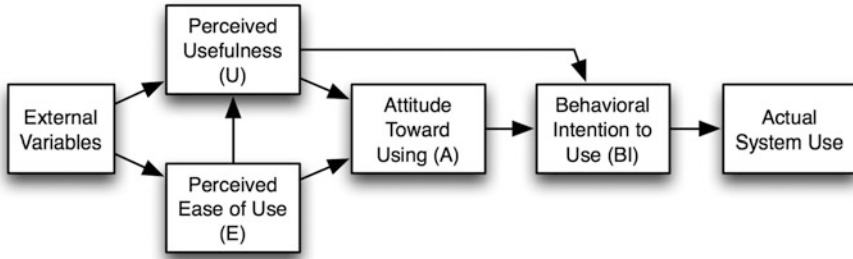

Fig. 6 Graphic representation of the TAM model (Davis et al. 1989)

context of teaching, that positive attitudes tended to lead teachers to incorporate technology into their teaching practices, and that the relationship between attitudes and beliefs was bidirectional (Smarkola 2008; Zacharia 2003).

However, because TAM and related models focus on the explanation of how characteristics of a specific technology affect user acceptance (Davis 1993), TAM draws on only two personal belief systems and excludes other independent variables which might influence perceived usefulness and ease of use (Bagozzi 2007). Thus, TAM may not be comprehensive enough to capture the effects of external variables or social factors (Bagozzi 2007; Smarkola 2008). Additionally, TAM has been largely used and tested in contexts in which technology use is voluntary (e.g., Benbasat and Barki 2007) and may have limited explanatory power in contexts like schools – where technology use is often mandated.

Unified Theory of Acceptance and Use of Technology

The unified theory of acceptance and use of technology (Venkatesh et al. 2003) builds on the TAM and has been widely applied and tested in educational contexts with students and teachers (Teo 2015). UTAUT is comprised of three constructs which together seek to determine an individual's intention to use a specific information technology (see Fig. 7). The three constructs are:

Performance expectancy: The degree to which the user expects that using the system will help him or her improve job performance;

Effort expectancy: How easy or difficult the user believes it will be to implement the innovation;

Social influence: The degree to which an individual perceives that others (whose opinions are valued) believe that he or she should implement the innovation. (Teo 2015)

As we saw with other models, researchers have identified limitations with the UTAUT model. UTAUT does not address knowledge factors like prior experience,

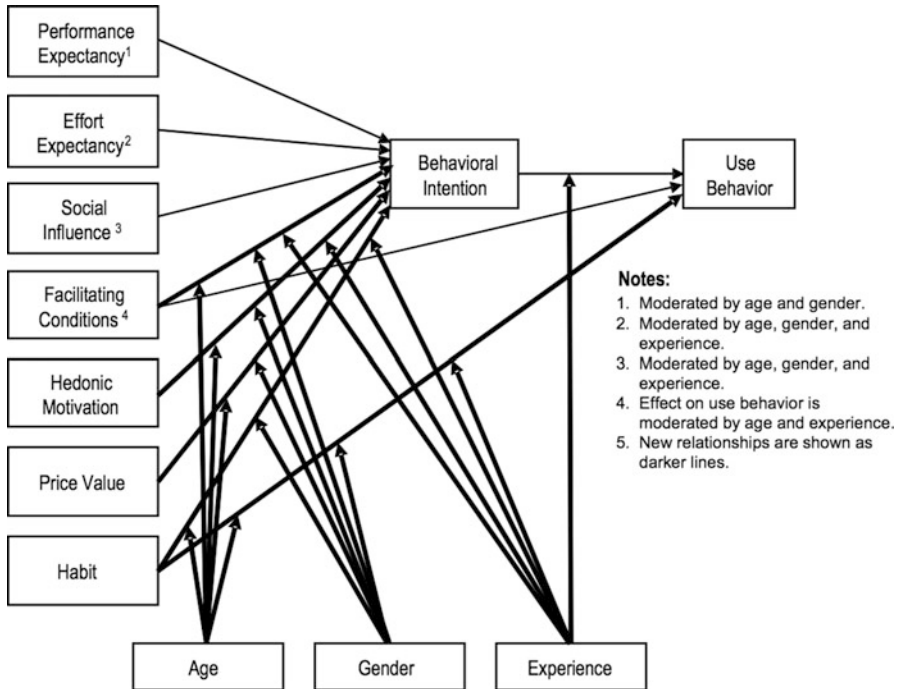

Fig. 7 Graphic representation of the UTAUT model (Venkatesh et al. 2012)

affective factors like perceived interest or enjoyment, or external facilitating conditions; and, like TPACK, assessing constructs typically relies on self-report as the primary data source. UTAUT has also been criticized as being overly complex, not parsimonious in its approach, and not well-suited to explaining individual behavior (Bagozzi 2007; Casey and Wilson-Evered 2012).

Will, Skill, Tool, Pedagogy

Will, Skill, Tool, Pedagogy provides a proficiency model that, in its original form, included three constructs relevant to classroom teaching selected from more than 30 variables that have been recognized as essential for student learning (Knezek and Christensen 2016). WST was initially designed to focus specifically on the school environment and the contribution of classroom technology integration to student learning (Knezek et al. 2000). Findings from some of the early WST research indicated that constructivist pedagogical practices lead to more effective technology integration (Petko 2012), which prompted the addition of teaching style (or pedagogical practice) to form the WSTP model (see Knezek and Christensen 2016). The WSTP constructs that influence the integration of technology in the classroom include:

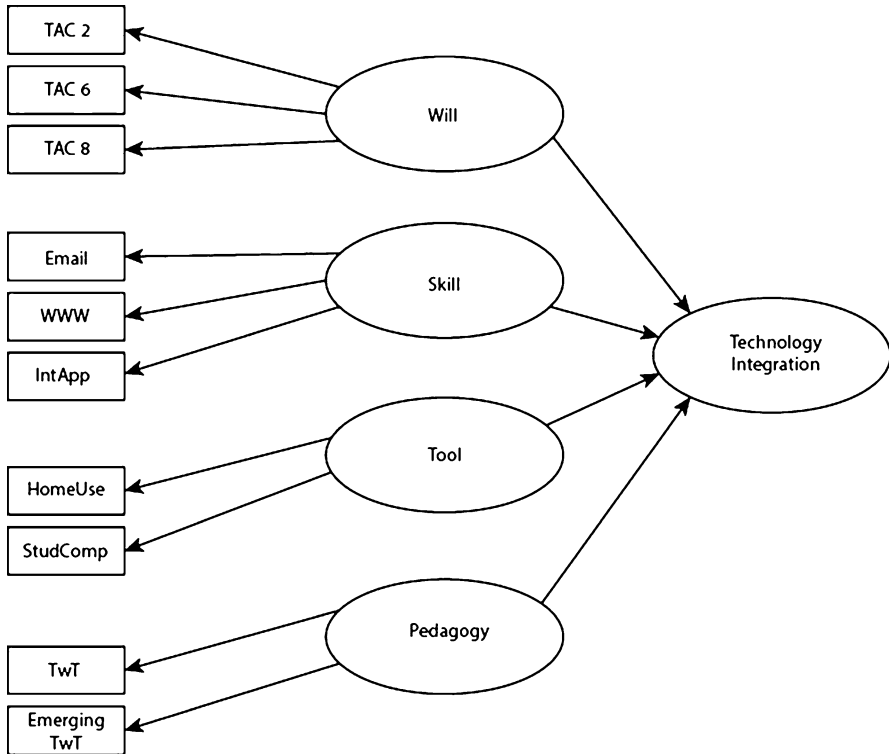

Fig. 8 Expanded Will, Skill, Tool, Pedagogy model of technology integration (Knezek and Christensen 2016)

Will: Holding a positive attitude toward instructional use of technology;

Skill: The ability to use and experience technology, as well as perceived confidence (self-efficacy) and readiness;

Tool: Availability, accessibility, and nature of the use of a given technology;

Pedagogy: Teaching style; pedagogical practice. (Knezek and Christensen 2016)

The main purpose of the WSTP model is to help educational leaders make informed decisions for teacher professional development to enhance teaching and learning. However, studies using WST and WSTP models support claims that the presence of technology does not guarantee effective classroom use. Results have indicated that 40–90% of a teacher’s level of technology integration can be explained using Will, Skill, Tool and Pedagogy data (Agyei and Voogt 2011). The complete model has a second stage in which level of technology integration is used to predict student learning and achievement. The technology integration portion of the WSTP model is shown in Fig. 8.

Conclusion

Findings from studies using the models and frameworks described above seem to point toward a need for pedagogical change if teachers are to adopt technology and use technology meaningfully in educational settings. It also seems that teacher technology adoption processes are strongly influenced by interpersonal characteristics, like predisposition to embrace or avoid change, and their attitudes and beliefs about the usefulness of digital technologies for learning in school (Ertmer 2005; Hew and Brush 2007). However, research on teacher technology integration tends to focus on teachers' self-reported perceptions of their knowledge (e.g., Schmidt et al. 2009), and beliefs about the value of technology for learning and/or self-efficacy beliefs, even though these conceptions alone appear to be too narrow for determining why there are differences in whether and how teachers integrate technology (Kim et al. 2013).

For example, characterizing Will as a positive attitude toward the use of technology in instruction (as measured by subscales from the Teachers' Attitudes toward Computers (TAC) and Teachers' Attitudes Toward Information Technology (TAT)) represents a techno-centric view that, in general, technology use is good. This techno-centric view that technology is good fails to explain how two teachers could have strong positive beliefs about the value of technology for student learning; with one teacher only using technology to present content to students, while the other consistently uses technology to create interactive learning experiences (Kim et al. 2013).

Additionally teacher beliefs, as currently conceptualized in models of technology integration, do not appear to account for the "new mindsets" needed for the adoption of new technology tools that have fundamentally changed the way knowledge is constructed and distributed (Lankshear and Knobel 2007). For example, researchers found that Advanced Placement (AP) teachers and National Writing Project (NWP) teachers use Wikipedia at much higher rates than US adult Internet users as a whole (87% vs. 53%) in their personal lives (Purcell et al. 2013). However, these same teachers reported that they discourage or bar students from using Wikipedia because of concerns about the reliability of its content. Additionally 77% of AP and NWP teachers say the impact of using the internet and other digital technologies on students has been "mostly positive," and 76% of teachers surveyed "strongly agree" with the notion that the Internet "enables students to find and use resources that would otherwise not be available to them yet (76%) complain that "search engines have conditioned students to expect to be able to find information quickly and easily" (Purcell et al. 2013, p. 16).

Findings like these seem to contradict models for technology integration that suggest the ability to use a particular technology (Skill) is a strong predictor of technology integration in the USA (Velazquez 2007) or because there is a perception that a particular technology is easy to use, as TAM and UTAUT models suggest. Although teachers' TPACK may be a strong enabler for effective technology integration, it does not explain why teachers with sufficient knowledge utilize technology differently (Hall 2010).

Lankshear and Knobel (2007) suggest that “new mindsets” may be needed for more meaningful uses of technology in school. For example, teachers who make rules against using Wikipedia for learning in school reflect a *physical-industrial* mindset where expertise and authority are *located* in individuals and institutions. However, teachers who ask students to become editors of Wikipedia articles represent a *cyberspatial postindustrial* mindset where Wikipedia is not suspect but valued because it provides a space where individuals with diverse points of view can collaboratively construct knowledge.

Models and frameworks that can help capture and support the development of the cyberspatial postindustrial mindset may help educators adopt technologies in ways that better prepare students for the realities of twenty-first-century work and learning. To address these issues, current models and frameworks may need to expand to more directly address the kinds of learning that are currently valued in school (Kim et al. 2013).

As society adapts to the new-world-order prompted by the rapidly increasing progression of technological innovation, it is essential that we continue to develop and refine our models. Thoughtful progress in promoting meaningful instructional technology integration is predicated on a deep understanding of how teachers continuously adapt to an ever-changing school culture in an increasingly technological world. It is through ongoing development of these theories and models that we will better understand the complex dynamic processes involved in technology-using teacher development. The models discussed in this chapter provide teacher educators, school administrators, and educational policy-makers with powerful tools that help explain how technology integration occurs, allow us to make informed decisions about how to use technology resources, and provide insights that can support effective ways to diffuse effective and meaningful technology integration that can transform schools.

Abstract

In this chapter we feature instruments to measure teacher attitudes, competencies, and pedagogical practices judged to be important for effectively integrating technology into the classroom learning environment. The ability to assess a teacher's level on these attributes is important because positive attitudes, proficiency, and effective pedagogical strategies are necessary to foster quality student learning. Specific instruments that serve as exemplars for teacher appraisal are introduced. The importance of including more than one type of measure to comprehensively assess teacher needs and prescribe appropriate professional development is discussed.

Introduction

Teacher attitudes, beliefs, and practices are important to investigate and understand in advancing effective instruction. Most teacher attributes related to effective teaching can be assessed in multiple ways that include self-report, interviews, artifacts, lesson plan reviews, observation techniques, and a combination of these techniques. However, not all assessment techniques result in measurements as defined in the following quote.

Measurement is the assignment of scores to individuals so that the scores represent some characteristic of the individuals. [Measurement requires] . . . some systematic procedure for assigning scores to individuals or objects so that those scores represent the characteristic of interest. Psychological measurement is often referred to as psychometrics. (Price et al. 2015, Chap. 5, p. 1)

In this chapter we will restrict discussion to instruments that assign scores to individuals.

Over the decade that has passed since the publication of the first edition of this International Handbook in 2008, perspectives on the measurement of teacher attitudes, competencies, and pedagogical practices for teaching with technology have evolved from being viewed as unique domains to components of an integrated whole. Especially beginning with the broad-scale acceptance of Bandura's thoughts on self-efficacy (Bandura 1993), and continuing until the current day's recognition of the significance of TPACK (Technological Pedagogical Content Knowledge) as an important conceptual framework for technology integration – we must acknowledge that technology integration proficiency is a multifaceted attribute of an individual teacher that involves not only technology knowledge and skills but also pedagogical expertise, merged together with content knowledge in a discipline. But even this framework is incomplete as we also recognize that positive attitudes and long-standing positive dispositions are necessary for teaching with technology to flourish in any teacher's classroom.

Researchers have developed models with necessary components for successful integration of technology into the classroom (e.g., Rogers 1999). Many of these are described in a different chapter in this handbook (► [Chap. 22, "Instructional Technology Integration Models and Frameworks: Diffusion, Competencies, Attitudes, and Dispositions"](#) by Niederhauser and Lindstrom). For the purposes of the current chapter, teacher integration of technology into the classroom is assumed to have at least three major components that reside within the teachers' realm of control or influence: attitudes, skills, and pedagogical practices. Many scholars in the field consider these second-order barriers (Ertmer 1999) or intrinsic factors. This chapter

will include an introduction of how measures might be selected to assess teachers' dispositions and preparation for using technology in the classroom. Measures for attitudes will be discussed first in this section. Measures for skill (competency), pedagogical practices, and technology integration will be incorporated in the following sections, and finally the interaction and application of these measures will be examined.

Selection of Quality Measures

Many forms of valid and reliable instruments exist for obtaining measures related to technology in teaching and learning. One ongoing dialog in the scholarly community is with respect to the value of self-report versus observation data. This is an area where tools exist to accurately address the issues. Cattell (1973) pointed out that almost every information-gathering procedure in education employs an observer. When the observer is the person about whom the information is being gathered, we call this procedure self-report. The primary issues in this area are three:

- Is an outside observer a more accurate (consistent, reliable) reporter of activities such as the level of technology integration a teacher is able to accomplish in his/her classroom, than the teacher him-/herself?
- Is an outside observer a more appropriate (unbiased, relevant, valid) judge of activities such as the level of technology integration a teacher is able to accomplish in his/her classroom?
- What are the practical limits, including instructional time ramifications and cost-benefit considerations, of the two techniques?

These questions do not typically have simple answers, and yet there are emerging areas of consensus where quantitative and qualitative research is triangulated for stronger outcome measures. It appears that well-done self-reporting (no high-stakes, valid, and reliable instruments) on a large scale, complemented by well-selected (nonintrusive, randomly assigned, systematically reported) observations of the same environment, may be the most cost-effective approach to gaining a true picture of information technology use in most educational environments. Initial findings are emerging that indicate that a well-trained outside observer may provide a slightly more valid (relevant) appraisal of a classroom environment than the teacher him-/herself but that the teacher may provide a more reliable (consistent) appraisal than an observer who is typically in the classroom 1 or 2 hours of a school year (Knezek et al. 2005; Mayes 2014). One finding that has emerged in recent decades is that both the teachers themselves and outside observers with rich knowledge of daily classroom activities are reasonably accurate judges of teachers' classroom integration abilities (Christensen and Knezek 2008). While there are many techniques used to measure, this chapter will predominantly focus on self-report assessment.

Attitudinal Measures

Researchers have known for decades that IT attitudes and beliefs have powerful influences on actions. Teachers' attitudes are known to play an important role in the effective use of technology (Buabeng-Andoh 2012; Sang et al. 2010). Attitudes affect the teachers' level of confidence in using technology as well as their personal use and adoption of technology for use in class. Teacher attitudes can often determine the success or failure of an initiative to introduce technology into the classroom. While there are many attitudes that impact instruction, the longer-term dispositions that tend to impact technology integration in education include anxiety, beliefs, confidence, and perception of usefulness. In this chapter, we will follow the general definition of dispositions published by Allen et al. (2014): "We call these human qualities dispositions – a person's core attitudes, values, and beliefs demonstrated through both verbal and non-verbal behaviors as one interacts with oneself, others, one's purpose, and frames of reference" (Allen et al. 2014, p. 2).

Measuring teachers' attitudes is one important step in obtaining an overall picture of an educator's level of readiness for or proficiency in technology integration. This area of measurement is focused in the affective psychological domain and is commonly identified with concepts such as receptivity, motivation, will, interest, propensities, or long-term dispositions. Instruments to measure attitudes of teachers toward technology have been available in the literature for more than 30 years and are still being developed and refined today. Concepts measured by these instruments are normally validated through factor analysis and will frequently be referred to as constructs (core concepts identified through factor analysis) or simply factors in this chapter. Exemplars of instruments measuring teachers' attitudes are presented in this section.

Loyd and Gressard (1984) developed the 30-item **Computer Attitude Scale** (CAS) to measure attitudes toward computers for students, but it has been adapted over the past three decades for use by preservice and in-service teachers. The subscales include *computer liking*, *computer confidence*, and *computer anxiety*. Loyd and Gressard (1984) found that positive attitudes toward computers are positively correlated with teachers' extent of experience with computer technology and that with familiarity, anxiety decreases while confidence increases. The scale has been widely used for decades and translated into other languages such as Turkish and Hebrew for use in other cultures, retaining respectable reliability and validity.

The **Teachers' Attitudes Toward Computers** (TAC) questionnaire was developed to measure teachers' attitudes and was based on 14 previously published instruments for assessing attitudes toward computers, including Loyd and Gressard's (1984) CAS (Christensen and Knezek 2000). The TAC (Christensen and Knezek 2009) includes nine factor-validated constructs: *interest/enthusiasm*, *comfort* (lack of anxiety), *accommodation*, *interaction* (electronic mail), *concern* (negative impact), *utility/productivity*, *perception*, *absorption*, and *significance*. Findings comparing teachers who received year-long, needs-based technology integration professional development versus those who did not revealed a significant increase on computer importance and decrease in computer anxiety for those who received professional development (Christensen 2002).

More recently, Leng (2011) developed an updated version of the Loyd and Gressard's (1984) CAS by updating the items from referencing exclusively computers to referencing the broader area of ICT and also modifying items in other ways to make them more suitable for current environments. The **Information and Communication Technology Attitude Scale for Teachers** (ICTAST) instrument was tested for validity and reliability and found to retain good reliability and construct validity (Leng 2011). Leng (2011) retained the three original subscales, *anxiety*, *confidence*, *liking*, and added the additional subscale, *usefulness*. Findings indicated a strong relationship between attitudes and access to technology (Leng 2011).

Albirini (2006) developed the **Attitudes Toward Computer Scale** (ATCS), consisting of a scale to measure overall positive or negative attitudes toward technology. In addition, the instrument includes four subscales: *access*, *competence*, *perceived usefulness*, and *perceived cultural relevance*. In a study involving more than 300 teachers, attitudes toward technology were found to be predicted by computer attributes, cultural perceptions, and computer competence. In another study using the ATCS to measure teachers' attitudes, Hart and Laher (2015) found perceptions of usefulness of technology to be the strongest predictor of teachers' attitudes. The increasing emergence of usefulness of technology indicates that it is an important construct for instruments measuring teacher attitudes. Davis defined perceived usefulness as "the degree to which a person believes that using a particular system would enhance his or her job performance" (Davis 1989, p. 320).

Attitude measures are one major component of teacher development for technology integration. The following section will address two other major components – competency and self-efficacy.

Competency and Self-Efficacy Measures

In the competency-based environment that surrounds twenty-first-century education, proficiency in technology has assumed an important role, whether it is used to enhance instruction; for communication between teachers, students, and parents; or to assess student learning. The ability to integrate twenty-first-century technology for learning in schools is an expectation for teachers in most parts of the world today. Because technologies are constantly changing and the most productive use of technology is dependent on content, it is now considered more important to develop general competencies focused on how technology can be used for teaching and learning. For example, in Norway, there is a focus on a cross-curricular approach to technology competence in the curriculum. This approach includes the areas of processing information, creating and communicating information, and the ethics of technology use (Tondeur et al. 2017).

Measuring whether or not teachers are confident in their ability to integrate the evolving tools is important in order to target professional development. Using valid and reliable instruments to assess teachers' perceived proficiency with twenty-first-century technology tools is an important step in targeting appropriate levels in school-wide

training activities, as well as planning meaningful developmental pathways for individual teachers.

Researchers have developed survey instruments to assess teacher self-efficacy and technology use to determine the role self-efficacy plays in the integration of technology in the classroom. Milman and Molebash (2008) developed a survey, **Confidence in Personal and Instructional Use of Technology**, that specifically addressed their state standards for educator technology proficiency for undergraduate and graduate students enrolled in an introduction to technology course. Their analysis showed their course was effective in increasing personal confidence in using technology, both pre to post and longitudinally 5–7 years later when they the former students were practicing teachers (Milman and Molebash 2008).

Wang et al. (2004) used the **Computer Technology Integration Survey** to measure the development of preservice student confidence, by including vicarious learning experiences and goal-setting activities in an introductory technology course. The survey measured confidence levels using two factors: *computer technology capabilities and strategies* and *external influences of computer technology uses*.

Research on a large sample ($n = 5938$) of teachers in Taiwan used an **ICT Integration Proficiency Measure** to assess changes over time in teachers (Hsu 2017). The instrument includes six factors: (1) *preparation*, (2) *production*, (3) *communication*, (4) *instruction*, (5) *development*, and (6) *issues*. Findings from this study suggested that teachers' pedagogical usage of technology changes more slowly than other technology measures included as scales. However, in the area of issues related to students' health and safety, teachers' concerns grew over time regarding Internet usage (Hsu 2017).

The **Technology Proficiency Self-Assessment (TPSA)** was initially developed in 1999 to measure teacher confidence (self-efficacy) when using technology for educational purposes (Ropp 1999). The original instrument included four scales (*email*, *WWW*, *integrated applications*, and *teaching with technology*) and has been refined over the past 15 years with the continual goal of measuring educators' self-efficacy in their ability to integrate technology into the classroom environment. The TPSA was based on the International Society for Technology in Education (ISTE) standards for educators in place at the time of development. Ropp (1999) reported significant improvements in technology proficiency and computer self-efficacy measures during a semester-long hands-on technology in education course. Christensen and Knezek (2017a) gathered teacher data, including the TPSA, over ten consecutive years from a large school district. Data gathered from the approximately 1320 teachers indicated that teachers generally gained over time in their confidence in their competence in using technology as well as teaching with technology (Christensen and Knezek 2017a). Researchers in Turkey translated the original TPSA into Turkish and conducted a reliability and validity study with in-service teachers, finding the instrument to be a reliable source for assessing technology self-efficacy in teachers (Gencturk et al. 2010).

Christensen and Knezek (2017a) revised and extended the TPSA to include two new scales for twenty-first-century competencies related to teaching with emerging technologies. The updated 34-item TPSA, called the **TPSA C21**, assesses educators

on the following 6 constructs: *email*, *WWW*, *integrated applications*, *teaching with technology*, *emerging technologies*, and *teaching with emerging technologies*. The revised TPSA C21 constructs can be categorized according to two higher-order dimensions, with old versus new technology tools along one axis, while teacher-introduced technologies used with and by students to promote student learning, versus technologies for teachers' own professional development, serve as the distinguishing characteristics along the second axis (Christensen and Knezek 2017a).

The **Intrapersonal Technology Integration Scale** was developed to measure intrapersonal variables that impact educators' dispositions toward integrating technology for instruction (Niederhauser and Perkman 2008). The survey was validated on preservice teachers and includes four subscales: *self-efficacy*, *outcome expectations*, *interest*, and *behavioral intentions*. The self-efficacy subscale was intended to measure confidence in integrating technology in the classroom, while the interest subscale was intended to measure the level to which the educators were interested in integrating technology in instruction. Outcome expectations were used to measure the benefits these educators anticipated would occur with technology, and the behavioral intentions assessed the intention to integrate technology in the future. Use of the Intrapersonal Technology Integration Scale with preservice teachers revealed that self-efficacy and outcome expectations were related to each other and both contributed to the prediction of performance (Perkman and Pamuk 2011).

The **Technology Uses and Perceptions Survey** (TUPS) was initially developed by Hogarty et al. (2003). It has been updated to include new technologies and pedagogical strategies. The revised TUPS measures ten domains related to classroom technology integration (Rizhaupt et al. 2017), including *teacher confidence in their competence in using technology*, *teacher attitudes toward integrating technology*, and *teacher perceptions of the usefulness of technology for learning*. It is recommended as a descriptive tool to inform school improvement efforts related to technology implementation programs (Rizhaupt et al. 2017).

Researchers in Belgium (Tondeur et al. 2017) developed a **Preservice Teachers' ICT Competencies** instrument to measure teacher ICT competencies. They found a two-factor structure and confirmed that the instrument measures *competencies necessary to support student learning in the classroom* and *competencies needed to design instruction*. This competency structure aligns with measures on the TPSA C21 in which there are tools to prepare teachers to teach and also the use of technology to enhance learning.

In the area of assessment of competencies, many highly respected instruments exist that are not classified as self-report questionnaires. Two examples are described in the following section. The first might best be described as a technology literacy test, while the second is a structured observation instrument using technology to support the observation.

The **WayFind Teacher Assessment** created by Learning.com is an online performance-based assessment in which teachers or school districts pay to complete a 1–2 hours assessment of *technology literacy* following ISTE standards (Learning.com 2012). While the WTA appears to have a useful place in teacher education,

it has a required fee, and someone must download, analyze, interpret, and manage the results (Banister and Reinhart 2012).

During the twenty-first century, it has become more practical for expert observers to use handheld technologies to complete structured assessments and record the strengths and weaknesses of technology-using teachers' performance during an actual class where students are learning. One tool that supports observational data collection is the **Technology Integration Matrix (TIM)** developed by the Florida Center for Instructional Technology at the University of South Florida (Mayes 2014). The Technology Integration Matrix (TIM) was produced by blending Jonassen's five characteristics of meaningful learning (Jonassen et al. 2003), with the stages and levels of adopting technology into the learning environment as defined by the Apple Classrooms of Tomorrow (ACOT) project (Dwyer et al. 1989). The combination of these two conceptual frameworks resulted in a rubric-like instrument for measuring levels of technology integration. This type of theory-based instrument and high-quality, interactive, user interface designs allow less obtrusive counting and recording of specific instances of teaching and/or learning behaviors in an authentic classroom. TIM is one example of a hybrid system that uses technology to help validate concrete instances of teaching and learning with technology.

Evidence is emerging that hybrid systems involving teacher-technology partnerships are destined to become more sophisticated and more prevalent in primary and secondary teaching and learning in the future. Tools are currently being created to give teachers nearly instantaneous feedback on the performance of their students. Many of these are based on artificial intelligence technologies (Luckin et al. 2016). Commercial examples such as Khan Academy, which as of 2017 aims to offer individualized instruction in primary and secondary math and select topics in science, history, business, art history, and test preparation, already make more than 100,000 practice exercises and instructional videos available for potential guidance by primary and secondary teachers (Edusurge 2017). Primary and secondary schoolteachers need competency to accept and use new tools in classrooms to determine learning needs, prescribe learning tasks or enhancements, and monitor student progress using data feedback systems. As advances are made in learner analytics and "big data" analysis that could possibly provide daily feedback to the individual teacher level, we can anticipate the prospect for cooperative planning and modifications of learner activities among the classroom teacher and school leader levels.

Pedagogy Measures

The instructional strategies that teachers use in the classroom are evolving due to the influences and influx of technology. Watkins and Mortimore (1999, p.17) offered a definition of pedagogy as "any conscious activity by one person designed to enhance learning in another." For the purposes of this chapter, pedagogy includes teaching style (teacher-centered, student-centered, etc.) and encompasses what is normally understood as teaching approach or instructional strategy.

Measures of pedagogical style have been developed over past decades and refined by researchers. For example, Jacobson et al. (2010) refined the **Learner and Teacher-Centered Pedagogical Practices Survey** (Center for Research of Pedagogy and Practice 2005) based on data gathered from 1882 teachers in 51 schools in Singapore, in order to assess *deep thinking/creativity connectedness*, *transmission instruction* (vs. constructivist instruction), *assessment*, and other constructs not reported here because they were represented by no more than 2 items per construct. Jacobson et al. (2010) also used the same dataset to refine additional scales from instruments by Becker and Anderson (1998), including the (a) **Use and Impact of Computers in Schools** and (b) **Teachers' Perceptions of Their Work Environment**. Validated scales include *learner-centered use of computers*, *assessment of teachers' computer skills*, *perceived advantages of computer use*, *perceived disadvantages of computer use*, *work environment indicators*, *teachers' professional development*, and *practices encouraged by school*. Findings from this large study were that teachers who used computers more frequently in learner-centered ways had more positive perceptions toward technology and used computers more frequently per week (Jacobson et al. 2010).

Shulman's Pedagogical Content Knowledge (PCK) framework emphasized the intersection of pedagogy and content knowledge, encompassing knowledge about different types of learning and the many different ways to teach (Shulman 1986). TPACK added the technology component to the pedagogy and content knowledge (PCK) framework (Mishra and Koehler 2006). An assessment instrument based on the Technological Pedagogical Content Knowledge (TPACK) framework was developed to measure teachers' understanding of each component of the TPACK framework (Schmidt et al. 2009). Four of the components related to pedagogy: *pedagogical knowledge* (PK), *pedagogical content knowledge* (PCK), *technological pedagogical knowledge* (TPK), and *technological pedagogical content knowledge* (TPACK). Since the TPACK survey was developed (Schmidt et al. 2009), it has been adapted and used by many researchers and translated into several different languages. Archambault and Barnett (2010) administered the TPACK survey instrument to 596 K-12 teachers online. The researchers reported that three separate factors (*pedagogical content*, *technology-curricular content knowledge*, and *technological knowledge*) were extracted and there was a strong correlation between pedagogy and content.

Koh et al. (2010) revised the Schmidt et al. (2009) survey and found that the pedagogy items combined pedagogical knowledge and pedagogical content knowledge into one factor. Researchers gathered data using questionnaires for *pedagogical beliefs* (9 item pairs), *teaching activities with technology use* (5 item pairs), and factors associated with technology integration (30 items) (Liu 2011). The goal of the research was to determine the factors related to pedagogical beliefs of teachers and technology integration. The results indicated that while most of the teachers held learner-centered beliefs, less than one third of the teachers implemented learner-centered activities with technology.

Several models of technology integration include measures of attitudes, competency/self-efficacy, and pedagogy as determinants of technology integration.

Measures have also been developed to assess levels of technology integration directly. The following section will address several of these measures.

Technology Integration Measures

A collaboration of public schools, universities, research agencies, and Apple Computer Inc., began the study of technology-infused classrooms as opposed to the previous focus on technology skills (Dwyer 1994). This research began in 1985 and influenced the study of technology-infused classrooms and how we look at teaching and learning with technology. The Apple Classrooms of Tomorrow (ACOT) project, as this longitudinal study was called, influenced the direction of research on educational technology by focusing on technology-using teacher proficiencies in developmental stages. Many measures have since been developed using a stage-based developmental framework compatible with ACOT, often based on well-regarded theoretical perspectives. Several of these are discussed in this section. For the purpose of this chapter, technology integration is defined as the adoption and use of technology by teachers for classroom learning.

One long-lasting product of the ACOT longitudinal study was an instrument to measure teacher development in technology integration. The **Apple Classrooms of Tomorrow** (ACOT) survey (Dwyer et al. 1989) defines educator progress in terms of five stages: *entry*, *adoption*, *adaptation*, *appropriation*, and *invention*. The five stages were defined by researchers and practitioners as developmental stages that teachers go through as they advance toward higher levels of technology integration in the classroom.

Another measure of technology integration is **Stages of Adoption of Technology** (Stages) (Christensen 2002). Stages is a self-assessment of a teacher's level of adoption of technology. There are six possible stages in which educators rate themselves: Stage 1 (*awareness*), Stage 2 (*learning the process*), Stage 3 (*understanding and application of the process*), Stage 4 (*familiarity and confidence*), Stage 5 (*adaptation to other contexts*), and Stage 6 (*creative application to new contexts*). Because the Stages of Adoption of Technology instrument is a single-item survey, internal consistency reliability measures cannot be calculated. However, a high test-retest reliability estimate (0.91) was found on a pre-posttest including a large group of teachers (Christensen and Knezek 2001a).

The **Concerns-Based Adoption Model Level of Use** (CBAM LoU) instrument is targeted toward describing behaviors of innovators as they progress through various levels of use – from *nonuse* to *managing* and finally to *integrating use of the technology*. The instrument is based on the eight levels of use defined in the Levels of Use Chart (Hall et al. 1975). The levels of use are (0) *nonuse*, (I) *orientation*, (II) *preparation*, (III) *mechanical use*, (IVA) *routine use*, (IVB) *refinement*, (V) *integration*, and (VI) *renewal*. The concept of levels of use also applies to groups and entire institutions. The instrument is time-efficient to use as an indicator of an educator's progress along a technology utilization continuum.

While ACOT, Stages, and CBAM LoU are each one-item instruments, Hancock et al. (2007) found that these three single-item instruments, taken together, produce a **Technology Integration Scale (TIS)** with an internal consistency reliability of $\alpha = 0.84$ for a typical set of teachers.

As previously described as related to pedagogical measures, the **Technological Pedagogical Content Knowledge (TPCK)** model, also known as Technology, Pedagogy, and Content Knowledge (TPACK), was formalized by Mishra and Koehler (2006). This instrument contains seven components in the TPACK framework, i.e., *technological knowledge (TK)*, *content knowledge (CK)*, *pedagogical knowledge (PK)*, *pedagogical content knowledge (PCK)*, *technological content knowledge (TCK)*, *technological pedagogical knowledge (TPK)*, and *technological pedagogical content knowledge*, all of which are components necessary for describing complex interactions in technology-supported classroom environments. Several instruments have been developed to assess TPACK components. The **TPACK Assessment Instrument for Pre-Service Teachers** was developed and validated to measure all seven TPACK domains (Schmidt et al. 2009). The TPACK Assessment Instrument was produced as a 47-item instrument with scale internal consistency reliabilities ranging from $\alpha = 0.75$ to $\alpha = 0.85$. Later Heitink et al. (2016) extracted eight **TPACK Core** items, with $\alpha = 0.91$, from the original instrument by Schmidt et al. (2009).

Measures of technology integration described in this section are often used as direct outcome measures (goals in themselves) or as dependent variables to study how professional development in areas such as technology skill or pedagogy contribute to higher levels of technology integration in the classroom. Technology integration measures can also be viewed as intermediary variables, where the goal is to study how higher levels of integration contribute to greater student learning. The following section will focus on uses of technology integration measures.

Use of Information Technology Measures in Education

The ubiquitous presence of technology in society would indicate that emerging technology tools should not only be introduced into education but used effectively to support learning. Teachers at all levels are encouraged to incorporate technology into the classroom with the expectation that it will enhance student learning. Technology integration, in which the students are the primary users, has been shown to increase student understanding, engagement, and critical thinking (Sheehan and Nillas 2010). Whether or not teachers are prepared or even receptive to integrating technology into the learning environment is a multifaceted issue. Many factors contribute to successful teacher-led integration of technology in the classroom. Some of the identified factors include professional development, school culture, administrative support, access to technological resources, adequate planning time, pedagogical teaching style, beliefs about technology and learning, attitudes toward technology, and self-efficacy in using technology for learning.

Most education professionals in the twenty-first century agree that good teaching practices should determine technology use rather than technology driving the practice of teaching (International Society for Technology in Education (ISTE) 2010). “If the use of technology to enrich learning is ever to become effective, we must stop regarding it as a separate entity and see it as part of everyday instruction” (Johnson 2013, p. 84). Having precise, multifaceted measures of teachers’ abilities regarding important attributes related to information technology in education can aid in ensuring that decision-makers of the future are properly introduced to important IT-focused societal goals.

Combining Measures to Create a Comprehensive Context

Psychometricians have known for decades that many of the constructs measured by the instruments presented in this chapter are related to each other. Figure 1 illustrates the relationship between lack of computer anxiety (*comfort*) as well as other attributes measured by the Teachers’ Attitudes Toward Computers (TAC) instrument, as teachers advance from lower to higher stages of adoption of technology. This strong linear relationship of an increase in comfort (decrease in anxiety) as teachers advance through higher stages of adoption of technology has been found in multiple studies (Christensen and Knezek 2001a, b). Similar trends have been found for Concerns-Based Adoption Model Level of Use (CBAM LoU) and Apple Classrooms of Tomorrow (ACOT) teacher stages (Christensen and Knezek 2001a). This linear relationship allows researchers and professional development practitioners to estimate (approximate) the probable median level of technology integration proficiency of a group of teachers (e.g., educator’s from one school) by assessing their

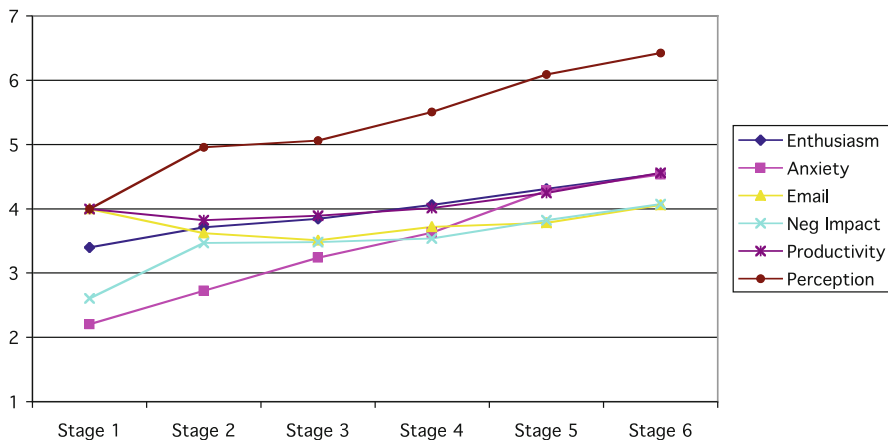

Fig. 1 Teacher attitudes toward computers by stages of adoption of technology

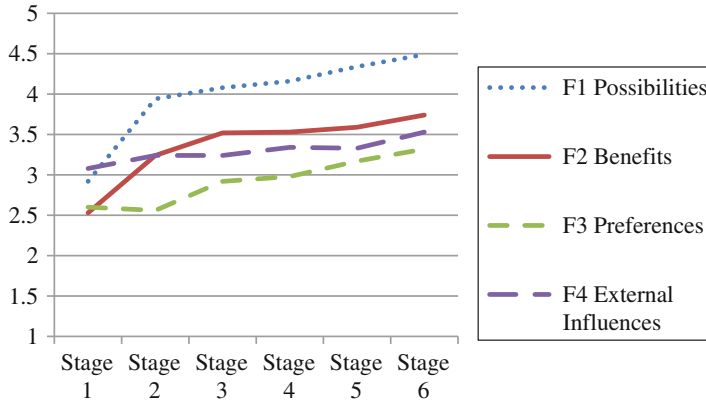

Fig. 2 Teachers' mobile learning readiness by stages of adoption of technology

attitudes toward technology – or vice versa. Targeting professional development is then possible without administering an extensive battery of instruments to obtain comprehensive measures in all areas.

Newer technologies such as mobile learning devices have shown similar linear relationships to stages of adoption of technology. Christensen and Knezek (2017b) demonstrated that the general progression toward higher technology integration proficiency as attitudes become more positive also applies to teacher willingness to accept newer information technologies such as mobile learning. The **Mobile Learning Readiness Survey (MLRS)** includes four dimensions of readiness to teach with mobile devices. These four factors are *possibilities*, *benefits*, *preference*, and *external influences*. As shown in Fig. 2, teacher willingness to adopt mobile learning in their classroom has a strong relationship with their level of technology integration, as was true for the longer-established attitudinal constructs that produced Fig. 1 (Christensen and Knezek 2001b). This relationship indicates that the mobile learning readiness constructs (*possibilities*, *benefits*, *preferences*, and *external influences*) are positively associated with teacher level of proficiency in technology integration, as measured by the Stages of Adoption of Technology instrument.

Sherer et al. (2017) examined the relationship between three measures of technology attitudes and TPACK self-efficacy beliefs. The three core attitudes toward ICT measures included the *General Attitudes Toward ICT (GATT) scale*, the *Attitudes Toward the Educational Use of ICT (EDATT) scale*, and a *Perceived Ease of Use ICT scale*. Using structural equation modeling, the researchers showed that there is a positive relationship between the attitudes and the TPACK self-efficacy dimension (Sherer et al. 2017). Specifically, the more general attitudes were related to the pedagogical and content-related dimensions of the TPACK. However, the more technological attitudes showed a stronger relationship to the technological knowledge dimension of TPACK (Sherer et al. 2017).

Discussion

Many factors enter into choosing the best instruments in the technology in education arena. Among the most important considerations for choosing and using particular instruments are (a) the appropriateness of the instrument for the task at hand, (b) the quality of the measurement tool, (c) the amount of disruption to the environment, and (d) the cost. Well-validated and reliable instruments are required in order to produce credible results. Each of the instruments presented in this chapter has associated publications that verify that the constructs they purport to measure have well-established validity (content, construct, and criterion-related) that demonstrates they are appropriate for the measurement task at hand. The scales of each instrument have also been reported to have acceptable reliability (consistency of measurement) based on standard criteria.

There are limitations to the list of instruments presented as examples in this chapter. The list was compiled based on the criteria of breadth, with the goal of introducing a wide range of respectable instruments that exist for attitudes, skills (competencies), and pedagogical practices, in the general realm of technology integration within the domain of information technology in primary and secondary education. The trade-off is that depth is shallow within any specific focused area. Numerous other instruments exist that are reliable and valid but not described in this chapter, and others will undoubtedly emerge.

Another limitation is that the instruments presented in this chapter are predominantly self-report surveys, which are described by the US Northeast and Islands Regional Technology in Education Consortium as psychological inventories that are reported by the subject, commonly asking direct questions related to perceptions, attitudes, or intended actions (NEIRTEC 2007). There are numerous rationales for using self-report surveys to assess information technology (IT) attitudes and competencies and some special considerations as well. One rationale is that the technique typically has an anonymous quality not possible through outside observation. Another is that it is difficult to observe certain indicators such as attitudes and beliefs from outside the person, and therefore data provided by the subject may be more accurate than data gathered by an outside observer. Also, in many situations, time constraints and funding restrictions make self-report the only practical solution for gathering data.

A primary reason for focusing on self-report surveys in this chapter is that they have a long-established tradition for reporting empirical evidence of their accuracy (reliability) and appropriateness (validity) for the task at hand, as justification for their worth. As we look to the future, we can envision a day when currently emerging technology recording aids ranging from physical activity monitors to learner analytic systems assign “quantifiable scores to individuals” as required for measurements as defined in the opening paragraph of this chapter. These are viewed by the authors as complimentary rather than competitive prospects for the future measures, compatible with the current generation of instruments described in this chapter.

Conclusion

Teachers are the key players in the success or lack of success of any technology initiative in the classroom. Teachers must perceive that technology is a useful tool for improving learning for their students before it is adopted into classroom practice. The perceived usefulness of technology can influence teacher attitudes toward technology which contribute to the overall receptivity of technology integration.

Most countries of the world agree that technology competencies are important for twenty-first-century teachers. Reviewers of the 2016 US National Educational Technology Standards (NETS) have stated the issue succinctly as “Technology is a reality but students and teachers need new ways to envision its purpose and possibilities” (Stoeckl 2016, np). Therefore technology integration proficiency for teachers involves more than just technology skills; it includes being able to envision technology’s purpose and possibilities and having confidence in the path chosen.

The preparation of teachers is recognized as a critical ingredient for the integration of technology into the classroom. The “effective professional development of teachers in the integration of technology is necessary to support student learning” (ISTE 2008, p. 3). Teachers who have had technology training are more likely to show positive attitudes toward use in the classroom (Miranda and Russell 2012). Thus education can help teachers to feel less anxiety and more confidence and generally value technology more highly (Lambert et al. 2008). Teachers with classroom experience who have not received technology professional development are less likely to use technology in the classroom and less likely to see the benefit of the use of technology in the classroom (Cope and Ward 2002).

Numerous instruments have been developed to help diagnose where teachers need assistance and to accurately prescribe how development can be fostered to aid teachers in integrating technology into teaching and learning practices. It is desirable to include more than one type of measure to more comprehensively assess teachers’ needs and prescribe appropriate professional development. A multifaceted profile can provide a robust description of a teacher’s current level of development, which can serve as a solid foundation for prescribing additional training leading to greater proficiency in technology integration. Greater technology integration proficiency should lead to better educated students with higher IT skills, which will in turn better serve the goal of productive future citizens in our society.

Section V

Professional Learning and Development of Teachers

Section Introduction: Professional Learning and Development of Teachers 24

Peter R. Albion and Jo Tondeur

Abstract

Teachers play crucial roles in realizing the potential of technology for transforming education in a rapidly changing world. Their ongoing professional learning underpins their capacity to respond to the needs of learners. This section examines the knowledge required by teachers and how that can be developed.

Keywords

Professional development · Professional learning · Agency

A casual observer of education might wonder why both “learning” and “development” appear in the title of this section, assuming that professional learning naturally flows from professional development. However, as argued by Timperley (2011) and others, the link is not so clear in practice, with much professional development resulting in a little or no change in the professional behaviors of teachers. Moreover, much teacher professional learning that does produce effective change in teacher behaviors occurs outside of formal professional development. The authors in this section are conscious of the difference and address both professional development and professional learning where appropriate, with the fourth chapter contrasting

frequently top-down formal professional development with the mostly informal and self-directed professional learning.

Similarly, because the focus of the handbook is on the application of information and communication technology (ICT) to enhance learning in school classrooms, teacher learning about the use of ICT is the appropriate focus of this section. However, the power of ICT for enhancing learning is as applicable for teachers as it is for their students. Hence the chapters in this section consider both what teachers need to learn about ICT and the application of ICT to promote their professional learning.

In the first chapter of the section, Albion and Tondeur observe that education and the work of teachers must evolve in response to rapid development of ICT and concurrent changes in society. They argue that the rate of change is such that centralized recommendations for new pedagogical applications of ICT and associated teacher professional development cannot match the pace. Moreover, the circumstances of teaching are highly varied so that teachers must orchestrate available ICT with their own skills to meet the diverse needs of learners in different contexts. The solution proposed is to promote teachers' agency to individually and collectively engage in appropriate teacher learning. This approach promotes the capacity of teachers to respond creatively to contextual needs rather than the prevailing trend to standardize classroom activity.

In the second chapter, Angeli and Valanides explore the knowledge required by teachers for effective integration of ICT. Despite a degree of consistency around Technological Pedagogical Content Knowledge (TPACK), they conclude that the continuing emergence of new elaborations makes development of a robust theory improbable. Instead, they propose an approach based on affordance theory. ICT offers teachers both technical and pedagogical affordances but they must first perceive and appropriate technical affordances before they can move to perceiving pedagogical affordances. Angeli and Valanides argue that there is a need to focus on deepening understanding of teachers' technological knowledge, the TK of TPACK, in relation to how teachers appropriate the affordances of ICT to solve pedagogical problems. The step from technical to pedagogical affordances can be challenging and probably relies upon acquiring sufficient technical skill with a tool that it becomes transparent in use, thereby enabling focus to shift to creative application to pedagogical problems.

Forkosh-Baruch, in the third chapter, considers the preservice preparation of future teachers to transform education with ICT. She begins by examining how identity affects the use of ICT by teacher candidates and, in common with Angeli and Valanides, notes the gap between personal and pedagogical use of ICT. Examination of approaches to teacher preparation around the world leads to proposal of a model in which technical skills with ICT provide a foundation for development of pedagogical skills through collaboration between academic courses in universities with practicum in schools. Concrete practical recommendations for preservice teacher training are provided at the end of the chapter.

Prestridge and Main, in the fourth chapter, examine how teacher professional learning occurs in the context of teams, communities, and networks. Their focus is

on the pedagogical application of ICT that rests upon the necessary foundation of technical skills noted by Angeli and Valanides and Forkosh-Baruch. The methods they propose engage teachers in learning from each other, which enables the lessons learned by individual teachers experimenting with the application of ICT in their classrooms to be appropriated by colleagues. The interactions among teachers can be mediated and facilitated by ICT so that teachers personally experience the benefits of learning with ICT. Thus, collaboration becomes an effective method of multiplying the benefits of teacher agency in which teachers explore the application of ICT in their own contexts and share their learning with colleagues.

The often-strained relationship between research and practice in education, including the application of ICT, is tackled by McKenney and Pareja Roblin in the fifth chapter of this section. They consider the opportunities presented by directly engaging practicing teachers in research modes such as teacher inquiry and design-based research separately or together. Enabling teachers to research their own practice draws upon and extends their agency for discovering and confirming the value of practices attuned to their individual contexts. When coupled with the collaborative approaches described in the previous chapter, these modes of research can be powerful for quickly extending the reach of effective practices for applying emerging forms of ICT to meet the changing needs of education.

In the sixth and final chapter of the section, Baran explores how teachers engaging in pedagogical inquiry can become the agents of their own transformation to work effectively with online and mobile learning. Models such as mentoring, professional learning communities, and design-based learning resonate with the ideas presented in the previous chapters, but the practical recommendations for implementation are specifically related to the field of mobile learning.

Taken as a whole, the six chapters in this section attest to the need for teachers to be empowered to operate as professionals who can take substantial responsibility for their own professional learning. By exercising their personal agency to learn about the technical and pedagogical affordances of ICT, gathering evidence through practice-linked research to guide development of ICT supported pedagogy, and engaging in collaborative learning for and with ICT, teachers can be significant agents of educational transformation through ICT.

Abstract

The quality of teachers is a very strong influence on the quality of education. In an era when societies and technologies are changing rapidly, both the nature of the education that is appropriate and the means available for its delivery are also changing rapidly. Hence, if teachers are to contribute to the ongoing transformation of societies by transforming education through the use of technologies, they will need to engage in personal transformation through ongoing learning. The wide variety of contexts in which teachers work with differing resources, the variability in their prior learning and in the needs of learners, the rapid changes in technologies, and the shifting expectations of society make it impossible for

central authorities to prescribe educational experiences that will be suitable for all circumstances. Teachers must be empowered to practice their profession by orchestrating resources and activities to match educational provision to learners' needs. Recognizing the agency of teachers as professionals is essential to enlisting them as contributors to the ongoing transformation of education through application of ICT. This chapter addresses the essential role of teacher agency in the transformation of teachers and the education systems in which they work.

Transformative Effects of ICT in Society

Evidence of the transformative effects of information and communication technology (ICT) is widely visible in the changing ways that people around the world live and work. Over the past half-century, computers, laptops, and tablets have changed common practices in most work environments and in many homes. Smartphones are practically ubiquitous in developed countries and increasingly prevalent everywhere, enabling almost continuous connection to people and sources of information around the world. Significant changes in the ways that people access information and interact with each other have laid foundations for broad changes in society (Lim et al. 2013). As a consequence, there will be changes in the education required to prepare young people for full participation as citizens (Hawkridge 1990; Spector 2010). The transformative effects of ICT in most aspects of modern life can be seen in changing patterns of communication and commercial activity as well as in the processes and products of manufacturing. These developments have contributed to the “flattening” associated with globalization (Friedman 2006) and initiated changes in the composition and requirements of the workforce, resulting in the hollowing out of the middle class in developed countries (Milanovic 2014).

Professional and service occupations have generally been sheltered from the disruptive effects of ICT because they required intellectual or manual capabilities that were not replaceable in the same way as the skills typically employed in manufacturing. Now there are signs that sheltered status may be disrupted by new developments in artificial intelligence (AI) and robotics that will constitute a fourth industrial revolution following the prior revolutions based on the widespread adoption of steam power, electricity, and electronics (Peters 2017). Developments in data science open the possibility for ICT to substitute for humans in a variety of nonroutine cognitive tasks while advances in sensing and manipulation are enabling robotics to perform an increasing range of manual tasks.

New forms of ICT including AI and robotics are expected by some to reduce the need for human labor in widening areas of activity (Peters 2017), potentially constraining choices about how we live. Nevertheless, there are voices that question the breadth of recent claims made about the coming revolution in AI and robotics.

Some question the extent of the capabilities that can be developed by machines and some argue for the importance of human society playing its proper role in creating the future rather than accepting the inevitability of outcomes flowing from technological determinism (Wajcman 2017). Regardless of the extent to which a fourth industrial revolution catalyzed by ICT through AI and robotics changes the nature of work and how much work remains available to humans, it seems certain that there will be changes in both the quality and quantity of work required for society to function.

Education System Responses to Developments in ICT and Society

Whether education is regarded from a utilitarian perspective as preparation for work or more holistically as developing the full potential of human beings, it must change in response to broader societal change. As Peters (2017) notes, ICT will not spontaneously transform education in the ways required to adapt to these changes. That will require educators, policy makers, and societal leaders to seek and implement appropriate solutions to transform education in parallel with developments in ICT (Aesaert et al. 2013). Almost 30 years ago, Hawkrige (1990) discerned four different rationales that drive educational policies related to the integration of ICT in education: (1) an economic rationale: the development of ICT skills is necessary to meet the need for a skilled work force, because learning is related to future jobs and careers; (2) a social rationale: this builds on the belief that all pupils should know about, and be familiar with, ICT in order to become responsible and well-informed citizens; (3) an educational rationale: ICT is seen as a supportive tool to improve teaching and learning; and (4) a catalytic rationale: ICT is expected to accelerate educational innovations.

These rationales continue to be relevant and are visible in the policies and actions of governments around the world. To illustrate, in Australia by the turn of the century, statements from the national and state governments had expressed expectations that young people would leave school as creative and productive users of ICT and that ICT would transform learning and teaching in Australian schools (DEEWR 2008). The expectations were accompanied by substantial investment but progress has been acknowledged as uneven. Similar aspirations have been voiced in other countries and by international organizations promoting transformation of education for the global good (UNESCO 2011).

The past decade or so has seen developments in school computing curricula around the globe. Fluck et al. (2016) described the incorporation of computer science in the curricula of Cyprus, the United Kingdom, and Australia as examples of what is happening in many countries. They made a case for inclusion of computer science in school curricula and suggested how it might be implemented. The Australian Curriculum includes, within the Technologies learning area, a Digital Technologies subject with a focus on creating digital solutions by applying computational, systems, and design thinking in addition to an ICT General Capability intended to develop ICT skills across all learning areas (ACARA 2015a). Similarly, in 2008 the

Flemish government responded to the expectations of the society by providing a set of ICT attainment targets, formulated as ICT competencies (Aesaert et al. 2013). Besides the importance of competencies to direct or support teaching and learning, the Flemish government also emphasizes the importance of ICT as catalyst to innovate teaching and learning approaches (catalytic rationale): ICT can boost the creation of a powerful learning environment. Other countries have engaged in similar educational reforms with the intention of embedding ICT in curriculum and pedagogy.

Nevertheless, several studies have observed incongruence between national ICT curricula and the actual level of adoption of integrated ICT use (e. g., Hatzigianni et al. 2016; Tondeur et al. 2008). For instance, a large-scale study found that Australian children aged 8–9 years were using ICT at school in conventional ways with little evidence of use to support creative and project-based activities (Hatzigianni et al. 2016). This suggests that children may be acquiring basic skills with ICT as envisaged in the ICT General Capability but are less likely to be developing as creators of digital solutions as envisaged by the Digital Technologies subject (ACARA 2015a). Moreover, there is evidence from a national assessment of ICT skills (ACARA 2015b) that, far from improving over time, skills measured by that assessment have decreased. One plausible explanation for such a decrease is that the skills measured in the assessment relate mostly to the use of applications on personal computers but the focus of schools and students has shifted to emerging forms of ICT such as tablets and handheld devices like smartphones. New technologies require different skillsets and the rate of change in ICT is sufficiently rapid that attempts to compare very specific skills over time may be futile if they have been made less relevant by changes in ICT.

Even where children are developing relevant ICT skills in school, they may not be experiencing learning and teaching transformed by ICT. Some lag in implementation of new curriculum imperatives is to be expected but the changes promoted by new curricula including elements of computer science will require substantial changes in the practice of teachers (Sentance and Csizmadia, 2017). In the USA, a recent survey of 700 teachers found that, although a majority regard themselves as risk takers or early adopters of ICT, their most frequent classroom uses of ICT were for conventional applications such as drill and practice (Rebora 2016). Creative and transformative applications were less frequently reported. Although the survey was not statistically representative, it did include teachers from varied schools across the USA and is indicative of the broad patterns of ICT use in education. The major challenges to more extensive ICT use were reported as limited access to digital devices, lack of training, curriculum demands, and unreliable Internet access.

From the research findings, it seems that the aspirations of national educational authorities do not automatically result in changes in classroom practices. These results raise questions as to how the priorities of ICT policies can be implemented. In this section, we challenge policy makers and schools to develop a vision about teachers' professional learning within the field of ICT for teaching and learning. In this respect, Lim et al. (2013) noted that the expectation of educational transformation through application of ICT had driven extensive investment by governments

and others to provide ICT for use in schools. They cited international research that demonstrated some successes but concluded that transformation had not happened on the anticipated scale and that, like many previous innovations, ICT had scarcely affected the practice of most teachers. They identified two gaps in educational use of ICT. The first relates to usage; the breadth and depth of students' use of ICT in school are much less than outside school. The second relates to outcomes; compared to sectors beyond education, the effects of ICT on schooling are much less. Although they suggested paths to improvement, including development of effective policies and plans and provision of effective leadership by principals, there is no universally applicable solution to effecting transformation of education through ICT.

Nevertheless, the imperatives for change stemming from the broader transformational effects of ICT described in the first paragraphs (Friedman 2006; Milanovic 2014; Peters 2017; Wajcman 2017) remain. Neither the content nor the process of education as conceived to meet the needs of the earlier industrial revolutions can suffice to meet the challenges of the present time. Hence it is appropriate to consider how teachers and educational institutions respond to ICT and what may be done to support their roles in effecting the transformation of education to more effectively meet the needs of our time.

Understanding Teachers' Responses to ICT

Consistent with the findings described above, Ertmer and Ottenbreit-Leftwich (2013) observed that most teachers are using ICT primarily as aids to content delivery rather than to effect meaningful change in classroom activity and student outcomes. They described the most common experiences of students as learning *from* ICT through online searches for information and preparation of written assignments. They ascribed the problem to schools and systems placing emphasis on technology when the solution rests with pedagogy. In their view the goal should be to shift the conversation to *technology-enabled learning* so that the focus is on learning *with* technology rather than ICT integration as an isolated goal.

Even in developed countries, some teachers still report limited access to ICT or its unreliability as barriers to use (Rebora 2016). However, the significant investments by governments over recent decades have enabled access in most classrooms in the developed world (Ertmer and Ottenbreit-Leftwich 2013; Hatzigianni et al. 2016; Rebora 2016). That is also true in many parts of the developing world, although in some instances, provision of ICT has apparently taken priority over employment of teachers to use it (Livingston 2016). As noted by Ertmer and Ottenbreit-Leftwich (2013), access to ICT is no longer a significant barrier to transformation of education in most contexts. In this respect, the quality of teaching and teachers seems to be the most important determinant of student achievement (Hattie 2008). Clearly, if education is to be transformed by the application of ICT, then the manner of that application will depend upon the presence of teachers who are appropriately prepared to apply ICT to enhance learning and teaching.

Consequently, the benefits of teacher preparation for working with ICT will depend upon teachers implementing that learning in their classrooms. However, as noted above (Ertmer and Ottenbreit-Leftwich 2013; Ertmer et al. 2014; Hatzigianni et al. 2016; Lim et al. 2013; Rebora 2016), when teachers use ICT in their classrooms the applications tend to be mostly routine rather than transformational. Thus, it becomes important to consider what factors enable or retard transformational use of ICT in education. Numerous studies of factors influencing teachers' use of ICT have been conducted over recent decades. There have been extensive developments in the availability and capability of ICT over that period but there are some consistent themes in the responses of teachers.

Like the more recent studies cited above (Hatzigianni et al. 2016; Rebora 2016), an earlier study of a representative sample of more than 4000 teachers across the USA found that most computer use in classrooms was relatively mundane. Computer use mostly occurred in specific courses in computer education or business education or for word processing work for presentation but, under the right conditions, computers were an effective instructional tool (Becker 2000). Those conditions were convenient access to equipment, a degree of teacher skill and comfort with technology, support by teachers for constructivist pedagogies, and freedom within the scheduled curriculum for students to use computers.

Ertmer (1999) distinguished between first-order barriers, external to teachers such as resources, training, and support, and second-order barriers, internal to teachers such as confidence and beliefs. Of the four conditions identified by Becker (2000) as favoring computer use, constructivist beliefs fit the category of second-order barrier, internal to teachers, but the others are external, first-order barriers. In more recent work, Ertmer et al. (2012) suggested that, in the USA at least, the first-order barriers such as access to resources had been reduced in significance, making it opportune to examine the effects of second-order barriers in the form of teacher beliefs. Their study of 12 teachers selected for their award-winning technology practices found alignment of pedagogical beliefs with practices and that, consistent with earlier findings about constructivist beliefs (Becker 2000), student-centered beliefs were associated with enhanced use of ICT in classrooms. Change in teachers' behaviors is more likely to occur when professional development experiences are situated within the context of teachers' own curricular needs (Koehler and Mishra 2009).

Teacher Agency and ICT Use

A useful concept in this context is teachers' agency, that is "their active contribution to shaping their work and its conditions" (Biesta et al. 2015). Similarly, Martin (2004) defined agency as the capability to make choices and act on these choices in a way that makes a difference in their lives. In the field of ICT, agency can be described as the ability for individuals to control and manage their use of ICT and online presence, including managing identity, initiating interactions, using technologies for self-identified purposes, and modifying or developing digital tools (Starkey 2017). As a consequence, requirements for developing digital agency are very

closely aligned with earlier conceptions of uses of digital technologies that are differentiated into “consumer” or “producer” activities and outcomes (Shonfeld et al. 2017).

The concept of teachers’ agency stresses the importance of professional development as an iterative process, aimed at extending and updating the professional knowledge and beliefs of teachers in the context of their work (Tondeur et al. 2016b). Several studies suggest that the involvement of teachers in collaborative design constitutes an effective strategy to develop digital resources in line with their pedagogical beliefs (cf., Kafyulilo et al. 2015; Sang et al. 2010; Voogt and Tondeur 2015). These types of initiatives also have the potential to bolster teachers’ self-efficacy, which in turn has been found to influence teachers’ beliefs about ICT use (Holden and Rada 2011).

Although Becker (2000) did not use the term, his fourth condition might be interpreted as corresponding to *agency*, which is a way of describing how teachers engage with policy and enact their professional practice (Priestley et al. 2015). Becker reported that teachers who were bound by fewer specific constraints about how they should teach could exercise professional judgment about their use of ICT and were more likely to find ways in which they could use it. Around the same time, Cuban (2001) studied primary and secondary school teachers in Silicon Valley, where it might be presumed that positive dispositions to ICT would be unlikely to restrict use. He found that teachers at all levels used computers for research and preparation but that classroom integration was more common in primary school classrooms than in secondary. The simple explanation related to timetable constraints in secondary schools limiting teachers’ capacity to adjust to technical issues within a single teaching period compared to primary schools where the teacher was with a class all week and could rearrange activities to accommodate issues when or if they occurred. Again, more teacher agency to make and implement decisions was associated with more integrated use of ICT.

Almost two decades later, in a period of rapidly changing technologies and diverse classrooms, it is more important than ever that teachers can exercise professional judgment about the application of ICT to meet the needs of learners. ICT presents challenges because of the rapid pace at which it continues to develop. As new hardware and software appear in classrooms they bring new possibilities for learning and teaching and sometimes result in the disappearance of familiar capabilities and changes in the skillsets required by teachers and learners (ACARA 2015b). Preparation of teachers for working with ICT must be ongoing and will ideally prepare them to adapt to changes in ICT as they appear in their classrooms. Teachers, learners, and the classroom contexts in which they work differ widely so that there is no universally applicable approach to achieving educational goals. Professional development can address the knowledge and skills of teachers but what they learn must be applied to support learners who differ widely on dimensions including facility with ICT, and the ICT available in schools is far from uniform. It is the work of skilled teachers to plan and implement instruction that matches their own skills with the needs of the learners in their context to achieve the educational outcomes specified by the curriculum. Teacher professional agency is important to

both the application of ICT in their classrooms and the provision of appropriate opportunities for professional learning about ICT.

Teacher Agency and Accountability

There are good reasons for education at all levels to be directed toward equipping graduates with the knowledge and skills required for full participation in society. That necessarily entails a degree of standardization around outcomes to be achieved and methods for assuring that achievement. That is, education systems and educators should be accountable to the societies that establish and fund them. In reviewing the apparent lack of progress in teacher professionalism over the past decade, Sachs (2016) noted that teachers tend to identify their accountability as being to students they teach and the communities in which they work, what can be described as *responsive accountability*. On the other hand, governments and employers focus on *contractual accountability* for learning outcomes that may be measured by performance on standardized tests.

The latter entails management of performance against standards and can lead to tightly regulated regimes in which teachers have little apparent agency and may be constrained into monitoring behavior of colleagues as well as themselves. The consequent erosion of trust develops habits of risk aversion and reluctance to stray from established practices regarded as safe. Bahia et al. (2017) studied the reactions of a group of university teachers in Portugal to the changes resulting from the Bologna process which is intended to ensure that higher education produces comparable outcomes across Europe. They found that the teachers struggled with reconciling the assessment requirements of the process with their focus on promoting learning by students. Achieving an appropriate balance between the standardized outcomes and attention to the needs of individual learners is challenging.

When, as appears to be the case in many countries, educational policy is directed toward improving achievement as measured by standardized tests, teachers may be constrained in how they approach their work. Buchanan (2015) argued that the emphasis on standards and accountability does not value teacher autonomy. She cited Hargreaves' (2000) conceptualization of teacher professionalism progressing through four historical phases (pre-professional, autonomous professional, collegial professional, and post-professional or postmodern) and expressed concern that the current circumstances match Hargreaves' dystopian vision of a post-professional phase in which the work of teachers is devalued and their autonomy eroded. In many contexts teachers and the schools in which they work are constrained by requirements of accountability against standardized tests and other measures to maintain legitimacy. In her study of nine elementary teachers across three schools in the USA, Buchanan (2015) found that agency was linked to whether their context supported teaching in ways consistent with the professional identity they had developed through their career histories. Where there was a good fit of identity with school culture, agency was expressed by going beyond expectations. Conversely, where there was not a good fit, teachers resisted requirements that did not match their

professional identities. In her view, teacher agency could be understood as an expression of teacher identity in action but those identities were constantly being reconstructed in response to teachers' experience of practice. Teachers whose entire professional experience is in contexts with very limited professional autonomy will interpret that as normal and develop professional identities with limited expectations of agency.

Hargreaves and Fullan (2012) argued for education to move beyond the industrialized model to models that promote innovation and creativity for the information age. Pressing for teaching to be recognized as a profession if that transformation is to be achieved, they described the qualities of a profession in terms of professional capital, which they presented as an amalgam of three forms of capital: human, social, and decisional. Human capital embodies individual talent and encompasses the knowledge, skills, and dispositions developed through teacher preparation and experience. Social capital emerges from interactions with others, especially professional colleagues, which increases human capital by enabling access to the human capital of others. Decisional capital is the essential quality of a profession in which individual professionals have discretion to make decisions without constant reference to superiors. Nolan and Molla (2017) identified decisional capital with teachers' professional agency and linked it to the degree of autonomy and empowerment teachers have in day-to-day practice. It is this agency that empowers teachers with the relevant knowledge and skill to make decisions about how best to meet the needs of learners in their context rather than merely implementing some generalized practice received from higher authority.

Biesta et al. (2015) have argued that agency is not a property or characteristic possessed by individuals but is manifest in the actions that they perform. That is, agency exists only insofar as it is exercised and does not exist in the abstract. In this view agency is a phenomenon that emerges as an actor engages with a situation. They suggest that it is best understood as a fusion of past influences, future intentions, and present engagement. In their view, teachers too often lack a sense of longer term purpose for education, focusing instead on short-term goals and thus limiting their agency to implementing policy directives rather than contributing to developing vision for educational transformation. The focus on short-term goals may result from a combination of the need to deal with day-to-day activity and limited opportunities to affect broader aspects of their work.

Teacher agency is visible in the actions of teachers and potentially in tension with accountability requirements. Governments and other stakeholders are entitled to expect that education systems and educators will be accountable for providing the education appropriate to the needs of future citizens, but a too tightly constrained view of what is appropriate and how it should be delivered may be counterproductive. In a rapidly changing world, even among those who argue for a traditional curriculum and pedagogy, there is likely to be a degree of acceptance that future citizens will need to be prepared to be innovative and creative in the face of ongoing change. Consequently, there is potentially a paradox of expectations in seeking to maintain a highly accountable system that will prepare students to be innovators. Educational contexts involve complex human systems, and teachers need flexibility

of action if they are to respond appropriately to the needs of individuals in their class within a changing technological and social environment.

The twin imperatives for technology identified in Australian Government documents (DEEWR 2008), namely developing children as fluent users of ICT and enhancing learning and teaching through application of ICT, are important in any modern education system. Both are affected by rapid changes in ICT. Teachers require current knowledge in both domains, the operation of ICT and application for learning and teaching. They also require appropriate degrees of agency to enable them to deploy available ICT effectively. The pace of change does not permit sufficient time for centralized systems to assess the potential of emerging ICT and prescribe its use in ways that will be equally applicable in widely varying contexts.

Teacher Agency in Educational Systems

A focus on teachers' agency could lead to "individual blame" rather than "system blame." Therefore, one should also stress the role of the school or institutional level (see e.g., Aesaert et al. 2015; Mouza et al. 2014). In this respect, Priestley et al. (2015) preferred to regard agency as emerging from the ecology of teachers' practice as they engage with their environments. Clearly, educational institutions differ with respect to performance levels, innovation capacity, and contextual characteristics (Tondeur et al. 2016a, b). This implies that agency should consider to a large extent the "power of site or place" (cf. Fullan 2007).

But although there is a strong belief among educational leaders, this does not always translate into "digital agency" (Starkey 2017). Therefore teachers should be engaged in ICT policy planning in their schools (Tondeur et al. 2008; Vanderlinde et al. 2010). It seems that successful ICT implementation depends upon goals shared by different actors and at different organizational levels. System and school administrators have power and responsibility for provision of ICT and other resources, often including the resources necessary for teachers' professional development, but may engage teachers in the decision-making processes. Ketelaar et al. (2012) argued that effective school leadership for innovation requires careful balancing of collaborative activity and respect for the individual identities of teachers. By enabling teacher agency and encouraging collaboration, leaders can draw upon the creative energies expressed through teachers' agency to implement an innovation more effectively. Thus, teachers' agency is related to actions taken at the institutional level as well as those taken individually. Examining institutional characteristics associated with teachers' professional development has the potential to lead to a greater understanding of the systemic nature of ICT integration in education.

The characterization of agency as an emergent phenomenon rather than an individual capacity (Priestley et al. 2015) invites investigation of the conditions under which teachers can achieve agency. Priestley et al. noted that agency is often linked to the idea of "change agent" in the context of school improvement agendas, but in many such cases teachers are merely implementing policy determined by others and have very limited scope for genuine professional agency. Past educational

reforms have often failed due to a mismatch between the innovation and the meanings attached to the innovation by those involved in the instructional process (Hermans et al. 2008). But technological innovation in the classroom is not independent and isolated; it is situated in the ecological system of the school and connected to its broader systems. It also affects the relationships within and outside the school, and the ongoing interaction catalyzes changes in social relationships (Lim et al. 2013).

According to Zhao and Frank (2003), the dynamic coadaptation and coevolution of teachers' agency, school leaders, and students with technology and the system determines whether the affordances of technology for teaching and learning can be realized in schools. In this respect, the literature about school improvement (e.g., Reynolds et al. 2000) stresses the importance of "leadership" in developing a commitment to change (see also Dexter et al. 2016). The capacity of (teacher) leaders to develop and articulate, in close collaboration with other actors from the school community, a shared vision about educational technology use is considered a critical building block in this process. Therefore, professional development and/or learning of these leaders is crucial. This perspective adds to the holistic approach to teachers' agency.

Teacher Agency and Professional Learning

The ICT available to teachers and learners is evolving rapidly but is unevenly distributed. The technical features and operating procedures for new hardware and software change frequently; some changes are subtle but others are more substantial, such as the change from mouse-driven interfaces to touch screens. At the same time, the affordances of the devices and software for learning and teaching are changing. Teachers need to continually update their knowledge and skills for both technical operation and pedagogical application of emerging ICT available in their contexts.

Traditional professional development prepared and delivered from central authorities inevitably struggles to match the rate at which ICT is changing because of the lead-time required to design and implement programs updated for new hardware and software. Moreover, availability of ICT varies across contexts, even within the same system, possibly requiring multiple versions of professional development to ensure relevance (see, e.g., Lim et al. 2014). Pedagogical applications are prone to be even more challenging because the educators responsible for producing professional development must first master the technical aspects of emerging ICT before they can explore the educational affordances and only then can they prepare related professional development.

The mechanisms by which new forms of ICT enter classrooms range from system-wide initiatives to the actions of teachers who introduce their own ICT for a specific educational purpose. In recent years, there has been a growing trend toward "bring your own" approaches in which students in the one classroom may be using devices with very different capabilities (Prestridge and Tondeur 2015). That presents teachers with both challenges in managing the variety of ICT and

opportunities to explore their affordances for learning and teaching. Hence, professional learning in situ is an important enabler for their application of ICT to enhance and transform learning and teaching.

Research has established connections between teachers' agency and their professional learning. Heikonen et al. (2016) noted that teacher agency enables teachers to manage their own learning with the intention to enhance student learning in response to contextual variables and that a sense of agency has a positive effect on intentions to remain in the profession. In a study of more than 1200 Chinese teachers, Liu et al. (2016) found that teacher agency and the sense of being trusted in their school positively mediated the effect of principals' leadership on professional learning. Moreover, higher levels of trust had a positive effect on teacher agency. Thus, feeling trusted as a professional encourages teachers to exercise agency by taking initiatives, and both trust and agency encourage engagement in professional learning. A small case study in a New Zealand high school reported evidence of the value of teacher agency for driving professional learning through teacher inquiry specific to the context as more effective than instrumental professional development sourced from outside providers (Charteris and Smith 2017).

The importance of balancing teacher agency with collaboration among teachers (Ketelaar et al. 2012) was noted above but it is also important when considering teacher agency in relation to professional learning which increasingly occurs in the context of professional learning communities and networks in which teachers share experiences and ideas. In a study involving 2300 Finnish primary and secondary teachers, Pietarinen et al. (2016) used structural equation modeling to investigate the relationship between teacher agency in professional community and classroom. They reported that agency does not automatically transfer between contexts but that learning in a professional community does affect learning in the classroom, and agency in the classroom is significantly dependent on agency in the community. Thus, it seems that teachers who feel supported by a professional community may be empowered to act with greater agency in their own classrooms. This appears to be supported by a study of professional learning communities in Scotland (Philpott and Oates 2016) where it was found that robust evidence obtained from classrooms supported teacher agency by enabling teachers to authoritatively evaluate practices.

Teachers' agency is important for empowering them to explore the possibilities inherent in new ICT and make decisions about whether and how they can enhance learning and teaching in their context. When that individual exploration is coupled with sharing through professional learning communities or similar venues, its potential for enhancing learning and teaching and for transforming the broader educational landscape through the application of ICT is multiplied. Access to the experiences of other teachers in professional learning communities can provide teachers with the authentic evidence they need to validate or modify their practice (Philpott and Oates 2016), and learning through professional communities has a positive effect on teacher agency and learning in the classroom (Pietarinen et al. 2016). In a time of rapidly changing ICT, trusting teachers as professionals and harnessing their contextualized learning about emerging ICT is likely to be more

effective for realizing its potential for educational transformation than centrally mandated practices supported by packaged professional development.

Conclusion

Technology, especially information and communication technology (ICT), is changing rapidly. The transformational effects of those changes are visible in many areas of social and commercial activity but there is widespread concern that education is not being transformed at the same rate as other sectors. If children are to leave school equipped to thrive in the modern world then the content of their education must evolve to ensure they acquire knowledge and skills necessary to make effective use of ICT in a wide variety of activities. Moreover, there are widespread expectations that the introduction of ICT should transform education in ways parallel to those experienced in other sectors, but there is little evidence of that happening on a broad scale. If the content and experience of education are to be transformed through ICT then it seems evident that the challenges must be approached differently than they have been until now.

Across many parts of the world a consistent response to a perceived need to improve educational provision has been to increase accountability of schools and teachers. The expectation is that the desired outcomes can be achieved by clarifying standards to be reached, testing achievement against those standards, and in some cases mandating practices to be adopted by teachers. It is ironic that what is an essentially industrialized approach is being adopted to solve a problem in the postindustrial world without notable success in many contexts.

In this chapter we have argued that, in a time of rapid and variably dispersed technological change, top-down solutions emanating from a centralized authority are unlikely to be able to respond as quickly as necessary to the highly contextualized needs of learners and teachers. Rather than further constrain the actions of teachers by mandating practice it will be more effective to recognize their professionalism and support teacher agency for professional learning and classroom application of ICT. By encouraging teachers to explore the possibilities of emerging ICT and share their findings in professional learning communities, the crowdsourcing facilitated by networked ICT can contribute to solution of the challenges it presents.

Abstract

This chapter systematically explores the knowledge base required by teachers for the effective application of ICT in education. The Technological Pedagogical Content Knowledge (TPCK) framework and developments in associated research are reviewed. The authors suggest an alternate approach for better understanding the knowledge base required for application of ICT in education by providing a theorization about technological knowledge in relation to how a teacher realizes and actualizes the pedagogical affordances of technological tools in teaching and learning. The authors conclude that this body of knowledge cannot exist outside the frame of reference of the teacher, can be developed through systematic learning activities targeting or facilitating its development, and grows with ongoing participation or involvement in valuable professional experiences. Implications for the nature of TPCK and its development are discussed.

Technological knowledge · Teacher knowledge · Technology affordances · Technological pedagogical content knowledge

Introduction

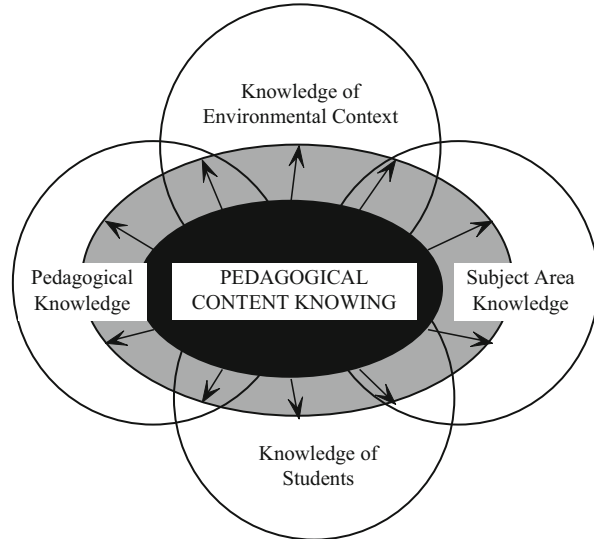

Technological Pedagogical Content Knowledge (TPCK or TPACK) was introduced in 2005 to describe the knowledge that teachers need to have to be able to teach competently with digital technologies (Angeli and Valanides 2005; Koehler and Mishra 2005; Mishra and Koehler 2006; Niess 2005). TPCK has been conceptualized as an advancement of Shulman's (1986, 1987) Pedagogical Content Knowledge (PCK) by adding to the existing PCK framework a new body of knowledge, namely, Technological Knowledge (TK). Consequently, the addition of TK expanded PCK to TPCK.

The purpose of this chapter is twofold. In the first part, the authors report on what we currently know about TPCK as a body of knowledge that teachers need to develop to be able to integrate ICT in their teaching. In the second part of the chapter, the authors argue that the existing body of research on TPCK has failed to explain TK theoretically, and propose a framework for directly addressing this gap in the literature. The chapter concludes with implications regarding the development of this new body of knowledge as well as the construct of TPCK in pre-service and in-service education.

The Theoretical Development of TPCK

PCK is the theoretical basis of TPCK (Angeli and Valanides 2015). Succinctly, PCK emphasizes the significance of transforming subject matter into forms that are pedagogically powerful and at the same time comprehensible to students (Grossman 1989, 1990; Shulman 1986, 1987; Cochran et al. 1993). Essentially, the transformation of subject matter requires a dramatic change in how teachers perceive their role *“from being able to comprehend subject matter for themselves, to become able to elucidate subject matter in new ways, recognize and partition it, clothe it in activities and emotions, in metaphors and exercises, and in examples and demonstrations, so that it can be grasped by students”* (Shulman 1987, p. 13). While researchers have proposed different PCK frameworks in terms of the constituent subdomains of teacher knowledge comprising the frameworks, four subdomains have consistently appeared in all proposed frameworks, namely, knowledge of subject matter (content), knowledge of pedagogy, knowledge of learners and their characteristics, and knowledge of context. A predominant model of PCK in the literature is the one proposed by Cochran et al. (1993), as depicted in Fig. 1. Cochran et al. (1993) preferred to use the term *Pedagogical Content Knowing* instead of *Pedagogical Content Knowledge* to emphasize that PCK is a knowledge base that is not static but dynamic and develops progressively as teachers are involved in useful teaching

Fig. 1 Cochran et al.'s (1993) conceptualization of PCK

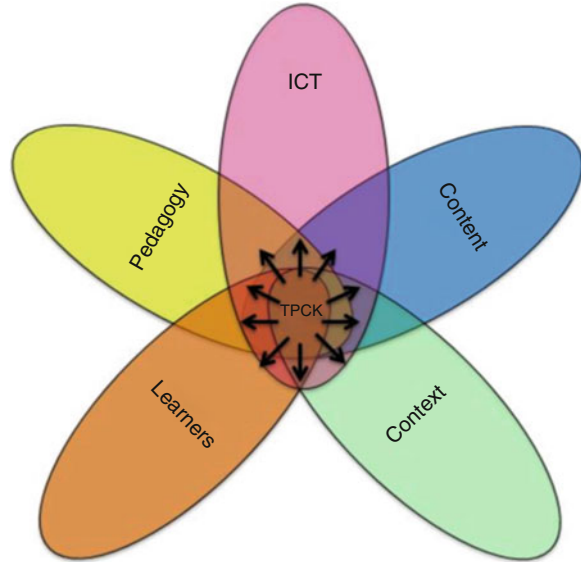

experiences. This is also the meaning expressed by the arrows in Fig. 1 signifying that PCK is a body of knowledge that changes due to teachers' new experiences and ongoing development.

In the early 2000s, different researchers proposed an enhancement to PCK in order to address the issue of teaching with technology (e.g., Angeli and Valanides 2005; Koehler and Mishra 2005; Mishra and Koehler 2006; Niess 2005). Niess (2005) and Angeli and Valanides (2005) used the four-component model of PCK shown in Fig. 1 as their theoretical basis and added a fifth component (i.e., a fifth domain of teacher knowledge), namely, knowledge of ICT, in order to specify TPCK as the knowledge that teachers need to have to be able to effectively teach subject matter with technology. Angeli and Valanides' (2005) conceptualization is depicted in Fig. 2 and shows TPCK as a unique body of knowledge defined in terms of five contributing knowledge bases, namely, content knowledge, pedagogical knowledge, knowledge of learners, ICT knowledge, and knowledge of context. In order to better define TPCK, Angeli and Valanides (2005) described the construct in terms of five competencies. Essentially, a teacher who has TPCK is able to:

1. Identify topics to be taught with ICT in ways that signify the added value of ICT tools, such as, topics that students cannot easily comprehend, or that teachers face difficulties teaching or presenting effectively in class. These topics may include abstract concepts (i.e., cells, molecules) that need to be visualized; phenomena from the physical and social sciences that need to be animated (i.e., water cycle, the law of supply and demand); complex systems (i.e., ecosystems, organizations) in which certain factors function systemically and need to be simulated or modeled; and topics that require multimodal transformations (i.e., textual, iconic, and auditory), such as, phonics and language learning.

Fig. 2 TPCK (adapted from Angeli and Valanides 2005)

2. Identify appropriate representations for transforming the content to be taught into forms that are pedagogically powerful and difficult to support by traditional means. These include interactive representations, dynamic transformation of data, dynamic processing of data, multiple simultaneous representations of data, and multimodal representations of data.
3. Identify teaching tactics, which are difficult or impossible to implement by other means, such as, the application of ideas in contexts that are not experienced in real life. For example, exploration and discovery in virtual worlds, virtual visits (i.e., virtual museums), testing of hypotheses, simulations, complex decision-making, modeling, long distance communication and collaboration with experts, long distance communication and collaboration with peers, personalized learning, adaptive learning, and context-sensitive feedback.
4. Select tools with appropriate affordances to support 2 and 3 above.
5. Infuse computer activities with appropriate learner-centered strategies in the classroom. This includes any strategy that puts the learner at the center of the learning process to express a point of view, observe, explore, inquire, think, reflect, discover, and problem solve.

Koehler and Mishra (2008) proposed a different TPCK framework in the literature depicted in Fig. 3. In Fig. 3, TPCK (a term that they changed to TPACK) is described in terms of seven knowledge domains, namely, (a) content knowledge (C), (b) pedagogical knowledge (P), (c) technological knowledge (T), (d) pedagogical content knowledge (PCK) – the interaction of P and C, (e) technological content knowledge (TCK) – the interaction of T and C, (f) technological pedagogical knowledge (TPK) – the interaction of T and P, and (g) technological pedagogical

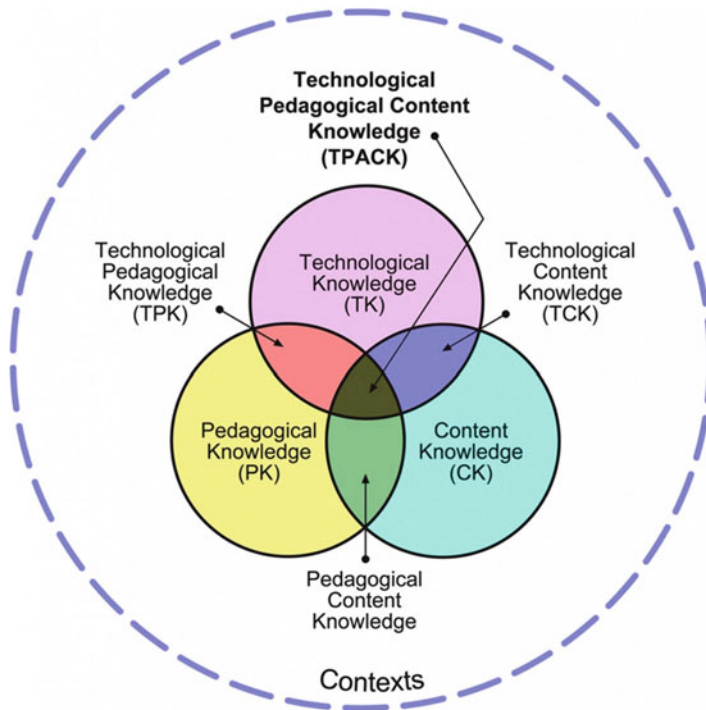

Fig. 3 TPACK framework (adopted from Koehler and Mishra 2008)

content knowledge (TPACK) – the interaction of PCK, TCK, and TPK. Angeli and Valanides (2009, 2013, 2015) discussed the differences between these two predominant conceptualizations of TPACK, as illustrated in Figs. 2 and 3, and stated that, while both models have the same theoretical basis (i.e., Shulman’s work on PCK), they are epistemologically different. Succinctly, the main difference between the two frameworks is that TPACK is conceptualized and researched as an integrative body of knowledge with an emphasis on identifying and assessing TPACK’s subcomponents, such as, TPK and TCK (e.g., Harris and Hofer 2011; Schmidt et al. 2009), while research based on Angeli and Valanides’ (2005, 2009) framework examines TPACK as a distinctive body of knowledge (e.g., Kramarski and Michalsky 2010; Krauskopf et al. 2012). This new body of knowledge does not develop spontaneously, goes beyond mere integration or amalgamation of the constituent subdomains of teacher knowledge, and constitutes a transformative and unique body of knowledge that bolsters teachers’ competency to elucidate subject matter in new ways by employing and investing on the affordances of technological tools. Furthermore, this body of knowledge can be developed only after deliberate instruction or training and grows progressively as teachers are involved in useful learning experiences.

In a recent review of the literature, Angeli et al. (2016) reported that, after 2008, a number of other TPACK models appeared in the literature that attempted to provide

more elaborated perspectives on TPCK in order to exemplify the complexities of technology integration in various educational contexts (e.g., Benton-Borghi 2013; Porras-Hernández and Salinas-Amescua 2013; Yeh et al. 2014). For example, Yeh et al. (2014) proposed TPACK-Practical and conceptualized TPACK as a body of knowledge that teachers possess and apply when dealing with lesson design in their actual practice. TPACK-Practical is conceptualized as a framework with eight knowledge dimensions – namely, using ICT to understand content, using ICT to understand learners, planning ICT-infused curriculum, using ICT representations, using ICT-integrated teaching strategies, applying ICT to instructional management, infusing ICT into teaching contexts, and using ICT to assess students – in five pedagogical areas, that is subject matter, learners, curriculum design, assessments, and practical teaching.

Porras-Hernández and Salinas-Amescua (2013) enriched Angeli and Valanides' (2005) framework, by considering knowledge of context along two important dimensions, namely (a) scope (macro, meso, and micro) and (b) actor (students' and teachers' inner and external context). According to this perspective, contextual considerations, such as teachers' and students' characteristics, needs, preferences, prior knowledge, self-efficacy, pedagogical beliefs, subject or school culture, ethnicity, culture, community, and socioeconomic background, are important variables to consider in TPCK research.

Our purpose here is not to describe every single TPCK framework that has been published in the literature, but to provide a constructive appraisal of this line of work to the research community. While no one unified perspective on TPCK exists in the literature, all existing TPCK frameworks use as their basis, implicitly or explicitly, the five fundamental teacher knowledge bases – that is, knowledge of subject matter, pedagogy, learners, technology, and context. Contemporary research efforts that elaborated on this basic model considered several other variables that were regarded important for practice, such as Yeh et al.'s (2014) TPACK-Practical, or research, as suggested by Porras-Hernández and Salinas-Amescua (2013). If the aim of the TPCK research community is to suggest a new TPCK framework for encompassing the uniqueness or the newness of a context, practical or research, then this line of research will never realize its desired goal; that of developing a robust theoretical conceptualization of TPCK. Accordingly, the authors here argue that part of the effort toward developing a robust theoretical conceptualization of TPCK should be to understand or theorize more about technological knowledge (the TK component in the TPCK framework) in relation to how a teacher realizes and actualizes the affordances of technological tools for the purpose of transforming subject matter (content) into more comprehensible forms for students.

In view of that, the authors, in the second part of this chapter, suggest an alternative approach for conceptualizing the knowledge base required for application of ICT in education by providing a theorization of the relationship between teacher and technology within the framework of Gibson's (1977, 1979) tool affordances – an area of work that has remained for the most part scarce in the field of technology and teacher education. The authors suggest that the specific theorization can be pivotal

for better clarifying the concept of TPCK and conclude with implications for the development of TPCK in pre-service and in-service education.

The Concept of Tool Affordances

While technology is a principal component of TPCK and the main reason for extending PCK to TPCK, so far the fields of instructional technology and TPCK research have provided inadequate accounts about how teachers learn to recognize, understand, and actualize the pedagogical affordances of ICT tools; an issue that is of critical importance for developing teachers' cognition about technology integration (Angeli and Valanides 2009, 2013; Krauskopf et al. 2012; Krauskopf et al. 2015). Consequently, as Oliver (2013) stated, "*current accounts of technology provide poor explanations of how technology use leads to – or fails to lead to – learning*" (p. 331), simply because we do not fully understand how teachers perceive and actualize tool affordances. A better understanding of affordances in teacher knowledge development can lead to better strategies in terms of training pre-service teachers in technology integration as well as supporting in-service teachers during professional development (Haines 2015).

According to Gibson (1979), "*. . .the affordances of the environment are what it offers the animal, what it provides or furnishes, either for good or ill*" (p. 127). An affordance has invariant properties, and exists independently of an actor's ability to perceive it; but, when it is perceived, it is always relative to the action capabilities of a particular actor (Gibson 1979). Gibson explained the notion of affordance by providing the example of a flat and rigid surface that affords support for one actor but not for another, due to his or her higher body weight. This means that the actor in the latter case is constrained by the affordances of the object, and that an affordance may exist for one actor but not for another. Thus, the "*offerings or action possibilities in the environment are directly related to the action capabilities of an actor*" (McGrenere and Ho 2000, p. 1). McGrenere and Ho (2000) stated that in Gibsonian terms, affordances are both objective and subjective.

They are objective in that their existence does not depend on value, meaning, or interpretation. Yet they are subjective in that an actor is needed as a frame of reference. By cutting across the objective/subjective barrier, Gibson's affordances introduce the idea of the actor-environment mutuality; the actor and the environment make an inseparable pair. (McGrenere and Ho 2000, p. 1).

Hammond (2010) stated that the notion of affordance has become popular in different fields in that it offers an alternative to the view that the world exists independently of the perceiver, while challenging at the same time the notion that properties are perceptual and exist only to the extent that they can be recognized. This view of affordance can be strongly criticized by radical social constructivists who would question the existence of inherent properties of objects outside of the actors' interpretations of them. Hutchby (2001) directly addresses this concern and argues that, while the uses of tools are socially determined, at the same time, tools have material properties that may not be realized by the actor. For example, if we

take Microsoft Excel as a point of reference, teachers may not realize that Excel supports dynamic transformations of data from one form/representation to another and may use it for mathematical calculations only. Nonetheless, the material properties or technical features of Excel affording dynamic transformations of data exist and are readily available for use at all times. It is this interpretation of the concept of affordance that we adopt in this chapter in order to propose a theoretical model for explaining the relationship between teachers and technology in terms of how teachers perceive and develop mental models about tool affordances for appropriation in educational settings. Appropriation refers to how technology is adopted in everyday practice (Dourish 2003; Leonardi 2011), and people appropriate artifacts in ways that may differ from the designers' intentions (Folcher 2003).

For teachers, the process of learning about tool affordances is more than just learning about the technical features or the technical affordances of tools. Instead, it is a process of thinking creatively about how the technical affordances of tools can be thought of as pedagogical affordances to bring about educational goals and objectives in classroom teaching and learning. Webb (2005) explored the notion of affordances within the context of using Microworlds to support learning activities. Conole and Dyke (2004) also examined the concept of affordance in the context of pedagogical design and proposed a general taxonomy of ICT affordances for the modern age, including accessibility, speed of change, diversity, communication, reflection, and multimodality.

Herein, the authors assume a different perspective and seek to propose a theoretical construction of teachers' ICT knowledge by focusing on the teacher-tool relationship within the context of pedagogical and learning design. Central to this theorization are the terms *technical affordances* of tools/software and *pedagogical affordances* of tools/software. A piece of software has technical features or technical affordances. For example, the technical affordances of Kidspiration include among others, Picture View, Writing View, Audio, and Hyperlink. These technical affordances are invariant and available to all, at all times. Pedagogical affordance is a term that Angeli and Valanides (2013) used to explain how teachers perceive subjectively the functional value of software in pedagogical/learning design. Table 1 shows an example of how some technical features of a software (in this case Excel) are mapped onto pedagogical affordances. It is noted that, in this conceptualization, technical affordances are invariant and defined by the designers and developers of the software, while pedagogical affordances are perceived by teachers in various ways. The latter is emergent and directly related to pedagogical and learning design for the purpose of attaining educational objectives. In a recent study, Haines (2015) studied two teachers' conceptions of blogs and wikis as tools for language learning, and found that, while teachers learned the tools easily, they faced difficulties in utilizing them in powerful pedagogical ways. She concluded that teachers' understanding of the pedagogical affordances of tools is an emergent and demanding cognitive process directly related to instructional design tasks. These conclusions are in agreement with earlier research reported by Stoffregen (2003) who viewed affordances as being emergent properties of both the teacher and educational context.

Table 1 Technical and pedagogical affordances of Excel (adapted from Angeli and Valanides 2013)

Excel technical affordances/features	Pedagogical affordances	Explanation
Insert – Cells/rows/columns/worksheet/chart/pictures Format – Cells/row/column/sheet/style Data – Sort/text to columns/group and outline	Excel as a tool for organizing data	Meaningful and clear organization of data Attractive and intuitive organization of data Appropriate selection of visualizations for young learners Integrated presentations of pictures, text, numbers, and spoken words Appropriate symbols to promote emergent literacy
Function/IF	Excel as a tool for providing context-sensitive feedback	Feedback is provided in different modalities taking into consideration students' current level of literacy skills
Hyperlink	Excel as a tool for creating a hypertext story	The story is presented from the perspectives of multiple characters The story has multiple possible entry points The story has many internal threads The story constitutes an integrated whole Easy navigation and learner control
Formula bar Insert – Function/sum/average/count/max	Excel as a tool for performing calculations	Arithmetic calculations and mathematical formulae Mining mathematical formulae
All of the above as needed	Excel as a modeling tool	Children see clearly how their decisions/actions affect the outcomes Children add or remove objects and observe the consequences The results of an action or decision are communicated with the use of appropriate visualizations when possible

Our theoretical discussion so far has exemplified the importance of two propositions: (a) the technical affordances of tools are invariant properties, while their pedagogical affordances are emergent and subjective; (b) the pedagogical affordances of tools derive meaning only within the context of the activities that teachers consider in their pedagogical designs. As Tchounikine (2016) stated, educational software packages “...are mobilized by users in the context of the activities they consider. They become instruments for users in the context of these activities, when and through the way they allow users to achieve the tasks that users consider in the way they consider them.” (p. 8). Thus, the teacher-tool relation is not to be thought of as a 1:1 relation, because one software package may be turned into multiple instruments.

All in all, the goal of the teacher is not to use the tool per se, but to solve different pedagogical problems with the tool. Thus, teachers' perceptions of software, in terms of pedagogical utilization, are related to the instructional design tasks they cogitate,

and how they use the software to help them realize the tasks, given teachers' current understandings, knowledge, work practices, and context.

A Theoretical Model of Teachers' ICT Knowledge

Based on the discussion to this point, we present in Fig. 4 a theoretical perspective of teachers' ICT knowledge developed through a process by which teachers turn software into instruments (Rabardel 2001), that is, into means for realizing their instructional designs. According to this perspective, educational software and tools have a mediating role, and the model in Fig. 4 addresses this by considering both the technical and pedagogical affordances of tools. This is illustrated as a process through which teachers transform the technical affordances of tools into pedagogical affordances within an instructional design context. The latter is a constructive, productive, iterative, emergent, and creative process that can benefit from explicit pedagogical training in pre-service teacher education programs and in-service teacher professional development. During this process, technical affordances are perceived and actualized as pedagogical affordances in instructional design lessons.

In more detail, the proposed theoretical framework, shown in Fig. 4, is represented as a five-stage process model. The first stage in the process shows that educational software packages are characterized by a number of built-in technical functions or technical affordances, as these have been determined by software designers and developers. These technical affordances exist independently of teachers' awareness of their existence. Subsequently, teachers, with certain knowledge, expertise, and educational goals, interact with the technical features of tools and come to recognize and familiarize themselves with the technical affordances of tools (Pozzi et al. 2014; Bernhard et al. 2013). Thus, the second stage related to

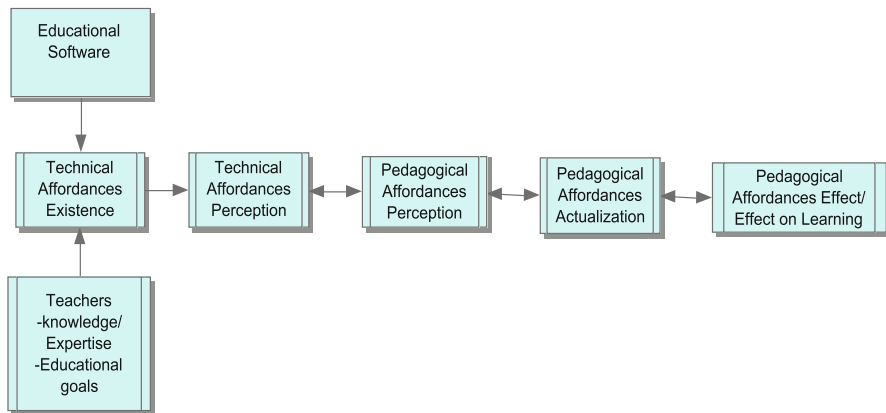

Fig. 4 Teacher ICT knowledge theoretical framework

technical affordances perception is about recognizing the existence of technical affordances and their potential for performing an action (Leonardi 2011). For example, teachers learn or find out about the SORT feature in Excel, and they ponder about how they can use it to sort a big data file in ascending order.

Subsequently, in stage 3, teachers come to realize/perceive the technical affordances as enablers of pedagogical action. This is an iterative and emergent process that involves transformation of the technical affordances into pedagogical affordances. For example, a teacher learns how to insert hyperlinks in an Inspiration diagram, but he or she gradually realizes that the use of hyperlinks in concept maps facilitates discovery and inquiry learning.

In a recent research study, Ioannou (2016) found that during a 15-h teacher professional development seminar about TPACK, teachers were not able to perceive the pedagogical affordances of tools. Interestingly, the teachers in his study were experienced computer science middle school teachers with excellent technical skills and knowledge about technology. Ioannou (2016) concluded that teachers cannot easily conceive how the technical affordances of tools can be transformed into pedagogical affordances and that the advancement of their understanding from technical to pedagogical affordances should be facilitated.

The fourth step in the model is actualization of pedagogical affordances. Actualization is a goal-oriented and iterative action during which pedagogical affordances are put into actual classroom practices (Leonardi 2011). McGrenere and Ho (2000) found that actualization is a gradual process with different degrees of difficulty. It can be an individual effort or a collaborative effort situated in real classroom practices. Haines (2015) also found that affordance actualization aids teachers to reconsider their perceptions of the pedagogical affordances of tools, in terms of action possibilities and constraints for their practice, and redefine them. Actualizing pedagogical affordances depends on several teacher-related factors, such as skills and instructional design knowledge, as well as school-related factors, such as availability of resources and a conducive curriculum. It is also, according to Bernhard et al. (2013), “*a function moderated by perceptions of the efforts that it takes to actualize the affordance*” (p. 6).

Affordance actualization results in (a) reconceptualization of pedagogical affordances and (b) learning effects. In essence, when teachers integrate tools in their lessons, they gradually develop more informed understandings of the added value of the tools and consequently more complete and sophisticated mental models of the pedagogical affordances of tools. At the same time, the integration of tools in instructional lessons mediates the transformation of the content to be learned into forms that students can understand better, while at the same time it enables the implementation of new pedagogical practices promoting the active role of students in learning. Consequently, the actuation of an affordance produces measureable results such as changes in student learning. In sum, as Volkoff and Strong (2013) stated, actualized affordances provide explanations of causality at a level that is specific with respect to the technology (i.e., what is the added value of the technology in teaching?) and the organization (i.e., how does technology affect student learning?).

Implications for Theory and Practice: The Development of Teachers' ICT Knowledge

The model in Fig. 4 is aligned with current research evidence and theoretical conceptions about tool affordances and instructional/learning design. It explicates that the development of teachers' ICT knowledge requires a systematic and goal-oriented process targeting the development of teachers' understandings of the notion of pedagogical affordances within the context of rich instructional design practices. The model can be implemented in both pre-service teacher education courses and in-service teacher professional development programs. In pre-service teacher education, the five-stage model can be implemented in the context of instructional technology courses and methods courses. Teacher educators and trainers must explicitly inform teachers about, as well as exemplify, the five-stage model, the expected outcomes per stage, and what it entails in terms of their preparation. The process depicted in Fig. 4 should be enacted for each tool taught in a course or training session. Depending on the difficulty of the tool, the duration of each cycle of enactment can be about 10 h on the average, so that over the course of an academic semester, teachers can receive training on about four different ICT tools. Succinctly, teacher educators first engage teachers in activities where the focus is to learn how to use a tool. The goal during the first two stages is for teachers to become familiar with the technical features and technical affordances of tools. The third stage in the model aims at linking the technical affordances of tools with teaching. For this to happen, teacher educators need to make explicit connections between the technical affordances of tools and their pedagogical affordances. This can be done in the context of instructional design activities during which pre- or in-service teachers learn to think about technology as a pedagogical tool to solve teaching/learning problems. This third stage in the model is the most challenging to enact, because it is emergent, demanding in terms of time and effort, and does not constitute a 1:1 correspondence between the technical affordances of tools and their pedagogical affordances. The link between technical affordances and pedagogical affordances can be strengthened during the stage of actualization, which must: (a) have a focus on content (subject matter) (Desimone 2009); (b) be grounded in teachers' own classroom practices (Putnam and Borko 2000) to promote ongoing and sustainable teacher development (Darling-Hammond and McLaughlin 1995); (c) address obstacles to student learning (i.e., student misconceptions or alternative conceptions) and enablers of student learning (i.e., content transformations, approaches to destabilizing student misconceptions) (Angeli and Valanides 2009; Dopplet et al. 2009); (d) use preferred instructional practices utilized in teacher development, such as modeling and coaching (Ioannou and Angeli 2013, 2014; Angeli and Ioannou 2015; Darling-Hammond and McLaughlin 1995); (e) be grounded in inquiry, reflection, collaborative problem solving centered around pedagogical problems or problems of practice that are teacher-driven (Angeli and Valanides 2009; Darling-Hammond and McLaughlin 1995); and (f) be collaborative with a focus on communities of practice rather than on individual teacher practices alone (Darling-Hammond and McLaughlin 1995). Within this situated teacher development

framework, aspects of the learning-by-design framework are incorporated for facilitating the development of complex and interrelated ideas among content, pedagogy, learners, context, and technology (McKenney et al. 2015; Angeli and Valanides 2009). Conway and Zhao (2003) stated that within the context of learning by design “*it becomes crucial to ally teachers’ knowledge about not only various general pedagogical approaches, but also pedagogical content knowledge, as well as the learning affordances and constraints of various computer-based technologies allied with the current more ambitious reform-based educational goals for students*” (p. 27).

Finally, the fifth and last stage allows for reflection based on the educational outcomes observed or obtained, enabling teachers to reconsider their perceptions of the pedagogical affordances of tools and their actualization in learning design tasks.

Obviously, effective technology integration presupposes robust knowledge and understanding of the technical affordances of tools and how these can be transformed into pedagogical affordances, in order to be used in teaching and learning for the purpose of elucidating content into more understandable forms for the learner. The development of this body of knowledge is, therefore, directly related to the development of teachers’ TPCK, and has implications for the existing theoretical conceptualizations of TPCK or TPACK.

To remind the reader, in the first part of this chapter the authors referred to two prevailing views of TPCK in the literature: (a) the transformative view explicating TPCK as a distinct or unique body of knowledge that needs to be taught (Angeli and Valanides 2005, 2009), and (b) the integrative view defining TPACK as a body of knowledge that is created from other forms of teacher knowledge *on the spot* during teaching (Koehler and Mishra 2008). These two views have raised important research questions during the last decade regarding the construct of TPCK and its development. For example, research questions framed from the transformative view investigated the construct of TPCK itself, while research questions framed from the integrative view inquired about the constituent components of TPACK, such as TPK and TCK.

In fact, many researchers pursued studies from the perspective of TPACK as an integrative body of knowledge and sought to identify and measure the constituent knowledge bases of TPACK, such as, CK, TK, TCK, TPK, and PCK. Recent research findings from this line of research have been reported by Shinas et al. (2013) who examined the construct validity of the Survey of Preservice Teachers’ Knowledge of Teaching and Technology, a survey that according to its developers is grounded in the integrative framework of TPACK and is designed to measure seven subdomains of TPACK (Schmidt et al. 2009). Shinas et al. (2013) administered the survey to 365 pre-service teachers enrolled in an educational technology course and conducted an exploratory factor analysis on the data. Their results revealed that participants did not always make conceptual distinctions between the TPACK domains and raised issues about the validity of the TPACK framework and the research instruments that have been developed based on its theoretical foundations. Shinas et al.’s (2013) results are in agreement with the research findings of other researchers who also problematized the validity of the TPACK framework and the

inherent difficulty in distinguishing the boundaries between the constituent sub-domains of TPACK, such as TPK and TCK (Angeli and Valanides 2009; Archambault and Barnett 2010; Cox and Graham 2009; Graham 2011).

From the perspective presented and discussed in the present chapter and the line of argument that was developed based on the theoretical discussion about the technical and pedagogical affordances of tools, TCK, for example, cannot possibly exist without the mediating role (action capabilities) of an actor (teacher) and his (her) knowledge, expertise, and educational aims and goals. Thus, TCK should not/cannot be included as a common and identifiable body of teacher knowledge in any framework describing teacher knowledge. This inference is also supported by Shinas et al. (2013) who concluded that “*factors were congruent across only technological knowledge (TK) and content knowledge (CK) and not congruent across pedagogical knowledge (PK), pedagogical content knowledge (PCK), technological content knowledge (TCK), and TPACK*” (p. 339).

Concluding Remarks

In this chapter, we presented an alternate perspective on teachers’ knowledge of ICT. A theoretical model has been proposed illustrating a five-stage process through which teachers perceive and actualize the pedagogical affordances of tools in the context of learning design activities. In order to better situate the new theoretical framework depicted in Fig. 4 with the existing body of research on TPCK, it is specified that the model in Fig. 4 provides a theorization about technological knowledge (TK) in relation to how a teacher realizes and actualizes the affordances of technological tools in teaching and learning. This theorization in conjunction with contemporary research evidence seems to refute the existence of at least some of the knowledge bases integrated in the TPACK framework (Mishra and Koehler 2006, such as, for example, TCK, and provides further support to the transformative perspective of TPCK (Angeli and Valanides 2005, 2009). The proposed model contributes to the bigger effort related to the theoretical conceptualization of TPCK as an extension of Shulman’s PCK and the knowledge that teachers need to have to be able to teach competently and adequately with technology. It should be emphasized also that this conceptualization maintains the point of view that TPCK is a way of *knowing* that can be developed only after deliberate instruction or training and can grow progressively through involvement in useful professional experiences.

At this point, the model should be considered as an emergent theoretical model, since it has not been tested empirically yet, although ample research evidence converges with the model’s theoretical conceptualization. Mixed-method research designs may be adopted for providing details about the validity of the model in terms of how the concept of pedagogical affordances emerges, and what influences positively and/or negatively teachers’ conception and actualization of pedagogical affordances in their professional practice. In conclusion, the model provides further support to the transformative view of TPCK as a unique body of knowledge that requires purposeful training, and cannot possibly exist and/or be studied in terms of

artificial and fabricated bodies of knowledge, such as TCK, outside the frame of reference of the teacher.

Abstract

Preparation of preservice teachers for their changing role in the information era requires equipping them with the knowledge, skills, and dispositions required to transform education, assisted by the vast capabilities made available by information and communication technologies (ICT). This chapter tackles the complex undertaking of preparing preservice teachers to integrate ICT, in light of its promise to transform education. Initially, we attend to the issue of professional identities of preservice teachers and teacher candidates in the twenty-first century. We review preservice teacher training in the twenty-first century, examining their proficiency in utilizing ICT in general and for educational purposes in particular,

noting the gap between needs and ICT skills and utilization for pedagogical practices. Then, an array of examples of cases portraying ICT-integrated training worldwide is presented, illustrating attempts to encounter current state and training needs in order to attain the best ICT-integrated pedagogical practices. As a result, three possibly coinciding modes of preservice teacher training toward ICT integration are offered, as well as an exploration of their possible overlap. The chapter ends with recommendation for policymakers, practitioners, and researchers when attempting to improve preservice teacher training.

Preservice teachers · Information and communication technologies (ICT) · Teacher education · Teacher training · Teacher identity

Identity of Preservice Teachers in the Twenty-First Century

Teacher identity is the professional personality structure constructed during the period covering an individual's educational process and career development, from their preservice stages. It is related to how teachers make themselves known to others (Lasky 2005). Today, students attending preservice training are actively engaged with twenty-first-century technologies. Still, these uses do not make them experts on technology-enhanced teaching and learning. In accordance with other professions, preservice teacher candidates engage in digital literacies in modes that reflect their identities as preservice learners as well as their practice in technology integration (Burnett 2011; Niess 2015). The question is what learning trajectories can assist in preparation of preservice teachers to critically engage with information and communication technologies (ICT) as a lever for teaching, to technology-based best practices?

The current generation of candidates entering preservice teacher education institutes differs from previous generations of preservice teachers in two major aspects. The first, teaching in a twenty-first-century technology-saturated environment is challenging in itself, as change is in the setting at large. The second, candidates differ in their identities, as a result of the changing world in which we live (e.g., globalization and multiple impact sources, diversity as a result of inclusion policies) as well as a need for critical digital literacies, for example, additional skills and capabilities which were formerly uncommon among this population (Kimmons et al. 2015; Pangrazio 2016). However, they may not be technologically knowledgeable or exhibit ICT skills as anticipated; they may prove to be poorly prepared to utilize ICT as students and as future teachers (Kumar and Vigil 2011; Lei 2009). However, preservice teachers will be expected to play an active role in implementing ICT in education; therefore, expectations from them include utilizing ICT in their practice in a broader manner than former generations of preservice teachers.

Usage of digital technologies for transforming teaching and learning by preservice teachers requires understanding of their professional identity within a new digital world and understanding the impact on their pedagogical perceptions and actions. Since the new generation of preservice teachers uses technology in a

personal context, this can be a basis for utilizing ICT in a professional context as well, as ICT skills are universal in nature, penetrating our personal as well as professional lives (Chang and Chou 2015; Lim et al. 2011). Awareness of their digital identity, however, is only a prerequisite for developing a positive digital professional identity and understanding its impact on future educational practices.

Preservice Teacher Training in the Twenty-First Century

Preservice teacher education programs lay the foundations of the future of society by preparing preservice teachers to adapt education to the information era. Hence, they aim to supply the new generation of teachers with the knowledge and skills required for entry-level teaching, as defined by education systems worldwide (Niess 2015). These may include not only essential ICT knowledge and skills and preparation for integration of ICT in several subject areas and pedagogical experiences, but also developing up-to-date technology-enabled curriculum design skills to assist their future students to become twenty-first-century citizens, as well as digital curation and customization of existing resources (Deschaine and Sharma 2015). Despite this, new literacies in the knowledge society have meager impact on preservice teacher education institutes. Most teacher preservice education programs do not emphasize *de facto* technology use and fail to prepare preservice teachers to feel confident in their use of ICT in their future teaching (Istenic et al. 2016).

This may be the result of inadequate access to ICT as well as competition with print literacy, with which some preservice teachers, despite their belonging to the “digital natives” generation, feel more confident and competent (Burnett 2011). Indeed, being the first generation of “digital natives,” preservice teachers undergo preparation programs that sometimes address themes similar to those of prior generations. While expected to be literate as well as passionate about ICT integration and technology-saturated environments, preservice teachers, while possibly fluent in utilizing technology on a need to know basis, are not necessarily equipped with the ICT knowledge and skills expected from the net generation (Lei 2009).

When examining their beliefs regarding ICT as a lever for better pedagogy, attitudes, experiences, and ICT proficiency, a curriculum for preparing preservice teachers to implement technology in their future teaching can be developed. Positive attitudes to technology integration and beliefs in the usefulness of ICT for empowering teaching, as well as computer self-efficacy, affect technology acceptance and integration positively (Prestridge 2012; Sadaf et al. 2016). Hence, this, along with information about their preferences in technology utilization, for example, social media, may serve teacher educators in the selection of preservice candidates and, furthermore, in defining goals for preservice education in the information era (Hammond et al. 2011).

Research also identifies an apparent gap between statements about the need for ICT integration in teaching (e.g., digital learning environments), and specific and practical knowledge on how to use ICT for empowering teaching. The popular understanding of ICT in education consists mostly of deploying devices and tools, for example, Word, learning management systems, or interactive whiteboards; hence,

ICT utilization for teaching and learning is mostly confined to basic usage of digital tools; hence, the goals of teacher education programs are consistent with this line of practice that is common in schools. Moreover, the computerization of education systems is often perceived in terms of deployment of administrative systems (e.g., feeding student information, communication with parents), rather than pedagogical practices, again, confining training to immediate needs of the education system (Haley-Mize and Bishop 2015). Hence, there is vagueness regarding the desired goals for teacher training: should it be focused on present practices, or should it include future trends, thereby assigning a role of arrowheads to preservice teachers.

Teacher Education: Selection, Training, and Framework Construction

Preservice teachers are usually inexperienced in designing technology-based teaching and learning. Moreover, especially those trained to be elementary school teachers possess relatively basic ICT skills (Neiss 2015). In fact, also the use of ICT among teacher educators in preservice teacher education programs is low altogether, resulting in a low probability of modeling (Drent and Meelissen 2008). Positive attitudes toward utilizing ICT for education purposes and toward technology, as well as enhanced ICT literacy, may have positive effects on attitudes toward teaching as a profession (Celik and Yesilyurt 2013). Hence, if these are facilitated in teacher preservice training, the result may be empowerment of novice teachers altogether.

Selection of preservice teachers is becoming increasingly important, since teachers coming into the teaching profession need to be proficient in using ICT in general, and for improving teaching and learning in particular (Haydn 2014). Technological proficiency is currently not necessarily a prerequisite to entering teacher education programs, although preservice teachers are mostly proficient in basic technologies. However, their relative literacy in the more advanced and collaborative technologies may be insufficient, though possibly required in their future practice. This implies that preservice teachers may be in fact literate with basic technologies but might have some difficulties with the more advanced technologies. Hence, while advanced skills may contribute to constructing a more gradual and possibly differential ICT curriculum (Lei 2009), they are usually not considered as prerequisites in preservice teacher selection of candidates. Some programs aim to teach preliminary ICT skills in initial teacher education courses, thereby setting a threshold for these skills.

In summary, the literature addresses the need to establish a framework for teacher preservice education in an ICT-enriched school setting. Recommendations include research and development components, thereby setting a goal of capacity building. Programs should include a well-developed vision of ICT in education and teacher education (Stürmer et al. 2015), and according to this vision, a comprehensive curriculum (consisting also of practicum as well as courses), professional development of teacher educators (for modelling purposes), technical ICT plan (e.g., devices, software and application utilization, infrastructure), partnership between institutes within the educational milieu and beyond (e.g., industries), and accompanying research (Lim et al. 2011).

Review of Preservice Teacher Education toward ICT Integration

Although there is general agreement that ICT integration in teaching and learning is necessary for educating students in the information era, according to a review of preservice teacher education programs which integrate ICT, these do not seem to develop sufficient skills to reach this goal (Lim et al. 2011). Given the challenges of teacher preservice education in the digital age, capacity building may allow preservice teachers to examine their pedagogical beliefs in the framework of an ICT-enhanced teaching environment and explore ICT integration thoroughly as a means of empowering these beliefs.

Efforts have been made worldwide in attempts to achieve best preparation for preservice teachers in technology-enhanced teaching (UNESCO 2011). These efforts are evident not only in practice per se, but also in meticulous long-term planning, executing, and assessing outcomes of programs that focus on teacher preservice education in the twenty-first-century knowledge society, as described here. Modes of ICT integration are congruent with types of teacher training programs that are common worldwide, ranging from traditional modes of training (e.g., Saudi Arabia's traditional pedagogy, Belgium focusing on an ICT tool kit, or Finland offering basic ICT courses) to innovative pedagogical practices using ICT (e.g., attempts in Singapore to identify gaps in integrating TPACK for better teacher training), to integration in field practice.

ICT-Integrated Training Worldwide: Examples of Cases

The cases illustrated here are diverse in nature, in nationality, and in the depth and scope of ICT integration. This shows that there is no one mode of training used worldwide, but rather an array of training models.

Finland. This country had revised its teacher education program in the past decade. In a study at the University of Helsinki teacher education program, participants were interviewed and filled questionnaires at the faculty level. Data showed that ICT courses in different training programs varied widely (Meisalo et al. 2010). Courses focused on acquiring basic ICT skills had been recommended but not mandatory for preservice teachers. Student teachers acknowledged a gap between training and practice in their preservice education, which was perceived as rather conservative. Diffusion and adoption of innovative ICT usage was identified as a complex process, lacking the transfer from strategies to practice. Also, the study highlighted the need for more cooperation and teamwork, especially in multidisciplinary projects (Vihma and Aksela 2014). However, mentor teachers and teacher educators in some cases served as role models, which were of great value to preservice teachers attempting to produce innovative practices using the strategic guidelines presented by the national plan (Vahtivuori-Hänninen and Kynäslähti 2016).

Canada. A different angle on using technology for teacher preservice education also refers to a major challenge caused by a constant gap between the theory and actual classroom practice (Winslett 2014). Teacher education programs in Canada

utilize videos in teacher preservice education for analyzing real-life teaching and learning situations as well as educational events. This develops useful teaching skills, fostering reflection through self-observation or observation of others in the act of teaching and using various learning models (Blaik Hourani 2013). In the study facilitated by Canadian teacher education programs, three impacts were significant: anticipating and preparing for teaching practice, analyzing the teaching–learning situation, and stimulating reflection. Given the importance of self-efficacy for teachers’ professional development, online videos may be extremely useful, their use being flexible in terms of time and space (Karsenti and Collin 2011).

Saudi Arabia. In its preservice teacher education, traditional approaches in pedagogy are still broadly acknowledged, allowing less opportunity for effective ICT integration. Reasons include lack of infrastructure, accessibility issues, ineffective curriculum design, inadequate teacher educators’ computer literacy, and meager professional support, despite government initiatives in this field (Al-Zahrani 2015). Results show that preservice teachers are interested, enjoy using ICT, are confident, satisfied, and expect to integrate ICT with novel pedagogical approaches. However, interviews highlight frustration regarding expectations to adopt conservative teaching modes. Overall, results indicate that preservice teachers have the skill and capability to work effectively with a variety of ICT tools (Robertson and Al-Zahrani 2012).

Belgium (Flanders). Here, a self-report instrument that measures preservice teachers’ ICT skills in education was developed, based on an existing comprehensive framework. The underlying supposition for this instrument was that the dynamic nature of technological developments requires emphasis on generic ICT skills for teaching and learning. The result indicated two factors labeled “Competencies to support pupils for ICT-use in class” and “Competencies to use ICT for Instructional Design,” which represent two foci of training (Tondeur et al. 2016a).

Singapore. In a large-scale study, 1185 preservice teachers filled a TPACK survey. An exploratory factor analysis found five distinctive constructs: technological knowledge, content knowledge, knowledge of pedagogy, knowledge of teaching with technology, and knowledge from critical reflection. A major finding arose from relative inexperience of preservice teachers, explaining the merging of pedagogical knowledge and pedagogical content knowledge items: preservice teachers exhibited lesser ability to link content and pedagogy when ICT integration, in lesson planning and in their practice, compared to more experienced in-service teachers (Koh et al. 2013).

Chile. Another national study about the availability and use of ICT in teacher education institutes was launched as part of the OECD international “ICT in Initial Teacher Training project.” The main findings show promising conditions for pedagogical utilization of ICT in preservice teacher education, in infrastructure, support, policies, and self-reported ICT-related skills. Faculty and preservice teachers reported comfort in using ICT for teaching. Policies encourage ICT integration in teacher education, but few institutions formally implementing ICT in practice and it is low in their training priorities. Also, in common with other countries, most institutes integrate ICT in the curriculum as specific subjects or courses, rather than in a cross-disciplinary manner, which is less effective for promoting best

practices. In fact, most students are not trained to fully use a wide range of possibilities of ICT in teaching or to fully comprehend its impact on teaching and learning (Brun and Hinojosa 2014).

Asia Pacific Region. Another training program consists of creating a tool kit for teacher education institutions in the Asia Pacific Region (i.e., Indonesia, Thailand, the Philippines, and Vietnam) (Lim et al. 2011). The aim was capacity building in developing ICT in education skills (Lim and Pannen 2012). The 3-phase 1-year project included an initial integration of the tool kit involving over a dozen teacher education institutes; scaling of the integration; and ensuring sustainability of the program. The program enabled to combine top-down and bottom-up approaches toward a systematic perspective on planning ICT in education training. According to an additional study (Xiong and Lim 2015), feedback and reflections from preservice teachers' learning experiences in ICT integration are essential for rethinking about training programs in the information era. Hence, a reciprocal approach, consisting of supplying ICT tools for teaching, as well as constant evaluation of preservice programs and adaptation to current needs is essential for better-quality preservice education.

Turkey. ICT may be a means of connecting preservice teachers for better support in their training by peer-learning. Attitudes and practices were examined by a study intended to identify motivators and barriers in the development of online communities of practice for preservice teachers' professional development in Turkey. The study comprised of two phases: an initial mandatory period including preservice teachers, and a voluntary participation period, including also in-service teachers, as well as additional preservice teachers (Baran and Cagiltay 2010). Three types of barriers caused decreased activity and possibly decreased the quality of knowledge sharing: personal barriers (e.g., feeling of reluctance to initiate a dispute, lack of time, preference to access a less interactive knowledge source, hesitancy to misdirect other community members); interpersonal barriers (e.g., availability of other community members caused preservice teachers to think twice before sending messages or materials in fear of criticism, diversity of student background and disciplines); and environmental barriers (e.g., poor computer literacy courses, poor ICT access, difficulty in management of the asynchronous communication) (Özcan et al. 2016). In another Turkish study, consisting of almost 2000 preservice teachers, two major factor categories influencing ICT utilization were examined: external factors, for example, types of support from the college; and internal factors, for example, attitudes, self-efficacy, and ICT skills. Conclusions stated that effective ICT integration was dependent on both types of factors, which were interrelated; hence, the integration process is complex and multifaceted (Tezci 2011).

The conclusion from the body of knowledge is manifold: a) there is a gap between policy and practice; b) ICT skills are insufficient – the discussion should focus on new educational paradigms; c) training itself should adopt new paradigms, for example, online communities of practice, simulation of best practices; d) hindering factors as well as facilitating factors should be addressed and monitored; e) focusing on teacher educators as role models. This may be exhibited in three modes of training, as detailed below.

ICT Modes of Training

Three modes of training may coincide: the “constituent competencies” mode of training, the “integrating ICT through curricular design” mode, and the field practice component. The first two modes should not be seen as dichotomous, but rather as a continuum, since the actual utilization of ICT consists of several types of activities; the latter should be realized based on the two other modes. The Belgium self-report instrument measuring ICT skills indeed indicated the two factors, that is, the competency-related factor and the ICT for instructional design factor, representing the two emphases of training. Still, the overall focus of preservice teachers’ preparation regarding ICT integration in their teaching practice should be pedagogical; hence, the scope of training is determined according to the institute’s emphasis on technological proficiency versus pedagogical expertise using technology. The field practice is a result of the college vision regarding ICT integration in schooling.

Constituent Competencies

This type of preparation consists of separate courses for distinct proficiencies: content courses, which aim to develop knowledge in specified disciplines (subject areas) that are taught within the K12 national or regional curriculum; methodological courses, aimed to develop teaching methods as outlined by the curriculum for preservice education; technology courses, aimed to develop skills and proficiencies in using ICT in the classroom (e.g., utilization of computers and mobile devices, exposure to software – content-based as well as general software, fixing minor malfunctions), and practice in K12 institutes (Niess 2015). Indeed, studies emphasize the need to develop basic technological skills among preservice teachers as a prerequisite for developing their ability to implement ICT in their future professional lives (Instefjord and Munthe 2016), for example, the need to become familiar and possibly fluent with ICT and to master basic tools and interfaces so as to become a “native speaker” of the digital language, as evident in the case of Saudi Arabia. This focus is somewhat evasive, since technological proficiency is constantly changing given the frequency of technological developments and change.

While this mode of training highlights the importance of technological aspects, it assumes expertise in teaching with ICT. The latter, according to this mode, is attained separately and supplementary to technological expertise, in terms of content knowledge (according to the preservice teachers’ specialization) and pedagogical proficiency. Research has reported the ineffectiveness of technology courses that are detached from pedagogical themes in preservice teachers’ curriculum (Anderson et al. 2011), as portrayed in the Chilean case, in which most ICT integration is achieved in specific courses, rather than in a curricular design mode, which is seen as insufficient for promoting best practices.

Many of the preservice teacher education programs include, as practice of this mode, one single course focusing on ICT in education. This course is usually a preliminary course, which fails to prepare preservice students for the complexities of

teaching in twenty-first-century schools (Instefjord and Munthe 2016; Lim et al. 2011). Moreover, preservice students learn many of their ICT skills prior to their higher education studies (e.g., in school, online, from family members or friends, or by self-learning), for example, word processing, spreadsheets, presentation tools, social media, or search for information; this excludes, surprisingly, collaborative tools for sharing information and constructing joint products (Blackley and Sheffield 2015; Burnett 2011).

To sum up, many factors may be reasons for the lack of success in linking preservice education to the digital era. They may include time constraints within the traditional time frame, teaching paradigms that are not up-to-date, faculty technological skill, negative attitudes toward technology, and misunderstanding of ICT integration in teaching. The latter raises a fundamental issue, according to which preservice teacher education that offers courses focusing on ICT skills has limited impact on the quality of teaching. Skills for ICT use taught in separate courses that are disconnected from content and pedagogy, moreover, from educational practice, may be futile (Jordan and Elsdén-Clifton 2013).

Integrating ICT through Curricular Design

The principle behind this mode of teacher preparation asserts that separate educational technology courses aimed to enhance technological proficiency are not sufficient for preservice teachers' professional development (Haley-Mize and Bishop 2015), but rather an integration of pedagogy and technology and seeing them as intertwined, as attempted in the Singapore program. However, as shown also in the Finland case, this is a complex endeavor: the focus of this mode is to highlight pedagogical and curriculum design competencies rather than technological skills, thereby emphasizing instructional design processes. In terms of content, this requires various subject matter, content domains, and multidisciplinary topics, all aimed to demonstrate the pedagogical advantages and affordances of given technological tools (e.g., platforms, software) and devices (e.g., smartphones, geographic information systems) to transform teaching (Niess 2015). Furthermore, preservice teachers are instructed to work with technology-based systems that allow adaptation of learning materials to their students (Instefjord and Munthe 2016). The Asia Pacific Region case makes an attempt to scale and sustain the combined integration of technology and pedagogy in preservice training programs, thereby enabling two-way top-down and bottom-up integration processes; these are constantly reevaluated, aimed to improve training altogether, and ICT integration in particular.

Another focus of this mode is authentic real-world tasks in classroom settings, sometimes referred to as situated learning (Tondeur et al. 2016a). Focusing on instructional design engages preservice teachers to actually teach within their training process, utilizing technology not only for their practice as students, but also engaging K12 students in learning in a technology-saturated setting, as a major component of their role as future teachers. Naturally, this utilization of technology is not sufficient, but rather has to be accompanied by reflections and insights regarding

the role of ICT integration in teaching and learning (Niess 2015). Of course, the challenge would be to ascertain ICT competencies alongside and intertwined in pedagogical and curriculum design courses.

Finally, utilizing technology as a means of narrowing the digital divide, defined by socioeconomic status as well as by special and possibly diverse needs of students, means highlighting the social role that technology plays in twenty-first-century education. The focus of an instructional design mode, hence, is not on the technical proficiency with ICT, but rather on its utilization for the benefit of distinct needs, for example, equity and accessibility (Benton-Borghini 2013). The Turkish attempt to develop online communities of practice for training and professional development of preservice teachers is an example of utilizing the characteristics of ICT for peer learning, in which availability of several participants allows examination of several types of ICT integration.

Practical Field Experience

The preservice field practice is considered a major component of the teacher preparation process worldwide, as it exposed the preservice teachers to authentic teaching practice in schools. This, in turn, may strengthen the connection to courses within the college (Latham and Carr 2015). However, while this is a result of the two first modes of training toward ICT integration, the practicum framework does not necessarily include a carefully planned and systemic paradigm for ICT integration. Furthermore, schools play a major role in defining the nature of diffusion of technology into their curriculum, thereby posing possible conflict for preservice teachers. On the one hand, mentor teachers, those who receive the preservice teachers into their classrooms, follow an existing educational paradigm; this often results in assimilation of ICT practices into current pedagogy. On the other hand, preservice teachers are assumed to be prepared to implement novel pedagogies, which inherently utilize ICT as a necessity in curriculum and lesson planning as well as teaching and learning (Kimmons et al. 2015). In a recent book, several studies highlight understanding of ICT-integrated best practices in schools, for example, using tablets to empower pedagogy, game making using ICT, collaboration using online environments (Zhang et al. 2016); hence, these may serve as models for preservice teachers to follow and relate to in their field practice. This requires preplanning and careful assigning of mentor teachers, who are ICT literate and may be innovators in their practice, for example, an innovative teacher training model in High Tech High (Griswold and Riordan 2016).

Modelling would be of the utmost importance and a crucial element in the process of attaining knowledge and training preservice teachers to utilize ICT in their practice (Hill and Flores 2014). This is well portrayed in the Canadian case, in which technology is used for simulating teaching experiences. Teachers tend to teach in ways that they have been taught; hence, showing them or having them present integration of best pedagogical practices using ICT may change their knowledge

construction regarding their role as teachers as well as the role of ICT in their future teaching (Gill et al. 2015; Haley-Mize and Bishop 2015).

Notwithstanding, the risk of teaching ICT skills in the pre-preparation stage and focusing on pedagogy in preservice stages and in-service professional development may be an impediment for teachers who do not feel adequately prepared to integrate ICT effectively in pedagogical practices (Tondeur et al. 2016c; Hsu et al. 2013). Hence, while the major issue is whether twenty-first-century educational goals are being met in contemporary teacher preservice practice, de facto preservice teachers need scaffolding in the form of ICT support.

In summary, since the role of preservice practice is to better prepare teachers for their teaching role, and it is considered as a vital component for their professional development of practical teaching skills, integration of pedagogical practices using ICT is considered of vital importance (Jordan and Elsdon-Clifton 2013). Figure 1 summarizes an overview of the preservice education process and components.

The main idea behind the illustration presented in Fig. 1 is that the technical aspect of the training as a stand-alone training component is suited for the pre-program phase, that is, a threshold of ICT proficiency is required for teacher preservice education, though constantly addressed also within the teacher preparation period. However, it is handled on a need-to-know basis, according to educational needs. In preservice training, academic courses and school practice should be connected to each other, as well as to pedagogical methods and disciplinary content, all interrelated, with the general setting being an ICT saturated environment. These in turn assist and contribute to developing innovative pedagogical practices using technology, within top-down but also bottom-up paradigms, which continue in in-service training and practices.

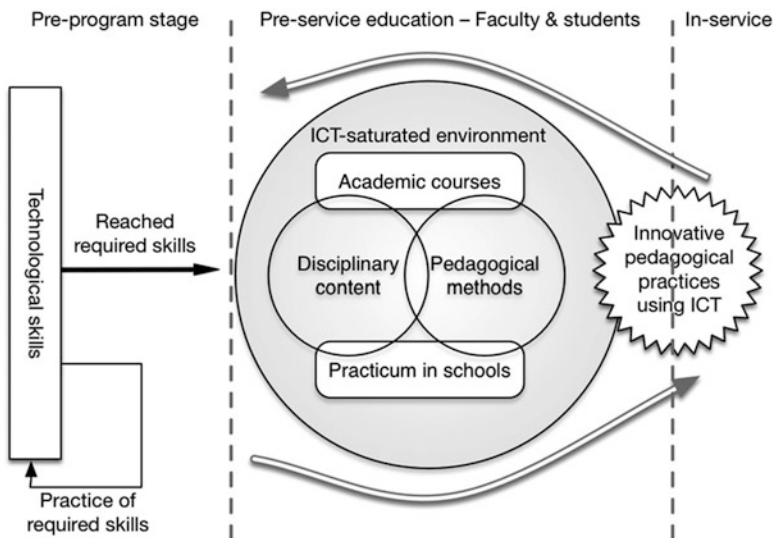

Fig. 1 An overview of the training process

Conclusion. Teacher preservice education focused on utilizing ICT is threefold in its major components. The first aspect is to apply ICT as student teachers in academic courses, consisting of technical knowledge aimed to promote ICT skills. The second component is to promote disciplinary and pedagogical knowledge that may assist future teachers to utilize ICT in novel ways, as a lever for educational change, whether as a process or in a relatively radical and disruptive manner. The third is the de facto application of innovative pedagogical practices in teaching within practice schools, which is the final target of the teacher preservice training process. Hence, we can identify three stages of training. The first stage includes knowledge of potential ICT uses in educational contexts in general; this consists of noncritical, nonselective use of ICT in academic courses. The second stage is of a more specific nature, including consideration of more specific possibilities for developing pedagogical methods and practice that implement ICT in context-specific scenarios, thereby acknowledging the complex nature of ICT application in educational contexts. The third stage consists of a more reflective nature, including creation of a systematic and systemic plan that gathers ideas, insights, and practical experience, in the course of constructing principles for critical engagement with ICT. In this final stage, the preservice student is able to identify and explore contingent conditions for best educational practices using various technologies, as well as to attain deep understanding of the complex nature of ICT integration in teaching and learning (Gill et al. 2015).

ICT Integration: Learning by Doing

Preservice teachers involved in ICT integration, either in courses or in their practicum within schools, are likely to acquire positive attitudes toward ICT integration, enhanced technological knowledge, and, most importantly, to implement ICT-based innovative practices within their practicum in schools (Polly et al. 2010). This depends on the quality of their training, in terms of preparing teachers for teaching and mentoring students, who are born into a world that is completely different from the one they were raised in, that is, the digital era that is in constant change.

For best impact, training requires that the ICT integration process be a spiral process, performed in a nonlinear mode. The top-down nature of the process in the initial stages of preservice teacher preparation allows more standardized assessment of its impact; however, the potentially disruptive nature of ICT integration requires facilitation of bottom-up initiatives. For best impact, the training process needs to be dynamic in nature: possibly technological to begin with, but subsequently focusing on the pedagogical and disciplinary opportunities for change and innovation. In some cases, it is unavoidable to be revolutionary and disruptive, while in other cases, it is more evolutionary and progressive in its nature. In many teacher education institutes, local initiatives for ICT-based teaching and learning are developed. These, in turn, sometimes have vast influence on didactic processes within schools in which preservice teachers are trained within their practicum (Jordan and Elsdon-Clifton 2013).

The impact of preservice training for ICT utilization is manifold, including stages of using ICT as students, as well as implementing ICT in classrooms as future teachers. Since ICT is implemented in different modes worldwide, its impact is controversial; this is evident in ICT integration in education in general (e.g., see OECD 2015). Therefore, collaboration between teacher training programs for universal construction of ICT integration approaches as well as for their assessment may serve local as well as global interests (Tondeur et al. 2016b). This may help to evaluate long-term impact and sustainability of ICT integration in teacher preparation programs. The following section details the actions recommended for best ICT integration in preservice teacher training, leading to sharing of best practices using ICT.

Recommendations

Teacher education colleges are compelled to provide adequate training in accordance with world trends. ICT has created opportunities for disruptive innovations in pedagogical practices that challenge the traditional educational milieu, change teaching and learning paradigms and practices, and make place for emerging new paradigms. The following recommendations are derived from the review of studies worldwide, as well as from the models of ICT integration in teacher training – de-facto and desired (but possibly difficult to achieve). Recommendations may assist practitioners, policymakers, and researchers in their pursuit of improving preservice teachers' education.

1. *Affective states matter.* Preservice teachers' attitudes and beliefs regarding ICT may indicate the extent and quality of ICT utilization. Hence, shaping positive beliefs about the role of ICT for educational purposes, as a means of transforming educational practices and education in general (i.e., vision of education in a global, ICT-enriched society), may facilitate its usage.
2. *Added value.* ICT should not be seen by preservice teachers as replacing or magnifying current educational practices, but rather preservice education programs should focus on the benefits of utilizing ICT to empower pedagogy innovatively, in a transformative manner (e.g., disruptive innovation). Hence, each teacher training institute must examine its vision of twenty-first-century education, in a global as well as a local perspective, and then define its goals accordingly with regard to ICT integration.
3. *Healthy variety.* While ICT integration is an international endeavor, pluralism and the freedom of choice in the ICT integration process is fundamental, at a national as well as an institutional level. For best utilization of ICT as a lever for educational change, flexibility is crucial. This requires dynamic ICT-based training, according to the characteristics of the institute, the population of preservice teachers, and the general student population of the country.
4. *Desired diversity.* Teacher training institutes should compose a clear vision regarding the role of future teachers in the education era. This does not imply

a top-down training process, but rather general guidelines that also encourage faculty as well as preservice teachers to initiate innovative pedagogical practices using technology. Preparing teachers to use ICT in different institutes, or even within an institute, may be of diverse nature but can still meet its goals.

5. *Final goal.* Training of preservice teachers should be practice-related, and related simultaneously to teaching as well as learning, thereby creating a holistic pedagogical master plan for ICT integration. Hence, preservice teachers can benefit from focusing on ICT integration in academic courses as well as in their practicum experiences. The combination of both modes enables them to experience ICT as a student as well as a teacher.
6. *Technological prerequisites.* With regard to technological skills – this should not be considered as part of the academic teacher training curriculum, but rather may be attained separately, as a prerequisite. Teacher training institutes may benefit if they collaborate on this issue, by creating mass courses for nonacademic credit, simply to assist students to reach a required threshold for their ICT proficiency.
7. *Pedagogy.* The focus of teacher preservice education should not be on mastering ICT skills (this was recommended to take place before the actual training, or in its initial stage, e.g., compulsory courses as a prerequisite for acceptance to a full program). After this compulsory (noncredit) stage, training should promote integration of ICT for better teaching and instructional design, and mostly – for better learning. This requires simultaneous attendance to technology, pedagogy, and content knowledge from the initial stages of programs for training teachers and should include ICT integration through curricular design. The process at large should benefit from the connection of teacher preservice programs to the K12 education system, that is, kindergartens and schools, which may be considered as laboratories for examining innovative instructional design and pedagogical practices using technology.
8. *Best practices.* These should be identified as a means of scaling ICT integration initiatives in preservice teacher training. This may include faculty initiatives for academic courses taught innovatively as a result of ICT-based practices, or preservice teacher initiatives for practicum practices within training schools. Encouraging sharing of experiences among preservice teachers and instructors may promote sustainable and scalable practices worldwide.
9. *Modelling.* Faculty within teacher training programs should set an example for their trainees, that is, preservice teachers. Training programs should undergo change in this respect, including faculty as co-trainees, in addition to their role as instructors, engaging them in a joint endeavor of co-learning with their students. Students may bring to this process their relative ICT proficiency, unconnected to its pedagogic utilization, while instructors bring their disciplinary and pedagogical expertise. Hence, the changing role of teachers in the information era also has bearing on the teacher educator's role.
10. *Quality assurance.* Teacher education programs should undergo continuous evaluation processes, in an attempt to adapt them to an era of constant change. These changes are evident in terms of developing technologies (e.g., holograms and augmented reality), pedagogies (e.g., online mass courses adapted to

personal learning by using big data), and even content (e.g., multidisciplinary trends). Consequently, academic research within and about teacher preservice programs should be mandatory. Learning from best practices as well as from failures or mistakes must be perceived as a means of improving the preparation of future teachers.

Concluding Remarks

The purpose of this chapter was to present an overview of the state of preservice teachers' preparation toward ICT integration. The chapter contributes to the reader an array of different initiatives (mostly followed by research) in countries worldwide. It further suggests modes of ICT integration, leading to a proposed comprehensive model aimed to tackle ICT competencies as well as ICT integration through curricular design, leading to better field practice. The ultimate goal is, naturally, to transform the K12 education system, by utilizing ICT in a way that facilitates novel practices – and these should be shared globally. The ultimate message to policymakers involved in preservice teacher education, as well as to researchers, is that pedagogy and curriculum design are imperative for better pedagogy in classrooms, but, in fact, ICT competencies should not be overlooked, as they are a prerequisite for the former. Hence, basic skills should be tackled prior to the educational training; then when entering the training program focus should be on twenty-first-century ICT-based pedagogy.

Abstract

Engaging teachers in cooperative and collaborative processes through which they learn from each other is fundamental in rethinking professional development as being ‘done’ to teachers compared with teachers ‘doing’ or driving their professional learning. This rethinking is underpinned by opportunities that have arisen not only through social networks and the pervasiveness of online media but also from the shift in valuing the exploration of individual interests and needs as well as in the pedagogical reform process. The tenets of effective professional learning, namely, active engagement, teacher voice, creation and collaboration, inquiry and reflection, will be explored in this chapter through two modes of discourse. First, a reckoning of what counts as professional learning activities is proposed to establish the driving force or purpose for teacher learning. This is then developed further in the second part of this chapter where we discuss the various approaches to professional learning with a theoretical analysis of teacher collaboration, teacher teams, communities of practice, and broader social networks.

Understanding the genesis, development, and purpose of professional engagement and interaction is key to supporting teachers as the ‘deliverers’ of educational reform who are those tasked with transforming education through ICT.

Keywords

Professional learning · Professional Development · Social Networking · Teacher Teams · Communities of Practice

Teachers are in a critical position as those responsible for *delivering* educational reforms, innovations in pedagogies, and curriculum change. With Information and Communications Technologies (ICT) as a driver, a deliverable, and a determinant, teachers are expressing the need for effective professional development that will enable them to create new visions, teaching practices, and dynamically flexible learning spaces that are technologically enhanced (Goldman and Lucas 2012; Tsiotakis and Jimoyiannis 2016). In response, some schools offer teachers professional training in specific technologies. They may also have in place opportunities for teachers to individually or collaboratively design curriculum units with an expert ICT teacher or have this teacher take the lessons. Additionally, there may be a school-wide approach to the adoption of a specific device such as tablets or iPads paired with specific training focusing on one flagship class/year level, the more competent teachers, or to meet the needs of a specific target group (e.g., extension group). Such school-based approaches have been found to be limiting as they do not cater to the highly diverse needs of *all* teachers and often replicate historical and cultural practices in schools (Phelps et al. 2011). In addition, teachers are seeking their own learning opportunities by completing targeted workshops on robotics or participating in a Massive Open Online Course, using Facebook to follow and extend their own teacher networks and/or listen to expert podcasts to further their knowledge and skill in ICT integration. With the permeation of the Internet in personal and professional life as well as the opportunities it brings for social networking, teachers have the opportunity now to add to their professional learning repertoire by taking part in such activities. This chapter will explore a few different aspects of professional development and professional learning associated with enabling teachers to harness the transformative potential of ICT in their classrooms.

Fundamentally, professional development is more about change in classroom appropriation of an ICT than access to, or competency with, a new tool or resource. Change is considered a reformation of both mindset, the philosophical disposition a teacher holds, and the pedagogical content knowledge that informs and therefore actions new teaching processes. Professional learning is not about replication of existing practice or the assimilation of ICT into existing teaching approaches. For too long, we have been satisfied with what Lankshear and Bigum (1999, p. 456) described as “technologizing” traditional teaching, which Bigum (2002) more resolutely confirmed as meaning that teachers are still ‘domesticating’ the computer in classrooms. This domestication of ICT is still evident today, with studies into classroom practice finding that teachers are still appropriating ICT as supplementary

or as an augmentation to existing practices (Ertmer et al. 2012; Prestridge 2012, 2016, 2017). An outcome of effective professional engagement is for teachers to ‘re’shape, ‘re’tthink, and ‘re’conceive ICT-infused pedagogies that effectively impact student learning.

Professional development and professional learning will be explored in the first section of this chapter to provide foundational understandings of the driving force or purpose to a professional activity. The difference between professional development and professional learning will be examined as these terms are often used interchangeably and that can affect the assumptions that drive and shape teachers’ engagement in these professional endeavors. Building on this in the second section of this chapter, we discuss the various approaches to professional learning with a theoretical analysis of teacher collaboration, teacher teams, communities of practice (CoPs), and broader social networks. These modes of professional engagement and interaction may be manifested at local sites or via online media and contribute significantly to supporting teachers as the ‘*deliverer*’ of educational reform.

Foundational Understandings About Professional Development and Professional Learning

When teachers are involved in trialing iPads in their classroom, would it be called professional development or professional learning? When teachers are involved in training on new software or following a hashtag on Twitter[®], is it professional development or professional learning? In educational theory, policy, and curriculum documentation, these terms are interchangeable. To help us understand the difference, if any, clarification of these terms is required as both have roles in the context of enabling teachers to improve their professional practice that positively influences student learning.

Teacher professional development has been defined as “activities that develop an individual’s skills, knowledge, expertise and other characteristics as a teacher” (OECD 2009, p. 49), which encapsulates most school-based staff development, in-service, and training events educators have come to associate historically with traditional structured professional development. This definition has been perpetuated over time and is still closely linked with a top-down training model of in-service based on the assumption that “teachers need direct instruction about how to improve their skills and master new strategies” (Lieberman and Miller 2014, p. 7). These and various other authors critique such assumptions that professional development is ‘*done*’ to teachers (Little 1993, 1999; McLaughlin 1994). Little, in her early work in the 1990s on the role of professional development in educational reform, proposed that the validity of professional development should be evident in its capacity to equip teachers to act as shapers, promoters, and well-informed critics of reform. Rather than being ‘*done*’ to teachers, professional development positions teachers as pedagogical experts who engage in the pursuit of genuine problems over time with a broader professional community that affects change in beliefs, attitudes, and

practice. The longstanding dissonance of professional development being ‘done’ to teachers compared to teachers ‘doing’ or driving their learning remains.

Professional learning, on the other hand, is more self-directed based on professional needs or interests. It has been explained as learning that is not formally planned or provided as part of the school strategic direction but considered as part of the serendipitous or natural study work that teachers undertake daily in their classrooms (Day and Sachs 2004). More so, it is considered to involve changes in a teacher’s capacity for practice associated with shifts in professional knowledge, attitudes, beliefs, and/or mindsets. These types of attributes are more complex barriers to the integration of ICT (Ertmer 2005) than barriers such as hardware or access, and have been found to be much more difficult to shift but have greater potential for enabling effective appropriation of ICT (Prestridge 2017).

Accordingly, then, professional learning orientates an internalized goal-centric model of learning that Raphael et al. (2014) explain as “ownership over compliance, conversation over transmission, deep understanding over enacting rules and routines, and goal-directed activity over content coverage” (p. 147). Essentially, professional learning is a ‘*growth in practice*’ model that values active engagement, teacher voice, creation and collaboration, inquiry and reflection. This type of learning can occur through professional learning communities within and beyond schools, through teachers’ personal networks, or organized special interest groups that exist in local school communities or online. This will be explored further in section “[Approaches to Professional Learning](#)” of this chapter.

One nuance associated with professional learning that differentiates it from professional development is in what Raphael et al. (2014) alluded to in their explanation, that is, “goal-directed activity over content coverage.” In traditional professional development, a program of activity is consumed by teachers with expectations that new knowledge is gained and therefore transmitted by the teacher to ‘better’ or ‘more informed’ classroom practice. This would be considered by Raphael et al. as content coverage. Whereas, with respect to professional learning, the focus for what is considered ‘learning’ moves from product to process. This shift has been conceptualized by Evans (2014) as encompassing behavioral development – processual, procedural, productive, and competential change; attitudinal development – perceptual, evaluative, and motivational change; and intellectual development – epistemological, rationalistic; comprehensive and analytical change. These processes as goal-directed activity direct the outcome of professional learning as teachers becoming conscious of their pedagogical changes with the development of professional learning capabilities. Self-realization and learner autonomy have been identified as educational outcomes of online professional engagement (Prestridge and Tondeur 2015). Finally, some of the key findings of professional learning indicate that it is a messy unpredictable process that can be an unconscious incidental event (Smylie 1995), unanticipated through social activity (Adger et al. 2004), implicit (Eraut 2007), contributing to making conscious ‘knowledge-of-practice’ (Cochran-Smith and Lytle 2001), but usually situated (Hoekstra et al. 2007) and more selective and self-determined for teachers in a later career stage (Cameron et al. 2013).

What does this mean for ICT integration? Which is the better approach to enable teachers to transform their pedagogical practice with ICT? If we understand professional development as a series of activities for new knowledge about a tool or teaching practice that is more likely to be externally organized and professional learning to be about the process of engagement internally driven for self-actualization and learner autonomy to inform practice, then which concept should be foregrounded? Drawing from the literature mentioned here, it is clear that there are nuances, synergies, and convergences of features of each approach that makes it difficult to suggest a more preferred or more valuable option other than drawing on both professional development and professional learning elements that are relevant to the given purpose and context. However, in saying this, we believe that the teacher needs to be the driver, the center of any professional experience rather than the content or the ICT; that the learning process, the metacognitive gain and shift in mindset, is more important than gains in ICT skill competency or knowledge; and that learning takes place as part of a community where the contributions of the teachers are the currency for content rather than the teachers being the passive recipients of knowledge. In describing this, philosophically, professional learning precedes professional development in design.

The following section will explore approaches to professional learning that identify features that could be used to design effective engagement opportunities for teachers as drivers and critical participants in development activities for ICT integration. Informing understandings about teachers working collaboratively, teaching teams, communities of practice, and social networks will be examined.

Approaches to Professional Learning

Communities of practice, teaching communities, teacher teams, and learning communities are terms that have been used interchangeably within the literature. Each term has been used to describe a type of social structure used by educators to collaborate to improve their practice. Communities of practice have been defined as a self-selected purposeful social structure whereby educators regularly come together to work for the collective benefit of students (Lave and Wenger 1991). The term was conceptualized through a reexamination of learning theories that argued that much of an individual's learning is a result of our participation in social interactions. Communities of practice are designed to capitalize on that premise. DuFour (2014) argued that professional learning communities have two broad purposes: (a) to improve the skills and knowledge of educators through social interaction and professional dialogue, and (b) improve the learning outcomes of students. Much of the work of these two types of collaborative groups is accomplished through action research cycles of investigation of shared practice and ongoing learning. As such Communities of practices and professional learning communities are similarly structured and are closely aligned in their overarching goals.

Teacher teams can be defined as two or more teachers working collaboratively and taking responsibility for teaching the major part of the instruction for the same group of students. Team practices can include all or some of a range of activities including planning, teaching, resource sharing, and assessing (Main 2012). Thus, these professional interactions also initiate and provide professional learning opportunities as teachers learn from collaborating with others and that learning is ongoing through active engagement in improved practice (Voogt et al. 2016).

For professional learning to be effective, it must be relevant, collaborative, and future focused, and encourage teachers and leaders to reflect on, question, and continuously improve their practice (Australian Institute for Teaching and School Leadership [AITSL] 2012). Working collaboratively can be argued to be a very effective form of professional learning for teachers as it is embedded within the context of a teacher's own classroom, is conducted over time, and is positioned where they can receive feedback and reflect through an iterative cycle of planning, practice, and reflection. These elements have been designed in professional development activities that support teachers to become conscious of their ICT beliefs and practices (Prestridge 2013). With education systems now recognizing the wide range of benefits that can be realized by purposely having teachers work together, greater opportunities are being afforded for teachers to work together rather than in isolation. The benefits of teachers collaborating that align with professional learning include early career teachers learning from more experienced teachers (Westheimer 2008), increased professional dialogue that supports innovation and new ideas (Meirink et al. 2010), and the broadening of teaching strategies (Shiple 2009). Thus, when working collaboratively, either face-to-face or online, teachers have reported a wide range of professional and personal benefits (see, for example, meta-analysis by Blitz 2013, p. 6). Collaborative activities form a basis of professional development models and structures. The benefits of working collaboratively as well as how different formal structures of teacher collaboration, both face-to-face and online, are operationalized will now be discussed.

Teacher Teams

Teacher teams have been introduced in schools across the world as part of school improvement initiatives and school reform efforts. Recognizing the potential of teachers working together has resulted in a significant amount of research which has attempted to understand how effective teams function (see, for example, meta-analysis by Vangrieken et al. 2015). The size, configuration, and practices of teaching teams vary widely. Each team is unique and must accommodate differences among team members (i.e., levels and types of expertise, personalities, understandings of team practices), students (i.e., age, year level, class configurations), physical layout of classrooms, and the school program under which the team will be operating (i.e., interdisciplinary team or interdisciplinary curriculum, primary school, middle school, or senior school). These differences result in teaching teams and team practices looking very different across year levels, within year levels, and from

setting to setting across schools. However, there are also several commonalities that can be identified in any team's development. Key to effective collaborative practices is understanding the characteristics and tasks associated with each stage of the team's development.

Aligning with the seminal work of Bruce Tuckman (1965) around the life cycle of business teams, teaching teams have also been shown to go through a life cycle with a beginning, middle, and an end. Tuckman's theory of small group development outlined four key stages, namely, forming, storming, norming, and performing. There are a number of key tasks that need to be undertaken at each stage of the teams' life cycle for the team to move forward positively. First, in the forming stage, the main tasks are to establish the procedures that will govern the team such as its goals, individual member's roles, agreed upon rules and to set common expectations that will guide the team. Some of the most common reasons teams fail are disorganisation, unclear or conflicting goals and expectations, competing commitments (time management), lack of motivation, and conflict (Main 2012). The storming stage is an essential part of the team's life cycle where team members begin to challenge ideas and reassess the team's goals and expectations. During this stage, the team needs to develop a plan as to how the team will be able to achieve its goals which often requires reestablishing team rules and expectations. It is also critical at this stage for team members to put into place effective conflict management strategies that will ensure that they are able to manage conflict in a positive way and build trust within the team. The norming stage is where the focus has moved from the individual to uniting as a team and getting the job done. Team members begin to feel a sense of belonging and a stronger commitment to the team as trust builds and progress is made. The final stage, performing, is achieved when the team is working cohesively and there is a balance between achieving the team's goals and maintaining and building relationships between team members. Tuckman's theory has proven to have transferability across disciplines and, although teams do not necessarily progress through these stages in a sequential pattern, there are characteristics and tasks associated with each stage. As a team progresses through its life cycle, team members must manage three different processes simultaneously, namely, task processes (the job to be done), team processes (how the team functions), and relationship processes (how team members get along with each other).

Understanding the reciprocal dependency between team processes has increasingly been recognized as being critical to developing theoretical models of team effectiveness (Nicolaidis et al. 2014). For team members to be able to work together, there needs to be a simultaneous balance between using team processes (e.g., appointing a leader, setting regular meetings, assigning specific roles, agreed team rule) to complete the task (e.g., knowing how to plan, teach, and assess a unit; complete a special project) and maintaining the relationships (Main 2012, 2017).

The effectiveness of teams is measured by more than its productivity (task completion) or performance (team working together). It also involves the development of each individual's self-efficacy and personal satisfaction with their work (Main 2012). The professional learning that occurs through working in teams supports the development of one's sense of efficacy as well as enhancing their

commitment to the team. This positive cycle of influence creates a sustainable pattern of self- and team improvement through nurturing shifts in practice (Butler and Schnellert 2012). In their analysis of studies involving curriculum design teams, Voogt et al. (2016) found that where teachers' worked collaboratively and where their professional learning outcomes were focused on pedagogical content knowledge and design knowledge and skills as well as being linked to the curriculum, it led to "an improved quality of teachers' knowledge and skills (. . .) and the quality of the curriculum design process" (p. 136). They further noted that teacher self-efficacy was related to the teachers developing ownership in the curriculum change process and that this sense of ownership was a critical element for successful implementation of any change.

Teacher teams or curriculum design teams that are school, district, or wider reaching through online pathways can involve teachers in codesigning units of work which effectively use ICT. These can be a part of structured professional development or opportunistic, informal interest-based professional learning activities, for example, Teach Meets on Coding. A Teach Meet can be organized by teachers themselves within their school districts or by a professional organization such as a Department of Education or Computer Association. At these meetings, teachers share good practice on nominated topics and teachers who are interested attend. These face-to-face meetings can be organized through an online community where conversations can occur before and after, in ways that expand teachers' professional networks and their pedagogical understanding of ICT. The Teach Meet, if local, can give teachers the opportunity to meet face-to-face. In the fully online space, teams of teachers from different schools can work collaboratively to analyze lesson plans and video recordings of classroom teaching through an online platform, as found in Zhang, Liu, Chen, Wang, and Huang's study (2017). Using an online platform enabled the teachers in the study to collaborate across time and place, and the process of providing feedback and suggestions for improvement on lesson plans and delivery was considered by the teachers beneficial for linking theory to practice and exchanging information. Lin et al. (2008) researched virtual teacher teams who were collaborating on developing ICT lesson plans identifying the factors that affect the process of knowledge sharing and creation online, such as teachers taking on roles of task performers or idea providers. Teachers as active participants in the curriculum design process are driving their professional learning and are positioned as the expert within educational reform.

Communities of Practice

In the late 1980s and early 1990s, social anthropologists began to recognize the significant learning that comes from our participation in social life and personal interactions (Lave and Wenger 1991). Through a process of reconceptualizing the then current learning theories, the term "Community of Practice" was developed, as noted previously. A Community of Practice (CoP) was defined as a group of people who intentionally interact regularly with each other around a common concern or a

passion and work together to learn how to do it better, that is, how to improve their practice (Lave and Wenger 1991). The intent behind the term CoP is that the learning is embedded within a shared practice rather than just a shared learning experience. Thus, in the case of a CoP in an educational setting, it can be viewed as a form of ongoing professional learning with the process of learning setting its members on a positive trajectory for improving practice. Thus, in a CoP, a group of teachers work together to improve both their own performance and that of their colleagues in their day-to-day practice (Farnsworth et al. 2016).

Within a CoP, teachers work together and can collaborate on a range of curriculum and planning tasks and can also engage in co-teaching and peer observation to facilitate performance monitoring. Making these practices known breaks down professional barriers and establishes a sense of collaboration and community between educators within the setting (Ranmuthugala et al. 2011). Working in this way acknowledges the value of teachers as professionals and helps to further develop the established pedagogy and a vision to improve practice. As such, a CoP seeks to locate the learning in the process of co-participation (building social capital) and not just within individuals. Hence, collaborative practice can become the main method of professional development for educators improving practice and “learning” and for making educators who are working together accountable to each other (Main 2012).

Communities of practice or professional learning communities have been promoted for over a decade as an effective form of professional learning (DuFour 2014). In more recent times, the Internet and mobile communication technologies have extended and changed the construct of CoPs as well as the way that they operate within a school context, district, or beyond. With increased opportunities and greater flexibility of time and space, CoPs are extending to include not just teachers within a school but also drawing on outside expertise and developing hybrid CoPs that use a combination of face-to-face and online interactions. Blitz (2013) conducted a comparative review of face-to-face and online CoPs (professional learning teams) and noted that online communities could achieve many of the same beneficial outcomes as face-to-face CoPs (see, for example, Zhang et al. 2017). Those working in the online environment were also found to be more self-reflective; however, the professional learning was shown to be the same regardless of the model of CoP (Blitz 2013).

The success of online CoPs is reliant on the members of the community voluntarily sharing their knowledge and experience. Knowledge giving and receiving as social and cognitive practices in online CoPs are dependent upon teacher’s interpersonal connections and proactive self-regulation in these spaces (Tseng and Kuo 2014). In practice, the lack of engagement by members has been seen as a significant issue (Macdonald and Poniatowska 2011) and, as experienced in face-to-face CoPs, the presence of the “social loafer” syndrome can disrupt the flow and effectiveness and commitment of all members to the group. However, to overcome this, Matzat (2013) noted that a high level of embeddedness (i.e., the degree of off-line interaction between members of an online community) can promote commitment to the group and reduce the tendency for social loafing. Further, in this large-scale,

comparative study, Matzat (2013) found that “blended communities,” where there was a mix of off-line interactions that complemented the online community, “deliver more benefits than purely virtual communities” (p. 49). However, in one study, where only 7% of the members met and networked in an informal off-line meeting, the benefits including increased communication, more open sharing of materials, and an increase in trust between members were realized. Thus, it is possible to increase the effectiveness of an online CoP by increasing the embeddedness of the membership through strategies such as recruiting members within an area where some may already know each other or by providing opportunities for face-to-face meetings through conferences or other forms of professional development.

Social Networking

Educators’ professional learning landscape has shifted greatly with web-based technologies offering the opportunities for on-demand, 24/7 learning delivered to the palm of the *teacher’s* hand (Simonson et al. 2011). With the ease of use of Web 2.0 tools, the explosion of apps, and the growth of social networking, there has been a move by teachers to self-action their professional learning opportunities online (Prestridge and Tondeur 2015; Vu et al. 2014). Issues associated with isolation and cost, which have previously precluded teacher engagement (Cameron et al. 2013), are easily overcome within these virtual spaces. Social networking sites such as Facebook[®], Instagram[®], Pinterest[®], TeacherspayTeachers[®], Twitter[®], and Google Plus[®] provide the more common online places to communicate and contribute to a current worldwide topic. Additionally, professional societies use online environments that have the capability to group teachers, provide a space to build a personal profile, discuss and make a repository of resources which are also places teachers are networking.

The move from school-based training to online course work to self-generating on-demand learning shifts the approach from professional development with content delivery to professional learning through the primary practice of actioning teacher’s content generation, such that teachers themselves are generating the content through collaboration and independent inquiry. Simply, teachers use their classrooms as sites for investigation from which they explore issues, ideas, problems, questions that arise and share these out through social networks online. In these networks, teachers discuss, extend ideas, make suggestions, and work together. As such, inquiry-based professional learning is grounded in teachers’ intentional investigation and reflection on their own practice in light of other teachers’ practices, associated theories, knowledge, and the larger educational, social, and political contexts. Online social networks can provide both the space/place and tools to actively communicate, reflect upon, and collaborate with other like-minded teachers as part of facilitated professional development programs, as mentioned above in the online CoP created within a specific online software platform (Zang et al. 2017); or using more common media such as Facebook (Goodyear et al. 2014). These spaces can also support the more organic professional learning activities where teachers are moving in and out of

online social media based on their own timely needs and interests (Sumuer et al. 2014).

Research in this area is currently limited but it is an area that provides an abundance of opportunity as teachers themselves are currently exploring how to leverage social networks for their own professional learning. In this field, studies focus on varying elements such as Webinars as opportunities for authentic dialogue which network teachers worldwide (Albers et al. 2013); models of professional development online such as programs designed based on teacher-generated content and requirements for facilitated engagement (Prestridge 2016); the difference between the uptake of formal and informal professional learning activities (Petras et al. 2012); the alignment between networking and the conceptualization of learning-as-social participation (Niesz 2007); and ethical issues in social networks (Foulger et al. 2009). What is interesting and needs more research to understand will be the ways and whys that direct how teachers engage in these social networks, such as moving in/out and serendipitously between social media; the reasons for inactive, lurker activity compared to active participation; consumer culture verses contributing culture where teachers prefer to take ideas and resources rather than contribute their own; how an online presence or teacher profiling is created and contributes to a sense of connectedness and presence; the list goes on. What is evident in this field is that professional development in these kinds of social media-supported spaces requires the philosophical approach described earlier as professional learning. Thus, professional development through social media needs to be designed so that activities are self-directed by teachers based on internalized goals to fulfil their needs and interests as part of, and in alignment with, the greater grouping or community.

Final Words

It has been long established that technology integration in K-12 classrooms is usually overly teacher-centered and tends to replicate traditional pedagogies that supplement student learning (Al-Zaidiyeen et al. 2010; Ertmer and Ottenbreit-Leftwich 2013; Prestridge 2012, 2017; Tsai and Chai 2012). These classroom practices have been historically replicated in teacher professional development models that provide training on ICTs rather than pedagogical reform. It is the ‘chicken before the egg’ syndrome: ICT practices are being modelled in professional development approaches. Moving toward the use of ICT to support students’ engagement in higher-order thinking means moving toward models of teacher professional development that advocate for and embrace critical thinking paradigms. Whether it be considered professional development or professional learning that involves teachers working in teams, through CoPs, blended or solely face-to-face or by using social media, better professional outcomes are enabled when teachers collaborate. Teachers collaborating and teachers as drivers of their professional experiences has been the resounding message of this chapter.

In closing, we live in an ever-changing world. This world is getting smaller with the advent of technologies. Teachers are using ICT both as instructional devices and

to support students to use them as learning devices. Teachers worldwide can (while some already are) share, collaborate, challenge, and create new knowledge and understandings that influence what they do with their students in classrooms. However, for this to be the status quo, some things need to change. Fundamental shifts need to be made with regard to teachers as pedagogical experts influencing their professional learning as active members of a larger professional culture that ensures the continual renewal of self-understanding and a requirement for contribution to the pool of knowledge moving forward. Teachers are the deliverers of educational reform, as it is “education” that they co-construct that is most powerful.

Abstract

The relationship between research and practice presents challenges across the field of education including in the use of Information and Communication Technology (ICT). Educators in the field often see research as being divorced from the reality of their daily practice. Teacher inquiry and design-based research offer opportunities to engage practitioners in research by making more direct links to their own practice. This chapter briefly introduces the broad range of opportunities and hurdles posed by technology integration in K-12 education, and then describes three crucial dimensions that influence the way educators perceive

and handle technology use over time; these relate to teacher will, skill, and surrounding infrastructure. Thereafter, ways in which research-practice interactions might contribute to developing these dimensions are discussed, with specific attention to two kinds of interactions: teacher inquiry and design-based research. In addition to offering examples throughout the chapter, attention is also given to the fact that these two approaches used together can have productive synergies. The chapter concludes by pointing to new developments that hold potential implications for future work related to technology integration supported by teacher inquiry, or design-based research, or both.

Introduction

Technology Integration: Opportunities and Hurdles

Advances in technology provide new opportunities for improving educational practice, but making effective use of them presents many challenges to K-12 teachers. For example, Information and Communication Technology (ICT) has the potential to help educators better meet the needs of diverse learners through customization, differentiation, and (more equitable) access to information. Additionally, ICT can enhance teaching and learning experiences by making the learning of abstract concepts more concrete through visualizations or simulations or by combining technological media with other modalities such as hands-on work (McElhaney et al. 2015). Finally, ICT can render some aspects of teaching and learning more efficient by allowing re-creation of aspects of the real world that may be too difficult or time consuming to implement in conventional classrooms (e.g., rerunning a video takes less time than recreating a demonstration) or by facilitating learner tasks (e.g., by providing automated feedback or smart scaffolds).

As with most educational media over the last 100 years, realizing the added value of ICT, as opposed to mere substitution of analog resources by digital ones, is not easy (Christensen and Knezek 2002). This is due, in part, to the rapid pace of technological advances. Continuous developments in learning technologies make it difficult for educators to stay abreast of options and make informed choices, since options are constantly changing (McKenney 2013). It also means that investments into ICT and ICT use are regularly under threat of becoming obsolete, since operating systems and hardware requirements are changing so quickly. Further, harnessing the potential of ICT within the constraints of daily classroom practice requires understanding of cultural values that affect ICT use (Srite and Karahanna 2006). In fact, establishing norms regarding socially acceptable use of technology constitutes a struggle which plagues our offices, restaurants, and living rooms, just as much as it does our classrooms. Finally, there is a huge gap between what is technically possible and

what school ICT infrastructures can handle. Technical woes faced by teachers range widely from firewall barriers, to bandwidth limitations, to outdated hardware which lacks the processing power to handle large files or new media (Zhao et al. 2002).

The Importance of Will, Skill, and Infrastructure

Despite newspaper headlines and profits made through booming industries, the challenges of technology integration hurdles are not likely to be swept away by radical innovation, since it has long been recognized that radical change is not feasible in education (Berliner 2002). Rather, as educators learn and develop while on-the-job, they make incremental progress toward productive use of ICT. Incremental innovation targeted at what teachers and schools can realistically implement with sustainable amounts of guidance or collaboration has been referred to as innovation within the zone of proximal implementation (McKenney 2013). Building on previous work (Knezek et al. 2003; Knezek and Christensen 2016; McKenney 2017), we examine three crucial dimensions that influence the way educators perceive and handle innovation over time: will, skill, and infrastructure. Here we devote specific attention to implications for technology integration in K-12 schools.

Each of the will, skill, and infrastructure dimensions is necessary for productive technology integration in schools. For the purposes of this chapter, the term *will* broadly encompasses affective aspects that have been shown to influence how teachers perceive and handle technology use over time. These aspects include teacher self-efficacy (Lee and Tsai 2010) and confidence (Ertmer and Ottenbreit-Leftwich 2010), willingness (Baylor and Ritchie 2002) and commitment (Hennessy et al. 2005), as well as attitudes and beliefs (Ertmer et al. 2014; Ottenbreit-Leftwich et al. 2010; Tondeur et al. 2017). This dimension is crucial for technology integration because it is the gateway through which teachers consider the relationship between their own practices and the affordances of technology, and it typically mediates their professional experimentation. The term *skill* refers to teacher professional competencies including the knowledge that underpins them. These professional competencies include pedagogical practices and routines as well as the technological pedagogical content knowledge (Mishra and Koehler 2006) and classroom management and orchestration (Dillenbourg 2013), which enable the enactment of those techniques. Finally, the term *infrastructure* refers to the human and material resources that are known to foster or inhibit teacher technology integration efforts (Zhao et al. 2002). These resources include the ICT hardware and software present in the learning environment, the curricula, books, and other (digital or analog) educational resources (Lim et al. 2013), as well as the human resources readily available in terms of leadership, capacity, and support (Staples et al. 2005). This dimension provides regularization and sustainability; without it, only the zealous few are likely to initiate or sustain technology integration. Successful technology integration in schools attends to the will, skill, and infrastructure dimensions collectively.

It should be noted that these three dimensions influence and are influenced by the others. For example, frustrations with hardware (infrastructure) can have negative

influence on attitude (will), or observation of learning gain based on classroom use (skill) can have positive influence on beliefs (will). While each plays a crucial role in how educators perceive and handle technology use over time, it may not be feasible to invest in comprehensively developing all dimensions simultaneously. Rather, incremental investment that also attends to connections between these dimensions may be more realistic.

How Can Research-Practice Interactions Help?

While there are many ways for practitioners to develop the will, skill, and infrastructure needed for technology integration, interactions around classroom research can be particularly fruitful in this regard. It should be noted that research-practice interactions influence the processes of research and practice as well as the roles and expertise of researchers and practitioners. In line with the definition of Broekkamp and van Hout-Wolters (2007), the *process of research* in this instance is regarded as the systematic development of knowledge of education and *the process of practice* as the activity of those that are directly involved in teaching in educational institutions, determination of local and central educational policies, and development of educational tools. Accordingly, the term *practitioners* refers to teachers, school leaders, educational consultants, instructional coaches, or those who design curriculum, assessments, or professional development. Finally, the term *researchers* indicates those who, informed by state-of-the-art scholarship in the field, conduct scientific investigation with the goal of generating new knowledge to inform the work of others. We note that practitioners may engage in research processes, as is the case with teachers conducting inquiry into their own practice. Further, when practitioners and researchers interact, expertise can be exchanged to the mutual benefit of each.

There are many forms of researcher-practitioner interactions. These interactions can range from indirect relationships, which are typically focused on the extraction of data for researcher-defined purposes, to clinical ones in which the researchers provide services to meet practitioner needs, to more mutualistic ones, in which practitioners and researchers collaboratively set the agenda (Wagner 1997). This last type of interaction can be particularly beneficial for developing the will, skill, and infrastructure to support technology integration in schools, as it facilitates the exchange of expertise. Mutualistic interactions can benefit practitioners by increasing awareness of important advances in educational technology as well as of relevant scholarship, or by creating opportunities to develop and apply new knowledge (Coburn and Penuel 2016). Benefits to researchers are also present, since serving practice is a fundamental goal and collaboration enables that, especially because (i) studies situated in practice bring with them the ecological validity that renders the derived knowledge more useful (McKenney and Reeves 2012) and (ii) regular interactions with practitioners help keep researchers aware of, and sensitized to, the realities and concerns of those regularly working in classrooms (McKenney 2016). The following section discusses two forms of mutualistic research-practice

interactions and describes how they can be productive in developing the will, skill, or infrastructure for technology integration in schools.

Mutualistic Research-Practice Interactions

Teacher Inquiry

Teacher Inquiry Characteristics

Teacher inquiry can be generally defined as the systematic and intentional study of educational practice carried out by teachers in their own classrooms (Cochran-Smith and Lytle 1993). It is used as an umbrella term to refer to diverse forms of educational research where teachers play a central role, such as action research (e.g., Kemmis and Wilkinson 1998), teacher research (e.g., Cochran-Smith and Lytle 2009), self-study research (e.g., Loughran 2004), communities of inquiry (e.g., Cassidy et al. 2008), and lesson study (e.g., Lewis et al. 2006) among others.

Despite the diversity of forms and underlying epistemological principles, most approaches to teacher inquiry share several key features (cf. Cochran-Smith and Lytle 2009). First, teachers are viewed as knowers and agents of educational change, rather than as mere consumers of research produced by others (Cochran-Smith and Lytle 1999). Second, and in line with the expanded view of teachers' roles, teachers take on a researcher role, thereby becoming both subjects and agents of inquiry. Third, because teachers conduct research in the context of their own classrooms, problems experienced in their daily work become the focus of study. Fourth, the knowledge generated by teacher inquiry is primarily intended for application and use within the local context in which it is developed; however, the unique insights generated by teacher inquiry may also inform practice and policy beyond local contexts (Cochran-Smith and Lytle 1993). Finally, teacher inquiry is a collaborative enterprise, typically involving partnerships between practitioners and university researchers (Somekh 2006).

Research-Practice Interactions in Teacher Inquiry: Affordances and Challenges

Teacher inquiry can potentially make a strong contribution to create closer ties between educational research and practice. Next, we discuss how mutualistic research-practice interactions can be facilitated by teacher inquiry, examining both the affordances and challenges of this approach.

Whereas the duration, complexity, and rigor of the research process may differ, teacher inquiry generally encompasses iterative cycles consisting of the following phases: (i) identifying a problem specific to the local context of participating teachers; (ii) planning and implementing instructional solutions; and (iii) using evidence to drive reflection, analysis, and next steps (Ermeling 2010; Kemmis and Wilkinson 1998). It is through active teacher engagement in these phases of inquiry, in close collaboration with university researchers, that research-practice interactions materialize, and that teacher inquiry can provide a context for sustained

collaboration where the perspectives and expertise of both teachers and academics are brought to bear (Pareja Roblin et al. 2014).

Besides facilitating research-practice interactions, teacher inquiry has been shown to foster teacher learning and the development of a critical stance (Cochran-Smith and Lytle 2009; Hagevik et al. 2012), thereby leading to meaningful changes in teachers' practice (Ermeling 2010). For this reason, teacher inquiry is often viewed as a powerful strategy for professional development (Zeichner and Nofke 2001), which is reflected in its growing adoption across various pre-service and in-service teacher education programs all over the world (e.g., Carter et al. 2016; Dickson 2011; Dobber et al. 2012).

Notwithstanding the opportunities that teacher inquiry offers to facilitate mutualistic research-practice interactions and to foster teacher learning, this form of educational research is not without challenges. One key challenge relates to the development of teachers' research competencies. Teachers are unlikely to have the time needed to develop full and robust understanding of multiple research methods (Berger et al. 2005). Another related challenge pertains to the dissemination of the knowledge generated by teacher inquiry. Although teacher inquiry can (potentially) further our understanding of teaching and learning, it is not always motivated by a need to develop knowledge that could be generalized beyond the local context (Cochran-Smith and Lytle 1993). In fact, research suggests that knowledge generated via teacher inquiry rarely moves beyond local contexts (Enthoven and de Bruijn 2010). Both challenges have motivated criticism about the legitimacy of teacher inquiry as a form of educational research (Zeichner and Nofke 2001). The current move toward Masters level degrees in teacher education across many European countries, together with the growing integration of teacher inquiry in the curriculum of teacher education programs, represents important steps forward in supporting the development of teachers' research competencies and recognizing their role in the generation and dissemination of public knowledge.

Teacher Inquiry Can Help Develop Will, Skill, or Infrastructure for Technology Integration

Mutualistic research-practice interactions featured in teacher inquiry can contribute to the *will*, *skill*, and *infrastructure* needed for productive technology integration in schools. More specifically, teacher inquiry can support the *will* for technology integration by facilitating changes in teachers' beliefs about technology and its relationship to the curriculum. For example, Dawson and Dana (2007) investigated the benefits of integrating teacher inquiry into technology-enhanced field-experiences to help prepare teachers for technology integration. As part of the requirements to fulfil a three-credit, graduate-level course on Educational Technology, prospective teachers engaged in inquiry to systematically study their experiences integrating technology in elementary classrooms. Each prospective teacher had to identify an inquiry question, develop a plan for data collection and analysis, and report findings and conclusions in a paper. A case study of one of the teachers engaged in this program revealed that teacher inquiry led to major conceptual shifts in this teacher's beliefs about teaching in general and teaching with technology in particular.

Teacher inquiry can also help to develop the necessary *skill* for technology integration by expanding teachers' knowledge about the educational uses of technology (Laurillard 2008), and by promoting experimentation with innovative pedagogies supported by technology (Dawson 2006; Saunders and Somekh 2009). The Pedagogies with E-Learning Resources (PELRS) project (Pearson and Somekh 2006; Saunders and Somekh 2009; Somekh and Saunders 2007) is one example of how teacher inquiry might contribute to advance teachers' knowledge for technology use. Led by Manchester Metropolitan University between 2003 and 2009, PELRS sought to develop the necessary knowledge base in schools for using technology to transform students' learning. This was accomplished through a partnership between university researchers, teachers, and school leaders. Teachers engaged in action research with the support of university researchers, playing a leading role in planning learning events, participating in the analysis and interpretation of data, and presenting their work in public fora (Somekh and Saunders 2007). Through teacher engagement in action research, PELRS supported the development of new pedagogical practices that unlocked the affordances that technology can offer for transforming students' learning experiences (Saunders and Somekh 2009). Moreover, PELRS contributed to create the *infrastructure* needed to support technology use through the development of pedagogic frameworks for ICT integration. Collaboratively developed by teacher-researchers and university researchers, these frameworks prompt new ways of thinking about the use of ICT to support teaching and learning.

Design-Based Research

Design-Based Research Characteristics

Design-based research (DBR) is a genre of inquiry in which the design of innovative solutions to problems in educational practice provides the context for scientific investigation, yielding results that can also inform the work of others (DBRC 2003; McKenney and Reeves 2012). The solutions developed through DBR can take various forms, including programs, processes, products, policies – or a combination of these. As with other studies, the scientific understanding derived from DBR may be used to describe, explain, predict, or manipulate educational phenomena.

Educational design research is theoretically oriented, interventionist, collaborative, responsively grounded, and iterative (McKenney and Reeves 2012; van den Akker et al. 2006). DBR is theoretically oriented because it uses existing theoretical insights to frame both research and development, and because it strives to contribute scientific understanding (i.e., produce knowledge that can be of value also outside the specific research setting). Because DBR explicitly aims to make a positive contribution to practice, it is interventionist. DBR requires multiple participants (especially researchers and practitioners) with varied expertise, and therefore is collaborative. The DBR process uses findings from one phase to inform subsequent ones, which makes it responsively grounded. Finally, because DBR anticipates and

involves multiple cycles of inquiry and action, it is iterative. Design-based research thus features research-practice interactions through their *processes* as well as the *roles and expertise* of those involved. Studies that additionally focus on *multiple stakeholders' perspectives*, develop theory related to *implementation*, and work to develop *capacity for sustaining change* are better characterized as design-based implementation research (Penuel et al. 2011).

Research-Practice Interactions in Design-Based Research

Design-based research can be conducted by professionals in research institutes (e.g., universities), educational settings (e.g., schools, training groups), and related institutes (e.g., ministries, industry). Practitioners are inherently involved in educational design research, most often in reactive roles, though sometimes as codesigners and occasionally as researchers (Long and Hall 2015). While rare, practitioners may also function as lead investigators in design studies (Swanwick et al. 2013). Given its aforementioned collaborative nature, interorganizational partnerships in DBR are quite common. The DBR process varies widely depending on the context, goals, stakeholders, and resources available but, in general, three phases are central to the enterprise: analysis and exploration; design and construction; and evaluation and reflection (Bannan-Ritland 2003; McKenney and Reeves 2012). Each DBR project shapes these phases differently but through them the dual outputs of an intervention (which gradually matures throughout the project) and scientific understanding are pursued.

During each phase (analysis and design, design and construction, evaluation and reflection), attention is given to implementation and spread. During earlier stages, implementation and spread are considered by studying the problems to be solved and their root causes, as well as exploring inspiring examples, organizational strengths, and budding opportunities that might contribute to a solution. As a solution begins to mature, practitioners and researchers often take on additional roles, for example, those of organizers, consultants, designers, and developers, in working toward solutions. Later stages of DBR feature (especially formative) evaluation, often conducted in the target setting, with the goal of improving the designed solution and optimizing it for implementation.

Due to its scope and complexity, educational design research presents a tremendous challenge (Anderson and Shattuck 2012; McKenney and Reeves 2013). This is because it requires substantial expertise and time. Researchers require access to, and fluency in, multiple areas of literature (e.g., educational innovation, research methods, and the topic of inquiry) as well as a diverse skill set (e.g., educational researcher, intervention designer, implementation facilitator) (McKenney 2016). Given the nature of the work involved, DBR tends to be long term, spanning months and years, rather than days and weeks (O'Neill 2016). For those not able to devote major portions of their time to the effort (e.g., due to teaching load), the task may be insurmountable. Yet, despite the challenges, studies are beginning to show that the potential benefits to both immediate practice and scientific understanding can be gained (Plomp and Nieveen 2014).

Design-Based Research Can Help Develop Will, Skill, or Infrastructure for Technology Integration

Powerful collaborations in multidisciplinary teams have been central to successful DBR studies that focused on technology integration, as the following three examples illustrate. Related to *will*, Kim et al. (2013) describe their multiyear project which aimed to improve the use of technology in poorly performing rural K-8 schools. Over the course of 4 years, teachers received (at their choice) technologies, professional development workshops, and technical and pedagogical assistance. In addition to developing understanding about support to teachers, the team also examined how and to what extent the following were related to each other: teachers' beliefs about the nature of knowledge and learning, their beliefs about effective ways of teaching, and their technology integration practices. The study revealed that teacher beliefs, among other factors, influenced their technology integration practices. While some researchers have found that behavioral change can precede changes in beliefs (Guskey 2002), Kim et al. (2013) conclude that changes in beliefs are prerequisites to changes in teacher behavior, that the provision of adequate supports in line with teacher beliefs could improve teacher levels of technology integration, and that this is consistent with other research.

Design-based research can also help develop skills for technology integration. For example, Kafyulilo et al. (2016) describe the design-based research embedded in the creation of a professional development arrangement (including workshops, collaborative design in teams, and cycles of lesson implementation-reflection-redesign) to develop technology integration *knowledge and skills* among science teachers in Tanzania. Different versions of the program were designed and tested to accommodate the differing needs of pre-service and in-service teachers. Based on insights gathered through iterations of design and testing the arrangement, the study produced design guidelines for developing pre- and in-service teachers' technology integration knowledge and skills, as well as empirically based recommendations for practice and policy (Kafyulilo 2013). In addition, teachers participating in this study were able to make science animations using PowerPoint and record videos to use in their teaching. Further, in an impact study conducted with both the pre-service and in-service teachers well after the program concluded, results showed that most pre-service teachers and some in-service teachers retained their technology-using practices (Kafyulilo 2013). Further, this study also connects the knowledge and skills to the surrounding human *infrastructure*. Specifically, it notes that the pre-service teachers felt recognized and supported by the ministry of education and school principals, while many in-service teachers received little recognition or support from management. Therefore, the Kafyulilo study also concludes that these factors are important catalysts for continued use of technology integration practices.

An example of design-based research related to the material *infrastructure* is the multiyear development of Quest Atlantis, a 3D multiplayer virtual environment that helps students construct scientific understanding. Across multiple publications, the design research involved in developing this tool has been described, focusing on

characteristics of the tool (Barab et al. 2005), the sociotechnical structures in which they are used (Barab et al. 2007), and an emerging theory of learning during use, referred to as transformational play (Barab et al. 2010).

On the Horizon

As shown in this chapter, teacher inquiry and design-based research offer vehicles for research-practice interactions that can support educators in technology integration, especially through contributions related to teacher will, skill, and surrounding infrastructure. To date, teacher inquiry may have emphasized more will and skill aspects, whereas design-based (implementation) research has seemed to demonstrate a stronger focus on developing the aspects described under infrastructure (McKenney and Reeves 2012; Penuel et al. 2011). Each genre of inquiry offers interaction through research-practice processes, as well as the potential for interactions between individuals, facilitating the exchange of expertise between researchers and practitioners.

Teacher inquiry and design-based research are each valuable in their own right, but recent trends show that, together, they can have productive synergies (Bannan-Ritland and Baek 2008). For example, McKenney and Mor (2015) offer guidelines for tools to support teachers in data-informed educational design, while Dawson et al. (2013) developed an online tool to support teacher action research for technology integration. The trend toward design-based research in which researchers and practitioners collaborate to develop will, skill, and infrastructure for teacher inquiry related to technology integration seems extremely promising. Other new developments that hold potential implications in this area include increased attention for research-practice partnerships (Coburn and Penuel 2016), teacher inquiry to support technology-rich formative assessment (Luckin et al. 2017; Mor et al. 2015), and the use of design-based (implementation) research at scale to offer equitable opportunities for teacher professional development in relation to technology integration (Clark-Wilson et al. 2015).

While no panacea exists, the approaches of teacher inquiry and design-based research offer much to educators wishing to realize the potential added value of ICT. They are especially powerful because they embrace, rather than control for, the dynamic and challenging realities of daily classroom practice. Because of this, familiarity with these approaches seems essential for all researchers and practitioners committed to improving technology integration in today's schools.

Abstract

Teachers' successful transformation to online and mobile teaching requires a reexamination of their traditional pedagogies, the content they teach, the student profiles, and the context of learning. Professional development that promotes teachers' pedagogical inquiry is a key to such transformation. Creating online and mobile spaces to enhance professional learning, recent models implement situated, on-demand, anytime, and customized learning opportunities for teachers. This chapter examines how professional development can be delivered

effectively by looking at strategies to support teachers' effective online and mobile teaching. The following models are illustrated in this chapter with their focus on teacher transformation and teacher change in professional development programs for online and mobile learning: Mentoring, professional learning communities, and design-based learning. Several recommendations are presented to enhance teacher professional development programs for mobile and online learning.

Keywords

Professional development · Mobile learning · Online learning · Pedagogical inquiry

Introduction

The rapid diffusion of technologies in society has created a need to transform the educational landscape (Johnson et al. 2016). Formal and informal education environments are increasingly adopting emerging technologies that encourage re-conceptualization of teaching and learning at all levels. Within the widespread adoption of web-based and mobile tools in society, educators are now looking for ways to provide more flexible learning opportunities to the learners in various contexts. Meanwhile, the advances in learning sciences research provide educators new tools and approaches to foster, sustain, transfer, and measure learning with mobile and online technologies (Bransford et al. 2004). It is now widely accepted that for a change to occur in online and mobile learning environments, teachers' ability to implement reformed practices should be improved (Dede et al. 2009; Kearney and Maher 2013). This effort requires the study of the ways to support teachers' transformation for online and mobile teaching, and the development of necessary evidence-based professional development programs.

Teachers experience changes in their pedagogies as they transition from traditional teaching to mobile and online teaching. Their successful transformation from face-to-face teaching to online and mobile teaching requires a reexamination of their traditional pedagogies, the content they teach, the student profiles, and the context of learning. For example, they need to know the affordances of online and mobile technologies to be able to design learning experiences using these platforms (Kearney and Maher 2013). Adopting student-centered approaches, teachers need to give learners more control in their actions (e.g., promoting learner reflections, self-directed learning) in online and mobile learning environments (Means et al. 2009). Most importantly, they need to hold positive attitudes and beliefs towards teaching in online and mobile learning environments. Professional development is key to successful transformation. While earlier forms of professional development focused heavily on stand-alone courses and workshops, recent research suggests creating online and mobile spaces to enhance teachers' professional learning (Prestridge and Tondeur 2015). Professional development programs that utilize the affordances of mobile and online platforms can enhance teachers' situated, on-demand, anytime,

and customized learning (Prestridge and Tondeur 2015). This chapter examines how such professional development can be delivered effectively by looking at strategies to support teachers' effective online and mobile teaching.

Supporting Teachers' Transformation for Online Teaching

The growing interest in online learning challenges educational institutions to rethink their cultural, academic, organizational, and pedagogical structures in adapting to a new culture of teaching and learning (Howell et al. 2004). While educators and organizations around the world are more involved in online learning, growth in teacher involvement and acceptance has been slow, accompanied by limited change in pedagogies (Natriello 2005). Research has identified several reasons why there is still limited understanding about fostering higher-order thinking in online classrooms. The most important reason is the tendency to carry traditional educational practices to the online environment (Kreber and Kanuka 2006). Teachers often rely on their traditional pedagogical approaches formed over the years of developing expertise in the face-to-face classrooms (Kreber and Kanuka 2006). Having little (if any) prior experience of teaching in online environments, teachers tend to transfer traditional approaches to these classrooms and continue ineffective approaches that are already present in traditional classrooms (Roy and Boboc 2016). Most importantly, when technology integration is present, it is still implemented at a low-level with teacher-centered practices rather than high-level use with student-centered activities, such as problem solving and inquiry-based learning (Ertmer 2005). Research calls for a need to shift from teacher-centered to learner-centered pedagogy in online learning environments as teachers coordinate and regulate students' active learning (Baran and Correia 2009). Professional development programs for online teaching should integrate models for student-centered pedagogies in online learning environments so that online teachers design and implement such pedagogies in their teaching.

Moving from face-to-face to an online teaching environment, teachers experience changes in the way they structure and plan their courses, organize course management, establish teacher presence, monitor student learning, and connect to their students (Baran et al. 2013). These changes require the development of unique online pedagogies for online teaching (Kreber and Kanuka 2006; Natriello 2005). Effective online teachers have common characteristics that guide the implementation of these pedagogies. They create the course content with their extensive knowledge base about the subject matter, design and structure the online courses carefully, work on knowing and understanding their students' profiles and needs, use measures to enhance student-student and student-teacher relationships, guide and scaffold student learning using online tools, evaluate students' learning and progress, and establish teacher presence using various tools (Baran et al. 2013). Effective online teachers have a more "extensive, complex, and flexible repertoire of concepts of teaching effectiveness, they hold more developed concepts of self-efficacy, they use wider range of criteria for self-evaluation, and they draw upon almost twice as many strategies for enhancing student learning" (Hativa et al. 2001, p. 700). Professional

development programs for online teachers should integrate these effective practices to teachers' learning and address teacher transformation as well as teachers' shifting roles in online and mobile learning environments.

Professional development approaches need to address teachers' transformational learning for effective online teaching, while empowering them, promoting their critical reflection, and integrating technology into pedagogical inquiry (Baran et al. 2011). Professional development approaches can integrate teacher collaboration, content creation, sharing, and networked learning into online teacher learning platforms (Prestridge 2016). Other models may include action research projects that teachers carry in online platforms where they investigate an online learning problem, reflect on it, and engage in constructive dialogue with their colleagues (Prestridge and Tondeur 2015). Teachers' learning activities can involve critical reflection on their examination of personal beliefs and assumptions towards online learning, and support programs can help teachers engage in a dialogue about solving problems and making decisions regarding the design and implementation of online courses. Because several actors play critical roles in online course design, professional development programs can connect instructional designers, administrators, and technology experts with online teachers and help sustain communities of practices around successful online teaching (Holmes and Kozlowski 2015).

Professional Development for Mobile Learning

Mobile technologies have become more pervasive, affordable, and available among a wide range of age groups (Traxler and Kukulska-Hulme 2016). Their affordances for learning have been widely acknowledged and include mobility, access, immediacy, situativity, ubiquity, convenience, and contextuality (Kearney et al. 2012; Kukulska-Hulme et al. 2009; Sharples et al. 2009). Mobile learning has the potential to transform students' learning across multiple physical, conceptual, and social spaces. Teacher support and training regarding its effective use plays a critical role in mobile tools' integration into today's learning environments. Teachers need training and support regarding the advantages, challenges, and exemplary practices of mobile learning to make informed decisions in their teaching settings (Kukulska-Hulme et al. 2009; Schuck et al. 2013).

The definitions of mobile learning include common characterizations such as portability, authenticity, contextuality, social interactivity, and personalization (Kearney et al. 2012; Sharples et al. 2009; Stanton and Ophoff 2013; Traxler 2007). These concepts can be integrated into teacher professional development programs to promote teachers' meaningful learning with mobile tools. For example, the portability feature would allow teachers to receive and send information from different places, rather than a fixed professional development location. Teacher professional development programs could also take advantage of the authenticity feature by supporting teachers' authentic learning across contexts. Real time teacher observation and reflection activities can be conducted with mobile tools' different features such as tagging, video recording, collecting, sharing, and processing multiple

forms of data (Çelik et al. 2018). Another feature, social interactivity, could help the formation of teacher networks and connect teachers with experts, mentors, peers, and their students. With advances in mobile tools' social features (e.g., social networking), teachers could engage in constructive and social learning processes (Traxler 2016). Finally, the personalization feature would help customize scaffolding based on teachers' learning paths (Klopfer et al. 2002). Teachers can control the pace and time of their learning and their learning activities can be tailored to their needs and environment with mobile devices' context-awareness features (Kearney et al. 2012).

Several strategies can be integrated into the professional development programs on mobile teaching, including: hands-on explorations of mobile technologies, developing mobile lesson plans, microteaching mobile lessons, enacting mobile lessons in classrooms, reflecting on mobile lessons, planning mobilized curriculum, and attending to communities of practice (e.g., Ekanayake and Wishart 2015; Mahruf et al. 2010). Professional development strategies can use mobile learning pedagogies to promote teacher collaboration and peer-feedback, allow reflection on teaching, help share classroom practice, and assess performance (Baran 2014). Teachers' understanding of the affordances of mobile learning can also be enhanced by modeling such pedagogies in professional development programs, helping teachers explore their content areas with mobile tools, connecting teachers with communities of practice through mobile tools, creating personalized learning experiences, integrating alternative assessment techniques to the professional development programs, and designing learning experiences using mobile tools for collaboration and teamwork (Baran 2014; Cushing 2011; Husbye and Elsener 2013; Kearney and Maher 2013; Kommers 2009; Shotsberger 2003).

Mobile tools' emerging affordances can transform teacher professional development practices with new features that provide mobility and learning across different contexts, experiences in simulated and augmented classroom environments, and connectivity to different communities and audiences (Fritschi and Wolf 2012). With more tech-savvy teachers entering teacher education programs, professional development programs can meet their learning needs by integrating these platforms into professional development environments and modeling good practices. For example, teachers can investigate the use of mobile devices for enhancing classroom practices. These practices include: connecting teachers with mentors and teacher educators via mobile tools to share feedback on their teaching (Cushing 2011), promoting their reflections through microblogging and e-journaling on mobile platforms (Schuck et al. 2013; Shotsberger 2003), providing real-time coaching (Kommers 2009), and implementing self and peer-assessment practices (Chen 2010). When teachers experience mobile tool integration in their professional development programs, they may begin to use such tools in their own teaching practices (Husbye and Elsener 2013). Such exemplary uses can enhance teachers' self-efficacy and attitudes towards integrating mobile learning pedagogies in their future classrooms (Burton et al. 2011; Price et al. 2014).

With a focus on mobility of learning, learner, and technology, Schuck et al. (2017) used the "third space" metaphor to illustrate learning across diverse contexts that is facilitated by mobile learning. The third space metaphor is useful in rethinking

teacher learning that happens in different dimensions, such as formal, informal, virtual, public, asynchronous, global, and local contexts. The emergence of new mobile features holds promise for examining contextualized, authentic, situated, personalized, and collaborative teacher learning environments (Burden and Kearney 2016). Professional learning communities, for example, can be formed via mobile learning platforms to immerse teachers in the pedagogical inquiry while sharing their stories with other group members, giving feedback to each other, sharing expertise, and evaluating teaching practices (Schuck et al. 2013). Such investigations of teacher learning and education would contribute to discussions on future teacher competencies and necessary conditions for teacher preparation. The effective design of professional development settings for mobile learning requires concentrated effort in meeting the challenges, such as limited support, technical difficulties, accessibility issues, limited experience, and lack of curricular connections. To date there is limited literature about strategies for teacher education programs designed specifically with mobile learning pedagogies and theoretical frameworks (Baran 2014). Recent research has emphasized the barriers and challenges teachers face while using mobile tools for teaching and learning (Burden and Hopkins 2017) and developed mobile learning scenarios for teacher education (Burden and Kearney 2016). Future research should investigate professional development models specifically designed for mobile learning.

Professional Development Strategies

Challenges were noted previously in this chapter regarding teachers' slow transformation of pedagogies with technologies in their classrooms such as lack of time, limited resources and technology infrastructure, and lack of support (Al-Senaidi et al. 2009; Xu and Meyer 2007). Yet, a range of professional development and support programs (e.g., workshops, stand-alone courses) implemented to meet these challenges have had limited impact on teachers' adoption of online and mobile technologies in their classrooms, because they failed to answer teachers' unique needs in their authentic contexts with overemphasis on teaching about technology (Koehler et al. 2004). Current trends favor adopting professional development models that address teachers' unique needs and goals and include peer-learning and learning by doing activities within learning communities (Ertmer 2005; Georgina and Hosford 2009). The following models will be illustrated in this chapter with their focus on teacher transformation and teacher change in professional development programs for online and mobile learning: mentoring, professional learning communities, and design-based learning.

Mentoring

Professional development programs need to target teachers' individual needs and provide them opportunities to reflect on their existing knowledge, concerns, and practices and immerse them in collaborative learning activities (Ng 2015). As a

possible solution, mentoring programs can be integrated into teacher learning practices to provide customized, contextualized, and timely solutions to teachers' needs regarding the transformation of their pedagogical practices with online and mobile technologies.

Mentoring has traditionally been considered as a relationship intended to develop the skill and knowledge of others and influence personal and organizational development (de Janasz and Sullivan 2004; Hansford et al. 2004). Mentoring programs aim to provide teachers with one-on-one working opportunities with a mentor to encourage their learning about, and practice of, technology integration. Mentoring approaches have paired students with faculty members, graduate students with online instructors, online faculty members with graduate students, and experienced faculty members with less experienced ones (Baran 2016, Gabriel and Kaufield 2008; Koehler et al. 2004; Larson 2009). The one-on-one working model between a mentor and a mentee revealed several benefits for the participating teachers including increased confidence in using technologies, transformed teaching practices, and enhanced learning communities (Chuang et al. 2003; Gabriel and Kaufield 2008). Academic, professional, pedagogical, and technical benefits were also noted for participating mentors (Baran 2016). Learning community, compatible match, rewards, sustainability, celebration of accomplishments, and technology support are considered as critical elements of technology mentoring programs (Thompson 2008).

Recent research has revealed strategies that are critical to the success of technology mentoring professional development programs: (a) determining needs, (b) exploring technologies' affordances and limitations, (c) scaffolding, (d) sharing feedback, (e) connecting technology, pedagogy, and content, and (f) evaluating outcomes (Baran 2016). Success factors included motivation, meeting challenges, the nature of the mentoring relationship, communication channels, and support (Baran 2016). Mentoring programs can support the adoption of online and mobile technologies into teacher practice by meeting the challenges of traditional professional development models that are disconnected from teachers' actual teaching practices. Considering teachers' needs for immediate support and help, professional development models may target learning new online and mobile technologies, implementing mobile and online pedagogies, sharing best practices, providing mentors to the teachers if needed, and supporting learning communities. Acknowledging the mutual learning process for both mentors and mentees, educational institutions can adopt mentoring programs that promote shared responsibility, mutual benefits, accountability, reciprocal learning, and shared vision that contribute to the success of mentoring experiences.

Professional Learning Communities

Teachers' technology adoption is a "complex, inherently social, developmental process" (Straub 2009, p. 641). Professional development programs should go beyond show-and-tell models and focus more on the inclusion of peer and community centered learning that is designed around shared expertise, ongoing dialogue, and

pedagogical problem solving in learning communities. Learning communities play critical roles in the adoption of mobile and online technologies. For example, research found that “collegial learning groups were strong enabling actors that contributed to experimentations with technology, cross-fertilization of ideas, problem solving and, continuing dialogues on the topic” (Samarawickrema and Stacey 2007, p. 325). Teachers who belong to both formal and organized social networks and collegial learning groups as well as informal groups adapt better to web-based teaching environments (Baran et al. 2013). Creating learning communities with a focus on peer-observation and peer-evaluation may extend and sustain the conversation regarding effective teaching in mobile and online learning environments (Rovai and Downey 2009). Professional learning communities may also help teachers get support on teaching methods and provide psychological and emotional support regarding the problems experienced with mobile and online teaching (Lee 2001).

Learning communities are critical to teachers’ adoption of online and mobile pedagogies in their classrooms as they negotiate practical issues while collaborating and reflecting on their individual work with other teachers and challenge assumptions regarding effective teaching with online and mobile technologies (Zellermayer and Margolin 2005). Teachers’ participation in learning communities can help them socially construct their knowledge through peer-observation, peer-evaluation, and informal networks (Samarawickrema and Stacey 2007). Professional development programs can also include collaborative working teams, communities of practice, group discussions, and collegial learning groups. Teacher support and training programs may immerse teachers into community of practice (CoP) environments or professional learning communities (PLC) to promote their conversation regarding the use of mobile and online learning in different contexts. These environments can help teachers share best practices, exemplary applications, challenges, and solutions. Mentor or support systems can also be integrated into these environments (Herro et al. 2013).

Teachers in online and mobile learning environments need to update their technological pedagogical knowledge constantly to adapt to the changing needs of learners. Professional learning communities designed around sharing innovative and best practices can help teachers follow recent developments in their field. The tools integrated into such environments can include online and mobile tools that support teachers’ collaboration and create knowledge networks around exemplary mobile and online teaching practices (Gunawardena et al. 2009). These tools may include wikis where teachers reflect on their methods, share feedback and professional thoughts, provide specific and immediate feedback to each other, and construct a professional identity while collaborating with other mobile and online teachers who share similar expertise (Albion 2008; Hutchison and Colwell 2012; Samarawickrema et al. 2010). Teachers’ professional learning should be sustained over a period of time (Guskey 2000). Social networking tools can support online and mobile teachers’ continuous learning giving them a space for sustained interaction. These networks may promote the way teachers share their stories and encourage them to initiate teamwork and collaboration with other teachers after the professional development programs.

Design-Based Learning

Design of classroom activities, learning experiences, and assessment strategies are common practices in teachers' professional lives. Design activities are used in teacher training programs as a way to actively involve teachers in examining the relationships between and among content, pedagogy, and technology (Koehler et al. 2004). Within professional development contexts, teachers explore solutions to online and mobile technology integration problems within design teams (e.g., Jang and Chen 2010; Koehler et al. 2007). Recent research has identified design-based learning principles that can be used in teacher education and professional development programs to facilitate teachers' understanding of technology integration in action (Baran and Uygun 2016). These principles included brainstorming of design ideas, design of technology-integrated artifacts, examination of design examples, engagement with theoretical knowledge, investigation of information and communication technology (ICT) tools, reflection on design experiences, applying design in authentic settings, and collaboration within design teams (Baran and Uygun 2016). Professional development programs may integrate such design activities into their models and encourage teachers' engagement within contextual, situated, and authentic learning design experiences regarding the use of mobile and online technologies in their unique contexts. Design-based learning activities give teachers active roles in redefining and solving problems, examining learners' needs, and exploring the affordances of mobile and online technologies.

When teachers are engaged in design-based learning activities, they present solutions to ill-structured educational situations within online and mobile learning environments. Working on authentic design challenges, teachers can explore the connections between their content, pedagogical approaches, and the affordances of mobile or online technologies. Teachers can work together and develop solutions through their interactions with other design team members. This kind of collaboration helps design team members engage in a joint discourse on effective mobile and online technology integration (Baran and Uygun 2016). Once teachers design these artifacts within teams, they may then apply their design in their authentic contexts and bring their teaching experiences back to the design conversation to participate in a collaborative group reflection process. Reflecting on their mobile and online learning design experiences, teachers can identify difficulties they encountered and conduct self- and peer-assessment of their own learning and development (Angeli and Valanides 2009; Mouza et al. 2014). Professional development programs can use design-based learning to promote teacher agency and dialogue as teachers explore the potentials of emerging pedagogies for mobile and online teaching.

Recommendations

Recent conceptualizations of teacher professional development focus more on the study of teacher learning from the situative perspective (Borko 2004; Cherrington 2017), which examines teacher learning in individual and social learning contexts

including teacher practice within classrooms, communities, and professional development courses and programs (Borko 2004). In this respect, four key elements are identified: “(a) The professional development program, (b) teachers as the learners in the system, (c) the facilitators who guide teacher learning, and the (d) professional development context” (Borko 2004, p. 4). Putting teacher change to the center, teacher professional development for online and mobile learning environments can include these elements to help teachers’ transformation for successful online and mobile teaching. A professional development model that focuses on teacher learning and new findings of the learning sciences would be effective in transforming teachers’ online and mobile teaching practices. Several recommendations are presented to enhance teacher professional development programs for mobile and online learning.

Prioritizing Teachers’ Individual Needs

The quality of online and mobile learning environments is strongly correlated with how the professional development approaches respond to teachers’ needs, interests, and beliefs about learning. These needs should be addressed from the orientation phase when teachers are prepared to teach in online and mobile learning environments until the implementation and evaluation phases when they are supported through various channels. Teachers need to be equipped with information about the institutional culture, policies and procedures, online and mobile student characteristics and needs, online and mobile pedagogies that they can employ in their particular teaching contexts, recognition methods for quality work, and ways to develop a sense of collegial spirit among the online and mobile teaching stakeholders (Rovai and Downey 2009). Prioritizing teachers’ individual needs and targeting professional development programs to their concerns, motivations, and contexts would enhance effective adoption of online and mobile technologies into learning environments.

Providing Support at the Teaching, Community, and Organizational Levels

Professional development models should “handle multiple personal aspects – cognitive, affective, and contextual” (Straub 2009, p. 642), as well as organizational aspects such as support at the teaching, community, and organizational levels (Baran and Correia 2014). Professional development models that consider support at these levels are critical to teachers’ acceptance of, and participation in, online and mobile learning environments. Successful teaching in online and mobile learning environments is considered as the result of the complex interplay between personal, pedagogical, contextual, and organizational factors within education institutions. Therefore, by recognizing the importance of supporting teachers for teaching at various levels (e.g., technical, pedagogical, organizational), a holistic professional development approach is recommended (Baran and Correia 2014). In the holistic approach, the relationships between the community, teachers, and the organization

would be considered and the support programs would follow an integrated structure to promote effective mobile and online teaching.

The support and recognition at the organization level were stated as the critical motivational factors of teachers' commitment, sustained interest, and participation in online teaching (Cook et al. 2009). When teachers see online and mobile learning as academically respected, rewarded, accessible, and flexible within their organizational culture, they will be more motivated and confident to teach within online and mobile learning environments. A positive organizational culture towards mobile and online learning would motivate and sustain teachers' participation.

Promoting Pedagogical Inquiry with Mobile and Online Technologies

Professional development programs that target successful mobile and online teaching need to support teachers' pedagogical inquiry as they reflect on the affordances of mobile and online technologies, the pedagogical strategies in these platforms, content transformations, and student learning in their authentic teaching contexts. Professional development programs can target the program and support content to each teacher's individual needs and competencies. Rather than having a solely technological focus, programs can help teachers transform their existing pedagogical methods to these platforms and explore new pedagogical potentials of mobile and online technologies, restructure their content within mobile and online environments, and examine student perspectives and learning within these platforms. Pedagogical inquiry is a key element in professional development and support programs that address teacher transformation. Transformative ICT professional development (Prestridge 2010) is one example that can be used to enhance teachers' online and mobile learning practices. Putting reflective process at the center, the model includes three professional learning elements: Investigation, reflection, and constructive dialogue (Prestridge 2010). For example, teachers can investigate new online and mobile learning pedagogies, engage in written and verbal reflections individually and within groups, and participate to the constructive dialogue with colleagues or peers as they critically discuss what is happening in online and mobile learning environments, and stimulate new ideas (Prestridge and Tondeur 2015).

Examining Teachers' Learning with Mobile and Online Technologies

Research on mobile and online learning should investigate teachers' learning with mobile and online technologies. Online and mobile environments hold potentials for enhancing teachers' learning with their new affordances of anytime-anywhere learning. Professional development programs can be supported with online and mobile learning that extend teachers' learning spaces (Burden and Kearney 2016). Mentoring programs, for example, can integrate e-mentoring or mobile-mentoring approaches. Personal learning networks can be established on mobile and online platforms to

support knowledge exchange between teachers. Other advantages of mobile and online tools can be integrated into teacher learning environments to extend the time and space for learning (Kearney et al. 2012). For example, recent affordances for mobile tools (e.g., location awareness, augmented reality) can be used to create personalized, situated, contextualized, and authentic teacher learning settings.

Ensuring the Continuity and Sustainability of Teacher Learning

Teachers' successful transformation to online and mobile learning environments requires a sustained and systematic effort on implementing professional learning models. Professional development programs need to take measures to sustain the continuity of teacher learning (Dede et al. 2009). Establishing collegial learning networks, mentoring programs, and allocating resources to measure and track teacher learning over time would contribute to the long-term impact of these professional development models. Creating communities of practice on mobile and online platforms and supporting teacher interaction with the help of these environments could help teachers share best practices, receive immediate help and feedback, and encourage their sense of belonging to a group of like-minded professionals.

Examining the Impact on Student Learning

Professional development programs for mobile and online teaching can integrate data regarding student learning to the design of content and pedagogies of professional learning activities (Fishman et al. 2003). Collaboration with researchers would help design and implement research needed to measure student and teacher learning, and the effectiveness of teaching with online and mobile technologies in different contexts (Mouza 2009). Individual and contextual factors that impact student and teacher learning could also be investigated to gather evidence of the success or not of these programs. Collaborating with other stakeholders is another important success factor in this process. For example, teachers should be in constant communication with instructional designers, instructional and technology support centers, and other related staff to make informed decisions regarding effective use of mobile and online learning environments.

Conclusion

Professional development is a complex process, which requires the study of teachers' learning and transformation of their knowledge, beliefs, and attitudes into practice (Avalos 2011). New approaches to professional development for online and mobile learning shifted the focus from stand-alone teacher development programs to customized, anytime-anywhere, on-demand, and collaborative learning models. Such models grounded on teachers' pedagogical transformation include

mentoring, professional learning communities, and design-based learning. Focusing on teachers' pedagogical inquiry, professional development can engage teachers in reflection, problem solving, and professional dialogue about teaching in online and mobile learning environments (Prestridge 2016). The field of research on professional development for online and mobile learning is relatively young, and literature needs more robust research on the impact of programs on online students' learning. Programs can benefit from research on newer conceptualizations of teacher knowledge required for effective teaching in mobile and online environments.

Section VI

The Role of Leadership for Information Technology in Education

Section Introduction: The Role of Leadership for Information Technology in Education

31

Sara Dexter

Abstract

Leaders are essential for schools to realize the full potential of how IT can support teaching and learning. This section addresses how IT leaders might use their authority and expertise to foster IT integration through routines and tools to directly influence the role IT plays in schools, and exercise indirect influence by engaging, preparing, and supporting other leaders and teachers to contribute to the IT use in a school.

Keywords

IT Leadership · leadership · School's IT environment

Leadership for IT in education means influencing how school personnel work individually and collectively to use IT as means to support instructional ends. The focus of this section is what IT leaders can do to accomplish this and the conceptual frameworks and knowledge that can undergird those practices. Taken as a whole, this section provides IT leaders with guidance for leadership practices as well as new ways to frame their work.

In the first chapter (► [Chap. 32, “The Role of Leadership for Information Technology in Education: Systems of Practices”](#)), Dexter describes a *model* for leadership and then relates the empirical support for IT *leadership practices* in terms of the model's three leadership functions: setting directions, developing people, and developing the organization. The research base for IT leadership is not deep, and thus the chapter points to how we can draw upon the broader fields of educational leadership, teacher professional learning, and the organizational sciences

for further guidance. The subsequent chapters then support how IT leaders can leverage that knowledge base to direct their efforts.

► Chapters 33, “A Distributed Leadership Perspective on Information Technologies for Teaching and Learning,” and ► 34, “Leaders Fostering Teachers’ Learning Environments for Technology Integration” describe how distributed leadership and learning design perspectives can guide IT leaders. In ► Chap. 33, “A Distributed Leadership Perspective on Information Technologies for Teaching and Learning,” Halverson explains how we can consider leadership in terms of *what* tasks are taken on by *whom*, and *how* to intentionally coordinate the work of a group of leaders. He describes IT leadership in terms of its current concerns of infrastructure, policy, pedagogy, and culture and points to the affordances educators and students might realize by instead organizing a vision for IT in terms of the affiliations, expressions, collaborative problem-solving, and circulations characterizing IT usage outside of schools.

In ► Chap. 34, “Leaders Fostering Teachers’ Learning Environments for Technology Integration,” Howard, Curwood, and Scott urge leaders to take a learning design perspective when creating a school’s learning culture. They characterize as *sensemaking* teachers’ learning to integrate in light of their students, the curriculum, and the school’s expectations, goals, and policies for IT, and argue that leaders can enhance it by integrating teachers’ independent and informal learning with the typical formal learning experiences.

A series of mini-chapters finish out the section, in which authors present a set of tools and iterative processes IT leaders might use to set directions, build relationships, and develop people, or redesign the organization. Each author presents what the tool or process is, why leaders should use it, and how they might incorporate it into their leadership practices. Together they convey an action research orientation that can help IT leaders continuously improve how IT enhances teaching and learning.

The first three mini-chapters are particularly well suited to support leaders in setting directions. McLeod presents a variety of *frameworks* a leader might use to plan for future vision, goals, or performance expectations, or evaluate those already in place, to thereby bring greater coherence to a school’s IT environment. Nash presents *design thinking* as a process that leaders can use to find solutions for persistent IT problems, while keeping the concerns of users front and center. Tschannen-Moran and Hofer describe how the *appreciative inquiry* process helps an organization focus on its strengths as a basis for setting directions for IT.

The last two mini-chapters each describe a process to use in iterative fashion to create new leadership routines that can support continuous progress for developing people and redesigning the organization. Laurillard (► Chap. 38, “Teaching as a Design Science: Teachers Building, Testing, and Sharing Pedagogic Ideas”) describes a particular approach to engage a school’s teachers in thinking of their craft as a *design science*, which complements the Howard et al. chapter. She argues that such an approach allows for the rapid innovation and exchange among teachers that is demanded by IT. Eddy-Spicer then discusses how *improvement science through networked improvement communities* can engage school personnel in iterative cycles of improvement.

The Role of Leadership for Information Technology in Education: Systems of Practices

Abstract

Information technology (IT) leadership requires that school leaders understand both how IT specifically serves as a means to an instructional end and how to create the conditions that foster such uses. Driven by leaders' technological leadership content knowledge (TLACK), the system of practices for IT leadership presented here suggests how leaders act to in turn influence teachers' knowledge and practices to foster student learning with IT. It is suggested that this system of practices encompasses setting directions for IT uses, building relationships and developing people to succeed with that vision, and developing the organization to support school personnel's efforts towards those ends.

What Is a System of Practice for Leadership of IT and What Should It Encompass?

Leadership is often defined as exerting influence to facilitate a group to collectively use processes to act together to identify and accomplish shared goals (Leithwood 2012). But information technologies (IT) in and of themselves often do not specify their exact use and are, in fact, often described as “just a tool.” Therefore, IT leadership requires that school leaders understand both how IT specifically serves as a means to an instructional end and how to create the conditions that foster such uses.

Although school leadership has been shown to be second only to teaching in its influence on students’ learning (Louis et al. 2010), and so its potential contribution to successful IT implementation in schools is clear, there has been a dearth of research on how to effectively lead IT implementation in schools. Recent comprehensive reviews of the literature located only 116 empirical pieces on the topic in ERIC over the last 20 years (Dexter et al. 2017; Dexter and Richardson 2017). A recent review of empirical models of factors influencing teachers’ integration (Petko et al. 2018) concluded that school-level influences do indeed matter in terms of teachers’ uses but that there is little agreement about their component parts.

Fortunately, the broader field of school leadership offers far more evidence-based research on leadership practices that positively impact students’ learning, which provides insights that can be used to guide both practice and research in the field of IT. Indeed, a recent systematic review of key leadership practices identified many overlapping concepts and sources of agreement in the three most comprehensive models of effective school leadership proposed over the past 40 years of empirical work (Hitt and Tucker 2016). The most recent of those models (Leithwood 2012), based upon a large-scale study of how leaders positively impact student learning (Louis et al. 2010), indicates that successful leaders employ practices that set directions, build relationships and develop people, and develop the organization to foster this work. Altogether, the literature in school leadership suggests a cascading model in which learning affects practices, beginning with the leader and moving to teachers and finally students, as illustrated in Fig. 1. As reflected by bullets in Fig. 1 regarding what leaders must know about each step in this process, leaders must not only learn and employ their own effective practices but also ensure that the school as an organization is set up to nurture and support the new directions for teaching that may grow from their and their teachers’ learning.

This chapter addresses this series of influences upon student learning as a theory of action I’ll discuss here as an IT leaders’ *system of leadership practices*. Viewing IT leadership as comprised of sets of practices shifts the emphasis from the competencies or dispositions of individual leaders, such as the principal or head of school, to actions that actually influence IT integration, such as the ways tools, routines, and structures are employed to support teachers’ learning and instructional practices. This focus on practices also emphasizes the situated and social context of IT integration, which demands that leaders work with each other and through relationships with teachers to respond flexibly to situations in ways that can be learned and

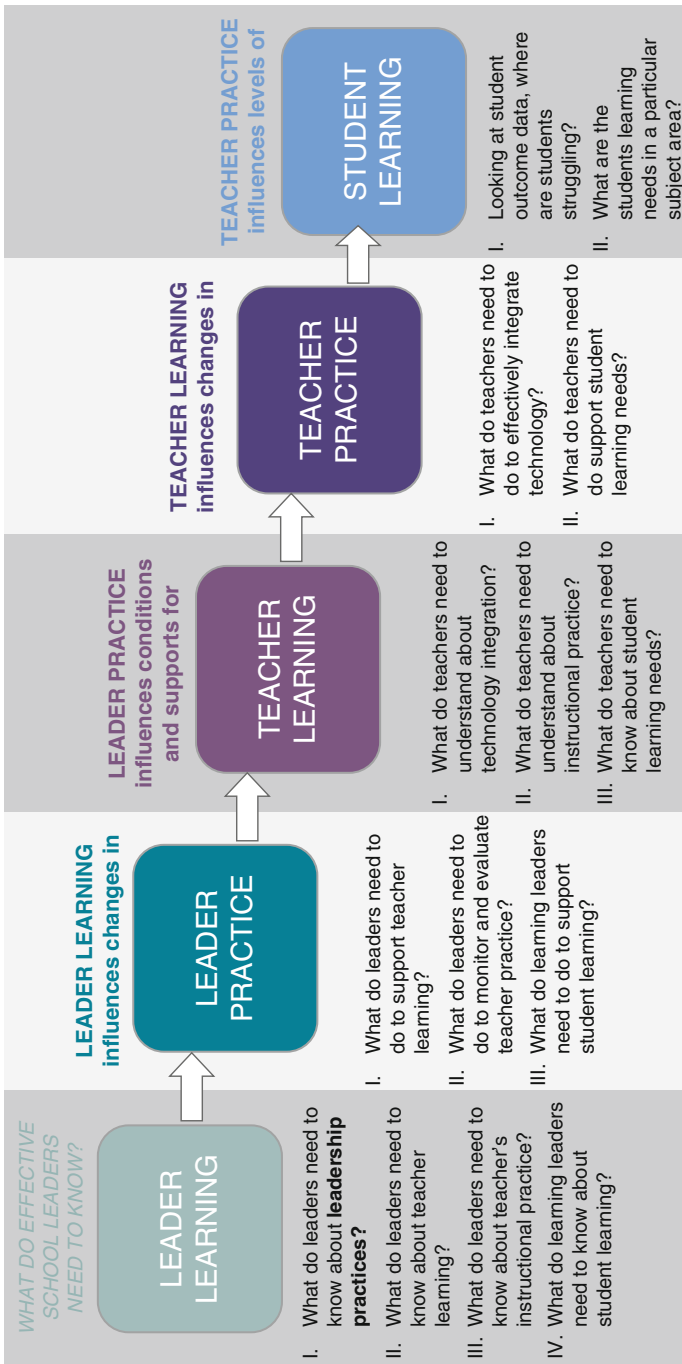

Fig. 1 Theory of action regarding the leadership of IT

improved with effort (Leithwood 2012). A system of practices is a set of actions that are combined to accomplish complex goals, such as the classroom-level integration and school-wide implementation of IT. (See also the discussion of distributed leadership in ► Chap. 33, “A Distributed Leadership Perspective on Information Technologies for Teaching and Learning” by Halverson.)

As Fig. 1 illustrates, a system of IT leadership practices encompasses leaders’ understanding of and influence upon teachers’ knowledge, which in turn influences teachers’ own systems of instructional practice and thus students’ learning. The knowledge that undergirds leaders’ systems of practices includes how to create, appropriate, or marshal the school-level tools, routines, and structures to accomplish this synergy, which has been called *leadership content knowledge* (LCK) (Stein and Nelson 2003) and viewed as analogous to teachers’ *pedagogical content knowledge* (PCK) (Shulman 1986). Stein and Nelson define LCK as an administrator’s ability to “know strong instruction when they see it, to encourage it when they don’t, and to set the conditions for continuous academic learning among their professional staffs” (2003, p. 424). Thus, an effective system of leadership practice for IT is one that builds teachers’ knowledge of how technology combines with their PCK to foster students’ learning of content, which many refer to as TPACK (Mishra and Koehler 2006), and enables teachers to be able to act on their TPACK by providing them with organizational support to integrate IT and ongoing opportunities to deepen their skills and understanding. Presumably, leaders’ technological leadership content knowledge, or T-LCK, would drive their IT leadership. This chapter will refer to the leaders’ knowledge that undergirds their system of IT leadership practices as TLACK, to ease pronunciation and thus communicating about this knowledge base for future research on it and to promote it in leadership preparation.

The most recent decade of research in the IT literature has identified a number of leader activities that should be included in a system of practices for the effective leadership of IT and, to a lesser degree, the TLACK needed by leaders to support these practices. To shape this discussion of an effective system of practice for leadership of IT, I have adapted the model provided by Leithwood and colleagues (Leithwood 2012; Louis et al. 2010) and suggest that successful IT leaders’ TLACK allows them to carry out three key functions. First, IT leaders must know what strong instruction with IT looks like in order to set directions for its integration; second, they must know how to develop people to cultivate those uses, in order to ensure they are adopted; and finally, they must know how to set the conditions for continuous adult learning in order to redesign the organization to support IT integration.

Leadership Practices That Set Directions for IT

Following this model, setting the direction for IT integration requires that leaders develop a shared vision, create shared meaning around that vision, determine expectations and monitor progress, and continue to communicate the vision and goals. The practices these goals might entail when applied to IT are depicted in Fig. 2.

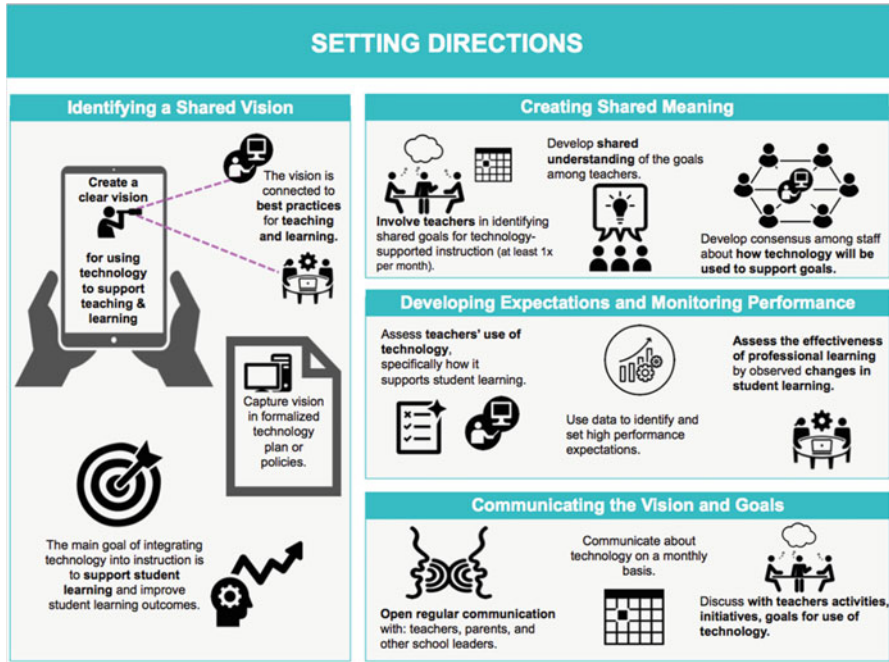

Fig. 2 Leadership practices that set directions for IT integration

Standards and policy discussions of IT and case studies from throughout the world have found that a coherent vision for the use of technology for teaching and learning is an important source of direction for a variety of decisions about staffing and other support related to IT integration (Dexter 2011; Tondeur et al. 2015; Vanderlinde et al. 2010). A leader’s vision for IT will determine, for instance, the distribution of IT resources among teachers or students, such as where computer labs are placed, or which grade levels or subject areas receive IT devices. Vision also drives decisions about the nature and number of support personnel and thereby influences the expertise and authority of the leadership. Just as leaders’ practices derive from their notion of what they want to accomplish, those in turn shape teachers’ understanding of what the IT is to be used for. As researchers have shown, “a shared vision on education influences all decisions made by the schools in the subsequent steps of ICT policy planning,” affecting which IT-supported instruction “will be prioritized, how new ICT activities will be implemented in the curriculum, and which concrete policy actions need to be taken” (Vanderlinde et al. 2010, p. 444). (For a discussion of how school leaders might use technology integration, leadership, or organizational support models and frameworks for instructional improvement, see ► [Chap. 35, “Technology Integration, Leadership, and Organizational Support Frameworks for Instructional Improvement with Information Technology”](#) by McLeod.)

A leader’s knowledge base, or TLACK, will obviously influence not only the nature of that vision but the detail and foresight it might encompass (Tondeur et al. 2015;

van Niekerk and Blignaut 2014), including where and how to focus teachers' efforts (Anthony 2012). Such school-level cultural characteristics as innovativeness, supportive leadership, and goal-orientedness have also been shown to be associated with greater IT planning, support, infrastructure, and usage by teachers (Tondeur et al. 2009). At the level of individual school leaders, significant correlations have been found between a principal's transformational leadership style and his or her own computer use (Afshari et al. 2008), and consequently how they serve as a champion for IT and operationalize IT and promote its use to teachers (Dexter 2011). Given that research has shown that the mere presence of technical, collegial, and school-level support for IT and teachers' personal use of IT may not lead to integrating twenty-first century learning and communication activities in the classroom (Rutkowski et al. 2011), leaders' vision does appear to play a moderating role in leveraging investments in IT.

Because vision is an aspirational statement about a long-term effort, the leadership literature has explored the intervening steps and processes through which that vision is brought to fruition by specific, short-term goals shared by the leaders and teachers in a school. The degree to which those goals are shared by the teachers and leaders has been characterized by Petko et al. (2015) in a typology of top-down, bottom-up, complementary (both top-down and bottom-up), and optional. Their investigation found that although the teachers at complementary schools, where "district initiatives, school leadership and teacher involvement go hand in hand (p. 55)," integrated IT slightly less often than those in bottom-up schools, they were more satisfied with their support environment and their students used IT more often because their schools had more IT resources and more teachers involved in learning about IT. This most effective top-down, bottom-up complementary approach thus suggests how leaders might develop expectations, monitor performance, and communicate the vision and goals:

The ICT adoption typically started out with a small group of teachers that gained increasing support from colleagues as well as from the head of school and school administration. Bottom-up processes were supported as a testbed to orient top-down steps. Both bottom-up and top-down processes were seen as steps going hand-in-hand with each other in order to achieve a common goal. (p. 51)

While the IT leadership research literature on this issue is scant, these results are consistent with case studies that indicate that effective school leaders use local data to make decisions about IT staffing and infrastructure (Vanderlinde et al. 2010) and make regular updates to IT plans as a means of monitoring their progress (Ritzhaupt et al. 2008) and that teachers report principals' encouragement and keeping up with their progress as a positive influence on their ongoing IT integration efforts (Wong et al. 2008).

To summarize, the current IT literature suggests that identifying a clear vision and shared goals is a vital aspect of conveying to teachers that they should integrate IT and why, but it provides little insight into specific practices for communicating expectations and monitoring performance. Case studies and some correlational studies, however, point to how necessary it is for leaders to have adequate TLACK to support those decisions, and the broader fields of educational leadership and teacher

education offer more guidance in these areas. See, for example, Laurillard’s (► Chap. 38, “Teaching as a Design Science: Teachers Building, Testing, and Sharing Pedagogic Ideas”) chapter on design sciences in this handbook.

Leadership Practices That Develop People

To help teachers and staff develop the skills and practices necessary for integrating IT, the Leithwood (2012) model suggests leaders must give attention not only to building the knowledge base of teachers as a group but to addressing teachers’ individual needs and harnessing their unique strengths, and to serving as models and leading by example. See Fig. 3 for examples of practices related to these needs.

As studies have consistently shown, teachers’ learning must be nurtured with ongoing support from staff and opportunities to learn that strengthen both teachers’ belief in the value of IT and their pedagogical skills for integrating it into the classroom (e.g., Ertmer and Ottenbreit-Leftwich 2010; Inan and Lowther 2010; Pan and Franklin 2011; see also the section *Professional Learning and Development of Teachers*, in this handbook). According to the broader professional development literature, “leadership plays a key role in supporting and encouraging teachers to implement in the classroom the ideas and strategies they learned in the PD” (Desimone and Garet 2015, p. 252). Although quantitative models studying the

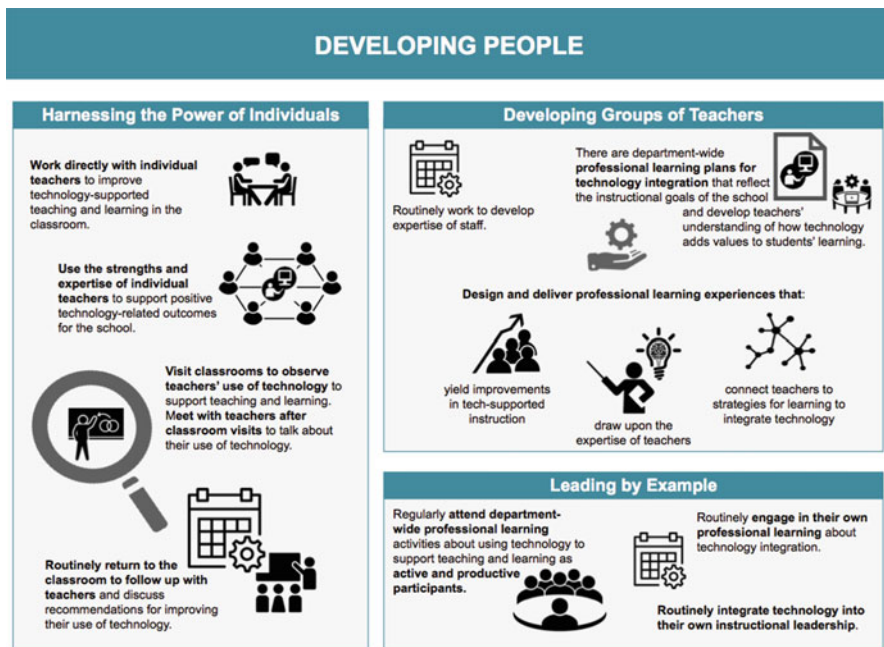

Fig. 3 Leadership practices that develop people

relationship between teachers' learning and their IT integration are few, they all concur that school-level support is essential to success and encompasses leadership practices that set direction, support people, and develop the organization. (For a discussion of these studies, see Petko et al. 2018.)

Studies have identified a number of specific design features – content focus, active learning, coherence, sustained duration, and collective participation – that leaders can employ to create effective learning opportunities for teachers to learn how to integrate IT (Desimone and Garet 2015, p. 252). By identifying specific matrixes of hardware, software, and instructional design strategies for different content areas, for instance, leaders can target the most appropriate tools to introduce to particular groups of teachers (Courduff and Szapkiw 2015). Focusing professional development activities on the highest yield interventions and resources to support student learning within a content area has been shown to maximize teachers' investment of time and resources and increase the likelihood they will find the learning relevant (Jones and Dexter 2014). The literature suggests that formal professional development should be structured to first allow teachers to learn pertinent tools and then to work together on curriculum integration, such as through weeklong residential sessions (Allan et al. 2010), ongoing collaborative design teams (McKenney et al. 2016), long-term collaborations among teachers across a series of workshops (Stevenson et al. 2016), or action research (Schrum and Levin 2013). By making clear the connections between these development activities and ongoing school improvement efforts and by grouping participants into communities of practice to foster ongoing informal collaboration, for example, based upon shared content areas, or grade levels, or common planning time, school leaders can increase the likelihood that teachers are actively engaged with sufficient time to take up and incorporate new instructional practices into their repertoire (Jones and Dexter 2014, 2016).

How leaders staff their support for teachers can also influence the nature and frequency of teachers' opportunities to plan IT-supported instruction. Whereas IT support staff based outside the school tend to provide instructional help for teachers' integration via planned classes, in-school staff can provide teachers with more frequent integration support through co-teaching classes or one-to-one coaching (Dexter et al. 2009). By distributing the leadership and support for IT integration strategically throughout grade levels, content areas, or the school building, leaders can also help develop teacher leaders who can provide school-level guidance for the initiative (Sheppard and Brown 2014) or peer coaching (Stroud et al. 2014).

While studies that focus on teachers' IT integration consistently emphasize the importance of providing sufficient support for professional learning for teachers, studies of leadership for IT frequently draw attention to the similar importance of supporting leaders' learning. Research has demonstrated that leaders' level of knowledge about IT is linked to their ability to address, assist with, manage, direct, and motivate teachers' IT integration (Beytekin 2014; Polizzi 2011; Stuart et al. 2009; van Niekerk and Bignaut 2014). To best support teachers' implementation of IT, according to Gerard et al. (2008, 2010), school leaders themselves need access to inquiry-oriented environments among peers to learn what constitutes strong instruction with IT for a variety of content areas and what impact IT will have on curriculum materials and student assessment.

As indicated in Fig. 3, effective leaders also recognize the importance of acknowledging and providing for individual differences and needs when creating opportunities for teachers to learn how to integrate IT. The pace and content of the learning opportunities teachers need (Robertson et al. 2006; Stroud et al. 2014) have been shown to be affected by variations in their beliefs about the efficacy of IT to improve teaching and learning and attitudes towards IT (Courduff and Szapkiw 2015; Courduff et al. 2016; Stevenson et al. 2016) and by their general experience with or access to IT (Pan and Franklin 2011; Trust et al. 2016). Although the current literature offers few models to help leaders conceptualize how to approach this need to individualize teachers' IT learning in practice, the previously discussed strategy of forming communities of practice among teachers could be purposefully designed to support a variety of different teachers' needs, as could simply providing a range of opportunities and allowing teachers to choose where, what, or how to learn (Svendsen 2016). By differentiating support and beginning with the teachers most ready to start integration efforts, leaders can catalyze changes that ripple across a school or create pilots that develop expertise and develop teacher leaders (Stevenson et al. 2016).

Two additional models for providing differentiated support for teachers' professional learning about IT have recently emerged in the literature. The first is the concept of PLNs, or personal learning networks, which are formed online by teachers' choosing to pursue information and participate with other educators based on their individual interests and needs (Trust et al. 2016). While little is yet known about the impact of PLNs on teaching practices, Trust (2016) found that participants in one network were guided primarily by specific questions they were seeking to answer and assessed, tested, and curated the resources they found there to adapt them to their own implementation context, thus meeting their individual learning needs. IT leaders might introduce teachers to PLNs as a concept and then provide time or other resources to participate in them as another way of meeting teachers' individual professional learning needs.

A second possible model for attending to teachers' differentiated learning needs is the holistic model described by Jones and Dexter (2014, 2016, 2018), in which leaders extend support beyond the formal professional development mode of learning by also facilitating teachers' independent and informal modes of learning with peers. Examples of such leadership activities would include designing information flow among the three modes of learning; modeling and creating a climate for learning exchange and collaboration; and providing digital tools, information sources, or collaboration sites to encourage give-and-take among peers and empower learning. Teachers seamlessly switch among the three modes as needed, and if school leaders recognize, support, and promote learning activities across all three modes, they generate synergies that will meet teachers' individual needs while also aligning teachers' learning efforts with organizational learning goals.

Although IT studies do not yet provide adequate evidence to make definitive claims regarding the impact of leading by example, the third dimension in Fig. 3, the persuasive appeal of leaders "walking the talk" is conceptually sound and has been shown to resonate with educators, as it does in other realms of life. In the case of this teacher, for example, attesting to the motivating role a school leader can play, "The

principal played a crucial role and she leads by example in that she integrates ICT in her lessons (Tondeur et al. 2015, p. 575).”

To summarize, the IT literature is emphatic that leaders must support teachers’ professional learning but does not yet provide a good deal of guidance as to how to do so. As with setting directions, the evidence base regarding IT leaders’ practices for developing people consists primarily of case studies and some correlational studies that describe leaders’ actions broadly, without clear indications of the TLACK needed by IT leaders. The broader fields of teacher education and professional learning offer more guidance in these areas, as discussed in this handbook in Howard et al. (► Chap. 34, “Leaders Fostering Teachers’ Learning Environments for Technology Integration”) and Prestridge and Main (► Chap. 28, “Teachers as Drivers of Their Professional Learning Through Design Teams, Communities, and Networks”).

Leadership Practices That Develop the Organization

To develop the organization’s capacity to support teachers’ integrating IT, the third set of practices identified in the leadership model employed in this chapter focus on building a collaborative culture within and beyond the school and structuring the organization and allocating resources to encourage such a culture and facilitate integration. Practices supporting these efforts are illustrated in Fig. 4.

A collegial and collaborative climate at a school has been shown to positively mediate teachers’ uses of technology (Scribner and Bradley-Levine 2010; Wong et al. 2008) by influencing how teachers make sense of IT and in turn the nature and extent of their uses of it (Cho and Wayman 2014). As noted earlier, this has been shown to be particularly the case when teacher-based “bottom-up” input into IT decision-making is combined with leaders’ “top-down” efforts (Petko et al. 2015). Although the current literature in the field provides limited guidance about practices that leaders might use to build a collaborative culture for IT, it suggests that they might establish the means for teachers’ exchange through a shared cloud-based server space or web-based apps for collaboration or through regular meetings of committees, communities of practice, or other decision-making structures that include expectations for teacher-to-teacher exchange or requests for input (Dexter 2011; Jones and Dexter 2014, 2018). Another suggested strategy is using shared curriculum development as a means for building collaborative cultures about IT. Leaders, for instance, might use open-ended processes like weekly or monthly scheduled meetings for exchanging ideas of interest within the community of teachers or outcome-oriented processes such as curriculum writing teams with schedules and deliverables (Allan et al. 2010; Wong et al. 2008).

Because the support environment for IT in a school is predictive of its teachers’ integration of IT in their teaching practices, numerous researchers have investigated ways school leaders can actively create and coordinate teacher support (e.g., Divaharan and Ping 2010; Inan and Lowther 2010; Petko et al. 2018; Stevenson et al. 2016; van Niekerk and Blignaut 2014; Wong et al. 2008). At a school level, for

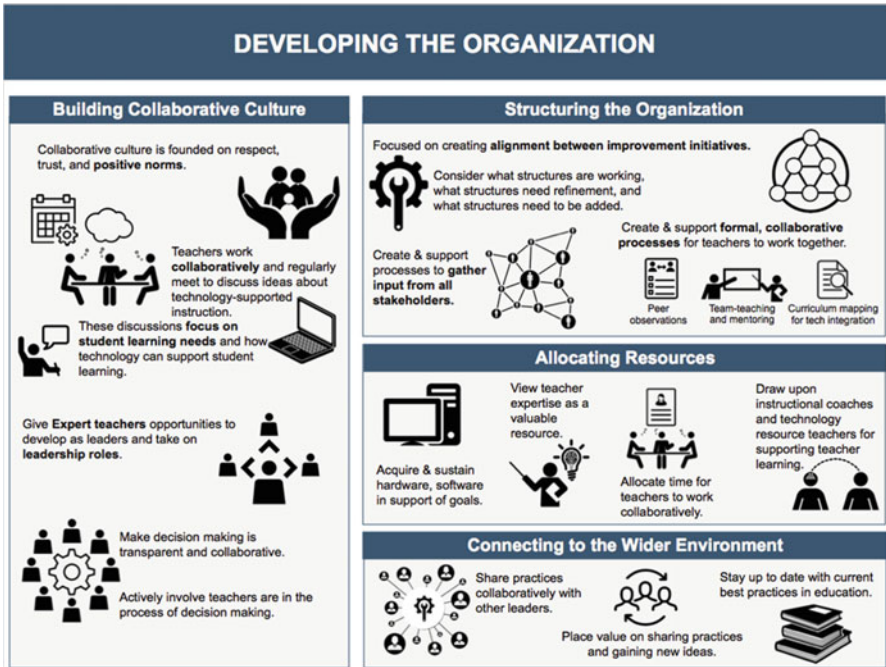

Fig. 4 Leadership practices that develop the organization for IT integration

example, this might include providing instructional support and coaching staff who are then included in the school leadership team’s decisions for IT and expected to attend department or team meetings to strategize with teachers about high-yield uses of IT and work one-on-one on classroom implementation. Teacher supervision or evaluation and annual school improvement planning can then include or refer to such uses of IT as part of a school-wide strategy.

While the dimension of allocating resources is often thought of in terms of providing IT hardware and software, the number of IT devices and access to the Internet in schools have so increased that the IT leadership literature published since the last edition of this handbook rarely mentions the lack of IT as a factor limiting teachers’ integration. Instead, the recent literature stresses that leaders’ responsibility for resource management must include budgeting to ensure the timely repair, refreshing, or updating of IT and distributing it equitably and with regard to school mission and vision (Devolder et al. 2010; Oliver et al. 2012; Levin and Schrum 2013; Vanderlinde et al. 2010). Researchers have also identified acquiring and allocating resources for teacher collaboration time and instructional and technical support staff as critical to successful IT integration (Courduff et al. 2016; Dexter et al. 2009; Vanderlinde et al. 2010). Altogether, the literature regarding leaders’ allocation practices has emphasized the importance of creating enabling conditions for integration, removing barriers to implementation, and managing IT as a resource important to achieving the aims of teaching and learning.

Another perspective often employed in leadership studies is the notion of distributed leadership, which recognizes that the ways in which multiple people work together to accomplish work are coordinated through routines and tools (see also ► [Chap. 33, “A Distributed Leadership Perspective on Information Technologies for Teaching and Learning”](#) by Halverson, in this handbook). By conceptualizing IT support personnel as a part of the group of leaders who are working together to accomplish goals for IT use, leaders can better identify and empower the specific ways they serve as communication linkages among school personnel (Hiltz and Dexter 2012; Sheppard and Brown 2014; Vanderlinde et al. 2010) and better position these support staff members to be viewed as IT leaders by teachers (Dexter et al. 2009; Scribner and Bradley-Levine 2010). Incorporating teacher leaders into the leadership team can further ensure that the classroom context, student learning, and curriculum concerns are considered in the design of the school’s IT support system (Robertson et al. 2006; Scribner and Bradley-Levine 2010; Staples et al. 2005; Tondeur et al. 2015).

Currently, the available research provides more support for the importance of IT leaders’ efforts to develop the organization through teacher collaboration and aligning the organization and its resources to the IT vision than through connecting to the wider environment, although the latter is occasionally mentioned in passing. Again, the evidence for IT leadership practices that can help develop the organization for IT integration comes primarily from case studies and to a lesser extent correlational studies using survey research. The broader field of educational leadership, however, offers additional guidance in specific approaches related to this domain; see, for instance, the chapters on design thinking (► [Chap. 36, “Leading Information Technology via Design Thinking”](#) by Nash), appreciative inquiry (► [Chap. 37, “Appreciative Inquiry: Building on Strengths for Integrating Information Technology in Schools”](#) by Tschannen-Moran and Hofer), and improvement sciences (► [Chap. 39, “Improvement Science Through Networked Improvement Communities: Leadership of Continuous Improvement with, of, and Through Information Technology”](#) by Eddy-Spicer) in this handbook.

Conclusion

Although most studies of IT integration have focused on how teachers influence its use in the classroom, the few studies that have offered a comprehensive model of influences or examined other contextual factors agree that teachers’ IT integration is both directly and indirectly influenced in significant ways by the actions and support of school leaders. Although the IT-specific literature is sparse, theoretical models and empirical studies from the broader field of leadership studies offer useable insights and can help suggest and refine future research in IT integration, particularly quasi-experimental or experimental designs to identify generalizable and causal leadership practices.

Several future directions for research are suggested by the leadership practices and leadership content knowledge models highlighted in this chapter. In particular, these models indicate a need to more clearly understand factors that facilitate

leaders' abilities to set directions for IT integration that will improve student learning, to develop teachers' TPACK, and to create the organizational conditions that will support teachers' ongoing success in integrating IT. Furthermore, as noted earlier, the existing literature provides almost no insight into what should constitute IT leaders' knowledge base, or TLACK. Currently, for instance, we know almost nothing about whether TLACK builds inductively from leaders' specific experiences with IT or can be deduced from their broader leadership experience and transferred to their IT leadership. A more comprehensive and deeper understanding of both IT leadership practices and the TLACK that drives them would allow existing and aspiring IT leaders to more effectively focus their learning and efforts.

Having models and conceptual frameworks helps the community of scholars who study a field discuss it and discern its interplay of relationships. Scholars of IT who learn of and use the models and frameworks proposed here and in other chapters in this section can build bridges to related fields of study to catalyze insights for the next generation of research in IT.

Introduction

This chapter considers how distributed leadership can describe and explain the role of K-12 school leaders in supporting technologies for teaching and learning. Leadership establishes and maintains the conditions that support the core practices of an organization (Spillane et al. 2004). When considering school leadership for technology, the role of leaders is to make it possible for educators and students to take advantage of the range of affordances offered by contemporary information technologies to advance learning.

Distributed leadership is uniquely suited to describe how schools lead for technological innovation. Distributed leadership is often thought of as a way to think about the social arrangement of leaders for teaching and learning (Bennett et al. 2003). To be sure, leading for technology is in large part a matter of defining and sharing practices among and across actors in the instructional context. Distributed cognition theory also emphasizes the role of the *tasks* enacted by actors across contexts of practice (see, e.g., Hutchins (1995). *Cognition in the Wild*. Boston: MIT Press). Spillane, Halverson, and Diamond's model emphasizes this task-focused approach to describe how multiple actors engage in leadership work. Distributed leadership describes how leaders use tools to redefine the tasks that constitute what is possible (and impossible) in schools.

This chapter will consider the range of tasks that define school leadership for technology. This work recognizes the considerable range of practices in which leaders currently engage to implement new technologies within schools. However, from another perspective, schools are situated in a much broader world of technologies such as social media, video gaming media distribution, and production which are redefining what counts as teaching and learning outside of schools (for a discussion of how technologies are transforming learning outside of schools, see Ito et al. (2013). *Connected Learning: An Agenda for Research and Design*. Irvine, CA: Digital Media and Learning Research Hub; Jenkins et al. (2007). *Confronting the challenges of participatory culture: Media education for the twenty-first century*. MacArthur Foundation Digital Media and Learning White Paper Series. <http://newmedialiteracies.org/files/working/NMLWhitePaper.pdf> and Barron et al. (2015). *The Digital Youth Network: Cultivating New Media Citizenship in Urban Communities*. Cambridge: MIT Press). Because leaders are responsible for creating environments that best advance learning opportunities for all students, our analysis addresses what currently counts as a learning technology task for leadership as well as a consideration of what is on the horizon for technology work in schools.

Distributed Leadership Framework

Spillane and colleagues describe distributed leadership as a theory that seeks to explain how leaders establish the conditions for supporting and improving core organizational practices. They seek to understand leadership in terms of the key tasks supported by networks of people and tools. From the Spillane et al. perspective, distributed leadership draws on the theoretical sources of distributed cognition to explore how actors, artifacts, and tasks together define and engage in the situation in which practice unfolds:

- The *task* is a discernable unit of action engaged in by actors and supported by the context.
- The *social* distribution of practice refers to how tasks are shared, obstructed, and constructed across multiple actors over time. These actors can receive tasks given from outside their context of action (e.g., requirements to implement a policy) or can design tasks locally to support core elements of their work.
- The *situational* distribution of practice refers to the artifacts (such as tools, language, and routines) that mediate task engagement in a given context. In schools, some of these artifacts are inherited as elements of the local context (e.g., the school calendar); others are imported into the context as guidelines for action (e.g., standardized tests); and still others are designed locally to address community concerns (e.g., professional learning plans).

Together, these concepts of task, social, and situational distribution explain how practice unfolds in real time.

Distributed leadership adopts these concepts of task, social, and situational distribution to explain the work of leaders. The distinctive role that leaders play is to support the core practices of the organization. For example, leaders engage in hiring, training, and evaluating educators; providing resources and training to improve performance; and adopting and designing assessments of core organizational practices. In schools, leadership tasks are defined around the support and improvement of teaching and learning. School leadership involves tasks such as establishing a focus on learning and learners, monitoring teaching and learning, building professional capacity of staff, acquiring and allocating resources, and building a safe and effective learning environment for all students (Halverson and Kelley (2017). *Mapping leadership: The tasks that matter in school improvement*. Jossey-Bass: San Francisco CA). Distributed leadership analyses of these tasks illustrate how leaders build structures and resources to improve core organizational practices (Diamond and Spillane 2016).

Applying the Spillane et al. perspective to how leaders frame and support the tasks of technology leadership identifies the tasks necessary to draw the wide range of technologies in and out of schools into the core practices of teaching and learning. While there is a significant body of research available for how leaders support current technologies in schools, there is relatively little research on the direct role of school leadership for bringing the affordances of new media technologies into

schools (► Chap. 32, “The Role of Leadership for Information Technology in Education: Systems of Practices” by Dexter and Richardson). The argument presented here brings together conventional leadership research on technology with work from other fields of technology development to outline an agenda for where leaders should currently focus as well as where they can focus next.

A Task-Based Distributed Approach to School Technology Leadership Research

Anderson and Dexter (2005) have shown that effective leadership for information technology is a significant predictor used by teachers and students in schools. There is considerable research that documents the leadership tasks for designing and supporting technologies for student learning, professional development, and data systems in schools (see, e.g., Anderson and Dexter (2005). School technology leadership: Its incidence and impact. *Educational Administration Quarterly*, 41, 49–82; Tan (2010) School technology leadership: Lessons from empirical research. Proceedings from the 2010 Annual ACSILITE Conference. Sydney. http://www.ascilite.org/conferences/sydney10/procs/Seng_chee_tan-full.pdf).

Leaders who successfully engage in the work of improving teaching and learning take a system-wide perspective on the nature of the tasks and the range of the partnerships required. Tan’s (2010) review of international research on technology leadership identified four task domains necessary to engage in successful leadership within and across schools: *infrastructure, organization structure and policy, pedagogy and learning, and school culture*.

Infrastructure refers to building and maintaining the technical capacity for information technologies to support teaching, learning, and school operations. Infrastructure includes selecting, purchasing, and maintaining hardware and software systems as well as developing the professional capacity to assess, monitor, and improve technical resources. In recent years, an important aspect of technical infrastructure is the development of capacity to collect and disseminate standardized testing data for school improvement. Investment in these technologies are sparked by the requirements of policies that press schools to develop the capacity to generate and use student outcome information to make decisions about school management, teaching, and learning.

The ability to use these data has led to large-scale investment in information management and communication tools. In the 2000s, local and national education leaders around the world began to invest in data systems to collect and track accountability data to assess school performance and to make information visible to communities. By 2010, 99% of US public school districts had student information systems, 77% had data warehouses, and 64% had curriculum management systems (Means et al. 2010). By 2014, the global market for management and information technologies had swelled to a \$1 billion industry (Herold 2014). Over time, schools came to realize that standardized test data alone had limited value in guiding instructional decisions. During the 2000s, schools began to invest in interim assessment tools that would use computer-adaptive testing technologies to provide instant,

standards-based feedback on student learning. Technology leaders not only must be able to select the appropriate tools to enhance teaching and learning in schools but must also design technical infrastructure to coordinate how these tools interact with one another and with users in increasingly sophisticated technology systems.

One area where schools are investing in technology infrastructure is to provide data-driven decision-making support for students with special needs. In the USA, the development of specialized technologies to support individualized education program (IEP) requires educators to use data to develop customized learning plans for students. Programs such as Response to Intervention (RtI) aim to identify students before they begin to struggle and to assign students to appropriate instructional support systems (Batsche et al. 2006). RtI programs use data for universal screening in order to guide students toward different tiers of learning support to address student learning needs prior to assignment into special education. Similar data-driven programs have been developed for behavior management and discipline (e.g., Positive Behavior Interventions and Supports (PBIS)). Contemporary technology leaders use these intervention and support models to build systems to organize data acquisition, distribution, and recording systems to track how students fare in these kinds of information-rich instructional environments (new approaches to analytics can provide the same kinds of insight for the kinds of technology support needed by different types of teachers. Graves and Bowers found four categories of technology-using teachers: *dexterous* teachers able to move between systems and tools, *assessors* interested in using technologies for measurement, presenters who use technology to complement instructional delivery, and *evaders* who seek to sidestep technology use. For more detail, see Graves and Bowers (2017) *Toward a Typology of Technology-Using Teachers in the “New Digital Divide”: A Latent Class Analysis (LCA) of the NCES Teachers’ Use of Educational Technology in U.S. Public Schools, 2009 (FRSS 95). Teachers College Record*).

Taken together, standards-based planning and data-driven instructional supports result in sophisticated information networks organized around diagnosing student needs and diagnosing student outcomes. These systems are increasingly integrated into the core practices of teaching and learning in schools and provide powerful tools for educators to better understand student needs and the outcomes of instruction.

Organizational and policy change refers to the governance and partnership models that oversee the design and implementation of technical capacity in the school. Technology planning is a central leadership task in this area around the world. A sampling of planning documents includes:

- Singapore’s Masterplan coordinates information technologies for teaching and learning across the nation. The core components of the plan include (a) building the capacity of school leaders, (b) integrating instructional technologies across the curriculum, (c) encouraging innovative technology practices in schools, and (d) ensuring ethical and responsible usage of technologies (Singapore Ministry of Education 2014).

- A UNESCO sub-Saharan Africa report emphasizes the preservice training in the effective use of information technologies for teaching and learning in the classroom through teacher training and a variety of in-service and virtual learning opportunities (UNESCO IICBA 2016).
- A European Commission report calls for investment in technology infrastructure and training in schools. The report claimed that between 20% and 50% of learners use digital texts, games, or virtual learning environments and only 20–25% learn in classrooms with technologically skilled teachers. The Commission sponsors frameworks for technology development and innovation, tools that support the development and measurement of digital literacies, and spaces to support the sharing of open education resources (European Commission 2017).
- The US Department of Education (2017) National Technology Plan Update describes key tasks necessary to engage in successful planning for technology leadership. The authors emphasized the role of establishing a vision for the use of technology in the school, to develop funding models for sustainability and leading for equitable access to learning technologies.

These plans suggest local and regional leadership engage in a variety of tasks to design and enact broad agendas for technology and learning:

- At the national and regional level, policy makers and school leaders are called to focus on providing broadband access to all school districts and to consider initiatives that put computation technologies in the hands of all learners. Legislators and state agencies need to provide funding and increase support beyond technologies that measure the results of schooling and move toward technologies that support teaching and learning in and out of classrooms, including learning management systems, communications tools, and computer-adaptive teaching and learning tools.
- At the district and school level, educators are called to collaborate on articulating a vision for equitable access and uses of technologies for learning, building the capacity for assessment technologies, and providing professional development for teachers on data literacy and on effective technology uses for standards-based instruction.
- At the classroom level, teachers and learners are called to integrate information technologies into everyday teaching and learning practices, including computer-adaptive learning and assessment tools. Classrooms need to provide greater access to opportunities for personalized and blended learning and need to participate in distributed, virtual communities that extend the walls of the classroom to access relevant professional and learning resources.
- At the community level, schools are urged to develop communication strategies that meet the information needs of all members of the community as well as using learning technologies to allow families to access and participate in student and classroom learning opportunities, to support families in the active uses of technologies by early learners in home environments, and to develop plans to safely share information with relevant community partners.

Data security and digital citizenship. The distributed nature of technology systems makes them increasingly vulnerable to hackers both inside the community and around the world. Because school data systems distribute identifying information about minors and families, and typically lack the resources necessary to invest in state-of-the-art security tools, education institutions need to plan to collaborate on sharing best practices for ensuring secure data systems. The US's National School Boards Association's 2017 report distinguishes between data privacy practices that ensure the confidentiality of student and teacher information and data security practices that protect the data system from internal and external attacks. The report recommends that each school develop a data governance plan to oversee the "data life cycle" through the collection, storage, protection, usage, sharing, and retiring of information (National School Boards Association 2017).

Digital citizenship has emerged recently as an important organizational issue for schools. The ability of the Internet to connect learners across communities around the world requires the establishment of shared standards for interaction. Open access to information has led to the need to teach students and teachers how to engage in online information exchange and interaction as twenty-first-century citizens. For example, communities such as E-Twinning have provided virtual opportunities to learn norms for digital interaction for over 2 million learners from 38 countries to collaborate on classroom and professional learning projects (Cassells et al. 2016). Digital citizenship should also focus on issues of social media interaction within schools with attention to issues of cyberbullying and helping learners to use social media as a resource for leaning (Espelage et al. 2012). Orchestrating interaction around these key tasks helps to organize technology planning around the habits of mind and practice expected of educators and students in schools.

Pedagogical and learning change describes the work of technology leaders to advance the practices of teaching and learning in schools. This work involves providing professional learning opportunities for staff and faculty, selecting and supporting virtual learning and learning management tools for classroom instruction, and assembling relevant instructional support technologies for learning outside of the classroom.

Designing technologies for pedagogical and learning change involves the assembly of systems designed to address a variety of learning needs in schools. For example, contemporary school leaders often engage in the provision of learning management systems to support teaching and learning. The global market for learning management systems is expected to grow from \$5.2 billion in 2016 to a \$19 billion in 2022 (Learning Management System Market (Distance Learning, Instructor-Led Trainings and Others) for Performance Management, Content Management, Communication & Collaboration and Others Applications: Global Industry Perspective, Comprehensive Analysis and Forecast, 2016–2022. <https://www.zionmarketresearch.com/report/learning-management-system-market>). In European higher education markets, open-source tools based on Moodle continue to dominate (<http://www.micromarketmonitor.com/pressreleases/europe-learning-management-system.html>), while in the K-12 world, platforms such as Google Classroom (<http://www.prnewswire.com/news-releases/google-apps-for-education-anticipated-to->

reach-110-million-users-by-2020-300107878.html) are being used in classrooms around the world. Professional development tools such as ETIPS provide case-based guidance for educators to plan and support technology-rich learning environments (<http://www.etips.info>). The market for testing and curriculum tools such as benchmark assessment systems and digital instructional content has grown dramatically in recent years as well. In addition, specialized platforms for special education (https://www.rti.org/sites/default/files/brochures/ict_ed_training.pdf), computer-adaptive learning (<https://www.edsurge.com/research/special-reports/adaptive-learning/software>), and individualized learning (<http://www.edweek.org/ew/articles/2016/03/07/facebooks-zuckerberg-to-bet-big-on-personalized.html>) are being used more widely in schools. Professional learning opportunities should be organized around research in technological pedagogical content knowledge (TPACK) that guides educators through the tools and tasks that best represent a subject area (Voogt et al. 2013).

Many schools have turned toward personalized learning as a model for taking the practices of data-driven learning supports to the student level. A recent Education Week review (2014) synthesized a variety of recent personalizing learning to define four key features:

- *Competency-based learning progressions* that define trajectories of content for learners and provide ongoing, formative assessment toward learning
- *Flexible learning environments* organized around the needs of students
- *Personal learning paths* that customize activities to learner motivations and goals
- *Learner profiles* to capture the progress students make toward learning goals

Personalized learning encourages teachers to work with students to develop learning plans for *each* student, instead of *types* of students. This shift requires leaders to implement new kinds of technologies, such as Google Classroom and learning relations management systems, which enable students to participate in data-driven instructional decision support. As an aspect of personalizing learning, schools are implementing a variety of computer-adaptive curriculum systems that provide a standards-based trajectory of curriculum units customized to demonstrate student abilities (for a discussion of the varieties of computer-adaptive learning systems, see Pugliese 2016. Adaptive Learning Systems: Surviving the Storm. *EDUCAUSE Review*. <http://er.educause.edu/articles/2016/10/adaptive-learning-systems-surviving-the-storm>). Computer-adaptive curriculum packages, based on technologies developed in cognitive tutoring research, allow educators to link assessment to learning plans for students.

Cultural change describes the work of technology leaders to focus the use of information tools on supporting and advancing opportunities for teaching and learning. This work involves modeling appropriate work practices for collaboration and use of information tools by school leaders and staff, providing occasions for collaborative design with technologies for teachers and students, and developing a suite of tools (such as websites and social media) to communicate the progress and mission of the school to community members and stakeholders.

Because new technologies are always being introduced, a number of researchers characterize change in terms of building a culture of innovation. In *Where Good Ideas Come From*, Johnson (2011) describes innovative contexts as sites of “liquid” social and intellectual capital in which actors who share loosely related agendas share insights across areas of expertise to spark new insights in their fields. Leaders interested in creating this form of liquid capital in their schools can create opportunities for professionals with different forms of expertise to learn from one another. Liquid capital environments provide dynamic contexts that invite people to adapt the ideas of colleagues to new purposes, cultivate promising hunches, and set up conditions for serendipity.

Unfortunately, there is abundant evidence that the promise of information technologies is often unfulfilled. Peck et al. (2002) found that technology initiatives seldom improve teaching and learning across the organization. Without significant attention to pedagogical and cultural change, information technologies can simply be used to reinforce existing instructional practices, rather than acting as a force for change. Fletcher (2009) notes “When leaders are clueless about technology and the impact it can have in classrooms, they are powerless to change their school or district into one that provide tech enabled instruction for students” (p. 22).

Clearly, the work specified by these task domains goes considerably further than the positions of technology coordinator or principal. Anderson and Dexter (2005) found that the work of technology leaders across the school has a direct impact on quantity and nature of technology use for teaching and learning in schools. Often creating cultures of innovation requires a distributed perspective in order to establish new norms and routines of practice across the school. Christiansen and colleagues (2006) use the term “disruptive innovation” to describe how advances in one area of a market can overturn status quo practices in other areas. Creating Johnson’s liquid networks requires strong, informed leadership to create connections, build collaborations, and find new opportunities for innovation. From a distributed leadership perspective, engaging in system-wide tasks such as *infrastructure, organization structure and policy, pedagogy and learning, and school culture* can help reshape the conditions that can thwart the work of isolated educators and school leaders.

Social Distribution of Technology Leadership Tasks

Effective technology leadership is socially distributed across the organization. At the district policy level, Turner (2014) found that superintendents created subject matter expert teams and arranged collaborative design meetings to develop and implement district-wide technology initiatives. Penuel’s (2006) review of one-to-one computing initiatives suggested that drawing teachers together in collaborative design work has a better chance of improving practice and creating opportunities for student learning. Research on technologies implemented to support special education (Zorfass and Rivero 2005), learning management systems (Dagada and Mungai 2013), and virtual schooling (Abrego and Pankake 2010) all emphasize the role of leaders to

intentionally distribute work across networks of subject matter professionals and community members to realize the potential of information technologies in schools.

A socially distributed leadership perspective on these core tasks reveals variation in how educators engage in technology leadership. Spillane (2006) described three idea forms of social distribution: collaborative, collective, and coordinated. A *collaborative* approach describes the ideal situation of technology planning in which leaders charged with technical, logistical, instructional, and resource allocation work together to achieve a coherent plan. A *collective* approach might describe the distinct roles that leaders play in enacting a technology-driven learning plan. For example, educators might collectively agree to implement a digital citizenship curriculum that requires each person to engage in a separate role across subject areas to reinforce norms of twenty-first-century learning across the school. A *coordinated* approach describes the operation of a large-scale learning technology system where the instructional technology staff monitor infrastructure and security issues; educators handle the day-to-day student-technology interactions; business leaders acquire and allocate necessary human and material capital resources; and formal leaders make the case for the value of the system to internal and external audiences.

Ideally, these levels of activity are coordinated so that information generated from each level is shared across levels to monitor system breakdowns. Of course, in practice, there are many ways for these systems to malfunction and for the resulting work to be disconnected from effective practices in teaching and learning. Bauer and Kenton (2005), for example, found that technologically adept teachers struggled to adapt their skills to the quality of the technology infrastructure available in their schools. The work of Peck et al. (2002) illustrates the limited reach of technological innovations to reshape everyday classroom routines; and Warschauer and Matuchniak (2010) contrast the promise of instructional technologies at the system level and how actual classroom practices tend to reproduce race, class, and gender inequities. System breakdown signals how errors are not noticed or not acted upon by actors at other levels of the system. A socially distributed leadership perspective enables observers to follow task enactment across multiple levels of action in order to identify areas for supporting best practices (for a discussion of how following information pathways allow for the identification of breakdown in distributed systems, see Hutchins (1995)).

Leading for Twenty-First-Century Learning

In upcoming decades, the leaders will face new challenges of integrating emergent learning technology tasks into everyday practices of teaching and learning (the following section draws on a paper that describes how technology leaders can bridge participatory cultures into schools: Halverson et al. (2016). *Participatory Culture as a Model for How New Media Technologies Can Change Public Schools* (WCER Working Paper No. 2016-7). Retrieved from University of Wisconsin–Madison, Wisconsin Center for Education Research website: <http://www.wcer.wisc.edu/>

[publications/working-papers/](#)). Collins and Halverson (2009) identify these emerging practices as “seeds of a new system” that serve to draw on the generative world of social, consumer, and entertainment to outline possible areas for growth in learning technologies.

It might seem strange to label users as learners in these kinds of contexts. After all, playing video games or hanging out in Reddit does not resemble a typical school experience. However, the information-rich contexts of these environments are changing what we mean by learning in the everyday world. Google Maps users learn how to navigate unfamiliar spaces; fantasy sports players learn how to predict the outcomes of players and sporting contests; and hearthstone players learn which virtual card decks are popular among experts. Users develop favorite sources of information, such as Facebook, Twitter, or Spotify, for social interaction and entertainment. New media technologies put unprecedented power for learning in everyone’s hands. To take advantage of these powerful learning tools, technology leaders in schools will need to create new opportunities to drive learning in schools.

Bridging the potential of these learning opportunities into the lives of teachers and learners creates significant challenges. Twenty-first-century educators and students learn to participate in learning communities in and out of schools, but the barriers for working across the divide are quite high. Issues of student identity and safety, as well as network security, present the initial obstacles for ready integration. The interest-based learning goals that define entertainment and social media communities threaten the tight controls over the content of student learning in schools as specified by standards and accountability policies. In many classrooms, an uneasy truce exists between the technologies that thrive within the schools and the technologies that engage interaction outside the school (Halverson and Shapiro 2013).

Henry Jenkins and his colleagues (2007) developed the idea of participatory cultures to capture the kinds of social learning interactions that emerge naturally around new media technologies in the wild. Participatory cultures begin with the idea that gaming, making, writing, and fan cultures are social learning communities. They propose four aspects of participatory cultures: *affiliations*, *expressions*, *collaborative problem-solving*, and *circulations*.

Affiliations describe the interest-driven aspect of participatory cultures. Members choose to affiliate with a group first to learn more about the topic and then to guide others in participation. Affiliations admit members based on interests and, over time, often inspire members to acquire new interests. Players of a certain game, for example, hear about the release of a similar game through affiliation, which leads them to play the new game. Affiliations typically include members with a differing ability levels whose expertise becomes a community resource for mentoring and the induction of novice participants. Over time, novice members come to serve as guides for the next generation of new users.

Technology leaders in schools interested in designing for affiliations could look to examples such as *maker spaces*, which are “informal sites for creative production in art, science, and engineering where people of all ages blend digital and physical technologies to explore ideas, learn technical skills, and create new products” (Sheridan et al. 2014). Opening up school libraries, for example, as maker spaces

can invite students and teachers to tinker with 3-D printers, circuit design, knitting, or craftmaking as a place for multiage expertise within the school. School leaders can repurpose common-use spaces to support interest-based exploration; and use making activities to support bridges to disciplinary learning in science, social studies, computation, and the arts.

Expressions define learning as creating products that matter to the affinity group. Expressions include products such as videos, games, and critiques (Halverson 2012). In schools, conventional assessments typically take place after the learning has happened and are not meaningful in contexts apart from the learning task. For example, a math test happens after the learning has occurred, and the test in itself has meaning only in rating the performance of the student. In participatory cultures, learners demonstrate membership by making expressions that are critiqued and approved by the community.

YouTube communities provide a model for how expressions lead to authentic assessment. YouTubers watch the work of others on the way toward developing interests. Full membership requires providing feedback and guidance to new members through critique as well as making products (in this case videos) valued by the community. School leaders can look to YouTube communities as inexpensive examples for how to support technologies that build student interests and authentic audiences into daily practices. Many schools already have multimedia capstone projects designed to draw together aspects of the student's education experience across disciplines. Using expression communities as a model can point toward viable pathways for technology leaders to organize teaching and learning around real-world learning opportunities.

Collaborative problem-solving defines learning as exploring open questions in the company of other interested inquirers. Participants in collaborative problem-solving cultures work together to coordinate inquiry toward solving unknown questions, distributing knowledge across the community, and then specifying the next set of questions on the horizon.

School leaders interested in providing opportunities for students to engage in collaborative problem-solving can turn to citizen science. Citizen science communities coordinate engagement in basic science research by connecting experts who set the terms of the inquiry with amateurs who collect, and sometimes analyze, data to address the question. There are thousands of participants of all ages engaged in hundreds of citizen science projects – ranging from bird census data collection (<http://eBird.org>) to planet mapping (<https://www.planethunters.org>) and from protein folding (<http://foldit.org>) to Zika viral infection tracking (<http://www.citizenscience.us/imp/>). School leaders interested in building collaborative problem-solving into their schools could consider working with teachers and community members to integrate citizens-science projects as opportunities for learners to engage in collaborative problem-solving.

Circulations describe how knowledge and relationships flow through interest-based communities. Schools, of course, are places where knowledge and relationships readily circulate. However, they are also bounded by place and limited to the kinds of expertise resident in the institution. Virtual circulation networks allow

members to access knowledge and build relationships anywhere. Participants who engage in multiple networks learn how to interact with people from different backgrounds and interests and can come to acquire new interests through joining a wider range of networks. Circulations have across-network benefits as well. Participants in multiple networks can bring solutions from one community to address the problems of other communities (for a discussion of how circulations in knowledge communities spark innovation, see Johnson (2011). *Where good ideas come from*. New York, NY: Riverhead Books).

Most people already participate in thriving circulation networks. Bringing some of these networks into schools can help to expand the boundaries of school-based networks. Pinterest, for example, has been co-opted by millions of teachers as a professional development and lesson circulation network. Teachers from around the world use Pinterest to find and exchange instructional resources. When teachers pin a board to their collection, this opens an opportunity to learn about everyone who pins on the new board and allows teachers to expand their professional network beyond the school community. School leaders interested in expanding circulations within the school can consider leveraging communities like Pinterest to extend the reach of the school network.

Affiliations, expressions, collaborative problem-solving, and circulations provide design guidelines for school leaders to infuse existing school communities with new opportunity. Leaders can get a head start by experimenting with robust, ready-made participatory cultures that already include millions of learners engaged in self-sustaining communities. However, building on this potential will require school leaders to expand the distribution of leadership beyond the range of conventional actors within the school. Consider, for example, how a community like Pinterest challenges the control of professional learning from a school-based leadership perspective. Distributed leadership networks that take advantage of new media communities will need to rethink the boundaries of the school and what counts as an educational resource.

Conclusion

A distributed leadership approach to technology leadership describes the tasks and the tools necessary to support teaching and learning in schools. In the first part of this chapter, the discussion considered the key tasks and social distributions of practice involved with implementing technologies that support contemporary standards-based learning practices in schools. In the second part of this chapter, the discussion highlighted possible communities and practices that leaders might use to bridge the learning affordances of entertainment and social technologies into the lives of teachers and learners in schools. Schools need twenty-first-century leaders who can work in both worlds to build single, coherent vision around the tasks that matter in using technology to guide teaching and learning.

Fortunately, there are robust models available to guide leadership practice toward this coherent vision of integrated technology systems. The connected learning framework (Ito et al. 2013), for example, is a collaborative research and development project

that brings together academic, social, and recreational computing into a vision of future schooling. Mimi Ito and her colleagues define connected learning in terms of:

- *Peer-supported* environments that allow colleagues to interact around contributing, sharing, and responding to their work
- *Interest-powered* spaces that bring together members who share a passion for learning around a common topic
- *Academically oriented* initiatives that guide learning toward outcomes and that count toward advancement in formal education settings
- *Production-centered* spaces that provide access to the kinds of tools that allow making and expression as evidence of learning
- *Openly networked environments* that draw on technologies for assessment, tracking performance, and supporting collaborative and productive work in locally designed information ecologies
- *Increasing accessibility to knowledge and learning experiences* that create pathways to the resources and relationships that support collaborative inquiry

Blending social, interest-based, and academic goals into a common learning space provides a model for technology leaders to connect learning across the organization to advance opportunities for all learners.

Of course, drawing the potential of both contemporary learning technologies as well as new media technologies presents a significant reframing of the work of technology leaders in schools. The expansion of this work requires formal technology leaders to work with colleagues to form networks of professionals who can advance the potential of learning technologies across the organization.

- At the school level, leaders need to create cultures that permit educators and learners to adapt the power of new technologies to existing practices.
- Special educators, school psychologists, and data analysts need to explore information resources that can fit technologies to learner needs and to assess how new tools advance learning outcomes.
- Educators need access to the variety of tools that can form both standards-based and new media learning environments.
- Learners and families need guidance on how to integrate learning tools available outside of schools into the everyday work of schooling.

School leaders are responsible for assembling technology environments that improve teaching and learning. The distributed leadership perspective focuses attention on the key tasks of this work, which involve bringing together the tools for instruction, assessment, creativity, and interaction into a common space so that all teachers and learners can get access to high-quality and high potential learning environments. Models like participatory cultures or connected learning, as described in this chapter, can provide a framework to guide the new work of school technology leaders to name the tasks and to coordinate the work of leadership at multiple levels in order to fulfill the promise of contemporary technologies for learning.

Abstract

This chapter addresses how school leaders can support teachers' professional learning and technology integration through a learning design perspective. Through this perspective, teachers engage in sensemaking to enact policy through teaching and learning. This can afford an authentic and contextualized approach

to teachers' professional learning. To do this it is necessary for school leaders to create a culture of learning and experimentation. School leaders can do this through fostering teachers' engagement in contemporary professional learning, such as developing personal learning networks and communities. These can be online or face-to-face in local schools, or a mixture of the two, formal or informal, and structured or unstructured. The chapter highlights that professional learning should be flexible and personalized to teachers' contexts. This is increasingly possible as teachers have access to diverse networks and communities, which support engagement with a wide range of professionals, resources, and experiences that may not be available in local schools. The chapter concludes with recommendations on how school leaders can employ a learning design perspective to create this includes opportunities for teachers to make sense of technology integration and experiment and continuously learn to support digital technology use in their school context.

Professional learning · School leadership · Culture of experimentation · Learning design process · Technology integration

Introduction

Since the 1980s, availability of digital technologies in schools has consistently increased, but integration in teaching and learning continues to be inconsistent and not well understood (Perrotta 2013). This issue has been attributed to the complexity of integration and solutions being difficult to identify (Tallvid 2014). To better understand and improve technology integration, Educational technology research has tended to focus on factors of teacher practice. Specifically, teachers' level of confidence with and knowledge of information technologies (IT) and how school leaders guide teachers in technology use have been seen as ways to improve technology integration. As a result, significant federal and state educational resources have been put toward developing both teachers' professional learning and school leadership, but only minimal gains in improving technology integration have been observed (Ertmer and Ottenbreit-Leftwich 2010; Howard and Gigliotti 2016).

In this chapter, we consider a shift in the "problem" of technology integration to focus on how school leaders can support teachers' professional learning and technology integration through a learning design perspective. Usually, teachers' technology-related professional learning is viewed from the perspective of professional development about technology integration (Salomon 2016). A more authentic approach is to consider a *learning design* process through which teachers engage in sensemaking to enact policy through teaching and learning (Cobb and Jackson 2012). When teachers are engaged in a learning design, or sensemaking, process, they are evaluating, selecting, and integrating various resources and strategies to address policies, school expectations, and learning goals. This process

of sensemaking can be conceptualized as a space for teachers to identify where they may want or need support. It affords more authentic and contextualized learning, which is responsive to teachers' and students' needs. A design perspective is able to embrace the complexity of technology integration and bring to the fore the interdependences of leaders' and teachers' roles in improving IT integration.

A design perspective is implied in key leadership functions of setting directions, developing people, and redesigning the organization (Louis et al. 2010), which encompass the numerous questions about how leaders might facilitate teachers' learning design processes. It has become increasingly difficult for school leaders to create a coherent and consolidated approach to professional learning to support and improve digital technology integration. In the current digital landscape, it is possible for teachers to access a wide range of opportunities, locations, resources or networks, in formal, informal, and/or independent spaces and networks (Jones and Dexter 2014, 2016), such that professional learning may be structured or unstructured, include face-to-face and online contexts, and be accessed from a range of resources that may not be visible or accessible to others.

In this chapter, we first explore some of the complexities of teachers' professional learning and technology integration design, the implications of these complexities in teachers' learning, and the role of school leadership in developing a school culture to support professional learning. This is followed by a discussion of the range of contemporary professional learning options and how different approaches facilitate teachers' technology-related learning and, finally, some consideration about how school leaders can foster contemporary professional learning and build up a culture of experimentation in schools to support technology integration.

A View of Technology-Related Professional Learning

Complex and wicked problems can be understood as those involving a large number of variables, which exist in dynamic, contextually bound, and interdependent relationships (Morrison and van der Werf 2016). These problems are enduring and often not easily solved. It is known that the classroom level, specifically teachers' practice, has the greatest effect on student learning (Muijs et al. 2014), but this relationship is complicated. A learning design perspective can bring out the complexities teachers experience when engaging with school and other educational policy: how, what, and why they are expected to change their practice. Teachers' confidence employing digital technologies can be addressed through more authentic and collaborative "on-the-job" professional learning (Zhang et al. 2017) and improved access to effective professional development (Ertmer et al. 2012). To support these two aims, school leaders should develop a culture of experimentation and learning to encourage teachers' use of ITs in the classroom (Howard and Gigliotti 2016). School leaders can then provide the necessary appropriate support and resources to facilitate technology-related change. To do this, it requires an understanding of the current landscape of teacher learning and technology integration.

Professional Development Versus Professional Learning

The terms *professional development* and *professional learning* are often used interchangeably, but we argue that they involve very different experiences for teachers, each with different roles in technology-related teacher change and implications for school leaders to support teachers' change processes. *Professional development* is used to connote the typical teacher learning experience: related to practice, often structured as a single session workshop with no follow-up and often leader-directed, but it may be online, blended, or face-to-face in or outside of the school setting. Traditionally, the most common form of professional development is the formal workshop, which includes institutes, courses, conferences, and other forms of training to acquire a skill or knowledge in some area (Desimone 2009).

In contrast, *professional learning* is used here to connote an active, collaborative, iterative, and ongoing process based on a teacher's personal interests, professional goals, and sociocultural contexts (Desimone 2009; Wei et al. 2009). Opfer and Pedder (2011) describe professional learning as a holistic approach which may include multiple systems: the individual teacher, e.g., their beliefs, personal experiences, and how these are enacted in classroom practice; the school, e.g., the context and support for teaching and learning, cultural beliefs, and norms; and the activity, e.g., learning activities, tasks, and practices in which the teacher participates. Jones and Dexter (2014) found that teachers learning to use technology may engage in formal, leader-driven workshops but then actively pursue additional learning experiences through informal or independent efforts, such as through collaborations with colleagues and pursuing resources beyond their school, because these other modes offer different affordances for their learning.

While technology-focused formal professional development has typically comprised workshops delivered in a traditional face-to-face format, they are increasingly delivered online and/or through a blended model, including both face-to-face and online components. Zhang et al. (2017) present an example of an increasingly popular blended professional development model, which has a strong focus on collaboration and social support over time. Teachers worked with a chief teacher and engaged in formal online group discussions, and they also designed, delivered, and video recorded a lesson in order to receive feedback. Results showed that teachers felt positively about the experience, but engagement and interactions in the online space were very limited. Participants felt constrained by time, a common issue with formal professional development, and could not participate in discussions to the extent they desired. Interestingly, the researchers suspected that teachers were initiating additional interactions offline, which is common in blended professional development models (e.g., Chen et al. 2009) and an important point for school leaders to note. Teachers will naturally work across all available spaces, which suggests natural movement toward combining leaders- and teacher-directed formal and informal professional learning, as Jones and Dexter (2014) found. Were school leaders to facilitate and support this combined learning across online and offline communities, it would enhance an apparently natural approach teachers often use and take advantage of affordances of different modes of learning (Jones and Dexter 2016) in terms of flexibility, immediateness, and trust in asking a colleague while affording the deeper breadth of knowledge possible in an online space.

As technology has developed, professional learning has increased in online spaces. Trust et al. (2016) outline how teachers are moving to online professional learning networks (PLNs) to access professional learning resources specific to their needs, when they need support and expertise beyond their local school. This reflects increases in independent and informal learning. The flexibility of these modes is particularly effective when learning about technology integration, where teachers are negotiating different tools in a specific school context (e.g., Howard and Gigliotti 2016). Combinations of formal, informal, and independent learning reflect the complexity of technology integration learning, of which school leaders need to be aware to appropriately support teachers' technology integration and change.

Technology Integration

Two of the most commonly studied factors in relation to understanding technology integration have been teachers' use of digital technologies and technology leadership in schools (Vanderlinde et al. 2015). More recently, how students use digital technologies to support learning has become a more pressing issue (Zheng et al. 2016). Therefore, improving how teachers use digital technologies in teaching and learning is of great concern. This is reflected in the current International Society for Technology in Education Standards for Educators (ISTE Standards for Teachers 2017), which call for teachers to be a:

- Learner – continually growing their practice
- Leader – seek opportunities to support student empowerment
- Citizen – inspire students to positively participate in the digital world
- Collaborator – work with students and colleagues to improve practice
- Designer – create authentic and learner-driven activities and environments
- Facilitator – support learning with technology for student achievement
- Analyst – understand and use data to support student achievement

The above are considered essential ways teachers should engage with technology. Research has focused on the scope and quality of teachers' professional development opportunities to increase technology use and the above practices to foster modelling, to access higher-order thinking, and to design better learning experiences for students (e.g., Ertmer and Ottenbreit-Leftwich 2010). Broadly, many of the reasons why teachers have not engaged with digital technologies in these ways are, to a certain extent, well known, but not well understood. Reasons typically include lack of time to plan with the curriculum, relevance of ITs to curriculum, confidence in using digital technologies, lack of support from leaders, and access to appropriate professional development (e.g., Howard and Thompson 2016), but teachers' values and beliefs are among the most significant factors (Ertmer et al. 2012). Tondeur et al.'s (2017) meta-aggregative review of qualitative evidence synthesized five key points about the relationship between teachers' pedagogical beliefs and technology use. First, the relationship between pedagogical beliefs and technology integration is bi-directional. Beliefs lead to actions, which can reaffirm beliefs. Second,

pedagogical beliefs can also act as barriers to technology integration. This is often in the form of beliefs about lack of time, a focus on testing, lack of relevance in learning, etc. School leaders should take steps to identify and understand teachers' pedagogical beliefs and identify how these may fit with policy and school expectations of technology integration.

The third point highlights how school leaders can begin to take action to support integration. The research shows, once beliefs have been identified, it is necessary to address the multidimensional and even contradictory relationship among those beliefs and how this may affect integration (Tondeur et al. 2017). This can begin to make visible the complexity of teachers' beliefs, which can help school leaders identify which are the most pressing and need to be addressed in relation to professional learning. This leads to the final two points which highlight for school leaders that working with a better understanding of these beliefs can facilitate creation of a more supportive school context for professional learning. In the following sections of this chapter, we explore how school leaders may better support technology integration and learning through supporting teachers' adoption of a learning design perspective.

Understanding the Complexities of Professional Learning and Technology Integration

Engaging in flexible, accessible, and personalized professional learning supports teachers to adapt their teaching and technology integration in response to the rapidly changing social, cultural, and economic environments in which they and their students live and work (Desimone et al. 2013). While digital technologies have been heralded as a way to increase student engagement and achievement, they are also increasingly considered a critical component of teachers' professional learning. Given the importance of authentic and personalized experiences when teachers are learning about the integration of digital technologies, technologically supported professional learning provides the opportunity to "learn to use and use to learn" (Karpova et al. 2009, p. 35). In this section, we consider the complex nature of technology integration and professional learning and how it is shaped by new contexts, tools, and reforms – elements largely shaped by school leaders. Given that effective technology integration depends on intensive, accessible, and ongoing professional learning, it requires the support of school leaders to be successful. By grounding the discussion in a learning design perspective, school leaders can support teachers' sensemaking of technology integration expectations and, ultimately, change.

A Focus on Learning

Drawing on the concept of learning design, Cobb and Jackson (2012) outline three aspects of thinking about educational policy and school expectations that school leaders can employ to help teachers make sense of possible changes in their practice.

They propose that policy should be considered from the perspectives of what, why, and how. The *what* is identifying teaching practices that will support desired learning goals related to a policy or expectation. The *how* includes supports for learning specified in the policy or expectation. The *why* encompasses the rationale for support provided to fulfil the learning goals. "Policy" can be understood on a number of levels, from department and state mandates to school expectations and goals. In this discussion, we use it to mean any expectation on teachers that they will change practice and integrate technology in their classrooms.

By engaging from a learning design perspective, technology-related change can be understood from within teachers' subject matter and teaching and students' learning in relation to IT use. Spillane et al. (2002) assert that conventional accounts of why reforms fail do not consider the complexity of teachers' sensemaking processes. Critically, in the current landscape of technology integration, teachers are faced with technology-enhanced ways of learning that are unfamiliar and often challenge existing conceptions of teaching and learning. While authentic professional learning is considered highly complex, Ching and Hursh (2014) argue that "teachers' attitudes, intents, and confidence are still the most powerful factors influencing technology integration . . . even in the most supportive environments, teacher decision making is still key" (p. 73). This reflects Tondeur et al.'s (2017) finding that educational change initiatives requiring new teaching strategies must fit with teachers' existing conceptions of student learning.

In the past, connecting change initiatives, such as new educational policy, with teachers' motivations to learn has been difficult, particularly if monetary incentive is absent and participation is voluntary (Gorozidis and Papaioannou 2014). This can be minimized by approaching technology-related change from the learning design perspective. Engaging in sensemaking of policy from this perspective can provide the space for teachers' to process prior knowledge, values, and emotions as well as social, organizational, and historical influences on their interpretations and decision-making related to change (Allen and Penuel 2014). Moreover, it is important to identify that teachers participate in different groups within a school culture, some formal and some informal, that will each contribute to teachers' sense of belonging, values and beliefs, and motivation to learn and engage in change. Understanding of the complexity of school culture is particularly important as school leaders negotiate how they engage teachers in the use of new IT and changes in the learning environment.

The Question of Capturing Professional Learning

Professional learning, broadly conceived, extends beyond government-endorsed workshops or school-based initiatives to include self-directed and self-regulated (informal and independent) activities, which are often invisible to accrediting organizations and schools. A report from the International Academy of Education (Timperley et al. 2007) has argued that teachers have "very diverse professional learning needs arising from the specific demands that their particular students place

on their teaching skills” (p. 12) and that these needs cannot be readily met by short-term, skills-focused professional development provided by an outside expert. Specifically, online and/or offline informal networks are a significant part of teachers’ wider social systems and professional learning, and they offer teachers mentorship opportunities inside and outside of their local schools.

There are generally four motivations for teachers to participate in professional learning: gaining new skills to improve classroom practice, higher salary, career promotion and/or maintenance, and career mobility (Stout 1996). Initiatives focusing on technology integration tend to relate to the first of these motivations – gaining new skills to improve practice. However, if a teacher believes that they must be the sole expert in the classroom, they may be reluctant to integrate new digital tools or allow students to exercise agency related to technology. Teachers often feel shame if they are not willing or are uncomfortable to use digital technologies in both the classroom and their own learning and may be reluctant to ask colleagues at their school for support (Howard 2013). Seeking online support through a loose network of peers offers a safe place to explore. Moreover, for teachers in remote areas of the world, online contexts offer tremendous potential for professional learning, including reflection, communication, and collaboration. Not only does this afford access to new strategies, activities, and perspectives, but it also provides a space to share fears or frustrations that they are not comfortable with expressing to immediate colleagues (Jones and Dexter 2016; Trust et al. 2016).

The core features of effective professional learning experiences for school leaders to consider are content, duration, and active learning, which repeatedly emerge as aspects of teacher learning that improve teaching practice and promote student achievement (Desimone and Garet 2015). Professional learning should address specific areas of teaching, such as pedagogy, and should be targeted at the correct level to be effective and relevant to teachers’ context. Activities need to occur for a sufficient duration, such as over the course of a school year, to allow enough time for implementation, evaluation, and reflection (Desimone 2009). Contrasted with passive forms of professional development, such as attending a lecture, active learning is linked to more positive outcomes for teachers, and it is most effective when learning is embedded in authentic professional work (Darling-Hammond 2013).

School leaders can nurture professional learning opportunities by fostering an active culture of experimentation and professional learning. To create a culture of experimentation, school leadership should:

- Make clear that technology integration, learning, and change are important
- Commit to learning and change as a school
- Make learning, change, and experimentation social
- Celebrate success and failure
- Make change visible
- Keep plans for change current and active but also flexible and responsive to needs of teachers and the school

Throughout this process, leaders should make opportunities for teachers to use the learning design approach to make sense of the “what, how, why” of changes in practice (Cobb and Jackson 2012). They can do this in part through encouraging teachers to engage with and experience a range of professional learning networks. This may include joining pre-existing networks or creating their own system of colleagues. These may include interacting with colleagues face-to-face, online, or a combination of both. Through these, teachers can be motivated to experiment with new practices and are more likely to persevere in learning (Trust et al. 2016). Where possible, it is vital that leaders involve teachers at each phase of implementation of a change initiative, from initial conception to classroom implementation. In a technology-related change process, this approach can afford important learning experiences for teachers as they negotiate change and design problems of technology innovation such as how new IT tools are used to foster new forms of learning, which may not be familiar to teachers. Leaders actively supporting teachers' engagement in processes of negotiating professional learning, through experimentation with new technologies and practices, may result in potentially less misinterpretation of learning goals and greater commitment to achieving desired school change.

With technology integration, a one-size-fits-all approach to professional learning is not effective. As noted by Tondeur et al. (2017), professional learning needs to be closely aligned with teachers' beliefs about IT in learning, learning objectives, students' needs, and school resources. When teachers participate in self-directed (informal or independent) professional learning, they may engage with the wider education community beyond their school on these issues; thus leaders' support and guidance need to be provided to keep the focus on the school's students' learning and learning goals (Jones and Dexter 2016). The difficulty is how, given the sheer range of options, contemporary learning processes are captured and identified so other teachers and school leaders can all benefit from new strategies and learn how to engage in sustained professional learning. To consider this question, we take a look at some of the specific ways teachers are currently engaging in formal, informal, and independent professional learning.

Considering New Technologies, Tools, and Contexts

In the context of technology integration, ITs can both facilitate teachers' professional learning and support students' learning. With the growing accessibility of social media tools and online spaces, and the recent popularity of informal community-based meetings, teachers are engaging in professional learning in a variety of new ways. Technology, in this sense, is often related to both the product and the process of professional learning. These approaches are rapidly gaining momentum at a grassroots level. This is a new area of research, but some recent work has offered case studies considering specific popular online contexts, including Facebook, Twitter, Instagram, and Pinterest (e.g., Biddolph and Curwood 2016; Carpenter and Krutka 2015), as well as within community-based meetings, such as TeachMeets

(e.g., Esterman 2013), in an effort to understand the different ways teachers interact on- and offline, and how these spaces afford professional learning. A common finding across the body of literature of note for school leaders is that teachers engage and interact in these spaces with educational purposes to support their practice. An underlying principle guiding teachers' choices in professional learning is the capacity to interact with other teachers.

Sustained interactions can be referred to as professional learning networks. There is no clear definition of a professional learning network (PLN), but they can be understood as "new spaces in which teachers may learn and grow as professionals with support from a diverse network of people and resources" (Trust et al. 2016, p. 17). Social media tools and online spaces offer teachers the opportunity to engage in PLNs relevant to their interests, aimed at improving their practices, and situated within a wider community of educators. Trust et al. (2016) highlight how teachers use a range of digital technologies and offline approaches. For example, one teacher states that they "participate in Twitter chats, read blogs, reflect and write/attend conferences and courses, talk to colleagues" (p. 20). Curwood and Biddolph (2017) found that English teachers using Twitter as part of their professional learning also engaged in reciprocal learning as they shared resources and ideas. Particularly for teachers in rural and remote areas, the availability of flexible and accessible online resources and communities is significant, as they may not otherwise have high-quality professional learning resources.

Digital PLNs, in this sense, offer both a pedagogical tool as well as a professional learning community (Ertmer et al. 2012). On a daily basis, teachers engage in problem-solving design issues relating to technology and pedagogy. They ask questions, collect multiple sources of data, engage in sensemaking processes, implement new practices, and consider how technologies and their teaching directly impact student learning. The natural affordance of PLNs as a sensemaking tool lends itself to the learning design perspective to support change. Research has in fact shown that teachers engaging in PLNs feel more empowered to ask questions in a change context (Ertmer et al. 2012). However, school leaders must also provide teachers with the time, space, and tools to engage in self-directed and digitally mediated professional learning (Jones and Dexter 2014, 2016). As outlined earlier, this approach encourages teachers to explore, experiment, and take risks to make sense of how digital technologies can support learning outcomes. Leaders providing time and space for teachers' learning and experimentation reaffirm to teachers that their learning is valued. Some specific strategies for school leaders to encourage may be engaging in action research, collaborating with colleagues and students, and/or joining an established online community. These practices can help teachers make sense of their beliefs about IT and about the relationships among teaching, learning, and technology. However, some other considerations must be made to implement a learning design perspective of change, supported by a culture of experimentation, and to foster sustainable technology integration at a school level.

Adopting Real Teacher Learning in Schools

Having established that technologically-focused professional learning is ideally constituted by an active, collaborative, authentic, and ongoing process based on a teacher's personal beliefs, professional goals, and contexts (Desimone 2013; Wei et al. 2009), we now turn our attention to the question of how teacher professional learning, specifically use of PLNs, can be supported in school settings. To do this, school leaders need to negotiate a range of tensions relating to learning about, with, and through technology, model inquiry, take steps to create a culture of experimentation conducive to teacher learning, and support innovative technology integration (Jones and Dexter 2016).

Learning About Technology: Some Tensions

Teachers' technology-related learning often features the language of "integrating" IT into teacher practice. Over the decades, authors writing about professional learning have argued that "it's not about the tools, it's about the pedagogy" and "pedagogy before technology." More recently, it has been argued that digital technologies should support meaningful, twenty-first century teaching and learning, "which enables students to construct deep and connected knowledge, which can be applied to real situations" (Ertmer and Ottenbreit-Leftwich 2010, p. 257). The intent of these declarations has been to counter previous leanings toward technological determinism, by positioning digital devices and online materials in a way that they may be used meaningfully to support learning. This also emphasizes the importance of "avoiding simplistic claims about impact, effect and technical causation" (Oliver 2011, p. 382). The aim is to have teachers, as part of sensemaking, consider, for example, why they should bother getting students to use a device for personal note-taking when a pen and paper would easily suffice and perhaps be more efficient.

Oliver (2011) acknowledges that moving beyond technologically deterministic accounts of technology in learning "does not mean [believing] that technology has no properties" (p. 382). IT integration objectives can ignore critical realities for teachers' professional learning, such as ways in which technology practices are changing the learning environment, including:

- Sharing learning in public spaces
- Collaboration in on and offline spaces
- New dynamics between students and teachers
- New digital and media literacies

With teachers' values and beliefs about digital technologies in learning being a key barrier to engagement with professional learning (Ertmer and Ottenbreit-Leftwich 2010), the tension between acknowledging the impact of technological change and contexts in which change occurs and learning is constructed is one that

requires informed and reflective navigation by teachers and school leaders. Using the learning design framework, school leaders can work with teachers to address the “what, how, and why” of technology-related change. As part of this process, robust discussions about the relationship between technology and pedagogy should be encouraged, with a strong focus on learning goals. This should form part of making technology-related change as important, in a culture of experimentation and professional learning.

However, the extent to which external frameworks can be applied at the school level to frame teacher learning is another point of tension for educators. For example, conceptual frameworks such as the technological and pedagogical content knowledge (TPACK) model (Mishra and Koehler 2006) are one source that educators might look to for guidance on how to conceptualize the relationship between technology and pedagogy. The TPACK model can provide some explanatory potential in relation to teachers’ use of technology. However, in regard to professional learning, there are problems with how the TPACK model compartmentalizes teachers’ professional knowledge and IT knowledge and makes unnecessary distinctions made between pedagogical and content knowledge. Placing these components into categories presents an “attempt to reduce the complexity of education phenomena, and which are too often used to standardize practice” (Bulfin et al. 2016, p. 122). The tension that school leaders face between the explanatory and reductive powers of frameworks and standards is an area that requires attention in schools seeking to grapple with the complexity of teaching, learning, and technology integration (Phelps and Graham 2010).

Further, broad application of frameworks or highly structured reform in schools has the potential to be in direct conflict to the flexibility and personalization of professional learning. Critics of standards-based education reforms have expressed concern about compliance mechanisms and professional standards inhibiting inquiry-based learning by imposing control and prescription on teacher professional learning (Parr 2010). A prescriptive approach is likely to erode the professionalism and agency of teachers by intensifying teachers’ work, emphasizing compliance and conformity, and reducing teacher control. However, this is not to say that frameworks or standards of practice do not have a place in professional learning. School leaders would want to consider how frameworks align with existing school strategic goals and initiatives. School leaders should discuss adoption of an explicit framework to support technology integration and change with their teachers, to determine if particular tools are appropriate for their beliefs about integration, teaching context, and learning goals (see also McLeod, ► [Chap. 35, “Technology Integration, Leadership, and Organizational Support Frameworks for Instructional Improvement with Information Technology,”](#) this volume).

Models for Building Capacity and Personal Learning Networks

The disruptions caused by theoretical and practical tensions provide opportunities for teachers and school leaders to have conversations, question pedagogical assumptions, and think critically about professional discourses and learning. However, schools

require a culture of trust that is open to risk and experimentation for such conversations to occur and lead to professional learning (Howard and Gigliotti 2016). Tensions relating to technology integration can be effectively negotiated in schools that are conceptualized as *learning organizations* (Opfer and Pedder 2011; OECD 2016), drawing on communities and networks as needed to learn individually and together.

The Organisation for Economic Co-operation and Development (OECD 2016) proposes an integrated model of schools as learning organizations. This model offers four transversal themes – trust, time, technology, and thinking together – underpinning these seven action-oriented elements (OECD 2016, p. 1):

- Developing and sharing a vision centered on the learning of all students
- Creating and supporting continuous learning opportunities for all staff
- Promoting team learning and collaboration among all staff
- Establishing a culture of inquiry, innovation, and exploration
- Embedding systems for collecting and exchanging knowledge and learning
- Learning with and from the external environment and larger learning system
- Modelling and growing learning leadership

These themes and elements highlight the values and processes that tend to be evident within schools that are transforming into a learning organization. This model constructs the learning organization as a broad community of practice, with student learning as the common learning goal and team learning promoted within the community around more specific areas of inquiry. A strength of the OECD model is that practitioners are acknowledged as existing within a socially situated environment – the school – but also explicitly encircled by a network of external connections such as parents, local community, and other schools in their network. The model highlights the importance of information flow between and beyond schools, which can be supported through the development of strong teacher PLNs, employing a range of learning resources. The range of resources and support structures available to teachers to support continuous, collaborative, and personalized learning should be promoted in the school as a valid and valued approach to professional learning. While individual teachers may participate in professional learning on their own, “access, support and encouragement to participate are heavily determined by the school” (Opfer and Pedder 2011, p. 393).

Further, the OECD model recommends that schools as learning organizations establish a culture of inquiry, innovation, and exploration. Such a culture of experimentation requires understanding the subcultures within a school and possible formal and informal leadership roles of those groups and networks (Howard 2013). Formal groups may be led by school principals and other administrators and assigned by disciplines, grade levels, or faculty room locations. Informal teacher-organized groups are more likely to be based on teachers' interests, values, practices, and beliefs about learning. How well school leaders are able to align formal and informal networks in schools will have implications for creating a culture of experimentation and learning. In both types of groups, leaders need to foster inquiry and experimentation.

An orientation toward inquiry and experimentation can empower teachers to take up professional learning that is in the service of contextualized and situated problems relating to learning goals. This supports the notion that technology integration is really about solving a learning or teaching problem. Identified leaders in both formal and informal networks can employ reflective questions to direct teachers in their cycle of design, enactment, and study to collect evidence of “what is going on” for their learners, producing design knowledge incorporating common examples, patterns, and principles (Könings et al. 2010). Such approaches expect educators to operate as experts and knowledge producers. As part of fostering a culture of experimentation, school leaders would encourage and support teachers to develop robust PLNs as resources for this work. Through this mechanism teachers can access a wide range of international resources to identify and address questions in their technology-related learning designs and problem solving.

It is also important for school leaders to recognize the costs of technology-related professional learning. Trust et al. (2016) argue that “cognitive, social, affective and identity needs” (p. 16) must all be met in order to develop “whole teachers.” Some research in the area of teachers’ professional learning describes how acquiring knowledge of technology happens in relation to developing discipline/subject expertise (Ertmer and Ottenbreit-Leftwich 2010). This intersection of disciplinary concerns and technological solutions is important, and it presents a space where frameworks, such as TPACK, can be useful in conceptualizing implications and effects of these intersections. There is also an important intersection between teachers’ personal and professional lives in professional learning (Cameron et al. 2013). The impact of personally significant events on teachers’ learning trajectories can shape their professional needs. PLNs can provide the specific support needed for teachers’ learning at various career stages and the increased ability to choose learning opportunities with direct relevance to classroom pedagogy.

To complement teachers’ individual PLNs, school leaders can provide space for teachers to develop formal professional learning communities (PLCs) within schools, with a focus on providing high-quality learning opportunities and integrating informal professional learning. Dexter et al. (2016) found that these different types of opportunities within learning communities can be fostered by school leaders. In fostering PLCs, school leaders should keep in mind the role of different community configurations. Diverse learning communities will have distinct characteristics, which may offer different affordances for technology-related professional learning. Vangrieken et al. (2017) identified three types of communities: formal, member-oriented with a preset agenda, and formative teacher communities, additionally commenting on the impact of top-down or bottom-up realization. Informal learning that is initiated by the teacher, rather than being imposed from above, is reported as more oriented toward specific learning needs as questions and directions arise from community members (Vangrieken et al. 2017) and thus could be better suited for technology-related learning for specific learning goals. In a digital and networked culture, the potential for locating new communities, shifting identities, and accessing current information is vast.

School leaders can create bridges to those possibilities through the opportunities they create in formal learning, where they “model high-quality, informal, reflective practices and support the sharing of independent learning” (Dexter et al. 2016, p. 1202). While online communities may be difficult to observe or measure, school leaders can actively bring the work teachers do as a result of online interactions back to the school setting to be reflected upon and discussed. To insure that flexibility and personalization are part of teachers' PLNs, school leaders must focus on valuing both online and offline communities for professional learning. As previously outlined in this chapter, teachers are already using digital technologies and community-based approaches to support professional learning and develop communities. By encouraging PLCs, school leaders can create a priority in the school culture for teachers to consciously expand their PLN, with an aim to include both virtual and everyday physical environments and interactions. In doing this, they can increase the diversity and possible number of “weak ties” available to teachers that can be accessed for information, actively building their PLN, and to tap into information flow.

However, some teachers may need support in employing this type of professional learning strategy. To support teachers, simple online strategies can be shared across the school, such as employing the use of event or topic hashtags, as seen in TeachMeet events (Esterman 2013) and Twitter chats (Biddolph and Curwood 2016). These are already overtly used by some schools and professional associations to create event back channels for sharing information and reflections with a wider network. Teachers are typically quite good at engaging physically. Fostering a mixed approach to learning, through combining online with the more familiar in-person networks in a school, establishes the cultural value of engaging and learning online. Through this approach developing strategies for information seeking, problem-solving, and reaching out into teaching and learning networks is valued. Importantly, school leaders' practices should encourage teachers' work improving learning, refocusing technology integration, and harnessing ITs to be in the service of learning.

Conclusion

As Zheng et al. (2016) state, “as activity shapes the value of tools, tools simultaneously shape the nature of activity” (p. 2). Researchers have called for a refocusing of technology integration, away from just using IT, to instead be grounded in learning. If the success and effectiveness of technology integration are going to improve, school leaders need to support and encourage teachers to conceive of technology integration and change from a learning design perspective. Critical to this work is that teachers also engage in relevant professional learning and experimentation that support this aim.

As discussed, teachers are already engaging in professional learning. Learning happens through a range of formal, informal, independent, and on- and offline modes, which each have different affordances and support different interactions.

However, the question for school leaders is how to harness these different activities into a coherent approach to professional learning to improve technology integration. As a learning organization, school leaders can take an approach of embracing grassroots practices and the complexity of technology integration. Much of teachers' informal and independent learning is difficult to see and thus even more difficult for leaders to support across a school. Rather than focusing learning on any one tool or approach, the idea can be to embed a priority of learning and networking within an identified school change or policy related to technology integration. In particular, prior research proposed the idea that new classroom innovations, including technology integration, will be more effectively executed by teachers if they are included in a design process and provided with time to plan and reflect on the process. School leaders can involve teachers in technology-related program and design decisions, problem-solving, and troubleshooting at individual and school levels. They can do this by supporting teachers to work collaboratively, drawing on PLNs, and working online and offline to develop technologically integrated learning designs, foster inquiry, and a culture of experimentation around change and learning. Teachers are more likely to dedicate their time and energy in making the planned changes, from which they can control and directly benefit, and changes are likely to be more sustainable.

While the complexity of technology integration has traditionally made it difficult to affect change across school organizations, this chapter has outlined ways in which school leaders can address technology-related change from a learning design perspective. The aim of this perspective is to help teachers make sense of changing their practice and prioritize a culture of experimentation and learning through digital technologies. The most critical component of this approach is continued dialogue between school leaders and teachers and to continue engaging in the “what, how, and why” of technology-related change. The one constant of technology integration is that the technology will change, its role in learning will shift, and how it is used will be adapted. By school leaders and teachers always returning to a learning design perspective focused on what is the change, how are we changing, and why, it is possible for a school to keep pace with how they are using digital technologies to support learning in their context.

Abstract

Leaders for IT can use integration, leadership, and organizational support frameworks to guide their planning or assess current conditions. This chapter introduces a number of useful frameworks for leading IT, provides a rationale for their use, and suggests how to put them into practice.

Keywords

Leadership · Technology integration · IT · Administrators

An increasingly important but often challenging responsibility of school leaders is the need to facilitate effective IT integration within their school organizations. Compounding the challenge is the fact that preservice preparation programs and in-service professional development initiatives infrequently pay robust attention to school administrators' learning needs in this area (Dexter et al. 2016; McLeod and

Richardson 2011). Fortunately, school leaders have a number of different IT integration, leadership, and organizational support frameworks available to them to help guide their instructional improvement work with classroom educators and students. School administrators and instructional coaches will find that different frameworks have different purposes and thus should be used in ways that best align with organizational needs and contexts. The sections that follow describe some of the available frameworks and offer suggestions for how they might be utilized by principals and other instructional leaders to improve building- and classroom-level IT integration.

What Are *Learning and Teaching* Frameworks for Instructional Improvement with IT, and Why Use Them?

The dominant IT integration model utilized by instructional technology researchers and faculty members is the Technological Pedagogical Content Knowledge (TPACK) framework. Extending the work of Shulman (1986), Mishra and Koehler (2006) noted that optimal IT integration occurs when educators operate at the intersections of their pedagogical, content, and technological knowledge. TPACK is useful as a mental model but is relatively ambiguous regarding guidance for instructional design and also is fairly unknown by PK-12 educators. The International Society for Technology in Education (ISTE) standards for students (ISTE 2016), teachers (ISTE 2017), IT coaches (ISTE 2011), and administrators (ISTE 2009) are more visible to PK-12 practitioners and are attempts to delineate the IT integration understandings and skill sets desired of educators. Similarly, the United Nations Educational, Scientific, and Cultural Organization (UNESCO) has outlined IT competencies for teachers (2011).

Taking a slightly different approach, Dexter's (2002, 2005) Educational Technology Integration and Implementation Principles (eTIPs) offered three principles that teachers should use to guide their instructional decision-making when considering the use of IT in the classroom. They were based on the premise that teachers acting as instructional designers must consciously plan for the use of the technology if it is to support student learning. The first principle is that learning outcomes should drive the selection of IT. The second is that IT should be integrated only when it adds value to teaching and learning. The third principle is that IT should assist in the assessment of learning outcomes; for instance, by making students' thinking visible or allowing educators to capture versions of students' work during its progress.

Moving beyond general principles, mental models, or standards documents that articulate stocks of knowledge or skill that educators should possess, three other frameworks have taken a hierarchical or staged approach to the assessment of educators' IT integration efforts. Puentedura's Substitution Augmentation Modification Redefinition (SAMR) framework (2006) – arguably the most well-known model in PK-12 circles – postulated that, at the Substitution level, technology merely serves as a direct tool substitute, with little to no functional change. At the Augmentation level, technology begins to offer functional improvement, and at the

Modification level, technology allows for significant task redesign. At the top of the hierarchy, Redefinition, technology allows for the creation of new, previously inconceivable tasks. Many schools are attempting to use the simple SAMR continuum to help teachers move their IT integration efforts beyond technological replication of traditionally-analog learning activities, instead striving to utilize the new affordances of digital learning tools to engage in instructional work that would be difficult or impossible without IT. The SAMR framework is similar to earlier work done by Hughes (2005) and Porter (2001). Hughes et al. (2006) postulated a three-stage transitional framework of Replacement, Amplification, and Transformation (RAT), rooted in both conceptual research and the authors' analyses of classroom observations and teacher interviews. Similarly, Porter's Literacy, Adapting, and Transforming (LAT) continuum noted that, at early stages, teachers are rooted more in IT tool learning or replicative learning but then hopefully move into more adaptive and transformative uses. Both the RAT and LAT frameworks collapse the often confusing middle two categories of SAMR (Augmentation and Modification) into a single, transitional stage (Amplification or Adapting) between replication and transformation.

Two popular IT integration frameworks from the United States, the Florida and Arizona Technology Integration Matrices, added a second dimension for educators' consideration (Arizona K12 Center 2010; FCIT 2007). The horizontal axis of the matrices resembles the three- or four-stage continuums of the SAMR, RAT, or LAT frameworks but instead is broken into five integration levels labeled as Entry, Adoption, Adaptation, Infusion, and Transformation. The vertical axis of the matrices articulates characteristics of the learning environment. These characteristics represent descriptions of students' learning that can be enhanced by educators' IT integration efforts:

- *Active* – students are active users, rather than passive recipients, of IT.
- *Collaborative* – students use IT to collaborate with others.
- *Constructive* – students use IT to construct deeper understanding and share with others.
- *Authentic* – students use IT to engage in meaningful, real-world work.
- *Goal-directed* – students use IT to plan, organize, and reflect on their learning.

An educator thus could use the matrix to assess where she is along each of the characteristics and decide, for instance, that she wanted to work toward the Infusion level of students' collaborative work rather than her present level of Adoption.

Several other frameworks have overlaid conceptions of student thinking and activity with IT integration. For example, Churches (2010) created a continuum labeled Bloom's Digital Taxonomy that attempted to identify IT tools and uses that correspond with the six levels of educational objectives identified in Anderson and Krathwohl's (2001) modified version of Bloom et al.'s (1956) original taxonomy. In Churches' framework, using IT tools for filming, animating, and blogging would be more likely to correlate with higher-order thinking skills, while using them for highlighting, searching, and bookmarking would be more likely correlated with

lower-order thinking skills. The Levels of Teaching Innovation (LoTi) framework from Moersch (1995) articulated a continuum of eight levels of teaching innovation: Nonuse, Awareness, Exploration, Infusion, Integration (Mechanical), Integration (Routine), Expansion, and Refinement. Higher levels of the continuum correspond with higher levels of cognitive complexity of student work. The LoTi levels also embed movement of student activities from teacher-directed and practice-based toward student-directed and problem-based (LoTi Connection 2016). Finally, Kimmons (2016) extended the RAT framework in his PIC/RAT model by adding a second dimension of student activity, ranging from passive to interactive to creative.

What Are Leadership and Organizational Support Frameworks for Instructional Improvement with IT, and Why Use Them?

While many IT integration frameworks are focused closely on classroom-level learning and teaching, some of the IT leadership and organizational support frameworks focus instead on building-level or system-level support structures. These frameworks are particularly relevant for school leaders because they recognize that IT-infused classroom activities are embedded within surrounding organizational contexts that can foster or impede the success of what happens between teachers and students. For instance, the Apple Classrooms of Tomorrow (ACOT) framework (Apple 2008) was created nearly a decade ago to help superintendents and principals think about systemic supports that foster effective classroom IT usage. The ACOT framework identified six design principles for “21st century” high schools: Culture of Creativity and Innovation, Relevant and Applied Curriculum, Informative Assessments, Social and Emotional Connection, 24/7 Access to Tools and Resources, and 21st Century Skill Outcomes. These design elements are intended to work in concert to formulate new conceptions of learning and teaching by modern schools and educators.

The ACOT framework explicitly embedded one of the more visible organizational support frameworks, the list of “21st century skills” identified by the Partnership for 21st Century Learning (2007). The Partnership created a famous “rainbow” diagram in which Core Subjects and 21st Century Themes; Learning and Innovation Skills; Life and Career Skills; and Information, Media, and Technology Skills constitute the core learning outcomes needed by 21st century students. In the framework, these core outcomes should be supported by appropriate and relevant Standards and Assessments, Curriculum and Instruction, Professional Development, and Learning Environments.

An additional organization-level view is the list of 14 “essential conditions” identified by the International Society for Technology in Education (ISTE 2000). According to ISTE, the organizational conditions necessary to effectively leverage IT for learning are Shared Vision, Empowered Leaders, Implementation Planning, Consistent and Adequate Funding, Equitable Access, Skilled Personnel, Ongoing Professional Learning, Technical Support, Curriculum Framework, Student-Centered Learning, Assessment and Evaluation, Engaged Communities, Support Policies, and a Supportive External Context. Similarly, a list of “essential conditions” was created by the North

Central Regional Educational Laboratory (Lemke 2002), those of Vision, Systems and Leadership, Effective Practice, Educator Proficiency, Access, and Equity.

In the United States, the Texas Education Agency took a different approach with its Technology Immersion Model (TIM), noting six critical – and primarily technological – components of effective IT immersion: Hardware, Software, Digital Content, Online Assessment, Technical Support, and Professional Development (Hanover Research 2013). The latter two components are more oriented toward the human side of the organization rather than the technical. Finally, the Future Ready Framework (U.S. Department of Education, Office of Educational Technology 2014; Alliance for Excellent Education 2015a) postulated that school districts must align seven key categories – or “gears” – in order to ensure successful digital conversions for “future readiness”: Curriculum, Instruction, and Assessment; Use of Space and Time; Robust Infrastructure; Data and Privacy; Community Partnerships; Personalized Professional Learning; and Budget and Resources. All of these gears must work together to enhance IT integration and robust student learning. Although they are configured and organized differently, all of these frameworks explicitly recognize that surrounding contexts have significant impacts on instructional success.

How Might School Leaders Use IT Integration and Organizational Support Frameworks?

School leaders have several options for utilizing these IT integration and organizational support frameworks. For instance, schools that wish to inform their organizational restructuring and professional development initiatives could use one of several assessments to gather data on their systems and staff. Older assessments include the enGauge survey (Lemke 2002) and the Learning with Technology Profile Tool (NCRTEC 1997). Newer diagnostics include ISTE’s Lead & Transform Diagnostic Tool (ISTE 2014), the Vision K-20 survey from the Software and Information Industry Association (SIIA 2008), the Clarity Technology and Learning surveys from BrightBytes (2010), the Future Ready District Assessment from the Alliance for Public Education (2015b), the Principals Technology Leadership Assessment (Anandan et al. 2005), or the School Technology Leadership Assessment (CANLEAD 2017). Schools then could align their findings, for example, with the ISTE standards and essential conditions, the TPACK framework, or the Future Ready Framework to assess organizational capacity and individual readiness for IT-related change efforts.

Zooming in closer to the classroom, the easiest – and probably most prevalent – mechanism would be for a school to utilize one of the basic continuums (SAMR, RAT, or LAT) to try and spark internal conversations about moving IT integration to be less replicative and more transformative of existing pedagogical practices. Many school administrators, instructional coaches, and technology integration coaches are doing this work daily, blending particular learning technologies into their instructional conversations as appropriate. Schools that find the relative vagueness of the continuums to be insufficient to guide their work could utilize one of the more specific frameworks, for

example, either the Florida or Arizona Technology Integration Matrix – or the LoTi framework – to add depth and context to their conversations.

Several researchers have created resources that help school leaders and classroom educators go even deeper in their implementation of the models and frameworks described here. For instance, Hofer and Harris (2015; see also Harris and Hofer 2009) have done extensive work to describe various grade-level and subject-specific IT-supported learning activities that support implementation of the TPACK framework. These instructional exemplars can help PK-12 educators more concretely visualize TPACK's potential influence on their instructional planning and design work and classroom integration. Educators possibly could use the Digital Bloom's Taxonomy alignment of digital learning tools to higher-order thinking skills in a similar manner.

Another resource that can be helpful to school leaders' IT integration efforts is the 4 Shifts Protocol (formerly trudacot) created by McLeod and Graber (2018; see also McLeod 2015). The 4 Shifts Protocol is intended to facilitate teachers' thinking about the instructional purposes driving their IT integration decisions. Educators are asked to reflect on and discuss sets of questions that are designed to help them shift their classroom lessons, units, and activities toward deeper learning, greater student agency, more authentic work, and richer IT infusion. Additionally, Hutchison and Woodward's (2014) Technology Integration Planning Cycle, which emphasizes seven key steps that classroom educators employ in effective IT integration, can help guide educators' thinking and practice. Finally, the online Educational Theory into Practice Software case-based learning platform (www.etips.info) allows school leaders and teachers to immerse themselves into rich, descriptive, electronic cases of school- and classroom-level IT integration (Dexter et al. 2008; Tucker and Dexter 2011). School leaders can practice applying key IT integration, leadership, and organizational support principles within "hypothetical but realistic K-12 school settings" (Tucker and Dexter 2011, p. 251) in order to improve their own IT leadership knowledge and skills.

Taken together, existing IT integration, leadership, and organizational frameworks can accommodate a wide diversity of school settings and leadership needs. IT leaders can use these frameworks – along with some concurrent assessments and implementation resources – to help further the IT-related instructional initiatives that are occurring within their schools and districts. School leaders that utilize these frameworks in thoughtful and purposeful ways for assessment and improvement should see meaningful and positive impacts within their school organizations.

Abstract

Design thinking is a solution-finding process that offers a user-centric approach to find new, previously nonexistent solutions to persistent challenges people face in the adoption and implementation of IT. This chapter explains what design thinking is, why it would be of use to leaders of IT, and how to put it into practice in the leadership of IT.

What Is Design Thinking?

Some call design thinking a creative problem-solving process (Liedtka et al. 2013). I think calling it a solution-finding approach is more accurate. IT leaders who practice design thinking are able to find new, previously nonexistent solutions to persistent challenges they face in the adoption and implementation of IT, and the solutions which they develop tend to stick. This is because design thinking is a process that integrates three key tenets of innovation success: “what is desirable from a human point of view with what is technologically feasible and economically viable” (Brown 2009, p. 3). It’s an appealing approach as it represents a set of tools which can be applied to a vast array of problems (Brown, 2011).

While there are several flavors of design thinking discussed in the literature (Boland and Collopy 2004; Brown 2009; Hasso Plattner Institute for Design 2010; Liedtka and Ogilvie 2011; Meinel and Leifer 2011), all have some central common features. For illustrative purposes, we’ll draw on an approach advocated by the Hasso Plattner Institute for Design (2010). The tenets are:

Empathize. Empathy is the foundation of design thinking (Hasso Plattner Institute for Design 2010). Design thinking is a process focusing on creating solutions for others. Thus, you must have an empathetic understanding of the needs of the people for whom you are serving (IDEO 2015). For instance, it may be the case that integrating IT is a policy imperative in a school, but the manner in which you unveil that process can be greatly enhanced by involving students and teachers in the process because they are, ultimately, the users of the change.

Define. To define is to use the empathy you gain from the previous phase and craft an actionable problem statement. Once one understands the needs of the users who will be impacted by your initiative, you must define, from the user’s point of view, the precise challenge your initiative is supposed to solve. Say you are interested in integrating IT into instruction in your district. And suppose other neighboring school districts have implemented a one-to-one laptop program. Do you just jump on their bandwagon? No. Implementing a strategy in the same fashion as it’s done in other districts doesn’t mean it will meet the needs of your stakeholders. Therefore, you should define the problem regarding what you hope for and what could work for your stakeholders. This leads to an actionable problem statement upon which you can brainstorm, or ideate, solutions. For instance, “How might we enhance students’ success at finding and solving complex problems in social studies and science through integration of technology.”

Brainstorm. To ideate is to brainstorm. It’s the portion of the design thinking process wherein a great many ideas are developed to address the specific need you defined in the previous step.

Prototype. Once you have a feasible idea that seems worth trying, the next step is to create a prototype of the idea so users can play with it. The main benefit of creating a prototype is to provide a situation where you can fail quickly and cheaply. Testing the prototype of a curriculum idea, or an online learning environment with, say, one class over a week’s time will tell you if users like it, whether it’s feasible, etc., without investing a lot of time and money up front.

Test. Testing tells you if your prototype was on the right track. It also tells you more about the intended users of your design. By testing a prototype of a curriculum or instructional technology, you are offered another chance to build empathy for your users' needs by observing them in context.

Why Is Design Thinking a Tool Leaders Should Consider for Implementation of IT in Schools?

The leaders of modern primary and secondary schools tend to emanate from graduate programs of educational leadership which imbue them with a level of professional expertise. The results are a double-edged sword. On one edge, their expertise and knowledge of the field are vastly expanded. However, as Hess (2013) notes, this can create a cadre of decision makers who are thought-constricted in that “those who have spent their career immersed in the rhythms of any profession come to regard its policies, practices, culture and routines as givens” (p. xiii). The way IT is integrated into schooling is no exception. There are too many educational leaders who come into their position believing there is only one solution to every problem. Leaders who fall into this camp possess, according to Boland and Collopy (2004), a decision attitude. Such leaders:

- Believe there only exist a finite set of alternative solutions to problems, mostly provided by outsiders (other schools, vendors, the literature)
- Assume it is easy to come up with alternatives to consider, but difficult to choose among them
- Assume that the alternative courses of action are ready at hand
- Are lulled into the belief that there is a good set of options already available, or at least readily obtainable
- Are trapped in a role as a passive decision maker, making the untenable assumption that the alternatives presented in advance include the best possible alternatives

Contrast this with leaders who describe as having a design attitude (Boland and Collopy 2004). These kinds of leaders:

- Work with stakeholders to develop custom solutions that are not known at the start
- Are concerned with finding the best answer possible, given the skills, time, and resources of the team
- Develop alternatives for local conditions, thus decisions about which alternative to select become trivial
- Take for granted that the initiative will require the invention of new alternatives
- Know that their stakeholders are best suited to say what their needs are and options are created based on those needs

- Are active designers of a team of decision makers who help develop alternatives that have not yet been thought of and are usually better

In essence, design thinking can add value to the way IT is adopted and integrated into students' learning by broadening the spectrum of possible solutions that are both more innovative and more tailored to student needs.

How Might School Leaders Incorporate Design Thinking into Their Leadership Practices?

What follows is an approach for how leaders can use of design thinking to support thoughtful school-wide adoption or implementation and classroom integration of IT. Since 2010, I have applied the tenets of design thinking to challenges faced by school leaders which fall into a broad category of student agency and IT. The idea of this effort is as follows: school leaders empathize with students (from all grade levels) to better understand their lives, and treat them as partners in the policy process, to better adopt and integrate IT for learning. This involves two things IT leaders rarely do:

1. Taking the time to empathize with students
2. Treat students as trusted partners in the policy planning and implementation process

Finding ways to empathize with students doesn't take as long as leaders may fear, but it goes beyond the hackneyed approach of student sounding boards principals tout, often comprised of safe, high-performing college bound students (Holdsworth 2000; Thomson and Holdsworth 2003). This involves purposeful selection of students from the margins, high and low, along with equally purposeful dialogue designed to elicit information which leads to unique and workable solutions to tricky challenges, like getting IT right.

Let me summarize how we do it, and I'll point you to a handout you can use to try it yourself:

1. Block out about two and a half hours on a particular day.
2. Identify around a dozen students to interview, picking firstly from the edges, or extremes. Therefore, one-third of the students you select should be on the high side of the continuum you're concerned with. These might be students who "fit the mold" or are typically thought of as being "ideal" for school. Then, one-third should be from the other extreme – those who may not always be a "fit" for school, or who struggle (or rebel) for one reason or another. Lastly, one-third should be from somewhere in between ("average" students). Then select a set of teachers and administrators who will interview the students. Create design teams

of three to four adults who are joined by one to two students (say, six to ten teams).

3. Conduct empathetic interviews with the students. There are many ways to gain empathy with another person, and a good way to do is by having a good conversation. I use a framework developed by IDEO (2011) called “Open Specific, Go Broad, Probe Deep.” Interviews take between 20–40 min.
4. Unpack what was said during the interview and prove to the students you heard them. In this phase, the adult interviewers take a few moments, in the presence of the students, to unpack what they heard and restate it to the student interviewees. The students indicate whether the interviewers “got it right.”
5. Codesign the problem. At this stage, the students become full members of the design team, or “codesigners.” Participatory codesign is a technique which enhances the likelihood solutions will stick by leveraging the insider knowledge of the user (in this case, the students). As a team, the members define the precise challenges that should be solved, based on constraints posed by the organization and the new empathetic understanding of the users.
6. *Brainstorm*. Using the challenge statement created in the previous step, usually framed as a “How might we . . .” question, team members develop scores of potential solutions in a matter of minutes. I press teams to develop 50 ideas in 6 min.
7. *Prototype*. Based on how fruitful the brainstorm was, teams harvest the brainstorm for one or two key ideas they’d like to prototype. Teams develop something to show the group, be it a model, storyboard, role play, or diagram.
8. *Get feedback*. The most promising prototypes are “shopped around” the school by teams asking for feedback from a broader set of stakeholders. The information obtained is used to improve the prototype and inform a decision on whether to take it to scale.

Try It Out

Here is a link to my workbook, “Improving School Tech with Student Agency via Design Thinking,” which describes the steps above and includes interview questions and team tips: <http://dlab.us/it-designthinking>.

Conclusion

IT solutions for teaching and learning have been a part of education for decades, and as a staple of schooling will likely remain a steady future investment. School leaders should seek a strong return on such an investment, in terms of both cost and student learning. Partnering with students, teachers, and others as codesigners, through design thinking, can lead to IT implementations which are more desirable, feasible, and viable.

Abstract

Appreciative inquiry is both a philosophy and a process for fostering individual and whole-system change by focusing on strengths and what is going well rather than on dwelling on problems, gaps, or discrepancies. It provides IT leaders with a helpful lens to engender conversations and a shared vision to consider what IT efforts might uniquely support teachers and students.

What Is Appreciative Inquiry?

Appreciative inquiry is both a philosophy and a process for fostering individual and whole-system change by focusing on strengths and what's going well rather than on dwelling on problems, gaps, or discrepancies (Watkins et al. 2011; Whitney and Trosten-Bloom 2010). The thesis of appreciative inquiry is that by exploring and amplifying strengths, an organization can overcome the problems and gaps more effectively than by focusing on the problems directly. By inquiring into the dynamics that allow the organization whatever successes it currently enjoys, participants can amplify and build on those strengths. It builds collective efficacy and ignites the imagination of participants as to what might be possible in the future. The introduction and expansion of the use of educational technologies is especially well suited for the use of appreciative inquiry because of the heretofore unheard-of affordances and new possibilities that they make possible in schools.

Although it may seem counterintuitive to focus on strengths, especially if things are going poorly, there is a robust research base that attests to the effectiveness of this approach (Cooperrider et al. 2008). Developed three decades ago at Case Western Reserve University, Appreciative Inquiry has been used around the globe in arenas as diverse as international aid organizations, social services, major corporations, and the military, it is less well known in the realm of education. However, a fledgling research base in education has begun (Dole et al. 2014). Growing out of the tradition of action research, the practices of appreciative inquiry are undergirded by five interrelated principles (Watkins et al. 2011):

1. *The Positive Principle* asserts that there is real power to transform problems simply by shifting the focus to identifying, appreciating, and amplifying the strengths inherent in the situation and the people involved. So even if the initial motivation for considering the introduction of a new instructional technology is to remediate students who are falling behind, to close achievement gaps, or to increase the engagement of students who have mentally checked out, the positive principle suggests that investigating the most successful current practice will lay a more solid foundation for new initiatives than digging in to identify the root causes of those gaps or disengagement. If providing students with more opportunities for differentiation and extension activities is valued, then finding examples of where blended learning has been successfully implemented will foster the kinds of conversations that inspire teachers to expand on these practices. By bolstering the collective efficacy of teachers, this positive approach broadens thinking, expands awareness, builds resilience, bolsters initiative, and generates new possibilities. It helps to provide a meaningful purpose for considering how IT can support the collective vision of the school.
2. *The Constructionist Principle* asserts that positive energy and emotion are constructed when people have positive conversations and interactions. When conversations focus on problems and the underlying causes of discontent, people are likely come away feeling glum and discouraged, while interactions that focus on possibilities and a vision for a positive future leave people feeling hopeful and

energized. The PLAYDATE model (Magiera et al. 2013) for IT exploration for teachers is a good example of the constructionist principle in action. PLAYDATE is a different type of informal conference that provides a space for teachers in a local area to come together explore multiple educational technologies. Rather than offering structured sessions, keynote addresses, or even a schedule, PLAYDATE encourages teachers to play, tinker, and explore together. It provides a positive and playful way for teachers to discuss new ideas and approaches to integrating new technologies in their work.

3. *The Simultaneity Principle* claims that conversations and interactions become positive in new ways the instant we ask a positive question. A search for the root causes of problems often ends up identifying culprits, thereby initiating a barrage of finger-pointing and defensiveness that detract from the creativity needed to confront complex challenges. Asking about aspirations and possibilities generates a vision of a positive future, grounded in the strengths of the present. These positive conversations foster collective efficacy by directing attention to the things that teachers know and do well. Asking teachers to reflect on their most positive experiences with infusing IT to support their own or their students' learning cultivates greater openness to consider new uses than dwelling on frustrating or even disastrous experiences in the past.
4. *The Anticipatory Principle* asserts that positive questions and reflections flow from a positive outlook. In the absence of hope, it is hard to seek out, much less to celebrate, the positive. When we anticipate a positive future, however, we become more creative, resourceful, and resilient in looking for ways to bring that positive future into existence. The more concrete and real the image, the more yearning and movement it creates. When the educators in an underperforming school catch hold of a clear and compelling vision of the school as a vibrant learning community infused with new technological tools to support the learning and growth of their students, they cultivate a sense of optimism and an increased sense of collective efficacy in moving forward toward that vision.
5. *The Poetic Principle* invites us to become mindful of what adds richness, texture, depth, beauty, significance, and energy to life. Poets draw our attention to the simple, ordinary aspects of our lives in ways that imbue them with a sense of meaning and purpose. By focusing on the ways current reality is aligned with our core values and our sense of purpose, life becomes a work of poetry. A maxim from appreciative inquiry reminds us that "what we appreciate, appreciates." When we focus on problems, we see more problems. When we focus on possibilities, we see more possibilities. Appreciating the ways that new technologies have enhanced our lives in the past and in the present can foster the curiosity, openness, and courage to explore new more challenging technologies in the future.

Taken together, these five principles form the rationale for abandoning well-worn practices of examining the ways that individuals and systems are falling short of our aspirations, and to instead to focus our attention and energy on building upon the existing knowledge and strengths present.

Why Is This Something Leaders Should Consider for Implementation of IT in Schools?

In K-12 schools today, educational technologies are integrated with a variety of aims: to engage students in personalized and adaptive learning often designed to close the achievement gap; to help them develop twenty-first century skills; to enable students to explore problems through inquiry, and many more. Whatever the aims, it is important to remember that technologies are not neutral (Nye 2007). Schools are complex and interdependent ecologies, where the introduction of new variables influences the whole system (Nardi and O'Day 1999). Thus, the introduction of new technologies shapes the learning experience for students and teachers.

Instructional technology tools and resources are imbued with values and assumptions about teaching and learning. For example, personalized and blended learning models provide opportunities for students to learn at their own pace, place, and mode in ways that are difficult, if not impossible, in a traditional classroom (Means et al. 2013). Engaging students to grapple with real problems using analytical tools and data similar to that used by professionals creates a sense of authenticity and relevance for students (Jonassen and Hung 2015). In both of these models, however, there are foundational assumptions about teaching and learning. There are assumptions that through increased autonomy and relevance students will be motivated to do sustained rigorous work. There are assumptions about the role of teacher as facilitator – or activator – that fundamentally alters how teachers interact with and guide student learning (Fullan and Langworthy 2014).

What often is not taken into account with many of these IT-supported initiatives is the unique context, culture, and ecology of the schools in which they are operationalized. How do schools and districts initiate these new efforts? In some cases, new initiatives spring from lagging test scores or decreased student engagement. In others, there is what Papert (1987) terms a “technocentric” focus on the affordances of new technologies that can supersede a focus on larger issues related to teaching and learning. In many cases, these new initiatives are instigated and implemented in a top-down fashion that does not reflect the unique culture and potential of schools, teachers and students. Appreciative inquiry provides a helpful lens to engender conversations and a shared vision to consider what IT efforts might uniquely support teachers and students.

How Might School Leaders Incorporate Appreciative Inquiry into Their Leadership of IT

School leaders who marshal the principles of appreciative inquiry to guide their IT leadership in schools and districts are likely to experience a very different energy surrounding those initiatives than from more traditional top-down approaches. The Four-I cycle is one of several models of appreciative inquiry that can offer a productive and joyful way to connect instructional technology to the purpose and values of school (Watkins et al. 2011). In the section below, we offer the template of

an appreciative inquiry exercise informed by design thinking principles (Brown 2009) that can be used in any context.

Initiate: Focusing on Strengths

The first I, *Initiate*, involves the choice to use a strengths-based approach to addressing an area of concern. In focusing on IT integration, it is equally important to make a conscious choice to put the shared vision for teaching and learning ahead of particular IT tools and resources. It is essential to agree at the outset to allow the appreciative inquiry process to drive the selection and focus for IT, rather than the other way around. For example, a new superintendent may express an interest in making a substantial financial investment in new IT tools in order to improve mediocre student outcomes. Before dashing out to the next technology expo, appreciative inquiry would invite the educators in this system to consider their hopes and aspirations for supporting student growth and learning and then design an inquiry into ways that those aspirations are already being enhanced by the IT currently in use. The clarity that will emerge from this inquiry will guide the planning for new IT initiatives tied to these aspirations rather than getting wooed by the razzle dazzle of IT that may be impressive but are not aligned with the most salient learning goals of the district.

Inquire: Sharing Uplifting Stories

After the decision is made to use a strengths-based approach, as well as the focus of inquiry, the next step is to design an interview protocol that will “map the positive core,” discovering instances of strength and success in the area of inquiry (Whitney and Trosten-Bloom 2010). Appreciative inquiry is a deeply participatory process that seeks to engage as many stakeholders as possible. Therefore, the second I, *Inquire*, begins with conducting paired interviews in which people interview one another about the focus of the inquiry. Rather than taking a group of district leaders to an offsite location to sit around a conference table to discuss the learning and IT needs of the district, school leaders, teachers, students, and parents are all invited to tell stories and explore the positive experiences they have had when IT enhanced their learning and growth. An interview protocol is developed to invite the exploration of those positive experiences in the past as well as the core values, generative conditions, and aspirations for the future. An example of such a protocol might be:

- Tell me about one of your best experiences of learning something new in which IT played a role. What were you learning and why was it important to you? What challenges did you face and how did you overcome them? What contributed to making that such a positive experience? Describe that experience in detail.
- When you are at your best, how do people, policies, or tools and resources in this school help you to learn and grow?

- What do you value the most about the learning environment in this school? In what ways are you able to contribute to the expression of that value in the life of this school?
- Imagine that you could transform teaching and learning in this school in any way you wanted. What would that look like? How might that change heighten the vitality and health of the school community? If you had three wishes for bringing your vision into being, what would they be?

If the appreciative inquiry is taking place in a face-to-face environment, when each pair has had sufficient time to tell and explore their stories as well as to appreciate one another's values and wishes, they join with two other pairs to form small groups. Each person then recounts briefly his or her partner's story, values, and wishes to the group. As the sharing unfolds, participants identify three to five themes that energized and enlivened them. These are shared with the large group and the themes are then grouped into similar meta-themes for the group as a whole. Colored dots may be used for each individual to indicate the three themes that most resonate or energize them. If the inquiry is taking place asynchronously online, and making use of technological tools to allow for the involvement of a larger number of people than could be gathered in one location, then after the paired interviews each partner might summarize their partner's stories, values, and wishes on a web form or in some creative way using other digital tools. These data would then be shared and analyzed for the most salient themes as a guide going forward.

Imagine: What If?

The next phase in the process, the third I, *Imagine*, participants may be invited to form groups around the theme that most energizes or inspires them. In this phase, each group develops creative images of what the school would look and feel like if it honored fully the themes selected and if the school were just as people desired. They convey those images through drawings, collages, music, or skits. Participants may be encouraged to use creative digital tools or other analog approaches. They then share those images with the group as a whole. Only after the groups have developed their creative images of the future, do they attempt to articulate them in a set of bold claims for the school, framed as though these new aspirations were already fully expressed in the school.

Innovate: Taking Action

In the fourth phase of the process, *Innovate*, small groups convene to design and plan action steps for moving the school closer to the beautiful, vivid images that participants developed in the *Imagine* phase. It can be helpful here to think smaller rather than bigger. Rather than trying to put major new IT initiatives in motion all at once, it can be more productive to consider small "hacks" to build momentum towards

realizing the aspirations identified in the Imagine phase. In this way, it can be easier to take the first steps, reflect, iterate, and move the vision forward, one small step at a time.

As the planning progresses, participants designate the responsible parties for each action step, schedule activities, identify locations, and plan the logistics of getting things done. Strategies over which the team members have control are listed as Commitments. Strategies that require the involvement, permission, or resources from another party are listed as Requests. The process is not complete until all these logistics are captured in writing. Once the school has tried the suggested innovations, the process can begin all over again. It is an iterative, ever-evolving process of organizational learning, growth, and change.

Logistically, the four phases of the AI cycle could be completed in a day-long planning and development summit or across several shorter meetings over a longer period of time. The creative use of IT can allow for the participation of an even broader array of stakeholders than might be possible in a single event. Whatever the logistics arrangements, the *Appreciative Inquiry* process provides an inspiring and engaging way for educators and their constituents to engage in productive conversations to explore their visions for their schools and the role that IT can play in enhancing those visions. This process keeps the focus on the curriculum-based learning needs and opportunities. Instructional technology is then utilized to support those goals rather than to drive the learning experience.

Conclusion

We live in magical time in which technological advances make possible previously unimaginable feats. It is easy to get caught up in the razzle dazzle of technological tools and programs and to lose sight of the teaching and learning goals the technology is meant to serve. Investing the time and energy to imagine together how technology can support the collective aspirations of a school community can focus the positive energy of that joint attention and put the magic to work in service of our highest hopes and dreams.

Abstract

Approaching teaching as a design science encourages teacher collaboration, to harness the inquiry that goes on every day in classrooms and channel it into shared knowledge that could benefit the whole community of teachers. This chapter explains what teaching as design science is, why leaders of IT should consider it when implementing IT, and how to put it into practice in their leadership of IT.

What Is Teaching as a Design Science?

Educational researchers have tried hard to influence teaching, and with some success, but never with the resounding large-scale improvements that teachers and researchers all want to see (Morris and Hiebert 2011). In part, this is because pedagogic content knowledge development “is a complex process that is highly specific to the context, situation, and person” (Van Driel and Berry 2012). Teaching knowledge cannot be reduced to a set of guidelines or captured on video by “expert teachers.” These techniques may help, but they do not assure improvement.

At the same time, our education systems could be seen as massive uncoordinated experiments, where every day, every teacher has the opportunity to try out and test new techniques and learn from their students what works and what does not. The idea behind “teaching as a design science” is to acknowledge this: to formalize and celebrate an approach to teaching that enables teachers to innovate, test, and share their teaching knowledge. If teachers were to share, test, and build on each other’s learning designs, teaching would be a design science – “improving its practice, in a principled way, building on the work of others” (Laurillard 2012).

Seen as a *design science*, teaching can then harness the inquiry that goes on every day in classrooms and channel it into shared knowledge that could benefit the whole community of teachers.

It is certainly feasible. The next three sections show that teachers are already adopting a more collaborative approach to teaching innovation, and there are now digital tools and online communities to support this activity.

Teacher Collaborative Inquiry

Teacher professional learning is increasingly seen as a socio-constructivist activity that shifts the focus from *what can be done for teachers* to *what teachers can do for themselves* (Makri et al. 2014; Najafi and Clarke 2008; Van Driel and Berry 2012). The research shows that:

teachers’ learning is facilitated and sustained in communities that are collaborative endeavors, acknowledge and value participants with different levels of expertise, and focus on practice-related issues. (Najafi and Clarke 2008, p. 244)

To go beyond local endeavors to the community as a whole, Morris and Hiebert propose an approach to improving teachers’ methods of teaching by creating and

sharing artifacts or instructional products (Morris and Hiebert 2011). Such an approach enables understanding to be accumulated over time. Teachers and researchers create materials, try them out, and “feed the information from the trials back into the products”(Hiebert and Morris 2012).

This iterative process of collaborative sharing of scholarship-informed practitioner knowledge could be the key to reconfiguring teaching as a design science, because it addresses the challenge of teacher-led inquiry (Laurillard 2012). It helps teachers build their knowledge of teaching by encouraging them to engage in the production and continual improvement of ideas of value to the community. Teachers work in “design mode” (Hong et al. 2009), with a collective goal of innovation and knowledge advancement (Scardamalia and Bereiter 2010).

Teachers are not so much scientists – who try to understand how the world works. They are more like engineers – who try to make the world a better place. Like engineers, they use science, where it improves what they do. And like engineers, they use feedback, redesigning their teaching in the light of what happens in practice. “Design engineers” – the term suits what teachers actually do.

A recent report on 10 years of research on professional development of teachers emphasized the value of the collaborative sharing of practice in teacher networks and identified the importance of tools, especially digital tools, to support professional learning (Avalos 2011). Others suggested that “knowledge sharing” could transform educational institutions into “learning organizations” (Argyris 1994; Buckley et al. 2004). Collaborative teacher inquiry is a significant change in professional development because it means that teachers can move progressively from their teacher-centered thinking toward more student-centered actions (Butler and Schnellert 2012; Chang et al. 2015).

Teacher collaborative inquiry was recently advocated as policy for the profession in the USA (United States Department of Education (USDoe) 2014). However, unlike engineers, teachers have few tools to support professional learning their design work.

Learning Design Approach and Tools

Over the last 10 years, the development of digital tools to support teachers’ use of effective pedagogy has been driven by the need to represent learning designs in digital form (for example, the Learning Designer (<http://learningdesigner.org/>) is a freely available online design tool for teachers), to make it feasible for teachers to share good pedagogical practice online (Masterman et al. 2013). The learning design approach to planning teaching and learning activities enacts exactly this kind of collaborative inquiry. It enables teachers to make their intuitive processes both visible and shareable (Ghislandi and Raffaghelli 2015) and encourages them to be more learner centered (Dobozy 2013). The digital form of learning design promotes high-quality learning activities and reduces the investment of design time (Agostinho 2006), because the design work is shared across the community.

However, these digital tools have not yet been widely deployed in the educational mainstream (Masterman et al. 2013). So while digital tools for learning design have

become more sophisticated, allowing teachers to discuss, redesign, and reuse learning designs on the small scale, it is not yet clear how easily they can be adopted into the widespread daily practice of teaching and learning (Ghislandi and Raffaghelli 2015).

Online Teacher Communities

The potential for online technologies to support the development of larger communities of practice has prompted researchers to examine what they could do for teacher professional development (Lin et al. 2008; Matzat 2013; Zhang 2009), although they argue that the area is seriously under-researched (Dede et al. 2009; Schlager et al. 2009). Nonetheless, the evidence is slowly accruing that teachers value online communities for the exchange of ideas and links to resources (Duncan-Howell 2010; Rolando et al. 2014) and find that it encourages a more student-centered approach and the use of digital technology (Archambault et al. 2010; Vavasseur and MacGregor 2008).

The gradual shift toward the ideal of a widespread community for teacher collaborative inquiry is now transformed by the availability of massive open online courses (MOOCs). The pedagogic form of such courses is generally highly didactic for very diverse participants, but the platforms do also support discussion. Teacher development courses are more collaborative in nature and can achieve the significantly higher engagement of 30–40% of participants, in comparison with the modest 2–3% of most such courses (Laurillard 2016).

For the first time, therefore, there is a congruence between the digital tools to support the sharing of pedagogies, the digital platforms to orchestrate collaboration on the large scale, and the ambition for teachers to be able to engage in collaborative inquiry. For the first time, teaching is viable as a design science.

Why Should Leaders Consider Using This for Implementing IT in Schools?

IT in schools typically begins with implementing the hardware and software and with good intentions to support teachers in using it. However, the good intentions fade fast. A recent United Nations Educational, Scientific and Cultural Organisation (UNESCO) review of IT in primary education showed that in national policies the distribution of funding resource between human capacity and technical capacity always favors the latter (Kalaš et al. 2012). This makes no sense. Teachers play the principal role in changing how effectively learners learn, and they need good solid support if they are to succeed in the difficult task of harnessing technology.

The argument for using the idea of teaching as a design science goes like this:

- Schools must adapt continually to their changing environment.
- Schools must innovate to keep pace with the requirements of their context.
- Rapid technology change means that teachers must use collaborative inquiry to manage the workload required for pedagogic innovation.

Who else is there to work out what the new pedagogies might be, and how to make optimal use of continual digital innovations? Who is better placed to discover what works? How can teachers be seen as anything other than a professional community of designers who build on each other's best ideas to make progress in the face of continual change?

Schools Must Adapt to a Changing Environment

School leaders are aware that their school – the curriculum and its teaching – has to develop in response to the changes in the very complex social-cultural-political-economic-technological-financial environment it inhabits. All these forces create pressures and constraints, against which the school leaders are trying to construct a forward-moving vision for their school and their students. Continual responsive development is necessary, but rarely funded.

Schools Must Innovate

Innovation moves forward when there is the opportunity for professionals to collaborate, exchange ideas, experiment, and share the results. This is the model we are familiar with in the world of scholarship and research, as well as in many fields in which professionals have to adapt fast to changing contexts, such as architecture, engineering, policymaking, and IT design. The organization of schools, the configuration of classrooms, the curriculum, and the pedagogies have all undergone change and development in recent decades, but despite the increasing focus of national policies on the use of IT in schools, it is not being used to support the most powerful forms of learning (Ertmer and O'ttenbreit-Leftwich 2010). To do this, it is essential that teachers:

- Are involved in the change and development process
- Have the opportunity to develop their own beliefs and sense of self-efficacy with IT
- Have strong support from professional learning and from the management and culture of their school (Association for Learning Technology (ALT) 2014; Ertmer and O'ttenbreit-Leftwich 2010)

Governments have made little provision for such activities, and the responsibility for this quite dramatic shift in school practice has been left to the schools themselves in most countries. International surveys show that digital technologies have not yet been fully integrated in teaching and learning (Organisation for Economic Co-operation and Development (OECD) 2016).

Teachers Must Collaborate to Innovate

Innovation is costly and inevitably increases workload in the short term, even if there is a planned payoff in the longer term. It is especially difficult for schools to innovate

when both policy and technology change at alarming rates. IT can be highly effective, but it takes time to learn how to best use it and embed it in the curriculum.

Collaboration spreads the cost of innovation. It accelerates successful innovation, as each teacher builds on the work of others, and contributes to building community knowledge. This is the model for science and scholarship, orchestrated through peer-reviewed academic journals and conferences. Teachers must also be innovators now. They need their own tools and support mechanisms to accelerate and distribute the responsive innovation schools need, as the next section shows. This is what it means to treat teaching as a design science.

How Might School Leaders Incorporate the Idea into Their Leadership Practices?

Academic studies repeatedly demonstrate the need for teacher self-efficacy in IT and more teacher development, but school leaders receive little support for making this a normal part of the school workload. However, given the now near-ubiquitous presence of IT communications systems and design tools, there are more ways of lowering the threshold of innovation. This section suggests how IT can support not just students in collaborative learning but teachers as well.

One approach is to use the *Learning Designer*, a tool for teachers that mirrors the academic journal process, by enabling teachers to build on what has gone before, experiment, innovate, test, redesign, test, and publish. It can work well as a useful adjunct to meetings and discussions.

A related approach is for staff to do a relevant massive open online course (MOOC) together, as a way of keeping up-to-date with developments in blending digital learning with conventional class and homework activities.

A Tool to Support Learning Design

The Learning Designer is a digital tool that supports a pedagogical knowledge-building community by creating a constructionist learning environment for teacher development (Laurillard et al. 2013). (The tool is open and free to all on simple registration at <http://learningdesigner.org>.) As “teacher-designers” (Goodyear and Yang 2009), they can use a knowledge-building process, building on the work of others in the community, developing and testing their own innovative ideas, and then sharing the results with the community (Ferrell and Kelly 2006; Laurillard and Masterman 2009). Being online, the community has the capacity to reach all teachers wherever they are.

The pedagogy underlying the tool promotes the appropriate inclusion of the six types of learning operationalized by the Conversational Framework (Laurillard 2012; Laurillard et al. 2013), giving them feedback on their design. As they plan the sequence and duration and for each activity select the appropriate learning type, a pie chart displays a graphic of the current balance of their pedagogy across

learning through acquisition, inquiry, practice, discussion, collaboration, and production. In this way it prompts the teacher to articulate an optimal learning design, i.e., a sequence of teaching-learning activities for a specified learning outcome. Their design then becomes a digital object which can be shared with other teachers, adapted to other's contexts (Zhang and Laurillard 2015), and exported as a Microsoft Word document, or a plan for implementation in a virtual learning environment.

An Online Collaborative Teacher Development Community

For scaling up the collaborative inquiry process, MOOCs now offer the kind of platform that succeeds in engaging teachers in discovering and experimenting with new forms of learning, such as blended learning – mixing IT solutions with conventional teaching, both in class and at home. (A MOOC on *Blended Learning Essentials*, for teachers, runs on the FutureLearn platform: <http://bit.ly/28RNQpI> and <http://bit.ly/2cV2Od9>.) For example, there are two courses on Blended Learning Essentials: Getting Started and Embedding Practice. Teachers in schools and colleges have been following them together, as a school-based group, for example, so they can discuss the ideas as they apply to their own context.

The Learning Designer is used in both courses, as well as in MOOCs run by other platforms, where it has been embedded as a form of collaborative exercise for the participating teachers. The evaluations so far show that teachers are excited by the tool and willing to share their ideas and to adapt others' patterns to their own context.

Leadership Practice

What can the school leader do? It is most important to demonstrate the value the school leadership puts on teacher professional learning, on innovation, and finding out how to make optimal use of digital learning. Teachers are very good at helping themselves and are happy to run the whole process, once it is endorsed by the leadership team. Here is one way to approach it:

1. Propose a collective focus on blended learning or digital learning as a way of tackling a challenge of interest to the teachers, such as student motivation, class behavior, difficult concepts, and skills. It should be an issue of interest to the teachers where pedagogic innovation could have an impact.
2. Decide which MOOC(s) to look at and when (search for “ICT blended digital learning” through Coursera (<https://www.coursera.org/>) and FutureLearn courses (<https://www.futurelearn.com>)) to fit with the plan.
3. Plan a sequence of collaborative workshops over a term, each around an hour or so, and the series of workshops could go through the following sequence of activities:

- (a) Identify the good challenge(s) to work on and describe what you hope to achieve through a new pedagogical approach and the groups who will work together to do this.
 - (b) Use a session to explore the Learning Designer tool: sign up, go to the Browser screen, and explore the Education designs; click on one and review it in the Designer screen; experiment with changing the duration of some activities to see how the pie chart changes; click on Turn editing on, and edit the design by changing the text, adding/deleting activities within a segment, and teaching-learning activities (TLAs), changing times, learning types, etc.; and save and export as a Word doc or as the code for others to use.
 - (c) Explore other designs to see how they use digital resources, and look at some of the reviews as well.
 - (d) Use the ideas from the MOOCs to plan a session that defines the learning outcome you want to achieve and uses blended learning, where you add a resource to define the uniform resource locator (URL) students will use and plan the activity around how they will use it.
 - (e) Exchange and peer review other groups' designs, and reflect on the feedback you give and receive to revise your design.
 - (f) Test it out in class, and note what happens.
 - (g) Discuss the results in the next workshop session.
4. Report back to a plenary staff session on where to go next on embedding digital learning as a way of addressing teaching-learning challenges and how best to work collaboratively across the school to do this.

Such a program of within-school innovation could build slowly but would put the teachers in the driving seat of change.

Conclusion

Innovation is essential for schools to flourish in the face of unpredictable changes in political, financial, and technological forces. Teachers are best placed to innovate, because they can understand and discover what their students need, what works, and how to mix the old with the new. But they have never had the support and trust of the education system that would enable them to develop the program of teacher collaborative inquiry that could drive forward the effective innovation we need. By reconceptualizing teaching as a design science, supported and orchestrated by the right digital tools, we could define a new vision for a teaching workforce able to innovate and adapt effectively.

Abstract

Improvement science through networked improvement communities offers leaders of IT a systematic approach to quality improvement in education, which can be applied when implementing IT in schools.

What Is Improvement Science Through Networked Improvement Communities?

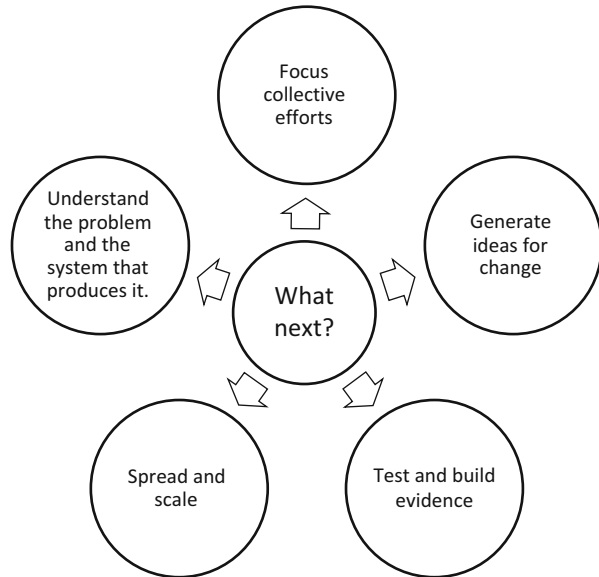

Improvement science through networked improvement communities (NICs) is an emerging approach to quality improvement in education promoted by the Carnegie Foundation for the Advancement of Teaching (Bryk et al. 2015; LeMahieu et al. 2017; Russell et al. 2017). Quality improvement has a longstanding history in industry and, more recently healthcare, as a rigorous and systematic means of continuously improving organizational processes, practices, and routines with the aim of bringing about sustainable change to programs, products, and services (LeMahieu et al. 2017, p. 5). Improvement science shares with realist approaches to research and evaluation a central concern for “how and why does this work and/or not work, for whom, to what extent, in what respects, in what circumstances and over what duration?” (Westhorp 2014, p. 4). It shares with Action Research an emphasis on building proactive knowledge through practitioner-based inquiry and learning as the means through which answers to that question might be addressed. Improvement science through networked improvement communities differs from Action Research by employing systematic and rigorous approaches to using evidence to understand what has happened and could happen through integrating evidence-informed improvement strategies into ongoing work.

Improvement science as a systematic approach to quality improvement in education is rooted in the work of W. Edward Deming (1986), particularly as those ideas have been taken up in healthcare (Health Foundation 2011; Lewis 2015; Langley et al. 2014). The improvement science cycle of inquiry resembles other cyclical inquiry processes in related disciplines oriented to improvement in education (e.g., action inquiry cycle; action learning cycle). In improvement science, the cycle of inquiry or “model for improvement” (Langley et al. 2014, pp. 23–25) is characterized as a Plan-Do-Study-Act (PDSA) cycle.

The Carnegie Foundation is not the first to promote Deming’s work in education (Holt 1993; Leonard 1996); but its approach is the most ambitious in terms of spread and scale of improvement. The Foundation turned to the work of Douglas Englebart (2003) on knowledge networks as a potential means of rapidly increasing the type and scale of change within and across schools and school systems. Carnegie’s approach advocates promoting the scaling up of proactive knowledge through networked improvement communities (NICs), which (Bryk et al. 2015) characterizes as scientific learning communities.

The Foundation has supported a series of “proof of concept” initiatives as what is now called the Networked Improvement Science (NIS) concept has deepened and broadened. Initially, the Foundation provided direct support for several NICs, such as the Carnegie Math Pathways NIC, the Building a Teaching Effectiveness Network (BTEN), and the Student Agency Improvement Community (SAIC), a network of NICs, and most recently in its support of the development of NICs by others in the field of education. The efforts of the Foundation are now focused on what it terms “field-building activities,” most notably in the creation of networks of educators in

Fig. 1 Networked improvement science “Cheat Sheet” (Greenberg et al. 2017). (Used with permission © 2017 Carnegie Foundation for the Advancement of Teaching (CC BY-NC))

higher education who are designing and running courses and programs in improvement science for school leadership, the Carnegie Higher Education Network (HEN), and in support of higher education and school district partnerships through the Improvement Leadership Education and Development (iLEAD) initiative. Carnegie disseminates its approach through its annual Carnegie Summit on Improvement in Education and publications (Bryk et al. 2015; LeMahieu et al. 2017).

The aim of networked improvement science is to identify and solve problems. The systematic processes of improvement science enable practitioners to achieve this aim by focusing on high-leverage problems of practice (e.g., new teacher effectiveness, developmental math for community college students) and refining standard organizational processes and professional practices that might then be adaptively integrated across a wide range of organizational contexts (Mintrop 2016, p. 15). Associates at the Carnegie Foundation put forward an “Improvement Science Cheat Sheet” that encapsulates phases in an improvement process and corresponding tools and approaches (Greenberg et al. 2017) (Fig. 1).

The “hub and spoke” organization of this model, in contrast with the circular representation of the PDSA cycle, is to emphasize that improvement does not necessarily follow a linear path. Each phase begins with the central, animating question, “What next?” The typical trajectory of an improvement initiative would first involve understanding the problem and its root causes within a wider system. The other phases, however, need to be approached flexibly, and progress made contingent on what needs to be learned next to advance improvement efforts (Anna Kwar, 31 October 2017, personal communication). The phases are iterative and overlap in ways that respond to the learning needs of the improvement initiative.

The improvement science phases are distinct from other approaches to inquiry because of the six foundational principles they seek to cultivate and sustain:

1. Make the work *problem-specific* and *user-centered*.
2. *Variation in performance* is the core problem to address.
3. *See the system* that produces the current outcomes.
4. We cannot improve at scale what we cannot *measure*.
5. Anchor practice improvement in *disciplined inquiry*.
6. Accelerate improvements through *networked communities*. (Bryk et al. 2015, p. 2)

A common maxim in improvement work is that, “Every system is perfectly designed to get the results it gets” (Berwick 1996, p. 619). Donald Berwick, a leading figure in improvement science in healthcare, called this, “the central law of improvement” (1996, p. 619) underscoring the importance of the first three principles – emphasizing attention to the “user” experience in delineating problem focus and attending to variation in that experience to provide important insights into the system that produces the problem (see also ► Chap. 36, “Leading Information Technology via Design Thinking,” John Nash, this volume). The final three principles shift attention from clearly seeing systemic causes of complex and problematic outcomes to focusing collective efforts on practical and sustainable solutions. These also encapsulate the “science” of improvement by attending to systematic and rigorous inquiry based on practical measures. These measures are oriented towards practice improvement, not solely outcome indicators designed for accountability or data for research designed to increase disciplinary knowledge (Yeager et al. 2013). This step of evidence-based inquiry grounded in practice and the importance of clarifying one’s assumptions and testing those assumptions through the clear delineation of practical measures is brought to scale through social learning among teams involved in networked improvement communities.

Why Is Improvement Science a Tool Leaders Should Consider for Implementation of IT in Schools?

Improvement science through networked improvement communities offers a methodology for generating proactive knowledge that involves IT throughout the phases and in support of the principles described above. Technology has many potential roles in amplifying the leadership of continuous improvement in schools through improvement science, from the support role of facilitating rigorous approaches to exploring complex problems to the transformational role of scaling up change across many different organizations. IT offers leaders at all levels means of orchestrating interactions and engagement that hold the promise of generating proactive knowledge, the “alert and lively” use of knowledge that bends towards action (Perkins 2008, p. 3). Networked improvement science offers systematic processes that IT can amplify for accelerating individual and team learning and supporting larger-scale,

context-sensitive approaches to organizational and system-wide learning (Bryk et al. 2015; LeMahieu et al. 2017).

One way of delineating the ways technology might amplify leadership of continuous improvement is suggested by the tripartite exploration of *effects with*, *effects of*, and *effects through* technology (Salomon and Perkins 2005). *Effects with* corresponds to the use of IT tools and IT-enabled processes to enhance the leadership of collective inquiry and knowledge-building. *Effects of* characterizes the ways in which technological affordances may support leadership even after their direct use. *Effects through* evokes a more transformational role in terms of reorganizing performance to enable a qualitatively different kind of leadership than would be possible without IT. The following provides a brief introduction to the tenets of improvement science through networked improvement communities and then examines in turn effects with, of, and through technology in terms of the leadership of continuous improvement through improvement science.

How Might School Leaders Incorporate This into Their Leadership Practices?

A crucial aspect of the leadership of continuous improvement is the orchestration of influence in the uses of IT throughout the inquiry process. Identifying how technology amplifies the leadership of continuous improvement entails understanding effects with, of, and through technology (see Table 1).

Effects with. . .

Effects with technology comprise the ways that leadership of continuous improvement relies on approaches that support systematic methods and tools for viewing systems and processes, gathering and organizing information, understanding variation, analyzing relationships, explaining variation, and overall project management (Langley et al. 2014, pp. 409–451). Leadership of continuous improvement hinges on ensuring improvement teams have access, skills, and support to use the necessary IT tools that are essential to this work. IT tools for data collection, analysis, and visualization are crucial in the initial phases of discerning collective focus on a specific problem of practice and the system that produces it and moving on to generating change ideas. These may be as simple as common word-processing and collaboration tools (e.g., Google Drive and Docs, Microsoft Cloud) that make possible the rapid accumulation and sharing of information. Many useful data and process visualization tools are available, such as the charting features of common spreadsheet applications. More specialized tools for visualization, such as Lucidcharts, support collaborative representation of retrospective and prospective causal analysis (e.g., cause and effect diagram, causal loop diagram, interrelationship

Table 1 Amplifying understanding of improvement science (IS) with, of, and through technology: Phases in the improvement science cycle of inquiry

IS “Cheat Sheet” steps	Effects with. . .	Effects of. . .	Effects through. . .
(1) Understand the problem and the system that produces it	Digital documentation and representation of problem focusing Data collection and analysis Collective analysis of data Communications	Synthesis and archive of learning journey Systematic documentation of historical variation	Collective meaning making around problem and system
(2) Focus collective efforts	Learning platforms that enable collaboration	Shared visualization of the system Representation of multiple perspectives	Seeing the system from different perspectives
(3) Generate ideas for change	Exploration of databases, repositories of information Use of collaborative online protocols	Collective discernment of improvement aim, drivers, change ideas	Collective meaning making and prioritization of change ideas
(4) Test and build evidence	Design and use of practical measures Shared protocols for testing	Explicit predictions Articulating and testing assumptions Collective meaning making around results	Building proactive knowledge around change ideas
(5) Spread and scale	Use of collaborative online platforms that enable widespread communication and distributed knowledge-building	Collective meaning making around variation in relation to context Identification of “positive deviants”	Support for adaptive integration of change ideas in varying contexts

digraph, driver diagram), system processes (e.g., flow diagrams), and event mapping (e.g., journey mapping). Similarly, online tools for concept mapping (e.g., Xmind, Padlet) are crucial for generating ideas and focusing collective efforts. A final vital area that enables leadership is that of collaborative project planning and management through tools such as Trello.

Effects of . . .

Leadership of continuous improvement builds on the enabling effects with technology described above to orchestrate meaning making between members of improvement teams and among improvement teams across a NIC. The products of visualizing the system through technology-enabled representations and generating change ideas through concept mapping serve as the substrate for the collective interpretation,

evaluation, and meaning making that support the leadership of continuous improvement. Problem focusing and framing, as well as visualizing the system, are all enduring effects of analysis and visualization enabled by IT. In addition to supporting real-time, collaborative data representation and visualization, IT serves as distributed memory of the group's processes of meaning making through collective repositories of artifacts as well as historical archives. These enable leadership to build consensus around specific problems and improvement aims. Ultimately, the effects of shared meaning making through technology serve as means of generating sustainable, proactive knowledge around specific problems.

Conclusion: Effects Through . . .

Collaboration and knowledge-building technologies hold the promise of giving rise to qualitatively different ways of accelerating improvement through networked improved communities. NICs are predicated on the existence of a distributed infrastructure of technology that enables not only the rapid sharing of proactive knowledge from one location to another but also the accretion of proactive knowledge across diverse organizational contexts. In its current state, effects through technology are beginning to be evident as a result of amalgamating existing platforms for online, collaborative learning with the kinds of analysis and visualization tools described above. For example, High Tech High Graduate School of Education sponsors a number of Networked Improvement Communities and orchestrates the generation of proactive knowledge across distributed sites nationwide through a constellation of IT tools that include a homegrown collaboration platform, Google Docs, and a suite of online tools such as Padlet, Lucidcharts, and concept mapping software. A next generation of networked technologies for collaboration around improvement science initiatives is emerging. The University Council of Educational Administration Professional Development Network (UCEA PDN) is currently experimenting with adapting a networking tool for collaboration for its NICs (Dexter 2017). The Carnegie Foundation is also testing its own version of an online learning platform that aims to support the organization and leadership of NICs. These comprise a new generation of IT tools specifically designed for improvement science that require new forms of leadership and could enable a fundamental reorganization of the ways NICs operate and the scale and spread of improvement ideas.

Abstract

The use of IT-enabled assessments has been increasing rapidly, as they offer promise of cheaper ways of delivering and marking assessments as well as access to vast amounts of assessment data from which a wide range of judgements might be made about students, teachers, schools and education systems. In many countries in recent years renewed focus on assessments to support learning has been pushing against the burgeoning of testing for accountability. This introduction to the section presents an overview of the six chapters which examine issues and opportunities for using IT-enabled assessments to support students in their learning as well as providing for the wider needs of education systems.

about students, teachers, schools, and education systems. In many countries, in recent years, a renewed focus on assessments to support learning has been pushing against the burgeoning of testing for accountability (Black 2015; Shute et al. 2016), which in some countries renders effective formative assessment practices almost impossible (Black 2015). Thus, a key challenge for IT-enabled assessment is to support a move toward IT-based assessment that can serve learners' needs as well as the broader needs of education for evaluation of institutions and systems (Webb et al. 2013).

In order to achieve the learning benefits that should accrue from IT-enabled assessments and especially developments in assessment analytics, teachers and students will need to be engaged not only in the production of new tools that visualize the information, for example, to help shape how the new tools provide the most useful and understandable information (Ifenthaler 2014), but also in the dynamic creation of meaning from the use of those tools in learning situations, for example, to create personal insights from the experiences as well as the reflections made possible by the new tools (Webb and Gibson 2015). Thus, by engaging teachers in these development processes, it will be possible to achieve the more extensive assessment literacy needed to take full advantage of opportunities provided by new and more diverse methods of assessment. It is envisaged that it may take many years for IT-enabled assessments to achieve their potential to support formative as well as summative assessment. In the medium term, the need is to integrate IT-enabled assessments where appropriate alongside more traditional methods including teacher and peer assessment. Assessment analytics has massive potential for improving learning but is important for all educators, including policymakers, to understand that decisions about the use to which assessment data is put are critical as they may have unintended consequences for assessment validity as well as for learner motivation (Gibson and Ifenthaler 2017).

In addition to embracing opportunities provided by IT-enabled assessment, schools need to address ethics and privacy issues linked to data-driven assessments. They need to define who has access to which assessment data, where and how long the assessment data will be stored, and which procedures and algorithms to implement for further use of the available assessment data (Ifenthaler and Tracey 2016). In this section, we analyze research evidence and examine theoretical considerations relevant to the opportunities and issues associated with IT-enabled assessment.

Webb and Ifenthaler present an overview of the range of different opportunities for IT to support assessment with a view to provide a vision for assessment design to move forward with designers, teachers, and learners working together to design assessments that support learning in the twenty-first century as well as the broader needs of education. In this shared endeavor, data can be collected and represented to enable learners and teachers to identify achievements, collate evidence of those achievements, diagnose needs, both cognitive and affective, and decide on suitable pedagogical approaches for enabling the next steps in learning. Webb and Ifenthaler review key theoretical issues related to assessment and examine new and potential approaches to assessment that are facilitated by IT as well as the challenges that these new opportunities create.

Van der Kleij and Adie review evidence for ways in which IT has been used in formative assessment, focusing specifically on digital learning environments, game-based assessment, classroom response systems, Web 2.0, and video feedback. Their analysis suggests that using IT as a platform for feedback provides opportunity to individualize feedback, increase student engagement, collect learning evidence for all students, facilitate reflective processes, and support self-regulated learning. Reported potential challenges to the utilization of IT include time restrictions, limited response formats, technical difficulties, access to evidence of student learning for teachers, and teacher knowledge and skills. A key finding is that, although innovations in technology have evolved considerably, many promising possibilities are not yet being exploited for the purpose of formative assessment. Most importantly, research demonstrates that it is not the technologies themselves but the ways in which they are used that impact on their formative potential.

Whitelock and Bektik review progress and challenges for automated scoring and feedback systems for large-scale assessments. Large-scale assessment refers to tests that are administered to large numbers of students, and are used at local, state, and national levels to measure the progress of schools with respect to educational standards. In order to have accurate and fair measurements, large-scale assessment systems need to include all available students, which means a high volume of students with large numbers of exams to be marked. The need for large-scale assessments and the high cost of manual marking and limited “turn around” time have led to developments, over some years, of automated assessment and marking. Whitelock and Bektik review the history and development of automated assessment systems using findings from empirical research as well as highlighting the theoretical considerations that emerge from such developments. In addition, they explore the practical aspects of developing such assessments with examples, including, the systems and tools available, the current capabilities of natural language processing (NLP) approaches and their limitations, ethical concerns, and future potential.

Shute and Emihovich focus on the scope for game-based immersive environments to assess problem-solving skills as an example of constructs that are typically very difficult to measure for a variety of reasons (e.g., lack of a clear and agreed-upon definition, psychological and/or statistical multidimensionality of the construct, subjectivity of scoring). Adding to the challenge of validly measuring problem-solving skill is that formal education settings tend to focus only on well-structured problems – those that have correct and incorrect answers. However, these problems tend to have little transfer to the real world. In short, there is a gap in the kinds of problems being assessed and taught in schools and those desired in workplace environments. However, game-based immersive environments, such as well-designed video games can be used to both measure and promote the development of problem-solving skills in formal education settings.

The increased availability of vast and highly varied amounts of data from learners, teachers, learning environments, and administrative systems within educational settings is overwhelming. Therefore, Ifenthaler, Greiff, and Gibson examine the challenge of how data with a large number of records, of widely differing

datatypes, and arriving rapidly from multiple sources can be harnessed for meaningful assessments and for supporting learners in a wide variety of learning situations. They conclude with future directions in the broad area of analytics-driven assessments for teachers and educational researchers.

Lodge attempts to extrapolate from current developments to examine how the future of assessment might play out. New technologies afford possibilities for focusing assessment on learning as an ongoing developmental process, rather than on performance. There are prospects for assessing students continuously while they learn in a developmental way through the use of data and analytics. The resulting picture of student development will allow for a more holistic and systemic approach to assessment in the years ahead. Thus, the future is likely to entail more continuous, personalized forms of assessment that focus heavily on helping students to make better judgments about their own learning and development.

Abstract

IT-based assessment has been advancing rapidly, and its growth is set to accelerate with emerging opportunities for automatic data collection as well as increased possibilities of communication and interaction mediated by IT. In this chapter we aim to present an overview of the range of different opportunities for IT to support

assessment. We identify and discuss challenges for moving toward a situation where IT-based assessment can serve learners' needs as well as the broader needs of the educational system for evaluation. We examine theories related to assessment more generally as well as specifically to IT-enabled assessment and review recent research and development. Scenarios for IT-enabled assessments may take many different forms, some of which hold much promise for supporting learning, but there are theoretical, developmental, technical, and human challenges to be overcome. Our vision is for IT-based assessment design to move forward with designers, teachers, and learners working together to design assessments that support twenty-first-century curricula and pedagogy. In this shared endeavor, we expect that data can be collected and represented to enable learners and teachers to identify achievements; collate evidence of those achievements; diagnose needs, both cognitive and affective; and decide on suitable pedagogical approaches for enabling the next steps in learning. We argue that open assessment resources provide a vehicle for enabling the large-scale developments that are needed to support the development of IT-enabled assessment across the broad spectrum of learning. Some of the more complex twenty-first-century skills of collaboration, problem-solving, critical thinking, etc. present particular challenges. We envisage that it may take many years for our vision to be realized. In the medium term, the need is to integrate IT-enabled assessments where appropriate alongside more traditional methods including teacher assessment.

Keywords

Formative assessment · Summative assessment · Self regulated learning · IT-enabled assessment · Feedback · Analytics

Introduction

The future of assessment faces major challenges including, perhaps most importantly, the extent to which assessments, when enabled by IT, can serve simultaneously the needs of learners and those of the enterprise of education (Bennett 2015; Gibson et al. 2012). In many countries, in recent years, a renewed focus on assessments to support learning has been pushing against the burgeoning of testing for accountability (Black 2015; Shute et al. 2016), which, in some countries, renders effective formative assessment practices almost impossible (Black 2015). Furthermore a strong focus on summative assessment for accountability can reduce motivation and disengage many learners (Harlen and Deakin Crick 2002). At the same time, the use of IT-enabled assessments has been increasing rapidly, especially in some developed countries such as the United States (Shute et al. 2016), as they offer promise of cheaper ways of delivering and marking assessments as well as access to vast amounts of assessment data from which a wide range of judgments might be made about students, teachers, schools, and education systems.

Scenarios for IT-enabled assessments may take many different forms, some of which hold much promise for supporting learning (Gibson et al. 2012). Thus, while much effort in institutional and national testing systems is focused on harnessing the power of automated systems in order to reduce costs and increase efficiency (Bennett 2015), a range of different assessment scenarios have been the focus of research and development, often at small scale (Stödberg 2012), for some years. IT-enabled assessments may involve, for example, a pedagogical agent acting as a virtual coach patiently tutoring someone and providing feedback in anything they would like to learn (Johnson and Lester 2016), scaffolding students to complete a task and measuring how much support they need (Ahmed and Pollitt 2010), an analysis of a learner's decisions during a digital game or simulation (Bellotti et al. 2013), students reviewing and commenting on each other's digital creations through an online discussion (Webb 2010), a multimedia-constructed response item created with an online animation and modeling application (Lenhard et al. 2007), students receiving remote asynchronous expert feedback about how they worked with each other via IT to solve a problem and communicate their understandings (Rissanen et al. 2008), an emotionally engaging virtual world experience that unobtrusively documents progression of a person's leadership and ethical development over time (Turkay and Tirthali 2010), or semantic-rich and personalized feedback as well as adaptive prompts for reflection through data-driven assessments (Ifenthaler 2012).

This set of vignettes begins to outline a broad range of possibilities that place IT in a variety of roles including a medium for communication, learning assistant, judge, test administrator, and performance prompt, practice arena, and performance workspace (Webb et al. 2013). However, according to Bennett's (2015) review of the evolution of educational assessment, from a paper-based technology to an electronic one, the current state of educational assessment is between a first generation focused largely on infrastructure building and the second generation driven by efficiency. It will be in the third generation of assessments, not driven by technology but focused on cognitive principles and theory-based domain models, that will enable assessments to serve both the needs of learners and those of institutions, and this evolution is likely to take many years (Bennett 2015).

In this chapter, we examine the implications for learning, learners, teachers, and other stakeholders of new technological developments and the developments in assessment possibilities that have ensued or are envisaged. In this endeavor, we discuss aspects of theory that have underpinned assessment in education more generally and may inform future developments with IT-enabled assessment, such as self-theories affecting motivation (e.g., Dweck 2000) and theories and models of pedagogy (e.g., Shulman 1986) and self-regulating learning. We also highlight areas of theory that are developing rapidly in response to challenges and opportunities presented for assessment by new technologies. Our aim is to provide an overview of this dynamic field and to outline the challenges for practice, policy and theory, and key questions for future research. We start by outlining the various types of assessment and the terminology in this area in order to set the scene and discuss areas of contention in the use of terms that can and have led to confusion.

Types of Assessment and Terminology

The nature of formative and summative assessment and the difficulties of characterizing their differences and interrelationships have been much discussed in the literature (Assessment Reform Group 2002; Bennett 2011; Black and Wiliam 2009; Harlen and James 1997; Wiliam 2011). In order to provide some clarification for teachers, the terms “assessment for learning” and “assessment of learning” were proposed to replace formative assessment and summative assessment, respectively (Assessment Reform Group 2002). In these more teacher-friendly terms, it is the purpose of the assessment and the use to which the findings are put that typically characterize the assessment (Assessment Reform Group 2002; Black and Wiliam 2009). Thus, assessments *of* learning are used to assess a student’s learning at a particular point in time, usually at the end of a unit or course. A judgment will usually be made based on criteria, standards, or benchmarks, and the outcome may be used for accreditation purposes and entry to further courses and/or to inform decision-making regarding setting students into groups. On the other hand, assessments *for* learning have the formative purpose of supporting decision-making about the next steps in instruction. Thus, according to Black and Wiliam (2009),

Practice in a classroom is formative to the extent that evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers, to make decisions about the next steps in instruction that are likely to be better, or better founded, than the decisions they would have taken in the absence of the evidence that was elicited. (p. 9)

This definition places formative assessment at the heart of learning and classroom practice. The emphasis on the improvement of learning together with evidence, from meta-analysis of research studies, that formative assessment improves learning with strong effect sizes (Black and Wiliam 1998; Hattie 2009) has led to a renewed impetus for assessment to support learning. Thus, the phrase “assessment for learning” has become used widely in both compulsory and post-compulsory education not only in Western cultural settings but also in Confucian Heritage settings (Brown and Gao 2015; Carless and Lam 2014; Cheng 2016; Lee and Coniam 2013).

However, making a clear distinction between assessments on the basis of their purpose has proved more complex. For example, one of the useful formative practices that emerged in studies with teachers was the “formative use of summative tests” (ref p. 31) in which, for example, students might engage in peer discussion and feedback activities focused on reviewing their performance on summative tests. Thus, there is a recognition that these definitions and characterizations of types of assessment are not yet sufficient (Bennett 2011; Wiliam 2011). One of the reasons for the lack of clarity is that the word assessment is used for both processes of gathering evidence and feeding back comments as well as a label for the judgment of results. Thus, there are at least four ways to think about assessment, all of which can be supported or enhanced by the use of IT (Webb et al. 2013) (see Table 1).

One perspective is of the formative process – learning from the feedback information provided by an assessment process. Another perspective focuses on the results, which may be evident, for example, in revised lesson plans or in targets set by students for themselves, of adaptations made to instruction based on an interpretation of the

Table 1 Four ways to think about assessment (Webb et al. 2013, p. 453)

	Process focus	Results focus
Assessment <i>for</i> learning	1. Feedback information	2. Improvement decisions
Assessment <i>of</i> learning	3. Degree of engagement with/understanding of process	4. Value judgments

evidence from the assessment. The third is the understanding of the assessment and the degree of engagement by students and teachers in the assessment process. The fourth is the value judgment of results which provides summative information based on the evidence. Perspectives 1 and 3 in Table 1 are crucial for assessment to be formative and can be either short-term learning processes involving “interactive regulation” during the vast numbers of minute-to-minute interactions in classrooms (Perrenoud 1998) or in longer-term processes involved in planning lessons, designing activities, and setting targets (Perspective 2). Perspectives 3 and 4 are essential for summative assessment. Perspective 3 is important for both formative and summative assessment because unless students engage with the process of assessment, the information generated will not be valid. Furthermore, if the students fail to engage with the feedback information, there will be no effect on their learning. Perspective 4, in particular, is where there may be significant conflicts between the formative and summative assessment purposes. Making value judgments may be important at key transition points for the purposes of grading, accreditation, setting, etc., but such processes impact on students’ engagement with learning (Harlen and Deakin Crick 2002) as discussed later in this chapter.

Assessment *as* learning is a phrase that has crept into common use in education and reflects a renewed focus on the nature of the integration of assessment and learning. Key aspects of assessment *as* learning, which also supports the perspectives on assessment *for* learning outlined above, have been identified by Dann (2014) as the centrality of understanding the learning gap and the role of assessment in helping students and teachers explore and regulate this gap. Thus, feedback and the way students regulate their response to feedback (Perrenoud 1998) are critical for assessment *as* learning just as it is for assessment *for* learning.

Of particular interest for this book are the ways in which IT-enabled assessments can support the four perspectives that we have outlined. Therefore, in the following sections, using the framework shown in Table 1, we will examine how IT may support assessment now and in the future and what challenges arise.

Focusing on the Assessment Process: Feedback

Feedback is clearly essential for formative assessment, but feedback is not always useful for students’ learning, and much research has focused on the nature of effective feedback. Thus, for example, Sadler in emphasizing the importance of the quality of feedback stated “we now realise we have to understand not just the technical structure of the feedback (such as its accuracy, comprehensiveness and appropriateness) but also its accessibility to the learner (as a communication), its

catalytic and coaching value, and its ability to inspire confidence and hope” (Sadler 2010, p. 84). The challenge for IT-enabled assessment, however, is not only to deal with the subject matter but also to take into account a range of learners’ characteristics. Sadler was referring to quality in relation to feedback as a particular piece of information. However, we have characterized feedback as a process, in line with Wiliam (2011), to emphasize the importance of feedback processes as part of a system, because unless learners make use of the information, it is ineffective. Therefore, feedback becomes part of a communication process between learners and between learners and the teacher thus placing emphasis on interaction. Such interaction may be mediated by IT systems thus increasing the range of opportunities for interaction that may support assessment. In these processes, IT systems can enable synchronous communication at a distance using text, voice, and/or video links or asynchronously at different times using a range of discussion boards and social media applications. Such processes are now widely used across many areas of education and have been harnessed specifically to support assessment in a range of studies (e.g., Coll et al. 2014; Webb 2010).

While IT systems can provide the media for increasing feedback opportunities, the major challenge remains of gaining access to the learner’s understanding. Thus, as Perrenoud (1998) stated “one can only stimulate, reinforce, reorient, readjust or accelerate the pupil’s mental processes, in the hope of modifying the learning processes. This intention can only be effective if a window is found into the cognitive system of the learner”. The difficulties of understanding students’ specific cognitive needs for feedback have meant that automated feedback systems have tended to be restricted to particular subject areas and topics where the subject matter renders diagnosis of errors and misconceptions relatively straightforward (Mislevy et al. 2003a). However, automated feedback systems are an area of rapid research and development, and current evidence is examined in detail in “Formative assessment and feedback using IT” (van der Kleij and Adie) in this assessment section of this handbook. The technical challenges and future possibilities are also examined in depth in “Progress and challenges for automated scoring and feedback systems for large-scale assessments” (Whitelock and Bektik), in this section of this handbook. Feedback processes are, of course, also challenging for teachers, and typically good teachers manage this by means of a teaching/assessment cycle which according to Black critically incorporates assessment at each stage of the cycle (Black 2012, 2015) as discussed later in this chapter. Therefore, when developing IT-enabled feedback systems, it is a matter of not only building on teacher and classroom practices but also looking for ways in which the interaction and mediation capabilities of IT can be harnessed to support more focused and/or timely feedback.

Focusing on the Assessment Results: Improvement of Decisions

The results of an effective feedback process will be (1) good teaching focused on students’ needs and (2) students who understand or are coming to understand their own learning needs. This increased understanding is prerequisite for students to be

able to self-regulate their learning and thus to achieve autonomy in learning. Self-regulated learning is generally regarded as desirable for learning especially for online learning. There is evidence of improved performance in online learning correlating with some aspects of self-regulated learning. For example, in a study of over 800 community college students studying an online course, effort regulation, one aspect of self-regulation, as measured by the Motivated Strategies for Learning Questionnaire (MSQL) was significantly related to performance (Puzziferro 2008). Furthermore, a study of nearly 5000 students on 5 MOOCs (Kizilcec et al. 2017) showed that the goal-setting and strategic planning aspects of self-regulated learning predicted attainment of personal course goals.

On the other hand, autonomous learning is often claimed as being enabled by the use of IT (Chang et al. 2015), so there is potential for synergy here between assessment purposes and IT use in the promotion of learner autonomy. At the same time, development of the theoretical basis of self-regulated learning has moved toward increasing focus on co-regulation, socially shared regulation, and the importance of peer interaction (Chan 2012; Järvelä and Hadwin 2013) as discussed later in this chapter.

Focusing on the Assessment Process: Degree of Engagement and Understanding

The importance of affective factors in accurate assessment and effective feedback processes has been recognized by many in recent years and has been supported by detailed studies (see, e.g., Ifenthaler 2015) but has not always been given the attention it deserves (Sadler 2010). Vygotsky identified the separation of cognitive and affective factors as a major weakness of traditional psychology since “it makes the thought processes appear as autonomous flow of ‘thoughts thinking themselves’ segregated from the fullness of life, and personal needs and interests, the inclinations and impulses of the thinker” (Vygotsky 1986, p. 10). The recognition that engagement and motivation are important for learning goes back at least to the time of Dewey (1913). More recently, analysis of large datasets such as PISA test results, for example, has shown that affective factors contributed significantly to achievement in science and mathematics (Ozel et al. 2013).

In classroom-focused research with primary teachers, Webb and Jones (2009) found that developing effective formative assessment required a culture change associated with a range of affective factors, such as mutual support for each other’s learning and willingness to take risks as well as changing learners’ expectations. This culture change necessitated substantive change in classroom practices and indicated the major challenges for teachers in establishing effective formative assessment.

Dweck’s work on “self-theories” (Dweck 2000) has been particularly important in understanding students’ belief systems that are important for assessment for learning. In summary, Dweck found that students with a learning orientation seek to develop their skills and understanding because they believe that they can achieve

with sufficient effort. On the other hand, students who are oriented toward performance want to show their capability, and hence they shy away from more challenging tasks because they are concerned about failing.

Affective factors and engagement are equally important, in formal situations, where test anxiety is a significant concern for the validity of assessments. For example, a study of 50 fourth-grade students revealed a significant relationship between the students' levels of test anxiety, as measured by pulse rate, and performance on the New York State Standardized Science Test (Fulton 2016).

Given the importance of engagement for effective assessment and the evidence of affective factors influencing assessments, we will next consider the scope for IT-enabled assessments to support or hinder engagement in assessment. Ways in which IT-enabled assessment may promote or at least not hinder engagement include on-demand testing; background data collection enabling "stealth assessment" (Shute 2011) or "quiet assessment" (Webb et al. 2013); nonreactive assessment (Ifenthaler et al. 2010), which use traces in online learning environments; peer assessment supported through online discussions; as well as other more informal approaches.

Peer assessment is an active research area given the opportunities for IT-enabled peer interaction and the perceived potential for peer feedback to contribute to learning experiences in massive open online courses (MOOCs) (Suen 2014). Evidence of the value of peer assessment using IT is discussed further in "Formative assessment and feedback using IT" (van der Kleij and Adie), in this assessment section of this handbook.

Stealth assessment, coined by Shute (2011), is an approach to performance assessment by collecting and processing data from online activities automatically and unobtrusively while the students are interacting. While such an approach will enable the learners to focus on the activity rather than being concerned about the assessment, it also seems to take away learner control rather than encouraging learners to take responsibility for their learning and might also raise ethical issues. Therefore Webb et al. (2013) proposed an alternative approach described as "quiet assessment" in which students are well informed of the assessment process but can choose to carry on and ignore or "turn up the volume" in order to see a trace visualization of their performance and progress. Such quiet assessment requires methods of presenting such data in a meaningful way to students and teachers as well as a good standard of assessment literacy as discussed later.

Focusing on Assessment Results: Value Judgments

Recognizing students' achievements has always been an important element of education, and some judgments such as identifying appropriate courses for students and organizing groupings to support learning and teaching are clearly in students' interests. IT provides additional opportunities for making the necessary value judgments. For example, digital badges offer the opportunity to recognize learning anytime, not only in formal but also in informal learning environments (Mah et al. 2016). In addition to the recognition and bridging of learning inside and outside

educational institutions, the main roles of digital badges in education include motivational effects, signaling of achievements, and capturing learning paths (Gibson et al. 2013; Jovanovic and Devedzic 2015). Digital badges not only recognize personalized learning paths; they also have an impact on learning and learning motivations. So far, there are few empirical findings concerning how badges exactly affect learner motivation. Abramovich et al. (2013) concluded, in their small-scale study of approximately 50 students using an intelligent tutoring system for mathematics, that patterns of badge acquisition differed according to the prior knowledge level of the learners and that different badge types affected different learner motivations. In another small study of the perceptions of badges by 38 participants in MOOCs, where badges have been promoted as a method of dealing with the assessment of large cohorts, learners reported a generally positive response to the role of badges but with a range of different opinions concerning their value for both formative and summative assessment and some doubts about how their value would be perceived by employers and colleagues (Cross et al. 2014). Further research is needed to determine whether and how badges can be designed to affect motivation positively and to overcome the potential negative effects of their emphasis on extrinsic motivation.

As mentioned earlier, the focus on value judgments in summative assessments can be counterproductive for learning owing to adverse effects on students' motivation (Harlen and Deakin Crick 2002). For example, the use of assessment data for making judgments about teachers, schools, and courses may not be in students' best interests if such judgments adversely affect teaching and students' motivation and self-esteem. Harlen and Deakin Crick's systematic review (Harlen and Deakin Crick 2002) revealed that high-stakes tests can result in changes to teaching to a transmission style that only caters for a limited range of students. Furthermore, a strong emphasis on testing produces students who are extrinsically oriented toward grades and social status rather than being oriented toward learning (ibid.).

Perversely, opportunities enabled by IT for assessments may have exacerbated the problems caused by the results focus on value judgments associated with high-stakes assessment by giving administrators access to large datasets and new ways of manipulating the data to produce reports highlighting trends, issues, etc. Consequently, administrators see opportunities to use the data for a range of judgments without being aware of the consequences of such actions. Unintended consequences of assessments can result in threats to validity. Current theories of validity in relation to assessment are associated with not the assessment instrument itself but the use to which it is put and validity as affected by how the data is to be used (Messick 1994). Thus, an instrument designed to measure students' performance with a view to supporting their learning may be seen as engaging and interesting by students who are supported and encouraged by the teachers to perform as well as they can. However, if the results of this assessment are later to be used for making judgments about teachers, the teachers may put pressure on the students and "teach to the test," thereby increasing students' anxiety and decreasing their engagement. In this way, the validity of the assessment is threatened, and students are not well served.

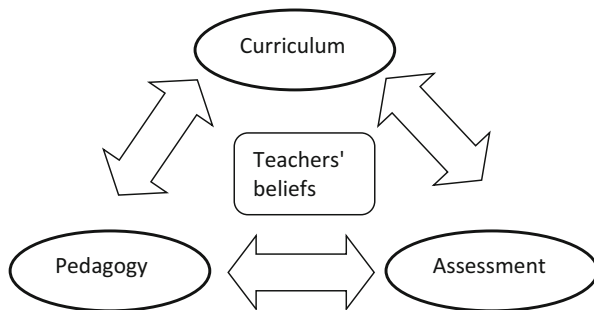

Assessment Within Learning Systems

As we have seen, assessment is closely associated with learning. In this section, we examine the relationships between assessment, curriculum, and pedagogy. A classic way of conceptualizing the relationship between curriculum, pedagogy, and assessment is in a triangular arrangement (see Fig. 1) with a push-pull relationship between curriculum, pedagogy, and assessment moderated by teachers' beliefs about learning.

Thus, where teachers believe strongly in the value of formative assessment and have sufficient freedom to implement their ideas, there will be a dynamic fruitful relationship between pedagogy and assessment perhaps to the extent of assessment becoming fully integrated into pedagogical practices. At the same time, the curriculum will inform pedagogical practices, and both pedagogy and assessment will determine how the curriculum is interpreted and delivered. However, where high-stakes assessments dominate, assessment can exert a controlling influence on pedagogy and may also influence the curriculum directly or indirectly through pedagogical practices which tend to focus on elements that are to be assessed. If the assessment is only able to assess parts of the intended curriculum, then the curriculum will become impoverished (Harlen and Deakin Crick 2002). Therefore, a key message indicated by the triangular push-pull relationship between curriculum, pedagogy, and assessment is that any changes in assessment approaches, including those based on technological developments, whether for formative or summative purposes, are likely to affect both curriculum and pedagogy. Summative assessment practices present a high risk to pedagogy as explained earlier. However, if summative assessment addresses curriculum goals comprehensively and well, then curriculum, pedagogy, and assessment can remain in a steady-state relationship in which all can change when necessary but they continue to support each other. Arguably formative assessment is always likely to support good pedagogy because both formative assessment and pedagogy focus on improving learning and their integration is an important goal.

We now turn to how pedagogical practices can integrate assessment. In commenting on the prerequisites for effective formative assessment and particularly feedback interactions, Perrenoud (1998) identified two levels of the management of learning processes: the first is the setting up of activities that provided opportunities

Fig. 1 A conceptual model depicting relationships between curriculum, pedagogy, and assessment

for learning based on curriculum requirements and the second is the interactive regulation which takes place within didactic situations (Perrenoud 1998). Perrenoud's explanation makes clear the crucial role of assessment information influencing key aspects of pedagogy. More recently Black built on Perrenoud's ideas and proposed a more comprehensive model of assessment in pedagogical practices (Black 2012, 2015) consisting of five stages with clear links between them and all involving assessment:

1. Clear aims: The first stage of planning
2. Planning activities: Setting up activities with the potential to achieve the aims
3. Implementation in the classroom
4. Review of the learning: Using informal assessments to check achievement
5. Summing up: Using assessment to guide decisions about the next stage of students' work

This model looks very similar to other models of pedagogical practice including Shulman's seminal model of pedagogical reasoning (Shulman 1986). However, there is a difference of emphasis. In Black's model the importance of assessment is emphasized at each stage. On the other hand, in Shulman's model, assessment must be assumed to take place since teachers' knowledge of the learners for which they are planning lessons is a crucial element in their pedagogical reasoning, but assessment is underemphasized. In addition to the central role of assessment at each stage, the links between all the stages are crucial because if any are broken, the whole system becomes broken (Black 2015). Furthermore Stage 5 is essential for planning the next step in teaching and learning, so the whole process is iterative.

A useful model for characterizing the particular roles of teachers and learners in the assessment elements of the pedagogical process was developed by Wiliam and Thompson (Black and Wiliam 2009; Wiliam and Thompson 2007) and later adapted to indicate the potential roles for IT as shown in Fig. 2 (Webb 2014). In this model as in Black's model of assessment in pedagogy, while the processes are numbered in an apparent sequence, the model is actually iterative as explained above (Webb 2014), and there are dynamic links between the processes which are essential for effective pedagogy. Roles for various types of IT have been identified as being supportive of each process.

Theories and Models of Self-Regulated Learning

As mentioned earlier self-regulated learning is enabled by self-assessment, and both of these aspects are important for learner autonomy and for supporting online and blended models of learning and assessment. Most theoretical models of self-regulated learning involve multiple components and phases (see, e.g., Pintrich 2000; Winne and Hadwin 2008). Thus, self-regulated learners have the potential to engage in continuous and concurrent regulation of metacognitive, behavioral, motivational, and emotional processes. Furthermore, they regulate these processes through a series of phases while performing a learning task. An increasing focus

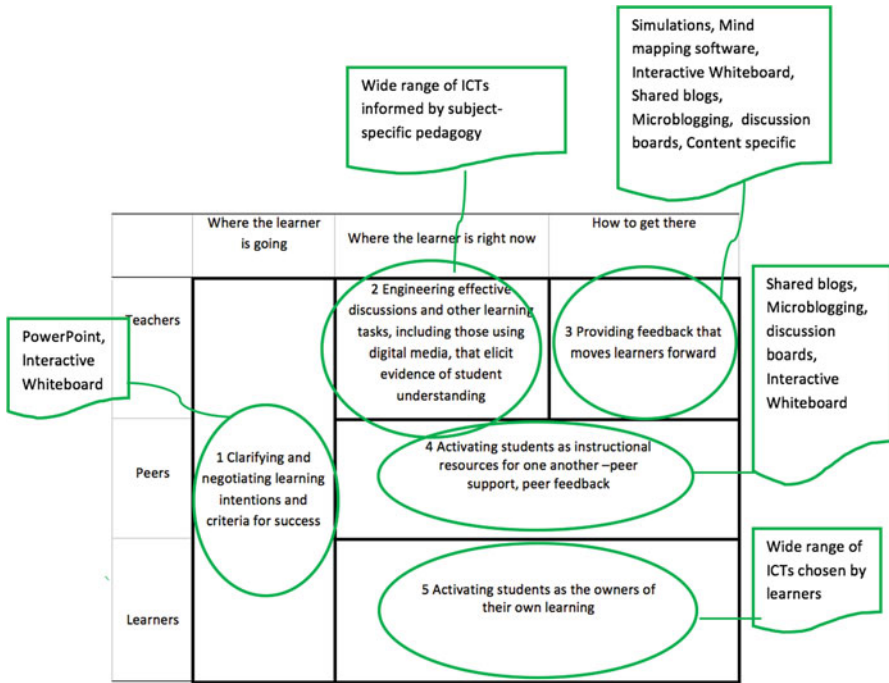

Fig. 2 Technologies in support of aspects of formative assessment adapted from a framework developed by Black and Wiliam (2009)

on collaborative learning places more emphasis on co-regulation or socially shared regulation of learning in which multiple group members regulate their joint activity in order to achieve a shared goal (Hadwin et al. 2010; Jarvela et al. 2008). Understanding of how groups regulate their learning and how these processes can be facilitated by teachers or technology is still building (Chan 2012; Ucan and Webb 2015). A detailed study of 14- to 16-year-old learning collaboratively suggested that the design of the activities at an appropriate level to challenge students and a positive socio-emotional atmosphere were crucial for enabling socially shared regulation not only of planning, monitoring, and metacognitive processes but also of social and emotional interaction (Ucan and Webb 2015). A study focusing on performance of teams demonstrated how IT-based systems can identify team-based performance on complex tasks on the fly as well as visualize the individual’s contribution to the group of learners (Ifenthaler 2014).

Assessing Twenty-First-Century Skills

So far in this chapter, we have discussed theoretical issues relating to assessment, learning, and pedagogy. Furthermore, we have focused on **how** to assess, but another consequence of the digital age is the changing range of knowledge and skills that

students need and thus a consideration of what to assess. Most frameworks of twenty-first-century skills acknowledge that new assessment frameworks are needed (Voogt et al. 2013). Typically, twenty-first-century skills or competencies comprise of a number of areas that have always been important but not always assessed adequately including collaboration, communication, citizenship, problem-solving, and critical thinking together with some newer aspects of learning including digital literacy, creativity, and productivity (ibid.).

Assessing some of these skills, especially social skills such as collaboration, has relied previously on teacher assessment and has often been difficult and hence underemphasized. More recently an IT-enabled approach to assessing collaborative problem-solving has been developed for the Organisation for Economic Co-operation and Development (OECD) Programme for International Student Assessment (PISA) (PISA 2015) – see “Making use of data for assessments: harnessing analytics and data science” (Ifenthaler, Greiff, Gibson) in this handbook.

In summary, IT-enabled assessments are expected in the future to offer new powerful and reliable ways of assessing twenty-first-century skills, but the challenges are significant, and in the short and medium term, it will be important to make use of teacher assessment for these more complex skills (Gibson and Webb 2015; Webb and Gibson 2015).

In order to develop these new approaches to IT-based assessment, it is not only important to build on new technological capabilities but also to develop a theoretical base for designing assessments.

Theoretical Underpinning for Developments of IT-Based Assessment

Reviews and group discussions of global ICT and assessment since 2009 (Webb et al. 2013) have combined research-based findings with classroom observations of assessment practices (Black and Wiliam 1998) and evidence-centered assessment design (ECD) (Mislevy et al. 2003b) to conceptualize ways of enabling assessments to support a range of needs and purpose. The ECD framework has become quite widely used among designers of IT-based assessment as it makes explicit the interrelationships and substantive arguments among the main elements of the design and implementation: domain models, validity, assessment designs, and operational processes (Mislevy et al. 2003a). The framework has diagnostic capabilities and provides opportunities for stakeholders to view estimated competency levels, to examine the evidence on which these judgments were based, and to use this information for a variety of processes as appropriate (Shute 2011, p. 9). It is also the primary organizing theoretical framework for the PISA assessment of collaborative problem-solving discussed earlier. In order to move toward assessment systems that support learners and teachers as well as automating elements of the assessment process and hence making it more efficient, Webb et al. (2013) argued that the ECD approach needs to be combined with formative assessment frameworks outlined earlier in this chapter and that teachers and students need to develop assessment literacy.

Understanding and Engaging with Assessment: Assessment Literacy

The need for assessment-literate teachers, students, and parents has long been recognized (Stiggins 1995), but research suggests that years of predominantly external testing have damaged teachers' confidence and ability to design assessments themselves and to understand validity considerations (Black 2015). In order to achieve the learning benefits that should accrue from IT-enabled assessments, teachers and students will need to be engaged not only in the production of new tools that visualize the information (e.g., to help shape how the new tools provide the most useful and understandable information) but also in the dynamic creation of meaning from the use of those tools in learning situations (e.g., to create personal insights from the experiences as well as the reflections made possible by the new tools (Webb and Gibson 2015). This implies that teachers will need to develop their assessment literacy but these tools in themselves can and should be designed to support teachers in this development. Furthermore, reconceptualizing assessment design as a shared process involving teachers enables a focus on the purposes of assessment, with due consideration of validity, while at the same time considering the optimum ways of combining technology enhanced assessment with other methods in order to achieve those purposes. Thus, our vision is for a future in which technology supports teachers and students working together with technologies to understand their learning needs, move their learning forward, and develop evidence of their achievements. We believe that this vision can best be achieved by teachers working together with designers to design both assessments and learning materials as well as involving learners in these design processes wherever possible.

Addressing the Challenges of Assessment: The Promise of IT-Based Developments

We have already mentioned a number of IT-based developments that show promise in supporting twenty-first-century learning as well as the needs of educational systems. These developments include the use of a range of communication software tools to support teacher and peer feedback, quiet assessment to enable background collection of assessment data whose volume can be turned up to enable self-assessment, digital badges that may motivate students in informal learning as well as formal settings and are discussed further in "Assessing Problem-Solving Skills in Immersive Environments" (Shute and Emihovich) in this assessment section of this handbook, and automated feedback systems that are discussed further in "Formative assessment and feedback using IT" (van der Kleij and Adie), also in this assessment section of this handbook.

A promising current area of rapid research and development is learning analytics applied to large datasets that can enable the learning scenario and the actual performance of an individual or a team to be stored and analyzed in real time (Ifenthaler 2015). Intelligent adaptive algorithms for personalized feedback have

been developed; however, only a few have been implemented in educational settings (Ifenthaler 2015) as discussed in “Making use of data for assessments: harnessing analytics and data science” (Ifenthaler, Greiff, Gibson) in this handbook.

Developing a suitably wide range of assessment instruments to enable the vision we have outlined here presents a considerable challenge, so finding a way of sharing and building on developments is also an important goal. Open educational resources (OER) are learning, teaching, and research resources that reside in the public domain or have been released under an intellectual property license that permits their free use and repurposing by others. Open assessment resources (OAR) include free automated formative assessments (and free support for semiautomated and fully human formative assessments) to advance the trend toward scale. In order to support higher level learning, we propose to focus the OAR on transferrable deep learning processes (e.g., collaborative problem-solving, creativity, self-regulation, metacognition) from specialized fields into broader contexts (Gibson et al. 2016) as discussed further in “Making use of data for assessments: harnessing analytics and data science” (Ifenthaler, Greiff, Gibson) in this handbook.

Conclusion

In this chapter, we have outlined current thinking in relation to assessment generally as well as the developing field of IT-based assessment in order to map the theoretical landscape and outline new opportunities. In this endeavor, we have shown that IT-based assessment is developing rapidly but is still at an early stage of development toward a goal of such assessments being based soundly on cognitive principles and theory-based domain models as well as taking account of affective factors in learning. Our vision is for IT-based assessment design to move forward as a shared endeavor where designers, teachers, and learners work in partnership to ensure that assessments match changing curricula, support learning needs, and provide data representations that are meaningful to learners and teachers, as well as provide information to policymakers where appropriate. Realizing this vision across the whole spectrum of learning is likely to take many years. As we move forward, it is important to recognize the need to combine various types of assessment in order to ensure that assessment addresses the whole curriculum and, in particular, some of the more complex areas to assess, such as twenty-first-century skills of collaboration and critical thinking, are not ignored. Thus, teacher assessment should be recognized as playing an important role, and the need for supporting and enabling peer assessment with and without IT remains. Important implications for learners of new opportunities for IT-enabled assessment of first that they not only may find new ways of learning, enabled by IT, both within school and outside but that their achievements in all these situations can be measured and recognized. In order to take advantage of these opportunities, learners need to develop skills in self-regulated learning, and teachers need to support them in this development. Furthermore, teachers have responsibilities to develop their assessment literacy and to become engaged in assessment design. For policymakers, it is important to facilitate a shared approach

to assessment design in which all stakeholders participate to maximize the opportunities and consider the potential consequences of design decisions, including decisions regarding the purpose and use of assessments, for curriculum and pedagogy as well as for the validity of assessments.

We have identified a number of challenges for moving toward a situation where IT-based assessment can serve learners' needs as well as the broader needs of the educational system for evaluation at various levels. Thus, future research on IT-based assessment may focus on the following challenges:

- To what extent can the validity issues associated with using assessments from multiple purposes be overcome to enable needs of learners and of evaluation of education systems?
- How can assessment data be made accessible and understandable to all stakeholders?
- How can assessment data support stakeholders?
- How far can peer assessment and feedback replace or complement teacher assessment, and what are the social and cultural factors that need to be considered?
- Can we develop the synergy between the opportunities presented for autonomous learning through IT systems and the feedback opportunities presented by IT-based assessments?
- How can assessment information from distributed networks and unstructured data be directly linked to additional educational data collected within an institution's environment?
- What opportunities arise from the development of automated natural language processing (NLP) capabilities? The major challenge besides the development of real-time NLP is the validation of such algorithms and the link to quantitative educational data.

The chapters within this assessment section of this handbook address many of these challenges and open up additional issues which need to be addressed as educational technology is evolving rapidly.

Abstract

Formative assessment including feedback to students on their learning is widely recognized as an effective means to support student learning. Research has found that the potential of formative assessment in improving student learning is often not fully realized in classroom practice. IT provides a possible solution for overcoming some of the obstacles when implementing formative assessment. This chapter reviews various ways in which IT has been used in formative assessment, focusing specifically on digital learning environments, game-based assessment, classroom response systems, Web 2.0, and video feedback. The results suggest that using IT as a platform for feedback provides opportunity

to individualize feedback, increase student engagement, collect learning evidence for all students, facilitate reflective processes, and support self-regulated learning. Reported potential challenges to the utilization of IT include time restrictions, limited response formats, technical difficulties, access to evidence of student learning for teachers, and teacher knowledge and skills. One key finding is that although innovations in technology have evolved considerably, many promising possibilities are not yet being exploited for the purpose of formative assessment. Most importantly, research demonstrates that not the technologies themselves, but the ways in which they are used impact on their formative potential. Bringing together IT and formative assessment may open up the potential for moving from convergent forms of feedback to more open, divergent feedback practices.

Feedback · Formative assessment · Classroom practice · Technology · Student learning

Introduction

Formative assessment is widely recognized as an effective means to support student learning (e.g., Black and Wiliam 1998). Feedback is a critical aspect of formative assessment (Hattie and Timperley 2007; Sadler 1989). Feedback in formative assessment refers to (i) insights into student learning provided to teachers and other stakeholders, and (ii) messages provided to students (by self, teachers, peers, digital devices, etc.) that are intended to directly influence their learning processes cognitively or metacognitively (Sadler 1989). Research has found that teachers and students do not necessarily fully engage with formative assessment processes, which in practice has resulted in disappointing outcomes. For instance, in the seminal work on feedback (e.g., Black and Wiliam 1998; Hattie and Timperley 2007), the importance of motivation in the feedback process is acknowledged in two ways: (1) feedback can motivate students to learn, and (2) students need to be motivated in order to use feedback to improve their learning. A recent review by Heitink et al. (2016) identified numerous prerequisites for the effective implementation of formative assessment in the complex reality of diverse classroom contexts. IT provides a possible solution for overcoming some of the obstacles when implementing formative assessment, such as providing timely individualized feedback on student learning in a way that engages learners.

This chapter evaluates the existing evidence of how IT has been used, and could be used, in formative assessment. The chapter commences with a brief overview of formative assessment and feedback to establish the conceptual framework in which the review is set. The following is a review of research into a range of IT tools and applications for formative assessment and feedback.

A Brief Overview of Formative Assessment and Feedback Research

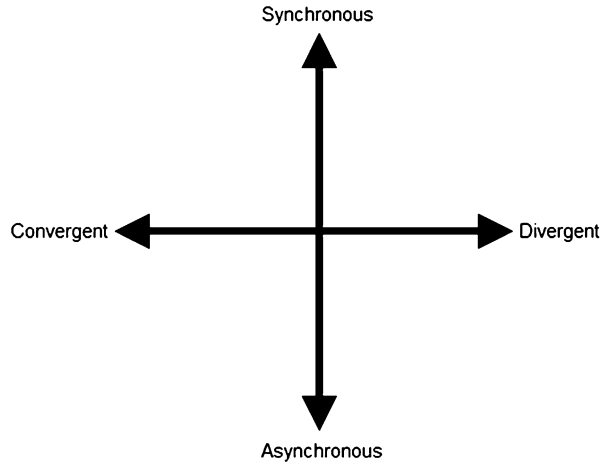

There is a long tradition of feedback research in education, yet evidence on feedback effectiveness is often inconclusive (Shute 2008). Research has demonstrated that the most frequently used type of feedback by teachers is praise, which unfortunately has limited value for student learning (Hattie and Timperley 2007). More elaborated feedback has generally been found to be more effective than simple corrective information (Hattie and Timperley 2007; Shute 2008). Results from a recent review suggest that formative feedback needs to be specifically related to the assessment task and student performance, and should provide suggestions for improvement (Heitink et al. 2016). Such feedback can positively enhance students' motivation for learning and result in improved learning outcomes (Hattie and Timperley 2007).

Most of the research on feedback in formative assessment has been conducted from a cognitivist perspective, in which feedback has been conceptualized as corrective information that is transmitted by an expert teacher to a passive learner, expected to result in improved learning (Evans 2013). However, recent literature increasingly emphasizes the importance of active student involvement in formative processes. For example, Black and Wiliam (2009) identify that internalization of feedback by the student is necessary for feedback to affect cognition. Thus, feedback is facilitative rather than directive, and ideally takes place in dialogue. The student's active role in seeking feedback is emphasized. Feedback may provide suggestions for improvement, but ultimately students decide what to do with feedback and whether to act on it (Evans 2013). Furthermore, the importance of the learning context and students' levels of motivation for learning have long been recognized to be fundamental to students' engagement with feedback (Black and Wiliam 1998).

A critical goal of formative assessment is to provide students with skills to self-regulate their learning (Black and Wiliam 2009). ► [Chapter 41, "Assessment as, for, and of Twenty-First Century Learning Using Information Technology: An Overview"](#) (Webb & Ifenthaler), in this assessment section of this handbook, contains a discussion of how theories of self-regulated learning relate to formative assessment practices. Self-regulated learners can effectively generate and use internal feedback, provide feedback, and become increasingly less reliant on externally provided feedback (Butler and Winne 1995). Peer and self-assessment can play an important role in developing students' self-regulatory capacities (Black and Wiliam 2009; Wang 2011). In peer assessment, students take on the role of assessor and provide feedback to their peers, demonstrated to be valuable in developing students' sense of quality (Yu and Wu 2013). Self-assessment requires learners to be actively engaged in monitoring their own learning progress, and generates internal feedback to self-regulate (Panadero et al. 2016).

Feedback practices can be understood within a two-dimensional continuum (Fig. 1), ranging from asynchronous (with a delay) to synchronous (real time) feedback interactions, and convergent to divergent feedback.

Fig. 1 Dimensions of feedback interactions

Torrance and Pryor (2001) first described assessment as convergent with reference to the practice of assessing whether students have met specific learning goals, where typically the teacher is the sole assessor. This notion extends to feedback interactions (Pryor 2015), in which convergent feedback describes that which addresses but does not go beyond prespecified learning outcomes. Convergent feedback describes those feedback instances where the focus is on detailing correct responses and specifically identifying where errors have occurred and how to correct these, thus closing the gap between current and desired performance (Sadler 1989). In contrast, Torrance and Pryor (2001) described divergent assessment as being exploratory in nature where students are given a chance to demonstrate what they can do beyond the bounds of curriculum. Thus, divergent feedback describes feedback that goes beyond prespecified outcomes and corrective information. Students, teachers, and peers engage in a feedback dialogue in which the student identifies the type of feedback they require to progress their learning, and students may also provide feedback to the teacher. Students are also actively participating as self-assessors, providing feedback to themselves that extends their individual and internalized learning goals. Divergent forms of feedback involve students as co-constructors of meaning in feedback interactions.

Digital platforms provide opportunities for feedback to be instantaneous and continuous. They also provide opportunities for asynchronous feedback through, for example, voice and video recordings that deliver personalized messages. The form of feedback as corrective or extending thinking may occur synchronously or asynchronously dependent on the application and learning focus. Figure 1 provides a framework to consider the form of feedback made available through the digital platform. The following section provides an overview of the various digital platforms in terms of the type(s) of feedback interaction they facilitate.

Formative Assessment and Feedback Using IT: Tools and Applications

Digital Learning Environments

In digital learning environments, feedback is often provided to students based on their correct or incorrect response to a task, either immediately or with a small delay. The potential advantages of the convergent and synchronous application of automating feedback in computer-based assessment have long been recognized. As early as the 1920s, Pressey invented the “teaching machine,” a machine that included multiple-choice questions and informed learners of the correctness of their responses, also known as knowledge of results. The purpose of providing such feedback was to reinforce correct responses, consistent with a behaviorist perspective on learning. Perspectives on learning and the potentials of technology have evolved considerably since; however, the way feedback is provided to learners in many digital learning environments is still remarkably similar to those in the teaching machine (e.g., Cayton-Hodges et al. 2015). And although computer-based assessments have been programmed onto a variety of tools, such as computers or tablets, the presentation of assessment tasks and feedback is still very similar to traditional paper-and-pencil formats with simple response formats and feedback in the form of ticks and crosses (e.g., Faber et al. 2017).

Currently, much of the research into digital environments with automated feedback involves a static set of tasks that is completed by all students, similar to paper-based tests (van der Kleij et al. 2015). Innovations in psychometrics and technology have opened up possibilities to tailor the difficulty of tasks to the ability level of the learner, which has the potential to enhance the effectiveness of digital learning tools. However, a recent meta-analysis (Kuo and Wu 2013) in mathematics and science indicates that both formative assessment and adaptive assessment are underutilized in digital learning environments.

While much of the previous research has focused on closed answer item formats such as multiple-choice, IT offers possibilities for providing automated feedback on more complex task formats. Automatic essay scoring systems have been developed for student writing tasks, which when utilized in conjunction with teacher feedback, have been shown to reduce teacher workloads and increase students’ writing persistence (Wilson and Czik 2016). However, automated feedback on writing by itself may not be very effective; a recent meta-analysis reported an average weighted effect size of 0.87 for adult-provided feedback compared to 0.38 for automated feedback (Graham et al. 2015). For additional discussion of this topic, see also ► [Chap. 43, Progress and Challenges for Automated Scoring and Feedback Systems for Large-Scale Assessments](#) (Whitlock & Bektik), in this assessment section of this handbook.

Regarding the effects of feedback in digital learning environments in primary, secondary, and tertiary education, a recent meta-analysis (van der Kleij et al. 2015) found an effect size of 0.05 for knowledge of results, which means that it is

essentially just as effective as no feedback. The meta-analysis found substantial differences between the effects of different methods for providing feedback, and highlighted the need to take into account the complexity of the learning to be achieved. When the aim is for students to memorize or understand material, providing them with knowledge of the correct response is generally moderately effective (overall $ES = 0.32$). In the case of more complex learning, where the learner is required to apply their knowledge and skills, *elaborated feedback* works best (overall $ES = 0.49$). Elaborated feedback includes information additional to knowledge of results, such as an explanation, strategic hint, worked out solution, or a reference to additional study material. This type of feedback includes elements of instruction and goes beyond the correctness of the learner's response (Hattie and Timperley 2007), which can help students identify *how* they can improve. Van der Kleij et al. (2015) found that elaborated feedback is particularly effective when it gives students hints or strategic information which stimulates students to think deeply about the task and their strategies, thus supporting self-regulation.

Intelligent tutoring systems provide a platform for the provision of elaborated feedback (Narciss 2013) or scaffolding to support next-steps in student learning. When used in this way, students receive subtle and gradual feedback to enable them to recognize and correct errors in knowledge and strategy, and use feedback in subsequent tasks. This use of intelligent tutoring systems for elaborated feedback has been found to establish the conditions for students to develop self-regulated learning skills. For instance, Narciss and Huth (2006) compared the impact of knowledge of correct response and "bug-related tutoring" feedback, which provides explanations for errors in addition to knowledge of correct response, in a sample of 50 German fourth-grade mathematics students. Students in the bug-related tutoring condition demonstrated higher levels of mastery indicated by correctly solving two similar mathematics problems, greater ability to self-correct errors, and improved academic performance from pretest to posttest. The research also reported enhanced student motivation levels in the bug-related tutoring condition: "The positive feedback effects on motivation are consistent with the view of current motivation theories which assume that mastery experiences resulting from successful task completion and the feeling of personal causation are crucial for developing positive perceptions of competence" (p. 319). Extending on these findings, a Taiwanese study in fifth-grade science concluded that the option for students to request hints as a guide toward correct responses increased achievement compared to knowledge of correct response (Wang 2008). In Wang's study, students were also able to ask the teacher questions asynchronously.

Several studies have explicitly explored the relationship between digital platforms and self-regulated learning. In a 2011 study involving 123 seventh-grade biology students, Wang examined the effects of five peer-supported self-regulation strategies in an e-learning environment. The strategies involved the use of answer notes to explain students' reasoning for choosing a particular response and the review of their peer's answer notes. Students who had access to the self-regulation strategies scored higher on a self-regulation behavior questionnaire compared to the control group who did not. Regulation feedback including questions relating to, for instance, task comprehension, strategy use, and reflection on the solution was the focus of another study

involving 65 ninth-grade mathematics students in Israel (Kramarski and Gutman 2006). In this e-learning environment, it was found that knowledge of results plus regulation feedback was significantly more effective than knowledge of results only ($ES = 0.44$). Timmers et al. (2015) used a similar self-regulation feedback strategy in their study of information literacy involving 50 thirteen-year-old students in the Netherlands, but also included a self-assessment component. They found significant positive improvements in performance and strategy use in girls only.

The effects of self-regulatory scaffolds have also been examined in the context of biology learning in a hypermedia e-learning environment for 53 tenth-grade and 58 seventh-grade students in the United States (Azevedo et al. 2005). Students were assigned to one of three conditions: no scaffolding, fixed scaffolding, and adaptive scaffolding. In the fixed scaffolding condition, students received a list of goals to guide their learning. In the adaptive scaffolding condition, students could request digital guidance from a human tutor, who would, for example, help them “monitor their emerging understanding” (p. 392). Students in the adaptive scaffolding and no scaffolding conditions outperformed those in the fixed scaffolding condition in terms of knowledge gain. Moreover, students in the adaptive scaffolding condition demonstrated better self-regulatory strategies.

A limitation of the research into digital learning environments has been the focus on textual feedback, with the potential of multimedia being underutilized (van der Kleij et al. 2015). Ostrow and Heffernan (2014) found the use of video feedback increased student engagement. Their study compared video and textual feedback in a digital learning environment for 139 eighth-grade mathematics students from the United States. The video feedback demonstrated a researcher reading a feedback message and referring to a worked solution on a whiteboard, while the textual feedback conveyed the same information. Students in the video condition spent more time engaging with feedback than students in the text only condition and completed subsequent mathematics problems more quickly. While the provision for students to ask questions and respond to teacher feedback was not an aspect of this study, it is an area requiring further consideration if feedback is to promote self-regulatory skills, dialogue, and deep engagement. In addition, researchers have called for systems that provide opportunities for classroom-integrated technology that informs the teacher of how students are engaging with the task (e.g., Faber et al. 2017). Further research is required into online systems that provide a range of feedback for both the teacher and the student while increasing the opportunity for dialogue about feedback and learning.

Gaming elements have often been incorporated into digital learning and assessment environments to enhance motivation or engagement (e.g., Wang 2008). The following section considers the form of feedback that game-based digital platforms may provide to teachers and students.

Game-Based Formative Assessment

Game-based digital platforms through their design can offer challenge and an element of play that motivates students to participate in formative assessment

(Wang 2008). In primary and secondary classrooms, tablets are popular devices for educational games. However, research (Cayton-Hodges et al. 2015) has found that although the majority of applications claimed to be game-based learning environments, in many instances, the assessment components were presented as explicit tasks that interrupted the gaming experience. Assessment tasks were usually presented in multiple-choice formats. Some exceptions included rich interactions using an array of presentation and response formats, such as drag-and-drop using visuals and written responses. Feedback was communicated visually, including the use of videos, or via audio. In some of the apps, feedback involved specific guidance to learners during problem-solving, identifying specific errors and providing explanations, and the option for students to request hints. While the majority of feedback was corrective in nature, or provided an overview of the number of tasks correctly solved, there was evidence of more sophisticated and divergent forms of feedback.

Advances in technologies have resulted in the development of more complex game-based assessment systems, for example, in the form of simulations (e.g., Shute et al. 2017). Well-designed games have the capacity to collect a wide range of data about the user's performance as they progress through the game, such as response time and whether or not students request hints, and utilize this information to generate individualized formative feedback (Cayton-Hodges et al. 2015; Shute et al. 2017). Shute (2011) used the term "stealth assessment" to describe the seamless assessment and learning environment, whereby the individual is unaware of the assessment process during their engagement with a digital game. However, the analysis of complex performance data (that goes beyond the correctness of a response) and the subsequent translation to feedback that will be useful to learners is a challenging topic of ongoing research (Azevedo et al. 2010; Shute and Kim 2014). Shute and Emihovich examine the progress to date in ► [Chap. 44, "Assessing Problem-Solving Skills in Game-Based Immersive Environments,"](#) in this section of this handbook.

Classroom Response Systems

Classroom response systems or "clickers" provide opportunities for nearly synchronous formative assessment in classroom settings and are most suitable in a convergent assessment context. Clickers consist of a handheld device used by students to transmit their responses to questions, which are then aggregated and displayed in a graph via a projection screen (Kay and LeSage 2009). Previous studies have identified a number of formative assessment applications for clickers, including identifying students' (mis)understandings of instructional materials, assessing students' capacity to transfer knowledge, student self-assessment, and ascertaining students' current knowledge base and capabilities (Caldwell 2007).

Classroom response systems enable teachers to obtain responses from all students, and use this information to modify course content or pacing to address student needs (DeSorbo et al. 2013; Feldman and Capobianco 2008; Vital 2011). Such systems are particularly valuable for students who are experiencing difficulties with content and may be reluctant to participate in class discussion. Many studies of

clicker use in schools have utilized simple handheld devices that allow for multiple-choice type responses, consistent with a convergent assessment paradigm. These appear to result in improved levels of student engagement (DeSorbo et al. 2013; Vital 2011) and achievement (Mun et al. 2009), possibly associated with increased demands for participation and the availability of (generic) formative feedback. Reported challenges regarding the use of clickers include the malfunction of the hardware, time pressure, student maturity levels, limited response formats, the construction of appropriate questions, utilizing feedback formatively, and discomfort with the new technology that interfered with students' learning (Kay and Knaack 2009; Lee et al. 2012; Vital 2011). However, with the increasing accessibility of technology and use in all aspects of life, it is anticipated that these issues would have diminished over time.

More advanced classroom response systems enable a broader range of response formats such as open-ended responses, therefore addressing some of the limitations of earlier systems (Shirley and Irving 2015; Irving et al. 2016) and opening up possibilities for more divergent assessment. A case study of the use of classroom response systems in elementary mathematics classes with the addition of interactive whiteboards and notebooks enabled opportunities for high cognitive demand questioning (Polly et al. 2014). Students were given time to solve a complex task and write down their solution steps before selecting a response on their clicker. A camera allowed students to project their work on the whiteboard and to discuss their reasoning and approach to solving the task. This resulted in deeper levels of student learning, as well as better teacher understanding of students' knowledge and problem-solving processes, which enabled teachers to provide students with more detailed feedback. In summary, the system facilitated the opportunity to elicit whole class responses which informed both teacher and student decisions about next-step teaching and learning.

Web 2.0 Platforms for Mediating Feedback

Web 2.0 refers to web-based media that enables interactive authorship to generate content such as blogs, social media, e-portfolios, or wikis (Fendler 2011) in both synchronous and asynchronous communication. Teachers can gain information on student strengths and weaknesses, and levels of understanding and interest through student contributions to Web 2.0 platforms, thereby enabling formative assessment and adjustment of curriculum content as required (Ruday 2011). Web 2.0 supports cloud-based collaborative writing allowing for interaction between students and their peers and teachers to facilitate formative feedback and learning. It also provides a platform to provide open-ended assessment tasks and feedback that is more divergent in nature.

The capability of deep student engagement with assessment and multiple forms of feedback can be found in blogging software. For example, blogging software was used as a platform for a 'book club' for a third-grade class in the United States (Stover et al. 2016). Students utilized the blog to discuss the book, and to reflect on previous posts, reading-related skills, and habits. The teachers shared a rubric to facilitate student self-assessment of reading comprehension. The class discussed

examples of blog posts and assessed their positioning on the rubric. Teachers interacted with students via the blog, providing comments to interrogate students' thinking and build comprehension. The blogs provided the teachers with more transparent information on student strengths and weaknesses in relation to reading comprehension and skills, which enabled them to differentiate instruction.

Another study, involving 40 Year 11 English students in China, used Facebook as the hub for peer and teacher feedback (Kio 2015). The teacher initiated and moderated a Facebook group for the class to provide peer support and feedback outside of school hours. To encourage participation, the teacher posted information about lessons, homework, assessment, and other activities. Students discussed class topics and provided peer feedback via the Facebook wall. While students reported that feedback from multiple peers was convenient and aided in motivation, it sometimes lacked the specificity and richness they required, and it remained a convergent form of feedback. A similar finding was found in a study that utilized a cloud-based platform for collaborative writing in four American schools Grade 6 to 8 English classes (Yim et al. 2014). The students used Google docs for simultaneous collaborative writing using the comment, highlight, and editing features. Students could choose who to share their work with, and request peer and teacher feedback over several rounds of revision. This resulted in focused dialogic feedback on the students' identified areas of need. However, while the platform overall supported the continual expansion and development of ideas through "the continuity of writing and revision" (p. 249), student feedback frequently focused on sentence-level features rather than broader-content-level issues. In addition, most students worked individually while providing, receiving, and using peer and teacher feedback rather than as a platform for collaborative writing. These studies demonstrate that the platform alone will not promote deep engagement – these skills need to be taught for the potential of the system to be realized.

The purposeful incorporation of an online platform with explicit instruction on self-regulatory skills was evident in a Scottish study involving 305 students aged 5–14 years (McLaren 2012). This study combined a multimedia "e-scape" portfolio and blog to assess and facilitate feedback on the skills of creativity, iterative design processes, and reflective thinking. Students were able to access a range of tools to record their thought processes including text, drawing, mind maps, photos, audio, and video. Examples of thought processes were captured using a rubric that required evidence of analysis skills, decision making, and justification. Students also recorded personal learning goals for the purpose of self-reflection and self-assessment. Each student was connected to the e-scape management system via classroom Wi-Fi, and teachers provided individual audio or textual feedback. Teachers indicated various approaches to feedback including probing for deeper thinking, encouraging self-reflection, or providing more information or instruction and directions for subsequent work.

Video Feedback

Video feedback has been utilized in classroom contexts for teacher feedback (Ostrow and Heffernan 2014) as well as supporting self-assessment (O'Loughlin et al. 2013),

peer assessment (Lenters and Grant 2016), and reflecting on the feedback process itself (van der Kleij et al. 2017). Ostrow and Heffernan (2014) suggested that “the use of video forces the learner to slow down and internalize the concept that is being taught” (p. 299). O’Loughlin et al. (2013) reported enhanced levels of motivation, engagement, and learning for students when video recordings of performance were used for self-assessment in an Irish physical education class of 23 nine- to ten-year-old students. In this case, rubrics were used to guide students in self-assessing their video-recorded basketball skills, and the teacher provided supplementary feedback as needed.

Using video for recording peer feedback has also been found to have instructional merit. Lenters and Grant (2016) reported on a Canadian trial using iPads and iPods as recording devices for peer feedback in fifth-grade writing. The teacher and students were familiar with written and face-to-face peer feedback processes using structures such as “I noticed . . .” or “I wondered about . . .” (p. 190). The teacher and students reported two benefits of using video recordings for feedback. First, students were better able to communicate their feedback in the way they intended, which they indicated resulted in fewer misinterpretations. Second, students could consult the recorded feedback as often as needed. Although some students reported a certain level of discomfort recording their feedback, many reported feeling more comfortable recording their feedback than having to discuss this face-to-face with their peer, which resulted in more objective feedback.

The use of iPads for videoing one-to-one teacher–student feedback conversations for supporting self-reflection and self-regulation was trialled in Australia with six teacher–student pairs in Year 9 (van der Kleij et al. 2017). Individual video-stimulated recall sessions were held with participants in which they were asked to stop the video recording and comment on the instances they identified as relevant. The video technology enabled teachers to self-assess their feedback practices and the effect of these on the student. Besides reviewing the feedback, students justified their responses to the feedback and considered their contribution to the conversation. Through this reflective process opportunities for self-regulation of both teachers and students were realized.

These studies demonstrate the relative benefits of video feedback over written or face-to-face feedback for both teachers and students. Video recording offers both a personalized connection with the feedback, as well as, in the case of peer feedback, some distance to provide more objective comments. Being able to articulate the feedback and demonstrate through examples enables individualized feedback otherwise not possible in limited class time. The opportunity to revisit the feedback is another benefit of video recording.

Conclusion

Formative assessment and feedback have been shown to contribute to effective learning but, as has been shown, within the situated reality of classrooms there will be variable outcomes (Heitink et al. 2016). This chapter reviewed various ways in which IT has been used in formative assessment, focusing specifically on digital learning environments, game-based assessment, classroom response systems, Web 2.0, and video feedback. Using IT as a platform for feedback provides opportunity to

individualize feedback, increase student engagement, collect learning evidence for all students, facilitate reflective processes, and support self-regulated learning. Reported potential challenges to the utilization of IT as a platform for divergent forms of feedback include time restrictions, limited response formats, technical difficulties, access to evidence of student learning for teachers (Faber et al. 2017), and teacher knowledge and skills, for example, in posing appropriate questions (Lee et al. 2012). However, most studies report on case studies in specific classes and more research on a larger scale is required to substantiate these findings.

One key finding is that although innovations in technology have evolved considerably, many promising possibilities are not yet being exploited for the purpose of formative assessment. Namely, digital assessment tasks frequently resemble paper-and-pencil tests, and feedback is often convergent, taking the form of ticks and crosses or written text of a corrective nature. Further, more research is warranted on the impact of regulation feedback and how this may enhance student learning (e.g., Kramarski and Gutman 2006). Moving forward, learning tasks could take place in, for example, 3D simulations, and feedback can be provided in the form of audio, video, and web links to online resources, on demand, or in dialogue with a virtual peer or teacher. It should be possible for students to ask for clarification or additional elaborations on feedback to enhance the usability of feedback. This would make feedback more accessible and engaging, and is likely to motivate students to engage with feedback.

Most importantly, research demonstrates that not the technologies themselves, but the ways in which they are used impact on their formative potential (e.g., Polly et al. 2014; Wang 2008). Skills in providing and accessing feedback need to be explicitly taught. As was highlighted in a recent review, teachers' knowledge and skills are vital to successful formative assessment practice (Heitink et al. 2016). For instance, if teachers do not have the skills to translate results into decisions for appropriate follow-up instruction and feedback (Lee et al. 2012), using IT will have limited formative potential. Another recurring issue is the quality of peer feedback (Kio 2015; Yim et al. 2014); if students do not possess skills in providing quality feedback, adding a digital tool for communicating such feedback is not going to enhance its effectiveness. Students need to be given guidance in the peer feedback process to make the process beneficial to both feedback providers and receivers (e.g., Lenters and Grant 2016).

Research to date suggests that formative assessment practices using IT are often convergent in nature, but possibilities exist for more divergent feedback practices. Once again, of importance here is how the technology is being used. For example, iPads can be used in very similar ways to paper-based materials, but also have the potential to be used by students to engage in formative assessment processes, through activities such as compiling digital portfolios to evidence their learning (Cumming and van der Kleij 2016), or by opening spaces for dialogue (van der Kleij et al. 2017). IT provides students with a platform for self- and peer assessment, and opportunities to develop a voice and exercise agency of their own learning journey. It can be designed to provide feedback with sufficient information to maintain achievable challenge, thus motivating students to continue. Developments in IT have produced promising results for providing timely, individualized, and challenging feedback that progresses student learning as well as scaffolding self-regulatory behaviors.

exams at this scale requires a lot of work, which means a high volume of exam scripts need to be marked by tens of thousands of examiners appointed by the exam boards. The need for large-scale assessments and the high cost of manual marking and limited “turn around” time have led to developments, over some years, of automated assessment and marking. This chapter reviews the history and development of automated assessment systems. It includes findings from empirical research as well as highlights the theoretical considerations that emerge from such developments. In addition, the practical aspects of developing such assessments are explored with examples primarily from the UK and USA, including the systems and tools available, the current capabilities of natural language processing (NLP) approaches, and their limitations, ethical concerns, and future potential.

Introduction

Large-scale assessment refers to tests that are administered to large numbers of students and are used at local, state, and national levels to measure the progress of schools with respect to educational standards. For instance, the Organisation for Economic Co-operation and Development (OECD)’s Programme for International Student Assessment (PISA) is a triennial international large-scale assessment study that assesses the skills and knowledge of 15-year-old students in compulsory education since 2000 (“PISA” 2017). The aim of the PISA program is to compare education systems across the participating countries in Europe in order to provide evidence-based information on domestic educational policies.

In order to have accurate and fair measurements, large-scale assessment systems need to include all available students (Thurlow et al. 2001), which means high volume of students, with large numbers of exams to be marked, which in turn requires extensive effort. For example, the previous two-hour-long international PISA test was taken by over half a million students, representing 28 million 15-year-olds in 72 countries and economies. The need for large-scale assessments and the high cost of manual marking have led to developments, over some years, of automated assessment and marking.

This chapter reviews the history and development of automated assessment systems together with knowledge from empirical research as well as the theoretical considerations that emerge from such developments. In addition, the practical aspects of developing such assessments will be explored with examples primarily from the UK and USA, including the systems and tools available, the current capabilities of natural language processing (NLP) approaches, and their limitations, ethical concerns, and future potential.

Large-Scale Assessment: Issues and Potential Solutions

In Britain (except for Scotland), the General Certificate of Secondary Education (GCSE), Advanced Subsidiary (AS), and Advanced Level exams (A-level) are the main academic qualifications taken by all school students at the age of 16 and 18 years. To illustrate the scale of marking that is required, “in summer 2012, 1.27 million candidates took GCSEs in 48 subject areas,” and “over half a million candidates took A levels (or AS) in 36 subject areas” (Ofqual 2013, p. 4). Marking exams at this scale requires extensive work, which means a high volume of exam scripts need to be marked by tens of thousands of examiners appointed by the exam boards. The following table summarizes the breakdown of exams taken from each exam board (Table 1).

“The time pressures on exam boards to process this volume of scripts is great” (Ofqual 2013, p. 5). Thus the management of such a high-volume process is complex. Examiners are contracted (not on a full-time basis) and geographically distributed in the UK (some Pearson Edexcel examiners are also based in Australia), and they are marking scripts at their own convenience. In September 2009, Edexcel announced that they intended to employ artificial intelligence-based systems to automatically mark exam essays for English language tests. Their rationale was centered around the good correlation between human judges and artificial intelligence systems (Irvin 2009; Harris 2009). This announcement caused quite a storm, and some academics found the idea of machines judging the quality of extended writing as “ridiculous nonsense,” which also sparked another concern which was the wide-scale use of automatic marking of GCSEs and A-levels (Harris 2009). Although it was revealed that Edexcel planned to start trials of automatically marking essays in dummy GCSE-style questions in 2006 (Harris 2009), it was not adopted for anything other than multiple-choice tests (Irvin 2009). However a move was made for human markers to adopt an online marking approach rather than working with pen and paper.

It was only in 2013 that examiners started to adopt online marking. Although traditional pen and paper marking was replaced with “paperless” on-screen marking, it sparked a high volume of criticism not just from head teachers, teachers, and parents but even from some examiners themselves who reported that errors occurred in calculating the final mark, using this new system (Harrison 2013). The large

Table 1 Breakdown of exams taken from each exam board (Ofqual 2013)

Exam board	GCSE external exam scripts marked	A-level external exam scripts marked
AQA	4,259,000	1,683,000
CCEA	264,000	115,000 ⁴
OCR	2,871,000	1,026,000
Pearson Edexcel	2,638,000	1,143,000
WJEC	1,170,000	284,000
Total	11,022,000	4,154,000

amount of criticism about the digitalization of exam marking and the legal challenge over the previous year's GCSE English exam grades led Ofqual to publish a review of its quality of marking (Duffin 2013). This subsequent report published in 2013 argued that on-screen marking was a positive step forward with respect to quality assurance, as it facilitated flexible and frequent monitoring of examiners, therefore improving the reliability of the examining process. It also revealed that 1% of all the marking for GCSEs, A-levels, and other academic exams in England were marked automatically because multiple-choice exam papers, predominantly for science GCSEs (Ofqual 2013), were used.

There have been more recent advances with systems which automatically mark primary school mathematics problems. Kurvinen et al. (2015) developed the VILLE tool and have shown that in Finland, pupils using this system received statistically significant higher grades than nonusers. Similarly in the UK, Adesina (2016) has shown that by using MuTAT, a semiautomatic computer-aided assessment system for primary mathematics, 26% savings in marking time were achieved compared to traditional paper and pencil marking. More importantly, the data from MuTAT allows teachers to see the arithmetic strategies employed by their students. This means they could provide more directed pedagogical assistance to individual pupils. The wide range of automated marking tools that are being developed and are now employed in primary schools suggest that these types of computer-assisted assessments can improve the quality of feedback and range of assessments for primary pupils while at the same time reducing staff workload.

Although there is controversy about automatic marking systems, Bektik (2017) has pointed out that there is also a problem with the reliability of human marking. "It is inevitable, with the best will in the world that two very experienced tutors can give a very different mark to the same assignment" (Bektik 2017, p. 194). Thus automated scoring systems can be helpful. "Human markers can disagree with each other and therefore they do not necessarily come to the same conclusion as their peers; which is a reliability concern. The automated output on the other hand is always the same, stays the same and is not subjective" (Bektik 2017, p. 253).

Moving toward the automatic marking of high-stakes examinations has been fraught with difficulties, but it is fair to say that the technology has advanced since 2009 when even on-screen marking triggered serious concerns and opposition. Almost a decade later, natural language processing systems have become more powerful in providing automated feedback. The next section discusses the development and improvement of automatic marking systems for essays and its potential for more wide-scale usage.

Early History: Automated Assessment and Scoring

Research in automated assessment and scoring began in the early 1960s. One of the first applications, and the idea of using computers to automatically score, came from a former high school English teacher, Page (1966, p. 238), whose aim was to "rescue the conscientious English teacher from his backbreaking burden." His article was

greeted with high skepticism as the idea of “grading essays by computer” seemed nonsense and impossible for many people (Shermis and Burstein 2013). Page’s admonition was that students, especially those with poor writing abilities, have to write more to be better writers. This was associated with the assumption that their academic tutors were spending too much time marking papers and were burdened with hours of grading written assignments. Page argued this is the biggest impediment to more writing as overburdened tutors would ask limited number of drafts from their students. Therefore, he worked on persuading educators that there is a need for computers to grade essays automatically and that this is feasible and promises to improve the quality of teaching (Page 1966). However, unlike skeptics, people who knew about disciplines such as linguistics and who understood about computers considered his approach as a “delightful toy” at that time (Page 1966, p. 238).

Page’s aim was to develop a computer program that could evaluate student writing “as reliably as human readers,” saving time and providing timely, speedy, reliable feedback to students (Page and Paulus 1968). However, access to computers was rare at that time apart from entering data via IBM’s punch cards which was costly and not well-suited for the average person. What Page was suggesting sparked a controversial debate on the idea of “replacing human markers with machines,” but there was no easily accessible hardware or software that was capable of doing half of what Page was suggesting.

Development of Automated Assessment Systems

When Page and Paulus (1968) published *The Analysis of Essays by Computer*, they visualized a promising future of automated programs that could evaluate both the aesthetic traits of essays and their content. However, it was not until the 1980s that such technology was accessible. As basic word processing systems became available in the 1980s, these systems made it possible to input text into automated essay assessment systems. By the early 1990s, the advances of the Internet and word processing systems made Page’s idea of automatically evaluating student writing a reality. With important developments in the following decades, several studies have been conducted on automatic essay scoring (AES) and automated writing evaluation (AWE); see (Foltz et al. 1998; Landauer 2003; Shermis and Burstein 2003) for detailed descriptions of AES and AWE.

One of the widely known applications of AES is E-rater™. E-rater has been used by the Educational Testing Service (ETS®) for AES in the USA and became the first large-scale assessment tool to incorporate automated essay scoring (Attali and Burstein 2006). It is a web-based system that provides automated scoring and evaluation of student essays. ETS detects errors in grammar, usage, and mechanics, identifies discourse elements in an essay, and recognizes elements of undesirable style.

Page also worked on his innovative idea with Petersen in 1995, *The Computer Moves into Essay Grading: Updating the Ancient Test*, through ETS (Page and Petersen 1995). Page and Petersen’s (1995) collaboration with ETS allowed them to show the possibility of Page’s initial idea: “in a blind test a computer can simulate the

judgement of a group of human judges on a brand-new set of essays” (p. 561). In recent days, this idea of computers simulating human judgment has been called artificial intelligence (AI)-based assessment. “AI can be defined as the ability of computer systems to behave in ways that we would think of as essentially human” (Luckin 2017, p. 1).

ETS is not the only testing service that makes use of automatic essay scoring systems. They have also been adopted as a second or check scorer in widely known American large-scale assessments, such as the Graduate Record Examination (GRE[®]), the Test of English as a Foreign Language (TOEFL[®]), and the Graduate Management Admissions Test (GMAT[®]). AES systems are also used as the primary essay scoring engine in various assessment and instructional products, including Accuplacer[®], the Criterion[®] Online Writing Evaluation Service, IntelliMetric[®], and the Pearson Test of English™, which are some examples of how AES has been developed following on from Page’s original idea. It was Page who supplied the spark that ignited the controversial arguments around using computers to grade essays, which is discussed below in the “[Ethical Concerns: Ongoing Controversy](#)” section below.

Automated Marking in School Exams

Automated *exam* scoring is a more objective mode of classification, in which answers are analyzed for the presence of concrete facts or statements instead of using any continuous measure (Frost 2008). Automated marking of student assignments is usually around three types of assessment, (1) multiple-choice questions, (2) short-answer marking in free text, and (3) essay marking.

Automated assessment of multiple-choice questions has been relatively easy to implement, compared to the other two, as even generating multiple-choice questions automatically has become possible (Johnson et al. 2013). Also, the answers to multiple-choice questions are definitive and not open to any subjectivity which is why it is the most common type of assessment where complete automation is used. For instance, the latest PISA test in 2015, where multiple-choice questions were employed, was marked automatically. PISA moved from paper-based to computer-based testing in 2015. Response codes were applied to test items, “either by a more or less automated process of capturing the alternative chosen by the student for a multiple choice answer, or by a human judge (expert coder) selecting a code that best captures the kind of response given by a student to an item that requires a constructed response” (PISA 2013, p. 30).

New approaches and developments to automated scoring have made it possible to develop ways into automatic short-answer marking, which is pedagogically more powerful than multiple-choice questions to measure students’ learning. For instance, research conducted by Sukkarieh et al. (2003) in Oxford University and in the Interactive Technologies in Assessment and Learning (ITAL) Unit of the University of Cambridge Local Examinations Syndicate (UCLES) showed that automatic short-answer marking (changing from a few words up to five lines) can also be possible

and effective. The approach automatically marks short free text responses for factual science questions, to question types, which ask the student to *state*, *describe*, *suggest*, and *explain*. This technique has been successfully applied to the GCSE exam (Frost 2008). Sukkarieh et al. (2003) work reveals that for Biology GCSE, there was 88% agreement between the human marker and their system.

The third type of assessment, automated essay marking, which is the main focus of this chapter, is far more complex and open to even more controversy. The next section outlines the possibility of large-scale automated essay marking through the use of natural language processing systems.

Capabilities and Challenges of Natural Language Processing Approaches

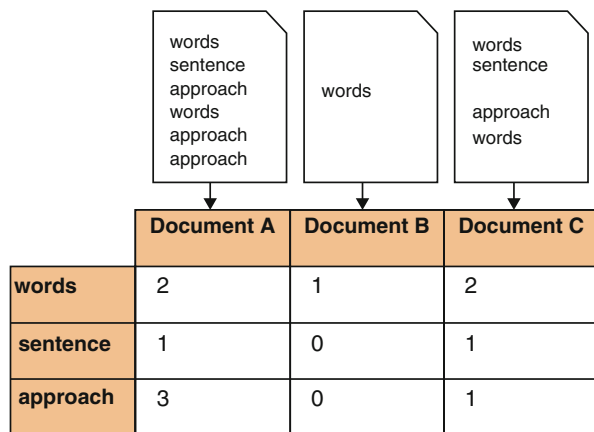

The main approaches in the field of computational linguistics relating to automated text analysis are “comparing text fragments as bags of words in vector space, using lexical resources and using Latent Semantic Analysis (LSA)” (Gabrilovich and Markovitch 2007). These techniques and their challenges are introduced below.

The Bag of Words Approach

Text documents can contain thousands of words which provide the starting point for approaches which treat a document as a metaphorical “bag of words.” For example, when a user wants to use a query to search for similar documents, the following steps are applied to find out the proximity of a query, how close it is, to a document. As shown in Fig. 1, the query terms (*words*, *sentence*, and *approach*) are searched for in documents (A, B, and C).

The term frequency is the total number of matches between query terms and occurrences (*words* occur twice in document A). A TF analysis would show that

Fig. 1 The bag of words approach – term frequency. (Bektik 2017, p. 75)

documents A and C are most similar to each other, with document A being the best match to the user query. A strength of this approach is that it scales to millions of documents.

In terms of its logic, this approach accepts that a document with ten occurrences of a term is more relevant than a document with one occurrence of the term. This might be true; but even if it is, it may not be ten times more relevant. Relevance does not increase proportionally with term frequency. One approach to overcome this problem is by calculating the score as the sum of one plus the log of the term frequency for each term in a document. This technique has been shown to return superior results in information retrieval.

The bag of words approach does not incorporate a semantic structure (Frost 2008). “Thus if the answer requirement is a statement such as ‘the cat chased the mouse’, then an answer of ‘the mouse chased the cat’ would be accepted despite the clear semantic inequality, due to the identical set of words” (Frost 2008, p. 3).

Since good academic writing requires the appropriate use of relevant vocabulary from the domain of discourse (Hyland and Tse 2007; Ivanič 2004), the term frequency is only a partial solution. It is hard to imagine a high-quality essay, which does not cover much of the expected vocabulary, and a bag of words approach will assist in giving feedback on those grounds. However, the absence of any understanding of the role that different words play in language is an important limitation. Approaches that take into account word meanings add greater sophistication, and these are introduced next.

Lexical Resource-Based Approaches

It is possible to go beyond exact word matching by using lexical resources, databases containing machine-readable dictionaries which rapidly search lists of words, making them a very popular natural language processing (NLP) approach (Vossen 1998). They provide the opportunity to consider various linguistic phenomena such as synonymy, antonymy, and hyponymy. Synonymy is similarity of meaning; in terms of substitutability, it is having the same meaning as another word or phrase in the same language. “The antonym of a word *x* is sometimes not-*x*, but not always. For example, ‘rich’ and ‘poor’ are antonyms but to say that someone is not rich does not imply that they must be poor; many people consider themselves neither rich nor poor” (Miller et al. 1990, p. 7). “A hyponym inherits all the features of the more generic concept and adds at least one feature that distinguishes it from its superordinate” (Miller et al. 1990, p. 8). To illustrate hyponym, maple is a hyponym of tree, and tree is a hyponym of plant.

Throughout the years, different ranges of lexical resources have been created for automatic semantic processing of text documents. There are various resources/databases (e.g., PropBank, WordNet, SentiWordnet) that serve a range of purposes, and each has its own strengths and weaknesses. Although some lexical databases have the same purpose, such as providing synonymy information, their results can vary immensely. In order to overcome this limitation, a common strategy is to combine the benefits of multiple lexical resources, which is referred to as lexical

substitution, e.g., Loper et al. (2007) and Sinha and Mihalcea (2009). This method was announced in the workshop on semantic evaluations (SemEval) in 2007. The idea is for the selected target (such as the word “bright”) to return synonyms from several lexical resources. The appropriate ones can then be selected (Sinha and Mihalcea 2009). This approach is most appropriate for individual word comparison although some resources allow predicate-argument structure. Therefore, its adaptation for comparing longer texts, sentences, or paragraphs requires an extra level (Gabrilovich and Markovitch 2007).

Latent Semantic Analysis

The third approach, latent semantic analysis (LSA), is a fully automatic, mathematical, and statistical technique for automatic indexing and retrieval. It was designed to overcome the problems of other retrieval techniques that try to match words within user queries with the words of the document. As discussed in previous sections, a key deficiency of these kinds of information retrieval techniques is that individual words may not be reliable enough to retrieve the conceptual content. This is because there are various ways of expressing any given concept; “the literal terms in a user’s query may not match those of a relevant document” (Landauer et al. 1998). LSA was designed to overcome this term-matching retrieval problem.

LSA assumes that there is some underlying latent semantic similarity between the user query and the documents. For instance, two documents might be semantically similar even if they do not contain the same words: “the words searchers use often are not the same as those by which the information they seek has been indexed” (Landauer et al. 1998). The fundamental deficiencies of most information retrieval techniques relate to three issues (Landauer et al. 1998):

- *Synonymy*: There are many ways to refer to the same object. Users in different contexts or with different needs, knowledge, and linguistic habits describe the same information by using different terms. For instance, there is only a 20% possibility that two people choose the same main keyword for a single well-known object.
- *Polysemy*: Most words have more than one distinct meaning. In different contexts or when used by different people, the same term can take on a different meaning.
- *Inadequate number of index terms*: The index terms identified for comparing two documents or the user query with documents are incomplete. They only contain a fraction of the terms under which users will try to look them up. The documents themselves do not contain all the terms that users will apply in their queries. For example, a writer might use the words “access” or “retrieval”; but a user might use the word “look-up” instead.

The LSA can be used for automating the marking. To do this, LSA needs to be trained in respect of domain-representative text (Foltz et al. 1999). It needs a “semantic space” which has been trained with the representative text, so, for

example, if the system will be used to mark biology essays, then it will be trained with a relevant biology textbook. In the LSA, the essay to be graded is compared to all other essays and text within this semantic space, and the grades of similar essays are then used to predict what grade the expert would have given. One example of a system that uses LSA is the Intelligent Essay Assessor (IEA), a set of software tools for scoring the quality of essay content.

Current Applications

Large-scale assessment is the area where the use of IT for assessment is most highly developed, and it is focused on summative assessment and accreditation, e.g., the Graduate Record Examination and the Test of English as a Foreign Language. More recently the possibilities for automated systems that support formative assessment through constructive feedback have been explored, especially in higher education, although there are also many opportunities for such systems for school-level students. For instance, the Paperless School Marking Engine (PS-ME) is the free text marking engine founded by Mason and Grove-Stephensen (2002) at Birmingham University in the UK, for both summative and formative assessment with little or no human intervention in British schools. It can be integrated as part of a school's learning management systems (LMS) and relies on NLP approaches to cover Bloom's taxonomy (1971) specifically knowledge, understanding, and evaluation levels. PS-ME has been applied to low-stakes coursework, National Curriculum Grade, and GCSE examinations in the academic domain.

The automated essay scoring systems explained in the "[Development of Automated Assessment Systems](#)" section focus mainly on summative assessment, rather than providing formative feedback (Rivers et al. 2014). Automated essay evaluation technologies, however, can be used not just for speedy scoring but also for providing students with feedback which is specific to their needs in order to help them to improve their progress (Whitelock 2015). "Automated assessment provides the possibility of increasing the amount of feedback a student can receive during the learning process (possibly automatically generated) and so receive greater support for their learning" (Johnson et al. 2013, p. 17).

Nowadays, various technologies exist that provide automated feedback on students' writing. For instance:

- *OpenEssayist*, a web application system, has been designed to help students in higher education understand the strengths and weaknesses in their draft essays. The system was developed to offer automated feedback in a number of forms: highlighting elements of essay structure, key concepts, dispersion of keywords, and sentences throughout the essays and summarizing the essay content back to the student for their own reflection. There are two components to the system, the learning analytics engine, *EssayAnalyser*, which is a summarization engine, and the web application that provides feedback for students, *OpenEssayist*. *OpenEssayist*

processes essays and offers feedback through key phrase extraction, by identifying which phrases are most suggestive of the content, and extractive summarization which identifies key sentences (Whitelock et al. 2015). Each essay is automatically preprocessed using modules from the Natural Language Processing Toolkit (Bird et al. 2009) that typically uses large bodies of linguistic data or corpora.

OpenEssayist invites students to engage with and reflect on their work, in any subject domain (Whitelock et al. 2015). It is for formative assessment purposes and not for giving the students marks but supports them to improve their work through their understanding of the requirements of academic essay writing (Whitelock et al. 2015).

The flow of activities in the system is as follows: (1) students prepare a draft essay offline and when they want to obtain feedback, (2) they log on to the *OpenEssayist* system and submit their essay for analysis, by copy and pasting their text; (3) *OpenEssayist* submits the raw text to the *EssayAnalyser* service; and (4) once finished, *OpenEssayist* retrieves and stores the summarization data. From that point on, the students can then explore the findings at their own pace. The system is simply offering repeated access to the summarization data and feedback, as a resource, until the students are prepared to submit and explore the summarization feedback on their second draft and on subsequent changes between drafts (Whitelock 2015).

The rationale for developing *OpenEssayist* was based upon the knowledge that university students find essay writing to be a challenging task. Therefore, a system that provides immediate feedback or “advice for action” (Feedback to students that they will take notice of and use in future learning, tasks, and assessments Whitelock 2011.) (Whitelock 2011) on students’ draft essays could be one way of overcoming this challenge. Advice for action enables students to “move forward in their studies by using the information obtained from the analysis” (Whitelock et al. 2014).

- A *Coh-Matrix* is another automated natural language processing tool that looks for “cohesion” indicators, i.e., how well the written text “hangs together,” including word characteristics, sentence characteristics, and the discourse relationships between ideas in the text (McNamara and Graesser 2012). “In *Coh-Matrix*, sentences, paragraphs, and texts are measured as weighted vectors and LSA values” (Crossley et al. 2008). The “cohesion” of a text refers to the presence or absence of cues in the text that help the reader to understand the relationship between the ideas presented, and “coherence” is perceived as what the reader takes from it. These cues include words and ideas repeated across sentences and sections, referential overlap, and connective words such as “because,” “however,” and “therefore” (McNamara et al. 2013).

McNamara et al. (2010) used *Coh-Matrix* to investigate the role of cohesive devices and linguistic sophistication in explaining human ratings of essay quality. The definition of writing quality has been based on human judgments, expert markers from academic communities, who have been trained to reliability using a standardized marking rubric.

Researchers explain that when the quality of writing improves, the number of cohesion features does not necessarily increase; there is no indication that higher scored essays were more cohesive. “Higher scored essays were more likely to contain linguistic features associated with text difficulty and sophisticated language” (McNamara et al. 2009, p. 73). More advanced readers and writers use cohesion connectives less (McNamara et al. 2014), and more skilled writers use more sophisticated language (McNamara et al. 2009).

Coh-Metrix has become the foundation in the Writing Pal intelligent system, which is explained next.

- *Writing Pal (W-Pal)* is an intelligent tutoring system designed to provide writing strategy instruction, game-based strategy practice, and personalized formative feedback for secondary-school and developing first-year undergraduate writers (McNamara et al. 2013). W-Pal provides students with training on the use of strategies to improve their writing quality and, more specifically, on how to write essays. With W-Pal, students are provided with lessons on strategies for the various phases of writing, such as generating and organizing ideas before writing; drafting an essay with strategies on building the structure of introduction, body, and conclusion; and revising the essay (McNamara et al. 2013). Each of these lessons includes practice in the form of mini-games.
- *LightSide Labs* is an educational technology company, dedicated to improving student writing skills. It has developed a framework which provides automated feedback on student writing in the K-12 classroom (Mayfield and Rosé 2013). The LightSide framework is open source allowing its users to develop new feature extraction and machine-learning technology features. LightSide is not an LSA application but instead a machine-learning application that uses samples of graded student writing as input into the algorithms to help the scoring engine learn and become more efficient through training with a large number of exemplar texts. Although it uses a machine-scoring algorithm, it also automatically generates specific and actionable feedback from student text during the writing process. The LightSide’s Revision Assistant, an online program to help school teachers when assessing K-12 students’ writing, provides automated writing support to students, on demand, as they draft, with each student’s process tracked for teachers to review. The Revision Assistant system requires training, by learning how educators grade, evaluate students’ work, and provide feedback. This information is then used to provide students with automated feedback throughout the writing process.

Ethical Concerns: Ongoing Controversy

Automatic feedback systems can start to produce meaningful dialogues between students and teachers (Ras et al. 2015). However, automated feedback systems, especially automated essay scoring applications, have been subject to significant controversy. On the one hand, there is significant support for AES as “automated essay scoring and evaluation becomes more widely accepted as an educational

supplement for both assessment and classroom instruction” (preface in Shermis and Burstein 2003). There are several studies showing that AES systems work well, with studies reporting high agreement rates between AES systems and human markers (Bridgeman et al. 2012; Burstein and Chodorow 2010; Landauer et al. 2003).

On the other hand, there has been and still is significant opposition to AES, particularly to the idea, originated by Page, that “it might replace human scoring” (Ericsson and Haswell 2006; Herrington and Moran 2012). Harsh criticism comes particularly from the community of writing researchers. The Conference for College Composition which is a major organization for writing researchers has, during the last decade, actively opposed AES. Writing professionals claim that such systems prepare their students to write for machines, writers writing to computers (Herrington and Moran 2001), and therefore they say: “Because all writing is social, all writing should have human readers, regardless of the purpose of the writing . . . We oppose the use of machine-scored writing in the assessment of writing” (Deane 2013, p. 8). They have not revised their statement yet, although there has been a great deal of AES deployment over the last 15 years. Critics argued that the replacement of human markers by a machine would not just threaten the jobs of tutors but also change students’ sense of what it means to write in school and at university (Herrington and Moran 2001).

Common criticisms of AES (based on Cheville 2004; Ericsson and Haswell 2006) focus on the capability of such systems to interpret meaning, evaluate factual correctness of the content, and quality of the argumentation. Machines cannot truly read, understand an essay, and interpret its meaning (Attali 2013). Therefore, there is a possibility that such systems can be gamed as AES systems can be insensitive to particular features in student writing that human markers might detect and penalize, such as repetition and lack of coherence (Deane 2013). There is little research regarding the impact of AES on writers’ behavior or on the view of it as a barrier to be gamed and manipulated by tricks rather than communicating with a person (Deane 2013). The biggest opposition to AES focuses on when it is deployed as a replacement for a human scorer, when it becomes the sole scorer. However, such an extreme situation is rare as even the widely known large-scale assessment systems, like ETS, only use AES as a complement to the human marker.

It is true that current AES systems do not mimic human markers’ ability to measure conceptual reasoning; thus AES measures a narrower range of skills than human markers (Deane 2013), though they could measure a lot that human markers ignore. Such systems are therefore criticized since they fail to measure higher-order writing skills such as high-quality and strong argumentation due to their limited nature (Attali 2013). For example, the E-rater measures efficiency in “knowledge-telling” writing and cannot score the “knowledge-transforming” writing to a currently accepted level. In his research, Bennett (2011) reports on the use of AES in the persuasive writing style. He concludes that although the overall correlation between human and machine scores is high, AES systems are better at scoring essays which are marked based on a text production rubric that values fluency, effective word choice, and accuracy of the text production than they are at scoring essays which are marked based on a critical-thinking rubric that values effective argumentation and attention to the audience.

When the focus of assessment is on students who need practice to improve their fluency, and control their text production processes with less cognitive load, the capacity of the AES is relatively strong (Kellogg and Raulerson 2007); but if the focus is on quality of argumentation, AES is relatively weak (Deane 2013).

Attali (2013) pointed out that there is a lack of understanding of what human markers do in their evaluation. He mentioned that the primary goal of AES is to ensure that human markers think similarly about what constitutes high- or low-quality student writing so that machine scores measure the same elements as human markers. However, there is evidence showing discrepancies between the ways human markers interpret the quality of the same essay (Attali et al. 2012).

If human markers are inconsistent and unreliable, then the machine cannot be trained effectively (Bridgeman 2013). Therefore, the aim of mimicking human markers is a difficult task to achieve. Bridgeman (2013) discusses how to assess the rater reliability so that machines can be trained better. However, in order to deploy an AES system by considering such limitations, this deployment must be sensitive to AES' own limitations as well. It does not understand the essay, and therefore it is limited to measuring a subset of the written context; therefore, AES should currently be considered as a "complement to human scoring" (Attali 2013, p. 194). A "division of labor" approach (Attali 2013, p. 194) between human markers and machines can be used to overcome such issues.

Concluding Remarks and the Future Potential

Authors of FuturICT, a visionary 10-year program which aims to revolutionize education, foresee that "automated assessment will have a huge impact on education in the future" (Johnson et al. 2013, p. 17). However, although authors foresee that within a decade understanding natural language will enable us to develop new generations of automated testing, skepticism and criticism have accompanied automated scoring and feedback systems over the years (Attali and Burstein 2006). "The past has been marked by argument rather than dialogue: one side is the researchers and developers of such systems and the other side is the critique of such systems from writing teachers and researchers" (Shermis and Burstein 2013, p. ix).

Since writing is an activity that is deeply human, its association with computational formulations is double-edged (Elliot and Williamson 2013). When algorithms are used by computers as the basis for assessing student writing beyond fluency or knowledge of grammar (Attali and Powers 2008), there is a suspicion that technology can corrupt the essence of a fundamental human activity (Ericsson and Haswell 2006; Herrington and Moran 2012; Elliot and Williamson 2013). Although, in general, AES systems mimic the human markers well enough, as evidenced by a number of high correlational studies that do not mean because the approach works well on average, there is no guarantee that it will work well in all population subgroups (Bridgeman 2013). Unlike the initial intention of Page, at the current time, AES should be used as a "complement to (instead of replacement for) human scoring, limited in its ability to measure a subset of the writing construct" (Attali 2013, p. 182).

It should be recognized that machines do not currently fully understand the language itself, the accuracy of the written material, the content, and the beauty and subtlety of sophisticated argumentation that would be credited by human markers because it flows beautifully (Bektik 2017). Machines have limited capacity to understand language and literacy; this capacity is mostly dependent on the rules that its developers have written to train them. On the other hand, human language has endless possibilities of creating and forming new sentences each time. Therefore, machines and human markers should complement each other, with the aim of providing better feedback to students.

Any feedback that is not fully understood or cannot be acted upon, however pertinent it may be, is likely to be ignored by the learner, thus will not facilitate learner improvement (Whitelock 2011). The detailed feedback process which is currently supplied by human markers should be supported by machines in order to provide timely, efficient, and reliable feedback. Similarly, developers of these machines should improve their tools so that they have a better understanding of what human markers really value and need. Therefore, the relationship between humans and machines should be mutually inclusive rather than exclusive in order to fully facilitate learner improvement (Bektik 2017).

More importantly these automatic marking systems that we argue can and should be used to provide the learner with formative feedback. This is because AES have the potential to change student learning from a more passive to a more knowledge building activity, where they start to be supported to criticize their own work and then to improve it.

Abstract

According to Pearson’s Law: “That which is measured improves.” But some important constructs, like problem-solving skill, are generally viewed as very difficult to measure for a variety of reasons (e.g., lack of a clear and agreed-upon definition, psychological and/or statistical multidimensionality of the construct, subjectivity of scoring, and so on). Adding to the challenge of validly measuring problem-solving skill is that formal education settings tend to focus only on well-structured problems – those that have correct and incorrect answers. However, these problems tend to have little transfer to the real world. In short, there is a gap in the kinds of problems being assessed and taught in schools and those desired in workplace environments. In this chapter, we focus on how game-based immersive environments, such as well-designed video games, can be used to both measure and promote the development of problem-solving skills in formal education settings. In this chapter, we discuss the theoretical foundations of problem-solving

V. J. Shute (✉) · B. Emihovich

and provide a worked example of assessing it from gameplay using a well-designed video game. We conclude the chapter with a discussion on future implications for using game-based environments to measure and promote problem-solving skills in education.

Keywords

Assessment · Game-based learning · Problem-solving skill · Stealth assessment · Video games

Introduction to the Problem

Over the past couple of decades, developed and developing countries are increasingly relying on a knowledge economy to help solve complex problems arising from globalization such as issues related to global warming including the depletion of the ozone layer and the scarcity of natural resources in the environment. Solving complex problems requires one to think critically, creatively, and systemically when planning solutions, thus involves cognitive processes aimed at achieving a goal when the solution is hidden from the problem solver (Mayer and Wittrock 2006). Educators consider the assessment and support of problem-solving skills a primary goal of teaching and learning (e.g., Jonassen 1997; Shute and Wang 2016).

Problem-solving is also becoming increasingly desirable in twenty-first century workplace environments (Partnership for 21st Century Learning 2016). One of the challenges in teaching problem-solving skills in formal education settings stems from limitations with providing authentic problem-solving contexts. That is, in formal learning settings, students are typically required to solve well-structured problems that have limited transfer after instruction (Jonassen 2000). A well-structured problem is one that can be solved with a particular sequence of steps that leads to a correct answer. Most classroom textbook problems – particularly in STEM areas – feature well-structured problems that have correct answers. However, an ill-structured problem possesses a claim and a justifying argument without a specific correct answer. An example of an ill-structured problem would be to figure out a viable solution to a problem like what can be done when the population of a community is growing but the current water supply will not support many new people.

Instruction designed on specific principles of learning related to solving a variety of problems – from well-structured to ill-structured – in an authentic context is important for initial and long-term learning as well as promoting problem-solving transfer to novel contexts (Van Eck et al. 2017). But again, there is a gap in the kinds of problems being taught in schools with those being required in the workplace. Recent survey data indicates that only 24% of employers who hired recent college graduates stated that the graduates were able to analyze and solve complex problems in their workplace environments (Hart Research Associates 2015).

Facilitating learning by using immersive environments, such as well-designed video games in educational settings, is one promising way to bridge the aforementioned gap between school-based versus workplace or real-world problem-solving

skills. Immersion in this context refers to the subjective impression one experiences when interacting with a realistic, digitally enhanced environment like a video game (Lessiter et al. 2001). This feeling of immersion enhances learning by allowing multiple perspectives, offering players a situated learning experience and promoting transfer (Dede 2009). In general, immersive environments support the following: distribution of knowledge across a community through situated learning, acquisition of fluency in multiple media, and interactions with different human or computer characters with different skills and abilities within authentic and novel problem-solving scenarios (Dede 2005).

Multiple perspectives in immersive environments allow for egocentric and exocentric frames of reference. Egocentric frames of reference engender motivation through embodied learning, whereas exocentric frames of reference promote abstract symbolic insights that are gained at a distance from the context of the environment (Dede 2009). In addition, immersive learning environments help learners practice as well as understand how to apply facts, principles, and concepts in context rather than abstractly. Learning abstractly via memorizing certain facts as well as abstract principles and concepts is how knowledge is typically taught in school (Barab and Dede 2007). But there is an alternative (and considerably more engaging) pedagogical approach to support learning. According to the recent report entitled “Essential Facts About The Computer and Video Game Industry” published by the Entertainment Software Association (ESA 2016), video games are played by 65% of US households and consumers spent over \$23 billion dollars in the video game industry in 2015. Given the success of the video game industry, education researchers are exploring how well-designed video games can be used to support learning and assessment, referred to as game-based learning (GBL).

Over the past decade, researchers have been examining and testing various ways to deeply embed valid assessment for learning directly into video games with a technology called stealth assessment (see Shute and Ventura 2013). Establishing validity is key; herein referring to the psychometric quality of the assessment relative to its accuracy in measuring what is intended to be measured (also known as construct or convergent validity). Stealth assessment is grounded by an assessment design framework called evidence-centered design (ECD; Mislevy et al. 2003). In general, the main purpose of any assessment is to collect information that will allow the assessor to make valid inferences about what people know, can do, and to what degree (collectively referred to as “competencies” in this chapter). ECD defines a framework that consists of several conceptual and computational models that work in concert. The framework requires an assessor to: (a) define the claims to be made about learners’ competencies, (b) establish what constitutes valid evidence of a claim, and (c) determine the nature and form of tasks that will elicit that evidence.

In this chapter, we first review the literature on problem-solving skills. Next, we discuss current methods for assessing problem-solving skills and describe an approach to address some of the issues by presenting an example of stealth assessment in a research project. We then address the benefits and challenges of using video games in formal education settings. Finally, we conclude with ideas for next steps in this field of research.

Problem-Solving Skills

Early research on problem-solving included Thorndike's (1898) experiments on cats tasked with escaping a puzzle box. Thorndike determined that the cats were able to escape by mere associations and habits, or essentially by trial and error. The seminal work of Thorndike's research is regarded as significant in contributing to early behavioral learning theory in psychology, but many scholars regarded problem-solving as an unexplainable human behavior before Newell et al.'s (1958) theoretical work on the mechanisms of thinking and learning related to problem-solving (Simon and Newell 1971). The gap in research on problem-solving directed scholars to correct the antiquated narrative on the topic from unexplainable thinking to analyzing how human beings behave and what cognitive processes engage this critical aspect of thinking and learning.

In general, problem-solving can be defined as cognitive processing aimed at finding a solution to a goal when the solution is not known to the problem solver (Mayer 1992). According to Mayer and Wittrock's (2006) definition, problem-solving consists of four interrelated elements: (1) occurs within the problem solver's cognitive system; (2) requires the problem solver to theorize and manipulate information; (3) is goal oriented; and (4) relies upon the intellect and skills of the problem solver to establish the order in which each obstacle is handled before finding a solution.

While the elements of problem-solving seem straightforward, can problem-solving skills be fostered and improved? Polya (1945) argued that problem-solving is not an innate skill, but rather something that can, in fact, be developed, "Solving problems is a practical skill, let us say, like swimming. . . Trying to solve problems, you have to observe and imitate what other people do when solving problems; and, finally, you learn to solve problems by doing them." (p. 5). So students are not born with problem-solving skills. Instead, these skills are cultivated when students have opportunities to solve problems proportionate to their knowledge. Polya (1945) went on to identify a four-step problem-solving technique: understand the problem, devise a plan, carry out the plan, and review/extend. Later, Bransford and Stein (1984) integrated the collection of problem-solving research and proposed the IDEAL problem solver. Each letter of IDEAL stands for an important part of the problem-solving process: identify problems and opportunities; define alternative goals; explore possible strategies; anticipate outcomes and act on strategies; and then look back and learn. Two years later, Gick (1986) presented a simplified model of the problem-solving process including the construction of a representation, the search for a solution, the implementation of the solution, and monitoring the outcome of the solution. Around that time, the focus of research had been shifted toward a knowledge-based representation such as schemata.

How domain-general versus domain-specific are problem-solving skills? Unlike the aforementioned work on identifying general problem-solving models, the study of problem representation recognizes the importance of domain-specific knowledge in solving problems. The representation of problems refers to how a problem solver

perceives and understands a phenomenon within the problem-solving environment. Jonassen concluded that “problem solving is not a uniform activity” (2000, p. 65). Instead, problems vary in terms of their structuredness, complexity, and the requirement for prior knowledge (Jonassen 2003). For example, the types of problems associated with driving a truck are quite different from those needed when negotiating a business deal. Thus, how well a person can solve a problem depends on the accuracy of the person’s representation of the problem scenario.

Jonassen (1997) noted that people confront various types of problems that differ according to the problem scenario, the cognitive processes required to find a solution, and the problem structure. As mentioned earlier, the structuredness of a problem can range from very well-structured (i.e., facts, rules, and principles) to very ill-structured (i.e., poorly defined, inconclusive, or conflicting solution paths). Providing students with repeated practice on solving various ill-structured problems can be beneficial in formal education settings because students of all ages experience ill-structured problems that arise naturally from daily interactions with other people and the environment. Trying to solve these types of problems requires students to define (and sometimes redefine) the problem and develop a solution pathway based on the skills needed to reach the solution (Jonassen 2002).

Recent research indicates problem-solving skills involve two facets: rule identification and rule application (Schweizer et al. 2013). “Rules” in problem-solving refers to the principles that govern the procedures, the conduct, or the actions in a problem-solving context. Rule identification refers to the ability to acquire knowledge of the problem-solving environment, and rule application is the ability to control the environment by applying the knowledge acquired. Typically, it is difficult to directly collect data on students’ rule identification ability. However, since rule application is the outward expression of one’s rule identification, the measurement of rule application may be used to reflect students’ ability to identify rules.

Complex problems usually combine a mix of basic rules with rules that require cognitive flexibility – the ability to adjust prior thoughts or beliefs and explore alternative strategies in response to changes in the environment (Miyake et al. 2000). Cognitive flexibility is the opposite of functional fixedness, which is the difficulty a person experiences when he or she is required to use objects (or strategies) in uncommon ways (Duncker 1945). Many researchers have targeted functional fixedness as the major obstacle to successful problem-solving (e.g., Anderson 1980). Moreover, problem-solving skills play an important role in everyday life and in many professions. Gagné (1980) believed that the central point of education is to teach people to become better problem solvers, and as noted earlier, problem-solving is recognized as one of the most important skills demanded in the job market (Partnership for 21st Century Skills 2016). Therefore, research on problem-solving skills and how to improve them are essential to prepare students for upcoming challenges in life and work. In the next two sections, we discuss challenges associated with assessing and supporting problem-solving skills in education followed by a concrete example of developing a stealth assessment for problem-solving skills embedded within a well-designed game.

Challenges with Assessing Problem-Solving Skills

Key measurement challenges for complex constructs like problem-solving skills include (a) lack of a clear and consensual definition and/or operationalization of the construct, (b) theoretical multidimensionality of the construct where certain dimensions may have internal as well as external sources, (c) difficulty disambiguating the generality of the construct (e.g., is there a single “problem-solving” variable or is it solely dependent on the context), and (d) reliance on outdated multiple-choice and self-report measures, the former narrowly focused and the latter flawed. Self-report measures in particular are problematic as they are subject to “social desirability effects” that can lead to false reports about behaviors, attitudes, and beliefs (see Paulhus 1991). In addition, test takers may interpret specific self-report items differently (e.g., what it means to enjoy solving “hard problems”) leading to unreliability and lower validity (Lanyon and Goodstein 1997).

Innovative and valid performance-based assessments of problem-solving skills are needed that assess how students apply this skill in the solution of complex, real-world problems. One way to approach this problem is to use video games or similarly immersive environments, to simulate a variety of problems for performance-based assessment (DiCerbo and Behrens 2012; Gobert et al. 2013; Quellmalz et al. 2012).

Early approaches to performance-based assessment in GBL included using serious games as tools to improve skills as seen in *Marine DOOM*, a modified version of the game *DOOM*, designed to improve military thinking and decision-making skills (Krulak 1997). New developments in GBL include the use of virtual reality (VR) technologies to promote collaboration and deep learning across a range of educational areas and for a broad swath of students. And while some researchers have attempted to design specific games to promote problem-solving skill (e.g., Van Eck et al. 2009), there are various commercial video games on the market that may be used for this research, such as *Portal 2* (Shute et al. 2015a) and *Plants vs. Zombies 2* (Shute et al. 2016). Such game-based environments can provide meaningful assessment by supplying students with scenarios that require the application of different facets of problem-solving skill. Next we describe a way to measure problem-solving skills continually and unobtrusively.

Stealth Assessment of Problem-Solving Skills

Stealth assessment (Shute 2011) provides a way to embed valid assessments directly into immersive environments like video games, extending the evidence-centered assessment design framework by delineating specific gameplay behaviors (specified in the evidence model) and statistically linking them to competency model variables (Shute and Ventura 2013). Stealth assessment thus complements the use of well-designed games to measure and improve skills by eliciting and aggregating student data during gameplay that can be used to provide real-time inferences about knowledge and skill states that can inform policies relevant to a range of stakeholders (Cukier and Mayer-Schoenberger 2013).

The results of this analysis are data (e.g., scores) that are passed to the competency model, which statistically updates the claims about relevant competencies in the student model. The ECD approach combined with stealth assessment provides a framework for developing assessment tasks that are explicitly linked to claims about personal competencies via an evidentiary chain (i.e., valid arguments that serve to connect task performance to competency estimates) and are thus valid for their intended purposes. The estimates of competency levels can also be used diagnostically and formatively to provide adaptively selected levels, feedback, and other forms of learning support to students as they continue to engage in gameplay.

To illustrate, Shute et al. (2016) developed a stealth assessment of problem-solving skill and embedded it in a game called *Use Your Brainz* (a slightly modified version of *Plants vs. Zombies 2*). The game was then tested with a sample of middle-school students. The research team began by developing a problem-solving competency model based on a review of the relevant literature and also reviewed the Common Core State Standards (CCSS) related to problem-solving. They came up with a four-facet competency model, which included: (a) understanding givens and constraints, (b) planning a solution pathway, (c) using tools effectively/efficiently when implementing solutions, and (d) monitoring and evaluating progress. The first facet maps to “rule acquisition,” and the remaining facets map to “rule application.”

After playing the game repeatedly and watching expert solutions on YouTube, the researchers delineated 32 observable indicators that were associated with the four facets (i.e., listed the specific actions a person would do while engaged in gameplay that would provide evidence – positive and negative – towards one or more of the facets). For example, sunflowers produce sun power, which is the sole source of power that players may use to grow plants. At the beginning of a level, typically there are no sunflowers on the battlefield. To supply power to grow plants, players must plant sunflowers at the beginning of each level before zombies start to appear in waves. The scoring rule for this particular indicator was: “If a player plants more than three sunflowers before the second wave of zombies arrives, the student understands relevant time and resource constraints of the level.” Table 1 displays a sample of indicators for each of the four problem-solving facets.

Table 1 Examples of indicators for each problem-solving facet. (From Shute et al. 2017)

Facet	Example indicators
Analyzing givens & constraints	Plants >3 Sunflowers before the second wave of zombies arrives Selects plants off the conveyor belt before it becomes full
Planning a solution pathway	Places sun producers in the back/left, offensive plants in the middle, and defensive plants up front/right Plants Twin Sunflowers or uses plant food on (Twin) Sunflowers in levels that require the production of X amount of sun
Using tools effectively and efficiently	Uses plant food when there are >5 zombies in the yard or zombies are getting close to the house (within 2 squares) Damages >3 zombies when firing a Coconut Cannon
Monitoring and evaluating progress	Shovels Sunflowers in the back and replaces them with offensive plants when the ratio of zombies to plants exceeds 2:1

Next, the researchers created a Q-matrix (Almond 2010) laying out all of the indicators in rows and the four facets in columns. A “1” was included in the crossed cell if the indicator was relevant to the facet and “0” if the facet did not apply to the indicator. They then went through each indicator and discussed how to classify it into discrete scoring categories such as “yes/no” or “very good/good/ok/poor.” The overall scoring rules were based on a tally of relevant instances of observables. Using the aforementioned sunflower indicator, if a player successfully planted more than three sunflowers before the second wave of zombies arrived on the scene, the log file would automatically record the action and categorize it as a “yes” status of the indicator.

Once all of the indicators were categorized into various states, statistical relationships were established between each indicator and the associated levels of the competency model variables. The researchers used Bayesian networks (BNs) to accumulate incoming data from gameplay and update beliefs in the competency model. A BN is a probabilistic graphical model that represents a set of random variables and their conditional dependencies via a directed acyclic graph. The relationship between each indicator and its associated competency model variable was thus expressed within conditional probability tables stored in each BN. There were a total of 43 BNs developed for this project, one for each level. Each of the 43 levels in the game had its own BN, reflecting the specific indicators of the level, as well as its particular difficulty and discrimination estimates. The statistical relationships carried in the BNs and the scoring rules described earlier formed the evidence model. For specific examples of scoring rules and BNs, see Shute et al. (2017).

To validate the stealth assessment, data were collected from middle school students who played the game-based assessment for 3 h (i.e., 1 h per day across 3 consecutive days) and then completed two external problem-solving measures (i.e., Raven’s Progressive Matrices and MicroDYN). Results indicated that the game-based stealth assessment estimates of problem-solving skill were significantly correlated with both Raven’s ($r = 0.40$, $p < 0.01$) and MicroDYN ($r = 0.41$; $p < 0.01$) which established the construct validity of the stealth assessment.

Next steps include running a larger validation study and developing tools to help educators interpret the results of the assessment, which will subsequently support the development of problem-solving skills. In the next section, we explore the benefits and challenges associated with using video games in a classroom environment.

Video Games in Formal Education Settings

Given the gap in problem-solving skills being taught in schools and those required in workplace environments, we suggested the integration of video games into formal learning curricula with the goal of improving problem-solving skills, and to prepare students with the skills necessary to succeed in a globally interconnected society. Similarly, Schrader et al. (2006) argued that gameplay experiences within video games can promote collaboration and problem-solving skills for students through immersive game environments. However, while many students and teachers clearly

enjoy video gameplay, the majority do not fully understand how video games can be used to support learning outcomes (Selfe and Hawisher 2004).

Well-designed video games can support higher-level learning via offering players practice across multiple and varied problem-solving scenarios (Gee 2007, 2008; Van Eck 2006). Repeated practice with novel problems can improve problem-solving skills within a domain (Gagné et al. 2005). In K-12 settings, video games have been shown to improve creativity, recall of facts, and problem-solving skills when compared to computer-assisted instruction (Chuang and Chen 2009; Jackson et al. 2012). Overall, there seems to be consensus that video games can support changes in affect, behavior, knowledge, and skill acquisition for learners (Clark et al. 2016; Ifenthaler et al. 2012; Shute et al. 2015b; Sitzmann 2011; Wouters et al. 2013).

While well-designed video games can help improve cognitive competencies, there is also a need to bridge the gap between in-game knowledge and school knowledge (i.e., game-based learning and formal learning). One possibility involves the design of scaffolds that are both engaging and meaningful to instruction, such as presenting concepts that are directly tied to in-game performance and readily identifiable during gameplay (Barzilai and Blau 2014). As an example, avatars in *World of Warcraft* (i.e., the digital embodiment of a player in the game) communicate with each other to solve problems such as how to use given tools and resources to travel from one zone to another. Using tools and resources efficiently is a facet of problem-solving skill (Shute and Wang 2016). Introducing a problem-based scenario in *World of Warcraft* that requires students to learn how to reduce travel time from one zone to the next using resources (e.g., map and transportation hub) efficiently is one way to teach problem-solving skills in formal education settings.

In addition, reducing travel time is a relevant concept that can transfer from the game to the natural world. That is, designing scaffolding can challenge students to think critically during gameplay and provide them with meaningful connections between gameplay and educational concepts (Gee and Hayes 2011). Instruction that weaves gameplay concepts with educational content by using scaffolds can inform stakeholders and policy makers that video games are effective learning tools in formal education settings. Well-designed multiplayer video games like *World of Warcraft* also provide opportunities for collaborative learning and problem-solving that has relevant implications in workplace environments.

Certain well-designed video games that emphasize multiplayer interactivity during gameplay can also help players develop skills that are desirable in twenty-first century workplace environments. As an example, Symantec's former Chief Operating Officer (COO), Stephen Gillet, included *World of Warcraft* as one of his achievements on his résumé to highlight his experience in organizing large groups of individuals to solve difficult problems, demonstrate confidence in solving these problems through natural and immersive video game environments (i.e., analyzing different strategies and gameplay tactics with peers in-game and through social media platforms like Twitter), and distribute resources (i.e., gold, crafting components, weapons, and armor) to in-game friends (Pagliery 2014). These gameplay practices may lead to improvement in planning and executing strategies that can be applied to similar workforce-related collaborative projects in the natural world. We

now conclude with our thoughts on future directions of game-based learning and assessment in academic research and practice.

Conclusions and Future Implications for Game-Based Assessment

The demand for skilled workers who can solve complex problems in twenty-first century workplace environments requires a shift in how to measure and support problem-solving skills in formal education settings. In this chapter, we defined problem-solving skills and explored the theoretical foundations for GBL to explain how interactions within immersive environments can promote the development of problem-solving skills. We outlined some of the challenges associated with assessing problem-solving skills in formal education settings (e.g., the prevalence of flawed assessment methods such as multiple-choice type of items and self-report surveys) and highlighted the importance of using performance-based assessments in education. This suggestion coincides with the growing labor demand for multi-skilled workers in a constantly changing global economic landscape.

In addition, we proposed a possible solution to reduce the gap between school-based and real-world problem-solving skills via integrating immersive environments like video games into formal education settings to help students improve their problem-solving skills by preparing them with repeated problem-solving scenarios through immersive gameplay. To illustrate, we included an example of a problem-solving stealth assessment (see Shute et al. 2016). Furthermore, recent research on the effects of immersive gameplay on cognitive and noncognitive skills demonstrates that learning does occur – for problem-solving skills, persistence, visual-spatial skills, and attention (e.g., Green and Bavelier 2012; Rowe et al. 2011; Shute et al. 2015a; Ventura et al. 2013). Some researchers, however, have reported null effects of immersive gameplay on cognitive skill acquisition (Ackerman et al. 2010; Baniqued et al. 2013; Boot et al. 2008) so clearly, more research is needed.

One future GBL research thread may aim to bridge the gap between the worlds of commercial versus educational video games. Towards that end, we need a systematic approach to designing game-based assessment that produces engaging video games and valid assessments. This will require an interdisciplinary team (e.g., experts in assessment, game design, content, instructional design, psychometrics, and learning sciences). Sound research methods are needed to explore how well-designed video games can be used as reliable and valid assessments of multiple and diverse competencies. From an assessment standpoint, research is needed to determine the value added of game-based assessment over traditional assessment relative to the quality of the assessment (i.e., validity, reliability, and generalizability) and the impact on learning, engagement, and transfer. This research should also include analyses on how game-based assessment data predict important external criteria (e.g., high school or college graduation, state test scores, and so on) relative to traditional assessments.

The ECD framework used in stealth assessment provides a systematic approach to assessment design and also provides a transparent way to reason about student

performance. And while there are other ways to develop assessments, they often lack transparency as well as specification about the competencies and tend to focus on tasks that are too simple or inauthentic. This can result in creating assessments that measure unintended competencies and thus damage the reliability and validity of the assessment. In addition, using an ECD approach for the design of game-based assessments can provide a clear research and communication framework for assessment/learning experts and game designers who want to design and develop new educational and engaging game-based assessments that accurately measure important traditional and new competencies.

One final hurdle to surmount to weave such immersive video games into classrooms concerns the need for these games to provide easy-to-interpret reports to stakeholders – such as teachers, students, and parents. There are many ways an assessment can accumulate data (e.g., tallying frequency counts of events, automatically logging player information then mining the log file to make estimates of competency states via Bayesian networks). Regardless of the methodology for accumulating evidence, the ensuing estimates can be reported at various grain sizes (e.g., general problem-solving skill or specific facets) for diagnostic purposes (see Almond et al. 2009). And with regard to validity issues of game-based assessments, when embedded assessments are not only ongoing but also invisible, this can remove test anxiety, again leading to a more valid assessment.

In conclusion, we believe that conducting research with the goal of improving twenty-first century competencies like problem-solving skills for learners through immersive video gameplay environments is relevant and important to pursue given the emerging challenges of a globalized economy (i.e., renewable energy, pollution, climate change) and consequent problems to solve.

Assessment analytics · Learning analytics · Formative assessment · Large-Scale assessment · Data analytics

Introduction

During the past two decades, remarkable repertoires of computer-based applications and systems have been developed for supporting learning and teaching. The resulting changes in learning and teaching through the influence of emerging technologies require alternative perspectives for the design and development of learning environments (Spector 2009). Closely linked to the demand of alternative approaches for designing and developing learning environments is the necessity of enhancing the design and delivery of computer-based diagnostics and automated assessment systems (Almond et al. 2002). It is expected that advanced assessment systems accomplish specific requirements, such as (a) adaptability to different subject domains, (b) flexibility for experimental as well as learning and teaching settings, (c) management of huge amounts of data, (d) rapid analysis of complex and unstructured data, (e) immediate feedback for learners and educators, and (f) generation of automated reports of results (Ifenthaler et al. 2010).

In the meantime, the increased availability of vast and highly varied amounts of data from learners, teachers, learning environments, and administrative systems within educational settings is overwhelming. Addressing the challenges of processing such information are concepts of educational data mining (EDM), academic analytics (AA), and learning analytics (LA). Educational data mining, for instance, refers to the process of extracting useful information out of a large collection of complex educational data sets with mainly fuzzy relationships between different elements of the data set (Berland et al. 2014; Klosgen and Zytchow 2002). Academic analytics is the identification of meaningful patterns in educational data in order to inform academic matters (e.g., retention, success rates) and produce actionable strategies (e.g., budgeting, human resources) (Long and Siemens 2011). Learning analytics emphasizes insights and responses to real-time learning processes based on educational information from digital learning environments, administrative systems, and social platforms (Romero and Ventura 2015). Such dynamic educational information, sources, and analysis methods are used for real-time interpretation, modeling, prediction, and optimization of learning processes, learning environments, and educational decision-making (Ifenthaler 2015).

As noted by Ellis (2013), learning analytics fails to make use of educational data for assessment. Since then, despite recent advancements in learning analytics research, there are opportunities for applying dynamic findings to assessment challenges such as timeliness and relevance. Therefore, the focus of this chapter is on

how data with a large number of records, of widely differing datatypes, and arriving rapidly from multiple sources can be harnessed for meaningful assessments and supporting learners in a wide variety of learning situations.

The Purposes of Educational Assessment

Tracing the history of educational assessment practice is challenging as there are a number of diverse concepts referring to the idea of assessment. Newton (2007), for instance, laments that the distinction between formative and summative assessment hindered the development of sound assessment practices on a broader level. Scriven (1967) is often referred to as the original source of this distinction. Bloom et al. (1971) were concerned with the long-lasting idea of assessment separating learners based on a summative perspective of knowledge and behavior – the assessment *of* learning. In addition, Bloom et al. (1971) supported the idea of developing the individual learner and supporting the learner and teacher toward mastery of a phenomenon – the assessment *for* learning. Following this discourse, Sadler (1989) developed a theory of formative assessment and effective feedback. Formative assessment helps students to understand their current state of learning and guides them in taking action to achieve the learning goals. A similar line of argumentation can be found in Black (1998) in which three main types of assessments are defined: (a) formative assessment to aid learning; (b) summative assessment for review, for transfer, and certification; and (c) summative assessment for accountability to the public. Pellegrino et al. (2001) extend these definitions with three main purposes of assessment: (a) assessment to assist learning (formative assessment), (b) assessment of individual student achievement (summative assessment), and (c) assessment to evaluate programs (evaluative assessment). Despite an intense debate over the past five decades, the distinction between formative and summative assessment has not resulted in a precise definition, and the distinction between the two remains blurry (Newton 2007). For widening the perspective, other terms have been introduced such as *learning-oriented assessment* (Carless 2007) emphasizing the development of learning elements of assessment or *sustainable assessment* (Boud 2000) proposing the support of student learning beyond the formal learning setting. A common thread among the many definitions points to the concept of feedback for a variety of purposes, audiences, and methods of assessment.

A feedback-rich learning environment driven by formative assessment enables learners to progress in their individual learning journey (Ifenthaler and Seel 2005). In a broader sense, feedback is considered to be any type of information provided to learners (Wagner and Wagner 1985). Feedback can take on many forms depending on the theoretical perspective, the role of feedback, and the methodological approaches (Ifenthaler 2009). Feedback can be provided through internal (individual cognitive monitoring processes) or external (various types of correction variables) sources of information. Internal feedback may validate the externally provided feedback, or it may lead to resistance against the externally provided feedback (Narciss 2008). Widely accepted forms of feedback include (a) knowledge of result, (b) knowledge of correct result, (c) knowledge of performance, (d) answer until

correct, (e) knowledge of task constraints, (f) knowledge about concepts, (g) knowledge about mistakes, (h) knowledge about how to proceed, and (i) knowledge about metacognition (Ifenthaler 2009; Narciss 2008).

New opportunities arise from tools and technologies in classrooms which enable formative assessment practices to support twenty-first century learning (Spector et al. 2016). For example, automation as opposed to full- or part-manual approaches of formative assessment has created a new class of instructional and interactive technologies (Wiliam 2011). If the assessment can be carried out automatically and in real time, then its results can be used to inform (a) the learners during an ongoing learning process, (b) the teachers in order to create meaningful feedback and redesign learning events on the fly, and (c) the decision-makers to continuously optimize learning environments (Ifenthaler and Pirnay-Dummer 2014). Assessment results can then be aggregated, transformed, and thus utilized to create feedback panels or even personalized and adaptive feedback based on the current learner model. Such a formative assessment model with integrated real-time feedback requires access to rich data from various contexts of the educational arena (Baker and Siemens 2015; Ifenthaler 2015).

One example is the model-based assessment and feedback approach (Ifenthaler 2009), where a phenomenon in question is assessed in form of a written text or graphical representation. Model-based assessment and feedback aim at a restructuring of the underlying representations and a reconceptualization of the related concepts of the cognitive structure of the learner (Piaget 1950). New information provided through model-based feedback can be assimilated through the activation of an existing schema, adjustment by accretion, or tuning of existing schema. Otherwise, it is accommodated by means of a reorganization process which involves building mental models (Ifenthaler and Seel 2013). Hence, an analytics algorithm enables the generation of domain-specific feedback including different forms of model-based feedback. The automated language-oriented analysis can be applied domain independently for written texts or graphical representations against a single reference model or against multiple reference models (Coronges et al. 2007). Reference models can either be a person's prior understanding of a phenomenon in question, another person's understanding, a shared or aggregated understanding of the phenomenon of multiple persons, or an expert solution of the phenomenon in question. Automated model-based feedback models, generated on the fly, have been successfully tested for prelection and reflection in problem-solving scenarios (Ifenthaler 2012; Lehmann et al. 2014). Other studies using model-based assessment and feedback highlight the benefits of availability of informative feedback whenever the learner needs it, and its identical impact on problem-solving when compared with feedback models created by domain experts (Pirnay-Dummer and Ifenthaler 2011).

Harnessing Data and Analytics for Assessments

Interest in collecting and mining large sets of educational data on student background and performance has grown over the past years and is generally referred to as learning analytics (Baker and Siemens 2015). Learning analytics uses static and

dynamic information about learners and learning environments – assessing, eliciting, and analyzing them – for real-time modeling, prediction, and optimization of learning processes, learning environments, and educational decision-making (Ifenthaler 2015, 2017). As the field of learning analytics is growing, several frameworks have been proposed, which focus on available data, instruments for data analysis, involved stakeholders, and its limitations (Buckingham Shum and Ferguson 2012; d’Aquin et al. 2014; Greller and Drachsler 2012; Ifenthaler and Widanapathirana 2014). For example, Greller and Drachsler (2012) introduce six critical dimensions of a learning analytics framework including stakeholders, objectives, data, instruments, and internal and external constraints. These dimensions are critical when designing and implementing learning analytics applications and therefore provide a valuable guideline. Still, elaborated and more importantly empirically validated learning analytics frameworks are scarce (Ifenthaler and Widanapathirana 2014). Another limitation of learning analytics frameworks is the missing link of learner characteristics (e.g., prior learning), learning behavior (e.g., access of materials), and curricular requirements (e.g., competences, sequencing of learning). Ifenthaler and Widanapathirana (2014) addressed most of these limitations by introducing a holistic learning analytics framework. This holistic learning analytics framework combines data sources directly linked to individual stakeholders and their interaction with the online learning environment, as well as curricular requirements. Additionally, data from outside of the educational system is integrated. The processing and analysis of the combined data are carried out in a multilayer data warehouse and returned to the stakeholders, e.g., institution, teacher, learner, in a meaningful way. Each of these stakeholders has unique needs for understanding and interpreting data that is most relevant for the decisions that need to be made (e.g., by a student for reworking, by a teacher for assisting in providing guidance and advice to the learner, by an institutional leader for aggregating results to make programmatic and curriculum decisions).

Figure 1 illustrates a holistic learning analytics framework for formal learning environments. The arrows document the data flow within the environment. For example, learning outcomes for a unit are defined in the curriculum which is directly linked to the learning environment. Students and teachers (with individual characteristics) interact with the learning environment to achieve the expected learning outcomes. Data from (a) student characteristics and teacher characteristics and (b) interaction traces from the learning environment are processed in the learning analytics engine with dynamic algorithms and further refined for personalized and adaptive interventions. These interventions (e.g., prompts, hints) are displayed in the learning environment in near real time. In addition, a reporting engine can produce insights for stakeholders on a summative level.

However, a yet to be solved limitation of learning analytics is the lack of a stronger focus on dynamic or real-time assessment for learning as well the improvement of learning environments. While the abovementioned holistic learning analytics framework includes allusions to assessment data (e.g., prior academic performance, self-tests) and accompanying feedback (e.g., metacognitive prompts, personalized scaffolds) (Ifenthaler and Widanapathirana 2014), distinct assessment

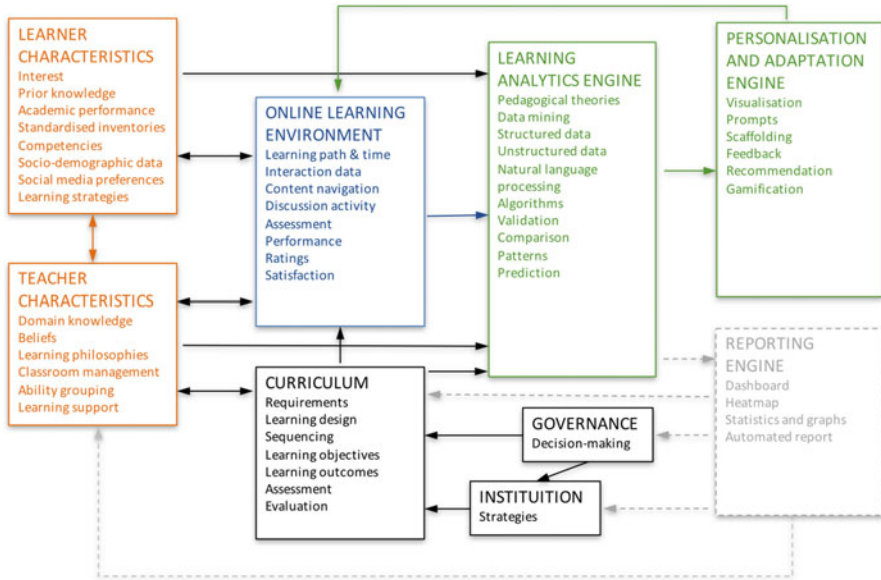

Fig. 1 Holistic learning analytics framework (Ifenthaler 2015)

analytics or analytics-driven formative and evaluative assessment features are not mentioned. Analytics-driven assessment harnesses formative data from learners and learning environments in order to facilitate learning processes in real time and help decision-makers to improve learning environments. Hence, analytics-driven assessment may provide multiple benefits for students, schools, and involved stakeholders. Distinct features of analytics-driven assessments may include (Ellis 2013; Ifenthaler and Widanapathirana 2014):

- Self-assessments linked to specific learning outcomes using multiple assessment formats (e.g., single- or multiple-choice, open text, etc.) and personalized real-time feedback (e.g., knowledge of result, knowledge about how to proceed)
- Peer assessments focusing on specific learning outcomes or general study skills (e.g., learning strategies, time management)
- Defining individual goals and desired achievements for subjects, modules, or classes and tracking learning-dependent progress toward them
- Semantic-rich feedback for written assignments in near real time using natural language processing
- Progress reports toward curricular required competences or learning outcomes including intraindividual and interindividual comparisons
- Reflective prompts highlighting persistence of strengths and weaknesses of specific learning events and assessment results (e.g., reoccurring errors, misconceptions, learning habits)

In order to implement analytics-driven assessment in classroom settings, advanced algorithms for assessment and personalization as well as systems for their continuous improvement have to be further developed. Only a few have been implemented in educational settings so far (Drachsler et al. 2008): (a) neighbor-based algorithms recommend similar learning materials, pathways, or tasks based on similar data generated by other learners; (b) demographics algorithms match learners with similar attributes and personalize the learning environment based on preferences of comparable learners; and (c) Bayesian classifier algorithms identify patterns of learners using training sets and predict the required learning materials and pathways. In addition, Ifenthaler and Widanapathirana (2014) report case studies that support the application of support vector machines (SVM) for learning analytics applications. SVM can efficiently perform a nonlinear classification using what is called the kernel trick, implicitly mapping their inputs into high-dimensional feature spaces (Cleophas and Zwinderman 2013). The flexibility for modeling nonlinear educational data, short training times for more robust models, and responsiveness to interactions and changing variables, as well as sensitivity to imperfect data sets are strong arguments for further implementation of SVM in analytics-driven assessments.

Given an analytics-driven assessment system outlined above, the learning environment can enable a personalized learning experience and adjust to the students' need in near real time. Making assessment data available to teachers may also help to change the culture of feedback in classrooms and to build positive perceptions toward analytics driven-assessment.

To sum up, making use of big data requires sophisticated learning analytics of formative assessment data, that is, analytics-driven assessment, collected from many different learners in a wide variety of learning situations and provided to relevant users at appropriate and meaningful levels of aggregation for analysis, insight, and decision-making. Analytics-driven assessments can thereby motivate individual students, help teachers adjust individual learning paths, and inform other stakeholders in schools of progress and achievements.

Computer-Generated Log Files in Large-Scale Assessments

One specific area of interest for learning analytics is the field of educational large-scale assessments (LSAs) because the wealth of data collected in LSAs allows for insights that are difficult to obtain in small-scale studies both in terms of the diversity of information covered and in terms of the population studied. Most of the LSAs have a political dimension to them as well and cover broad assessments of several learning outcomes (often referred to as competencies or proficiency levels) and background information in large and, of note, representative samples. This data is prone to be fully exploited by the emerging field of learning analytics, which directly relies on the use of computer-based assessment (CBA).

Over a decade ago, LSAs already employed CBA, but a widespread implementation of technology into the assessment process has only occurred recently. For instance, the largest educational LSA, the Programme for International Student Assessment (PISA) convened by the OECD on a triennial basis in over 70 countries (OECD 2013b), has comprehensively moved to CBA in its 2015 cycle and will even do more so in 2018. In fact, paper-pencil assessment materials are developed and maintained only for those participating countries that do not have the technological means of CBA. Given the unique combination of representative samples in LSAs, the carefully deployed background information in the form of self- and other-reported questionnaires, and the wealth of process information obtained within CBA, LSA data is an exemplary source for exploratory analysis and application in learning analytics.

However, the potential for LSA data has yet to be fully explored. In fact, LSAs have mainly focused only on comparisons between countries and have provided information on students' overall proficiency levels. One major criticism surrounding LSAs is that they only provide a rather distal summative assessment and that their results and implications are somewhat removed from actual applications and implications in the classroom. The wealth of data obtained within CBA in combination with the field of learning analytics has the as yet untapped potential of providing in-depth and fine-grained insights into learning processes and behavioral patterns on the basis of computer-generated log file analyses and extending the scope of LSAs into the realm of formative assessment. Despite the potential of applying learning analytics to assessment data obtained in LSAs, the currently available applications are scarce at best. For instance, only recently OECD has made (excerpts from) the computer-generated log file data available on a public repository for scientific analyses (www.oecd.org/pisa/data/). The actual use of insights obtained from such analyses in the reporting of studies such as PISA is something that has not been realized.

Educational data mining techniques are one way of exploring the relations between different variables, for instance, between behavioral patterns when working on the tasks and overall performance on the one hand and background variables on the other hand. This approach has yet to be fully utilized in the application of LSAs for mainly two reasons: (a) available software packages in the field of learning analytics are highly specialized and require substantial resources to be used, both financially and time-wise, and there is often a lack of both in LSAs; and (b) educational data mining is an excellent tool for initially discovering complex and fuzzy relations between variables. Thus, so far researchers have used more exploratory than confirmatory methods, but the latter in combination with a theoretical understanding will be required for fully understanding the educational implications of LSAs.

Recently, there have been some first attempts of investigating and incorporating analyses that were conceptually motivated and utilized information gained from computer-generated log file analyses into LSA. For instance, Goldhammer et al. (2014) used data from the Programme for the International Assessment of Adult Competencies (PIAAC; OECD 2013a) to show that time-on-task exhibited

differential relations to different performance indicators. As theoretically expected, a shorter time-on-task was associated with better performance in reading (indicating quick and efficient automatic processing), whereas a longer time-on-task was associated with better performance in problem-solving (indicating thoughtful and controlled processing). In a similar vein, Greiff et al. (2016) investigated how several actions taken by students related to working on a complex problem-solving task (e.g., time-on-task, the strategy used, and the number of active interventions) related to overall problem-solving performance in a national large-scale study in Finland. They found that for some of the process indicators, there was a linear relation to performance, whereas for others the relation was of a reversed U-shape indicating, for instance, for time-on-task, an optimal level to be spent on a task with higher and lower values associated with lower performance.

Results on the basis of computer-generated log file analyses can thus be used to explain group differences in LSAs and other settings. For instance, Wüstenberg et al. (2014) compared performance differences in complex problem-solving, which was internationally assessed in the PISA 2012 cycle under the label “creative problem-solving” (OECD 2014), between a Hungarian and a German sample. They found that overall performance differences were closely mirrored by differences in exploration strategy, thus providing a fine-grained predecessor (and possibly explaining variable) for differences between the two groups. It is this kind of analysis that adds a formative aspect to the originally rather abstract nature of summative assessments in LSAs by relating abstract differences in overall performance to differences in underlying processes and actual behaviors. Consequently, there are first attempts of incorporating indicators from computer-generated log files into the reporting and scoring for LSA. For instance, for some of the problem-solving tasks administered in PISA 2012, students would receive partial credit even if they obtained the wrong solution to the problem, but log files indicated that their initial approach toward exploring the problem space was adequate. This concept is closely related to the idea of “stealth assessment” (Shute 2011) in which information that can be considered a by-product of the assessment process is integrated into the scoring and used as additional source of information. Readers may also be interested in the “Rule Space Method” which provides a foundation for cognitive diagnostics (Gierl 2007; Tatsuoka 2009).

Information concerning a student’s task processes and behaviors during performance could also be used in providing very specific feedback to teachers about students’ needs in an attempt to utilize the information from LSA for the classroom. For instance, Greiff et al. (submitted) used data obtained from log files to identify different types of students with different patterns of exploring complex problem-solving environments across a number of tasks in a sample of Hungarian students. Interestingly, several of the different types of explorers showed comparable levels of overall performance and would have been considered equal in terms of overall proficiency levels. However, when looking at actual task behaviors, some of these students might require different (e.g., more intensified) support and intervention than others because they displayed suboptimal task exploration. Thus, providing individualized information on task behavior – in addition to and beyond overall task

performance – can yield valuable information to teachers in terms of a combination of formative and summative assessment data.

While such analyses have not been utilized on a large scale but are currently limited to single studies, this type of analysis could add substantial value to the current benefits of LSA. The conceptually motivated examples mentioned above could then be complemented by EDM techniques, which are best at discovering complex interactions between several actions but that are also more difficult to understand and to give meaning to. In the long run, additional information that is driven by assessment and learning analytics will help LSAs to gain legitimacy for student development and in the classroom.

Conclusions and Future Directions

The complexity of designing adaptive assessment and feedback systems has been discussed widely over the past few years (e.g., Sadler 2010; Shute 2008). The current challenge is to make use of data – from learners, teachers, and learning environments – for assessments. Several issues and future directions in the broad area of analytics-driven assessments arise for educational practice.

First, in relation to the challenges brought on by technology-enhanced assessments, the large amount of data now available for teachers is far too complex for conventional database software to store, manage, and process. In addition to the volume of available assessment data, the assessment data accumulates in real time. Finally, the source and nature of this enormous and quickly accumulating assessment data are highly diverse (Gibson and Webb 2015). Accordingly, technology-enhanced assessments underscore the need to develop assessment literacy in teachers and other stakeholders of assessment (Stiggins 1995). However, teachers seem not to be adequately prepared to assess students in classrooms in general (Mertler 2009) and, more importantly, when using technology-enhanced assessments. One historically well-documented reason for this inadequate preparation of teachers for assessments is the minimal preservice training in educational measurement and psychometrics experienced by most teachers (Plake 1993). Professional development in technology-enhanced assessment needs to focus on key issues of assessment (Stiggins 1995): (a) what to assess, (b) why to assess, (c) how to assess, (d) how to provide feedback, and (e) how to avoid assessment errors and biases. In addition, Mertler (2009) notes that workshops focusing on applied assessment decision-making can be beneficial for teacher's assessment literacy. Therefore, implementing new preservice and in-service programs for assessment literacy with a strong focus on technology-enhanced assessments seems to be of high priority. Along this line, empirical research is needed to investigate long-term impact on teachers' analytics-driven assessment practice. Such a new foundation of analytics-driven assessment methodology needs to provide teachers with practical hands-on experience on the fundamental platforms and analysis tools for linked big data, introduce several data storage methods and how to distribute and process them, introduce possible ways of handling analytics algorithms on different platforms, and highlight visualization

techniques for big data analytics (Gibson and Ifenthaler 2017). Well-prepared teachers may demonstrate additional competencies such as understanding large-scale machine learning methods as foundations for human-computer interaction, artificial intelligence, and advanced network analysis.

Second, additional design research and development are needed in automation and semiautomation (e.g., humans and machines working together) in assessment systems. Automation and semiautomation of assessments to provide feedback, observations, classifications, and scoring are increasingly being used to serve both formative and summative purposes. For example, automated scoring systems have been used as a co-rater in large-scale standardized writing assessments since the late 1990s (e.g., e-rater by Educational Testing Service). Alternatively, the instructional applications of automated scoring systems are developed to facilitate the process of scoring and feedback in writing classrooms (Ifenthaler 2016). These systems mimic human scoring by using various methods of scoring, that is, statistics, machine learning, and natural language processing techniques. Implemented features of automated assessment systems vary widely, yet they all are trained with large sets of expert-rated sample open-ended assessment items to internalize features that are relevant to human scoring (Ifenthaler and Dikli 2015). Automated scoring systems compare the features in training sets to those in new test items to find similarities between high-/low-scoring training and high-/low-scoring new ones and then apply scoring information gained from training sets to new item responses. Shermis and Hamner (2013) demonstrated that automated assessments are capable of producing results similar to human assessment for extended-response writing items. Currently, automated and semiautomated assessment systems can be reliably applied in low-stakes assessment (e.g., evaluation of written essays). For example, students can submit their written essay (from home or from in the classroom) to a web-based platform and receive near real-time feedback regarding their (a) writing style, (b) scope of writing, or (c) structure and depth of arguments. Such improvement toward valid real-time feedback is expected as these systems are being developed further and might even be used for high-stakes assessment in the near future.

Third, Gibson et al. (2016) propose an open assessment resources approach that has the potential to increase trust in and use of open education resources (OER) in formal educational systems by adding clarity about assessment purposes and targets in the open resources world. Open assessment resources (OAR) with generalized formative feedback are aligned with a specific educative purpose expressed by some user of a specific OER toward the utility and expectations for using that OER to achieve an educational outcome. The generalization of feedback can follow anonymous crowd behavior (e.g., common misconceptions, common pathways of performance) in the OER rather than individualized behavior. Further, the OAR approach is focused on a few high-level assessable outcomes (e.g., collaboration, problem-solving, communication, creativity) and the feedback (e.g., recommendations for improved performance, prompts for further elaboration of ideas, suggestions for alternatives) that pertain to supporting and achieving these outcomes within a specific OER with fewer ethical challenges. An OAR system will support a wide range of assessment applications, from quizzes and tests to virtual performance assessments and game-based

learning, focused on promoting deeper learning. The concept of *assessment activity* expresses the idea that authentic assessment is fundamental to learning, and the concept of *item bank* implies reusability, modularity, and automated assembly as well as presentation of assessment items (Gibson et al. 2016).

Fourth, utilizing data (i.e., in-game actions and behaviors that are digitally traced through numerical variables) from game-based learning environments may provide near real-time information about learners' performance and competency development. Still, the implementation of assessment into games adds an important but time-consuming step to the educational game design process. Ifenthaler et al. (2012) distinguish three types of game-based assessment: (a) game scoring, (b) external assessment, and (c) embedded assessment. Game scoring stems from traditional game design and focuses on targets achieved or obstacles overcome as well as time needed for reaching specific goals within a game. External assessment is realized outside of the game environment using traditional assessment approaches such as interviews, essays, knowledge maps, causal diagrams, or multiple-choice questions. A more effective form of assessment is the embedded or internal game-based assessment (Ge and Ifenthaler 2017). An unobtrusive version of embedded assessment is referred to as stealth assessment as mentioned before (for an application see Shute et al. 2016). Embedded assessment does not interrupt the game-play; however, it makes the purpose of assessment transparent to the learner. Embedded assessment is implemented in situ, that is, in action of the game-play. Hence, in situ assessment focuses on the learning-dependent progression and learning outcomes while playing a game. This opens up manifold opportunities in order to optimize learning processes and learning outcomes including personalized and adaptive feedback and scaffolds toward the intended learning outcomes of the game while at the same time coming along with several fairness-related challenges (Loh et al. 2015).

To conclude, analytics-driven assessments have yet to fully arrive in the everyday classroom but are rapidly emerging. In moving forward to embrace the opportunities that could be provided by analytics-driven assessment, the challenges that remain to be addressed must not be underestimated:

- (a) Professional development of teachers is vital for advancing meaningful assessment practices in schools.
- (b) Schools need to address ethics and privacy issues linked to data-driven assessments. They need to define who has access to which assessment data, where, and how long the assessment data will be stored and which procedures and algorithms to implement for further use of the available assessment data.
- (c) The application of serious games analytics opens up opportunities for the assessment of engagement and other motivational (or even broader: non-cognitive) constructs within game-based learning environments. The availability of real-time information about the learners' actions and behaviors stemming from key decision points or game-specific events provides insights into the extent of the learners' engagement during game-play. The analysis of single action or behavior and the investigation of more complex series of actions and

behaviors can elicit patterns of engagement and therefore provide key insights into ongoing learning processes.
