Abstract

Assessment is perhaps the area, like no other, where the utility of information technology in education is tested. The possibilities for assessing using these technologies are expanding rapidly. In particular, new technologies afford possibilities for focusing assessment on learning as an ongoing developmental process, rather than on performance. Building on notions of assessment grounded in measurement theory, there are prospects for assessing students continuously while they learn in a developmental way through the use of data and analytics. The resulting picture of student development will then allow for a more holistic and systemic approach to assessment in the years ahead. While it is often problematic to make predictions about the future, in this chapter, I will attempt to draw on current developments to provide suggestions about where the

intersections of assessment and information technologies are likely headed. That future is likely to entail more continuous, personalized forms of assessment that focus heavily on helping students to make better judgments about their own learning and development.

Keywords

Educational technology · Performance · Measurement · Continuous assessment

Introduction

Of the areas in which information technologies are poised to have an impact on education in the future, assessment is perhaps the most prominent. Across all levels of education, assessment influences student and teacher behavior, and the outcomes of assessment are key drivers of local, national, and international policy. With student learning increasingly occurring in ways that are mediated by information technologies, there is potential for fundamentally rethinking how assessment is conceptualized and implemented. There are simultaneously risks associated with not sufficiently catering to the changing information-rich world students increasingly find themselves in. There are also risks associated with expecting technologies to enhance assessment without necessary shifts in practice. While digitally mediated assessment practices were not long ago limited to computer-based testing, the possibilities for assessment with emerging information technologies have expanded rapidly. It is these fundamental shifts that will provide the basis for this chapter. However, the aim is not to focus on the technologies themselves but what these technologies mean for assessment practices. The resulting futures perspective will include possibilities for enhanced conceptualizations of assessment enabled through advanced information technologies. With the importance of assessment to policy and practice, the implications of evolving information technologies need to be considered carefully in the contexts in which they are to be applied.

Learning Versus Performance in Assessment

The notion of assessment *for* learning, as opposed to assessment *of* learning, has been discussed in the scholarly literature for some time (e.g., Black et al. 2003; Dann 2014; Wiliam 2011). In an attempt to capture the difference between these notions, Shute and Kim (2014) suggest that assessment of learning constitutes the summative aspects of assessment, while assessment for learning are the formative aspects (see also ► Chap. 41, “Assessment as, for, and of Twenty-First Century Learning Using Information Technology: An Overview” this volume). These definitions allude to assessment as a performative exercise. In other words, students perform a task, often leading to production of an artefact such as an essay or completed exam paper, which is then evaluated qualitatively and/or quantitatively. Teachers are able to use this

information in meaningful ways to provide feedback to help student learning, thus highlighting that complex and nuanced practices occur around assessments of this kind. However, particularly in the case of standardized tests, “assessment of performance” does capture the essence of the mundane purpose and execution of assessment in educational settings broadly. In reality, the assessment process, whether formative or summative, in the majority of cases, assesses performance as an outcome rather than learning as a process.

Information technologies open avenues for rethinking the role that assessment plays in student development. The affordances of advanced information technologies now mean that assessment can be realistically viewed as an integrated, continuous feature of education in much the same way as learning itself can be seen as an integrated, continuous process. For example, Shute’s (2011) notion of “stealth assessment” and Webb et al.’s (2013) “quiet assessment” both allude to a more sophisticated approach to monitoring student progress as it occurs (see chapter 6.1 for further discussion). In other words, assessment can evolve to become seamlessly integrated into the learning process rather than being focused on performance and/or artifacts as the central point at which teachers make judgments about and provide feedback on student learning.

Information technologies have already begun to afford possibilities for assessing student learning progress (see Lodge et al. 2018, for an overview). One way of abstracting the shift in assessment approaches now possible through the development of information technologies is therefore through the affordances these technologies provide for assessing learning while it is occurring. Assessment of learning has traditionally been about measuring student performance periodically as they ostensibly progress in their understanding. Despite the possibilities available through the ongoing, iterative design of assessment items and tasks, there remains a fundamental problem with this approach as learning is not a series of loosely related performances but a continuous, developmental process. Assessment *for* learning similarly treats assessment as being distinct from the learning process, which suggests a necessary turn to notions of assessment *as* learning. In a similar vein, Black et al. (2006) argue that assessment should be focused on learning as a process and beyond to support learning how to learn. These ideas allude to an integrated means of incorporating assessment more seamlessly around learning. The aim is for assessment to more directly support and monitor the process of learning as well as support students to learn how best to learn themselves.

The difference between learning as performance and learning as developmental process has concurrently been receiving increased attention in the psychological science literature. For example, Soderstrom and Bjork (2015) argue that there has been an overemphasis on learning as performative rather than the process that it is more accurately conceptualized. The importance of being mindful of the difference between learning as performance and learning as process cannot be overstated. Perhaps the most compelling phenomenon pointing to the importance of assessment to the process of learning is the testing effect (Roediger and Karpicke 2006). The testing effect occurs because students learn by completing tests, a finding that has

proven to be strongly robust and directly relevant to educational practice (Putnam et al. 2017). What this effect shows though is that it is not until the *process* of learning is considered that the real power of the testing effect becomes evident. While research on the testing effect has mostly been conducted in the laboratory, what it does provide a compelling example of assessment as learning when it is considered as a process and not just an outcome. Treating learning purely as an output or outcome also leads to neglect of the cognitive, affective, and other process-oriented elements of learning (see also De Houwer et al. 2013). This is perhaps again most evident in large-scale and standardized testing where there is a singular focus on assessing student learning as a snapshot of performance, and often only memory performance, at a single point in time.

Given that there appears to be a family resemblance between the movement in psychological and educational research toward reemphasizing that learning is an integrated developmental process and should be assessed accordingly, it is likely that this trend will flow across into educational practice. That is not to say that the translation of the research attempting to better understand these processes in the laboratory to the classroom will be seamless or easy (see Horvath and Lodge 2017). Despite the difficulties, educational technologies allow for new approaches that better capture learning as a process. For example, developments in information technologies allow for more fine-grained tracking and analysis of student learning as they progress through clickstream data and other real-time data collection methods (Lodge and Corrin 2017). The emergence and growth of the field of learning analytics affords new possibilities for collecting data continuously as students learn (Blikstein et al. 2014). This is a trend I will revisit later in the chapter. Suffice it to say that the evolution of information technologies will continue to support a necessary transition from assessment of performance to assessment as an integral part of the learning process (Lodge et al. 2018). A futures perspective in this context suggests that the distinction between formative and summative aspects of assessment might no longer be a useful dichotomy. Assessment as learning is a more integrated and continuous means of conceptualizing assessment that is enabled using information technologies. As part of the transition though, there is a need to review the role that assessment plays in measuring learning.

Assessment as Measurement

While there is a clear trend toward using assessment as a means of supporting learning, there remains an important role for assessment as a means of measuring. There will continue to be a requirement for ranking students and for ensuring that they meet particular standards throughout schooling. There will also be an ongoing need to compare performance within and between cohorts. While it is a laudable aim to attempt to use assessment as a formative support for student learning, there is no

indication that the summative aspects of assessment can yet be abandoned altogether. There will be a need to compare students to other students and against set criteria for the foreseeable future. As is the case with assessment for learning though, there will also be fundamental implications of development in educational technologies on assessment as measurement. Among these will be an increased emphasis on measuring learning as opposed to measuring performance.

While psychometricians and others concerned with the use of assessment for measurement have moved toward refining and improving assessment instruments over time, these improvements have not necessarily resolved the problems associated with assessment being primarily *of* performance. Measurement theory has had a significant impact on testing and assessment in education for many decades (Allen and Yen 2001). The focus of much of this work has centered on the validity and reliability of assessment items. For example, item response theory (van der Linden and Hambleton 1997) and sophisticated modeling techniques (e.g., Jonsson and Svingby 2007) have been used extensively to determine the validity of various instruments for assessing student performance. The issue with the focus of this work is that it too has overemphasized the performance aspects of student learning over the developmental process, that is, learning. Ultimately, no matter the sophistication of the measure or the modeling, these instruments are only becoming better at predicting how a student will perform on a test, not necessarily how much they have learned.

When examining what information technologies might contribute to this problem, it is apparent that the use of data and analytics is the key development that might lead to true measurement of learning. Value-added measures of student achievement have for some time claimed to capture the developmental progress students make during their educational journey (Meyer 1997). What these measures have failed to capture is the trajectory by which students move from point A to point B. Rather, even with the most sophisticated instruments, the students' progress is measured at point A and at point B only. Information technologies now afford possibilities for continuous data collection, providing a means of better understanding how students progress from A to B. More recent movements in measurement theory are beginning to make use of this data to provide a more nuanced evaluation of student progress rather than to rely on high-level snapshots. For example, Milligan and Griffin (2016) analyzed the learning patterns evident in a massive open online course (MOOC) as participants progressed from novice to expert learners. The processes by which the participants engaged with the course were analyzed through measurement models to determine how effectively they were learning. The result of innovations such as this, combining new technologies and measurement theories, is the possibility of valid and reliable assessment of student learning in real time as it changes and as students adapt and develop. The potential of these advances is the possibility of a truer reflection of an individual student's educational journey rather than a crude comparison of performance snapshots. In the future, we can expect that measurement theory will shift in focus from performance to learning further enhancing the possibilities for continuous monitoring and assessment of student learning.

Assessment as Continuous

I now move from issues associated with measuring learning to delve further into the idea that learning is a continuous process and is therefore best assessed as such. If we are to accept the premise that learning is more than just about snapshots of performance over time and that measurement can occur continuously, this notion raises questions about what assessment of learning as a process would look like. This is an issue that has been addressed to an extent by research into continuous assessment. While the notion of continuous assessment has been around for some time (e.g., Nitko 1995), it has morphed into a more granular analysis of learning in relation to game-based (e.g., Kim et al. 2016), quiet assessment (Webb et al. 2013) and stealth assessment (Shute 2011). In the case of the latter, the progress students make is monitored unobtrusively and often in real time as they progress (Shute and Ventura 2013). These more recent advances move the idea of continuous assessment from being anything more regular than a final summative exam to a truly continuous evaluation process.

What the emergence of genuine continuous assessment suggests is that information technologies are providing insights into student learning that were not previously available. Data about student performance in real time has been used in sophisticated ways to both assess how the student is progressing and then to use this information to provide students with feedback. The examples of the technologies that demonstrate the full potential of these systems and underlying approaches tend to be in procedural domains. For example, flight simulators have long been used to assess the progress being made by trainee pilots (Hays et al. 1992). More recently advanced immersive simulations have also been used to assist with the education of surgeons (e.g., Pirochchai et al. 2017) and dentists (e.g., Bakr et al. 2013). These technologies rely on sophisticated models of expert and novice behavior in the environment to model the performance of students relative to that of the expert. By constantly updating the weightings within the statistical models, predictions about how the student is progressing can be made in real time. This prediction is then used to trigger various forms of feedback within the system. This continuous monitoring and updating of predictive models provides continuous insight into student progress that has not been previously available.

One major hurdle for translating the research on simulated environments to the primary or secondary school environment is that it is not as straightforward to monitor and predict student progress in other domains beyond procedural tasks like flying an aircraft or performing surgery. Conceptual knowledge, in particular, is very difficult to capture through the behavior of students in a virtual environment. Conceptual knowledge is far more complex than procedural knowledge as it is more integrated, with multiple concepts overlapping and forming meta-constructs across multiple levels of organization in the mind (Caramazza and Mahon 2003). Perhaps the only example where systems have been developed to fully capture student progress through a conceptual lesson or environment are in intelligent tutoring systems (ITS; e.g., Woolf 2009). There are examples of these systems that have attempted to capture student progress as they develop conceptual understanding. For

example, the AutoTutor system helps students develop conceptual knowledge through a dialogue-based interface, monitoring and responding in real time (Graesser et al. 2005).

What the work in both procedural and conceptual simulations suggests for the future is that these systems are poised to become more sophisticated and better attuned to individual differences in educational progress. The potential therefore is that information technologies will be better able to provide personalized learning experiences for students across knowledge domains. In other words, the potential latent in the notion of continuous assessment is poised to come to fruition. For example, students in the near future will be able to interact with increasingly sophisticated interactive digital environments that will respond in real time to their progress, both assessing said progress and providing feedback to keep them on track. While this potential has mostly only been realized to date with procedural tasks, the development in ITS suggests that there is a distinct possibility that systems will be developed in the near future that will effectively monitor and respond to students as the acquired conceptual understanding.

Assessment as Systemic

Considering assessment as a continuous process is a significant step toward a more holistic view of assessment relying on information technologies and the data they generate. Following on from these possibilities, it might then be feasible to consider assessment systemically. Traditional assessment practices have been criticized for only focusing on some aspects of students' development or knowledge. This is perhaps most evident in the widely adopted approach of using multiple choice questions (MCQs) in examinations. MCQs are criticized for allowing students to successfully complete the assessment task relying almost exclusively on recall or familiarity to respond to the questions (Roediger and Marsh 2005). The types of innovations alluded to in this chapter, however, provide means for not only continuously assessing students but also to consider assessing their progress more holistically and systemically.

In a recent paper, Jacobson et al. (2016) suggested that learning theory needs to be transformed into something more akin to a systemic epistemology. They highlight the ongoing debate between cognitive and embodied views of learning as necessitating a shift to more systemic ways of conceptualizing learning. The argument aligns with that of other authors and theorists (e.g., Mason 2008), who for some time have been claiming that educational practices occur in complex or super-complex environments. These environments therefore necessitate a complex, systems-based approach to research and practice (Jacobson et al. 2016), including in the design and execution of assessment. The implications of this argument for assessment practices are profound. A holistic, systemic approach to student assessment differs markedly from the approaches that have traditionally been used. For example, there are few, if any, assessment processes that directly evaluate student affect. This is despite the growing body of research demonstrating how fundamental emotion is in the learning

process (Pekrun and Linnenbrink-Garcia 2014). Confusion, for example, appears to be an important part of the process of conceptual change (D'Mello et al. 2014). Future assessment design could therefore move beyond assessing cognitive elements of learning to also incorporate affective components.

Emotion provides one of many aspects of learning that could form part of a reimagined approach to assessment built on notions of systemic learning. There are many others including problem-solving, decision-making, capacity for self-regulation, and metacognition. In this way, assessment could be extended beyond performance and move toward the aim of supporting students to learning how to learn, as advocated by Black et al. (2006). Information technologies and particularly the possibilities provided by continuous assessment allow these factors to be considered seriously as part of the assessment process. One way of conceptualizing how this might occur is to consider what a systemic, continuous approach to assessing conceptual change might look like. The research literature on conceptual change is vast (e.g., see Amin and Levrini 2017 for recent overview), providing a solid foundation to speculate about what a rethinking of assessment in this domain might entail. Let's assume that a student has a fundamental misconception about a scientific phenomenon like gravity. Young people often misconceive the effect of gravity on falling objects of different mass (Clement 1982). A traditional approach to assessment might ask students to complete an exam with questions about how gravity really works. At best, this approach might help to develop some sense of their capacity to produce a response based on their understanding. If not designed well, however, the exam will merely gauge their capacity to remember what they were taught previously and produce a response at that moment in time. This approach might not give any indication that the student has effectively changed their mental representation of gravity as a concept.

A systemic, continuous approach to this problem would undoubtedly provide more insight into the progress the student makes in updating their mental representation. For example, the student might be asked to work through a conceptual simulation. The simulation could begin by asking the student to predict the rate at which two objects of different mass might fall to the ground. They then enter a simulated virtual space where they are able to experiment with different objects of different mass and observe as they fall. Their behavior in this simulation will provide clues as to how they interpret the concept. For example, students who rapidly cycle through the simulation may be overconfident suggesting that they will not adequately incorporate the new knowledge they are supposedly acquiring into the existing mental model they have (Lodge and Kennedy 2015). Another student might stop for an extended period while using the simulation, perhaps suggesting some level of confusion or disequilibrium that the student is actively trying to resolve (Arguel et al. 2017). What this example demonstrates is the power of a data-driven and systemic approach to continuous assessment. Aspects such as engagement, affect, confidence, and capacity for self-regulation can all be gleaned through the data collected. While the behavioral data might not directly measure these variables, the information provided to assessors is undoubtedly far richer and more complex than if the student merely completed an exam post-instruction.

Assessment as a Conversation

The discussion so far in this chapter has focused on the aspects of assessment related to measurement and continuous learning. In both these cases, I have suggested that data-driven approaches will contribute to a more holistic and systemic approach to assessment. One issue that arises from this suggestion is that the evaluation and feedback on student progress will become automated and require no human intervention. While this is true of some aspects of assessment, particularly the more procedural aspects, that is not to say I am predicting a purely automated approach to assessment in the foreseeable future. With advances in learning analytics, machine learning, and artificial intelligence, there will be increased use of automated systems for assessing student progress and providing feedback. Significant progress is already being made on systems to provide an evaluation and feedback to students. For example, advanced systems are increasingly becoming available that provide students with feedback on elements of their writing (Buckingham Shum et al. 2016). Automated assessment has also been experimented with in several contexts including massive open online courses (Pieterse 2013).

Despite the progress being made in these automated systems, there will continue to be a role for teachers and tutors into the foreseeable future. The main reasoning behind this is also due to the increased impact machine learning and artificial intelligence will have on society. The kinds of knowledge domains that can be easily encoded into a system such as declarative and procedural knowledge will become less important for humans. In other words, if machines can manage and make evaluative judgments about the development of knowledge in these domains, there will be less need for humans to acquire this knowledge. The jobs of the future will predominantly focus on the knowledge and processing that machines (as we currently conceptualize them at least) cannot do. Education will therefore increasingly need to help students to develop skills in high-level analysis, synthesis, and critical evaluation.

In order to model the kinds of thinking that machines are not good at, students need to observe these forms of thinking in action in another human. There will therefore continue to be a need for teachers and tutors to provide the kind of evaluative judgment and feedback to students that machines are not capable of. There will also be a continuing need for teachers to help students develop their capacity to make evaluative judgments about their own progress. Information technologies can also play a significant role in enhancing these processes. One way to think of this is to compare the traditional production of an artifact for evaluation and the process of providing feedback as a conversation. When students create an artifact, submit it, and wait for feedback, it can be a long and slow process; the conversation takes time. The use of information technologies allows both for this process to be sped up and for the conversation to be more nuanced and wide-ranging.

Building on the previous discussions of assessment as continuous and systemic, the use of information technologies also offers additional means of providing information to teachers about how students are progressing. The data generated as students interact with information technologies can be used to provide teachers with

information about how students are doing through visualizations, dashboards, and alerts. What this then means is that teachers can not only evaluate what students produce but they also get more insight into how students are producing the artifact. Again, the process that people go through to make sense of and use knowledge will become increasingly important as machines impact on society. The information will allow teachers not only to assess the process of learning as well as the product or outcome, but it also allows more sophisticated means of intervention as there is more information upon which the teacher can intervene.

One way of considering the possibilities for this more sophisticated view of assessment as conversation is to look at the ways in which more sophisticated instruments are used in cognate areas. In clinical psychology, for example, highly precise psychometric instruments are not used as a means of measurement as much as they are to generate points for conversation between the client and psychologist. In a similar manner, dashboards and visualizations provide diagnostic information that can allow teachers to have a fuller discussion with students about how they are learning and not just what they are producing. For example, a science student might be unsystematic when attempting to understand a complex scientific concept, manipulating variables in a digital environment in a haphazard way. Systematic approaches are often more effective at attempting to understand complex phenomena (e.g., Dalgarno et al. 2014), so, if a teacher is provided with information that the student is using a less effective strategy, there is a possibility for the teacher to intervene and assist the student to adopt a more effective approach.

Information technologies therefore can provide teachers with a means of conducting cognitive diagnostic assessment (c.f. Leighton and Gierl 2007) in a more holistic way than is possible by assessing something that a student produces. By using information technologies to provide information to teachers about how students learn, they are better equipped to have a fuller conversation with students about how they are learning, thus helping to realize the promise of assessment and feedback cycles as an ongoing discussion between students and teachers. This, in turn, will give students more insight into the critical learning and thinking approaches that they can only learn from humans and that they will need to master in the twenty-first century.

Conclusion

Taken together, there are clear affordances being provided by advances in information technologies that are poised to have an impact on assessment in all educational settings. Whether or not these affordances are going to significantly advance student learning will depend on whether assessment practices also evolve as the technologies do. This evolution needs to be led by what is understood about the learning process and not by the tools themselves. Much has been written in the last decade about the risks associated with putting technology ahead of pedagogy (e.g., Selwyn 2014). Another foundational issue for developing effective practices for assessment using new technologies is that the evidence often lags behind the technical innovations

(Lodge and Horvath 2017). Solid, rigorous evidence about the ways in which new technologies can be best implemented in educational settings tends to take far longer than do the technologies to filter through to practice. New technologies often seem to educators and administrators to be a silver bullet for improving education or resolving a specific issue. The reality often does not meet the hype surrounding these new innovations. The timeline of new technologies and their use in relation to the evidence that they work is best captured in the Gartner hype cycle (Gartner Inc. 2015). Many innovations are initially overhyped, but then the initial hype dies down (into the trough of disillusionment) before reaching a point where the evidence about how best to use them catches up. There are risks in this cycle for the ways in which assessment is implemented and executed as information technologies continue their evolution.

While it is always difficult to make future predictions, my aim in this chapter was to examine some trends in relation to various aspects of assessment practice and project where those trends might take us in the future. These trends suggest a future where information technologies will afford more continuous, personalized ways of evaluating student progress and providing feedback to enhance their own capacity to learn and make evaluative judgments. The potential in these approaches is latent in the online, data-driven digital learning environments that are increasingly becoming available to educators and students. The risks associated with the growing use of these technologies are that assessment practices do not keep pace with the rate of change. I have attempted in this chapter to outline some of the key areas for attention from researchers and practitioners. These include considering the relationship between assessment and learning as a process and more holistic, systemic approaches to assessment allowing for more nuanced conversations between teachers and students. In doing so, the advantages of emerging technologies can be best deployed to support teachers and students rather than in a redundant attempt to replace teachers. Reconceptualizing assessment as a key part of the process of learning will go a long way to ensuring that the future of assessment mediated by information technologies will lead to better outcomes for students and teachers alike.

Section VIII

Flexible, Distance, and Open Learning in the Twenty-First Century

Section Introduction: Flexible, Distance, and Open Learning in the Twenty-First Century

47

Roumen Nikolov and Kwok-Wing Lai

Abstract

This chapter provides an overview of the five chapters included in Section VIII of the Handbook – *Flexible, distance, and open learning in the twenty-first century*. These chapters focus on the pedagogies and designs of technology-enhanced environments developed to support flexible, distance, and open learning.

Keywords

Flexible learning · Distance learning · Open education resources · Massive open online courses · Virtual schools · Online communities · Personalised learning

With the proliferation of digital and mobile technologies and applications in the last decade, there has been significant growth in the delivery of distance and flexible education in the primary and secondary sectors globally; and the advent of MOOCs (Massive Open Online Courses) and OERs (Open Education Resources) has created new open learning opportunities. However, this growth has also led to new pedagogical and technical challenges at the classroom and policy levels, as there are issues of how best students can be supported in the new learning environments and how their learning needs and expectations can be met. In this section of the

Handbook, the authors have reviewed and synthesized research on the theories and pedagogical practices of developing and facilitating online, flexible, and open learning environments and communities designed to support knowledge inquiry and collaboration.

The first chapter of this section, ► [Chap. 48, “Distance and Flexible Learning in the Twenty-First Century”](#) (Nikolov et al.) provides an overview of how new digital and mobile technologies can afford personalized and flexible learning; and in particular, how curriculum flexibility is supported by the use of these technologies. The concept curriculum flexibility, in terms of what, how, where, and when learning takes place, is used to frame the discussion. The elements and dimensions of a flexible curriculum designed to address learner diversities are also discussed. This overview chapter also provides a brief discussion of the issues and challenges facing flexible and distance teaching and learning in the twenty-first century.

In the second ► [Chap. 49, “Virtual Schools: A Global Perspective,”](#) Davis and Ferdig begin by outlining the evolution of virtual schooling in the US and discussing the benefits and challenges of this mode of education. An organizational perspective on K-12 virtual schooling and online distance education is provided, with a detailed discussion of the roles and responsibilities of different players in this new learning environment. An illustration using an example from a US nonprofit virtual schooling, based on a framework developed by the first author, concludes the chapter.

In the third chapter, titled ► [Chap. 50, “Open Education Resources, Massive Open Online Courses, and Online Platforms for Distance and Flexible Learning”](#) Dron and Ardito discuss the constraints and resources needed to support current schooling, and argue that with the advent of ubiquitous networked technologies these constraints can be reduced and educational systems can become more open to students. The authors then review some main features of open learning and explore different kinds of openness that can support learning. How this openness can benefit primary and secondary students is also discussed in the chapter.

The fourth ► [Chap. 51, “Online Learning Communities in K-12 Settings”](#) (Tang and Lee), details how emergent technologies can afford social and interactive networking, and the authors review four established online learning communities, including the Knowledge Building communities, Quest Atlantis, Virtual Math Team, and Web-based Inquiry Science Environment as exemplary practices. In addition, two emergent online learning community platforms, Canvas K-12 and Brightspace are discussed. The concept and boundary of online learning communities, and issues in developing and implementing them; as well as major trends of research and key issues for future research are also reviewed in this chapter.

In the fifth and final chapter of this section of the *Handbook*, ► [Chap. 52, “Designing Blended, Flexible, and Personalized Learning”](#) Pratt and Kovatcheva argue that an approach to implement flexible and personalized learning is to conceptualize them as blended learning, which can occur both online and offline. Models of blended learning are then reviewed. Design principles for blended learning are explored in detail, and the authors consider it critical that the design

process be learner-centered, rather than driven by new technologies. Issues of future research are also outlined in this chapter.

Using digital technologies to afford learning at anytime and anywhere is not a novel concept. However, with the recent rapid advance in learning and social technologies, there has been increasing demand for learning to be more flexible and personalized, in order to support individual needs. In meeting these expectations, organizational structures as well as teaching and learning processes have undergone tremendous changes in the last decade. In reviewing these changes, the chapters in this section have highlighted the centrality of the learner in the learning process and how different approaches of technology-enhanced learning can support these changes.

Abstract

With the huge increase in Internet connectivity and mobility of learning devices, learning can now become much more flexible. In this chapter, we discuss how new technologies can afford personalized learning, and in particular, how curriculum flexibility is supported by the use of technologies. We frame curriculum flexibility in terms of what, how, where, and when learning takes place. Advances in curriculum flexibility are reviewed and the elements and dimensions of a flexible curriculum addressing learner diversities are discussed. Some of the issues and challenges of flexible and distance learning are also discussed in this chapter.

Keywords

Flexible learning · Distance learning · Curriculum flexibility · Personalized learning

Introduction

Since the publication of the first edition of the *International Handbook* (Voogt and Knezek 2008), an exponential increase in accessibility and connectivity of digital and mobile technologies has occurred. Reportedly in 2017, half of the world population are Internet users, with North America having the highest Internet penetration rate (88%) and even in Africa, being the region having the lowest Internet penetration rate, over a quarter (28%) of its population had Internet accessibility (Internet World Stats 2017). In fact, the growth of mobile devices has been very rapid in the developing regions in recent years, and it is estimated that by 2020, the smartphone adoption rate in the less economically advanced countries will reach 65% (GSMA 2015). This huge increase in connectivity has afforded new opportunities for learning in particular to support distance learning for children and young people globally.

This chapter frames information and communication technology (ICT) as a catalyst of a global educational reform that is based on designing and adopting new learning environments which do not have clear boundaries between the physical and virtual worlds. We consider that to successfully integrate these two worlds, appropriate instructional design strategies based on sound learning theories need to be employed. We begin this chapter by discussing how the new digital technologies support personalized learning and increase the flexibility of learning with regard to space and time, and thus afford learning at a distance. With the recent advances in research and practice in the flexibility of learning, we adopt *flexible learning* as a central concept. We will present a framework of flexible learning consisting four categories of flexibility (what, how, where, when), and these categories are discussed in subsequent sections, focusing on how technologies may benefit the learner. This chapter closes with a discussion on issues and challenges of flexible and distance learning.

Learner and Personalized Learning

Over the last decade, the prevalence and accessibility of digital and mobile technologies have changed drastically the way children and young people communicate, learn, and entertain (► Chap. 10, “The Learner and the Learning Process: Research and Practice in Technology-Enhanced Learning” by Lai, in Section III “The Learner and the Learning Process” of this *Handbook*). In formal education, teaching and learning increasingly rely on online electronic and multimedia resources rather than on printed materials. Learners thus have the opportunities to study on their own using aesthetically formatted and interactive multimedia learning materials. The increasing access to information also allows students to study individually according to their needs, skills, interests, and cognitive characteristics, and thus have greater control over their learning process. The recognition of the importance of learner agency for making learning more relevant to students is increasingly being recognized. Thus, there is a call for personalization, which is learner-centered, rather than individualization and differentiation, which are essentially teacher-centered (Bray and McClaskey 2015). A review conducted by Williams (2013) suggests that a personalized learning environment should be facilitated by (a) shifting the locus of control and ownership of learning to the students, with students becoming “co-authors’ of learning” (Campbell et al. 2007, p. 138); (b) teachers knowing the capabilities of the students, their attainment as well as the progress of the students; (c) engaging students in authentic learning experiences; (d) developing a collaborative culture “where learners see themselves as both participants and contributors to the learning process” (p. 9); (e) the effective using of ICT; and (f) creating a student-centered environment where “learners feel supported to take ownership and risks with their learning” (p. 13). In using technologies to support personalized learning, the recent advent of social media seems to be effective as young people use social media increasingly for communication and learning (► Chap. 14, “Bridging Formal and Informal Learning Through Technology in the Twenty-First Century: Issues and Challenges” by Lewin and Charania, in Section III “The Learner and the Learning Process” of this *Handbook*).

Advances in Flexible Learning

Nowadays, the term *flexible learning* is widely used, but the term is not universally defined (Tucker and Morris 2011). It is a misconception that flexibility is only connected to technologies, since it is also strongly connected to pedagogies. Flexible learning is not an alternative mode of education but an overall scheme for providing the learners greater opportunity for control over their learning process. Collis and Moonen (2001) maintain that the opportunity for the learner to make choices is one of the most important characteristics of flexible learning:

Flexible learning is a movement away from a situation in which key decisions about learning dimensions are made in advance by the instructor or institution, towards a situation where the learner has a range of options from which to choose with respect to these key dimensions. (p. 10)

More recently, Cheong (2013) follows the same line of thought, arguing that “the nature of ‘flexibility’ revolves around learners: what choices are available and how they affect their learning” (p. 2). Several scholars have framed flexible learning into categories, or dimensions; for instance, Bergamin et al. (2012) provided a framework with 22 dimensions and seven categories: time, space, methods, learning styles, content, organization and infrastructure, and requirements; Tucker and Morris (2011) structure approaches to provide flexibility into five categories: time, content, access/entry requirements, pedagogy/instruction approach, and design and delivery. While categories and dimensions of flexibility proposed by scholars are slightly different, they primarily focused on the key elements of what curriculum flexibility is required in the twenty-first century education.

Curriculum flexibility (also called a *flexible curriculum*, *flexible learning*, *flexible education*) is regarded as a means for responding to learner diversity (Rao and Meo 2016). Central to a flexible curriculum are: (1) choices and options, and (2) the adaptation to/central position of individual student’s needs. Within this body of research, it is found that curriculum flexibility in general supports student learning in diverse classrooms. This could be profitable for all learners (Rao and Meo 2016) as well as for specific groups of learners (e.g., for gifted learners, see de Jager 2013; for learners with special needs, see Lakkala et al. 2016).

The flexibility of learning can become visible in terms of what learning entails, and how, where, and when it occurs (Tucker and Morris 2011), thus involves all curriculum elements. In this regard, information and communication technologies (ICTs) are frequently mentioned in connection with curriculum flexibility. Offering the choices, options, alternatives, and variety via which a curriculum can be adapted to the learners’ needs, can become realizable and manageable through the use of ICTs (Bingham et al. 2016; Collis and Moonen 2001; Granić et al. 2009; Heemskerck et al. 2011). More specifically, Rao and Meo (2016) state that “digital tools help to create flexible environments” because, for instance, “digital texts inherently include options that increase flexibility” (p. 10). Delivering content digitally makes it easier to adapt education to learners’ pacing and learning paths, which ease the burden on individual teachers (Staker and Horn 2012). However, Bingham et al. (2016) found in their study that available digital content needed a lot of supplementations in order to match it to the individual learner’s needs, therefore demanding extra efforts from the teachers.

Specific curriculum elements are explicitly connected to the aim of addressing learner diversity:

- Learners can work toward their own goals or levels of mastery (Mccarthy and Schauer 2017), or standardized goals from the starting point with flexible ways to reach these goals (Murphy and Rodriguez-Manzanares 2009; Rao and Meo 2016).
- Goals can be flexible and the way and form of assessments may vary, according to the individual preferences (Murphy and Rodriguez-Manzanares 2009; Rao and Meo 2016).

- Content can be offered through differentiated instruction, which “enables teachers to individualize so they can better respond to students' needs” (Tomlinson 2008, p. 29).
- A variety of learning activities is needed in order to support differences in perception, comprehension, processing, expression, and engagement amongst learners, thereby making sure each learner has the support to the degree to which it is needed (Rao and Meo 2016).
- Offering variety and choice is often mentioned as a means for matching materials/resources to different learners (Granić et al. 2009; Lakkala et al. 2016).
- Deliberately making use of grouping is another element that could address differences in learner’s needs (Lakkala et al. 2016; Mccarthy and Schauer 2017). Varying grouping assumes flexible use of classrooms and learning spaces (Lakkala et al. 2016; Tomlinson et al. 2003).
- Time can be a flexible element in all lessons and in all lesson phases. Altemueller and Lindquist (2017), for instance, argue that using a flipped classroom design helps for the “modification of the traditional classroom [the amount of classroom time spent interacting and allows]. . .for more differentiation” (p. 343). Murphy and Rodriguez-Manzanares (2009) suggest offering asynchronous communication in order to support individual learner’s pace and timeliness. However, de Jager (2013) concluded in her study that the majority of teachers never used time as a flexible element.
- Last but not least, the teacher role is important in a flexible learning environment. The teacher is the one who should offer the choices and adapt the lessons to the learners. Offering more flexibility to the learner puts higher demands on the teacher, and requires additional competencies and more time and effort from the teacher (Collis and Moonen 2001; Granić et al. 2009). Concerning the learner, it also requires higher level of self-initiative, self-motivation, and self-control. The active learner assumption is axiomatic (Nikolova 2001; Nikolova and Collis 1998).

Table 1 provides a summary of all elements and dimensions of a flexible curriculum. In the following sections, the main elements listed in Table 1, in particular, the environment, time, aims, and objectives, as well as learning and teaching strategies will be discussed.

Environment

When we talk about flexibility of learning, the learning environment refers to the place or space where learning takes place. Distance learning is now frequently undertaken within a virtual learning environment, and thus in some countries such as the USA, distance learning is often referred to as *online learning* or *e-learning*. An information space supported by the Internet and the Web provides a *learning space for complementing a physical environment*. Punie and Cabrera (2006) maintain that the contemporary learning space has to be a:

Table 1 Elements and dimensions of a flexible curriculum

Flexibility regarding	Curriculum elements	Dimensions
<i>Aims and objectives (what)</i>	Aims and objectives	<ul style="list-style-type: none"> • Levels: Multi or one for all • Uniform or personalized learning paths
	Content	<ul style="list-style-type: none"> • Topics: Choice, interests • Levels: Basics-repeated-enhanced (possibly beyond a given grade-level) • Instruction: Differentiated – Shorter/longer instruction, smaller/bigger steps, content broken down into different sized pieces, more/less structured • Form: Approach, ways in which the content is presented, various options for perception/comprehension • Presence or lack of guiding questions, depth of guiding questions
	Assessment	<ul style="list-style-type: none"> • Grading: Personalized rubrics or same standards • Level of outcomes/products • Ways to demonstrate goal achievement: Choices in forms for the end product, alternative options to show what is learnt (Murphy and Rodriguez-Manzanares (2009))
<i>Teaching and learning strategies (how)</i>	Learning activities	<ul style="list-style-type: none"> • (More) open-ended or (more) close-ended • Levels of study skills • Learning styles • Amount of guidance • Assignments: Product and task options, homework • Ways to acquire knowledge, options for processing/expression/engagement
	Materials/resources	<ul style="list-style-type: none"> • Choices • Variety • High and low (or no!) tech • Texts at varied reading levels
	Grouping	<ul style="list-style-type: none"> • Grouping configurations: Individual/small groups/whole-class • Collaboratively or individually • Seating arrangements and student groupings: Fixed or flexible
	Teacher role	<ul style="list-style-type: none"> • Make adaptations, create individual learning paths • Solo/co-teaching/engagement (external) others • Guide toward autonomous learning • Scaffold support
<i>Environment (where)</i>	Learning environment	<ul style="list-style-type: none"> • Inside/outside classroom/school • Use of building/rooms • Traditional/blended/digital
<i>TIME (when)</i>	Time	<ul style="list-style-type: none"> • Pace • Duration • Time span • Moment • Sequence • Synchronous/asynchronous communication • Deadlines: Fixed or loose

- *Connecting and social space*: Since learning is a social process, it needs to bring different actors together to share learning experiences. Learning spaces are both physical and virtual spaces that favor a learner-centered model but connected with the other actors involved in learning and with other social networks. As such, learning spaces should also link learning individuals with learning communities, organizations, and even learning cities and learning regions. Nikolov et al. (2016) argue that a new type of smart learning environments emerge based on the spatial intelligence of the cities: “Embedded networks of sensors and devices into the physical space of cities are expected advancing further the capabilities created by web 2.0 applications, social media and crowd sourcing. A real-time spatial intelligence is emerging having a direct impact on the services cities offer to their citizens. Collective intelligence and social media have been a major driver of spatial intelligence of cities” (p. 341).
- *Personal digital space*: Every learner should have a personal, digital learning space where all learning material is accessible anywhere, anytime, anyway (via multiple devices and media). Scott (2015) asserts that “personalized learning also enables the flexible use of space, which includes moving away from the classroom and into the community, and dividing up larger learning spaces into smaller ones” (p. 5).
- *Trusted space*: Learners should be able to trust and feel confident (e.g., on quality and reliability) about the digital learning spaces where learning content is co-produced and shared. Booth (2012) contends that “trust is a key facilitating factor for knowledge sharing in online communities” (p. 24) and the use of social network analysis as a methodological tool may be helpful to better understand the role of influential members in cultivating and sustaining knowledge sharing and trust.
- *Pleasant and emotional space*: ICT could make learning content more attractive (e.g., media-rich virtual environments and simulations) and support a space for communicating emotion (e.g., by connecting people with different personalities). As Psotka (2013) claims, such spaces can integrate a range of personalized strategies and “students who may have difficulty performing in class could potentially have time away from teachers and peers to engage in virtual problem-solving strategies synchronized to a learner's individual pace” (p. 78).
- *Creative/flexible space*: Learning spaces should support the development of creativity, rather than focussing exclusively on presenting and reproducing knowledge. Sriraman and Haavold (2016) report that “recent empirical studies have also found evidence that mathematical problem solving and problem posing can be used to develop creative abilities in mathematics for all students” (p. 15).
- *Open and reflexive space*: Future learning spaces would need to be open and module-based, enabling learners to re-enter the space whenever they wish.
- *Certified space*: Future learning can only be different from learning today if the current accreditation systems and learning assessment systems are adapted to the requirements of the knowledge-based society. The acquisition of ICT skills, digital competence, and other new skills, be it through formal education or nonformal or informal learning, should be demonstrated, evaluated, and also

certified. Yang (2015) claims that the new paradigm would include a shifts “from a centralised and state-controlled system to a decentralised, regulated, coordinated and partnership-based system; and, from a “diploma oriented system” to a system whose target is the professional inclusion of youth” (p. 19).

- *Knowledge management space*: The strength of most organizations lies in their people, hence the need to share experience and knowledge among colleagues, within the organization, and even across organizations to facilitate knowledge management. Cheng (2012) argues that the knowledge management at school “is a set of relatively new organisational activities that make use of knowledge as an important resource to improve organisational behaviours, decisions, student learning, teaching processes and collegial relationships that enable schools to improve their overall performance” (p. 590).

Kalay (2004) used *place* as a metaphor for a learning environment conceptualized (in the physical world) as the “setting that transforms mere spaces and activities into unique sociocultural events: the coming together of people to the same location, at the same time, for the purpose of participating in a common, authentic, one-of-a-kind, memorable activity” (p. 195). As maintained by Kalay (2004),

place-making, rather than page-making, is a more appropriate metaphor for designing cyberspace: in addition to communication and information management, this metaphor affords a contextualized locus for situating the activities themselves, much like physical places do. Thus, the virtual places will include socio-cultural and perceptual qualities, enriching them to the point where they may approach - perhaps even surpass - comparable physical settings. (p.196)

Time

Flexibility is also about when learning takes place. In terms of the time aspect, the changing nature of distance learning becomes clearly visible. While traditional distance learning is designed to facilitate self-study where all learning materials are provided to the student with no or minimum teaching needed, the advent of specialized video-conferencing technologies and more recently the Internet-based video-conferencing systems allow increased interactivity between the teacher and students and also among students (Lai 2017). Mobile technologies also increase the flexibility of distance learning, to be undertaken truly at any time and any place. There has also been a changing profile of distance learners in the last ten years. Universality of primary and secondary education in the economically more advanced countries made many urban school students take online distance courses to personalize their learning, since distance learning provides them a lot of flexibility without having the need for face-to-face contact. We have also seen an increase of open learning courses, popularized by the Massive Open Online Courses (MOOCs) being initially designed for higher education

(► Chap. 50, “Open Education Resources, Massive Open Online Courses, and Online Platforms for Distance and Flexible Learning” by Dron and Ardito, in Section VIII “Flexible, Distance, and Open Learning in the Twenty-First Century” of this *Handbook*) but subsequently also offered at the school level (Atkeson 2014). In the past, distance education has always been considered by policy makers as *education on the edge*, but increasingly with urban students now taking distance courses by choice, online distance education has fast become mainstreamed (Naidu 2016). However, it should be noted that online distance learning requires a higher level of self-directedness, and thus it may not be suitable for all learners. While there is a paucity of research of distance learning at the school levels, a large-scale review of 40,000 tertiary students in the US reports that some learners had problems in adapting to online courses, with gender, ethnicity, and age being factors affecting persistence and achievements (Xu and Jaggars 2013). We can expect that these demographic factors will also have an effect when primary and secondary students are involved in distance learning.

Aims and Objectives

This category refers to what has to be learnt: the aims and objectives, the content, and the way learning outcomes are assessed. For many online learners, distance learning is by choice rather than by need because online learning gives them a higher degree of control over their learning pathway. In some countries, policymakers thus encourage online distance learning as an alternative route to formal education. For example, there are now regulations in most of the states in the U.S. that high school students have to take at least one online distance course before they graduate. Various reports estimated that there are between two and six million distance students in the USA (Barbour et al. 2016). Similarly, there were more than 200,000 students enrolled in distance courses in over 300 virtual schools in the UK (UK Department of Education 2014).

Learning and Teaching Strategies

This category refers to how learning and teaching are conducted, underpinned by learning theories. It includes the learning activities, materials/resources, grouping, and the role of the teacher. The flexibility provided by Virtual Learning Environments (VLEs) makes it possible to adapt learning to the individual needs and preferred learning modes. However, it means that teachers have to step out of the traditional instructor’s role and serve as a learning consultant, collaborator, and facilitator. Also, the majority of teachers do not, or hardly ever, adapt the curriculum to the learner’s needs (de Jager 2013). At the best, teachers make minor adaptations in their lessons, but in order to respond adequately to diversity, it is important for teachers to “consistently, defensibly, and vigorously adjust curriculum and instruction in response to student readiness, interest, and learning profile” (Tomlinson et al. 2003, p. 131).

In flexible and distance learning, the learner is not considered just a consumer of the learning content but rather as a co-producer of such content. With the predominately Web 2.0 tools and applications being used in schools (► Chap. 10, “The Learner and the Learning Process: Research and Practice in Technology-Enhanced Learning” by Lai, in Section III “The Learner and the Learning Process” of this *Handbook*), Web-based virtual learning environments now provide opportunities for students, teachers, parents and other stakeholders to contribute useful educational resources (► Chap. 50, “Open Education Resources, Massive Open Online Courses, and Online Platforms for Distance and Flexible Learning” by Dron and Ardito, in Section VIII “Flexible, Distance, and Open Learning in the Twenty-First Century” of this *Handbook*). A lot of Web 2.0 School oriented portals provide access to web services and content for educational purposes in different school subjects, such as *Shambles: Education Project Asia* (<http://www.shambles.net/>).

An example of applying an innovative learner-centered strategy in a learning environment is the European project *WebLabs* (Kahn et al. 2011). The *WebLabs* learning model and the VLE supporting it, facilitated 10–13 years old students, together with their teachers and geographically dispersed researchers to involve in science and mathematics explorations by means of technology (a software environment for visual modeling). The students acted as partners in a research process and developed an understanding of mathematics as a science by posing questions, searching for information, formulating hypotheses, carrying out experiments, and solving open-ended problems. Based on their explorations by constructing infinite processes, they discussed within the *WebLabs* community such complex mathematical notions as *infinity*, *cardinality*, and *convergence*. They communicated and shared their experiences with peers, teachers, and researchers locally and globally through a Web-based collaborative system, in the form of so-called *Webreports*. During this communication, they acquired specific social experience and were stimulated to build valuable personal skills such as the ability to:

- Generate and verbalize ideas;
- Present their results according to specific standards;
- Share their experience by means of electronic communication;
- Work in a team and discuss their work, and
- Be (self-)critical to the work published in the virtual environment.

Another example to facilitate regular dissemination and sharing of know-how and best practices in using VLEs in science education is the *Scientix* project designed for the community of STEM educators across the European Union (EU) (Aguirre-Molina and Gras-Velázquez 2011). It has developed an online portal, which collects and disseminates teaching materials and research reports from European science education projects financed by EU under the 6th and 7th Framework Programmes for Research and Technological Development, the Lifelong Learning Programme and various national initiatives. It embraces a great number of science education projects (current and finished alike), thus assuring their further dissemination among a large spectrum of stakeholders – teachers, researchers, curriculum developers,

policymakers, students, and parents. The portal is free-to-access and free-to-use, which makes the Scientix community open to anyone interested in science education in Europe. At present, there are more than 600 learning objects, findings of 200 STEM projects carried out over the past 10 years that can be accessed from the portal. The philosophy of the portal has been summarized by its creators in the following keywords: *search*, *find*, and *engage*, thus emphasizing the role of Scientix as a knowledge building platform (Aguirre-Molina and Gras-Velázquez 2011). The fact that all the projects on the Scientix platform include elements of e-learning and various online technologies for education, communication, data collection, and dissemination could provide a valuable insight into what e-learning methods work best and what conditions make them more likely to succeed in supporting science education in Europe (Gras-Velázquez et al. 2013).

To support distance and online learning, a very popular and innovative didactic resource accessible at the Scientix portal are *online laboratories*. A good example of how to make use of them is the Go-lab project. It offers work with real (remote) laboratories that can be remotely operated by students to gather data from a real laboratory setup (e.g., Faulkes Telescope, offering not only a database of astronomic pictures but also the opportunity for the students to remotely operate the telescope and to take their own pictures of the Cosmos). The second type of online labs are the *virtual labs*, enabling students to simulate real equipment and experiments, e.g., LHC Game simulating the process in a particle accelerator such as the Large Hadron Collider used at CERN, or the Galaxy Crash simulating collisions of galaxies and letting the students check their hypotheses on how galaxies form and evolve in the Universe. The obvious advantage of online laboratories in e-learning is the opportunity for teachers and students to access high-tech scientific instruments and use them for research purposes, in harmony with the inquiry-based education. Furthermore, students can carry out experiments in the virtual labs to observe phenomena that cannot be seen in real situations. The main difficulty would be the incompatibilities to implement activities using the online laboratories while complying with national or school curriculum.

With younger students (primary/secondary levels), offering curriculum flexibility is often the task of the teachers. Only when students become older, the focus of curriculum flexibility shifts from the teacher to student. In higher and vocational education, the focus merely lies on student's choices and responsibility within the context of an educational program (Collis and Moonen 2001; Carlsen et al. 2016). This also applies to high school distance learning, as in the study of Murphy and Rodriguez-Manzanares (2009).

Issues and Challenges

Need for a Clear Focus on Pedagogies and Learning Theories

When designing distance and flexible learning, educators mostly refer to one of the three popular learning theories: behaviorism, cognitivism, and constructivism (► Chap. 11, “[Information and Communication Technologies, and Learning](#)

[Theories: Putting Pedagogy into Practice](#)” by Dennen et al., in Section III “The Learner and the Learning Process” of this *Handbook*), although the connectivist learning theory (Siemens 2014) has been gaining popularity, in particular in reference to the implementation of MOOCs in recent years.

The inquiry-based learning (IBL) approach provides a variety of good pedagogical practices. As Mikroyannidis et al. (2013) claim, when applying IBL,

...learners take the role of an explorer and scientist as they try to solve issues they came across and that made them wonder, thus tapping into their personal feelings of curiosity. IBL supports the meaningful contextualization of scientific concepts by relating them to personal experiences. It leads to structured knowledge about a domain and to more skills and competences about how to carry out efficient and communicable research. Thus, learners learn to investigate, collaborate, be creative, use their personal characteristics and identity to have influence in different environments and at different levels (e.g., me, neighbourhood, society, world). (p. 2094)

It should be noted that in designing flexible learning environments, attention should be focused first on the pedagogy used to support learning, before the affordances of the technologies to support such a pedagogy are considered.

Role of the Teacher

Closely related to the previous challenge is teachers’ insufficient understanding of their role in a virtual learning environment. Teaching in a digital (perhaps online) and flexible learning environment is not a replication of face-to-face teaching (Lai 2014). There is a need for a change of epistemic beliefs, of how knowledge is created and developed, and how learner agency is facilitated. Professional development and learning has to be designed and implemented to support a change of pedagogical beliefs and practices. While teachers teach increasingly online, adequate teaching preparation in online teaching has not been recognized. It is thus not surprising to see many online courses which are based on behaviorist principles (Daniel 2012). Also, virtual schooling nowadays attracts many students who fail in the conventional systems or whose learning styles are not well accepted by traditional schools. How to support these students to be successful lifelong learners is a challenge for teachers and policymakers.

Problem of Information Overload

The enormous information overload of individuals and organizations is among the most important changes nowadays due to the low cost of multimedia information production and distribution and the diversity of distribution channels available. The information overload problem is being transformed to an information overkill problem as the filtering of the great volume of information cannot be easily made and only small amounts of information can be transformed into usable knowledge. Some new technologies that target this problem are under development, such as the

semantic web, intelligent search agents, and learning analytics. The competitiveness of individuals and organizations highly depends on their ability to rapidly transform such information into applicable knowledge, which should be selectively distributed and used for just-in-time decision making and learning. The new generation of highly interactive multimedia and hypermedia learning environments foster learner-centered educational models and provide a different perspective for school education. To make use of the new opportunities offered by the ICT based online learning, in a world full of powerful instruments of producing and getting access to any kind of information at any time and any place, young learners need to acquire and develop the skill of not just accessing information but evaluating information critically to be transformed into useable knowledge. This is yet another challenge.

Conclusion

In this chapter, we have summarized some recent research trends in the fields of distance and flexible learning in primary and secondary education. We began by focusing on the learner and discussed the support provided by digital technologies to facilitate flexible and personalized learning. The technologies for distance and flexible learning and the virtual learning environments with fuzzy boundaries between the physical and virtual worlds provide a great variety of opportunities. It was identified that flexibility of what, how, where, and when to learn could adapt learning to the individual needs and preferences of the learners. Some important research issues and challenges have been identified in this chapter as well, including connecting pedagogies and learning theories with learner-centeredness and distance and flexible learning, the changing role of the teacher, the possible information overload, and the needs of new skills.

Abstract

Each year, millions of K-12 students study one or more courses at a distance. Although the highest participation has been from learners in the USA, online flexible and distance K-12 schooling has become available to students from many countries around the globe. Its implementation and evolution is due, in part, to the varied ecosystems in which it appears. It began as a sharing economy; it now includes for-profit, nonprofit, and mixed business models that impact whole education systems and may continue to spread globally. Virtual schooling

(VS) research overlaps in some ways with research in both traditional K-12 schooling and postsecondary online education. However, given its unique nature, research also specifically addresses virtual schooling's benefits, challenges, strategies, services, and varied impacts on educational systems. This chapter provides an organizational perspective on K-12 online distance education. It includes a synthesis of the research and a discussion of the misconceptions of roles and responsibilities. The chapter concludes with a detailed illustration of a nonprofit service, depicted within (Davis 2018, pp. 99–127) Global Arena Framework to clarify its complexity and potential.

Virtual Schooling · K-12 distance learning · Organisational culture · Blended learning · Online learning · Distance education

Introduction

K-12 online and blended programs arguably gained their initial foothold in the USA in 1996 with the introduction *The Virtual School* and the *Florida Virtual School* (Ferdig and Kennedy 2014). Over the last 20 years, virtual and blended opportunities have exponentially grown for K-12 schools in the USA and in some parts of the world. For instance, it is estimated that millions of students each year participate in some form of K-12 online or blended instruction (Gemin et al. 2015). There is also a rich and growing body of research evidence supporting teaching and learning in such programs (Ferdig and Kennedy 2014, 2018; Davis 2018). What was once considered potentially a useful option solely for home-schooled, detained, or health-stricken students is now mandated in some locations. In sum, online flexible and distance learning has become one of the global modes of K-12 schooling.

The purpose of this chapter is to provide an organizational and brief historical perspective on K-12 virtual schooling in order to (a) set the stage for a deeper understanding of its multiple facets, (b) to provide illustration of the evolution of a nonprofit virtual school provider in the USA in order to paint a more comprehensive portrait of the benefits and challenges facing this mode of K-12 education, and (c) to introduce alternative and sometimes contentious contrasting points of view on virtual schooling.

Sketching the Landscape

Roblyer (2008) presented a history of virtual school establishment in the USA up to 2006 that began with the establishment of Utah's Electronic High School in 1994. At that time, virtual schooling largely focused on a few courses within secondary school programs where students would typically attend a face-to-face school in their home district (Roblyer 2008). They would enroll in an online program where they might take one or more classes in an online environment using a learning management

system (LMS) and/or other online tools that complemented the LMS. The school or school district would still be responsible for providing some mentoring (typically a school counselor or administrator) and would report grades to the “face-to-face” school district, while the online service would provide the teacher and the content. These supplementary courses and programs were initially offered at the secondary levels. Given the rudimentary nature of early technologies available for online instruction and weak organizational structure, learners were expected to be relatively autonomous. Full-time programs were also offered by a few organizations, some of which had evolved from correspondence schools and colleges. However, this conception has changed, and virtual programs now commonly span primary and secondary offerings, and the terminology has moved away from virtual schooling to include terms such as blended and personalized online learning (Gemin et al. 2015). For a more recent historical view with a more critical perspective, see Barbour (2014, 2018).

Originally these online offerings emerged to serve the needs of students in districts that did not have enough mass to offer specialized courses (e.g., world languages and some sciences); today they have expanded into more mainstream curriculum courses to serve needs such as “credit recovery” and to overcome scheduling conflicts. Although these offerings appeared particularly inviting and promising for home-schooled students, students who had dropped out, teens who left school due to parenthood, students with health issues, or detained students, research suggests that many of these courses were heavily enrolled with gifted and advanced students looking for more curricular options and also students heavily enrolled in extracurricular activities who needed an augmented and flexible schedule (Ferdig and Cavanaugh 2011). Such schedules could also include online courses offered by universities to recruit and prepare the bright students that can be supported in the USA with public funding for dual enrolment in high school and in university.

While the growth of virtual schooling has been unusually strong in North America, particularly the United States, the emergence of virtual schooling remains patchy globally. The growth of virtual schooling naturally is related to the evolving needs of the population, the funding arrangements for public schooling, and the access to online infrastructure and practice (Davis 2018). In many countries, the role of correspondence distance education continues to serve these needs. For instance, in New Zealand, supplementary courses appeared around the same time as in the USA to address unmet needs (particularly in rural areas); the uptake has remained small and few regulatory changes had occurred (Powell and Barbour 2011) until recently. Arguably even those have had a relatively small impact compared to changes in the USA (Tolosa et al. 2017).

The growth of online and blended schooling has either necessitated or encouraged policy change. For instance, even in a supplementary role, virtual schools can face challenges from K-12 schools to local districts because they tend to compete for the same funding sources. In the USA, the National Educational Policy Center has raised awareness of this threat to the traditional goals of that nation system of public education, raising concerns about the “Macdonaldization” of public schooling and related disruption of enculturation into mainstream society (Miron and

Gulosino 2016). On the other hand, VS providers (e.g., Iowa Learning Online and the Virtual High School) work strategically to partner with rather than compete with the schools they serve (Davis 2018). Additionally, the growth of online learning in postsecondary education has stimulated changes in the regulation of education in some states within the USA to require students to participate in online learning experiences prior to graduation from high school (e.g., State of Michigan 2006). This has stimulated many additional states to develop a virtual schooling provider and/or cooperatives to support this mode of schooling and to inform policy development (Gemin et al. 2015). In contrast, Bacsich et al. (2013) noted that policy makers in countries that have few offerings have often been unaware of its potential and challenges. Their wiki with comprehensive worldwide coverage exhibited few cases in Europe or Asia where courses were taught by a distant teacher. Instead, online learning and teaching in Europe and Asia have largely added flexibility to provision by the same school campus or after school tuition services (see <http://www.virtualschoolsandcolleges.eu>).

Thus, research-based knowledge about virtual schooling is limited; even in the USA (see Archambault et al. 2016b) virtual schooling providers continue to evolve and emerge. The lack of experience and accurate information about this mode of K-12 schooling and the diversity of offerings has led to misleading preconceptions about virtual schooling that can fuel heated debates. An example from those in favor of VS is the Clayton Christensen Institute's so-called "proof points" (see <http://www.christenseninstitute.org/publications/proof-points/>). The points are essentially evaluative reports by academics connected with the Institute in the form of 12 case studies describing how traditional school districts have improved student learning outcomes after the implementation of blended learning. An example produced by those against VS is a series of reports published by the National Education Policy Center in Colorado (e.g., Miron and Gulosino 2016) who describe VS as threat to a somewhat twentieth century vision for K-12 public schooling.

Given these conflicting and often naïve or limited perspectives on the very diverse landscapes of VS, it is important for practitioners, leaders, policy makers, and researchers to become more aware of the enormous variety with virtual school providers and the ways in which they are evolving locally, nationally, and globally. It is also critical for such audiences to be aware of the highly variable quality of information that is published about them, which may be overly biased and/or influenced by strongly held beliefs.

Models of Virtual Schooling

Regardless of the supplementary or full nature of the online program, the landscape has become increasingly chaotic with the proliferation of online providers with a diverse range of practices and business models. The early VS providers adopted a "shared economy" business model that aimed to partner with K-12 school districts and schools rather than to compete. Examples include VHS, which emerged as part of a nationally funded research project and traded seats in science courses for the

online teaching by science teachers nationwide (Zucker and Kozma 2003), Iowa Learning Online (illustrated later in this chapter), and New Zealand's Virtual Learning Network community of services that continues to use this model (Tolosa et al. 2017). Other business models with layers of online services have emerged; by 2015, there were many services and products marketed by nonprofit VS providers as well as by for-profit companies such as K12 Inc. and Pearson Education.

It has become increasingly difficult to estimate the number of K-12 students who participate in VS each year, as the annual report of K-12 virtual schooling has documented. For example, Gemin et al. (2015) estimated that millions of K-12 students took online classes that year; they also estimated that US\$ 380 million was spent on learning management systems and platforms in the USA where for-profit companies such as K12 Inc. were listed in the Stock Exchange. Estimating the numbers of enrolled online *and blended* students up to postsecondary levels is too complex to aggregate figures accurately. This is due to the broad notions and multiple definitions of blended learning. In addition, many virtual schools that offer completely online courses and programs also offer services that support face-to-face blended courses, thus making enrolment estimation difficult or impossible. Finally, the for-profit companies that provide many of the services are understandably reluctant to disclose their business model and outcomes. In summary, online and blended programs are now embedded as a mode of learning in pre- as well as postsecondary education in many forms that continue to evolve and coevolve together with knock-on impacts whole systems K-12 schools including bureaucracy and politics nationwide and possibly globally.

Does Research with Adults Learning at a Distance Online Transfer to K-12?

Prior to synthesizing the existing research related to the major components of virtual schooling, it is useful to question why research differs between virtual schooling and traditional face-to-face education. In other words, there is a need to clarify why an educator might be cautious of directly applying educational research in more traditional settings to inform expectations of virtual schooling experiences. Ferdig et al. (2009) identified this in relation to the 80/20 rule that is well published in other disciplines. In evaluating virtual schools in 22 of the 50 states in the USA, they found strong evidence that 80% of virtual school practices, opportunities, and challenges were shared regardless of state border, while 20% of such processes and problems were unique to the educational context of the virtual school. The unique finding was that many virtual schools and programs were completely unaware that 80% of their problems and opportunities were similar to those of other virtual schools. Many of these schools were under the impression that what they were practicing or, in some cases, attempting to practice, were unique to their situation.

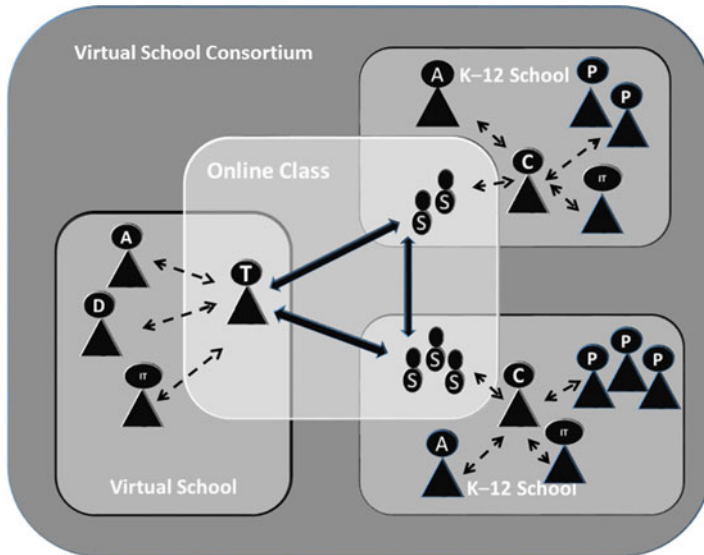

This same 80/20 principle was then applied by the same researchers to the existing research in the field of virtual schooling. DiPietro et al. (2008) studied teacher processes and practices in online programs to explore and compare (a) K-12

online vs. K-12 face-to-face and (b) K-12 online vs. postsecondary online. Researchers found that there were indeed research, practice, and policy outcomes that were equivalent between K-12 teachers in virtual schools and K-12 face-to-face programs as well as in between K-12 online teachers and postsecondary online teachers, such as similarities in classroom management, instructional strategies, and assessment techniques. The researchers also found unique circumstances within K-12 online instruction that did not appear in K-12 face-to-face education or postsecondary online education that included communication, community issues/concerns, and support strategies. In sum, when further examining research related to the components within virtual schools, it is necessary to examine but also go beyond traditional K-12 face-to-face and postsecondary online research findings because of the unique nature of K-12 virtual schooling. In some cases, the research is emerging, while in others researchers have discovered significant outcomes.

Identifying the Players and Their Roles

In research into face-to-face K-12 classrooms, three traditional components are commonly recognized: the teacher, the learner, and the curriculum content. This is not to downplay the role of the others. Parents, administrators, and others including support staff such as school counselors obviously support and engage students in their learning (to varying degrees). However, these roles become significantly enhanced and/or modified in virtual schooling due to the nature of engagement in online settings; some would use the term “decoupled” to indicate that a role has become spread across multiple people. Such decoupling with the deployment of computers is common in other sectors such as banking where organizational structures have become flatter (Davis 2018). In most VS contexts, the roles of the traditional players (student, teacher, content) are commonly modified by their new settings and particular contexts, and, where this does not occur, the quality of education can be reduced.

The changes in roles have been easiest to research in supplementary schooling because this involves collaboration between organizations, which naturally leads to the decoupling of roles, reporting lines, and changes in the evolving business models. Davis and Niederhauser (2005) contrasted the case studies of supplementary course models: (1) an Australian VS service that developed and offered online courses into traditional public schools with (2) schools in the USA that cooperated so that a teacher in one school designed and offered his course across multiple schools that deploy some sort of bartering arrangement. The second model is more challenging because the teacher leading the course is innovating as an online teacher in addition to remaining embedded in the traditional culture. As a result, such a distant teacher is rarely supported by a traditional school as much as a teacher employed to teach distant students by a virtual schooling provider. The latter is often embedded alongside people who are committed to supporting K-12 online learning and the related evolution of practices. The difference between campus based and online cultures of K-12 schooling are discussed in more detail including a

Davis CC BY-SA 3.0

Fig. 1 The roles and responsibilities for an online class offered by a virtual school as a supplementary course for students in other K-12 schools. (First published in Davis et al. (2018) under CC by SA. Key: *A* administrator, *C* coach, *D* instructional designer, *IT* technician, *P* parent or guardian, *S* student, *T* teacher. The dotted line indicates sporadic communication, whereas the unbroken lines between the teacher and students indicate that communication is ongoing)

contrast with the emerging practices of co-teaching in innovative learning environments enriched with Cloud-based tools by Davis et al. (2018).

Figure 1 illustrates an approach where a virtual schooling service provides a supplementary course into two schools. Readers are encouraged to imagine the increasing complexity with the more common situation of a class of students spread across five or more schools and may wish to note that such complexity is not likely to be encountered in cooperating schools because it becomes impractical. A diagram is useful to appreciate changes in the roles and responsibilities of those involved in K-12 education because multiple organizations are involved and the three traditional roles introduced earlier become decoupled and spread across a number of people. The adoption of online learning also brings in new players such as instructional designers who collaborate in the construction of LMS course shells filled with relevant content and activities for a particular curriculum.

As illustrated in Fig. 1, the VS class has an online environment that is spread across at least three organizations: an online teacher (*T*) who is an expert in the content area leads a course offering from within the virtual school for students (*S*), who are located in at least two different K-12 schools. The course shell in the LMS is the main virtual environment, and it is loaded with relevant content and activity structures that may be deployed multiple times by different teachers. The work to design and load such an LMS course tends to include an instructional designer (*D*) as

well as one or more teachers who are expert in the content area and/or the pedagogy of the virtual school. As a result, the teacher (T) leading a particular course offering may be restricted by the administration policy of the virtual school from adapting the materials or pedagogy. Virtual schools may also purchase such course shells and adapt them; for example, Gemin et al. (2015) note that a service for Christian schools had purchased course shells and adapted them to reflect Christian values before incorporating them within their menu of course offerings. Additional technologies are usually blended with the LMS to reduce the perceived distance between the participants and to increase student engagement. For example, desktop videoconferencing is relatively common between the teacher and students in the class. The critical role of these digital tools leads to the inclusion of an IT support role (IT) in all locations because technical issues can block access. However, the biggest decoupling has led to the recognition of the importance of the role of a facilitator (F) who is located on the same campus of each site with students and who, in addition to advocating for and coaching the students, is responsible for liaison with their parents (P). For home-schooled students, this facilitator is likely to include a parent complemented by another adult to provide independent quality assurance of summative assessment.

A virtual schooling service commonly sets a style for its approach and pedagogy and provides an induction for its teachers and the other participants. So while practice varies between VS organizations, it is likely to be standardized within the organization, e.g., the early VHS pedagogy was documented by Zucker and Kozma (2003). This is similar to the ways in which traditional schools evolve to fit within their stakeholders including local, regional, and national regulation and cultural expectations. VS services have evolved to address challenges including strategies for accurate and timely assessment and the secure administration of credits that are part of the process required for students to progress through an educational system. There is therefore a role for an administrator (A) on each site and knock-on impacts for administrators at the state and national level; this is illustrated later for Iowa Learning Online.

Some of the current literature in the field is described below as it relates to the learner, teacher, administrator, parent, and facilitator; more research is needed to enhance knowledge of these and other roles, their variations with cultural differences, and evolution over time.

The Learner

The central participant in VS schooling is the learner. Early work in this area examined characteristics of learners who are more or less successful in online and blended learning environments (e.g., Roblyer and Davis 2008; Roblyer and Marshall 2002) in the hope that this could be applied to improve selection and advice to students and their parents. A reliable instrument did not emerge due in part to the continuing evolution of VS, including increased induction and ongoing support for students who were less autonomous. More recent investigations have examined the

challenges and opportunities for particular types of students such as those recognized to be “at-risk” of underachieving (e.g., Repetto and Spitler 2014; Ferdig 2010b), students with disabilities (Greer et al. 2014), and students facing health and medical issues (Fernandez et al. 2016; Thompson et al. 2012). More traditionally marginalized populations enroll in online courses at higher rates than other student populations (Thompson et al. 2012), such as students with disabilities, and this increases the challenges for course design and facilitation. This research indicates that virtual schooling can lead to successful outcomes, particularly for more autonomous, motivated learners who have IT skills. However, not all learners are successful in these environments, and only some may become successful when necessary supports are put in place (an example of such is a biology course adapted by Iowa Learning Online for credit recovery is described later). It is also important to note that students benefit from relevant counseling, plus induction to online learning environments that include development of both technical and study skills (Roblyer and Davis 2008).

The Teacher

The second central participant is the teacher. Teacher here refers to the actual instructional leader of a particular offering of an online or blended course (the facilitator at each school where student reside is a separate role described later). Research in this area has described the types of preparation required for successful online and blended practice during which the teacher often gains experience in learning online and may construct a course shell to use subsequently (e.g., Dawley et al. 2010). Researchers have also examined teacher standards (Kennedy and Archambault 2012b), preservice teacher field experiences (Archambault et al. 2016b; Compton and Davis 2010), online best practices (DiPietro et al. 2008), and teacher mentoring and continued professional development (Dawson and Dana 2014a, b). This research provides evidence that teaching K-12 online and in blended environments has some similarities to teaching K-12 face-to-face and some similarities to teaching postsecondary online. There are also some important differences; for instance, postsecondary education andragogy (rather than pedagogy) does not have the duty of care that is necessary when teaching minors. In sum, there are nuances in teaching in these K-12 virtual environments that require continuing teacher professional development (Ferdig 2010a), and such professional development varies with the content area, curriculum, cultural contexts, and time.

The Administrator

There are at least two types of administrators identified in online and blended K-12 instruction. The first is the administrator of the virtual or blended school; the second is the administrator of the face-to-face school where the online student typically resides. Unfortunately, although a large body of literature exists on traditional

educational administration, there is little research on best practices of each of these types of administrators in online or blended environments (McLeod and Richardson 2014; LaFrance and Beck 2014; Richardson et al. 2015; Archambault et al. 2016a). What research does exist reinforces the important role of the administrator in providing opportunities for online and blended instruction as well as in providing professional development for staff including teachers and facilitators (Ferdig et al. 2016). In an exploratory study, Beck and Maranto (2014) asked teachers in two virtual charter schools in the USA to compare their experience in virtual charter schools with their prior experience of traditional public schools and found that they tended “to rate the virtual charters more positively on empowering and respecting teachers, and on developing a student-centered school culture, and there was potential for more innovative personal practices” (p. 68), but little evidence of social constructivist practices was found.

The Parent

Parents (and/or other guardians) obviously play a critical role in the education of a child (e.g., Barton et al. 2004). In online and blended environments, parents are often asked to play a larger role given the fact that students are not colocated with their teacher and may study more at home. These roles vary between management (e.g., timekeeping) and basic instruction (providing scaffolding) as well as counseling in the choice of courses (Beck et al. 2014b). As in other areas, although the research in this area is sparse, there is evidence that role of the parent is influential (e.g., Black 2009), that levels of parent involvement vary, and that they require guidance including less formal professional development that includes strategies for supporting children who are learning online (Hasler-Waters et al. 2014).

The Facilitator

Online and distance programs introduced a new (or at least changed) role that we call the facilitator, although many other terms are used including mentor, student coach, and eDean. The facilitator is someone on each school campus who acts as the contact person for the students taking online courses from provider(s) of VS services. The facilitator is critical because the mental and physical distance between teacher of a course and his or her students can lead to high rates of student attrition. Facilitators advocate for VS students on their school campus and help them navigate instructional issues, communication with instructors, limited content scaffolding, and technological problems. They may also have a role as a proctor for the quality assurance of summative assessment. They are also likely to brief parents, administrators, and school counselors on the students' progress. More research is required, but evidence indicates that facilitators have a positive impact on student success and reduce attrition (Borup and Drysdale 2014; Pullar and Brennan 2008). Descriptions of the contexts and roles of mentors in Michigan have been useful to illustrate the

evolution of their practice and the importance of school leadership support (e.g., Bruno 2017). In one outstanding case study, the school principal had selected a teacher who had counseling qualifications and supported him to establish innovative practices. The students who needed most support studied in a closely supervised classroom on the school campus, whereas less formal arrangements that were negotiated with more autonomous students included studying from home when that suited those students' needs.

The way in which these and other roles work together varies with the organization of VS, so an illustration of these and other key roles is now illustrated by describing a course offered by the Iowa Learning Online. The evolution of the service over time is also mapped using Davis' (2018) Arena of Change with digital technologies in education to clarify the complex interactions impacting the evolution of VS practices.

A Case Study of Virtual Schooling in the USA

As stated above, practice in VS varies enormously and continues to evolve with changes in educational systems locally and globally. The decoupling of roles and the collaboration between educational organizations and services are complex and difficult to comprehend and communicate. Therefore this section focuses on one particular instance of a statewide virtual schooling service. It aims to set this particular instance of VS in a global context in order to illustrate the importance of multiple partnerships between schools and services that collaborate as well as the decoupling of traditional roles of participants in supplementary courses provided by Iowa Learning Online (ILO).

This case study of a VS service called Iowa Learning Online is drawn from collaborative research led by the first author that began as this service emerged in 2004 (a more detailed account appears in Davis 2018). A decade after it was established, Gemin et al. (2015) reported that, in terms of size, ILO was one of the smallest of the 24 state providers within the USA. The associated state Department of Education tweeted in 2015: "Iowa Learning Online proudly partnership with ~150 schools to serve 1500+ [course] enrolments." Having coevolved with online learning to serve K-12 schools and administrators of its state (as described in detail in Davis 2018), ILO has retained four clear equitable objectives that it has published on its web site. Iowa Learning Online (ILO):

1. Is a supplemental program that partners with local school districts and cannot replace them. Local districts continue to award their students the credits earned upon successful completion of ILO courses.
2. Serves a variety of educational needs and a broad range of learners. It is open to meeting the needs of all high school students.
3. Collaborates to provide quality learning opportunities for students anywhere in the state.

4. Values continuous improvement toward innovative, quality learner opportunities utilizing emerging technologies (see <http://www.iowalearningonline.org>).

The survival and steady growth of ILO provides evidence that its strategy remains fit for purpose in this largely rural state. In 2016, changes in legislation recognized the need for the ILO to network nationally with a national/international association for K-12 online learning (iNACOL) in order to better inform the state's politicians and administrators. In contrast with some other states, Iowa has kept its investment low beginning with an unfunded mandate in 2004 that required the founders Gail Wortmann (the master teacher who identified the need for ILO) and Pam Pfitzenmaier (the first administrative leader within the state Department of Education) to work within existing resources. Their vision and funding regime may have supported ILO to retain its tight focus on the needs of its state, in contrast with nationwide initiatives such as VHS that have spread overseas and for-profit services such as K12 Inc. (Zucker and Kozma 2003; Davis 2018).

Case studies of courses within ILO include the first course (high school anatomy) that was created and taught by founder Gail Wortmann, with support from instructional designers in Iowa Public TV (Davis et al. 2007). The structure of this first ILO course acted as a guide for subsequent courses, particularly those of high school physics and chemistry, not least because Gail's role as ILO master teacher started with the recruitment and mentoring of ILO teachers and her role grew to include many forms of professional development leadership and quality assurance, including ongoing appraisal of the ILO teachers to retain their licenses to teach within the state of Iowa. The research of these and other courses led the production of Fig. 1 to clarify the changes and variations in the roles and responsibilities of VS participants, particularly the facilitator. It is interesting to note that an ILO course in basic biology that was designed to increase the range of students served by addressing the needs of those unable to graduate from high school due to their lack of science credits enhanced the role of the facilitator for these students. In this case additional support provided by teacher aids for students with exceptional needs provided the additional facilitating resource required.

Harms et al. (2010) applied communication theory to interpret Gail Wortmann's atypical strategy for videoconference (Wortmann retained it largely for "office hours" so that students could drop into her virtual office); at that time other teachers commonly used videoconference to present content. Where the message (topic or practice) to be communicated is less clear, a high bandwidth improves the chance of effective communication. Given that the bandwidth can be increased for only limited periods in distance education, the narrow communication bandwidth of a LMS or web site is more appropriate for the content and messages of the teacher because she knows what she wants to communicate and so there is less uncertainty. In contrast, the teacher is much less certain what her students' responses are likely to be and often needs to check those messages and understanding. Thus the high bandwidth enabled by multiple media and the two-way communication of videoconference is prioritized for student-to-teacher conversations that can correct misunderstanding and misconceptions, and these

sessions are also likely to include aspects of formative and occasionally summative assessment.

During the first virtual field experiences developed in collaboration with Gail Wortmann for preservice student teachers, this videoconferencing pedagogy was observed, analyzed, and reflected upon. For the field experience, Gail added online chat as back channel for communication with the preservice teachers during this observation, which was followed by debriefing conversation over videoconference after the high school students had disconnected from her virtual classroom. The preservice teachers were also guided to undertake observation activities within the LMS course shell (Compton and Davis 2010).

The landscape of VS is complex and continues to evolve under many influences local, regional, and global. Although Iowa Learning Online only serves students in the state of Iowa, it continues to be impacted by global as well as local changes as shown in Fig. 2. A global perspective of the ILO physics course offered by ILO in 2004 is depicted in Fig. 2 using the Arena Framework developed by the first author (Davis 2018), which applies human ecology theory to the coevolution of both digital technologies and education. The ecosystem of teacher and his class was embedded within many layers of ecosystem communities within the global ecosphere. The physics teacher (T) who was leading this offering of a collaboratively designed ILO

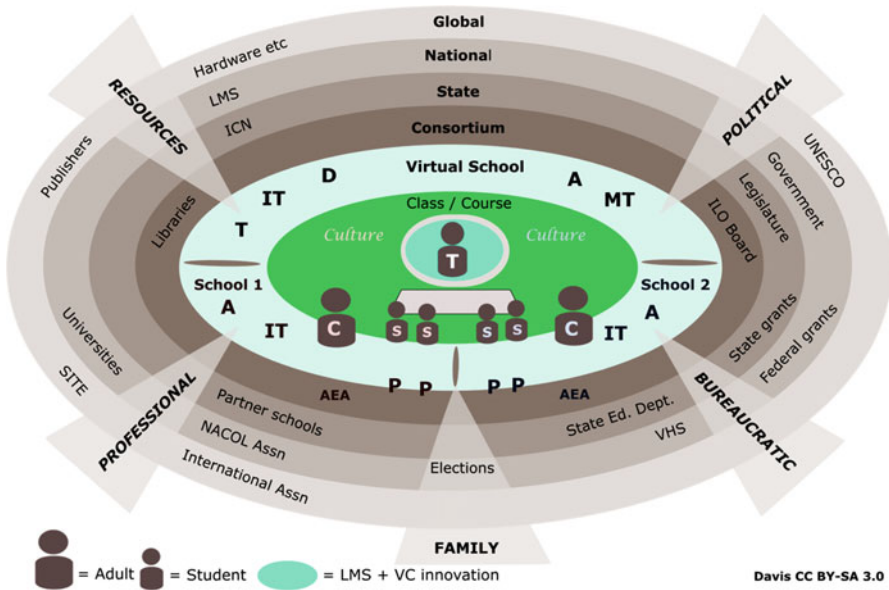

Fig. 2 Iowa Learning Online’s first online physics course offering in 2004. The physics teacher is at the center set within the global ecosphere. (Derived from Davis et al. (2013), under a CC by SA license. Key: A administrator, AEA area education agency, C ILO student coach also known as facilitator, D instructional designer, ICN Iowa Communications Network, IPTV Iowa Public TV, IT technician, LMS learning management system, MT master teacher, NACOL North American Council of Online Learning, S student, T teacher, VHS the Virtual High School)

course is pictured at the center of the global ecosphere through the screen of a computer. High school students in at least two high schools were in his virtual classroom, and the word culture is repeated to indicate that many cultural influences that influence behavior in this class ecosystem have been brought into the course ecosystem by the teacher, the students, and the multiple schools within which they worked. In each school the ILO required that an ILO coach (C) adopts the role of facilitator who, in addition to coaching ILO students, advocated for them and worked in other ways with parents (P), ILO staff, and his or her own school staff including administrators (A), technicians (IT), plus staff in the area education agency (AEA) responsible for that public school. The ILO teacher had similar collaborators in the ILO, plus Gail Wortmann the master teacher (MT) and an instructional designer (D) who supported the development of the LMS course site and other resources. The agencies noted in the outer layers of the ecosphere also influenced this and many other VS courses. These influences have been grouped into five sectors; for example, in the resource sector the Iowa Communications Network videoconference (ICN VC) service was provided by the state into all high schools, the LMS was a provided by a nationwide for-profit company, and the textbooks were purchased from international publishers.

Figure 2 shows a map of all of these influences, and this landscape would have close similarity to that of another ILO course offering. However, a course offered by a different VS organization, such as the Virtual High School, evolved different practices because those ecosystems would have evolved under different conditions. Mapping in the Arena Framework clarifies that the central physics teacher's practice is interlinked with the practice of many other participants. Participants who are closer to the class have more influence on behavior within the class, but it is notable that the influence extends globally not least through resources that have become part of the virtual schooling environment. For example, videoconferencing has become accessible over the internet on personal devices and so by 2015 that was used in preference to the Iowa Communications Network (ICN) classroom in each high school. Administrative practices have also evolved since 2004, but most obvious is the increase in the guidance material available for all participants, including parents plus many other roles that were listed in the 2017 ILO online guidance.

Conclusion

In our synthesis of the research, we have found that it is important to interpret research findings and position papers about VS with caution due to heated debates, polarized views, and widespread misconceptions. Authors who have been involved in virtual schooling are likely to be more positive (e.g., iNACOL), while those with strong beliefs about the traditional purpose of schooling in their country may be biased in the opposite direction (e.g., Miron and Gulosino 2016). Finally there are those who are new to this phenomenon who may overgeneralize from their personal experience of online learning or lack of it.

While the positive or negative impact of VS is debated, it has evolved in many contexts to serve particular needs of a range of K-12 students and communities. What began as a sharing economy with open resources now also includes for-profit, nonprofit, and mixed business models. Virtual schooling decouples the roles and responsibilities of educators and learners, spreading the traditional role of a school teacher across more people and places. In the USA, at least, it has increased the presence of for-profit companies in education. This may expand globally where there is a cultural and economic fit. While concerns about the “Macdonaldization” of K-12 schooling are being met with changes in bureaucracy in many states of the USA and nations with foresight, it is likely that some policy makers will remain ignorant of the challenges and potential range of VS. It is likely that the overlap with “smart” innovative learning environments that increase opportunities for Cloud-based personalized learning and cooperative teaching will continue to converge and confuse the landscape of virtual schooling within flexible and distance education for K-12 students. What is not contentious is that more research is needed and that such research would do well to adopt holistic perspectives that allows for systemic analyses. The application of Davis’ Arena Framework to one VS service in this chapter shows that VS can be interpreted from a coevolutionary perspective in a way that can unmask of the many interacting layers of VS that influence the practice, potential, and challenges of K-12 virtual schools and services locally and globally. This sets the stage for a more nuanced and accurate view of K-12 VS in the future, including mapping further growth and challenges.

Acknowledgments We would like to acknowledge all our collaborators, particularly Gail Wortmann and Iowa Learning Online. The research informing this chapter was funded in the USA by FIPSE, in New Zealand by the Ministry of Education and by the European Commission, as well as by participating universities including Iowa State University and the University of Canterbury.

Introduction

Our educational systems as we know them today evolved in a physical context defined by scarcity. The constraints of the physical realities of schools of various types – agora, one-room schoolhouses, and more modern schools of all types – and the need for all students and teachers to gather in one place at one time set limits on the availability of teaching, space, time, and resources. The advent of ubiquitous networked devices that cheaply connect us with one another, and with the reified interactions and the content we create, has greatly diminished such constraints, as have new pedagogies more suited to these open and connected learning environments. We are only beginning to adapt our educational systems to fit this new, less rivalrous, less bounded, more open reality. This chapter describes some of the main features of this more open universe, explores the different kinds of openness that are enabled, and describes some of their consequences for primary and secondary educators and learners.

Openness and Constraint

Openness is, fundamentally, about freedom from constraint. Constraints – of space, time, economics, legislation, path dependency, capability, and so on – conspire to reduce choice, creating limits on what we can and cannot do: they close avenues and doors that we might otherwise step through. This is not necessarily a bad thing. As Stravinsky put it, “The more constraints one imposes, the more one frees one’s self” (quoted in Simpson 1988). We need structure, and we need something to kick against, if we are to do or create anything. As Boden (1995) explains, “constraints, far from being opposed to creativity, make creativity possible. To throw away all constraints would be to destroy the capacity for creative thinking. Random processes alone can produce only first-time curiosities, not radical surprises” (p. 123). Limitless choice is almost as bad as no choice at all, reducing our ability to control our lives. As Schwartz (2004) puts it, “Having the opportunity to choose is no blessing if we feel we do not have the wherewithal to choose wisely” (p. 104). For all that, having no choice at all, when we wish to choose, is unequivocally a bad thing. When something is closed, it prevents us from being able to choose. When something is open, it presents an avenue of opportunity, but doors and windows only have any value when they are surrounded by walls. This relationship between constraint and

freedom is also relevant in traditional closed educational settings and pedagogies as well in more open contexts (Drexler 2010; Dron 2007).

The focus of this chapter is on systems and structures of all types that, when assembled, result in and from an increase in openness: open online tools, systems, and content, open educational resources, open pedagogies, open-source software, and open learning experiences. By this, we imply that they exist in a context of closed systems and structures and, importantly, that they represent a continuum and a spectrum of openness. These have been infrequently discussed in primary and secondary educational contexts. Part of our focus here will be to discuss the practices of open education in all of its forms in higher education, then to use that work to explore openness in primary and secondary settings.

Openness and Educational Contexts

There are many shades of meaning of the word “open” as it is applied in an educational context. Until the late twentieth century, discussion of “open education” was largely limited to higher education and was focused primarily on enabling open access. This was in contrast to the typical (and still common) competitive admission requirements of much of higher education that deliberately excludes those with insufficient qualifications. For most primary and secondary schools, in most nations, some level of ubiquitous access was achieved many decades or centuries previously. Indeed, in most countries, children are required to go through at least primary schooling. However, there is a world of difference between *allowing* anyone to have access to education and *mandating* that they must. The very thing that open universities fought to achieve for adults – access to education – is not a right but an obligation for children in many countries, and, for most people, the opportunities to diverge from the defaults provided are limited. In many countries, legislation and/or economic constraints limit the capacity of people to choose, for themselves or their children, the form, content, location, timing, pacing, or outcomes of education. Parents may be able to pick between schools, or even to homeschool their children, but schooling (of a defined character) is not optional. Thus, openness in primary and secondary schooling is to some extent the opposite of openness in higher education: *it is concerned with means to escape or bypass mandatory schooling and/or the constraints it imposes, rather than to gain access to it.* To some extent this difference is unsurprising: for many years, “open” education was closely bound to the concept of “independent learning,” so, as children are often described as “dependent” and assumed to lack the maturity to manage their own learning, allowing them autonomy is not an option. But there is much more to openness than just access.

Generations of Distance Learning Pedagogies

The first open universities, schools, and colleges to bear the name sought to reduce other barriers apart from access, mainly through correspondence or broadcast models of distance teaching, which allowed learners freedoms in time, place, and, to some

extent, pace of learning. There were sporadic innovative approaches to reaching geographically dispersed school children by two-way radio, such as through the Australian School of the Air (Connor 1970), albeit that these were more often used as a supplement to traditional classroom teaching than as fully distance technologies. However, whether through correspondence or broadcast technologies, up until the final decades of the twentieth century, distance education focused heavily on content delivery and skills acquisition, not by choice but by necessity. Limited opportunities for dialogue meant that the first generation of distance education pedagogies inevitably employed largely behaviorist/cognitivist approach to teaching, with an instructivist ethos and a focus on individuals as independent learners able to follow guidance by themselves (Anderson and Dron 2011). These courses were highly scalable, often enrolling hundreds or even thousands of simultaneous learners, all of whom independently worked their way through study packs of materials, rarely if ever meeting another student or their tutor. Such courses were typically developed by teams, with specialties in a variety of areas such as subject matter, instructional design, editing, and video production. Though this scalability was seen as a strength by many (Peters 1994), such pedagogies lent themselves best to an indoctrination model, in which the wise imparted knowledge to the less wise. In this chapter, we are using the term pedagogies in the broadest sense to refer to the wide range of practices, strategies, and interactions employed in learning settings. They were objective-driven and, of necessity, teacher-controlled. In pedagogical terms, they were anything but open, limiting learner choice considerably, notwithstanding the fact that how these content producers believed that what they were teaching was seldom if ever exactly how learners were learning (Haughey and Muirhead 2005).

As richly functional and widely available Internet technologies emerged, two-way communication became cheap, effective, and reliable. This opened up opportunities for a second generation of distance education pedagogies, anchored in the social constructivist tradition that was already well-developed in traditional teaching and educational settings, following thinking from the likes of Vygotsky (1978) and Dewey (1897), taking advantage of the freedoms offered by online tools (Jonassen 1994). Typically, such courses relied upon discussion forums of one form or another, from early bulletin boards (Mason 1994) to later quite ubiquitous uses of learning management systems, through both synchronous and asynchronous communication tools. While such courses might sometimes make use of open (freely available and modifiable) content and, at least in open universities, were typically open in terms of access, their small-group-oriented pedagogies scaled very poorly, and they were limited to relatively small cohorts of synchronously taught students (Annand 1999). The need to synchronize the activities of a group of learners reduced the openness of pace enjoyed by their first-generation counterparts and tended to greatly increase the cost of delivery compared with their instructivist forebears, which therefore continued (and continue) to thrive. Indeed, the first-generation instructivist model of distance teaching remains perhaps the most common form of distance education, including in most recent MOOCs (massive open online courses).

In recent years, as both openly available content and openly shared networks and communities became widespread and ubiquitous, a third generation of distance

education pedagogy has emerged, which Anderson and Dron (2011) describe as the connectivist generation. This centers around a set of theoretical models, exemplified in the eponymous connectivism itself (Siemens 2005), that attempt to explain and predict knowledge creation in the world of plenty enabled by the Internet. Connectivist-generation theories:

- Incorporate concepts of distributed cognition (Pea 1993; Clark 2008), in which knowledge is distributed across a network of human and nonhuman actors.
- Make use of complexity theory, in which patterns and structures in both minds and social engagements are emergent more than designed (Doll 2008; Doolittle 2000; Hase and Kenyon 2007).
- Assume ubiquitous access to a vast network of people and resources, meaning that traversal of that network and sensemaking in a context of plenty are both critical tools and central objects of learning.
- Stipulate that sharing of knowledge within a network is a *sine qua non* of learning. Everyone teaches everyone.

Connectivist models are scalable, social, and inherently open, but they fit uneasily within a context of formal education: with a focus on networked individuals and emergence, rather than planned curricula, they are difficult to adapt to an educational machine that is grounded in measurable, uniform outcomes. Since these characteristics essentially define primary and secondary educational settings, these connectivist models have rarely been applied in their study and practice. The advent of connectivist approaches has thus done little or nothing to diminish the ubiquity and value of first- and second-generation models, which remain as popular as ever. This is a theme we will also see in the development – or lack therefore – of open education in primary and secondary settings.

Kinds of Openness

The word “open” is meaningless unless seen as one end of a continuum with “closed.” Fundamentally, openness is about freedom. Early distance universities provided freedom for learners to engage in forms of learning that were otherwise closed to them. These freedoms extend not only to access but to the ways that learning happens once access has been granted. Morten Paulsen has classified six cooperative freedoms that might be provided in an online distance context: time, place, pace, medium, access, and content (Paulsen 1993). Paulsen’s model was designed for a specific formal learning context and was developed when Web and mobile technologies were still in their infancy. Using Paulsen’s cooperative freedoms as a basis, Dron and Anderson (2014) have built on his model to extend it to cover social learning in contexts beyond the classroom and to cater for the affordances of modern tools and systems. Dron and Anderson reject “access” as a freedom, seeing it more as a precondition for learning than a controllable aspect of it. Their ten freedoms are:

1. Content – what is learned
2. Place – where it is learned
3. Disclosure – what is revealed of ourselves to others and to whom
4. Delegation – the extent to which we delegate control of our learning trajectory to others
5. Time – when it is learned
6. Medium – the format (e.g., text, video, animation, audio, etc.)
7. Technology – the physical and virtual tools we use
8. Relationship – whether and how we relate to others
9. Method – the pedagogies and other processes used to support learning
10. Pace – the rate at which learning happens

This formulation of cooperative freedoms coupled with the more modern pedagogies such as connectivism begins to point to models of educational settings of all types with increased levels of freedom. Access to high-quality materials – open content – for this type of learning is also essential.

Open Content

Libraries, museums, galleries, and broadcast media (from open lectures through to television) historically gave some measure of open access to rivalrous content, allowing knowledge to be shared at relatively low cost to knowledge seekers. It was, though, not until the growth of the Internet and, especially, the World Wide Web that non-rivalrous learning content became viable at a large scale. Indeed, in the early days of the Internet, especially following the invention of the World Wide Web, open access was the default. However, the growth of learning management systems and digital rights management in the mid-late 1990s decimated the availability and usefulness of the open educational content and systems that had flourished in the early days of the web. In reaction to this, MIT's OpenCourseWare and related initiatives emerged in the early 2000s to become a significant movement, with participating institutions freely sharing content such as lecture notes, assignments, lesson plans, and even textbooks. This movement continues to grow, through initiatives like the OERs (a not-for-profit network of institutions offering free online courses) and Lumen Learning.

There are, however, many different ways to understand openness of content in this context. David Wiley (Wiley et al. 2014, p. 783) has defined the five potential freedoms of OERs, including the rights to:

1. Retain – the right to make, own, and control copies of the content (e.g., download, duplicate, store, and manage)
2. Reuse – the right to use the content in a wide range of ways (e.g., in a class, in a study group, on a website, in a video)
3. Revise – the right to adapt, adjust, modify, or alter the content itself (e.g., translate the content into another language)

4. Remix – the right to combine the original or revised content with other material to create something new (e.g., incorporate the content into a mash-up)
5. Redistribute – the right to share copies of the original content, your revisions, or your remixes with others (e.g., give a copy of the content to a friend)

These rights are reflected in a set of widely used open copyright licenses for content, developed in the early 2000s, Creative Commons (CC). CC took inspiration from earlier open software licenses such as GPL (General Public Licence), Apache, and Berkeley (which involve complexities not found in most content, such as patent law, source code requirements, and functional roles in machinery), applying the general principles that they embody to a broad range of cultural works. CC licenses range from completely open (CC0) that explicitly mirrors the total abnegation of rights provided by public domain resources, to uses that allow all the five Rs but that add constraints such as the requirement to attribute the original source (CC-BY), or to release derivative works under the same license (CC-SA), to almost completely closed variants that are not far removed from the traditional closed “all rights reserved” licenses of commercial copyrighted materials (e.g., CC-BY-ND-NC, which allows no commercial use and no revisions or remixes). These types of open materials have made their way into primary and secondary educational settings. This has been more constrained in places where instruction and curriculum development has been seen as more of a closed system due to national, regional, and local standards and norms, which are intensely prevalent.

The spectrum of openness of content and process in any given context can be rich and complex. For example, one of the mostly widely used resources in primary and secondary schooling, the Khan Academy, makes much of its content (videos and tutorials) available freely but does not allow commercial use, demands attribution, and that all derivatives apply the same license. However, this is not true of everything on the site. The Khan Academy strongly defends its rights over not just the rest of its own content but also to any comments, help, or tutorials given by visitors to the site. Moreover, to gain more than skin-deep access to the site itself, it is necessary to give up some privacy, whether through sharing via social media or signing up to the site itself.

Reuse, revision, remixing, and redistribution are typically of greatest value to those that provide an educational service (teachers) rather than those that use the service (learners). Learners are, of course, the ultimate beneficiaries, both in terms of receiving higher-quality tuition and in avoiding the costs of textbooks and other resources, but the audience for many OERs is teachers or learning designers that orchestrate the learning transactions. Open content is concerned with learning resources, rather than learning processes. This has been criticized for its reinforcement of an institutional model that is, in many ways, closed. As Fiedler (2014) puts it, “OER initiatives tend to remain within the boundaries of the established activity systems of ‘schooling’ that are formed around the seemingly incontrovertible claim that all serious learning activity has to be closely-coupled to a corresponding teaching activity (executed by either a human actor or technical system) and its instrumentation” (p. 2). This focus is, at least on the face of it, somewhat at odds with the openness of connectivist-generation pedagogies.

OERs do, though, have great value in such contexts, not just in reducing costs for all concerned but in enabling the evolution of better resources, spreading good practice, and increasing the range of content available to learners. Thanks to the low costs and widespread availability of OERs, students as well as teachers may have greater freedom in choosing appropriate methods of learning. Perhaps most significantly, the content of first-generation instructivist distance education courses, that in the past cost around \$100,000 to develop, can now be shared, remixed, customized, and reused for a fraction of the price. This has led, since the early 2010s, to the obvious next step – the MOOC.

These online asynchronous connectivist educational settings have become more and more common for adult learning of various types, but have not yet demonstrated much presence in primary and secondary settings, and so will not be further discussed at this point. It is worth noting that the second author has done some work to introduce these concepts into a secondary setting and that this work holds promise for wider adoption. This work is discussed in more detail below.

Open Pedagogies

The technological origins of most formal educational systems in the world today lie mainly in a need to efficiently spread doctrinal knowledge, be it of a religious, professional, political, or military nature, within a technology- and resource-constrained context. Educational systems were a response to the fact that there was a body of knowledge held by a few that needed to be passed on to many: they were a solution to scarcity. Prior to the advent of printing and later technologies of mass distribution, the most effective means of passing on such knowledge was for an individual to stand in front of a crowd of people and to lecture and/or demonstrate. Often this involved reading from a (scarce and expensive) book. Indeed, a “lecturer,” a term still widely in use today, is, literally, one who reads. For this to be effective, learners had to gather with the lecturer in one place at one time: timetables and gathering places were needed. There would be no sense in delivering lectures when everyone was away or on holiday, so there would be periods when no lectures were given, and “terms” over which they ran. For convenience and comfort, it made sense for buildings to be constructed to house these people – classrooms, schools, etc. Rules, both explicit and implicit, were needed to maintain order in classrooms and to ensure people attended. From that emerged a wide range of further constraints that limited the range of possible pedagogies that could be used. Dron (2016) refers to these physical contingencies in learning environments as p-learning. He uses the term to refer both to the physical components, like classrooms and textbooks, but also to the associated pedagogical methods, organization procedures, and rules that form conventional, non-digital educational technologies.

This model of p-learning is still the one most prevalent in the vast majority of primary and secondary educational settings.

As with almost all technologies of any significance, with pragmatic solutions to the constraints of physical and temporal boundaries came side effects. One of these

was a loss of learner control. Structurally, disempowerment of students was made highly probable through a combination of factors such as:

- The power structures that naturally evolve when one person needs to maintain order among many
- The architectural features that reinforce that authority
- The constraints of having to manage the time of many people and teach them largely the same things at the same time
- The simple fact that a teacher has to fill the time with some kind of directed activity and thus is in control, even when they choose to delegate that control to students
- The rules and norms of behavior needed for classrooms to work effectively
- The demands of assessment

When everyone is taught the same thing in the same way at the same time, there will always be some who find it too boring and others that find it too confusing. Additionally, there will be some who learn faster or slower than others. Forcing everyone to learn the same things in the same way and on the same schedule is guaranteed to lead to at least some unwilling or unmotivated learners. With luck and a good deal of teaching skill, perhaps a good number of students will be challenged and curious about the subject matter, but the chances of all individuals in a class having their curiosity, need to attain competence, and need for challenge fulfilled at any one time are slim. The necessary combination of teachers being in control and the need to overcome boredom and confusion – along with a process model that, for organizational convenience, makes every course some multiple of a particular length, largely determined by mediaeval holiday patterns, fitting into timetables designed for efficient resource allocation rather than learning, with classrooms designed for lectures, split into disciplinary areas that exclude one another – has formed the context and the environment in which the bulk of pedagogical theory and practice has developed.

This model is the one most commonly employed in primary and secondary settings, although the set of justifications differ slightly. In those settings, authorities and the common wisdom have insisted that a lack of freedom and openness is necessitated by developmental and conceptual immaturity of young people. For a variety of reasons, this mind-set has not been much changed by powerful work with young people described by Dewey, Papert, Resnick, and others. This will be discussed further below.

Effects of p-Learning on Motivation

Intrinsic motivation cannot arise without support for autonomy, competence, and relatedness (Deci et al. 1999; Frey and Jegen 2000; Hartnett et al. 2011; Reeve et al. 2008; Deci and Ryan 2008). Although educational institutions typically provide good support for social relatedness, it is seldom close enough to compensate for

failings in autonomy and competence support. Because the educational system impedes (if not saps) intrinsic motivation by default, one typical response of schools and teachers is consequently to apply extrinsic motivation, primarily in the form of rewards and punishments, as well as in enforced rules of behavior and conduct. Grades are a particularly ubiquitous form of extrinsic motivation and are particularly harmful because they invariably encourage a strong focus on the goal of passing the tests, rather than on love of learning for its own sake. The power relationships that are entailed also teach some bad meta-lessons, such as that it is OK for one person to deliberately manipulate and coerce another to do their bidding. However, if the ends were worthwhile, it might be justifiable. Unfortunately, extrinsic motivation, at least in its externally regulated reward/punishment form, kills intrinsic motivation (Lee et al. 2016; Legault 2016). Formerly intrinsically motivated learners who are offered rewards or punishments not only lose their initial intrinsic motivation, but the effects persist when the rewards or punishments are taken away. In effect, rewards and punishments replace intrinsic motivation, for a long time after they are applied and, often, permanently. When extrinsic motivation is taken away, there is nothing left or, worse, an actual antipathy to the subject. Schools and universities are thus structurally inclined to kill the love of learning in their students.

Online and Open Education in Primary and Secondary Settings

Over the past few years, primary and secondary schools started to embrace online learning. This adoption of some aspects of online education has two forms. The first is in the form of platforms that provide online supplements to the traditional face-to-face experiences, such as Edmodo or Moodle or Google Classroom. The second is in the more expansive form of virtual middle and high schools. While it is certainly possible that teachers and schools using these platforms may also be making use of open education resources, the platforms themselves are typically proprietary – and controlled by publishers like Pearson – and have frequently raised concerns about student data privacy. At the same time, these platforms even when they appear to have social networking build in (like Edmodo) tend to reinforce an instructivist model, with the same types of limits to student freedoms and openness. This is unsurprising, because their underlying p-learning patterns are not just inherited from their physics-bound forebears but must integrate and interoperate with them.

There are some pedagogies commonly used in primary and secondary settings that work to maximize the students' cooperative freedoms and classroom openness. In project-based learning, students typically work in groups to apply and deepen what they are learning by engaging with a project. When well designed, these types of projects have been demonstrated to enhance student learning and self-regulatory skills, such as collaboration (Ardito et al. 2014; Egberink et al. 2015; Liu et al. 2009). Problem-based learning, another student inquiry-focused pedagogy, has students work toward mastery of various contents and skills by working individually or collaboratively to solve authentic problems. When the problems are authentic and seem to have no obvious or singular solution, students exhibit deep engagement and

learning (de Jesus et al. 2005; Savery and Duffy 1995). While these and other inquiry learning-based pedagogies promote student choice and pedagogical openness, they have met with some resistance in the face of educational reform efforts favoring standardized curricula and testing.

There are, however, some models of student-centered and technology-enhanced learning environments in primary and secondary settings that support student freedoms and the employment of newer open pedagogies. Some of these models stretch back over three decades.

As discussed above, new pedagogies like connectivism have been developed to support student-centered, technology-enhanced learning in settings such as connectivist massive open online courses (cMOOCs). Per Siemens (2012), cMOOCs are distinguished by four characteristics: autonomy of the learner; diversity of tools, learners, and knowledge; interactivity; and openness of access, content, and assessments. While they occur more sparsely at the primary and secondary levels, there have been some notable examples of learning environments which have been very open in all the ways we have been discussing. Perhaps not unsurprisingly, these have featured extensive use of technology.

Seymour Papert, a mathematician and former colleague of Jean Piaget, came to believe that in contrast to Piaget, all thinking was ultimately concrete (Papert and Harel 1991). From this insight came a learning theory, constructionism, which posited that learning takes place through the process of building things. Then Papert started playing with the earliest personal computers and came to understand that a computer could be the ultimate learning machine since it could be programmed to be anything that the child is interested in exploring (Papert 1993). This flexibility would allow the child to learn in response to his/her intrinsic interests. From this work came LOGO, a software that allowed children to learn computer programming through controlling a turtle affectionately known as Seymour.

Papert organized and designed some of the earliest learning settings that make extensive use of computers. He designed software – LOGO – which boldly sought to teach the formerly esoteric and rarefied skills of computer programming to young people, even those in primary grades, to positive effect (Clements 1985). For several years, both the tools – like LOGO – and the pedagogies, like constructionism, gained some footing in primary and secondary educational settings. Their focus on student creativity and multiple means of expression and representation achieved powerful results in a variety of settings – in primitive online settings featuring collaborative construction (Evard 1996), children building robots (Martin 1994), and with adjudicated youth (Cavallo et al. 2004). Many of these ideas and programs came to fruition in the One Laptop Per Child (OLPC) project, which developed both an open learning device, the XO laptop, and an open software platform (Sugar), both of which could be modified by users (Urrea and Bender 2012). Despite being powerful open primary and secondary educational experiences, this type of student-centered, open-ended learning was soon overcome by the fallout of *A Nation at Risk* in the United States and other reports suggesting that more control was needed of curricula and assessment if students were to truly learn (Gardner 1983).

Currently, backlash from these types of stringent, instructivist educational reforms is showing some promise in terms of providing opportunities for educators to experiment with learning environments that are designed with real openness in mind. More and more primary and secondary classrooms are supporting a 1:1 laptop model and/or Bring Your Own Devices (BYOD) programs. Rather than powerful tools like cell phones and tablets being excluded from the classroom, they are being actively embraced by more teachers and schools. This allows students to access the Web and its wide selection of open educational resources like Wikipedia, YouTube, Khan Academy, and TED Talks in formally sanctioned ways.

Some recent work in a secondary educational setting has demonstrated a potential new model for open education through the use of the same tools that have empowered open learning in higher education settings, such as cMOOCs. The second author is a former secondary science teacher (and current teacher educator). Following up earlier work on the use of technology tools to foster, support, and promote student ownership and motivation (Clayton and Ardito 2009), he completely redesigned his biology class as a set of fully self-directed units in order to maximize student autonomy, relatedness, and competence. In this redesign, students were free to navigate through the units of the course in whatever order they wished, working with others or not as they chose. This learning environment was supported by some technological tools to allow ease and freedom of access. Moodle was employed as a learning management system, and Edmodo (a social network designed for school settings) was used as a communication tool. The students, as evidenced by the development of powerful self-regulatory behaviors, their academic achievement, and their own self-reports, thrived in this unique learning environment. Student work demonstrated more creativity and depth than in the more teacher-centered iteration of the course. The needs of individual students were better met. Students with learning challenges reported feeling for the first time in their school lives not being “yanked along” to catch up, while higher-achieving students described “feel free to go as fast as they wanted.” Both groups of students had been freed from the arbitrary constraint of teacher-imposed pacing (Ardito 2015).

Other types of open educational settings are being piloted, particularly in technology-rich areas as STEM (science, technology, engineering, and mathematics) and makerspaces (Martinez and Stager 2014) and efforts to bring computing programming into schools (Resnick et al. 2009), but much more work is needed to alter the expectations and norms of school administrators, teachers, parents, and students. As discussed above, education is a complex system, and its design must be altered for lasting change in the area of openness, particularly in primary and secondary settings.

An initiative that has probably had greater publicity than most is Sugata Mitra’s Hole in the Wall project (Mitra 2012). Recognizing the cost of effective teaching in India, Mitra hypothesized that children, given a network-connected computer, would be able to teach themselves. He reported that children apparently learned together how to use machines and attained learning not too far removed from that of children educated in schools. Though lacking theoretical foundation, his methods were to a large extent a physical manifestation of connectivist thinking. The children were not

teacherless – they had millions of teachers and, especially in their physical social groups, taught one another exactly as connectivism recommends, determining their own goals, forming physical social networks, and inventing open pedagogies. Unfortunately, Mitra’s excitement was a little premature, and the holes in the wall are now exactly that, victims of vandalism and neglect. Without focus, without role models, without protection from bullies and overdominant children, and above all without the enthusiastic observation of excited researchers, the system proved not to be self-sustaining. Mitra himself has moved on to run the SOLE (Self-Organized Learning Environment) project, which has led to mentors and guides in traditional schools, along with far more restricted access to machines, rather than the self-organization he originally sought, but that retains a similar learner-driven focus. As with our other examples, a hybrid of a high level of openness combined with a little structure enables open pedagogies to be used in otherwise traditional environments.

Barriers to Adoption

One of the most surprising barriers to adoption of open educational resources is resistance from teachers, with widespread perceptions that, despite all evidence to the contrary, OERs are of lower quality than closed content. It is certainly true that many OERs do not go through the same kinds of quality control processes of published content, nor are there many organizations dedicated to collecting and curating them. Good-quality resources can therefore be hard to find in a swamp of lower-quality materials. It is easy to see how teachers’ perceptions might be colored by this. Among the services publishers provide are that they market their goods well and do all that they can to provide teachers with relevant, targeted resources that have been through editorial processes. There is a need for a greater number of similar services for OERs, but, also, there is a need for a shift in culture. When teachers understand the value of being able to modify, remix, and adapt content and when that becomes a norm, OERs can offer a vastly improved experience for learners. When teachers share the improvements they have made with other teachers, the resulting OERs evolve to be ever-higher quality. This virtuous circle needs to be kick-started with intentional initiatives, at government and institutional levels. However, a much bigger barrier remains.

Mitra’s Hole in the Wall project and the OLPC initiative highlight one of the biggest barriers to openness of all: open, online learning is only possible at all with networked devices and access to services they provide. Online access is virtually ubiquitous in only a very few regions, and there are still billions of those that would most benefit from open education who have little or no access at all. While growth of Internet access continues unabated, with around half of the world’s population online (<http://www.internetworldstats.com/stats.htm> accessed 10th February, 2017), and prices of connections and devices fall daily, the digital divide remains a huge and pressing concern. Most benefits of open, online learning can only be achieved if everyone has access to their own device, which is anything but the case in even advanced economies like the United States, Canada, or Europe. It is frustrating that

many initiatives that might reduce that divide are cynical, commercially driven ventures. For example, Facebook's internet.org project – an attempt to bring wider access through free data services in developing countries – has been extensively and rightly criticized for being a closed service that primarily benefits Facebook, denies access to many open resources, and is aimed at locking in future customers. E-book readers might potentially offer access to vast libraries of millions of free books, papers, courses, and other content, paying for themselves in hardly any time at all, but are deliberately locked in and crippled by digital rights management and ever more publisher-friendly copyright laws.

Conclusion

Online learning (e-learning) has far fuzzier and less fixed boundaries than collocated learning (p-learning), even in its most classroom-like forms such as webinars. For most variations, including almost all MOOCs and all open educational resources, learners control the time, the place, and the pace (at least to some extent) of their learning. Even in synchronous online classes, learners always inhabit more than one space, each with its own distractions. Other online environments and communities are at most a click of a mouse away and may inhabit the screen simultaneously, and the distractions of the physical environment are ever-present. In truly open educational settings, learners may choose how they dress, how they behave, and how they react, without fear of censure. They may chat with others and, indeed, are often encouraged to do so. Cell phones are hardly ever banned in online classrooms. Content is more fluid, whether intentionally hyperlinked or not: features such as right-clicks for word definitions, copy and pasting to search Wikipedia or Google, and searchable (though not always easily browsable) content are the norm. The learner has, inherently, more agency than their p-learning counterparts. Given such advantages, it is not surprising that e-learning is a phenomenally successful form of intentional learning. From Wikipedia to Google Search to MOOCs to the Khan Academy to Lynda, not to mention vast amounts of learning shared on social networks, YouTube, SlideShare, Stack Exchange, Slashdot, and countless other social sites, e-learning is the dominant starting point and often the central motif for intentional learning among Internet-connected people on this planet. The affordances and shifted boundaries of e-learning are what gave rise to the theory of connectivism. It is precisely this combination of a surfeit of people and resources, easy connection, open availability, controllable engagement, distributed cognition, and fluid boundaries that the theory attempts to address, making it one of the first net-native pedagogical theories.

For all its strengths, e-learning (as already noted, especially in a connectivist tradition) does not fit well with patterns of teaching and learning designs that are made to work in a physical setting. In particular, extrinsic motivation loses much of its power when there is limited perceived social pressure, no requirement of attendance, no surrounding social safety net, and a limited sense of being part of a crowd. Simply transferring open pedagogies into a traditional educational setting is unlikely

to be universally welcomed and unlikely to fit neatly into a system that has evolved for over a 1000 years to prevent such anarchy. There are existing primary and secondary schooling models that would make more fertile ground, such as those found in schools based on the Summerhill model (Neill and Lamb 1995) or perhaps in Montessori or Steiner (Waldorf) schools. Such methods also have a significant growing role in homeschooling, where the benefits of a learning network beyond the home are particularly strong and the value of accessible, open educational resources and communities is unusually high. Movements such as unschooling, edupunk, and hacking education (Stephens 2013) are making waves of increasing importance, built on open access, open content, and open pedagogies, combined with open networks of learners and teachers that share a passion for learning and a willingness to break out of the closed cloisters of academic institutions.

There are some rich history and some current efforts to bring this type of open education (and its many benefits) into primary and secondary settings. Much of this work is promising, and it remains to be seen whether it can help change the norms and expectations of administrators, teachers, parents, and students. This work also suggests that new models and opportunities for learning and education can be explored within these types of open settings. We certainly hope that they can and will be used to that effect.

Abstract

This review is a major update of the chapter on online learning communities in K-12 settings in the first edition of this handbook. This chapter clarifies the concept and boundary of online learning communities, identifies major trends

of research, and suggests pertinent issues for future research. Four established online learning communities, which have sustained for more than a decade and are supported by research, are reviewed on their changes and evolutions over the last decade. They include Knowledge Building Communities, Quest Atlantis, Virtual Math Team, and Web-Based Inquiry Science Environment. The success of the intended design principles and characteristics of these learning environments are evaluated along the cognitive, social, and technological dimensions. Two emergent online learning community platforms, Canvas K-12 and Brightspace, are also reviewed. These platforms make use of emerging technologies such as social and interactive networking, which are new trends that online learning communities are gravitating toward. Potential issues surrounding K-12 online learning communities are discussed. These issues include infrastructure, culture and practices of school teaching and learning, development and assessment process of authentic knowledge, usage and ethics of learning analytics, and possibilities and impact on education due to advances in technologies.

Online learning communities · K-12 · Cognitive dimension · Social dimension · Technological dimension

Introduction

The pervasiveness of technological innovation and usage in this digital age has provided affordances for online learning communities to take on multiple structures and forms. The turn of the century has also seen previously emerging technologies becoming mature and stable, and these technologies are gradually integrated into larger and scaled-up learning systems. Historically, online learning communities started with the introduction of the World Wide Web (WWW) by Tim Berners-Lee in 1989, which provided an information space for hosting resources that are accessible through the Internet. Consequently, communicative and physical barriers between communities are constantly being broken down, and the way in which people connect is changing dramatically. Networking technologies have also brought communities, especially online communities closer together, and it has significant impact on K-12 students' learning. It is a timely development for twenty-first-century learning where students are required to develop knowledge-creation competency and integrate knowledge innovation with digital literacy, which are critical skills for individual's growth and contribution to new economies (Anderson 2008). There is a need to look at the presence of cultural will to "live for work" (Cooke 2002, p. 1), which entails capabilities of learning and innovation as key economic instruments that are at the heart of the *knowledge society*.

With the advancement of technology, K-12 learning communities are continuously embedding different forms of technologies and tools within the learning environment to nurture desirable attributes within students. Online learning communities have gradually shifted away from the mindset of using digital technologies and

platforms just to transfer and distribute learning resources; teachers, with their modus operandi of teaching, have realized how the affordances of technologies can provide alternative methods of achieving learning objectives with greater efficiency and effectiveness. As an emerging field of study that has garnered more attention over the last decade, this review aims to highlight the changes and improvements to four established online learning communities and seeks to examine the emergence of newer online learning communities in the context of innovative technological advancements, changing perspectives, and cultural practices.

This review is organized around the following questions:

1. What technologies have been introduced over the last decade that could be used to establish and sustain online learning communities?
2. Are the established online learning communities – Knowledge Building Communities, Quest Atlantis, Virtual Math Team, and Web-Based Inquiry Science Environment – successful in their intended goals? Are there changes in their themes of research or have the direction of communal learning been modified?
3. What are the emerging online learning community platforms and how are they different from the four established communities?
4. What are the potential research and practical implementation issues that might surface and need to be explored?

Disruptive Technologies in the Past Decade

Educational technologies have advanced beyond the initial prototyping stages of development and matured into stable products, platforms, and media that provide students with endless opportunities for learning and sharing of knowledge (Dede 2004). Newer disruptive technologies have since been developed, after the introduction of the World Wide Web (WWW) in 1989 and the Internet in the mid-1990s. The semantic web was developed to allow common data formats to be shared and exchanged across the Internet, with the semantic web markup becoming a mainstay in millions of web domains (Guha 2013). Search engines (e.g., Google, Yahoo) are game changers that provide users with accessible and efficient methods in searching for information. While the first generation of websites, or Web 1.0 sites, are useful for providing access to data on the web throughout the community, they constrain most users to passive viewing of content. Web 2.0 websites, on the other hand, encourage interoperability and user-generated content, thus allow users to interact and collaborate with one another and create opportunities for easier formation of online communities.

Disruptive and influential technologies are subsequently built on top of the abovementioned elements. Internet-based encyclopedias such as Wikipedia, which was introduced in 2001, provide knowledge sources that culminate from users' contributors and moderation. Social media platforms such as Facebook (founded 2003) and Twitter (founded 2006) have also changed the landscape of how information can be propagated through the Internet and how information can be virally shared through social networks. These technologies provide mechanisms and means

for inter-user interactions within and outside of users' communities, while the technology providers play the sole purpose of hosting user-generated information. Social technologies, in the form of blogs, wikis, and social networks, are breaking down traditional organizational walls and allowing the establishment of newer communities that encourage user's contribution of content. The method of presenting and archiving of knowledge has also been enhanced, as exemplified by the way media is presented and distributed through blogs (e.g., Blogger) that is archived in cloud storage. Together with massively scaled-up media distribution platforms such as YouTube (founded in 2005), cutting-edge technology is constantly pushing the envelope in which online learning is occurring in K-12 settings.

The communities that are forged online through social technologies are self-sufficient in generating, sharing, and building of knowledge within their communities, as the participants take on the agency to share and distribute knowledge that is of both individual and communal interests. However, new mindsets and epistemologies (Lim et al. 2010) are needed to leverage these social technologies for participatory learning rather than the acquisition of knowledge (Sfard 1998). Hence, time is required to overcome cultural resistance and early failures. The trend of facilitating social interactions among learners and encouraging learner's agency can also be felt in more traditional technological platforms. By making use of robust and mature technology in developing online platforms and creating new social networks, learning management systems (LMSs) have seen prevalent usage in schools and institutions. LMSs that were once used mainly for the management of learning have been enhanced to enable social collaborative learning.

Another novel online creation is the massive open online courses (MOOCs) that aim to provide open access to courses and content to online learners via the Internet. Stand-alone online courses provided through individual delivery platforms started gathering a critically large number of users, and the major service providers such as edX, Coursera, and Udacity began associating themselves with institutions to host MOOCs across the world and deliver content to large numbers of interested learners in their respective physical locations.

With the emergence of LMSs and MOOCs, it is not surprising that companies create products and learning platforms that appeal to the broad masses of learners by populating their platform with a wide range of topics that learners will be interested in. Also, the increasing prevalence of mobile learning technology means that learners could now learn at different locations and contexts, while learning designers focus on the learner and learning process (Sharples 2006). Learning on demand and consuming knowledge in bite-sized lessons could, therefore, shape the future of learning for students (Armstrong and Sadler-Smith 2008).

These technological advancements have ramifications for K-12 education through platforms that could potentially support deep learning among learners and afford efficient teaching and management on the teacher's part. For example, harnessing the power of learning analytics, teachers could track students' learning progress and class performance through indicators in LMS or MOOCs and decide on relevant actions, such as paying more attention to specific students who might require assistance or providing formative feedback promptly to rectify

misconceptions. Also, students are able to follow their interests and choose to participate in the online communities that they are comfortable with.

Defining Online Learning Communities

Since inception, online learning communities have been labeled by researchers as Virtual Learning Communities (Henri and Pudelko 2003) or Cyberspace Classrooms (Palloff and Pratt 2001). Online learning communities are tangible entities that are used to express desired characteristics of learning communities, formed through the mutual shaping of the community and the identities of its members, as the community progresses toward shared learning goals (Khoo and Forret 2015). The concept of an online learning community can be explicated by examining each of the three terms: *community*, *learning*, and *online*.

As a *community*, an online learning community is a cohesive social entity where members are connected in mind (McMillan and Chavis 1986); this *sense of community* has four sociological dimensions, namely, membership, influence, integration and fulfillment of needs, and shared emotional connection. A community is and must be inclusive, requiring commitment and consensus among members (Peck 2010). Interaction among community members helps develop mutual influence and trust upon each other while fostering a sense of communal identity and belonging that helps define the boundaries and criteria for membership to the community. Being able to identify oneself within the community allows individuals to contribute to the community and, conversely, to be influenced by the community. Cultures and norms within the community provide the fulfillment of needs for individuals and simultaneously reward and reinforce their practices. A community is, therefore, both a system and a process where diverse human needs such as survival, socialization, and sense of identity can be fulfilled.

As a *learning* community, an online learning community is a Community of Learners (CoLs) that aims to instill and foster deep disciplinary understanding of both subject matter and ways in which the disciplinary community works with knowledge within a certain domain (Bielaczyc et al. 2013). Four characteristics of a learning community were identified (Bielaczyc and Collins 1999), namely, shared objective of advancing collective knowledge, diversity of expertise among members, emphasis on learning how to learn, and the mechanism for sharing what is learned. A learning community has a “culture of learning such that everyone is involved in a collective effort of understanding” (Bielaczyc and Collins 1999, p. 271). The common goal of learning entails sharing “a set of knowing, a set of practices, and the shared value of the knowledge that these procedures generate” (Riel and Fulton 2001, p. 519). The participating members of the community are valued for the knowledge they possess as an individual with their desire to learn within the community to achieve the common goal of learning. By collectively working together to engage in inquiries or conduct investigations, both learners and the community as a whole develop social capabilities in learning how to learn, and knowledge can be constructed through involvement in the community’s shared values, beliefs, languages, and ways of

doing things. In short, members in a CoL are “socialized into the world of knowledge” (Bereiter 2002, p. 220). For CoL to be successful, community members have to be organized around a structural dependence principle. “Frequently, the students do not have a clear picture of where and how they fit into the school experience” (McCaleb 2013, p. 49), which often results in school failure and dropouts. In forming the CoL within K-12 settings, “the community should be organized such that students are dependent on other students’ contributions in some way. It is important to have a valid reason for students to work together that makes sense to the students, such as common task that requires joint effort” (Bielaczyc and Collins 1999, p. 288).

Within an *online learning community*, technologies are used to support the service of learning, with the distinct characteristic of embedded pedagogical support in the software. Examples of such technologies include Knowledge Forum (Scardamalia and Bereiter 2003), Collaborative and Multimedia Interactive Learning Environment (CaMILE), Scaffolded Multi-user Integrated Learning Environment (SMILE) (Guzdial et al. 1997), and Future Learning Environments 3 or FLE3 (Muukkonen et al. 1999). These are called computer-supported collaborative learning (CSCL) technologies. With the affordances generated by cutting-edge networking technology integrated with educational practices and pedagogies, platforms that were previously only used for hosting and informational viewing have been transformed into user-friendly and interactive interfaces. Users can draw on and contribute diverse opinions and views, as part of the process of forming an inclusive and interactive online learning community. Accessibility to online courses has been enhanced due to newer technologies that support massive open online courses (MOOCs) in tertiary institutions and universities (e.g., Khoo and Forret 2015), which are also increasingly being offered to K-12 schools and classrooms (e.g., Manlove et al. 2006). Novel technologies are also developed in conjunction with the integration of modern hardware and software, such as the Zydeco application, a context-aware platform, that allows mobile devices to integrate and share multimedia resources for students and their peers to review. Zydeco can be used for supporting knowledge claims (Cober et al. 2015) or supporting student inquiry during collaboration (Kuhn et al. 2010).

Review of Established Online Learning Communities in K-12 Settings

This section summarizes studies on four established online learning communities, namely, Knowledge Building Communities (KBC), Quest Atlantis (QA), Virtual Math Team (VMT), and Web-Based Inquiry Science Environment (WISE). These communities are chosen based on the following criteria: learning in K-12 settings, usage of the computer network as a mediation tool, and evidence of a design effort toward fostering a sense of community. Both formal and informal learning, as well as online and blended environments, are considered, but studies based on ad hoc groups displaying no evidence of effort toward fostering a sense of community are excluded. These online learning communities are evaluated with respect to their

intended goals, research themes being pursued, the direction of communal learning, and circumstances that lead to changes.

Knowledge Building Community

A Knowledge Building Community (KBC) consists of learners with shared common goal in advancing knowledge of the group, and learning is intentional and collaborative. Pioneered by Scardamalia and Bereiter (2003), knowledge building involves “the production and continual improvement of ideas of value to a community, through means that increase the likelihood that what the community accomplishes will be greater than the sum of individual contributions and part of broader cultural efforts” (p. 1370). In contrary to traditional teacher-led instruction, teachers in a knowledge building community play the role of cocreating knowledge together with students, instead of being the sole authoritarian source of information within the classroom. Over the years, KBC has grown, with the development of Knowledge Building International (KBI) (<http://www.ikit.org/kbi>) that is dedicated to research and practice of knowledge building and the launch of a multinational design research project called Building Cultural Capacity for Innovation (BCCI) (<http://www.ikit.org/bcci>). The project is dedicated to the twenty-first-century principle of knowledge for public good and seeks to provide a place for everyone in the knowledge society. As part of the online learning community, knowledge building channels students’ efforts toward solving authentic societal problems to serve the community.

1. *Cognitive dimension.* The central principle of knowledge building is idea-centric learning that starts with students putting their ideas in a shared space (e.g., discussion boards, online forums). Students’ ideas become shared objects of inquiry to be discussed, revised, built upon, and superseded. Cognitively, students are engaged in knowledge building discourse aims at co-construction of knowledge backed by evidence, while taking collective responsibility in idea improvement. It entails deep learning and higher-order thinking such as metacognition. Recent developments have provided students with avenues for indicating their perspectives of opinions and highlighting portions of discourse that are deemed promising, so that more promising ideas can be further discussed and developed. Recent studies have reported success in improving student learning within K-12 settings (e.g., Zhang and Sun 2011).
2. *Social dimension.* KBC encourages users to use Knowledge Forum (<http://www.knowledgeforum.com/>) as a platform for learners’ views and opinions to be shared and viewed by the community members so that learners’ ideas can be built on and developed further. The increased online visibility invokes more interactions between learners, and the success of the KBC highly depends on the establishment of socio-cognitive norms and values that members of the community are aware of and strive to work toward. Within KBC, the renegotiation of institutional power (Tan and Tan 2006) is needed to foster greater student responsibilities for their learning. Recent studies have shown that students in KBCs have taken initiatives as leaders within their communities to lead the group

at different points in time of discourse (Ma et al. 2015). Rotating leadership seems to be an emergent phenomenon of knowledge building, with the potential to be an indicator of collective cognitive responsibility.

3. *Technological support and infrastructure.* The general interface of Knowledge Forum has been largely the same with the stable version of 4.8, but more recent updates (versions 5 and 6) have integrated newer analytical tools with a more vibrant look and feel that appeal to students. Templates with customizable scaffolds are provided to facilitate knowledge building discourse. The introduction of the *Promising Ideas* tool allows peers to highlight part of a discourse and append reasons that the highlighted ideas should be pursued further. These added features of the technological platform encourage idea improvement by allowing time-efficient reviewing of notes and encouraging users to efficiently synthesize and summarize ideas at a higher level of understanding. With a wide range of Web 2.0 tools and emphasis on learning analytics, researchers have also provided additional analytical tools to understand further forum discourse. Examples include the temporal analysis of discourse using social network analysis with KBDeX (Oshima et al. 2012) and the identification and analysis of ideas within discourse using keywords (Lee et al. 2016).

Atlantis Remixed (Rebranded from Quest Atlantis)

Atlantis Remixed (ARX) project (<http://atlantisremixed.org/>), previously known as Quest Atlantis, is now supported by Arizona State University. ARX is a three-dimensional multiuser virtual world that incorporates strategies of online gaming and narration, targeting learners aged 9–16. The design of ARX combines academic concepts and meaningful play with disciplinary practices to help students develop the triadic foundation of *education, entertainment, and a set of social commitments*. With the rebranding of QA to ARX, QA storyline has also changed. Participants, called *remixers*, are provided with the opportunity to direct their learning and to conduct meaningful work in a playful environment, through socialization efforts with other participants from around the world and through engagement in ideas using in-game structures. ARX's user base has expanded to over 100,000 children in 18 countries.

1. *Cognitive dimension.* ARX is designed based on a participatory framework that emphasizes action and reflection as central components of learning. Three elements are prominent within the game: *quests, missions, and units*. These elements help connect students to academic standards, social commitments, interrelated tasks of multiple learning opportunities, and are designed to provide authentic, engaging, and meaningful learning experiences. Students travel through worlds and villages in Atlantis to solve real-world, inquiry-based challenges; such experiential game-based learning encourages students' self-directed learning. Recent studies have shown a positive impact on students regarding gains in literacy, persuasive writing, and engagement (Arici and Barab 2013). Game tools and scaffolds are added in the revamped environment so that students

can act “a head above” with their current literacy capabilities, and teachers provide in-game formative feedback as the *editor*.

2. *Social dimension*. ARX maintains the goal of fostering social commitment and providing students with a safe and protected environment for learning. ARX remains committed to empowering individual students and communities to foster social commitment via seven principles, namely, personal agency, diversity affirmation, healthy communities, social responsibility, environmental awareness, creative expression, and compassionate wisdom (Barab et al. 2004). As an environment that hosts the online learning community, ARX has extended its support in classrooms by offering help to students on ways to navigate the virtual world and ways to interact with peers and teachers within the context of the learning through the game (Thome 2014).
3. *Technological support and infrastructure*. The virtual world of Atlantis in ARX can be accessed using a client web browser to display content and connects users via the Internet. A remote host server stores the resources and connects the participants. The virtual world consistently underwent multiple versions of content and visualization changes, but the core element of massively multiplayer online games (MMOG) ensures that it is capable of supporting a large number of learners simultaneously. Students are continuously rewarded for good play, and the advancement system ensures there is a progressive acquisition of knowledge and sustained participation in ARX.

Virtual Math Team (VMT) Project

The VMT project (<http://vmt.mathforum.org/VMTLobby/>) started in 2002 and is still active in 2017. It provides an online synchronous environment where students around the world can gather in teams to engage in deep conceptual mathematical reasoning (Stahl 2009). VMT is an extension to the regular suite of interactive math education services (e.g., The Problem of the Week, Ask Dr. Math) offered in The Math Forum, and it is also an expansive resource for the improvement of mathematics learning, teaching, and communication (Virtual Math Team n.d.). The Math Forum is a center for mathematics and mathematics education on the Internet (<http://mathforum.org/about.forum.html>) that started in 1992 at Swarthmore College. Funded by the National Science Foundation, it started as the Geometry Forum, and later evolved into The Math Forum in 1996.

1. *Cognitive dimension*. The VMT project has three primary goals: to develop and provide stimulating online mathematics learning for student teams around the world, to play the role of educational technology designers that foster mathematical discourse and collaborative knowledge building, and to understand the nature of team interaction during discourse within the online learning environment (Stahl 2009). The online learning environment consists of different discussion chat rooms to meet the demands of various situations and requirements, and such flexibility encourages learners to be active members of a math-discourse virtual

community, that in turn helps to grow the community. To determine cognitive effects of using assistive tools within VMT, the system included a Replayer tool that can trace a student's learning session. This allows researchers to review the student's interactions with the tools and observe what was displayed to the student when solving mathematical problems (Weusijana et al. 2010). By making mathematical thinking visible and analyzable within a session, it is possible to analyze how students construct solutions and reason in the joint problem space (Sarmiento and Stahl 2008).

2. *Social dimension.* To encourage ownership among students, VMT allows the students to establish social practices that structure the behavior of participants, but it also attempts to define expectations about how the informal learning space could be used (Virtual Math Team n.d.). Over the years, VMT strives to supplement small group's experiences of VMT chat and incorporate adaptable and personalizable interactions (Virtual Math Team n.d.). Collaborative knowledge building is fostered through math discourse among the users, and the online learning environment set up within VMT provided ample affordances for social interaction among the participants. The need to monitor and observe students is necessary for effective mentorship, and the process was enhanced by the addition of whiteboards that allow mentors to provide feedback synchronously.
3. *Technological support and infrastructure.* From the initiation of VMT, some tools that support learning and communication – such as textbox, whiteboard function, chat log, and referencing tools – were made available. Previously, only the textbox is synchronous. The team at VMT has been making major updates to their toolkit in recent years to implement a multiuser synchronous dynamic mathematics whiteboard to improve inquiry of mathematical disciplinary content (Weusijana et al. 2010). In addition to the original whiteboard's history and chat referencing feature, the newer whiteboard function uses the open source GeoGebra system (<https://www.geogebra.org>) to provide a dynamic shared space for drawing mathematical objects and graphical representation of the problem, as well as the added functionality of importing and exporting worksheets. Users can make use of saved worksheets to build on their peer's work; newcomers can also pick up from where other students have left off in the previous sessions of the problem-solving process.

The Web-Based Inquiry Science Environment (WISE)

The latest version of WISE Virtual Learning Environment (<https://wise.berkeley.edu/>) is a web-browser-based environment that affords (1) free customizable curriculum projects on topics central to science standards and (2) guidance for teachers on how Internet-based projects can assist improvements in teaching and learning within Grade 6–12 science classrooms (Slotta and Linn 2009). Through WISE, students have access to real-world evidence from the Internet and will be able to engage in exploration of authentic scientific controversies (Raes et al. 2012). A large user base of over 15,000 teachers and over 100,000 K-12 students have participated in WISE projects, and findings over the years on curriculum and assessment have culminated

in effective models of professional development that enable effective implementation and practices of science inquiry within classrooms.

1. *Cognitive dimension.* Premise on socio-constructivist approach of learning (Vygotsky 1978), WISE provides prompts as scaffolds to support students in self-regulated learning; this important feature in WISE has seen increasing usage (Bannert 2009). As Internet resources are fundamental to WISE projects, students learn to use online resources critically and productively to elicit ideas and to deepen their understanding of a topic (Linn et al. 2003). By making science visible and accessible with technological enhancement and a better user interface, students can learn from one another and develop skills in conducting scientific inquiry and learn to be active contributors to the scientific enterprise.
2. *Social dimension.* Apart from tools such as asynchronous discussions and anonymous contributions that encourage students to interact, critique, and learn from one another, tools such as *Idea Basket* provide persistent space for students to collate and sort multimedia information. Students can use the *Explanation Builder* to formulate arguments using evidence from the *Idea Basket*. The provision of animation tools *WISE Draw* and the *Flipbook Animator* allows students to represent their arguments by creating drawings, diagrams, or animation; students can playback their flipbook-style animations to illustrate concepts or processes that are better explained in animation. Arguments can be translated into various representational formats so that students, who have different explanatory theories and perspectives within the discussion groups, can engage in scientific arguments and work toward achieving a consensus.
3. *Technological support and infrastructure.* Versions 4 and 5 of WISE were introduced in recent years with significant technological updates. For example, the real-time functionalities in WISE afford new kinds of student interactions such as adaptive navigation and provide support for displaying content on mobile devices. Real-time communication has been integrated across tools such as the *Classroom Manager* and student project interfaces so that automated assessment and feedback tools can generate real-time alerts and scaffolds. Student learning process is further improved through timely feedback with greater communication efficiency between teachers and students, while greater accessibility of content is achieved through porting of content onto mobile devices, which allows greater visibility of content and feedback.

Emerging Studies of Online Learning Communities in K-12 Settings

In recent years, a new trend emerged in the use of learning management system (LMS) technologies for online learning communities in K-12 settings. These online communities exhibit the following characteristics: (1) use of technological platforms with adaptive tools that are accessible, user-friendly, and simple to adopt by teachers and students; (2) shift away from traditional teacher-led instruction to become student-focused, while preserving the goal of learning; (3) ability to host both

student-initiated and teacher-provided content and assist teachers in designing and delivering instruction using customizable interfaces for various learning needs; and (4) provide built-in analytics and indicators that monitor student learning progress and provide real-time functionalities for discussion and feedback. For illustrative purposes, two emerging online learning communities that possess the features mentioned above are reviewed, while we acknowledge the presence of other systems such as Blackboard Learn (Bradford et al. 2007).

Canvas K-12

Canvas (<https://www.canvaslms.com/k-12/>) is a cloud-based LMS set up by Instructure (<https://www.instructure.com/>) that is based in Utah; the company also developed a MOOC platform named Canvas Network. Canvas K-12, designed especially for elementary and secondary schools, was launched in 2012. It is well known for its ease of use and adoption by communities, mobile-friendliness, and alignment to the pedagogical principle of student-centered learning.

1. *Cognitive dimension.* Canvas K-12 adopts an expansive view of student-centered learning by examining how better teacher-student relationship can help to develop students to be confident and self-directed learners adaptable to the knowledge society. In Canvas K-12, even though teachers still hold the authority in identifying the majority of content that has to be learned, students have the autonomy in choosing when and where to study and are encouraged to reflect on their learning habits. By encouraging students to learn based on their intrinsic motivation and interests, students assume more responsibility for their learning progress and pacing. Teachers are also able to monitor the learning progress to provide timely feedback or to incorporate new ways of engaging students in activities that foster productive learning habits.
2. *Social dimension.* Canvas K-12 seeks to provide and encourage interactive learning through their LMS platform. Teachers can design interactive digital materials that encourage meaningful interactions between teachers and students and among the students. Small group discussions can be set up for peer learning, including practices such as *peer tutoring*, *reciprocal teaching* (students take control to learn a new material and to teach their peers), and *cooperative and collaborative learning* by working on shared documents.
3. *Technological support and infrastructure.* The peer learning capabilities built into Canvas K-12 allow students to work together flexibly, be it ad hoc discussions or structured lessons for reviewing lessons or preparing for examinations. Students can drop in or leave discussion groups whenever there are consultation lessons arranged by schools, participate in synchronous tutoring if required, or engage in asynchronous discussion. Tools such as actionable analytics are also available for teachers, which help to relieve their workload of conducting an individual analysis of students. As reciprocal teaching only with text might risk losing a sense of humanness and personability (Graham 2006), Canvas included audio

and video modalities as options to help students retain connections on personal levels and also enhance their sense of community (Borup et al. 2012).

Brightspace

Brightspace, formerly known as Desire2Learn, is an integrated learning platform that provides support for competency-based education (CBE). It provides e-Portfolio tools for students and assists teachers through the provision of learning analytics and cross-platform support.

1. *Cognitive dimension.* Brightspace is designed to support CBE, where students learn to work on a single competency or a unit topic at a time. In CBE, students learn at their own pace to achieve the learning objective, while the teachers function as a facilitator. Upon evaluation and successful mastery of a unit topic, a student can proceed to develop other competencies within the learning space. Analytical tools within Brightspace can help teachers to assess and gauge the level of competency gained by students. For example, teachers can monitor students' progress in class and adjust their pace of learning or even allow students to skip certain topics if they can display mastery of these topics through quizzes and tests. Personalized e-Portfolio tool allows students to document their learning journey throughout courses.
2. *Social dimension.* Usage of *Brightspace Capture* allows teachers to create interactive events that help guide students toward achieving units' learning outcomes. Online collaborative tools such as video messaging and integrated social media profiles help to connect teachers, students, and peers beyond the classroom. Live polls can be run through Brightspace during lessons to keep students engaged and keep on task to achieve the learning objectives. *Brightspace Pulse*, a mobile app, allows students to participate in discussions between lessons, and information can be pulled from the discussions for the teacher to go over as a group in the next lesson. Students can create, add, and share interesting or personalized content in e-Portfolios and share it with their peers and teachers within their social networks. By working on the e-Portfolio, students can reflect on their accomplishments and use them as part of their social achievements outside of academic settings.
3. *Technological support and infrastructure.* The *Learning Repository* within Brightspace enables wide-scale aggregation of external resources onto a single platform, thereby saving teachers' time in designing courses and conducting searches through open educational resources (OERs) and other online digital libraries. Analytical tools such as *Success System* and *Insights* use data across the entire learning ecosystem to predict and determine evidence-based interventions that teachers can adopt in the lessons. Class-wide performance analysis is displayed with greater visibility on dashboards, together with individualized progress reports for students. Integrated and automated notifications can also provide teachers with timely alerts regarding learner activities and their progress. Also, learner activities can be tracked using *User Progress Tool* to determine

engagement levels of students, while activities can also be rewarded through automatic badging mechanisms.

Comparison Between Online Learning Communities and LMS-Based Online Learning Communities

The two newly reviewed communities (Canvas and Brightspace) are somewhat similar in their designs, goals, and purpose of existence and yet have their distinct characteristics when compared to the four established online learning communities. They are in fact LMSs enhanced with a wide array of social technologies to enhance their capabilities, which can appeal to students to contribute as a member of the community. The common characteristics between Canvas and Brightspace learning communities are discussed below, while the differences with the other online learning communities are summarized in Table 1.

1. Cognitively, like the established online learning communities, both LMS online learning communities base their tasks and activities on pedagogical principles, including student-centered learning and competency-based education. To encourage students to take responsibility for their learning, the online spaces are filled with abundant resources and scaffolds to support students as they interact with challenging tasks. Canvas K-12 provides an open platform where students decide on the best opportunity of learning based on their learning habits, while Brightspace uses mastery learning to help students achieve the competencies stipulated by teachers.
2. In the social dimension, the two emerging communities provide interactive environments in which individual students can seamlessly interact with the community during the learning process. With the affordances of network and

Table 1 Comparisons of the online learning communities

Established online learning communities (KBC, ARX, VMT, and WISE)	LMS-based online learning communities with social technology (Canvas K-12 and Brightspace)
Cognitive dimension	
Goals and tasks are grounded on theories and principles of learning; teachers play the facilitator roles	Learning tasks can be teacher-led or student-initiated, but the onus is on the students to determine suitable learning process and pacing
Social dimension	
Communities strive on the ability to share; the democratization of knowledge and enabling of students in purposeful contributions to the community	Focus shift from learning management to learning as smaller communities, such as groups and peer learning are set up to achieve the common learning goal
Technological dimension	
Leveraging technologies to achieve learning goals beyond face-to-face settings	Built-in learning analytics and synchronous functionalities to support immediate formative feedback

mobile technologies, interaction and learning can occur anytime and anywhere for the individual learner. For example, Canvas K-12 provides online spaces for small group discussion and peer learning, where students can participate at arranged time slots even when they are physically separated. Brightspace's mobile application allows the community to extend beyond the classroom, and students' customized e-Portfolios provide additional sharing and collaboration opportunities.

3. Technologically, algorithmic advances in machine learning coupled with educational technology have led to the development of learning analytics, which can provide advanced visualization of student data for actionable feedback. The two communities can provide insights for teachers (using Canvas graphic analytics and reporting) and also identify knowledge gaps and recommend content for students automatically (using Brightspace *LeadP*).

Pertinent Research and Implementation Issues

With the development of new technologies and enhancement of the established online learning communities, several pertinent research and implementation issues remain in this field of work.

Adaptation of School Infrastructures, Cultures, and Teaching and Learning Practices

There has been an increased emphasis on schools to include information and communications technology (ICT) within the educational setting, with the goals of enhancing the effectiveness of teaching and providing equity of access to education for all students. However, there are still barriers to the adoption of technologies, including costs and sustainability of implementing ICT, especially for schools with fewer resources and prevalent resistance to the adoption of technology. In schools where preparation for high-stakes national examinations takes top priority, it is understandable that teachers tend to revert to tried-and-tested method of traditional instruction in classrooms to achieve their goals, rather than exploring innovative approaches such as online learning communities. Nonetheless, there is evidence of increased usage of mobile computing devices, and students and teachers are increasingly exposed to more ways of connecting and situating their classroom community within the online learning environment. More schools are providing resources such as portable computing devices and are preparing students with the media literacy skills; these practices are conducive to the adoption of online learning communities. As schools begin to reap the benefits of increased participation within online learning environments, there is noticeably some effects of how current developments in technology such as MOOCs and LMSs have helped mold teaching and learning practices in the online communities to become more learner-centric and effective.

There are, however, some pertinent research issues that could still arise in the future, namely, (1) How can schools be better prepared for increasing systemic change due to increasing influence of educational technology that is integrated to facilitate implementation of online learning communities? (2) How would learning practices change and what are students learning from participation in online learning communities? (3) To what extent will the role of teachers change and how professional development could help teachers to transit from formal school settings to online learning communities?

Issues of Acquiring and Assessment of Authentic Knowledge

The participants within traditional classroom learning environments and online learning environments are often the same groups of students but with different learning behaviors and perceptions toward the respective learning environments. Therefore, when traditional learning communities in schools are perceived and criticized as inauthentic communities of practice, the same criticism also applies to online learning communities. As students are often motivated by the opportunity to solve real-world problems and prefer to learn by doing (Lombardi 2007), educators can introduce through the online learning environment authentic content, for example, replace mock-up scientific data with live sensory data, and provide problem-based activities closer to what practitioners for experiential learning. However, all efforts may be nullified if students are still being assessed based on multiple-choice questions and simple tests that only capture easy-to-measure low-level knowledge. There is a need to move away from standard assessment methods and adopt methods that integrate multiple forms of evidence. This evidence need not be limited to just statistics of clicks, views, and binary choices but could consist of qualitative observations and analysis of social interactions between students, the level of engagement within the community, and discourse between students, just to list a few examples. Thus, several issues remain: (1) In the pursuit of authentic knowledge, what entails authentic knowledge that schools can achieve and how could it be consistently acquired? (2) Through what measures could authentic learning be assessed and how could this be conducted?

Learning Analytics: Usage and Ethics

Learning analytics can assist understanding, visualization, and optimization of learning in educational environments. While it is a challenge to implement analytics within individual classes without technical help, most current state-of-the-art LMSs have integrated such capabilities into their platforms for ease of usage across the board. Learning analytics have thus far been used for prediction, personalization, intervention, and information visualization purposes, and these outcomes can benefit teachers and students in identifying knowledge gaps and possible areas

for improvement. The best analytical tools could pinpoint lapses and details that may be overlooked among the plethora of data available within online learning communities, but apart from automated feedback through the LMS, the implementation of interventions is still heavily dependent on the teacher. Thus, even though learning analytics might be a great assistance to the teachers, they need to understand the predictive and visualizations data to decide on relevant and meaningful interventions. Also, the abundance of data residing within the online learning communities has led to concerns regarding ethical data ownership and sharing (Slade and Prinsloo 2013). The ethical issues vary among different countries and cultures but inadvertently raise issues regarding trust in data collection processes and the role of humans in the process of research and sharing. Pertinent issues that need to be explored include the following: (1) In what ways could learning analytics be used effectively in improving student learning within online learning communities? (2) What are the skills required of teachers to be proficient in integrating learning analytics with lessons for effective teaching and remediation? (3) In what ways can ethics of collection, analysis, reporting, and accountability be governed and tracked by schools and institutes?

Technological Advances

Finally yet importantly, innovative technologies have never been more accessible to the consumers in many countries and economies, partly due to the integration and embedding of such technologies within mobile devices. Advances in social networks have connected learners to one another efficiently, and advances in technologies such as augmented reality (AR) and virtual reality (VR) continue to provide new possibilities for online learning communities. Even though VR have previously been used for learning purposes (Roussou et al. 2006), the availability and cost of hardware have been a major deterrence. This issue can be resolved with decreasing hardware costs and prevalence of mobile devices. It is currently possible to use such technologies to achieve challenging learning objectives such as emotional learning outcomes (Harley et al. 2016), which are new affordances yet to be leveraged in online learning communities. In addition, there is great promise for disruptive changes with the evolution of novel technologies such as the Internet of Things (IoT) (Gubbi et al. 2013), which refer to the embedding of electronics within everyday items to create *smart objects* that can be integrated with the physical and digital world for increased interactivity with learners. It is envisioned that the emerging IoTs can provide ubiquitous and context-aware learning. Pertinent research issues that could arise include the following: (1) What are the affordances of emerging technologies that could facilitate and not detract learning within online learning communities? (2) Are there novel learning outcomes that could be achieved through usage of newer technology? (3) How could online learning communities identify and develop themselves within new environments?

Conclusion

Online learning communities build on the foundation of communities of learners supported by networked technologies. The advancement in technologies has facilitated new mechanisms for increased inter-organizational and interpersonal connectivity. The ubiquity of the Internet has also provided affordances that were unfeasible in the past and opens up new frontiers for research and development in creating learning communities within online spaces. Intentional learning through social interactivity has remained as the main staple of online learning communities. This chapter has considered the design and implementation of online learning communities in the cognitive dimension, clarified the purpose and interactive boundaries of the communities in the social dimension, and considered how communities are technologically situated within the online spaces as part of a larger social and cultural framework. Four established online learning communities were examined, including Knowledge Building Communities, Atlantis Remixed, Virtual Math Team, and Web-Based Inquiry Science Environment. This review also took note of the key features and major revamps of these communities that were introduced to help keep the online learning communities relevant to the changing users and contexts. The fact that the four online learning communities are still thriving after more than a decade shows that the common pedagogical principles and intended characteristics of these learning environments are robust and appealing to sustain learners' interest in continuing their learning journey with the respective online learning communities.

On the other hand, the two emerging online learning communities show different characteristics. Mature and stable technologies help to take care of digitization of physical learning materials for online learning spaces, and new tools such as learning analytics and synchronous functionalities help to improve student learning. Emergent LMSs are increasingly providing useful features that could benefit educators and students. Teachers, with increased workload, can be assisted with regard to management of learning resources, while learning analytics provide timely alerts that remind teachers if students fall by the wayside during the process of learning. Student learning progress can also be archived and tracked for future references, and the analytics can augment understanding of the learning community or monitoring individual students. The new platforms can facilitate a shift from organizational and communal knowledge advancements to smaller communities of learning with a greater focus on student-centered learning processes. These changes can catalyze advancement of pedagogical and learning practices of teachers and students.

Research findings have shown the complexity and difficulty in establishing and sustaining online learning communities (Jacobs 2013). In this review, potential issues related to online learning communities are suggested, including infrastructural and sociocultural barriers to technology integration and practical issues from the ground regarding the implementation and assessment of authentic knowledge. In addition, the ethical issues that could arise from the usage of personal data has to be handled securely and in a steadfast manner to ensure confidence in the process of data handling and sharing by researchers.

Abstract

Blended, flexible, and personalized learning models are increasingly used to provide a more student-centered approach to learning. This chapter explores these models, and what current research and theory tells us about how to design these forms of learning. The aim of flexible and personalized learning is to meet the needs of student, with flexible learning focusing on how this can be done, and

personalized learning on the outcomes. A common approach to implementing either flexible or personalized learning has been to use blended learning; that is, learning that occurs both online and in-person. There are many different ways in which blended learning can be implemented, with an expectation that this will continue to expand as new technologies become available. This variation in the way blended learning can be operationalized make creating universal design principles difficult. Current approaches to designing blended learning aimed at delivering flexible or personalized learning largely draw on descriptive studies of blended learning, or on theories and lessons drawn from the online and face-to-face fields. It is also common for design principles to have come from the higher education literature, where more research on the use of blended learning exists. In designing for blended learning, both the physical and online environments need considered, as do the context in which teaching and learning is to occur, the desired pedagogical approach, and what technology is available. A critical part of the design process is to ensure that learning drives the use of technology, rather than the reverse. It seems likely that blended learning will continue be used to deliver flexible and personalized learning and more investigation into how blended learning can effectively deliver flexible and personalized learning in primary and secondary schools is needed.

Keywords

Blended learning · Personalized learning · Flexible learning · Student-centred

Introduction

Current rhetoric regarding teaching and learning has often focused on the needs of twenty-first century learners. While there is still debate regarding whether or not twenty-first century learners are, in fact, different from previous learners, there appears to be a general acknowledgement that the role of education has changed. No longer is education about providing students with skills for particular jobs, rather there is recognition that in their lifetime students are likely to be faced with jobs that did not exist when they completed their schooling. As such, the role of education is increasingly being challenged. The current emphasis tends to be on soft skills, rather than specific knowledge, and this has led to questions regarding how teaching and learning should occur.

For more than a decade, there has been a call for schools to rethink what they do, addressing the needs of diverse students (Alton-Lee 2003; Hipkins 2004), and preparing them for further study in a range of topics, and for work that may not yet exist (Darling-Hammond 2007). This can be summarized as a recognition that a more student-centered approach to learning needs to be adopted. There are numerous ways in which this can be realized and a number of terms for these approaches, including a focus on flexible and personalized learning. In adopting these approaches to learning, technology is often utilized, leading to an increased use of blended approaches to learning.

This chapter will explore these blended approaches to learning, focusing on their ability to provide flexible and personalized pathways to students. It will draw on literature from both the school and higher education sectors to explore issues associated with designing blended, flexible, and personalized learning. It will begin by considering flexible and personalized learning, before exploring the relationship between these and blended learning. Finally, information summarizing current knowledge in regarding to how to design blended learning that is both flexible and personalized will be presented.

Flexible and Personalized Learning

Talking about flexible and personalized learning is part of the rhetoric of teaching and learning in the twenty-first century. The focus of both of them is on the student; it reflects a move towards student-centered learning, where the teacher becomes a guide and support, rather than the director of learning and imparter of knowledge (Chandra Handa 2009; Hannafin et al. 2009; Pedersen and Liu 2003). This section will explore how these terms are defined in the literature, and how they related to one another.

Flexible Learning

The term flexible is likely to be familiar to anyone who understands English; it relates to variation. As the Cambridge dictionary (<https://dictionary.cambridge.org/dictionary/english/flexible>) explains, flexible means to be able to change or be changed easily according to the situation. Within education, it is a popular term; perhaps increasingly popular in today's rhetoric regarding the twenty-first century learner. What it means, however, in terms of teaching and learning, is less clear.

Discussions of flexible learning are not new; the term has been used with reference to higher education since the 1990s, and Collis and Moonen (2001) refer to it as “learner choice in different aspects of the learning experience” (p. 9). It was used with less frequency in the school sector but has been common for some time. In recent times, reference is made to the desirability of flexible learning without the provision of a definition as to what this entails. Further complicating the picture, the term flexible learning has also historically been used synonymously with distance education (Collis and Moonen 2001) and with alternative education models, used with students with special educational needs (Peters 2003).

The concept of flexible learning, while seemingly straightforward, is in fact very complex. Teaching and learning can be more or less flexible along a number of dimensions, and a number of areas within these dimensions. As Nikolov et al. (► Chap. 48, “Distance and Flexible Learning in the Twenty-First Century”) discuss in detail in their chapter in this book, these areas include the aims and objectives of what is studied, how this is studied (teaching and learning strategies), where it is studied (environment), and when it is studied (time).

Personalized Learning

Personalized learning, as with flexible learning, is not new. As with flexible learning, it is, on the surface, a simple approach to learning, relating to learning that is specific to individual students. While this is true, within the literature it is seen as encompassing a much more complex picture than this in terms of its approach to teaching and learning. A key issue is the differentiation between the process of personalizing learning and the state of personalized learning (Hargreaves 2006). This differentiation obviously impacts on the implications of the term for teaching and learning. In addition, the term is defined differently by different countries and/or researchers. This difference in definitions can be perceived both as problematic and advantageous; differences can make it difficult to understand the implications of personalized learning, while variations can also allow for different interpretations based on context (e.g., see Sebba et al. 2007).

Despite these variations in definitions, in general all users of the term appear to agree that it relates to student-centered or -controlled learning, with additional features being somewhat less consistent. For example, in New Zealand, personalized learning not only refers to student-controlled learning but also means they understand, own, and drive their learning, being co-designers of both their curriculum and their learning environment (<http://elearning.tki.org.nz/Teaching/Future-focused-learning>). In the United Kingdom, personalized learning refers not only to student ownership of learning but also makes reference to assessment and inclusion (Sebba et al. 2007). This is somewhat narrower than its original conceptualization, when Miliband (2004), the then United Kingdom Schools Standard Minister, identified the guidelines for personalizing education as including: needs assessment for learning and use of data and dialogue to diagnose every student's learning needs:

- The development of the competence and confidence of each learner through teaching and learning strategies which build on individual needs
- Presupposed curriculum choice which engages and respects students
- Demands a radical approach to school organization and class organization based around student progress
- Means the community, local institutions, and social services supporting schools to drive forward progress in the classroom (adapted from Peters 2014, p. 102)

This 2004 definition from the United Kingdom appears similar to a more recent United States of America definition (Jenkins et al. 2016, p. 3), which identified personalized learning as including the following elements:

- Instruction is aligned to rigorous college- and career-ready standards and the social and emotional skills students need to be successful in college and career.
- Instruction is customized, allowing each student to design learning experiences aligned to his or her interests.
- The pace of instruction is varied based on individual student needs, allowing students to accelerate or take additional time based on their level of mastery.

- Educators use data from formative assessments and student feedback in real-time to differentiate instruction and provide robust supports and interventions so that every student remains on track to graduation.
- Students and parents have access to clear, transferable learning objectives, and assessment results so they understand what is expected for mastery and advancement.

Common to definitions of personalized learning is the focus on student needs and ensuring that teaching and learning is focused on meeting these needs. There are also differences; the USA definition appears to focus on students gaining mastery and being prepared for college and careers, while the UK definition focusses more on the student being at the center of the process, with schools' and communities' duty being to support students in their learning needs.

Comparing Flexible and Personalized Learning

As identified, flexible learning focuses on variation in how learning occurs. Implicit in this is its purpose, which is to better meet the needs of students. As such, it shares the focus on the needs of individual students of personalized learning. Although the definitions of this vary, its key component on meeting the needs of students is shared. Where flexible and personalized appear to differ, then, is their focus; while flexible learning focuses on how to meet the needs of students, personalized learning focuses on the desired outcomes and identifies broad goals to guide how this might happen. Both flexible learning and personalized learning, then, are forms of student-centered learning, and indeed, at times the terms have been used interchangeably.

Student-centered learning approaches are usually contrasted with teacher-led approaches and are underpinned by a constructivist approach. This approach focuses on “the meaning-making activity of the individual mind” (Crotty 1998, p. 58). As the name suggests, students are central to a student-centered learning approach, with decisions about teaching and learning made with them, rather than the teacher or curriculum, in mind. It encompasses not only flexible and personalized learning but other approaches, such as problem-based learning.

What is clear is that whatever the focus on student-centered learning is, all aspects of the teaching and learning context need to be considered for it to be implemented effectively. The affordances of technology are such that a number of the conditions for flexible or personalized learning can be more easily met through the use of technology, meaning that the use of a blended learning approach is common.

Blended Learning

Given a long history of distance forms of education, and the newer and still well-established use of information technology to support teaching and learning, it is perhaps unsurprising that implementing both flexible and personalized using a form

of blended learning is increasingly popular. Blended learning has been common for some time in the higher education sector but is still an emerging approach in primary and secondary schools (Drysedale et al. 2013; Oliver and Stallings 2014), with the perceptions of its emergence dependent on how it is defined.

The term blended learning has been used in a variety of ways in the literature. For example, Lai et al. (2013) referred to blending formal and informal forms of learning. Generally, however, the term is currently being used to refer to learning that involves both online and face-to-face forms of delivery (e.g., see Alammery et al. 2014; Bailey et al. 2013; Delialioglu 2012; Drysdale et al. 2013; Ma'arop and Embi 2016; Vaughan et al. 2013; Worthen and Patrick 2015). The term hybrid learning has also been used to describe this mix of online and offline teaching (Allen and Seaman 2008). In discussing blended learning, emphasis is also often placed on the intended outcomes (Bailey et al. 2013) and pedagogy associated with it (Michigan Virtual University 2013; see also Alammery et al. 2014, for further discussion of blended learning). This pedagogical emphasis usually focuses on aspects of student control and the personalization of learning. A definition of blended learning that encompasses these key elements is that of Horn and Staker (2011). They explained that,

Blended learning is any time a student learns at least in part at a supervised brick-and-mortar location away from home *and* at least in part through online delivery with some element of student control over time, place, path, and/or pace (p. 3).

There have been a number of attempts to classify models of blended learning. In line with the SAMR (substitution, augmentation, modification, redefinition; see Cavanaugh et al. 2013; Puentedura 2009) model of using information technology to enhance education, Alammery et al. (2014, p. 443) identified three levels of use of online activities in their classification of blended learning models:

- Low impact: Online activities added
- Medium impact: Online activities replaced existing ones
- High impact: A new course is developed, utilizing both online and offline activities

Another similar classification is that of Bonk and Graham (2005, cited in McGee and Reis 2013), who identified blended learning models as enabling, enhancing, or transforming learning

Within the primary and secondary sectors, Staker and Horn (Christenson et al. 2013; Horn and Staker 2011; Staker and Horn 2012) have identified a number of different models of blended learning in primary and secondary schools. Initially they identified six models, reducing these to four after discussions with and feedback from those working in this area, with one model subcategorized to include four different subtypes. These four models are briefly described in Table 1.

These models show the dynamic in the blended learning area of research, as well as the common understanding that the main feature of blended learning is a

Table 1 Classifications of models of blended learning (based on Christenson et al. 2013)

Model	Key elements
Rotation	Students move between activities, including at least one that is online and one that is face-to-face. Movement occurs either on a predetermined schedule or as the teacher determines
Station-rotation	All students move between all activities, as identified previously
Lab-rotation	All students move between all activities, with these located in different physical spaces
Flipped-classroom	Students choose a time and place to receive much of their content, often in the form of videos, with face-to-face activities focusing on applying the content
Individual rotation	Students move between the activities, with the activities to be completed, and the timing of the movement between them determined on an individual basis
Flex	The majority of learning is completed online, although the teacher is physically present. The activities to be completed and the time spent on each are determined on an individual basis
A la carte	Students take a combination of face-to-face and online classes
Enriched-virtual	A school-based approach to blended learning where students do not attend a physical school on a daily basis, instead dividing their time between learning online and in a face-to-face environment

combination of in-person (the term “in-person” is becoming increasingly popular in the fields of K-12 online and blended learning, as the term face-to-face could be deemed to incorporate videoconferencing, where students are online and at a distance but still seeing their teachers and classmates) and online classes. In identifying and describing the models of blended learning currently being used, Staker and Horn (2012) noted that they expect this taxonomy to be further refined, as this relatively new field continues to develop.

These blended models are commonly used in courses that include distance elements but are less common in predominantly in-person classes. The exception to this is the Flipped Classroom Model, which has been gaining traction and attention in primary and secondary schools. This model is typified by students receiving the majority of their content at a time and place of their choosing, usually while they are alone, with in-class activities focusing on discussion about and application of this content (Christenson et al. 2013; <https://flippedlearning.org/>). This is often seen as flipping the traditional place of homework and in-class work. The underlying principle associated with this model is considering the most effective use of teaching and learning opportunities and utilizing the affordances of technology to implement them.

Advantages of Blended Learning

An obvious benefit of blended learning is that it can utilize the strengths of both online and face-to-face modes of learning (e.g., see Gerbic 2011; Schoonmaker 2014). In addition, as noted previously, a key benefit of blended learning approaches

is their ability to provide a more personalized and flexible approach to learning for students (Horn and Staker 2011). A number of learning advantages of blended instruction have been noted, with Oliver and Stallings (2014) summarizing these in their article exploring what teachers should know about blended learning. They noted that students gained skills and experience in managing their time, monitoring their own progress and success, and in self-motivation. Students also gained skills in using technology for learning and benefited from the ability to work at their own pace.

Research generally supports the claims made regarding the effectiveness of blended learning approaches (e.g., Alammery et al. 2014; Means et al. 2013; Murphy et al. 2014; Oliver and Stallings 2014). In their meta-analysis of published research that covered students of secondary age and older, Means et al. (2013) found that blended learning was more effective for students than face-to-face learning based on a comparison of effect sizes. This compares favorably to findings regarding online learning, with this meta-analysis supporting previous studies that have reported “no significant difference” between online learning and face-to-face learning (e.g., see Delialioglu and Yildirim 2008; Oliver and Stallings 2014).

As important, though, as identifying whether or not blended learning is more effective than alternative approaches to learning, is understanding what it is about these approaches that make them more or less effective. Blended learning approaches do not simply involve teaching and learning occurring in a mix of online and face-to-face environments but changes in what teachers and learners are actually doing. In general, they involve more learner-learner interaction and more resources than face-to-face teaching and learning (Means et al. 2013). As Powell et al. (2015) noted,

the importance of blended learning models [is] a significant shift toward optimizing and personalizing learning for each student. Digital content is only one part of the equation, albeit an important one, and the focus should be on the *shift in instructional models toward student-centred learning* (p. 15, emphasis in original).

Designing Blended, Personalized, and Flexible Learning

To date, there is limited research exploring the effectiveness of the different models of blended learning, particularly at the primary and secondary levels (McGee and Reis 2013; Shand and Glassett Farrelly 2018). What is clear is that blended courses need to be carefully designed.

As Means et al. (2013) noted,

[the] meta-analysis findings do not support simply putting an existing course online, but they do support redesigning instruction to incorporate additional learning opportunities online while retaining elements of face-to-face instruction. The positive findings with respect to blended learning approaches documented in the meta-analysis provide justification for the investment in the development of blended courses (p. 36).

The care needed in designing a blended course needs additional consideration if it is also to meet the requirements of being flexible and or personalized.

Many of the design principles being used in primary and secondary schools have come from the higher education literature, where the majority of studies relating to blended learning are situated (Oliver and Stallings 2014). While there are certainly lessons that can be learned from higher education, and parallels between higher and compulsory education, there are also key differences. The nature of primary and secondary school students, and the contexts within which they and their teachers work, differ in several key ways from students and teachers in higher education (Drysdale et al. 2013).

A number of researchers have worked to develop design principles for blended learning. In general, these are based either on theories and principles related to teaching and learning, or to technology use and online learning. Theories of blended learning (see Table 2 for an overview) have been developed based on the constructivist theories of cognitive apprenticeship and anchored knowledge in authentic situations (Abdelaziz 2012; the Four Dimensions Instructional Strategy) and on the work of Vygotsky (Béres et al. 2012; the CECIP model). In contrast,

Table 2 Examples of theories of blended learning and their key elements

Model	Key elements
Four dimensions instructional strategy (Abdelaziz 2012)	Instructor as coach Instructional strategy has four dimensions: “Designing a shared vision, developing a shareable e-learning task, delving learning through scaffolding and distributing learning through salvaging students’ knowledge” (p. 227)
CECIP (Béres et al. 2012)	Project based online collaborative student-centered learning model Collaboration – Evaluation – Critical thinking – Individual assessment – Learner profile (capitalization indicates origin of acronym) Begin by understanding who the learners are and ensuring they know one another Utilizes group, individual, and project work Achievement of learning goals assessed based on Bloom’s taxonomy Everyone involved in the evaluation of material and students’ attitudes and development
Complex adaptive blended learning system (Wang et al. 2015)	Based on the complex adaptive systems approach developed in science disciplines, treating learning as a complex system. Explores the relationships between the learner, teacher, content, technology, learning support, and the institution
Co-evolutionary framework (Davis et al. 2013; Zaka 2014)	Utilizes an ecological perspective Classroom was viewed as nested within the school, district, region, and nation, with teachers as the “keystone species”; with change not occurring until they were impacted

Wang et al. (2015) argued for the use of a complex adaptive systems approach to understand blended learning. Other researchers have focused on principles and theories related to the use of technology in teaching and learning in general (Davis et al. 2013; Zaka 2014; a co-evolutionary ecological model).

Work by Halverson et al. (2014) identified a number of other blended learning design models within higher education. In their thematic analysis of blended learning research from 2000 to 2011, they identified 19 articles, books, or book chapters related to theories or models of blended learning. Of these 19, only 2 pieces of literature used the same theory, which was Garrison and colleagues' (e.g., Anderson et al. 2001; Garrison et al. 2010) Community of Inquiry framework. They noted while diversity has its benefits, "theories and models should be driving the conversations in the domain of blended learning, providing the language and variables around which those conversations coalesce" (Halverson et al. 2014, p. 28). As the models described in Table 2 are all additional to those identified by Halverson et al., it is clear that researchers in this field still have some way to go before this can occur.

A key difficulty in identifying best practice in terms of designing blended learning is the number of ways in which online and in-person activities can be blended. While much is yet to be agreed upon in terms of how best to design blended learning so that it promotes flexible and personalized learning, as shown by the number of models and theories currently being used, there is agreement about some aspects.

In general, it is recognized that designing blended learning is more complex than other approaches, because of the need to consider not only issues related to face-to-face teaching and learning, but also issues related to online learning, and how to combine the two in ways that ensure the two work to complement one another, providing students with an enhanced experience (Bailey et al. 2013; Oliver and Stallings 2014). Despite being utilized for over a decade, there is currently no one accepted design process or principles of best practice. A number of researchers have, however, identified design processes and/or principles based on multiple case studies or literature reviews. For example, based on multiple case studies of blended learning in primary and secondary schools, Powell et al. (2015) noted that although the schools used different models of blended learning, four key lessons emerged. Firstly, they noted the importance of the school culture. The importance of school culture has previously been identified in terms of implementing change, such as the integration of information technologies into learning (e.g., see Gunn and Hollingsworth 2013; Neyland 2011), so it is perhaps not surprising it is also a key to successful implementation of blended learning. They noted that the school culture had to not only be open but also committed to change and to ensuring that the learning approaches used reflected current research on learning, particularly in terms of effectively personalizing learning. Knowing why they were using blended learning, understanding it as a vehicle for personalized learning, was also seen as key. As part of this, they needed to work with students to ensure they knew how to make the most of this environment. The third key Powell et al. identified was ensuring staff received ongoing professional development; ideally in the form of blended, personalized learning, so they gained experience of the model while also learning about

it. Finally, they identified a number of barriers to implementation. Many of these related to technology and showed the importance of technology that supports the school's goals of blended and personalized learning. Another key barrier was ensuring that the community understood why they were choosing to implement blended learning and how teachers and students could be supported to be successful in this environment.

Shand and Glassett Farrelly (2018) explored the higher education literature on blended learning and identified three areas that were “fundamental in effective blended course design” (p. 4). These were the need to:

- Plan course objectives
- Plan for content delivery and student engagement
- Plan the blend of in person and online components

These areas highlighted the importance on focusing on content and engagement, rather than on the technology. Shand and Glassett Farrelly (2018) emphasized the need to identify your course objectives, and then think about your content and your students, and identify what available technology tool will be the most appropriate for which activity, given its affordances. The final step should be to ensure you consider both online and in-person aspects of your course and ensure that they are blended; this ensures you will have a coherent course where online and in-person activities complement one another, rather than online activities being an add-on.

Also working in higher education, McGee and Reis (2013) conducted a qualitative meta-analysis with the aim of identifying best or effective practices in blended course design. After conducting their meta-analysis, they recognized that the blended learning design process “is a modified instructional design process in which consideration is given to learner needs, instructional outcomes, instructional strategies, and instructional scope” (p. 12). They identified five areas where best practices in course design were identified, noting key points about each. As Table 3 shows, they highlighted areas related to the design process, pedagogy, utilization, assessment, and implementation.

Although looking at different contexts, using different literature, and focusing on different elements, some similarities can be identified within these three examples of blended learning design approaches and principle. Something that is clear is that implementing blended learning, particularly with the aim of supporting personalized learning, requires consideration of all aspects of both the physical and online environments. These aspects can be classified into three interrelated categories: context, pedagogy, and technology (Oliver and Stallings 2014).

Context

In deciding whether, how, and what to blend, teachers need to consider the context in which they and their students work. This includes consideration of the topic, the available learning environments and any challenges associated with these, as well as

Table 3 McGee and Reis' (2013) summary of areas to consider when designing effective blended learning courses

The design process	<p>Focus on designing a course, even if you are adapting an existing one; this stops you from simply using existing activities or transferring in-person activities online</p> <p>Start by defining the course objectives, with these written from a student perspective</p> <p>Then develop the course content, including activities and assessments. As this is done, ensure that activities that are developed are complementary; online activities should not be able to be perceived as extra</p>
Pedagogical strategies	<p>These are critical to the course and need to reflect an integration of in-person and online activities</p> <p>There is general agreement that: A range of interactive activities and prompt feedback are key In-person activities that are both formal and informal should be considered Active learning is key</p> <p>Instructional strategies should be: Process driven Product oriented Project oriented (p. 14)</p>
Classroom and online technology utilization	<p>It is agreed that this is critical, but there is no clear agreement as to what this should look like</p> <p>There is general agreement that the technology should support the content and the pedagogy, not drive it</p>
Assessment strategies	<p>Few recommendations were found, with no general agreement. This may be due to contextual issues such as requirements of assessment policies.</p>
Course implementation and student readiness	<p>General agreement that students need: To know what is required of them and how to be successful To be/be encouraged to be independent learners, with good time management, communication, and study skills; if they don't have these, they need to be supported to develop them Basic technology understanding</p>

what support students would need to succeed in these environments (Oliver and Stallings 2014; see also Bailey et al. 2013). For example, if students are working in an environment where they have limited access to technology outside of class time, blended approaches with in class online activities will be required.

The physical layout of classrooms also impacts on which model of blended learning is most appropriate; for example, rows of desks facing a whiteboard do not always lend themselves to student-centered forms of learning, and the rotation models of blended learning require students to have access to different spaces, either within a classroom or external to them while at least one of these spaces must have internet access. In some schools, however, blended learning has become an integral part of the learning experiences through changes in the physical

environment. These changes, known as modern, innovative, or flexible learning environments are large, open teaching spaces, designed to be used as the teaching and learning requires, rather than dictating it (Benade and Jackson 2017). In designing learning spaces, Monahan (2000) thus proposes five properties of space flexibility:

“fluidity represents the design of space for flows of individuals, sight, sound, and air. . .Versatility indicates the property of space that allows for multiple uses. . .Convertibility designates the ease of adapting educational space for new uses. . .Scalability describes a property of space for expansion or contraction. . .[and] Modifiability is a spatial property of fluid convertibility: spaces that *invite* convertibility” (para. 2–6).

However, the effectiveness of this change in classroom design is, as yet, unproven. It may be that just as adding technology to a teaching and learning environment does not necessarily result in pedagogical change, so too, changing the physical environment does not necessarily lead to changes in teaching and learning, although it may make change simpler.

Pedagogy

If blended learning is to be successfully adopted, the pedagogical approach to be used also needs considered (Bailey et al. 2013; Oliver and Stallings 2014). For example, teachers who prefer a didactic style are likely to struggle in a blended environment, with its focus on students, and on a role that is more focused on supporting and guiding students than providing content information. If blended learning was introduced with the aim of providing flexible or personalized learning for students, then pedagogy needs to be chosen to match this aim.

Ensuring that there is a balance of activities, with these carefully matched to learning mode is also important. What this should look like will vary depending on the contextual variables, but these are all issues that should be considered. The desired outcome of the blended learning experience, whether it be understanding of key concepts or the sharing and building of knowledge, will also impact on what pedagogical approach and what forms of blended learning will be most appropriate.

Technology

Perhaps the most obvious category to consider when blending learning is that of the technology itself. While the term blended learning was not originally used to indicate the use of online technologies, it has evolved to represent this mix of the use of online and in-person activities. As technology has developed, and its affordances have subsequently expanded, so too has the ability of blended learning to truly represent personalized learning. As Shand and Glassett Farrelly (2018) noted, key benefits of using technology to provide blended learning include the potential for the differentiation of instruction, and the range of online tools and

activities that are available. All forms of blended learning, as categorized by Christenson et al. (2013), require the use of technology; how effectively this is done depends on a range of factors.

Technology can be used in a range of ways to support blended learning. Christenson et al. (2013) identified how technology can be used alongside in person learning; others have identified a range of technology-supported activities that can be used within Christenson et al.'s models. For example, teachers have access to a range of technological tools, including multimedia activities, games, tutorials, videos, virtual field trips, experts, overseas classes (e.g., so students can talk to native speakers of languages they are learning); interactive activities, tools that provide for outside interaction (e.g., wikis, blogs) and simulations (Keengwe and Kang 2012; McGee and Reis 2013; Shand and Glassett Farrelly 2018). In order for this technology to be effective, however, the availability of the technology, both in and out of class, and the affordances of that technology need considered and aligned with the blended learning approach and activities. Cloud computing has become popular in recent years, and some researchers (e.g., Donert and Kotsanis 2015) maintain that it can be a driver for transforming teaching and learning. However, it is important to note that technology should be used to support the chosen pedagogical approach, and to meet the needs of the students, rather than the reverse (Bower et al. 2010; Oliver and Stallings 2014).

Teacher Competencies

Supplementing the design processes and models previously described, a number of authors have identified the skills needed by blended learning teachers. Although the skills students need to be successful at blended learning, and indeed, that blended learning encourages students to develop, have been considered by a number of authors, less focus has been placed on the skills and dispositions required by blended learning teachers, although this has been identified as critical (Halverson et al. 2014; Ma'arop and Embi 2016). One piece of work that has focused on this issue is iNACOLs (the International Association for K-12 Online Learning) "*Blended Learning Teacher Competency Framework*" (Powell et al. 2014). Recognizing the ongoing development of blended learning, they called their framework "an evolving tool" (p. 6) and identified 12 competencies within 4 domains: mindsets, qualities, adaptive skills, and technical skills.

Conclusion

It seems clear that the focus on flexible and personalized learning will be here for at least some time and likely that blended learning will continue to be used to deliver it. It is also clear that using blended learning to deliver flexible and personalized learning is complex and requires consideration of all aspects of teaching and learning. It should be noted that, as pointed out by Bartle (2015), designing flexible

and personalized learning environments has significant implications on the curriculum, pedagogy, and assessment, and it is essential to provide teachers with support in professional learning, as well as developing a supportive school culture and effective infrastructure.

There is limited research focusing on blended learning in primary and secondary schools, and current blended learning theories have largely been extrapolated from research based in higher education, distance education, or related to the use of information technologies in general (McGee and Reis 2013). Further exploration of how blended learning can effectively deliver flexible and personalized learning in primary and secondary schools is needed (Futch et al. 2016; Oliver and Stallings 2014), with a focus on blended learning as a distinct approach, different from both in-person and online learning.

In addition to further research, policies need to reflect and encourage flexible and personalized learning. They need to be able to cope with variation in how learning occurs, as well as uncertainty, as the affordances of technology changes and continue to allow how learning occurs to change. Technology in and of itself will not change learning, but it does offer opportunities for learning to change and be truly flexible and personalized.

Section IX
Mobile Learning

Elliot Soloway and Cathleen Norris

Abstract

Mobile learning has continued to evolve since our state-of-the-art assessment in the first edition of this Handbook. As documented in the “mobile learning” section of this 2nd edition of the Handbook, (1) mobile learning per se is seeing limited adoption in classrooms in the USA, the UK, and in 17 countries in Asia, (2) while the young learners themselves are adopting mobile learning in a significant way outside the classroom. While the developing nations struggle with issues of device access, the developed nations struggle with seeing the value of mobile learning with respect to increased student achievement. Thus, while other educational technology trends (e.g., personalized learning, flipped learning, online learning) are attracting attention, mobile learning continues to evolve below the “radar” – with a comeback *into* the classroom occurring when educators better understand the significant impact mobile learning is having on this generation of young mobile learners.

In the first edition of this Handbook (Voogt et al. 2008), mobile learning commanded significant attention in the education community. Up until about the year 2000, under the heading of *Computer-Assisted Learning*, computers were being used to *direct* a learner down a learning path. But, with the coming of the Palm and the Pocket PC handheld devices, learners could actually hold a computer in their hand and use it to truly *assist* them in learning. Indeed, the handheld devices – morphing into Internet-connected, mobile devices – raised expectations about the transformative role that mobile learning might now be able to play in the classroom (► Chap. 57, “[Mobile Learning in K-12: Roadblocks to Adoption](#)” by Norris and Soloway).

Fast forward 10 years to the publication of the 2nd edition of the Handbook (this volume), K-12 has moved on to new trends, e.g., personalized learning, blended learning, flipped learning, and online learning. What happened to mobile learning? While the trendsetters in educational technology are off exploring these new uses of computing, mobile learning, as documented in the articles in the mobile learning section of the Handbook’s 2nd edition (this volume), has continued – with less fanfare – to empower real learners to do real learning *the world over*:

- Evans (► Chap. 54, “[From Engagement to Empowerment: The Evolution of Mobile Learning in the United States](#)”), drawing on substantial survey data collected by Project Tomorrow, provides a detailed picture of the current state of mobile learning in the USA.
- Whyley (► Chap. 55, “[Barriers to Mobile Learning Advancements in the United Kingdom](#)”), drawing on the insights of 16 educational consultants, describes the state of mobile learning in the UK – England, Northern Ireland, Scotland, and Wales.
- Churchill et al. (► Chap. 56, “[The Implementation of Mobile Learning in Asia: Key Trends in Practices and Research](#)”), drawing on mini-reports on the state of mobile learning in 17 countries in Asia, provide a summary of the current state of mobile learning in the developing and developed countries in Asia.
- And, complementing these empirically based reports, Norris and Soloway (► Chap. 57, “[Mobile Learning in K-12: Roadblocks to Adoption](#)”) provide a historical perspective on mobile learning – looking back at the early days of mobile learning to better understand the roadblocks that impeded adoption and looking to the future and how those roadblocks can be addressed.

Interestingly, as documented in the four chapters in this section, the following three statements are true for the students, teachers, and administrators in the USA, the UK, and the 17 countries in Asia.

- Since the arrival of the modern smartphone – the iPhone in 2007 – and the production of smartphones for all budgets, learners from 5 to 18 years old have been absorbing these “phones” as fast as their budgets (and the budgets of their parents) have allowed. And, these young people have been using their phones, on a regular basis, to engage in a variety of important learning activities *outside* of the classroom.
- Meanwhile, while school administrators and governments appear to be supportive of integrating these devices into the curriculum, classroom teachers are less

convinced of the need to transform their pedagogical practices and integrate computers in general and mobile devices, in particular, into the curriculum.

- And, without a demand for pedagogical change, it is not surprising that there is a dearth of curricular resources that truly exploit the affordances of the computers (and the mobile devices). Similarly, there is a dearth of opportunities for professional development to help classroom teachers transform their pedagogical practices.

Direct instruction pedagogy – teachers standing at the front of the classroom and lecturing – used by the Romans and the Greeks (Bonner 2012), still holds sway in classrooms in the USA, the UK, and Asia.

Still further, there are more findings that hold true across the three geographical areas:

- All three empirically based chapters find that educators want more research to be carried out. And, indeed, the teachers claim that they are reluctant to adopt mobile learning because of a lack of evidence that mobile learning (or computers in general) does lead to increases in student achievement. But, in fact, there are many studies that show the positive impact of technology on student achievement (Zheng et al. 2016; Project Red n.d.), and those studies are not hidden away in a closet. Why then do educators hold this belief about the lack of evidence? Will carrying out more research, as the educators have requested, help to change their belief?
- In all three geographical areas, the data suggest that the teachers all start using technology by substituting “a digital tool for a non-digital tool” (► Chap. 54, “From Engagement to Empowerment: The Evolution of Mobile Learning in the United States” by Evans). But, in all three geographical areas, teachers feel that “digital and mobile technologies are seen as having potential value across a whole range of subject areas” (► Chap. 56, “The Implementation of Mobile Learning in Asia: Key Trends in Practices and Research” by Churchill et al.).

While the teachers may well be reluctant to use technology inside the classroom, the young people are zooming ahead, using their mobile devices for learning outside the classroom:

- “. . . 58% of students in grades 6–8 and 54% of students in grades 9–12 say that they use technology more outside of school for learning than they do in school” (► Chap. 54, “From Engagement to Empowerment: The Evolution of Mobile Learning in the United States” by Evans).

Neither Whyley nor Churchill make comparable observations, which is understandable since they don’t have access to the sort of data available to Evans. However, based on other sources, it is clear that there is widespread adoption of mobile technologies by students, especially in grades 9–12 in the U.K.: almost 80% (Doyle, 2015) of 12–17 year-olds use a smartphone daily. In Asia, a comment about the use of mobile devices by millennials, from the Ericsson Mobility Report (n.a., 2017), a global survey, is most telling:

- “Born between the early 1980s and the early 2000s, millennials have grown up in the age of the internet and mobile communications. This age group is not only leading the way in terms of the adoption of digital devices but also will most likely set the demands on future digital networks and services due to its technical knowledge and skills, as well as its high expectation level.” (n.a., 2017, p. 26)

Assuming that U.K. and Asia teens are similar to U.S. teens, teens in the U.K. and Asia are probably using their smartphones much like their counterparts in the U.S., i.e., for learning outside the classroom.

A major roadblock to the use of mobile learning in the classroom noted by Whyley (► [Chap. 55, “Barriers to Mobile Learning Advancements in the United Kingdom”](#)), and Norris and Soloway (► [Chap. 57, “Mobile Learning in K-12: Roadblocks to Adoption”](#)), is the lack of curricular materials. However, Norris and Soloway (► [Chap. 57, “Mobile Learning in K-12: Roadblocks to Adoption”](#)) see that there are new opportunities for developing curricular materials that can exploit the affordances of mobile devices. For example:

- The agreement by the World Wide Web Consortium on a standard for HTML5 means that device independent apps can be developed that will run in any browser that is W3C standards-aligned. Safari, Firefox, and Chrome tend to keep their browsers up to date, and thus mobile-exploiting curricular materials will run, in a compatible browser, on current devices and future devices.
- There are worldwide efforts to make OER – Open Education Resources – available for use in education for free. Currently, there is a great range of quality in the OER, and studies find that teachers are spending inordinate amounts of time searching for OERs for their classroom. However, new tools on the horizon, based on machine learning, promise to make OER more accessible.

In summary, while the fanfare surrounding mobile learning has fallen away, mobile learning, as documented in this section, continues to empower learners worldwide, at least *outside* the classroom. Now, for mobile learning to move *inside* the classroom, a number of events need to take place. Teachers will need to change a strong belief – not a simple task – and see that mobile learning can and does have a positive impact on student achievement. To move mobile learning inside the classroom, teachers will need curriculum they can use that incorporates mobile learning and professional development on that new curriculum. Fortunately, as Norris and Soloway (► [Chap. 57, “Mobile Learning in K-12: Roadblocks to Adoption”](#)) argue, the tools to create curriculum to support the broad range of devices that are now considered to be “mobile” have come available. The final piece to the puzzle is this: a new cohort of curriculum developers/publishers needs to arise to provide teachers with the needed curriculum and the PD. Given the shifting trends in educational technology, it isn’t clear that such an industry will develop. One trend, however, is not shifting: teens are wedded to their “phones” which will continue to empower their learning – outside the classroom.

Abstract

In the initial phases of mobile learning, the emphasis in US schools was on the magic of mobile device usage in the classroom. Education leaders were bedazzled by the potential of these Internet-connected devices to grab students' attention in ways that other learning materials had fallen short. The primary objective espoused by many school and district leaders was solely to leverage these highly compelling devices to stimulate new levels of student engagement in learning. Student engagement has long been the elusive magic bean in American education; if nurtured appropriately, the belief has been that test scores and achievement outcomes would soar toward the heavens like the magic beanstalk when students were more engaged in learning. In this flurry of excitement around the potential of

mobile devices, education leaders placed only minimal emphasis on the hows or whys associated with the effective use of mobile devices and wireless connectivity within a learning environment. Real-world challenges associated with mobile device usage such as classroom management strategies, protecting student data, and the enterprise management of so many screens stifled innovation in too many classrooms and unintentionally locked in the perception that the only value of the devices was for engagement, not real learning. However, an interesting thing happened on the way to a new era of mobile learning. While educators have continued to chase the elusive magic bean of engagement over the past 10 years, students from kindergarten to high school have been using their own and school-provided devices as tools of empowerment, not just engagement. With a mobile device grasped firmly in the palm of their hand, students are self-directing learning beyond the sponsorship of teachers or pacing guides, personalizing learning paths that take into account their interests and passions as well as their strengths and weaknesses, and extending learning beyond the four walls and regimented desks of their classroom. As a result of these experiences, students now have a clear vision of what learning could be and articulate that vision around a guiding principle: learning should be social-based, untethered, and digitally rich. This new vision puts a stronger emphasis on the active “verbs” of the learning process while at the same time gently moving the passive “nouns” associated with mobile learning to the back burner. In this chapter, we will discuss this evolution of mobile learning from nouns to verbs by examining 10 years of longitudinal data from a large-scale quantitative study of the mobile learning activities, attitudes, and aspirations of K-12 students, educators, and parents. The study findings document the past and present environments for mobile learning in the United States and through the analysis of the corresponding trend lines provide an interesting glimpse into the future as well.

Introduction

Findings for this chapter come primarily from a widespread representation of US stakeholders in education. The Speak Up survey collection, organized by Project Tomorrow[®], has conducted national and international data gathering initiatives since 2003. Speak Up is a unique research project designed to collect and report on the authentic, unfiltered ideas and views of K-12 students and their parents, teachers, and administrators. The primary focus of the Speak Up project has been on education stakeholders in the United States though schools in Australia, Canada, and around the world have participated in the surveys for many years. The survey data comes from more than 10,000 school communities and more than 400,000 individuals including students, teachers, administrators, parents, and community members annually.

Many recent studies including from the education nonprofit group, Project Tomorrow, report that within the past few years teachers in the United States in particular are using more technology in the classroom than ever before (<http://www.tomorrow.org/speakup/from-print-to-pixel.html>). The number of teachers who report using online videos within instruction increased 39% from 2013 to 2016 (<http://www.tomorrow.org/speakup/speakup-2016-ten-things-teachers-national-digital-learning-november-2017.html>). The use of online curriculum increased as well. In 2013, one-fifth (20%) of classroom teachers reported using an online curriculum with their students; in 2016, 36% of teachers report usage of such products (<http://www.tomorrow.org/speakup/speakup-2016-ten-things-teachers-national-digital-learning-november-2017.html>). And following other well-documented trends, teachers have embraced classroom cloud-based tools such as the Google Suite for Education and Office 365 to a much greater degree than in the past years. Student access to mobile devices in the classroom has also increased in the past 3 years. In 2016, 26% of teachers reported that their students were personally assigned a mobile device to use in class, an increase of 10 percentage points over the 2013 reporting (<http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html>). Closer examination however of the types of digital activities undertaken by teachers, especially in support of new student learning environments, reveals that sophisticated usage leading to transformative activities is still in the emergent phase. In the United States, many school districts have adopted the Substitution Augmentation Modification Redefinition (SAMR) model to guide and assess teacher progress in integrating technology within learning. This model stipulates four distinct phases of technology adoption through which teachers gain proficiency and comfort in using digital tools to support new vistas for student learning. Practice has shown however that some teachers get stuck at a particular developmental level and do not progress to the more sophisticated phases of usage (<http://www.stephaniedemichele.org/blog/category/samr>; <http://www.stephaniedemichele.org/blog/the-problem-with-substitution>). Consequently, in many cases the valuation on the digital learning experience is more a reflection of that limited usage level rather than the potential it can provide for transformation in the classroom. Such is often the case with mobile learning implementations as well.

The adoption process for the use of mobile devices in the American classroom has followed a traditional technology adoption pattern. A teacher's journey in the use of mobile devices in their classroom usually starts with a decision by school or district leadership to implement devices in a particular grade level or to support specific subject matter or curriculum. Mobile devices are procured, and plans are devised to provide students and teachers with access to those devices, either personally assigned access or through a shared collection that can be scheduled for classroom usage. The teacher's awareness of best practices for usage starts with a professional learning class supplemented with possible support of an instructional coach or technology coordinator at the school. In some cases, the training builds on the teacher's own prior personal experience with the operations of devices such as a smartphone or tablet. The typical steps in the implementation process include the identification and installation of specific mobile apps, putting in place device check in and check out procedures, scheduling of device charging times, and the collection

of parental permission slips. The first exposure that most students have to their new mobile learning tool is often instruction about all of the things they are not allowed to do with the device (i.e., download games, access social media, use the devices for nonacademic tasks). For both students and teachers, the foundational context for using these highly interactive, convenient, and portable devices focuses on the “nouns” of usage: what device, what apps, and what policies. Too little emphasis is on the more important aspects of mobile learning usage – the “verbs” that enable and empower new learning modalities and approaches that transcend traditional learning practices. While some implementations eventually move to a greater emphasis on the verbs, the initial positioning on the nouns limits teachers to seeing these devices not as gateways to greater learning and teaching efficacy but as vehicles for sporadic student engagement or to access online information with limited legitimate educational value. The students’ perspectives, even with the initial overemphasis on the policy nouns of what you cannot do with the devices, prove to be radically different, and this sets up a dichotomy of usage by teachers and students.

Many technology adoption models including the SAMR model encourage a substitution activity as a starting place for classroom integration. The teacher identifies a traditional classroom practice and substitutes a digital tool for a non-digital tool to support that classroom task. A common substitution practice in a mobile learning implementation is to have students take class notes using a tablet or laptop, rather than writing those notes in a spiral bound paper notebook. Another is to have students read an online document on their device, rather than reading a printed document like an article or news story. If the substitution is deemed successful (most often defined as students being more engaged in learning with the digital tool than the traditional tool), the teacher continues to use that substitution and may even add new substitutions into his/her practice. The goal in this process is two-pronged: for the teacher to acquire comfort in the mechanics of device usage in class and for him/her to gain an appreciation for how the extra effort of using the devices results in new benefits for the teacher and students. The aspiration is that through these efforts the teacher will instinctually move beyond the mere replications of the traditional methods and visualize new ways to take advantage of the unique features and functionalities of the devices to transform the learning process. While the aspiration is commendable, the process of transformation is not necessarily instinctual for all teachers. In most cases, this transformation process requires a deliberate and strategic reimagining of the teacher’s instructional practice to design new technology-enabled activities that cannot be undertaken without the access to the devices and supporting tools. This often necessitates that the teachers suspend their belief set on the importance of the “nouns” of mobile learning (what devices, what apps, what policies) to shift their mind-set to the “verbs” (how will the transformed practice empower and enable my students to learn differently than before). While these traditional adoption strategies can result in changes in practice, too often the focus on substitution or replacement activities as the starting point only results in a continuance of those practices, not the reimagining of the entire instructional practice. The process of strategic reimagining of one’s instructional practice to use mobile devices effectively is a much more difficult venture in the real world

than in theory or academic discourse. School principals appreciate this reality everyday as they work with their teachers on technology adoption. Principals consider their most significant challenge with technology use in the classroom is how to motivate their teachers to change their instructional practices to use digital tools and resources available on a regular and seamless basis.

This early focus on the nouns and the reliance upon adoption models that emphasize substitution presents another challenge to sustainable, effective mobile learning. Both ultimately mask the identification of real benefits associated with student usage of the devices to support learning. When asked about the valuation of student use of mobile devices in the classroom, both teachers (75%) and administrators (83%) identify increased student engagement as the primary benefit (<http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html>). This spotlight on student engagement is not unique to mobile device usage as educators also highlight that benefit when enumerating the value of other technologies in the classroom as well including interactive digital content, online videos, and game-based learning experiences. The predominance of substitution type activities within the adoption process provides rationale for this perspective. In most substitution activities, the “innovation” employed through the use of technology is only one-dimensional in that the underlying learning process is not transformed, just the methodology for doing the traditional task is slightly altered (taking notes on a tablet rather than in a spiral notebook). The increased engagement that students demonstrate when using a digital tool or resource may actually be more of a reflection on how non-engaging the traditional learning process was, than a real statement about the high levels of engagement with the digital methodology. Taking notes in class is boring. Using a tablet to take those notes may be slightly more engaging than using a pencil and paper, but the overall academic task is still not compelling to the student; taking notes remains a perfunctory but boring classroom task. The adult perception however is that the inclusion of the device elevated student interest and engagement in taking notes. That may be a premature or false assumption. Since too many technology implementations, including mobile device projects, have not evolved to the point of changing the underlying processes of learning (moving beyond substitutions to redefining the learning process), the outward appearance of increased student engagement in learning has emerged as most common litmus test for measuring technology effectiveness. Almost two-thirds of district administrators (62%) say that their district uses appearances of student engagement as the metric for evaluating the impact of technology projects. The seemingly lower percentages of district administrators who cite quality of student work (30%), depth of student collaborations (24%), and student interest in extended learning (21%) as indicators of technology project impact demonstrate the current lack of maturity or sophistication in assessing digital learning today.

Researchers have long documented a positive relationship between student engagement and academic outcomes. Student engagement in the K-12 classroom certainly remains an important criterion for learning efficacy. However, in the context of understanding the impact of mobile devices and other digital tools on student learning, it is inherently an insufficient measure. The reason for this insufficiency rests with how the students themselves value a mobile learning experience. While educators talk about

the devices, the apps, and the policies that they have put in place to create mobile learning environments, the students focus on how and why all of those “nouns” of mobile learning have the potential to change their learning environment and outcomes. For today’s students the use of mobile devices is first and foremost about personalizing learning and learning effectiveness and efficiency. Given their vision that their learning world should be social-based, untethered, and digitally rich, the mobile device and accompanying apps and tools serve as a highly productive gateway to realizing that vision. The students appreciate the inherently engaging and compelling nature of these devices, but because their primary focus is on the empowerment of their learning potential, they have unique sight lines to look beyond what they view as simplistic engagement to see the unrealized benefits that would enable more personalized, contextually relevant learning experiences. Their ongoing frustration is with the lack of visionary acuity by the adults that oversee their formalized educational lives.

Beyond the increases in access to devices, many changes in perception and policies around mobile learning in K-12 education have emerged in the past 10 years. Over this time period, Project Tomorrow’s Speak Up Research Project on Digital Learning has had a front row seat in documenting many of these developments (http://www.tomorrow.org/speakup/speakup_data_findings.html). The Speak Up Project annually polls a geographically and economically diverse set of educational stakeholders, notably K-12 students, their parents, and teachers, to reveal not only how these audiences are using emerging digital tools to support learning, communications, and collaborations but also their attitudes about those activities and their aspirations for more effective usage. Since the project’s launch in 2003, over five million K-12 students, teachers, librarians, administrators, parents, and community members have reported on their digital learning views and ideas through this process. The Speak Up national data findings are used regularly to inform policies and programs at every level of education governance from the US Congress to the local school board. Most notably, Speak Up has provided a vehicle for the authentic, unfiltered voices of K-12 students to be part of these discussions. In many cases, the ways today’s students are using digital tools, particularly outside of school, and their aspirations for greater usage within the classroom, stand in stark contrast to the methodologies employed by their teachers to support classroom learning. In this chapter, we will explore the evolution of mobile learning in the classroom and then contrast those key trends with how students are leveraging mobile devices to self-direct learning outside of school. Additionally, we will examine the purposes and benefits associated with students’ use of mobile devices from the perspective of the student. Understanding the hows and whys behind these alternative development paths provides a new context for appreciating the disconnect between students and educators on the value of mobile learning and to offer new insights into the future trends on the horizon.

The Evolution of Mobile Learning in the American Classroom

A common refrain within education policy circles is that the American classroom has changed little since the 1950s (<https://www.fastcompany.com/1826287/we-know-our-education-system-broken-so-why-cant-we-fix-it>). While the physical structure

of a classroom with students sitting at desks may look familiar to most, the explosion of Internet-accessible, mobile devices in the hands of those students has definitely changed the way students interact with each other, with their teachers, with the greater education community, and with instructional materials. This is especially evident over the past decade, as schools have increasingly adopted mobile learning as a signature initiative using students' own devices as well as investing in tablets, laptops, and increasingly Chromebooks to provide their students with access to a wealth of relevant educational content and learning opportunities. Students having access to a mobile device to use in and outside of class – their own or a school-provided device – is now the norm rather than the exception. In 2013, only 38% of teachers reported that their students had regular access to technology through a 1:1 mobile device program within their school (http://www.tomorrow.org/speakup/SU13DigitalLearningPlaybook_EducatorReport.html). Two-thirds of district administrators (63%) now report that within their district students are personally assigned a laptop, tablet, or Chromebook to use at school to support classroom activities and tasks, almost doubling the number of students with mobile device access in just 3 years. This frenzied adoption of mobile devices within learning has presented many new challenges for education leaders. Understanding the challenges schools continue to face in the implementation of mobile devices in the classrooms lays the groundwork for greater appreciation of the changes in mobile learning over the decade as well as the unfilled promises afforded by the mobile tools and content.

Challenges: Encouraging Innovative Classroom Practices and Evaluating Investment Return

As school technology use has become more ubiquitous, school and district leaders have increasingly placed a higher value on the role of digital learning, particularly as it pertains to the preparation of students to compete and contribute in a global economy. Seven of ten school district administrators consider the effective use of technology as *extremely important* for their students' future success. This represents a significant increase of 34% in the number of administrators holding that view since 2011 (http://www.tomorrow.org/speakup/ConnectingDots2012_pres.html). Additionally, 85% of both school principals and central office administrators agree that it is important for students to be able to use a mobile device during the school day to support learning (<http://www.tomorrow.org/speakup/Ten-Year-Retrospective-on-Mobile-Learning-Leveraging-the-Past-to-Invent-the-Future.html>). Given that administrative support is considered a critical factor for effective technology use in schools, this strong endorsement of mobile learning from educational leadership should provide an optimum environment for effective mobile learning in the classroom. But why is that not the case?

Despite endorsements and edicts, incentives, and investments, school and district administrators report that they continue to struggle with how to elevate the use of the digital tools from sporadic, engagement-intensive activities to instructionally rich and sustainable learning experiences for students. When asked to identify the most

significant challenge they face with technology use in the classroom, a majority of administrators report that motivating teachers to change their teaching practices is the number one obstacle to more effective usage. Librarians echo a similar frustration based upon their work supporting teachers with new classroom strategies for using devices and digital content.

Evaluation of teachers' use of technology and, in particular, their attitudes about that usage demonstrates the depth of this challenge for school leadership. In contrast to the 71% of district administrators who indicate that the effective use of technology is extremely important to student success, only 43% of classroom teachers share that same valuation. While the number of teachers' appreciating the value of digital learning has increased since 2010 by 10 percentage points, the same period saw a more substantial increase by administrators from 51% to 71%. This lower valuation by the teachers on digital learning appears to be a universal teacher phenomenon that is not affected by years of experience in the field or community type (urban, rural, or suburban) and only slightly altered by grade level assignment. Rather, it is a reflection that in most teachers' classrooms, despite the physical changes associated with student devices, the day-to-day operations of teaching and learning have not really changed. Without a solid proof case as to the benefits, many teachers remain reluctant to reimagine their instructional practices to enable more sophisticated uses for the digital tools.

The limits of the transformation beyond the outward appearance of students with devices in hand are evident when the teachers report on the actual impact of technology use in the classroom on their students. While 49% of classroom teachers say that their students are more motivated to learn and are gaining a better understanding of class materials because of their use of technology within instruction, only 15% noted that their students demonstrate higher proficiency on tests as a result of the technology usage (<http://www.tomorrow.org/speakup/speakup-2016-ten-things-teachers-national-digital-learning-november-2017.html>). Additionally, only one-third of teachers ascribe students' enhanced abilities to understand difficult concepts, apply knowledge to practical problems, develop workplace skills, or take ownership of learning to the use of classroom technology. This challenge of motivating teachers to change their instructional practices to better leverage digital tools is therefore a chicken-egg dilemma. Without the tangible benefits that are core to teachers' self-efficacy, teachers are reticent to reimagine their teaching strategies. However, the paucity of those tangible benefits may be because the teachers are not seamlessly or effectively integrating the digital tools within instruction and, thus, not reaping the benefits of transformed learning strategies. The reality is that motivating teachers to transform their practice and integrate mobile devices and digital resources within their instructional plans remains a significant challenge even with the strong presence of administrative support and direction.

The dizzying pace in which mobile devices have infiltrated the classroom has obscured in many ways thoughtful evaluation of the efficacy of current mobile learning strategies or the examination of how and why certain types of implementations and interventions affect outcomes such as student achievement. Increasingly, governance organizations including school boards and funding

Table 1 Metrics for evaluating the impact of digital initiatives

Metrics being used in school districts as reported by district administrators	% of district administrators in 2016 (<i>N</i> = 603)	% of district administrators in 2013 (<i>N</i> = 933)
Student engagement in learning	62%	64%
Teacher feedback	62%	37%
Student achievement results	60%	47%
Student feedback	53%	40%
Parent feedback	44%	21%
Student skill development	37%	31%
Quality of student projects	30%	28%

© Project Tomorrow 2017

agencies are seeking more quantitative outcomes from the use of these tools within learning to justify the return on those investments. Consequently, administrators are starting to think differently about not only the metrics around digital initiatives but also the role of those metrics in community engagement. As illustrated in Table 1, while school leaders continue to rely upon student engagement in learning as the primary vehicle for evaluating impact, other factors such as student achievement results and feedback from key constituencies have increased in importance since 2013.

The recognition of the impact of these devices on achievement in particular lags behind the implementation statistics. While 52% of school site administrators report that their students are assigned a mobile device to use at school, only 41% acknowledge that the access has resulted in positive academic outcomes for those students (<http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html>). One-tenth state that it is too early to document those results. A smaller number of administrators (24%) see positive academic outcomes from students using their own mobile devices in school. Limited outcomes are also noted for online classes (42%), blended learning implementations (28%), and flipped learning models (18%). Contrastingly, administrators see positive outcomes already from the use of online assessments (52%) and using data to inform instruction (69%), tasks that more closely resemble substitution activities than the redefinition or transformative activities potentially enabled by mobile devices. While administrators may be highly supportive of mobile learning in the classroom, more work is needed at both the school, district, and governance levels to address how to best support teachers in the process of reimagining their instructional practices and how to meaningfully evaluate the impact of mobile devices in the classroom.

Inside the Classroom: How Students and Teachers Are Using Mobile Devices

American students and teachers today have unprecedented access to mobile devices to support classroom learning. With that access comes an expectation that the devices will be used to open up new learning vistas that will engage and extend learning beyond the classroom walls, for both students and teachers. For teachers,

mobile devices support professional tasks by eliminating the traditional isolationism of the classroom and provide new ways for teachers to engage with peers in professional learning communities, strengthen communications with students and their parents through more frequent and timely interactions, and leverage mobile apps that can support their effectiveness as a teacher. Evidence of that reduced isolationism exists in terms of teachers’ likeliness today to share online a homegrown lesson plan, graphic organizer, or other classroom aid. In 2008, only 5% of teachers had shared a lesson plan online; in 2016, 42% said they were likely to do that during the school year (<http://www.tomorrow.org/speakup/speak-up-2016-k12-administrators-and-teachers-speak-up-about-open-education-resources-march-2017.html>). The access to a mobile device not only makes communications and professional learning more easily accomplished but it also provides a unique opportunity for teachers to support student collaborations and investigations, and an increasing number of teachers are taking advantage of that potential for their students (Table 2).

Student access to mobile devices in the classroom today varies not only by grade level but also by product type or category, access location, and who owns the device as depicted in Fig. 1. Elementary students in grades 3–5 are almost four times more likely to be using a tablet in class than their older high school siblings (<http://www.tomorrow.org>).

Table 2 Teachers’ digitally enhanced activities in the classroom – comparative view 2008 versus 2016

Digitally enhanced classroom activities	% of teachers in 2008 (N = 29,715)	% of teachers in 2016 (N = 37,018)
Learn something from an online video	27%	66%
Review data reports to inform instruction	12%	58%
Facilitate collaborative projects between students	22%	42%
Create investigations for students	20%	30%

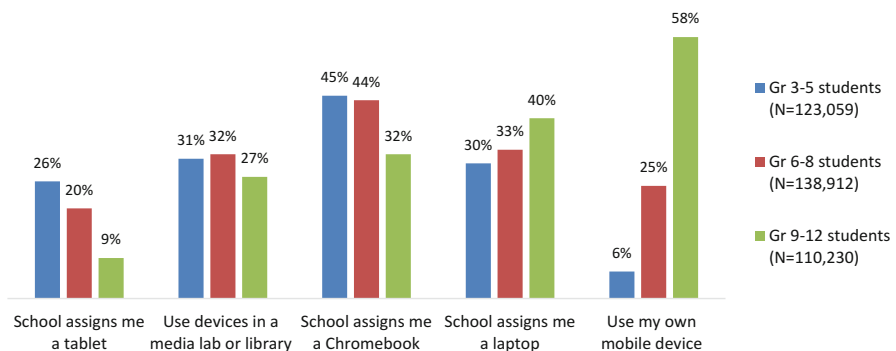

Fig. 1 Student access to mobile devices to support learning in school. (© Project Tomorrow 2017)

[org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html](http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html)). Chromebooks have established a strong foothold in the upper elementary and middle school years though twice as many high school students report being assigned a Chromebook in 2016 than in 2014, indicating that the web-based laptop may soon have a predominant base in high school classrooms as well (<http://www.tomorrow.org/speakup/speak-up-2016-ten-things-everyone-should-know-about-k12-students-may-2017.html>).

As illustrated, approximately one in three students in grades 6–12 still relies upon the school library or media lab for technology access when in school though that modality is on a steady decline. Contrastingly, in 2014, the media lab was used by 47% of students in grades 6–12. Reflecting the relaxation of many schools' policies around student use of their own mobile devices (called BYOD or bring your own device policies), 58% of high school students say they use their own devices to support learning when in class (<http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html>). Interestingly, one-third of those BYOD students are also using a school-assigned laptop or Chromebook, meaning that they are accessing multiple devices in class as needed to accomplish different academic tasks. This differentiated use of various devices for specific academic tasks is an emerging trend that represents how students may be taking a more sophisticated approach to mobile device usage than what educators might assume.

Since the advent of the first laptops, educators have been on the hunt for the holy grail of mobile devices for the classroom: a singular, uniform device that will serve all student academic needs and address institutional requirements for support, training, security, safety, and longevity. Administrators talk about one-to-one (1:1) programs within the context not just of one device per student but also as the identification of one product that can be used universally throughout their entire school or district from kindergarten through 12th grade and work equally well in the science lab as in Spanish class. For a period of time, that holy grail device was a smartphone, then a tablet, and more recently a Chromebook. The reasons why administrators want one device are understandable, but the goal is not realistic and directly thwarts efforts for greater personalization in learning. And yet in many districts, the hunt for that holy grail continues.

Students realize that their ideal learning environment should not be bounded by the limitations of one device per student but rather that ideal environment should support devices based upon what features and functions is best to meet the needs of a particular task. Instead of trying to make one device be all things, they want to use the right tool for the right academic task. This awareness stems from their familiarity with using various devices in their personal lives and appreciating the pros and cons of differentiated usage. Through those experiences, students have developed their own highly personalized typology for device usage that is not dependent simply upon the engagement level of the interaction per se but rather on the efficiency of the tool to meet the needs of a particular task. For example, a smartphone may be a highly convenient device to update your Instagram account with a photo of your lunch but is not the optimum tool for completing the application for that coveted summer internship at a local biotechnology company. Contrary to conventional wisdom, today's students are highly savvy about the utility and efficiency of digital

Table 3 Student typology for differentiated mobile device usage to support academic tasks

Academic task	Preferred mobile device for that task (<i>N</i> = 238,813 students in grades 6–12)
Create multimedia presentation or content	Laptop or Chromebook
Take online tests	Laptop or Chromebook
Write reports or essays	Laptop or Chromebook
Take notes in class	Tablet
Read an e-book or online article	Digital reader
Communicate with peers or teachers	Smartphone
Create and/or watch online videos	Smartphone
Use social media tools	Smartphone

© Project Tomorrow 2016

tools to support their interactions and activities. With increased access to mobile devices in class, students are now overlaying a similar typology on schoolwork activities. Table 3 describes the preferences of students for a differentiated approach to mobile device usage for academic tasks.

Just as within their personal lives, students want to use the right tool for the right task to increase the efficiency of their work. Tablets even when equipped with external keyboards are a poor substitute for a laptop with a full keyboard when you need to write a ten page report for history class. Digital readers are designed to have optimum screens for online reading and prevent less eyestrain than reading on a tablet or laptop. The in-built cameras in smartphones support better content creation than other devices, especially when combined with mobile apps that support editing and streaming. Students highly appreciate the value of personalized learning that is customized to their needs, and using the right tools to support their learning tasks is a key part of that personalization formula.

The importance of the differentiated tool-task typology and its relationship with personalized learning provides a fresh new explanation for students' interest in using their own mobile devices in school. Students want to use their own smartphone, laptop, or tablet for three fundamental reasons: (1) their device is already personalized to support their needs with custom apps, bookmarks, and programs, (2) they can leverage their tool-task typology by using their personal devices in addition to school-provided devices, and (3) their personal devices may be more current and fully featured products than what the school can provide. Initially, school leaders' impression was that students only wanted to use their own devices so that they could circumvent school policies for social media access or to cheat on tests. Again the administrators' focus on the nouns of mobile learning, the policies in this case, blinded them to understand the relationships between personalized learning and using a personal mobile device.

School policies on student use of their own mobile devices have changed dramatically in the past 5 years. In 2011, 65% of school principals did not allow students to use their own devices at school. By 2016, only one-third of school administrators report having no BYOD policy in place (<http://www.tomorrow.org/>

[speakup/Speak-Up-2016-Mobile-learning-June-2017.html](http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html)). This change in policy however does not mean that students have greater access to their own devices to use for learning. New policies in 44% of districts stipulate that the use of student owned devices in the classroom is at the discretion of the classroom teacher; in 2011, only 21% of districts left that decision to the teacher. This shift in decision-making authority means that students may be able to use their smartphone to research alternative views on the First Amendment in their American history class, but not be able to access Kahn Academy videos on their tablet in math class during the very next class period. While many districts were intrigued with BYOD policies initially to avoid large-scale investments in devices for student usage, that need is no longer paramount as increasingly schools are providing their students with devices, notably the lower cost Chromebooks. Correspondingly, 44% of middle school students and 38% of high school students continue to identify the inability to use their own mobile device at school as a significant obstacle to school technology use (<http://www.tomorrow.org/speakup/Top-10-Things-Everyone-Should-Know-about-Todays-Students-and-Digital-Learning-pres.html>). This obstacle is not fully appreciated by the technology leadership in most schools however. Only one-quarter of school and district technology coordinators and directors acknowledge that their students could still have a problem using their own device at school, even with BYOD policies in place.

Another interesting by-product of the increased access that students have to mobile devices in school is the reluctance of schools to allow students to take the devices home. Only 14% of teachers say that their students are allowed to take home their assigned, school-provided mobile devices to use for homework or to continue learning (<http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html>). The increased use of digital resources in the classroom and implementation of new classroom models such as blended and flipped learning often requires students to have out of school access to appropriate devices and the Internet. While some students may have appropriate, safe, and consistent technology access when they are at home, approximately one-fifth of students in grades 6–12 report being impacted by the “homework gap” where they are unable to do schoolwork due to a lack of access beyond the classroom (<http://www.tomorrow.org/speakup/speakup-2016-addressing-homework-gap-september-2017.html>). Despite advances in access to mobile devices at school, today’s students are too often caught in a mobile device dilemma. If they have a personal mobile device, they may not be able to use it in the classroom if their teacher prohibits student-owned device usage in his/her classroom. And if they have a school-provided device, they may not be able to take it home to continue or extend their learning. The result is a patchwork of disjointed access and unrealized potential that does not take into account what the students already know about mobile learning:

- Using the right tool for the right task improves efficiency and effectiveness.
- Personalized learning is dependent upon the ability to choose your own best tool.
- Mobile devices support untethered learning that extends the potential of learning beyond the classroom and the school and outside the hours of the school day.

- Mobile devices empower self-directed learning and the creation of a healthy ethos for lifelong learning.
- It is not about the devices. It is about what the devices enable you to be able to do.

Empowering a Student Vision for Learning Through Self-Directed Mobile Learning Experiences

For today's students, learning is a 24/7 enterprise. The school day encompasses just a small part of the learning continuum that students experience every day. In many ways, the school and classroom has lost its long-held positioning as the exclusive purveyor of knowledge. Today, students have access to information and knowledge at their fingertips through the ubiquitously connected mobile device in the palm of their hand. This access has certainly transformed the way students access information, but in addition, it has also created a new ethos around learning, whereas students feel they have a right and a responsibility to self-direct their own learning enterprise. Students feel that untethered learning that is not bound by the limits of their teachers' knowledge or the resources of their local physical community is the best way for them to be prepared for inclusion in a global society. Mobile devices enable untethered learning and provide an easy and convenient way for students to not only supplement what they are learning in school but also to be able to self-direct a new, personalized learning process around areas of their own interest and address individualized purposes. In many ways, how students are utilizing mobile devices on their own to access content, to communicate and collaborate with experts, and to develop workplace skills is a truer representation of the potential of mobile learning than what is exhibited today in many classrooms. The examination of how students are empowering a new vision for learning through their self-directed mobile experiences beyond the sponsorship or facilitation of their teachers has the potential to provide significant new insights into what could be possible in America's classrooms. Appreciation of these insights requires that students are respected and listened to not just because of their status as technology savants but as essential stewards of their own learning innovations.

Student Personal Access to Mobile Devices

Over the past 10 years, students have been increasingly coming to school with a personal familiarity with mobile learning that outpaced current usage in their classroom. This familiarity is based upon students' better access to mobile devices outside of school. Whereas the types of devices changed over time from 2007 to 2016, a common thread during this period was the steady increase in personal device access for students from kindergarten through high school as noted in Figs. 2 and 3.

Like the rest of society, students migrated from cell phones without Internet access to smartphones with Internet connectivity. The declining costs and increased functionality enabled a new tipping point in mobile access with 90% of high school

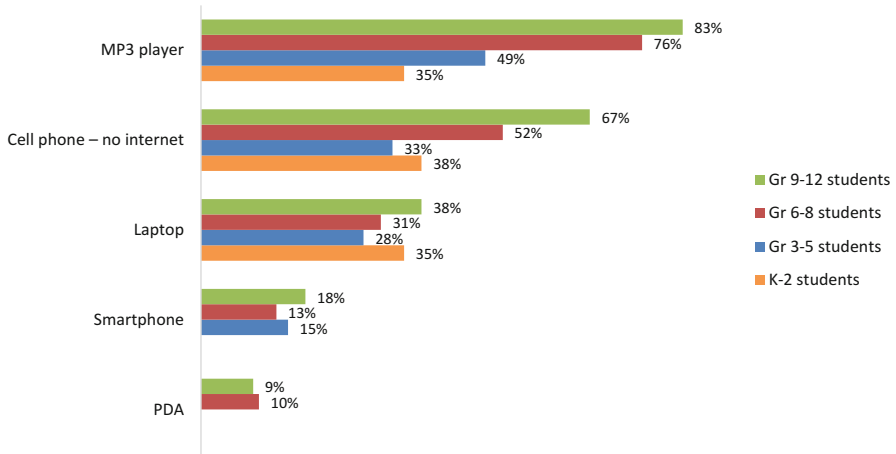

Fig. 2 Students’ personal access to mobile devices in 2007. (© Project Tomorrow 2008)

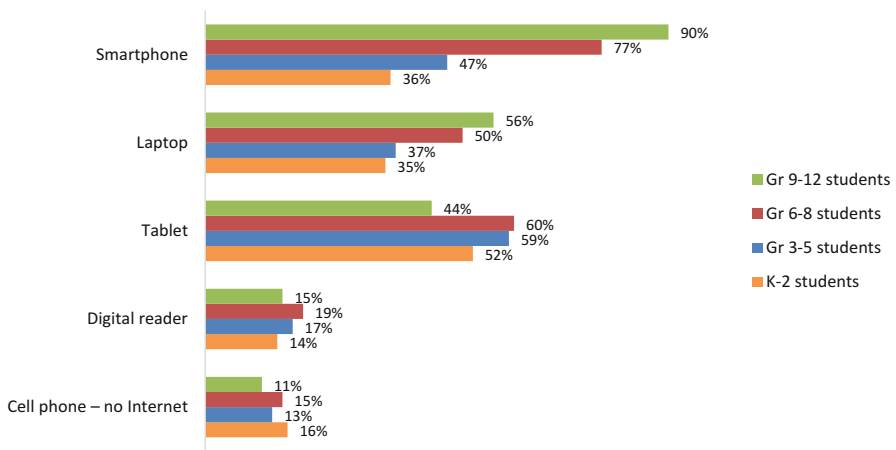

Fig. 3 Students’ personal access to mobile devices in 2016. (© Project Tomorrow 2017)

students having a smart device in 2016 (<http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html>). The advent of tablets and digital readers within the market is reflected in the students’ increased access in 2016 as well. New mobile product offerings are appearing within the students’ portfolio as well with 12% of students in grades 6–8 and 8% of students in grades 9–12 also reporting that they have a personal smart watch (<http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html>).

Beyond the shock and awe of the percentages of students, particularly younger elementary students, with personal mobile devices, several key characteristics of this access are important to note as it supports self-directed learning. First, in most cases,

students do not have only one device but rather they have multiple devices they can access depending upon task, preference, or convenience. Second, access to Wi-Fi through their devices is an enabling agent. It is not just about using the calendaring function to organize activities but rather how the Wi-Fi access enables the sharing of calendars with friends and family, thus increasing efficiency and connect-ability. Third, this new ethos of self-directed learning is not limited to just older students as many adults may presume. Rather, the increasing equity of access to devices empowers students of all ages to self-determine the direction of their own extended learning outside of school. Finally, the perception that student access to personal devices is only prevalent or pervasive in suburban communities where economic conditions support students having the latest Apple iPhone is incorrect. Students from urban or rural communities or from school identified as Title 1 schools (a common proxy for serving high-poverty families) were only slightly less likely to have access to these devices. For example, 77% of all middle school students reported having a personal smartphone (<http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html>). In urban, rural, and suburban communities, those percentages are 75%, 75%, and 80%, respectively. Additionally, 76% of students in Title 1 schools say they have a smartphone. While it is possible that product models or currency may differ, the fact that students across all of these communities and school types have access to a mobile device with Internet connectivity supports the idea that the potential for self-directed learning is not just for the privileged. As demonstrated in other sectors of society, personal mobile devices can be tools of equity.

Self-Directed Mobile Learning Experiences: Beyond the Classroom

Many educators are often unaware that students are regularly using their own personal mobile devices to support self-directed learning outside of school. This lack of awareness can be traced to adults' perception that the value of mobile devices in the classroom is centered almost exclusively on engagement and a lack of recognition of other benefits valued by students including the development of workplace skills, extending learning, and career exploration opportunities. Given this bias toward seeing engagement as the only benefit, teachers and administrators therefore question why students who are presented with so many other engaging activities outside of school would use their devices for learning purposes. Unfortunately, they are blinded by the engagement valuation.

As reported by the Speak Up Project, 58% of students in grades 6–8 and 54% of students in grades 9–12 say that they use technology more outside of school for learning than they do in school (<http://www.tomorrow.org/speakup/speak-up-2016-ten-things-everyone-should-know-about-k12-students-may-2017.html>). While their mobile devices provide the access to unlimited sources of online information and content, the impetus for these self-directed learning experiences rests firmly with students' desires to determine their own educational destiny and pursue academic passions beyond the classroom. A key characteristic of these self-directed learning

Table 4 Students' self-directed digital learning experiences using their mobile devices

Self-directed learning activity	% of students in grades 6–8 (<i>N</i> = 138,912)	% of students in grades 9–12 (<i>N</i> = 110,230)
Review websites about topics I am interested in	77%	79%
Watch a video to learn how to do something	75%	76%
Tap into social media to learn what others are doing or thinking about a topic I am interested in	37%	51%
Tap into social media to identify people who share my interests	42%	49%
Play an online game to learn more about a topic	53%	44%
Find experts online to answer my questions	33%	41%
Watch a TED Talk about people's ideas	40%	38%
Use online writing tools to improve my writing	38%	31%

© Project Tomorrow 2017

experiences is that the activities are purposeful. In general, four purposes or motivations drive students' use of various digital tools within these self-directed experiences:

- Self-remediation: interest in self-improvement in an academic subject
- Skill development: desire to learn skills they consider important for future success but not necessarily taught in school
- Curiosity: inquisitiveness about an academic subject or learning more about something discussed or learned in school
- Career development: exploring various career fields or future educational opportunities to assess personal fit

Beyond homework and assigned schoolwork, students are tapping into a wide range of online resources to support these purposeful self-directed experiences and to fuel their own academic interests as illustrated in Table 4. Despite some differences between middle school and high school students such as with online games and social media tools, the central theme prevails that beyond teacher sponsorship or direction, students are leveraging digital tools to support a new type of learning paradigm, one where the student is directing the process, outcome, and valuation.

From videos to websites, students are resourcefully seeking skills and ideas to support their own learning processes and to address very specific goals or purposes.

With so much emphasis nationwide on college and career readiness and preparation, students' use of mobile devices to support self-directed research on different career fields is particularly interesting. Traditional career exploration activities such as summer camps, afterschool programs, competitions, or even career technical education classes at school hold less interest for students today. However, new emerging uses of digital tools, including mobile-enabled experiences, are gaining and retaining student attention. Such experiences include playing an online or digital game about a career field (42% of students in grades 6–8 endorse this concept),

watching “day in the life” videos about different careers (39%), and using mobile apps or websites to learn more about careers (34%) (<http://www.tomorrow.org/speakup/speak-up-2016-ten-things-everyone-should-know-about-k12-students-may-2017.html>). The key characteristic in these emerging exploration methodologies is that the student is in charge of the experience and self-directing how they interact and consume the content on a highly personalized basis. The mobile devices therefore not only enable self-directed learning but also provide opportunities for a more personalized career exploration experience than traditional means. The self-directed learning experiences that students are facilitating through their mobile devices have another unintentional effect. Increasingly, through these experiences, students realize not only that they enjoy and benefit from the self-determination process but their aspirations for better in-school experiences become clearer as well.

For the students, the evolution of mobile learning, and the assessment of the value of using mobile devices to support learning, is not predicated on the experience they have using these devices in school. Rather, their valuation on mobile learning is based upon how they are using their own devices outside of school and beyond teacher sponsorship or direction, to empower a new learning paradigm, one in which they are in control of the learning process and that process subsequently, is both purposeful and personalized to address their interests and needs. The mobile-enabled, self-directed learning process is the embodiment of the student vision for learning where social interactions and collaborations are paramount, the learning is untethered and open, and the use of the digital resources supports context and purpose. It is with this mind-set that students envision their ultimate classroom experience.

The Ultimate Classroom: How Does the Student Vision Align with Educator Expectations?

Students articulate the value of using technology to support learning very differently than educators. Teachers (75%) and administrators (83%) emphasize that the use of digital resources and tools in the classroom including mobile devices increases student engagement in learning as the primary benefit (<http://www.tomorrow.org/speakup/Ten-Year-Retrospective-on-Mobile-Learning-Leveraging-the-Past-to-Invent-the-Future.html>; <http://www.tomorrow.org/speakup/Speak-Up-2016-Mobile-learning-June-2017.html>). A smaller percentage of teachers (65%) see value in using the devices in the classroom as a way to prepare students for college or a future job. Approximately 50% of teachers acknowledge that students have greater access to digital content when mobile devices are in the classroom. While these are all important outcomes, the students’ assessment on value of digitally based learning is more focused on how these tools support a transformed learning experience for them personally. As stated earlier, the educators’ assessment of mobile learning value is insufficient when the student perspective is taken into account. Students report the following types of outcomes that they associate with digital learning:

1. I am able to learn at my own pace.
2. I am developing creativity skills.
3. I understand what I am learning better.
4. I am learning in a way that fits my learning style.
5. I am applying what I am learning to practical problems.

Students acknowledge a level of increased interest or engagement in what they are learning when digital tools are employed effectively, but that benefit is of lesser importance than the ones identified.

It therefore follows that when envisioning the ultimate classroom or learning environment, students and the adults in their learning lives including teachers, administrators, and parents are on very different pages as illustrated in Fig. 4. Students in concert with teachers and administrators appreciate the importance of every student having access to a mobile device, be it a Chromebook, laptop, or tablet. The same is true for school-wide Internet access.

However, having a mobile device and Internet access does not fully support the students’ vision for a new learning paradigm or their ultimate classroom. Within that vision, students want access to mobile apps and game-based environments to support contextual or experiential learning, virtual reality experiences and media creation tools that present opportunities for untethered learning, and the use of social media vehicles that promote collaboration and communication with experts and thought leaders even beyond the classroom. These are examples of the types of tools that students will use to create content, understand context, and develop

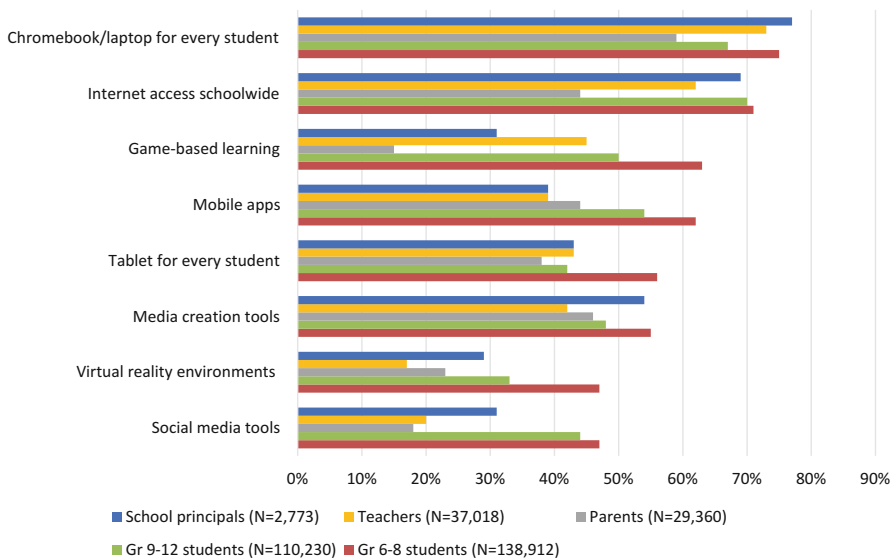

Fig. 4 Envisioning the ultimate classroom – different perspectives from education stakeholders. (© Project Tomorrow 2017)

collaboration skills, both in the classroom and on their own. For the students, these creation/context/collaboration tools are not optional but essential as they bring the verbs of mobile learning to the forefront. These tools when used in conjunction with the nouns of mobile learning (the devices, the apps, the policies) stimulate outcomes such as personalizing learning, developing workplace skills, and extending learning beyond the school day.

Some administrators, teachers, and parents want to see these creation/context/collaboration tools in their ultimate school vision as well. The percentages of adults supporting these tools except for principals' endorsement of media creation tools are less than the students, however. That translates into a potential lack of support or motivation for making such tools available to students for classroom usage and decreased teacher interest in changing their instructional practices to integrate these tools effectively. However, trend analysis of teachers' perceptions indicates that changes in valuation around these tools may have a precedent. Using this ultimate school scenario as a barometer of changes in perceptions, teachers have made large strides forward in their valuation of mobile devices in the past 8 years. In 2008, only 40% of teachers included a laptop for every student in their ultimate classroom vision, and only 14% visualized a time when a tablet for every student would be optimum (<http://www.tomorrow.org/speakup/2008NationalFindings.html>). Today, 73% of teachers endorse a 1:1 laptop program, and 43% feel the same about assigning tablets to students. Three insights from the students' experiences may help teachers (as well as administrators and parents) see the value of the tools of creation, context, and collaboration within a mobile learning environment: (1) how students are using these and similar tools outside of school to self-direct learning, (2) thinking beyond engagement to include benefits that support personalized student learning, and (3) suspending the focus on the nouns of mobile learning so that the verbs can drive more efficient and effective usage and, subsequently, more meaningful outcomes.

Conclusion

In so many ways, the real journey of mobile learning is just beginning. For the past 10 years, the focus in many schools and districts was on the nouns of mobile learning, the devices, the apps, and the policies that had to be in place before any meaningful assessment of value could take place. Along that implementation path, too many educators became fixated exclusively on the engagement value of putting a mobile device in the hands of a student, without carefully examining the benefits from the perspective of the student. As access to devices has steadily increased in both schools and homes, a curious thing happened on that frontier land of mobile learning. Beyond the sight lines of educators, and without deliberate prompting from their teachers, students from kindergarten to high school began using their own and school-provided devices as tools of empowerment, not just engagement. With mobile devices grasped firmly in the palms of their hands, students embraced self-directed learning beyond the sponsorship of teachers or pacing guides, personalizing

learning paths that take into account their personalized interests and passions as well as their aspirations and purposes, extending learning beyond the four walls and regimented desks of their classrooms. As a result of these experiences, students have a clear vision of what learning could be and articulate that vision around a guiding principle: learning should be social-based to support relationships and collaborations, untethered from the physical limitations of their classroom or community, and digitally rich to provide meaningful context and purpose. Empowered by their devices and tools that help them create content, context, and collaborations, the students have transcended what is happening in their classrooms. This presents a unique opportunity for educators to put aside traditional norms and to learn from their students. As we dawn on a new era in mobile learning, the prospect exists for educators to think beyond the nouns of mobile learning and to fully embrace the verbs that bring context to new mobile-enhanced learning environments by focusing on the types of meaningful outcomes our students are already experiencing. As the new journey begins, we should be assured that our students will be there to help us.

Barriers to Mobile Learning Advancements in the United Kingdom

Abstract

Since its ambitious, visionary beginning in 2003 in Wolverhampton, mobile learning continues to expand and evolve in the UK. Mobile technologies, as well, continue to expand and evolve with tablets, Chromebooks, and even laptops viewed as “mobile” devices. Drawing on a range of resources (e.g., interviews with 16 influential practitioners), then, this chapter addresses the question: what is the status of mobile learning in the UK some 15 years later? In developing an answer, we explore mobile devices, models of mobile device ownership, and the pedagogical uses of mobile devices for mobile learning.

Keywords

Introduction

In 2003, the belief was that mobile learning would change education in the UK. This belief was fuelled, at least in part, by the city of Wolverhampton launching the Learning2Go Project (Whyley 2014) which was “the largest collaborative Mobile Learning initiative for pupils in the UK” (Wolverhampton e-Services 2009, para. 2). The goal of the project was to give students “anywhere, anytime access” to an Internet-connected computing device, regardless of their financial circumstance. To that end, over 1,500 students in 18 schools were provided with mobile devices. After discussing the ambitious, visionary beginning in 2003, this chapter will address the evolution that led to the current status of mobile learning in the UK.

The definition of mobile learning developed in the Learning2Go Project can still serve us well: “Mobile Learning is the type of learning that takes place when the learner has some kind of mobile computer, making use of its connectivity, location awareness, content and applications to learn at a time and place of the learner’s choosing” (Whyley 2014). What has changed, however, is the definition of “mobile computer.” Initially, in the Learning2Go Project, a mobile computer meant a hand-held computer. But, the definition of what counts as a mobile computer has since broadened to include laptops, tablets, netbooks, Chromebooks, and, of course, smartphones. Given their ubiquity and reduced dimensions, all of these devices still enable a learner to learn at a time and place of the learner’s choosing.

Inasmuch as there is a paucity of reports on the current state of mobile technology and mobile learning in the UK, during the first 3 months of 2017, the author interviewed 16 influential practitioners in the field of educational technology in the UK. This chapter, then, is based on those interviews and provides a first-hand, qualitative picture of mobile technology and mobile learning in the UK. Because of their current positions, some of the individuals preferred not to be quoted directly, so summaries of the observations of those “influencers” (Gladwell 2000) are presented as they align with the following themes:

- Mobile technology: types of devices
- Models of mobile technology ownership
- Mobile learning: pedagogical uses of the mobile technology

It is important to point out that the UK is made up of four different countries – England, Northern Ireland, Scotland, and Wales. Each country has its own government and education policy even though their Members of Parliament meet in Westminster to govern the whole of the UK. However, the way in which education is supported in each of those countries is different.

1. Northern Ireland, Scotland, and Wales have a centrally supported school system which can provide a more coherent, strategic focus to the use of educational technology in general, and mobile learning, in particular. In Northern Ireland, the provision of mobile technologies is part of a strategic approach with a 5-year managed service which provides core infrastructure and systems, allowing

schools more freedom to explore their own mobile learning initiatives. Scotland and Wales similarly have a countrywide learning platform: Glow in Scotland (Glow Digital Learning for Scotland n.d.) and Hwb in Wales (Hwb Digital Learning for Wales 2017). These latter two platforms allow for a consistency of approach across schools wishing to implement mobile devices. Scotland also provides strategic support for those schools that choose to embrace mobile learning.

2. In 2010, the UK closed the government-funded British Education Technology Agency (Government to close BECTA 2009). Since then, there is less centralized coordination in England, with autonomy being given to schools and school leaders via the Academy and Free School initiatives (BBC 2010). Unfortunately, many schools in England have not received the impartial advice needed to deploy today's complex technological solutions in general and mobile learning in particular. This has made pedagogical and technological innovation more challenging in England compared to the other three UK countries.

Mobile Technology: Types of Devices

Mobile learning in the UK is now characterized in schools by the use of tablet and laptop devices. The 2016 British Educational Suppliers Association (BESA), National Association of Advisors for Computers in Education (NAACE) Leadership Briefing Paper showed that 68% of primary and 59% of secondary schools felt that they were under resourced with tablet computers, indicating that they were interested in improving on that situation. Spending on laptop computers was also regarded by schools as a priority (BESA NAACE Leadership Briefing Paper 2016).

In the UK, over the past six years, the devices used for mobile learning have shifted from being predominantly small portable handheld technologies to being predominantly tablet-based, finger input devices. Of these devices, iPads predominate, with fewer deployments of Android devices. (Learning2Go 2.0 opens doors to iPads and Android 2012). Many respondents articulated the view that the ease of use of the iPad had made it a favorite with teachers and learners alike. However, there is also a general view that as schools have gained experience in the use of iPads, they are beginning to understand its limitations. And, with requests for the iPads fading, there is fresh interest in the Microsoft Surface device due to its keyboard and digital pen input. Laptops, of course, are commonplace, and there is recent interest in Chromebooks.

Today's smartphones are the closest relative to the Pocket PCs which started the mobile learning revolution in the UK in 2003. They are now very powerful personal computers with excellent cameras (still and video), built in global positioning systems (GPS), and highly efficient browsers that can easily connect to the internet. Paradoxically, it is the very efficient way in which smartphones connect to the Internet and social networks that has made almost all schools in the UK wary of allowing their use in class for learning. Being an effective school leader requires balancing the risks for the learners in the care of the school. At the present time, the

overwhelming majority of school leaders regard the benefits of smartphones far outweighed by the risks they pose (Barkham and Moss 2012).

This position has been further reinforced by popular newspaper headlines such as “Schools that ban mobile phones see better academic results” (Doward 2015) or “Banning smartphones from classrooms could damage education, warn researchers” (Knapton 2016). School leaders are confused and generally have school policies that ban smartphone use in lessons, and some schools even ask for smartphones to be handed in to teachers at the start of the school day.

Models of Mobile Technology Ownership

The most common device ownership model in schools in the UK is where the school itself has purchased the devices for use in school and the devices remain in school. The majority of schools purchase shared sets of devices. These are usually purchased in sets of 30, and placed on mobile carts, for primary school so that 1:1 (one computer for each student), 1:2, or small group access can be provided. In secondary schools, shared devices on mobile carts for a department or learning areas are commonplace.

Typically, learners are not allowed to take the devices home. Prior to 2010, there was active UK government support via the “Home Access” initiative (BECTA 2010) to enable families and learners to gain access to devices and the Internet in order to enable them to engage in education and the wider social and economic benefits of being online. This was supported and enabled via a charity, now called the Learning Foundation (Learning Foundation 2018a). The Learning Foundation states that “For 15 years we have been providing independent advice and guidance to a wide variety of schools on the best way to introduce 1:1 technology, where every child has their own device to use in class and at home. During that time we have reached 250,000 children by helping 1,000 schools and all of this has been supported by 40,000 parents” (Learning Foundation 2018b).

1:1 – One Computer per Student

The overwhelming view of the 16 experts interviewed is that 1:1 (Penuel 2006) in the UK is only seen in a very small number of schools. One experienced technologist who supports a large number of schools in the Midlands of England went so far as to say, “*I don’t know any working 1:1 schemes in primary schools. I’m aware of secondary schools that have tried 1:1 and failed. I feel the lack of success has to do with the teachers/staff not actively preparing to teach with devices. As well, there are still some issues with the reliability of devices themselves, for example, long charging issues and work flow challenges.*” Also, all respondents agreed that funding for 1:1 remained a challenge for all but fee-paying private schools.

Specific points relevant to the less-than-rapid transition to a 1:1 mobile learning model in various parts of the UK include:

- In England, between 2010 and 2013, there was a surge of 1:1 projects centered around iPads but this has faded out as changes to funding have squeezed school finances, making the majority of head teachers risk averse. Some private schools have begun to make it compulsory for parents to provide a tablet device for each new student when parents enroll their children.
- Since 2010, there has been very little independent cost-benefit analysis or analysis of benefits to school improvement research to assist school leaders in their decision to go the 1:1 route. This has been a contributory factor in the slow adoption of 1:1 devices in the schools in England.
- In Northern Ireland, there are very few examples of 1:1 initiatives primarily due to budgetary issues. Some local authorities are engaging with projects targeting social deprivation.
- In Scotland, 1:1 is not widespread, but there are pockets of 1:1 use particularly in Edinburgh City, with some schools engaging with 1:1 device rollouts.

Bring Your Own Device (BYOD)

The experts in educational technology interviewed for this chapter were of the overwhelming opinion that “bring your own device” (BYOD) (Paddick 2016) was not very widespread in UK schools. In 2016, Steve Forbes (Forbes 2016), head of RM Networks, commented that, in his opinion, 29% of high schools and 9% of primary schools have some form of BYOD in place. Research for this chapter would seem to indicate that this is an overly optimistic point of view.

A number of reasons for the lack of uptake of BYOD exist. The premise seems so simple; many learners already own their own laptops, tablets, and mobile phones, so allowing them to bring them to school and use them in lessons would solve the budgetary problems for the schools. However, based on the initial projects, the reality is much more complex. Reasons cited for lack of greater BYOB success include:

- Many respondents cited leadership fears regarding e-safety as a major barrier. School leaders are not confident of the security of the data, information, images, and video contained on devices being bought from home and the accompanying risk that this poses to other learners and the school network.
- There are also practical, unresolved issues around liability for insurance, equipment breakages, and responsibility for the learning devices when carrying them to and from school. The question of “If a school asks for a device to be brought in to deliver the education at the school, then is it liable for the device?” has not yet been answered.
- There is also the question of how a teacher might prepare lessons for multiple device types and multiple operating systems being used in any lesson at any time? How might the school ensure that each student has the required apps or programs required for the lesson?

- How do schools address the question of inequality if a learner brings in his or her device and it is obsolete and incapable of running the necessary software or content? That learner may also have inadvertently been put in a potential bullying situation caused by device envy. In September 2016, the Midlothian Council in Scotland introduced an ambitious digital learning strategy which aspires to enable BYOD for all of its learners over the next few years (Midlothian Council 2016). It tackles the inequality problem head on by stating that schools will provide high-powered devices for use by learners from more disadvantaged socio-economic backgrounds.
- In the present state of educational technology development, the software and applications have not yet reached the nirvana of being truly device agnostic and platform independent. The result is that where BYOD is implemented, it is only able to support the lowest common denominator in learning – the browser. For the majority of UK schools, then, BYOD has been put on the “too hard to do” pile, for the moment.

Mobile Learning: Pedagogical Uses of the Mobile Technology

The devices may be mobile – but are they being used for mobile learning? While access to suitable devices has been on the increase, their use and the development of appropriate mobile learning pedagogy is extremely variable. As one leading expert in educational software development explained “*When I work regularly in schools – I do occasionally see transformational lessons - for example learners developing their own apps, but all too often the devices are used to deliver the weekly iPad Lesson.*”

The following perceptive analysis was provided by another long-standing expert in the field of mobile learning who currently works with a number of schools across a region in the north of England:

I think that tablet learning is pretty widespread, but describing it as mobile learning is wrong. Most schools using devices are as class sets, sometimes 1:1 and only used by that child, but rarely allowed to go home. Many schools do have shared class sets; this typically occurs in about 2–3% of schools. The majority of tablet uses are as research devices and accessing web games for the children and use of the camera or assessment apps by teachers. Using cloud services such as “Showbie” (Showbie 2018) does add a great cohesion to work; but teachers tend to use it to replace handing stuff out, rather than exploiting it as the digital classroom, with the physical classroom being a place they just happen to meet during the week. Unfortunately, the focus of their use does not begin with pedagogy, rather with ‘what the device can do’. Yes, it makes some lessons a bit more engaging and makes some traditional organisational ways of working more efficient, but few pupils are expected to use mobile devices in the way that an adult mobile worker would so that idea of developing independence and personal agency is rarely exploited.

The mundane use of expensive tablet devices was echoed by the majority of those interviewed.

Many respondents reported that they observed classes using the devices mainly for Internet searching – but then wrote up the research in exercise books with pen or

pencil. Use of the camera for documenting learning and recording activities was seen as being low, at 10% of all use. Educational apps and content were seen as between 20% and 30% of use.

The use of E-books was central to the early development of mobile learning, and it is still a mainstay of the use of mobile devices in the UK. Apps such as the British Educational Training and Technology (BETT) award winning “Book Creator” (Kemp 2015) form the mainstay of use on the whole range of mobile devices used in UK classrooms. In comparison to the past, currently it is much more straightforward to create an E-Book on a device and incorporate videos, sound files, and even automatically turn pages. Publishing to a shared library is also possible in order to build an audience for the E-book creations of learners.

In Northern Ireland, Scotland, and Wales, it was reported that where the devices were used in conjunction with the countrywide, cloud-based services (e.g., Microsoft Office 365), the use of devices was much deeper. In Scotland specifically, the view expressed was that deeper use was achieved when the school moved beyond just providing access to Internet reading apps to providing a wider range of document creation tools such as Microsoft Sway, Microsoft OneNote, or Google Apps for Education.

Since the inception of mobile learning, managing the assigning of work and its subsequent tracking and assessing is crucial to its effective implementation. In the pioneering days before cloud services arrived, a range of mechanisms were employed (e.g., beaming using the devices’ infrared capabilities) to keep track of the work that teachers assigned and learners subsequently created. The introduction of cloud services and storage, such as Microsoft Office 365 and Google Classroom (Keeler n.d.), have made the potential of seamless integration of digital work across all platforms a distinct possibility.

Unfortunately, that seamless integration has not yet occurred. A myriad of factors are limiting the uptake of efficient workflow on mobile devices, for example:

- Sharing devices among multiple students makes syncing each student’s work significantly more complex.
- iPad apps tend to store a student’s creations inside the app – not inside the device’s file system.
- Each manufacturer (e.g., Apple, Microsoft, and Google) tends to have its own “ecosystem” and each ecosystem is relatively unfriendly to the others.
- Schools in the UK, in order to comply with data security laws, need to be very careful about where data from using an app is stored – especially when some of the ecosystems do not guarantee that storage of data will remain inside the UK.
- The UK does not have a cohesive, strategic framework for the storage of student work (e.g., there is no standard, agreed-upon student digital portfolio).
- While “single sign-on” is the goal, currently, students – and thus teachers – must keep track of multiple login names and passwords.

For example, one expert who works across schools in the North of England observed that: “*Where cloud services are used well it becomes the first focus of their work with the devices. This tends to be in schools where there is a degree of 1:1 use*”

with the same class and the same teacher. Most shared sets [of devices] are simply handed out for a specific task like they would have handed out a piece of paper and a text book!”

Another expert summed up the way in which the majority of his supported schools approach the use of the iPad. “*Workflow is mainly based around the camera roll where children may have taken a screen shot or taken a photo and this is used as evidence or assessed manually when printed off. Children are being encouraged to print off their photos for the teacher to view. Other workflow solutions such as Apple Classroom, Google Classroom, and Microsoft Classroom, allow teachers to manage workflow for their students”* (Laycock 2017).

Working as an independent consultant across a range of UK schools, another expert observed, “*Every school I come across seems to find their own solution that works for them. Examples include using cloud solutions such as Google Classroom, Apple Classroom (Apple 2016, March) or Office 365. Others use tools for iOS such as SeeSaw (SeeSaw 2018) or Showbie.”*

Conclusions: Mobile Learning in the UK

There is still a great deal of enthusiasm for mobile learning in the UK. There are a number of teachers, technologists, and school leaders who continue to carry out pioneering work, and mobile technology is increasingly becoming available in the UK schools. However, the mobile learning transformation that the Learning2Go Project is still a work in progress.

As mobile devices have become more ubiquitous, a blurring between the concepts of mobile learning and simply using mobile technologies in the classroom has taken place. However, there is a difference between the two concepts. True mobile learning, as defined earlier in this chapter, cannot easily be delivered if personal, 1:1, ownership of mobile technology is removed. Benefits to using shared devices can be great, but the specific learner characteristics such as personal organization, absorption, decision-making, responsibility for learning, self-esteem, and communication will be difficult, if not impossible to achieve without personal, 1:1, ownership.

Still further, until the key issue of seriously valuing learners’ digital work is tackled, it is difficult to see how mobile learning can become more widespread. Learners’ digital work is not currently valued by school management systems and formal inspection services as highly as pupils’ work created using traditional pen and paper methods. Indeed, the teaching profession has had over 100 years to develop highly efficient and sophisticated ways of marking and assessing work written in exercise books or in cardboard folders. In contrast, while students seem to be producing digital artifacts, it is difficult to find robust examples of the effective assessment of those digital materials.

In Northern Ireland, Scotland, and Wales, there is a glimmer of hope for the future of mobile learning, as their school inspection services are beginning to recognize and report on the way in which schools integrate technology into teaching and learning. On an international level, the 2015 PISA tests (OECD 2015) showed that large scale

sophisticated digital assessments could take place without the need for a biro (ballpoint pen) and an A4 writing pad.

The debate surrounding mobile learning goes to the heart of the question that should be asked by all school leaders. How are we preparing our students to thrive in the world in which they will live and work? Mobile devices (and their connection to the associated personal services) are clearly becoming an essential part of everyday life. Their use and the integration with work and social interaction will continue to increase. Personalized, 1:1, ownership of mobile devices with a fully integrated digital curriculum could provide the learner development that future adults of the mid-twenty-first century will need.

Abstract

This chapter explores the implementation of mobile learning in Asia, with a particular emphasis on K12 education. A series of 17 individually authored or co-authored country-by-country reports gives an overview of the penetration of mobile devices and the mobile Internet in society and in education. These reports indicate the ways in which such technologies are and are not being employed in teaching and learning, reflecting on the roles of the public and private sectors as well as schools and teachers in their implementation. Common mobile educational practices and their pedagogical underpinnings are outlined, as are associated research projects and publications. The chapter concludes by integrating insights from these reports to establish key regional trends and make recommendations for future mobile learning research.

Keywords

Mobile learning in Asia · K12 mobile learning · Mobile devices in education · Mobile technologies for teaching and learning · Mobile educational practices · Mobile learning research

Introduction

Mobile learning is rolling out at considerable speed across the world. Taking as its springboard the global overview in Churchill and Pegrum (2017), and the associated special issue of *Interactive Technology and Smart Education* (vol. 14, no. 2) on the theme of “Mobile learning, emerging learning design and learning 2.0,” this chapter zeroes in on Asia, digging more deeply into mobile learning practices and research in 17 countries and locations across the region.

Scholars and practitioners from a large number of countries in Asia were invited to contribute short reports on the state of mobile learning in their various contexts, with reports being received from: Brunei, Cambodia, China, Hong Kong, India, Indonesia, Japan, Laos, Macau, Malaysia, Myanmar, the Philippines, Singapore, South Korea, Taiwan, Thailand, and Vietnam. It should be noted that for the purpose of this survey of mobile learning in different locations, it was logical to treat Hong Kong and Macau (each a Special Administrative Region, or SAR, of China) as well as Taiwan as separate contexts, each with its own distinctive trends and practices.

In order to ensure some commonality between reports, while simultaneously avoiding imposing too many restrictions on the diversity of views, general guidelines were provided in the form of key points which respondents were invited – but not required – to consider. It was suggested that respondents could comment on mobile Internet penetration and educational access in their locations; general trends in mobile technology adoption; major educational platforms or apps used or developed; major government or university educational initiatives, including in teacher education; major research projects and publications; and predictions for future mobile learning developments.

Individual authors or co-authors remain responsible for the reliability, comprehensiveness, and representativeness of their reports, as expressed in their own particular voices. It is important to recognize that each report represents a unique view of a given country or location, dependent on the perspectives and positionality of its authors or co-authors. As such, the reports should not be seen as complete accounts of mobile learning in each location, but rather as snapshots taken from the viewpoints of informed educators with significant local experience. It is hoped that bringing together such viewpoints will enlarge the understandings of a global audience of educators who may have had little personal contact with some of these widely varying settings.

The reports have been edited as minimally as possible for consistency, style, and length (though considerable variations in length are still present, reflecting differences in the original reports). Once the reports had been edited, they were coded for key themes by the three main authors of this study, who then collaboratively agreed on the presentation of these themes in the final discussion. The entire chapter, including all country reports and the culminating discussion, was then sent back to report authors for checking and to allow them to make additions, adjustments, and suggestions in light of the companion reports and the discussion themes identified. This led to a final review of the article by the main authors.

Country Reports

Brunei by Saiful Omar and Afzaal Seyal (Universiti Teknologi Brunei)

In 2016, smartphone penetration in Brunei reached 99%, total tablet ownership reached 62%, and laptop ownership increased to 93% (AITI 2016). The top four social media applications used via mobile technology are: WhatsApp (97.3%), Facebook (91.7%), Instagram (87.4%), and YouTube (80%). Individuals in the

15–34 age group have been the most active mobile and Internet users, engaging primarily with WhatsApp, Facebook, and gaming, and accessing content such as movies and TV series. At the same time, individuals in the 35–54 age group are more active with Internet banking and government e-services.

More than 90% of the Internet subscribers have access to fixed and mobile broadband (AITI 2016). Most users spend significantly more time accessing Internet information and social networks, taking pictures, sending emails, and accessing entertainment via mobile technology than via any other Internet-enabled device.

The use of mobile technology for learning is still at early adoption stage in Brunei. Nevertheless, the Ministry of Education Brunei Darussalam has been keen to explore possibilities for implementing mobile learning in schools, while the higher education sector appears to be exploring possibilities more actively. For example, the Universiti Teknologi Brunei (UTB) is taking a leading role in the adoption of e-learning. The School of Computing & Informatics of the UTB has been focusing on developing various learning apps through their undergraduate students' final year projects. Some examples of recent mobile app projects are: "Phonic Learning App," "Islamic Etiquette Mobile Game," "Enhancing the Learning of Malay Vocabulary," "Learning Numbers 1–20," "Year 1 Science," and "Gulintangan Kitani."

From a research perspective, more studies are needed to develop frameworks and explore the adoption and effectiveness of mobile technology. Such research might focus on exploring user perceptions, acceptance, and other critical factors for the successful implementation of mobile learning. A number of studies of student adoption of mobile technology in education at the UTB produced interesting results. Seyal et al. (2014) used a standard instrument to capture students' responses on the three basic constructs of the Technology Acceptance Model (TAM), including Perceived Usefulness (PU), Perceived Ease of Use (PEOU), and Attitude. The results suggest that PU remains the significant determinant of attitude, which in turn predicts intention for adopting mobile learning. Furthermore, Seyal et al. (2015) investigated student mobile learning adoption attributes based on the Diffusion of Innovation (DOI) framework and constructs including relative advantage, compatibility, complexity, observability, and trialability. The results suggest relative advantage and compatibility are the key determinants of adoption. Finally, Seyal et al. (2017) applied the Theory of Planned Behaviour (TPB) framework to the study of adoption attributes of mobile learning, including Subjective Norms (SN), Attitudes, and Perceived Behavioural Control (PBC). The results suggest that only attitude remains a significant determinant of adopting mobile learning technology. The results of these three studies suggest that the DOI framework is the most suitable predictive model of students' adoption of mobile learning in Brunei.

Cambodia by Kurt Bredenberg (Kampuchean Action for Primary Education) and Javier Solá (Open Institute, Cambodia)

The technological context in Cambodia is changing rapidly. By 2014, the number of mobile subscribers had topped 20 million users (Sokhean 2014). In 2016, the Open

Institute reported that 94% of Cambodians aged 15–65 had a phone and 48% of them a smartphone, a number that has grown very fast over the last 4 years (Phong et al. 2016). Urban youth under 25 are the group that is growing fastest in the use of smartphones and the Internet. For the education sector, this is opening up the possibility of schoolteachers and high school students using technology for teaching and learning.

The Ministry of Education, Youth and Sport (MoEYS) has decided to introduce Information and Communication Technologies (ICTs) as a subject starting in Grade 4 (it is currently only in Grades 11 and 12). It will be very difficult to access any devices at primary level, and even at lower secondary level (Grades 7–9), but the lower secondary part will be keyed to mobile devices, not computers, as no computers will be available for more than 1,000 lower secondary schools. Computers have already been partially introduced in upper secondary levels, and this will continue. At lower secondary level mobile devices, probably mostly used by the teachers, will support the teaching of Science, Technology, Engineering, and Maths (STEM) subjects.

Interesting work is also being carried out with early grade literacy. Nationwide tests of reading in Cambodia over the last several years have shown very low scores, with 54% of children failing a test of basic reading. As a result, the MoEYS is now revising its reading curricula; in addition, a number of civil society organizations have started to invest heavily in developing literacy software programs in the Khmer language with close linkages to the newly revised national reading curriculum. Notable educational software products in this regard include “Aan Khmer” (Grades 1–3) and “Smart Books” (Grades 2–3), which are closely linked with reading benchmarks set out by the Ministry’s Department for Curriculum Development. The profusion of mobile devices and use of social media networks in the country offer another new opportunity for dissemination of e-book applications.

Khmer language reading instruction in Cambodia has never really involved the use of differentiated classroom literacy structures that can give struggling readers the confidence they need to acquire reading skills (Abadzi 2010). The current readers are structured as a one-size-fits-all approach for children of all levels, with little guidance provided to teachers about how to address the needs of such children. Even if the MoEYS had developed print-based readers as a supplement, printing costs would be problematic, with textbook availability ratios for core subject textbooks hovering at around 69–70 per 100 students in Grades 1–3. The development of software programs such as Smart Books, which are electronic basals supplementing the core readers, offers significant promise for modulating reading programs according to the needs of individual readers. These basal e-readers possess special interactive features (e.g., digitized quizzes, animations, and audio to promote “multisensory” reading), combined with teacher protocols to promote leveled instruction that will help address the lack of differentiated literacy structures in classrooms (e.g., reading groups), which in turn will aid struggling readers.

Some of the key development partners supporting the MoEYS on literacy have also made significant strides in the electronic administration of Early Grade Reading

Assessments (EGRA) by using a well-known software application called “Tangerine,” developed by USAID and the Research Triangle Institute.

One promising set of developments concerns teacher education. As more than 50% of teachers have smartphones and access to Facebook, this has become a priority channel to reach them with microtraining; indeed, the MoEYS has a Facebook page with over 1.8 million followers. A targeted intervention can be seen in a set of applications from the Open Institute and Voluntary Service Overseas (VSO) which are aligned to the English curriculum in Grades 4–6, and allow teachers who lack confidence in English to listen to what they are supposed to say in English during class; there are menus which allow them to go to any lesson or activity and listen to what they have to teach. Moreover, a new Master Plan for ICTs in Education is currently in development. This will place mobile at the center of the Ministry’s teacher training efforts for in-service training. All materials will be designed in a microtraining format (1–2 min per video) so that they can be flexibly used in different channels.

China by Tianchong Wang (The Education University of Hong Kong)

The number of smartphone users in China has been skyrocketing and is estimated to reach 601.8 million by the end of 2017 (Statista [n.d.](#)). With penetration of smart devices continuing to rise, mobile learning in China is rapidly moving from concept to reality in basic education and beyond.

One of the most noticeable government-led efforts towards mobile learning in recent years has been the introduction of the e-Schoolbag for improving education quality. The e-Schoolbag was first established in Shanghai in 2010 with support from the East China Normal University, then in Beijing and several other major cities in 2011, as an overarching concept of large-scale one-to-one implementation of tablets with preloaded digital textbooks for selected K12 schools. It was intended to provide a multimedia, interactive, and collaborative learning environment where students could access digital content that is more pleasurable and conducive to learning, either inside or outside of classrooms. At the start, the initiative suffered from content being dominated by textbook publishers (Wang and Towey 2012). However, with the hype around the streaming video-based Wei Ke (微课, literally “Micro-Course”) in the last few years, a growing number of grassroots, teacher-designed learning materials have been developed for use via the e-Schoolbag platform (Gu et al. 2016). Despite the growing availability of learning materials, and an increasing number of schools joining the e-Schoolbag initiative, there is still hesitation among school leaders concerning students becoming distracted in class, as well as possible negative effects on eyesight (Li 2013). Students’ abilities to use mobile technologies to learn vary due to the socioeconomic status or the sociodemographic origins of their families, thus reinforcing the resistance of the school leaders to the introduction of the e-Schoolbag in many areas (Li 2013). Hesitation aside, it must be admitted that in a culture of classroom practice that is perceived by many educators as often being teacher-led, the effect of this project seems to be less pedagogically transformative than expected (He and Wray 2017).

Despite the regional disparity of development in China, there have been mobile learning field projects in the provinces of the Central-Western Region to explore how mobile technology can expand access to education and advance literacy and numeracy. For example, a pilot program, spearheaded by a government think-tank called the China Development Research Foundation, aimed to bridge the education gap between the country's urban and rural communities with the aid of a mobile-based learning platform, Mobiliya Edvelop (Aki 2015). Conducted at eight schools in the Qinghai and Guizhou provinces, the pilot program equipped students and teachers with tablets loaded with a system that allowed them to tune into live-streamed or prerecorded video-based learning resources provided by teachers of partner schools in urban areas. It was expected that such a model could be scaled up in order to address the issue of the lack of highly qualified teachers in rural schools, although the outcomes of this program have yet to be reported and analyzed.

In parallel with these government-led or government-supported initiatives and programs that target formal education, the last few years have seen the emergence of a new digital ecosystem, notably incorporating apps from the private sector, as a platform of knowledge distribution with “bite-sized” pieces of learning content. While a small number of educational apps are mapped to national or regional curriculum targets, and designed for use in classroom or homework settings, the majority are intended mainly for informal, personalized, on-demand, self-directed learning. Among these apps, the most popular category is English language learning, which also mirrors the huge English language learning demand in the country (Ambient Research 2015). One reason such a category is favored by students is because the use of apps for language learning is not only effective but also fun: many apps come together with a smattering of gamification, rewarding students for accomplishing their goals, and encouraging them to keep up with their peers.

Social media, most notably Tencent's WeChat (微信), have also been playing a significant role in mobile learning in China. As China's most widely used instant messaging platform, with 768 million monthly active users at the end of 2016 (WeChat 2016), it was never designed to act as a Learning Management System (LMS). However, through a WeChat subscription account (微信订阅号), learning content providers can broadcast information to their followers. For example, the British Council posts English language learning content; Miracle Mandarin delivers Chinese language lessons; and Xueda Education distributes K12 subject tutoring materials through this channel. This social platform creates an organic way for students to communicate with their teachers in one-on-one sessions or to collaborate with peers in webinars. It now appears that WeChat subscription accounts, as a learning platform, have succeeded where many traditional LMSs have failed: in promoting social interaction and taking education to where students already are.

To sum up, although mobile learning in China is still far from an integral part of K12 teaching and learning, it has already started to play an important role in improving access to education, as well as improving educational quality and efficiency. Students' favorable responses to learning apps, learning platforms, and social media confirm the positive impact of mobile learning. In light of such developments, the adoption of mobile learning will continue to grow.

Hong Kong by Yanjie Song (The Education University of Hong Kong)

Hong Kong SAR has one of the highest smartphone penetration rates in Asia. In 2015, 76.9% of 10–14 year olds, 97.9% of 15–24 year olds, and 98.8% of 25–34 year olds had access to smartphones (Census and Statistics Dept, HKSAR 2016). Most users spend more time using their smartphones than any other Internet-enabled devices for accessing information, using social networks, taking pictures, sending emails, and for entertainment anytime, anywhere (GO-Globe 2014).

Taking advantage of the high penetration rate of smartphones in Hong Kong, the government provides more than 100 mobile apps covering different kinds of services (GovHK 2017). Beyond Campus is one of the popular educational mobile apps designed and developed by the Education Bureau (EDB) of Hong Kong. It allows teachers to design their own mobile activities for outdoor learning, using the Global Positioning System (GPS) to display routes and tasks. Another large-scale EDB-supported e-learning venture that includes mobile learning practices has been initiated in 100 schools; it includes the development of curriculum-based e-textbooks aimed at fostering students' twenty-first-century skills. These schools have acquired sufficient mobile devices and have Wi-Fi access in all classrooms for using e-textbooks and e-learning resources.

In addition, universities in Hong Kong are conducting studies on developing apps to support school education, such as EduVenture and LearningVillages. EduVenture is a context-aware mobile learning system developed by the Chinese University of Hong Kong, which supports teachers and students in conducting outdoor field trip learning activities (Jong and Tsai 2016). Students' learning trails can be documented in the learning system. Supported by the built-in GPS system on mobile devices (such as iPads), learning tasks in a certain location are triggered when students walk through the physical target area. LearningVillages is an integrated mobile learning system operating in the form of a Massively Multiplayer Online Role-Playing Game (MMORPG) (Jong 2014); each virtual learning village represents an issue of inquiry to facilitate students' engagement in outdoor inquiry-based learning in social sciences and humanities education.

In addition to developing mobile apps, studies on mobile and seamless learning pedagogical design and practices are prevalent in Hong Kong. Various existing mobile apps have been integrated into pedagogical designs to support students' learning anytime, anywhere. For example, a series of studies on inquiry-based learning have been conducted in Hong Kong schools, employing mobile apps like Skitch (annotation app), Evernote (note-taking app), and Edmodo (a social networking platform) to support students' science and mathematics inquiries across multiple spaces (e.g., Song 2016). Innovative pedagogical designs have been tested, such as the integration of a Bring Your Own Device (BYOD) model into inquiry-based collaborative learning (Song 2014), and a "productive failure-based flipped classroom" pedagogical approach to support students' learning in a mobile learning environment (Song and Kapur 2017), which are effective in motivating students to learn and develop problem-solving skills.

To increase teachers' capacity in implementing e-learning, the EDB has developed a community of practice among teachers to share best practices and encourage collaborations between schools to renew the curriculum and transform pedagogical practices (EDB 2014). The EDB is continuing to enhance IT infrastructure, including providing Wi-Fi access in all public-sector schools since 2014 and building school professional leadership and capacity to foster ubiquitous learning in school education in Hong Kong.

India by Aji Divakar (Murdoch University)

With more than 1.51 million schools and a student population of over 254 million (MHRD 2016), India has one of the largest education systems in the world. With more than one billion mobile phone subscribers, of whom 20% are smartphone users, India is also one of the fastest growing nations in digital consumption (Rai 2016). As India is expected to overtake China in population by 2022 (UN 2015b), growth in the number of mobile technology users can be taken for granted. The Digital India initiative from the national government has not only secured supporters in Silicon Valley but has also acclimatized the nation for educational technology incubation. Recent investments in a learning content provider, Byju's, by Facebook and Sequoia Capital has led to high hopes for technology startups in the K12 market in India. With more than five million downloads, Byju's is a clear example of a success story to emerge from the Indian educational technology sector.

The Ministry of Human Resource Development (MHRD) has launched apps like ePathshala to make textbooks available online for students. The government has also launched digital initiatives like Saransh, a platform to unify data on student performances from schools across the states. In a diverse nation like India, where schools may operate under central or state examination boards, students can choose a local language or English as a medium of study. With policy differences among states, technology can be a unifying solution if it can manage these diversity challenges. Learning and teaching in the Indian education system is mainly about preparing students for various board examinations. That trend is also reflected in subscriptions to mobile learning applications among students in India, with examination-oriented apps like Meritnation and myCBSEguide being popular.

India stands to gain a great deal from ICT innovations related to ubiquitous learning environments (Kinshuk and Huang 2015), which could offer appropriate educational solutions in this massive country. On the hardware side, the manufacturer Datawind, which has local offices in India, entered the market with a \$35 tablet and has become the market leader in affordable tablets in India. In a country where one in five is poor (Narayan and Murgai 2016), but 61% of the poor own a mobile phone, if advancement in mobile learning is coupled with impact investing (Cronin 2017), there is considerable hope for education in India. However, the lack of academic research on these issues in India remains a concern.

Indonesia by Linawati Udon (Udayana University)

A survey by Indonesia's Internet Operator Association in 2016 showed that around half of the population has some form of Internet access. Most people use a mobile device, such as a smartphone, for this purpose (Widiartanto 2016). In 2014, 64.7% of senior high school students were using the Internet, while 2 years later, in 2016, this had increased to 69.8% (compared to 89.7% of university students who were Internet users) (MoCI 2016). Digital marketing research organization eMarketer speculates that in 2018 the total number of smartphone users in Indonesia will exceed 100 million. This could make Indonesia the fourth largest smartphone market in the world, after China, India, and the USA. At the same time, Indonesia is a leader in the adoption of Facebook via mobile devices (Noviandari 2015). In addition to social networking, messaging and web search activities have been widely adopted by mobile technology users in Indonesia (Auliani 2015).

There have been a number of initiatives in Indonesia that relate to ICTs in education and mobile learning. The Indonesian Government's Computer-Based National Exam initiative has been attempting to implement a technology-supported assessment strategy since 2013 (Pakpahan 2016). However, only 42 junior high schools, 135 senior high schools, and 379 vocational high schools have adopted this strategy. Taking into consideration the fact that Indonesia has 26,380 senior secondary schools, the 135 schools that have adopted this strategy represent a tiny minority. In simple terms, most Indonesian schools have to develop a suitable technology infrastructure and capacity to embrace such an initiative (MoEC 2016). Furthermore, the Ministry of Education and Culture (MoEC) has introduced an initiative to regulate and support the implementation of online learning (Abidin et al. 2015). There were previous attempts to integrate online learning technology in teaching and learning in Indonesia. For example, in 2007, the MoEC launched the Jardiknas National Education Network project with the aim of connecting senior high schools in a network of educational innovation and online learning (Yuliani 2010). However, the project was later suspended, due to what some suggest are political reasons.

More specifically with regard to mobile technology, the MoEC has developed the e-Sabak application that runs on tablets and offers access to e-textbooks for schools (Husada 2015; Mahardy 2015). The e-Sabak project provides more than 1,300 e-books which can be accessed through a dedicated app available for download via iTunes or Google Play. At the same time, the Ministry of Research, Technology and Higher Education has established a number of open Moodle-based courses since 2014 (MoRTHE 2017). Furthermore, other mobile learning applications have been developed by universities with the assistance of government research funding, or in rare cases by private companies such as Kalese (Husada 2015).

A number of interesting studies on mobile learning have been conducted in Indonesia, including studies relating to mathematics (Abidin et al. 2015; Tifani et al. 2016), language learning (Darmanto and Hermawan 2016; Seangly et al. 2016; Susanti and Tarmuji 2016; Ulfa 2013), media studies (Astra et al. 2015; Sulisworo and Toifur 2016), and students' learning strategies with mobile technologies (Sulisworo 2017). These studies largely focus on the obstacles to the

implementation of mobile learning in Indonesia. One obstacle that stands out is that the majority of schools prohibit the use of mobile devices in the classroom due to concerns over inappropriate uses by students, negative effects on students' mental health, and possible disturbances to students' learning. On a positive note, some studies have explored ways for Indonesia to become one of the pioneers in the field of mobile learning (Padmo et al. 2015).

Mobile learning in Indonesia can offer many opportunities to improve education quality. Mobile technology penetration in Indonesia is high, and it is continually increasing. Furthermore, emerging findings from international and local researchers, and experiences from implementations in other countries, are likely to encourage mobile learning adoption in Indonesia. However, the implementation needs strong backing from the government to overcome existing obstacles and provide support in areas such as access to electricity; the development of telecommunications and Internet infrastructure across the vast territories of the country; and encouragement to stakeholders to support mobile initiatives. Finally, it must be noted that the implementation faces challenges related to perceived ethical concerns and school regulations.

Japan by Eric Charles Hawkinson (The University of Fukuchiyama)

The timing of Japan's economic bubble and its rise to technological mastery at the end of the twentieth century set the tone, for better or worse, for the current state of mobile technology development and use. Japan saw rapid and widespread use of mobile technology from the 1990s. In 2002, over 40% of the population was in possession of an Internet-connected mobile device (Ishii 2003). When the iPhone came to Japan in 2008, it did not take too long before Japanese developers flooded the market with mobile applications as the market was ripe and ready for mobile purchases, so that iOS application revenue from Japan ranked second in 2012 (Arthur 2012).

Unfortunately, this wide-scale adoption of mobile technology has not made its way into public education to the same extent. Regulations and policies from the Ministry of Education, Culture, Sports, Science and Technology (MEXT) have prioritized student privacy over free use of mobile phones in schools (MEXT 2015). This has left an opportunity for the private sector to fill the needs of learners. The Japan Massive Open Online Education Promotion Council (JMOOC) started an online learning platform in 2013 that has become a large collection of learning content in Japanese (Yamada 2015). SoftBank's Cyber University is an interesting attempt to harness learning content for mobile phones by one of the largest communication network carriers in Japan (Zhang 2008). Other companies have sought to bring educational content to the Nintendo 3DS and other similar game systems, as they still have high market adoption among young Japanese. Software development companies have licensed textbook content and created supplementary resources for mobile Nintendo devices, including *New Horizons*, an English language textbook used by most Japanese middle schools. Japan's cram-school industry has also been much more open to mobile learning than public schools.

The combination of the timing of technological advancement with other cultural phenomena in Japan has produced a strange paradox of high tech environments, but radically traditional thinking. This “Galápagos Effect” (ガラパゴス化) has had a profound impact on the development of mobile learning in Japan. The clearest example is the extended use of flip phones in Japan. These phones required a specific design of webpages with minimal graphical content and a need for only a little bandwidth. This still has an influence on web design today in Japan (Hawkinson 2017). It has, in a way, put Japan at a disadvantage compared to other Asian countries, because it can be harder to update all users and technology, especially in respect to behavior, rather than starting from zero.

There are some interesting things in store in Japan. There are still a very large number of developers and technology companies looking to fill the needs of learners, mostly in informal learning environments. One promising development is the use of augmented reality (AR) and virtual reality (VR). There are many fascinating projects, and there is accompanying research going on into these technologies for learning. It remains to be seen if they can overcome societal and policy barriers to be implemented at larger scales in Japanese schools (Hawkinson et al. 2017).

Laos by Phonekeo Chanthamaly (National University of Laos)

In recent years, Laos has been adopting 3G and 4G technologies, and the Internet user base has grown impressively from 6,000 in the year 2000 to 1.4 million in the year 2016, constituting about 20% of the total population (Internet World Stats 2016a). However, the cost of Internet access remains relatively high compared to the average income, and most people still cannot afford it easily. Those who use the Internet in Laos are predominantly young people in the city areas and/or people from high income families. The cost of Internet access has seriously affected schools, and many are struggling to secure any funding for this. The Ministry of Education and Sports (MOES) has its national master plan that addresses some of the critical issues. However, the nature of the support for ICT integration is not entirely clear.

All teaching and learning in schools in Laos is conducted in a traditional face-to-face mode, and until now there has not been any additional e-learning adoption. From 2010 to 2015, the Laos Government, through the MOES, launched a project to support and extend educational opportunities across the country, piloting it in 17 provincial secondary schools, and enabling these schools to set up ICT centers with equipment provided. However, the strategy has been seriously constrained due to a lack of Internet access, a lack of e-content, and the overloading of teachers with regular teaching and administrative duties. At the same time, private companies specializing in ICTs in education and equipped to effectively support schools are almost nonexistent in Laos.

Until the present time, little data on K12 school students’ use of ICTs for their education have been available in Laos. However, in 2010, the IT Centre at the National University of Laos implemented a study of the use of digital technologies in higher education institutions in Laos, and the results showed that only 39% of

students owned notebooks. The majority of students were accessing the Internet in Internet cafés, not through computers at home or at their institutions. Nevertheless, since the introduction of 3G to Laos in 2012, many students, especially in the capital, Vientiane, have been using smartphones to access the Internet. Thus, smartphones are a primary means of accessing the Internet for learning, but as yet there are no institutions in Laos providing full e-learning or m-learning systems.

Macau by Christopher Fulton and Spencer Benson (University of Macau)

Here we describe the current state of mobile learning in K12 schools in Macao SAR. Our focus is on case studies of teachers working in a limited number of schools from the pool of 77 K12 schools in Macao (DSEJ 2015). The K12 school system in Macao is unique in that the majority of the schools are private, the primary language of instruction can be Portuguese, Putonghua, Cantonese, or English, and there is no government-mandated curriculum per se. A survey of school websites in Macao and conversations with teachers have revealed that the integration of mobile devices and computers into classroom activities is occurring in a limited number of schools. In our 2017 survey, only seven schools were identified as having established classroom environments in which laptops or tablet devices are used by students on a daily or weekly basis. Two Chinese-medium private schools have implemented a one-to-one laptop or tablet initiative. Other private schools are experimenting with laptops and tablet devices.

A one-to-one mobile learning initiative that was implemented at St. Paul's School (one of the larger K12 schools in Macao) in 2012 has been chronicled in the press (Lam 2012) and in a case study (Garcia et al. 2014). The initiative sought to change teachers' pedagogy from primarily didactic and transmission-based teaching to a form that was more collaborative and to increase student motivation and interest. One of the major changes involved replacing textbooks with touchscreen tablet computers (Lam 2012). However, the change from textbooks to laptops can be challenging for teachers, who often struggle to find time to prepare content and interactive activities for learners that capitalize on the devices' affordances. Garcia et al. (2014) listed potential issues with the school-wide mobile learning initiative and its impact on St. Paul's School's mission statement.

An issue of primary importance is the need to communicate to parents the purposes and advantages of mobile learning and the benefits of implementing an ICT initiative with a Learning Management System (LMS). LMSs allow schools to disseminate and document student learning activities and enable communications among stakeholders. When teachers use an LMS, learning activities can be better monitored and assessed. However, features, capabilities, and affordances of laptops, mobile devices, IT infrastructure and, most importantly, the LMS, all shape and influence pedagogies that are implemented within an institution's classrooms. Learning activities using LMSs, often during class time, involve students accessing the LMS and learning activities via tablet devices, laptops, or Chromebooks; this allows

for students to construct, write, and share ideas online. To create opportunities for social learning among young students, schools in Macao have experimented with Moodle, Edmodo, iClass, and DyKnow.

The development, setting up, and deployment of innovative learning activities using LMSs is generally perceived by teachers and students as time-consuming. For many teachers, a potential risk of conducting learning activities with mobile devices and networks is the feeling that the time is not used efficiently, while pedagogical objectives do not align with the technology available to teachers and students. These can be major obstacles to mobile learning integration. Moreover, conversations with school teachers in the surveyed Macao schools suggest that the support provided by IT departments often does not meet their needs. Additionally, the cost of the LMS is seen as an obstacle.

The types of mobile devices (e.g., iPads, tablets, Chromebooks, or laptops) that are supported and employed vary among the schools. For instance, the majority of teachers at one private school were allocated a touchscreen laptop with the Windows operating system, and at another school, teachers were able to choose, with a preference for Apple laptops. Conversations with teachers overseeing IT systems at the latter private school indicated that low-cost, portable devices such as Chromebooks, which have limited functions and can only display content in a web browser, were also used by teachers and students. The hidden costs of supporting multiple types of mobile devices, for example, laptops and tablets, and the practical issues of training teachers using those devices, have to be evaluated before implementation of any mobile learning initiative.

This limited exploration of Macao K12 teachers' practices indicates that, to a large degree, Macao schools are not capitalizing on the use of the most ubiquitous mobile device, i.e., smartphones, and thus the greatest opportunity for mobile learning is overlooked. Moreover, in nearly all K12 schools, smartphones are banned. One primary Macau teacher, from a school with a one-to-one tablet program, predicted that eventually students would be able to use their own smartphones at school as long as the smartphones met certain requirements. For instance, each phone would need to be registered and have an application installed to give schools or parents control over the smartphone. In Macao, like many other places, the learning potential in smartphones is not capitalized upon. This is a missed opportunity for young learners to gain experience and guidance at school on how to use their smartphones as devices that can augment and enhance their learning experiences, in and out of the classroom.

Malaysia by Rozinah Jamaludin (Universiti Sains Malaysia)

Malaysia has developed the Learning Beyond Boundaries concept, launched recently by the Ministry of Education (MOE). It is aligned with the Malaysia Education Blueprint 2013–2025, which incorporates ICTs in education under Shift 7 (involving leveraging ICTs to scale up quality learning across the country) (MOE 2013). This is in turn linked to the 1BestariNet project that aims to provide 4G

Internet access and the Frog Learning Management System (LMS) to over 10,000 Malaysian schools. Teachers have reported that with use of the Frog LMS, both students' academic progress and their communication skills have improved (Chonghui 2016). Online assessments are marked straight away and students receive their marks and feedback immediately. The platform also motivates students to express their views and is thus helpful to more introverted students who are shy to ask questions.

For primary and secondary school students in Year 6 to Form 1 (aged 12–13 years old), Scratch, a free programming language, has been introduced. In Form 4 (where students are 16 years old), they are introduced to the Windows Operating System, Microsoft Office, StarOffice, Microsoft Visual Basic, HTML, Java, JavaScript, Microsoft Access, WAMP-PHP, MySQL, and XAMPP, and they are encouraged to develop multimedia applications (Penang Education Department, personal communication). Web 2.0 tools such as Kahoot!, Padlet, and Today'sMeet, along with green screen technology, have been introduced to students in primary and secondary schools. This has also exposed students to game-based learning and introduced gamification into teaching and learning, as in Kahoot!, for example.

Some private schools such as Cempaka Schools Malaysia have been among the first Apple Distinguished Schools (ADS) in South Asia, as well as pioneers of the ground-breaking LMS Schoology in the Asia Pacific region. Since 2009, Cempaka Schools have been the leading schools in Malaysia to use a one-to-one learning environment where each secondary student has a laptop. Other international schools such as Nexus International School and Garden International School are accredited as ADS. Fairview International School in Penang introduces the use of iPads to children aged 5–7 years as a medium through which to learn about the world around them. Students from Grade 3 (7–9 years) in the International Baccalaureate program showcase to parents the use of iPads in school. Some fully residential schools funded by the government, like the Malay College Kuala Kangsar and Tunku Kurshiah College, also have a strong commitment to one-to-one iPad programs.

It should be noted, however, that because of issues such as discipline problems and disturbances during lessons due to the presence of mobile phones in schools, the MOE, under circular policy 2/2009, prohibited all students from bringing mobile phones into the classroom (Office of Director-General of Education Malaysia 2009).

The future of Malaysian education will involve online learning or blended learning as part of teaching and learning. Currently, learning with school-approved devices is seen as potentially the best way to maximize the use of ICTs for distance and self-paced learning, regardless of location or student skill level. Although there are some challenges faced by schools, like unstable connectivity, they must be resolved as quickly as possible if Malaysia is to move ICTs into the classroom to support twenty-first-century education (Soon 2014).

Myanmar by Thazin Lwin (Yangon University of Distance Education)

The Myanmar Government aims to enable every individual to acquire basic education. In order to meet the Millennium Development Goals (UN 2015a) and ensure

full access to quality primary education in Myanmar, there is a high demand for government expenditure on education, training and recruitment of teachers, better education standards, and increasing the number of schools and their facilities. Education is essential to end poverty in Myanmar. Many young people in developing countries, particularly girls, continue to lack access to education. Myanmar has laid down a policy of compulsory primary education with the aim of achieving 100% enrolment (Kyaw 2013). However, there are many challenges for Myanmar to improve its education. The average adult in Myanmar has received just 2.8 years of schooling, and only 36.5% of students who are eligible for secondary education actually enroll (Arohana Scholarships 2013). Today, two-thirds to three-quarters of children drop out of elementary school before Grade 5. It is foreseen that ICTs, including mobile learning, can significantly improve access to education across the country.

Only few years ago, less than 2% of the population in Myanmar had access to the Internet. Today ICTs are at the center of discussions related to education reforms in Myanmar. UNESCO is working with the Myanmar Ministry of Education (MOE) to support adoption of ICTs in schools. Since early 2015, UNESCO and the MOE have been implementing a multistep program to support ICTs in education, focusing on development of qualified teacher educators to lead the integration of ICTs into preservice programs, connecting schools to mobile broadband networks, and allowing teachers and students to benefit from access to twenty-first-century learning and applications (UNESCO 2015a). Through this UNESCO initiative, selected schools were provided with ICTs such as laptop computers, tablet computers, and projectors and support to enable teachers to best utilize this technology in the classroom.

Recently, mobile technology in education initiatives has begun to emerge in Myanmar; for example, UNESCO, Ericsson, the MOE, and other partners are collaborating on the Connect to Learn project with the aim of improving learning outcomes in literacy and numeracy via the use of mobile technology. Some 33% of households in Myanmar have mobile phones and many of them use mobile phones to access the Internet (UNESCO 2015b). This represents a starting point to explore the use of mobile technology in improving the quality of education. Yet there is still a need for more projects to promote mobile technology for learning. Mobile learning should serve as another important milestone for the MOE in the education reform process. UNESCO is continuing to support Myanmar as it enters the world of smartphones and Internet access, aiming for greatly increased mobile penetration rates in the near future to bring it into line with neighboring countries (UNESCO Bangkok 2015).

The Philippines by Melissa Orenca (Philippine Normal University)

The Philippines is a rapidly growing smartphone market in Southeast Asia, with 20% year-on-year growth (IDC 2016). The upsurge is attributed to the emergence of locally produced, cheap, low-end smartphones accessible to low-income Filipinos.

Smartphone penetration is expected to rise to 70% in 2018 from 40% penetration in 2015 (Camus 2015). In June 2016, Internet usage in the Philippines involved 52% of the total population (Internet World Stats 2016b). The majority of Filipinos use mobile phones to go online, and they commonly engage with social media platforms like Facebook and Twitter, watch digital videos, play games, engage in location-based search, and shop online. However, low connectivity, the necessity for higher memory capacity, and the cost of Internet access are challenges that must be addressed (Medenilla 2016). The Philippine Government established the Department of Information and Communications Technology (DICT), which crafted the National Broadband Program to ensure that problems of access and speed are tackled and to guarantee faster and wider Internet connectivity (CNN Philippines 2017; DICT n.d.-b; Telco.Ph 2016).

Teachers' continuing professional development, fast and reliable Internet connections, and regular updating of technology infrastructure characterize the private schools. Xavier School (XS) and De La Sale Santiago Zobel (DLSZ) are pioneers in effective K12 adoption of mobile technologies. Within a one-to-one device-to-student approach, mobile devices are used to promote personalized and authentic, experiential learning, making students more engaged, productive, and responsive. In XS, for instance, students engage in photo-blogging, podcasting, audio-recording, and v-logging in different subject areas. They use Puppet Pals and Toontastic apps for storytelling, Idea Sketch, and Mindomo to generate ideas and connections, Socrative and Nearpod for literature classes, and FaceTime for communication (Lee-Chua 2013a, b). In science, students create and extend their learning through virtual experiences, enrichment, and interactions via LMSs like McGraw-Hill's CINCH Learning (Bernabe 2013). In Science, Technology, Engineering and Maths (STEM) subjects, students explore experiences enhanced by mobile devices using 7D Experience, robotics, visual programming with Sphero, and 3D printing (Demegillo 2017). In DLSZ, teachers are even creating iTunes U courses to promote learning of science concepts (National Teachers' Month 2016).

In poor and marginalized public school contexts, learning resources tend to be scarce. Access to high-end mobile devices, Internet connections, and teachers' competence in applying mobile learning are generally inadequate. To address this, the government has initiated partnerships with the private sector. Text2Teach is the government's longest-running joint project with the private sector to date. The Department of Education (DepEd), Ayala Foundation, Nokia, Globe Telecom, Pearson Foundation, Toshiba, and Microsoft, along with local government units, are collaborating on the local implementation of the Global Bridge IT program conceptualized in 2003 by Nokia, Pearson, the United Nations Development Programme and the International Youth Foundation (Cristano 2014). Rich digitized teaching resources are delivered through mobile technologies, which has improved the quality of education in at least some far-flung and under-served public schools.

The University of the Philippines Open University (UPOU) has spearheaded mobile learning initiatives in both formal and nonformal education settings. In 2003, the UPOU implemented the TXT 700UPOU mobile learning program involving SMS-based mobile courses for English, maths, and science (Librero et al. 2007;

Pena-Bandalaria 2007; Valk et al. 2010). Then the UPOU partnered with the Molave Development Foundation and the DepEd's Alternative Learning Services and received research funding from the International Development Research Center in 2005–2008 for the Project MIND to train learners in English and mathematics in the nonformal education context (Ramos et al. 2007). In 2013, the Abot-Alam program, through the DepEd and the Technical Education and Skills Development Authority, involved collaboration with mobile operators using mobile-enabled learning services to reach out-of-school youths. In 2013, the UPOU investigated the impact of using tablet computers in selected public secondary schools with support from the Australian Agency for International Development (AusAID) (Australian Embassy 2013). The study revealed that teacher training and access to mobile devices affects learning improvement (UPOU Trailblazers 2015).

Specific policies and laws support mobile learning. The e-Government Master Plan 3.0 (eGMP 3.0) emphasizes strengthening of educational reforms (MITHI n.d.). The Philippine Digital Strategy 2011–2016 encourages public-private sector education stakeholders' exploration of mobile technologies for education (DICT n.d.-a). The DepEd ICT4E Strategic Plan supports new modes of delivering education including mobile learning (DepEd 2008). The Republic Act 10650, or the Open Distance Learning Act, identifies mobile learning as a mode of delivery for distance learning (Congress of the Philippines 2014).

The development of mobile apps has grown steadily in higher education in recent years. For instance, Cheng (2003) designed a framework for mobile learning development; Santos et al. (2010) created an augmented reality system for situated vocabulary learning; Red et al. (2013) developed Word Infection, a game-based app to learn about synonyms, antonyms, and homonyms; Odilao and Bautista (2014) used mobile learning devices for early interventions with children with an Autism Spectrum Disorder; Tulião et al. (2015) created iSuro, a kindergarten tool for teaching and learning aligned with the K12 curriculum; and Monzon et al. (2016) designed Maestra for beginning readers in Filipino. The increasing development of mobile apps provides much potential for enhancing learning and improving the overall quality of education.

Singapore by Kumaran Rajaram (Nanyang Technological University)

A recent Deloitte Technology, Media and Telecommunications survey revealed that Singapore has the highest smartphone penetration rate in the world; nine out of ten respondents had access to a smartphone (Today 2015). Some 98% of households with children who are enrolled in preuniversity education have access to the Internet (IMDA 2014).

Mobile technologies in Singapore have superseded their fundamental functions such as communications, entertainment, and social networking and have now extended their affordances into educational settings. The well laid-out infrastructure and easy accessibility of mobile technologies make the integration of mobile devices into classroom learning designs at schools seamless. Global startups such as

Quipper, SkillPixels, and Duolingo are developing applications and bringing mobile learning to classrooms across the region. SmartKid, an iOS game to teach maths for preschool, Grade 1 and 2 learners, emerges on the top 10 download lists in Singapore and other markets in the Asian region. The partnership of Singapore-based Marshall Cavendish Education with the award-winning mobile game developer Kenneth Tan produced Brainy Arkies, a mobile game designed based on the latest Singapore Ministry of Education (MOE) syllabus to supplement mathematics learning for primary school students.

Back in the 1980s, Singapore initiated the School Link Project for computers in schools (Koh and Lee 2008a). The Professional Computing Support Program commenced in the 1990s to develop teachers' IT skills. The MOE has launched four Masterplans for integrating ICTs into teaching practices and learning experiences in schools, covering the years 1997–2002, 2003–2008, 2009–2014, and 2015–2020, respectively. Masterplan 4 is an ongoing project that focuses on quality learning and aims to develop “Future-ready and Responsible Digital Learners” (MOE n.d.). FutureSchools@Singapore, a government-led initiative, endeavors to enhance the diversity of educational offerings to cater to learners' needs and integrate technology into the delivery of materials. The strategic partnership with infocomm industries has resulted in many new tools and applications that have transformed experiences, for both teachers and students. Notable examples include the augmented reality mobile learning trails developed by companies such as LDR and Rockmoon and deployed in many schools as well as tertiary institutions, with teachers and even students now designing their own app-based multimedia mobile learning activities (Pegrum 2016c).

Research and development (R&D) plays a crucial role in Singapore's endeavors to promote itself as a global education hub, explicitly integrating ICTs in learning. Several explorative pilot studies were conducted by the MOE in primary and secondary schools and junior colleges in the mid-1990s to comprehend the adoption of ICTs in education. These served as the basis for the development of the ICT Masterplans (Koh and Lee 2008a). The eduPAD project was launched in 1999 by the MOE and its industry partners in collaboration (Koh and Lee 2008b). In 2003, Microsoft Singapore and the Infocomm Development Authority of Singapore, with support from the MOE and the National Institute of Education (NIE), launched the collaborative project Backpack.NET, in which tablet-based applications were developed and tablets were deployed to secondary schools to study the potential of ICTs in education. One of the highlights of this project is the Classroom of the Future Live! (COTF Live!) that showcases applications of new technologies in everyday teaching and learning, set up at NIE in 2005. The Backpack.NET center was also launched, serving as a research and training center to integrate ICTs into education (Koh and Lee 2008b). Other R&D initiatives include FutureSchools@Singapore, LEAD ICT@Schools, Edulab, and the Learning Sciences Lab at NIE.

Continuous advancement and prevalence of mobile technologies is evident in Singapore, thanks to wide-ranging governmental support backed up with reliable technological infrastructure. The possible challenges include the sustainability of mobile learning projects. It is hoped that involvement by other stakeholders – such as

industry leaders in mobile learning, parents who have the purchasing power, and educational institutions that embrace the ecosystem of mobile learning – will create a smooth pathway for sustainable development.

South Korea by Michael Gallagher (The University of Edinburgh)

The technological infrastructure of South Korea, driven by massive government infrastructural investments of the late 1990s (Frieden 2005) and a thriving domestic mobile industry, underpins many of the mobile learning developments taking place in the country today. Some 97.5% of all households in Korea have broadband access (OECD 2016); there are 56.9 million mobile connections for a population of 50.4 million people (GSMA Intelligence 2015), and 99% of the population enjoys mobile broadband connections.

As a result, mobile traffic accounts for 37% of all web traffic in South Korea (We Are Social 2017). A total of 87% of the South Korean population actively uses social media, and 83% of that population is doing so through mobile as of 2017. Along with this connectivity comes a local capacity for digital software, applications, and social media environments; South Koreans are accustomed to using technologies and applications developed in and for South Koreans, from earlier social media (CyWorld, or 싸이월) to modern messaging applications (KakaoTalk, or 카카오톡), all accessed through domestic mobile technology (Samsung, LG, and more). Further, they use mobile at an early age, with 80.6% of Korean adolescents having their own mobile phone and, for example, 87.7% of 12-year-old Korean adolescents using mobile phones, far more than in other countries (Ok 2011, p. 330). These numbers have surely increased since 2011, and data collection has extended further into younger demographics as Internet use is measured to include children as young as three (Harpur 2017).

Korean students in primary and secondary education are using mobile technology in predictable ways: to reinforce a local sociality and maintain peer relationships, to reference or research, to take notes, to create and consume media, and more. They do this largely through domestic applications, such as KakaoTalk, in such a way that it reinforces the cultural landscapes in which these students find themselves. Jin and Yoon (2016) write: “the KakaoTalk-scape does not simply signify a radical rupture from young people’s ordinary cultural landscape but rather implies the possibility that smartphone technology is incorporated into the rhythm of young people’s everyday lives” (p. 520). These students, through their use of KakaoTalk, are reinforcing in the digital space the Korean environment they see in their daily lives through chats, texts, emoticons, and media.

This extends into social media with some slight idiosyncrasies: Korean social networks tend to be much smaller than their Western counterparts and people’s motivations for participation (social support, some information seeking, less casual relationships) speak to a close-knit social network that reinforces peer communities (Ok 2011). Social media, like mobile technology, “reconfirm young people’s peer networks, which continue traditional modes of sociality and cultural identity rather

than encroach on them (Na 2001)” (Ok 2011, p. 329). KakaoTalk continues the trend advanced in earlier Korean social networks, such as Cyworld (Hjorth 2007).

For education, this saturation of access and mobile technology has produced an environment where mobile learning is part of a larger interrelated whole. Smart learning involves “learning with resources and content available from both the public and private sector, including social learning as found through social media,” and “technology-embedded learning where technology is available to support anytime, anywhere learning” (Noh et al. 2011; translation by author). Mobile learning initiatives for primary and secondary education reflect this, such as the South Korean government’s USD 2.4 billion effort to digitize all educational materials by 2015, making them accessible through computers, tablets and smartphones (Pandit et al. 2012).

Research, however, on the effects of mobile learning is sparse and speaks to quantitative measures of acceptance and willingness to use mobile technology in K12 classrooms, rather than to learning impact. Considerable research exists in the informal mobile learning space of social media use and KakaoTalk (Hjorth 2007; Jin and Yoon 2016), but rarely is that bridged with formal learning in the K12 classroom. Some recent examples provide optimism for renewed interest in impact, such as Bae and Lee’s (2016) discussion of a mobile learning application for creative problem solving activities, but this research is limited in the larger body of mobile learning in Korea.

The use of mobile technology for formal learning will garner more attention and resources as Korea’s mobile industries continue to thrive and greater amounts of Koreans’ sociality is enacted in mobile spaces. Whether that transfers into research demonstrating the impact of mobile learning in formal education remains to be seen.

Taiwan by Chun-Yen Chang (National Taiwan Normal University)

There is an increasing prevalence of Internet usage in Taiwan (Internet World Stats 2017). Taiwan’s Internet users accounted for 88% of the total population in March 2017, as opposed to 67.4% in 2008. A survey of students’ Internet usage conducted by the Taiwanese Ministry of Education (MOE) in 2015 revealed that the percentages of students who possess their own smartphone devices include: 38.8% of elementary school students, 78.8% of junior high school students, and 93.3% of senior high school students (MOE 2015). In addition, the average time spent on the Internet per school day for these groups of students is: 45.1 min, 67.1 min, and 75.2 min, respectively, and 57.8 min, 115.8 min, and 147.2 min on the weekends. These statistics reveal that Taiwanese students, in general, spend a great deal of time surfing the Internet.

In response to global trends in information technology and mobile technology development, tablets and smartphones have gained increasing popularity. The MOE has developed the Teachers’ Teaching Application, which provides a platform for in-service teachers to share their innovative experiences and feedback about mobile teaching. The application has so far received more than 2 million hits, provided

700 varied teaching examples, and compiled a list of about 1500 teaching applications screened and recommended by teachers around the country. In addition, the MOE has taken the initiative of encouraging collaborations between the academic community, county and city governments, and the private sector. Examples of their efforts include the 2014–2016 Taiwan Mobile Learning for High Schools (<http://mlearning.ntust.edu.tw/>) and the 2014–2017 Mobile Learning for Elementary and Junior High Schools (<http://mlearning.ntue.edu.tw/>) projects. The purpose of these projects has been to encourage schools to actively integrate information technology and digital resources into teaching, and develop student-centered innovative instruction. In doing so, it is hoped to enhance students' domain knowledge and to help them develop important skills, such as communication, critical and innovative thinking, problem-solving, collaborative learning, and the like.

Higher education institutions in Taiwan are also actively developing new mobile technology systems to facilitate teaching and learning. The National Taiwan Normal University (NTNU), for example, has developed its mobile application CloudClassroom (CCR) to enable students to give feedback or responses to instructors' questions in real classroom settings in an instantaneous manner on a mass scale. CCR is written in HTML 5.0 and, without additional software or plug-in installations, it works on every mobile device such as laptops, PDAs, smartphones, and tablets. Once connected to CCR through their own mobile devices, the instructors can pose various types of questions to the entire class. Students are then able to use their devices to give responses to the instructors in the form of digits, texts, pictures, animations, or even multimedia. Since there is no pressure for the students to speak out their answers or to raise their hands when volunteering to speak, it creates a safer and more comfortable learning environment for quiet students to participate in during the class. On the other hand, verbal students' needs for interacting with teachers and peers may be met as well. Furthermore, CCR can automatically aggregate a report for the teacher to gauge students' learning in a timely manner. The usability of CCR has been validated in science classrooms in Taiwan (Chien and Chang 2015; Chien et al. 2015). Having developed this efficient mobile teaching and learning system, NTNU has made great efforts to share the system with primary and secondary school teachers and provide workshops and teacher training to assist them in making good use of the system to facilitate their teaching. At present, approximately 15,000 users have been registered in CCR. More than 120,000 classroom activities have been conducted by using CCR. It is anticipated that CCR will become more cost-effective as more and more schools start embracing Bring Your Own Device policies.

As wireless communications and mobile technologies continue to advance and gain popularity, increasing numbers of institutions are taking active roles in incorporating mobile technologies into educational settings, such as classrooms, museums, and labs, to enhance students' learning motivation and achievements. While it is important that schools and educators keep pace with the times by employing effective educational technologies in teaching, it is also essential to be reminded that technology, by itself, does not improve teaching and learning. It is only by taking into consideration learners' needs and implementing careful learning

designs and effective teaching strategies, that educators can use innovative technologies to truly facilitate and enhance teaching and learning as a whole.

Thailand by Vorusuang Duangchinda (Sripatum University)

Thailand is a fast-growing country with a population of over 68 million (Worldometers 2017). According to Veedvil (2016), there were 83 million mobile phone subscriptions in Thailand at the end of 2015, but only 4.3 million of them connected to a 4G network. However, the number of mobile subscriptions had increased to 90.94 million by January 2017, representing 133% of the population (Kemp 2017). A mobile phone of any type is the most common digital device, used by 96% of Thai adults, with some 70% using a smartphone, 26% a laptop or desktop computer, and 11% a tablet; most web traffic in Thailand is generated via mobile phones (66%), followed by laptops/desktops (29%), and tablets (5%) (Kemp 2017). Kemp (2017) indicates that 62% of the Thai population is active in using mobile social media, which is well above both the global and the regional average. Veedvil (2016) specifies that 74% of Thais use instant messaging every day, with smartphone users spending on average 94 min on communications and 62 min on apps, out of a total of 4.2 h per day spent on their smartphones.

Thailand is at a very early stage of adoption of smartphones in education. Currently, the predominant way of learning through technology in Thailand is by watching online teaching videos and searching for relevant information. However, the Royal Thai Government has introduced the Government Application Center (GAC), a centralized platform hosting freely downloadable mobile applications for all Thais (<http://apps.go.th/>). As of May 2017, there are 256 applications in 13 categories, including a dedicated section for education with more than 10 apps available. Each of the apps has been developed by a designated governmental department or a leading public university and serves a specific purpose, for example: “Thai Language Dictionary,” “Digital Learning Television App,” and “Museum Pool App.” These applications can be utilized to support learning in K12 education.

For K12 education, overseen by the Office of the Basic Education Commission (OBEC) of the Ministry of Education, there is a dedicated portal called the “OBEC Content Center,” housing educational apps as well as authoring tools for K12 (<http://contentcenter.obec.go.th/m/>). In addition, there is a collection of K12 apps under the One Tablet Per Child (OTPC) project established in 2012. This ambitious national project aimed to provide a free tablet device with quality educational content to all K7 students. However, the project has now been suspended, and OTPC applications have not been developed any further.

Reform of education, at all levels, is much needed in Thailand. This reform should include not only an improvement of the government’s strategic policies, but also strategic partnerships across public, private, and educational institutions. There has been strong support for such partnerships from international organizations including UNESCO. Examples of current initiatives promoting mobile learning in Thailand include Mobile Literacy for Out-of-School Children, a co-operative project

between Microsoft, True Corporation, and the MOE (UNESCO Bangkok 2016); the Thailand Cyber University Project (<http://www.thaicyberu.go.th>); Thai Massive Open Online Courses (MOOC) (<http://www.thaimooc.org>); and Thai Open Educational Resources (OER) (<http://oer.learn.in.th/>). In addition, the government has been working very closely with universities around Thailand. A national project under the theme of “Teach less and learn more” saw universities voluntarily assisting the development of schools near their campuses.

Looking to the future, the national online education credit bank system is in the final stages of development, and the UniNet initiative has been successfully implemented to include dedicated high-speed fiber optic networks linking all higher education institutions throughout Thailand (Nasongkhla et al. 2015). High speed Internet connectivity, mobile devices, and the explosion of Artificial Intelligence (AI), Virtual Reality (VR), and Augmented Reality (AR) will shape Thailand’s education in the near future. There is a strong need for research to examine the adoption of mobile and other technologies in education. Further research and development in AI, VR, and AR is also important to the advancement of the country under the Thailand 4.0 model (MOC 2016). Such technologies are likely to be integrated with mobile technologies, and thus together they will potentially shape the future of learning in Thailand.

Vietnam by Dang Hai Dang (Hanoi Open University)

In January 2016, internet penetration in Vietnam reached 50%, while the mobile phone subscriber base reached 152% of the population; among 35 million active social media users, there are 29 million active mobile social media users (Nguyễn 2016). With such growth in access, mobile technologies have a significant opportunity for adoption in K12 education in Vietnam.

In Vietnam, the K12 education system, with the total number of students exceeding 15 million, pursues rigorous academic goals. Its primary purpose is to equip students with the ability to attain a Secondary School Certificate (Grade 9) or Secondary School Diploma (Grade 12). All additional teaching and learning activities are adapted around the core curriculum designed to achieve such an end. This is the case with the adoption of educational technologies that make these additional teaching and learning activities possible. In 2012, Vietnam’s education authority issued Decision No. 711/QĐ-TTg approving the Education Development Strategy 2011–2020 (Nguyen 2012). In this decision, the government emphasized the important role of ICTs in building a learning society. However, the use of educational technologies in this strategy has been criticized for a lack of research, practical orientation, and quantitative indicators that show advancement in learning.

In the business sector, there are a number of innovative companies focusing on education, and these have been playing a critical role in spearheading the adoption of technologies in Vietnamese classrooms. Hocmai is the largest K12 online education provider with 2.5 million users. It provides both basic knowledge and exam preparation tests at competitive tuition rates. The learning content is mainly provided

through media such as videos and slides accompanied by multiple-choice questions, notes, and discussions. However, the provider lacks interactive content and live or synchronous courses. Another platform is Rokit Online, which focuses on content and tests in mathematics, physics, chemistry, and English for Grades 7–12. Furthermore, there are large online test-taking and practice platforms including Violympic (for mathematics and science) and IOE (for English). Other platforms include the Monkey Junior mobile application for children from kindergarten to 10 years of age. In addition, there are companies like Topica and Kyna, interested in developing K12 mobile learning products in addition to their existing adult e-learning courses. The private sector, especially via startup companies, is likely to play an important role in the development of the mobile learning market. If the universities and educational research institutions in Vietnam remain in their current rigid mode of operation, they may well be left behind in these developments. Nonprofit organizations are less likely to join and contribute to these.

With the radical reform of the national education system in the near future, the core K12 curriculum will be designed in a more flexible and sustainable way. There has been a general focus on cross-curricular and life skills courses. It appears that there is a positive atmosphere for mobile learning to enter education, and in particular to support initiatives related to Science, Technology, Engineering and Maths (STEM), language learning, and life skills courses.

Discussion

While there are certainly differences in the mobile learning possibilities in the 17 locations covered in the country reports, a striking number of commonalities emerge. Key themes are outlined below. It should be noted that the broad distinction made between developed and developing countries in the following discussion is based on the countries which do, and do not, feature in the United Nations Human Development Index as having a very high level of human development; the countries in the study which fit within this category include Brunei, Hong Kong, Japan, Singapore, and South Korea (UNDP 2016); non-UN members generally included in this category are Macau and Taiwan (“List of countries” 2017).

Availability of Mobile Technologies for Learning

Thanks in large part to governmental infrastructural development over many years, developed locations in the Asian region have some of the world’s highest rates of Internet penetration, mobile – especially smartphone – penetration, and mobile Internet penetration. Indeed, in many such locations, smartphones have become the usual way to access the Internet, with 3G/4G (and soon 5G) networks complemented by robust Wi-Fi access, including within educational institutions.

While it is unsurprising that developed locations have higher mobile and Internet penetration rates, a common theme in developing countries is that penetration is

growing rapidly. Unlike developed countries, where mobile Internet access is an alternative and complement to fixed Internet access, in many developing countries mobile phones – which increasingly means smartphones – are the primary or sole means of Internet access for large sections of the population. This becomes clear in a context like Laos, for instance, where students are now increasingly accessing the Internet through smartphones rather than needing to visit Internet cafés.

Countries like China, India, Japan, and South Korea have a number of local hardware and software companies, and some have produced a considerable amount of well-known software, with examples including South Korea's KakaoTalk (카카오톡) and China's WeChat (微信). This local focus may have the effect of reinforcing users' everyday "cultural landscapes," as noted in the South Korea report, while having the educational advantage of allowing teachers to bypass unpopular institutional LMSs in the process of "taking education to where students already are," as noted in the China report.

In terms of hardware, most country reports focus on laptop computers, tablets, and smartphones, which form an ecosystem of digital technologies that can be exploited for education, especially with the expansion of Bring Your Own Device policies across the region. Interestingly, however, the early entry of a country into hardware (and software) markets may not always translate into a long-term advantage, as seen in the case of Japan with its now famous Galápagos Effect (ガラパゴス化) where, for example, mobile phones evolved in a direction different in some ways from the rest of the world, placing certain limitations on future developments. Nor does a large-scale, government-sponsored hardware program, such as One Tablet Per Child in Thailand, have any guarantee of longevity, with this project now having been suspended. None of the reports make explicit reference to newly emerging and educationally promising hardware like smartwatches or smart glasses (e.g., Bower and Sturman 2015; Pegrum 2016a), but in line with current educational interest in independently or semi-independently mobile learning technologies such as robots (e.g., Hung et al. 2013), it is noteworthy that robotics rates a mention in the Philippines report.

In terms of software, in everyday life in both developed and developing contexts, there is a strong focus on the use of web 2.0/social media services (like Facebook, Instagram, Twitter and YouTube) and/or messaging services (like KakaoTalk, WeChat and WhatsApp), including the social networking facilitated by these platforms, flagged up in South Korea as reinforcing "traditional modes of sociality and cultural identity" (Ok 2011, p. 329). Games and gaming, often with educational purposes, surface in many of the country reports, including a reference to a Massively Multiplayer Online Role-Playing Game (MMORPG) format in Hong Kong.

The current international educational interest in virtual reality (e.g., Lewis 2016) is reflected in the Japan report, and as a future trend in the Thailand report. Meanwhile, the international educational interest in augmented reality (e.g., Bacca et al. 2014; Dunleavy and Dede 2014; Radu 2014) is evidenced in the Japan, Philippines, and Singapore reports, is present by implication in the Hong Kong report, and is again mentioned as a future trend in the Thailand report. Curiously, despite growing global interest in artificial intelligence (AI) – including in countries

such as China and Japan (Hsu 2017; Jolley 2015) – the Thailand report is the only one to mention its role, alongside other future projections.

Teaching and Learning Activities with Mobile Technologies

As mentioned in a number of developed and developing country reports, and implied in many others, the widespread use of digital and mobile technologies in society at large does not necessarily equate to the widespread use of these devices in education. This naturally leads to the question of what additional factors are necessary or helpful in supporting educational deployment of these technologies.

It is interesting to note that in most countries the government is taking a role in promoting digital and sometimes specifically mobile learning. This is often done via the governments' educational arms, such as Hong Kong's Education Bureau, which provides mobile apps to teachers; Singapore's Ministry of Education, which is now in the midst of executing its fourth five-year ICT Masterplan; and Taiwan's Ministry of Education, which provides a platform for teachers to share mobile learning experiences. In the developing world, the Philippine Department of Education's five-year ICT4E Strategic Plan encouraged new modes of educational delivery, including mobile learning, with the Philippine Digital Strategy of 2011–2016 promoting this further. Similarly, the Vietnamese Government's 2011–2020 Education Development Strategy includes a focus on ICTs, while the Malaysia Education Blueprint 2013–2025 includes the leveraging of ICTs as one of 11 transformational shifts in education, linked to the 1BestariNet project to provide high-speed Internet access to schools, and the rollout of the Frog LMS. The Thai Government, for its part, has set up a Government Application Center which offers freely downloadable apps, including educational apps, while the Office of the Basic Education Commission (OBEC), part of the Ministry of Education, hosts an OBEC Content Center, which offers K12 educational apps and authoring tools. Meanwhile, the Chinese, Indian, Indonesian, and South Korean governments, though their relevant ministries, have been working on digitizing textbooks, with the first three of these projects referred to as the e-Schoolbag, ePathshala, and e-Sabak initiatives, respectively.

The interwoven roles of the public and private sectors surface in many reports, potentially involving, in varying combinations, different levels of governments and their educational divisions; universities, and research institutes; telecommunications and technology companies; and nongovernmental organizations (NGOs), as seen in contexts as diverse as Cambodia, China, India, Indonesia, Myanmar, the Philippines, Singapore, South Korea, and Taiwan. In Myanmar, for instance, the Connect to Learn project promoting mobile learning is supported by the Ministry of Education, Ericsson, UNESCO and other partners; in the Philippines, the Global Bridge IT program, which spreads digital resources through mobile technologies, has been supported by the Department of Education, Ayala Foundation, Nokia, Globe Telecom, Pearson Foundation, Toshiba, and Microsoft; and in Thailand, the Mobile Literacy for Out-of-School Children project is supported by the Ministry of Education, Microsoft and True Corporation. In countries where there is less direct government

support, as in Japan, private companies may take on a correspondingly larger role. And while one-to-one initiatives are sometimes promoted at country level, as in the government-driven e-textbook projects mentioned above, in other locations it is up to individual educational institutions – which may initially mean private schools – to implement one-to-one computing or tablet initiatives, as noted in Macau, Malaysia, and the Philippines.

In developing countries in particular, social justice initiatives seek to overcome regional disparities and urban-rural divides (cf. Pegrum 2014). In some countries, school enrolment falls far below the targeted 100%, even at primary level; thus, in a location like Myanmar, a first priority is increasing primary school enrolment, in line with the United Nations Millennium Development Goals (and the post-2015 Sustainable Development Goals). Digital technologies are widely seen as having a role to play in expanding access to quality education. The Laos Ministry of Education and Sports, for instance, has set up a project to pilot the establishment of ICT centers in provincial schools, though this project faces challenges in terms of limited digital content and limited Internet bandwidth. In part due to a lack of fixed infrastructure outside the cities in large developing countries like China and Indonesia, there has been a focus on the use of mobile devices. The broad reach of mobile approaches can also be seen in the aforementioned Connect to Learn project in Myanmar and the Mobile Literacy for Out-of-School Children project in Thailand, while in Cambodia the Smart Books software helps to compensate for a lack of hard-copy textbooks, and in the Philippines there are co-operative partnerships providing informal mobile learning for those with limited access to the educational system. There is also scope for on-demand learning through apps which may supplement students' formal learning. It is reported that in India and Vietnam exam preparation platforms are popular, while in China there is great demand for English language learning apps. In India, digital technologies are viewed as a way of managing "diversity challenges" in a nation where students may be subject to varying state policies and learning in different languages.

Internationally, as reported in Churchill and Pegrum (2017), some key areas of educational exploration have included multimodal materials delivery, interactions, representations, and creations (e.g., Churchill 2017; Eisenlauer 2014; Kukulska-Hulme and Pegrum *in press*). In Asia, large-scale textbook digitization initiatives in countries like China and South Korea are likely to promote both multimodality and personalization of learning. Yet it would seem from the country reports that much multimodal online learning content, whether delivered via e-textbooks or apps or a combination of both, primarily involves information delivery accompanied by quizzes. Multimodal games and gamified apps can be highly engaging, and these are used with students, for example, in China, Hong Kong, Malaysia, and the Philippines. Going further, the concept of students becoming involved in multimodal creation and production with digital technologies is mentioned in reports from Malaysia, the Philippines, and Singapore, with a focus on app development in the first of these, and augmented reality app deployment in the last.

Internationally, there is a strong focus on digital collaboration and networking (e.g., Alhindy 2015; Ilic 2015; Pachler et al. 2012), something which is facilitated by the kinds of web 2.0 or social media platforms which are widely mentioned in the

Asian country reports. In Malaysia, for example, school students are introduced to Web 2.0 tools ranging from Kahoot! to Padlet, and it is indicated that similar kinds of tools are being used in at least some schools in the Philippines.

Internationally, there is also a focus on seamless learning inside and outside the classroom (e.g., Wong et al. 2012; Wong and Looi 2011). It is notable that two Asian country reports make explicit mention of seamless learning, namely Hong Kong and Singapore, with this idea being implicit in many other reports which highlight the use of mobile apps as a complement or even alternative to formal educational structures.

Finally, there is also a major international focus on the development of new literacies essential for twenty-first-century life (e.g., Frawley and Dyson 2014; Pegrum 2016b). There is an acknowledgment of the importance of so-called twenty-first-century skills, which include communication, collaboration, critical thinking, and creativity, in the Hong Kong and Taiwan reports. The development of digital literacies is essential to support such skills (e.g., Dudeney et al. 2013), and it is interesting to see that in some contexts, like Malaysia, the Philippines, and Singapore, students are being introduced to coding and creating with digital technologies, while students in Brunei (at least at tertiary level) are developing learning apps.

It is evident from the reports from developed and developing countries alike that digital and mobile technologies are seen as having potential value across a whole range of subject areas, from literacy and numeracy through to Science, Technology, Engineering and Maths (STEM); indeed, the STEM area, which has recently become a major focus in education systems worldwide, is mentioned explicitly in the reports from Cambodia, the Philippines, and Vietnam. Nevertheless, despite all of the apparent potential, in some developed contexts, integration of digital technologies in schools is still limited, as in Macau, and in some developing contexts there is little use of digital technologies at all, as in Laos. In some locations, like Macau, many schools may ban phones, while in others, like Malaysia, the Ministry of Education has banned phones. In various reports, challenges with digital technologies have been identified as arising around practical issues like a lack of electricity (Indonesia), limited and/or unstable Internet connectivity (Indonesia, Laos, Malaysia, Philippines), cost (China, Laos, Macau, Philippines), time (Macau), limited IT support (Macau), and sustainability (Singapore). There are concerns over students being distracted or disturbed in class (China, Indonesia, Malaysia); this arises against a background of broader societal concern over technology addiction (South Korea) and mental health issues for students (Indonesia). There are fears over physical health problems like poor eyesight (China), and potentially ethical issues too (Indonesia). There are also policy restrictions designed to protect student privacy (Japan). In addition, parents, families, and other stakeholders may need to be convinced of the value of digital, and especially mobile, learning, as noted in China, Indonesia, and Macau.

Pedagogical Approaches to Mobile Technologies

It has been argued that today's mobile hardware and software present opportunities for pedagogical transformation (e.g., Cochrane 2013; Kearney et al. 2015; Lindsay 2016).

Certainly, some of the Asian reports explicitly mention the notion of transforming pedagogy, shifting it away from didactic modes and towards collaborative, constructivist modes, as discussed, for example, in Macau.

It has become evident in international studies that there are at least three levels, or paradigms, of mobile learning (e.g., Churchill et al. 2014; Pegrum 2014, 2016c). At the first level, the devices are mobile, but the learners and the learning experience are not. Here, mobile devices are essentially treated as a replacement for, rather than a complement to, computers (Burston 2016). Typically, the pedagogy largely involves information transmission or behaviorist drills, with some scope for personalization but usually less scope for collaboration or authenticity (cf. Burden and Kearney 2017). E-textbook initiatives would generally fall into this category, as do many social justice or access initiatives in developing countries.

At the second level, the devices and the learners are mobile, but the learning experience is still not; here there is usually scope for both personalization and collaboration. Learners might be mobile in the classroom, collaborating around the technologies, or they might be mobile in their everyday lives, engaging in (probably distance) learning in moments of downtime in varying locations. However, in neither case does the context influence the learning. A key related concept is anytime, anywhere learning, often app-based in nature, as referenced in the Hong Kong and South Korea reports, and implied in many other country reports.

At the third level, the devices, the learners, and the learning experience are all mobile, opening up possibilities for education which is personalized, collaborative, and authentic. This is currently a major focus internationally in studies that in varying degrees emphasize contextual learning (e.g., Churchill and Lam 2017; Reinders and Pegrum 2016; Sharples 2016) and seamless learning across contexts (e.g., Song 2014; Wong and Looi 2011). While seamless learning may involve learning that bears no relation to its surroundings, the most promising kinds of seamless learning have a contextual element where students can at least sometimes apply their learning in varying environments and/or can create and share multimedia records of their learning captured in those varying environments. The use of mobile devices' location awareness functionality to design contextual learning activities is evident in Hong Kong, for example, and augmented reality learning trails are discussed in the Singapore report. In the process of engaging in and recording contextual learning activities, students are also very likely to develop a range of digital literacies.

Worldwide, there has been a great deal of commentary on the need for educators, faced with expanding possibilities for pedagogical transformation, to act as designers of learning materials, learning environments, and learning experiences for their students; they might do so independently or in collaboration with programmers and instructional designers (Churchill and Pegrum 2017). This point has been made in the general literature about digital learning (e.g., Garcia 2014; Gee 2015; Laurillard 2012) as well as the literature that focuses more specifically on mobile learning (e.g., Hockly 2016; Milrad et al. 2013; Sharples 2016). It is widely appreciated, as noted in the China and Taiwan reports, that technology by itself does not lead to pedagogical changes. Instead, the importance of appropriate learning

designs is recognized, as highlighted in the reports from Hong Kong and Taiwan. It is striking that in China's e-Schoolbag initiative, there is increasing scope for "grassroots, teacher-designed learning materials." In the Philippines, some teachers are creating their own iTunes U courses. In Hong Kong, teachers are encouraged to design customized mobile learning activities with the Beyond Campus app. In Singapore, teachers and students are creating their own augmented reality learning trails.

Some reports, from locations that stretch from Macau to the Philippines, mention the importance of appropriate teacher education or training. Hong Kong's Education Bureau supports a community of practice where teachers can share digital teaching experiences, while Taiwan's Ministry of Education provides teachers with a platform to share innovative mobile learning practices. In Myanmar, the Ministry of Education has partnered with UNESCO to support the integration of ICTs into preservice teacher education by qualified teacher educators.

Research on Mobile Technologies for Learning

In this rapidly evolving area, there is clearly a need for research to develop theoretical frameworks of mobile learning, linked to rigorous empirical studies (Churchill and Pegrum 2017). Internationally, there is a growing number of books and special journal issues devoted to mobile learning, each taking its own perspective on the issues at hand (e.g., Berge and Muilenburg 2013; Churchill et al. 2016; Churchill and Pegrum 2017; Lim and Churchill 2016; Palalas and Ally 2016; Parsons 2013; Traxler and Kukulska-Hulme 2016). This research is essential to better inform learning designs.

Some reports, both from developed countries like Brunei and Singapore, and developing countries like Indonesia and the Philippines, indicate that research has been conducted on learning with digital, including mobile, technologies. In Singapore's case in particular, such research often comes under the umbrella of research and development, or R&D. However, many reports indicate that academic research on the learning impact of digital technologies has been inadequate to date and that more research is needed; this point surfaces both in developed country reports, like Brunei and South Korea, and developing country reports, like India and Thailand. It would seem that there is considerable scope for more research which relates global themes to the particular teaching and learning contexts in each location, so as to inform and improve learning designs.

Conclusion

As noted at the outset of this chapter, the country reports do not necessarily represent a complete picture of mobile learning developments in each context, but they do give us a glimpse of each context from the perspective of well-informed educators. And

indeed, despite differences between these locations, it is striking to note the similarities in the themes that emerge.

It is apparent that with the continuing regional rollout of smart mobile hardware and fast mobile Internet access, there will be increased opportunities to leverage mobile learning in the future. While governmental support appears to be crucial to large-scale technological implementation, many other organizations – universities and research institutes, commercial entities, and NGOs – also have collaborative roles to play. In developing countries, such partnerships often target social justice agendas, where the pedagogy may be somewhat traditional but the emphasis is on access. In more developed locations, public-private collaborations are likely to involve integrating cutting-edge technologies into education in pedagogically sophisticated ways, with some of today's greatest promise appearing to lie in augmented reality interfaces used to support collaborative, creative learning situated in real-world settings.

Introducing new technologies, in and of itself, is no guarantee of pedagogical transformation, and it is essential that new tools are embedded in appropriate learning designs and that the challenges raised by mobile and other devices are faced squarely. This makes it all the more essential that further research is conducted to establish solid theoretical frameworks whose validity is demonstrated in empirical studies, in order to develop best practice principles that can guide governments, institutions, educators, and students on how best to capitalize on the teaching and learning potential of the mobile devices which are rapidly spreading throughout the region.

Abstract

Mobile learning and mobile technologies have garnered a significant amount of attention in K-12. As we define it, mobile learning is about 24/7, all-the-time, everywhere learning that is supported by mobile technologies. And, as we argue that mobile learning is increasingly a dominant form of learning, we look to better understand the roadblocks that are holding back its adoption in K-12. To that end, then, we look back in time and we look forward in time to identify the issues involved in mobile learning adoption in K-12. Rooted then in that analysis, we are optimistic that mobile learning can and will be adopted in K-12 over the next 5 years.

Introduction

The notion of “mobile *learning*” (Sharples et al. 2005; Traxler 2007; ► Chap. 55, “Barriers to Mobile Learning Advancements in the United Kingdom” by Whyley) has not changed substantively since the term entered into the education lexicon (about 1997) on the heels of the release and proliferation of mobile *technologies* such as the Palm Pilot. In the past, in the now, and, most likely, in the future, mobile *learning* is about support for 24/7, *all-the-time, everywhere* learning. Learning inside K-12 schools accounts for some opportunities to learn, but children spend much more time outside of school than inside. And, as Evans (► Chap. 54, “From Engagement to Empowerment: The Evolution of Mobile Learning in the United States”) points out, data from the Speak Up Survey shows that students are in fact using their smartphones to support their learning outside of the classroom.

Technology tools can facilitate learning in general and *mobile* learning in particular (Cole and Engeström 2007). Indeed, tools are important supporters of “the doing” – enacting, reflecting, remembering, and sharing. Pen and paper, a technology that has been most popular in K-12 schools, *can* be pressed into service to support all-the-time, everywhere learning, but pen and paper technology is, first and foremost, a technology to support some-of-the-time, in-place learning. However, mobile technology in the form of a featherweight, playing cards-sized package, that can record voice and record images, is connected to the Internet and can be manipulated literally with the fingers on just one hand – or now, via voice, promises to support *all-the-time, everywhere* learning!

Mobile learning – with support from mobile technology – is important: *mobile learning is the predominate type of learning*, since the type of learning done while sitting at a desk in school, increasingly, is occupying less and less of a student’s technology-based learning time (► Chap. 54, “From Engagement to Empowerment: The Evolution of Mobile Learning in the United States” by Evans). Yes, it is

relatively easy to provide tools that support a learner who is sitting at a desk, reading, and reflecting on that reading. However, supporting a *mobile* learner can be much more challenging. For example, consider the following scenario – a scenario that is representative of what learners experience when outside of school:

- A young learner, on a blustery spring day, is hurriedly walking to school, not wanting to be late. As she passes a Banyan Tree, she is struck by the tree’s elaborate root system. In school, the class was studying plants, and this young learner happened to be the “root expert” on her three-person study team. Of course, she was excited to take the “Banyan roots experience” to her team. So, with minimal fuss, as her school-provided smartphone was ready at hand, she withdrew it from the left-hand pocket of her jacket and, barely breaking stride, snapped several pictures of the root system! Back into school – our learner was indeed on time – she used the school network to send her root pictures to her team. Ultimately, the team, using their smartphones and the Mobile Learning Environment (Mifsud and Smordal 2006), created a multimedia report (Fig. 1) on plants, as required by the classroom teacher who incorporated one of the young learner’s pictures.

In our opinion, the above scenario is a type of “litmus test” for technology that purports to support mobile *learning* – learning that takes place inside and outside of school. In what follows, then, we apply this litmus test to other purported *mobile* technologies, e.g., 10-in. tablets, to see if those technologies do truly support mobile *learning*.

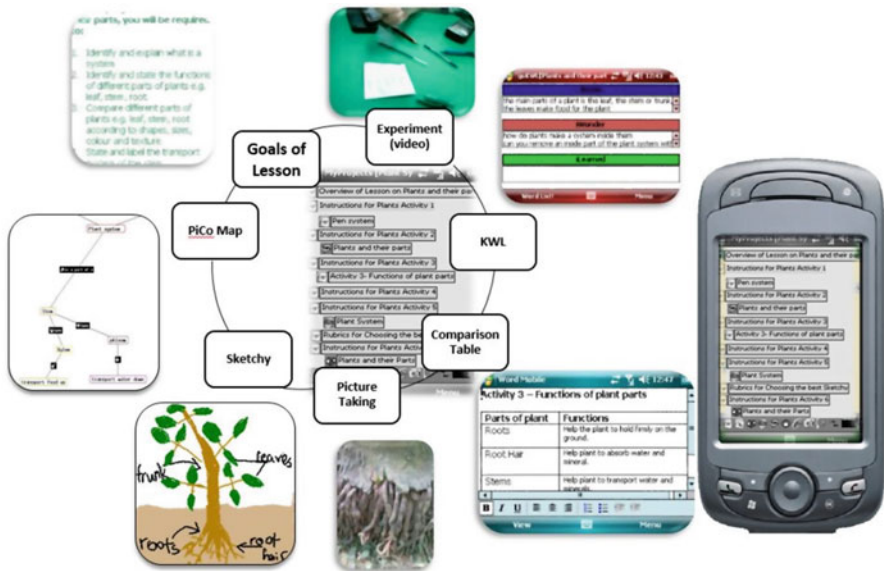

Fig. 1 A lesson on the plant cycle represented inside the Handheld Learning Environment (HLE)

What is the future of *mobile learning*? What are the roadblocks to its widespread adoption in K-12? That latter question is the focus of this chapter. To identify those roadblocks, our strategy is to look at the history of the adoption of mobile learning and identify those elements that have been key to successful adoption. As mobile learning and mobile technology are tightly connected, we can use Moore's "Crossing the Chasm" (Moore 1999) model of technology adoption to understand the three phases that mobile *learning* adoption has gone and is going through.

- Phase 1, 1997–2009: Given the early stage of mobile technology availability, it was only a small number of "early-adopting" teachers that jumped on board and made use of those initial mobile devices, e.g., the Palm and the Pocket PC.
- Phase 2, 2010–2017: During this second stage, *technology*, labeled as "mobile" – tablets, laptops, and Chromebooks – became more available, and the majority (the "early majority" and the "late majority," in Moore's terminology) of teachers accepted these devices into their classrooms. However, as we and others (e.g., Mageau 2012) argue, mobile *learning* was not necessarily being promoted.
- Phase 3, 2018–Onward: In 2018, *mobile* technologies are turning a corner – greater than 50% of upper elementary school students were using a smartphone (American Academy of Pediatrics 2017). In what follows, then, we explore the remaining roadblocks to mobile *learning* adoption.

Phase 1, 1997–2009: Early Mobile Devices for the Early Adopters

During Phase 1, the technology industry produced a broad range of handheld and mobile computing devices.

- **Palms:** Following his own, prescient, 1991 observation (Butter and Pogue 2002): "It is inevitable that all computing will be mobile" (p. 12). Jeff Hawkins co-founded Palm, Inc. in 1992 (Company Overview of Palm Inc. 2018). But, it wasn't until 1997, with the production of the Palm III series – black/white and color – that Palm devices became a very visible technology. The price point was acceptable (\$300–450), they were easy to use (the Palm OS sported a finger-touch, icon-based interface – much like the one on the iPhone), and there was a range of apps available (e.g., from calendaring to journaling, using pen input).
- **Newton:** For a short period of time, Apple had an entrant in the handheld device space: the Apple Newton debuted in 1993 with a great deal of fanfare and high expectations. Unfortunately, the Newton did not live up to the hype (Beschizza 2007), and it was one of first projects that was canceled by Steve Jobs when he returned to run Apple in 1998 (Beschizza 2007).
- **Pocket PCs:** Running a version of Microsoft's Windows Mobile operating system, Pocket PCs were introduced in 2000 and produced by a number of manufacturers, e.g., Dell and HP (Pocket PC n.d.). Typically, Pocket PCs were more expensive than Palms (\$500–\$700) and were more complicated to use.

Interestingly, the term “PDA” – personal digital assistant – arose (Bayus et al. 1997) to characterize all of these types of devices. While the Palms excelled at providing a calendar and a contact list, the functionality of these devices didn’t even come close to serving as an “assistant.” For example, attempts to do recognition of a user’s handwriting were not effective (Honan 2013; Plamondon and Srihari 2000). And, if Palms represented limited functionality and received kudos for their ease of use, Microsoft packed a great deal of functionality into their Windows Phone 6x/7x OS – functionality that was challenging to access on a limited-power, 3.5-in. screened device (Bayus et al. 1997).

Like all new technologies, these early mobile devices had “issues” especially for K-12: the devices tended to be fragile – even drops from 3rd grader heights were enough to shatter the screens; styluses resembled pencils and thus posed numerous issues for elementary and even middle school students. However, what we and the early-adopting educators – that 10% in Moore’s model – saw in the PDA was the realization of our dream. Finally, with availability of a low-cost computing device, purchasing one for each and every child was conceivable. While the business and adult world saw laptops as the way to achieve 1-to-1, we saw handhelds as the way K-12 would achieve 1-to-1. In what follows, then, we describe how the Hi-CE Project, which was representative of mobile learning projects, sought to help teachers more effectively adopt these newly emerging mobile technologies.

Hi-CE and Mobile Learning: For the Early Adopters

During the late 1990s, the Center for Highly Interactive Computing in Education (Hi-CE) had been developing educational software for desktop/laptop computers (e.g., Model-It, a learner-centered systems dynamics modeling tool (Metcalf et al. 2000); Artemis, a learner-centered interface to the UMDL (University of Michigan Digital Library) (Wallace et al. 1998)). But because the PDA, as an educational device, was most compelling, Hi-CE stopped developing for desktop/laptop computers and focused exclusively on developing educational software for PDAs.

In 1999, Hi-CE produced the “Cool Dozen” educational apps (Soloway et al. 2001), e.g., Sketchy, a drawing and animating app; PiCoMap, a concept mapping app; and Fling-It, an Internet tool, and made the apps free for download and use. Hi-CE then integrated the apps into an “educational operating system” initially called HLE (Handheld Learning Environment). In 2004, HLE became MLE – the name for the tool changed from Handheld Learning Environment to Mobile Learning Environment (Mifsud and Smørdal 2006). The term “handheld” was disappearing as handheld devices increasingly gained Internet connectivity.

A critical aspect of the HLE was an app called LessonLauncher; it “glued” all the Cool Dozen apps together. Using LessonLauncher, a teacher could create a lesson, a series of learning activities that employed the Cool Dozen apps and that would engage the students in a holistic learning activity. A teacher would then send the lesson, encapsulated in a LessonLauncher file, to each student. In addition, teachers could create different lessons for different students to support differentiated instruction.

In Fig. 1, a lesson about the Plant Cycle that the children worked on is displayed on the Pocket PC screen. (The Plant Cycle lesson was developed by 5th grade science teachers at Nan Chiau Primary School in Singapore in 2005 (Norris et al. 2016).) Each rectangle is an app-based learning activity; click on the learning activity/rectangle and the LessonLauncher opens that app in which the student will do her/his work. Arrayed around the lesson screen are the artifacts created in the various apps. While the HLE/Pocket PC supported learning-while-sitting, e.g., a concept map showing the relationship of the parts in a plant, an animation for what happens when a plant is watered, the HLE/Pocket PC also supported mobile learning, e.g., capturing on video three 5th grade students discussing the classic celery/osmosis experiment and capturing a picture of a plant's interesting roots.

Roadblocks to Mobile Learning: What We Learned During Phase 1

Phase 1 was an exciting time for K-12 and mobile learning. Conferences dedicated to mobile learning sprung up literally all over the world, e.g., International Conference on Mobile Learning (<http://www.iadisportal.org/pastevents>) and mLearn Conferences (Naismith and Corlett 2006). But Moore's Chasm model was spot-on: during Phase 1 only the early-adopting teachers – the visionaries and the innovators who were technology “aficionados,” who were looking for *major* changes in teaching and learning, and who were willing to put in major amounts of effort (e.g., creating curricular activities that exploited the mobile devices) – joined in adopting mobile learning.

Hi-CE's experience in K-12 classrooms was most telling:

- **Start-up:** The early-adopting teachers, about 10% on the left-side tail of the Bell Curve, stepped forward while school principals made funds available for software and professional development. GoKnow, Inc., the distribution arm of Hi-CE, had licensed approximately 40,000 units of the Mobile Learning Environment to schools in the USA, the UK, and Singapore, from 2002 to 2009.
- **Scale-up:** After a successful pilot in year 1, one school principal planned a scale-up. She/he instructed the teachers who watched during year 1 to get onboard. In Moore's Chasm model, this next group on the Bell Curve, about 30% the “early majority” teachers, are teachers who are not technology aficionados but who are only interested in what technology can do with respect to teaching and learning and who are not willing to work like the early adopters at making the technology effective. Indeed, the early majority teachers look with suspicion on recommendations from the early-adopting teachers. And, before the end of year 2, the project ended for the reasons identified below.

Why did scale-up fail?

- **Technology:**
 - **Devices:** The mobile devices kept changing; a model would be available for 1–2 years, and it would be replaced. In conversations with school information

technology (IT) administrators, they reported they were afraid to make the leap into mobile devices; maintaining the existing devices was a challenge, and supporting mixed-device classrooms was problematic for understaffed IT departments.

- **Network:** During Phase 1, for schools, it was still the “early days” for the Internet. Bandwidth, access points, etc. were all new elements for the IT staff. Wi-Fi was so unreliable in some schools that they used cellular connectivity to link the students’ mobile devices to the Internet – at significant cost. (Filtering – a requirement for schools – was a challenge to support on cellularly provided Internet.)
- **Software:** As the mobile devices were changing constantly, it was virtually impossible to keep the educational applications on the devices updated. There was no central repository for apps during Phase 1. Mobile device management (MDM) was a new and relatively expensive idea, at the time.

- **Curriculum and Pedagogy:**

Even if all the technological issues could have been overcome, there was a major hole as far as “early majority” teachers were concerned: curriculum – or the lack thereof. The curriculum created by the early majority the year before was idiosyncratic and worked because the early-adopting teachers made it work. The early majority teachers didn’t have the time nor the expertise to do what the early-adopting teachers had done.

Without curriculum that supports inquiry, early majority teachers found drill-and-practice software that they had their students install. Mobile devices could be pressed into serving direct instruction pedagogy without much effort.

Bottom line: during Phase 1, as we argued above, there were many roadblocks to the widespread adoption of mobile learning. However during Phase 2, as we argue below, some of those roadblocks were addressed.

The iPhone and the Age of Mobilism

Brynjolfsson and McAfee (2014) in their recent book, *The Second Machine Age*, argue that technology has had a bigger impact on civilization, on humankind, than “. . . Animals and farms, wars and empires, philosophies and religions. . .” (p. 7). In particular, in 1776, they observed that the steam engine, in fact, Watson’s version of the steam engine, “More than anything else . . . allowed us to overcome the limitations of muscle power, human and animal, and generate massive amounts of useful energy at will. This led to factories and mass production, to railways and mass transportation. It led, in other words, to modern life” (p. 7).

Brynjolfsson and McAfee (2014) go on to argue that “Computers and other digital advances are doing for mental power—the ability to use our brains to understand and shape our environments—what the steam engine and its descendants did for muscle power. They’re allowing us to blow past previous limitations and taking us into new territory” (p. 8).

But, consistent with Brynjolfsson and McAfee’s thesis, in 2007 technology again changed the world, (Wei 2012). The introduction of the iPhone by Apple, a device that fit in the palm of one’s hand supported instantaneous communications, world-wide, and supported supercomputer-level computation – computation which in turn supported all forms of media viewing, creating, and sharing. And, all that functionality was easy to access and it was affordable. The “Age of Mobilism” was underway (Norris and Soloway 2011)! Against the backdrop of that event and that technology, we pick up the history of mobile learning – Phase 2.

Phase 2, 2010–2017: Mobile Technology Goes Mainstream in K-12

During Phase 2, K-12 experienced a dramatic uptick in technology access. According to a Pearson Student Mobile Device Survey (2015), about 60% of K-12 teachers adopted computing technology. In Moore’s Chasm model of technology adoption, this 60% is composed of the “early majority” and the “late majority.” (It is important to note, however, that in the Chasm model there is still a healthy percentage of individuals – Moore calls the “laggards” – that still have not joined in and adopted computer technology in their classrooms. It is beyond the scope of the chapter to explore how K-12 is addressing this sizable group of non-technology-using educators.) We have identified four technology trends that supported this wave of adoption during Phase 2:

- Tablet computing devices became popular, starting in 2010 (Wainwright 2013).
- Laptop computers increased in popularity due in large measure to a decrease in their cost (Conway and Amberson 2011).
- Bring Your Own Device (BYOD) became popular, beginning in about 2011 (Halpin and Collier 2012).
- Chromebooks became popular starting in 2013 (Singer 2017).

Interestingly, the term “mobile” technology came to include a broad range of computing devices: smartphones, of course, were mobile learning devices, but tablets and even laptops were considered to be mobile devices. However, as we argue below, tablets are not really *mobile* devices.

iPads in K-12

Building on the iPhone, Apple released the iPad in 2010. With its 10-in. screen, in contrast to the 3.5-in. screen of the iPhone, the iPad was a “transportable” device, not a “mobile” device. Consider the story of the young learner described earlier.

- What is the likelihood of the youngster, walking hurriedly to school, snapping a picture of the roots of the Banyan Tree with a 10-in. screened iPad? The iPad would not have been in her pocket; rather, the iPad would have been protected

inside her backpack. Taking a picture of the roots of the Banyan Tree would have required that the youngster stop walking, take off her backpack, take out the iPad, take the picture, put the iPad back into the backpack, put the backpack on again, and now walk quickly so as not to be late to school.

But, in the classroom, the term “transportable” and the term “mobile” are, in effect, interchangeable; a student can move about the classroom holding an iPad, so an iPad is effectively a mobile computing device *inside* the classroom.

The above argument notwithstanding, schools, like consumers, became enamored with the iPad (Hu 2011; Wainwright 2012). The finger-touch interface made the iPad easy to use for elementary school children. Its ability to handle media came just when K-12 was finding the value of video for learning (Khan Academy n.d.). The iPad app store provided easily downloadable, supplemental resources (e.g., quiz apps, podcasts, and simulations) for classrooms. In 2013, Apple reported having sold 4.5 million iPads into K-12 (Etherington 2013).

BYOD in K-12

Starting in about 2011 (Halpin and Collier 2012), with the proliferation of student-owned computing devices, some IT staff began pushing for BYOD – Bring Your Own Device. From an administrative perspective, BYOD *appeared* to be a boon; here was a way to use technology in the classroom without the school having to pay for the devices.

But, from a teacher’s perspective, BYOD was a serious challenge. BYOD resulted in a heterogeneity of devices being brought into the classroom. Device-independent software (see Phase 3) was not available then, and thus a teacher couldn’t count on all the different devices having access to the same software (McCrea 2012). Essentially the only tool that a teacher could assume was available was a web browser. It is no surprise that web quests (Dodge 1995; March 2003), a form of digital scavenger hunt, became popular. Students would explore websites and take notes in whatever text editor was available on his or her BYOD computing device. While BYOD classrooms could well be 1-to-1 classrooms where every student had a computing device, given the heterogeneity of BYOD, technology could still only play a supplemental role in the curriculum (Mao 2017). And, from the school’s point of view, BYOD might well promote inequity just as schools were trying to address the growing digital divide (Office of Educational Technology 2016).

Laptops in K-12

George Moore (50 Years of Moore’s Law n.d.) has been credited with observing that the power (or the cost) of the CPU – the heart of the computer – doubled (or halved) every 18–24 months. This exponential growth greatly benefited K-12 schools during

Phase 2. Indeed, the availability of computing devices (so-called mobile technologies) in K-12 increased continually from 2010 to 2017, as documented by surveys of school technology (e.g., Pearson Student Mobile Device Survey 2015). Included below are some representative facts from that survey; in general, the numbers in 2015 increased from those in 2014 by about 15% (Pearson Student Mobile Device Survey 2015).

- “Laptops remain the most commonly used mobile device for school work. Eight in ten students (83%) report using a laptop to do school work during the school year” (p. 10).
- “At the elementary school level, tablets have replaced laptops as the mobile device that students use most often (78% for tablets vs. 66% for laptops)” (p. 10).
- “. . . 78% of elementary school students report that they regularly use a tablet. . .” (p. 11).
- Two in three middle school students (69%) report using tablets.
- Nearly half of high school students (49%) report using tablets.

Chromebook Up: iPads Down

While in 2013, Apple claimed that it had 94% tablet market share for [the] iPad (Cheng 2013), Apple began to see a reversal in 2014:

- “Around 715,000 Chromebooks have been shipped to U.S. schools in the third quarter, while Apple shipped 702,000 iPads to schools” (Tyrkina 2014, para. 2).

Why?

- “Chromebooks start at \$199, while last year’s iPad Air . . . costs \$379. . . . Another reason is that many school corporations seem to prefer the full keyboard found on Chromebooks instead of the touchscreen found on iPads. . . . while the touch panel is quite versatile, the keyboard is still associated with productivity” (Tyrkina 2014, para. 3).

Besides their cost, Google provided administrative software that made the management of Chromebooks relatively easy (Tyrkina 2014). Since 2014, the market share of Chromebooks has only increased – and increased dramatically (Global K-12 Mobile PC Market 2018) – while sales of iPads have continued to plummet (Singer 2017).

Roadblocks to Mobile Learning: What We Learned During Phase 2

Whereas we have been careful in this chapter to distinguish between mobile *technology* and mobile *learning*, K-12, in its public pronouncements (e.g., Kukulsk-

Hulme 2007; Martin and Ertzberger 2013), has not been nearly as careful. Indeed, for all intents and purposes, during Phase 2, mobile learning and mobile technology were synonymous – and recall, mobile technology included laptops! But, we were not alone in calling for the untangling of these two notions – and for providing educators with curriculum and pedagogical models to realize mobile *learning*:

- “For [mobile] computing to achieve its promise, it has to be accompanied by some pretty seismic shifts in how instruction is delivered, the kind of curriculum being deployed (and a group of apps do not count as a curriculum), the role of students in directing their own learning, and how systems and structures support school change. . . . But [schools are] not talking about these reforms; they’re talking about their iPad initiatives” (Mageau 2012, para. 5).
- “So, no more ‘iPad initiatives,’ please. . . . Let’s create and publicize initiatives in teaching and learning. . . .” (Mageau 2012, para. 8).
- “Although most educators would agree that mobile technologies have the potential to transform teaching and learning practices in schools . . . models to support this provision continue to be debated” (McLean 2016, para. 2).

Phase 3: 2018–Onwards!

By nature, techies are optimists! Thus, while mobile learning made little actual progress during Phase 2, we feel there are trends, as we describe below, in Phase 3 that might well break the logjam.

Technology

Phase 3 begins in 2018 for a particular reason – a technology trend that will have a major impact on bringing mobile learning into the classroom:

- **Many-to-1 is the New Normal:** As 1-to-1 became the “new normal” during Phase 2, many-to-1 is the new normal for Phase 3. Smartphones, Internet-connection supercomputers that fit comfortably into the hands of children, have now finally reached down into elementary school: in 2018, “. . . 59.8 percent of fifth graders, 50.6 percent of fourth graders, and 39.5 percent of third graders” in the USA are estimated to have a smartphone (American Academy of Pediatrics 2017, para. 4). While discussions about what is a healthy amount of screen time abound (e.g., American Academy of Pediatrics 2013; Middlebrook 2016), the trend is clear: smartphones will be as ubiquitous in upper elementary school as they are in the general population!

Recall the litmus test for mobile technology: taking a picture, hardly breaking stride, while walking hurriedly to school. During Phase 1, and the limited deployment of handhelds, only a very small number of 5th graders could take such a

picture. But, in Phase 3 with the increasing deployment of smartphones, virtually all 5th graders will be able to snap a picture while walking and then integrate that picture into their reports, using a Chromebook, while sitting at their school desks. *That* is mobile learning; finally, one piece of the puzzle is essentially in place. Unfortunately, the technology is the “easy” piece.

Curriculum

In 2018, there are three trends relevant to providing appropriate curriculum to support teachers in employing mobile learning in their classrooms:

- **Textbook use is decreasing** (Preville [n.d.](#)): Paper-based books, the mainstay of K-12 education, are decreasing in use. But textbooks, and their accompanying guides, have provided teachers with scope-and-sequenced, standards-aligned, curriculum that has been used day in and day out.
- **Digital curricula use is increasing** (Cortez [2017](#)): From applications to content, teachers are increasingly using the Internet as their source for resources. For example, there are literally millions of open education resources (OER) freely available on a multitude of OER marketplaces.
- **Device-independent resources are increasing** (Kleinfeld [2013](#); Norris and Soloway [2016a](#)): Initially, the iPad store was a wonderful source of resources *for the iPad*. But, in 2014, the World Wide Web Consortium approved the HTML5 standard (Bright [2014](#)). Coding applications (e.g., a concept mapping tool) or interactive content (e.g., a simulation) in HTML5 enables those resources to run inside web browsers. (As it turns out, only some web browsers adhere strictly to the standards as specified by the World Wide Web Consortium, e.g., Safari, Firefox, Chrome.) And, as virtually all devices run web browsers, content coded in HTML5 is device-independent, i.e., content coded in HTML5 can run on a laptop, on a Chromebook, or on the smartphone that elementary school children are now, increasingly, coming to own.

The new, new in the K-12 classroom is still the old, old: curriculum, curriculum. Curriculum is still the heartbeat of the classroom (Alvior [2014](#)). Research shows (Kane et al. [2016](#)) that high-quality curriculum materials, like the tide, raises all the boats – help struggling teachers to be more effective and help master teachers to excel still further. Toward providing curriculum that supports mobile learning, then, the above three trends bode well:

- While K-12 textbook publishers provide digitized versions of their paper textbooks, reading such material on a computer or a small handheld is not particularly appealing nor do paper-based materials take advantage of the interactive capabilities of the computing device in the hands of the students.
- But, finding relevant, appropriate materials online is a challenge: a study by Wywrot ([2018](#)) shows that teachers are spending 6–10 h per week searching the

Internet for digital resources, with only moderate success (Norris and Soloway 2016b). Thus, for now at least, it appears that digital resources are being used more as a supplement than as essential curriculum.

- There is a need for core, digital, curriculum, not just isolated digital elements used as supplements. The arrival of HTML5 may well be important for curriculum development in general and for curriculum development for mobile learning in particular. Specifically, as smartphones are a key to mobile learning – to 24/7, all-time-time, everywhere learning – and as smartphones run web browsers just like desktops and laptops, creating curricular resources for mobile learning and mobile learners using HTML5 does not require a special process. That is, in the past, curricular resources for mobile learning needed to be crafted specifically for the different types of mobile devices, e.g., Palm OS devices, Pocket PC devices, Apple OS devices, Android devices, and Windows Phone OS devices. Now, since all smartphones run web browsers, the same curricular materials can work across all types of smartphones.

As the curricular materials created in HTML5 can work on all devices, simplifying curriculum creation, HTML5 availability potentially removes a roadblock for the advancement of mobile learning.

Pedagogy

Mobile learning is all about inquiry learning – about being aware of one’s surroundings and wondering why: Why does thunder precede lightning? How does an ATM machine work? The Next Generation Science Standards (Improving Science Education Through Three-Dimensional Learning n.d.), with its focus not on the facts of science, but on the processes of science, and on supporting children in “figuring things out” (Norris et al. 2018) – explaining the phenomena that surrounds them – meshes well with an inquiry pedagogy.

Mobile learning is also all about synchronous collaborations: using computing devices, especially handheld computing devices, while working with others engaged in the inquiry. Collaboration is one of the twenty-first-century skills promoted by a broad range of standards, e.g., Partnership for twenty-first Century Learning (Framework for 21st Century Learning n.d.). For example, in our observations of 3rd grade classrooms in an elementary school in Singapore, we repeatedly overheard the children comment, when they had a disagreement or when they had a question, “let’s ask the phone,” which meant: let’s do some online research.

There is, however, a real tension in K-12: scoring well on standardized tests is a key element in many K-12 classrooms. And, while there is some evidence that inquiry-style pedagogies (e.g., project-based learning) can lead to enhanced student achievement (Geier et al. 2008) on standardized tests, direct instruction is a reliable test-preparation pedagogy (Reis et al. 2007). And frankly, evidence that mobile learning leads to enhanced student achievement on standardized tests is lacking. Thus, while mobile learning resonates with inquiry pedagogies, the need to

guarantee high test scores on standardized tests remains a roadblock to widespread adoption of mobile learning.

Conclusion

Learning is 24/7, all the time, and everywhere. Learning, like many other human endeavors, can be more effective when supported by tools. Fortunately, in this “Age of Mobilism,” the smartphone and its supporting ecological infrastructure (e.g., Internet connection) have become increasingly more sophisticated and more functional. In 2018, more than 50% of upper elementary school children, in the USA, have a smartphone – simply a “phone” to the millennials (American Academy of Pediatrics 2017). Given this context, we stand by the statement made at the outset of this chapter: *mobile learning really will be the predominate type of technology-based learning in the future.*

And, while K-12 may well be on to other technological pursuits, e.g., personalized learning (Feldstein and Hill 2016), the reality is this: outside of school, smartphones are used for mobile learning. What’s the evidence? Just look around. But, there is a disconnect between what individuals are doing with their handheld, Internet-connected, supercomputers and what K-12 feels is an appropriate use of mobile phones. There is indeed considerable debate among educators about the appropriateness of cell phone use in the K-12 classroom with data that suggest that test scores go up when mobile phones are banned from the classroom (Doward 2015).

Now, as we have argued in this chapter, there are specific issues with technology, curriculum, and pedagogy that must be addressed in order for teachers to feel comfortable and be effective in supporting mobile learning in their classroom. And, as we have argued in this chapter, we see indications that those issues will be addressed – and that mobile learning may well be advanced during Phase 3.

Educational Data Science	880
Introduction to the Chapters	882
References	883

Abstract

This introduction to a section of the *International Handbook of Information Technology in Primary and Secondary Education* introduces concepts from educational data science that are central to researching and understanding games, simulations and emerging technologies. It then outlines briefly each of the chapters in the section.

Keywords

Educational technology games · Digital simulations · Emerging educational technologies · Educational data science · Digital media learning · Evidence-centered design · Game-based learning · Virtual reality · Augmented reality · Makerspace · MOOCs · Online learning · Cloud-based tools

This section of the *International Handbook of Information Technology in Primary and Secondary Education* faces two challenges. The first is to define and scope the

wide-ranging topics implied by the title and the second is to provide a research-based overview. These are challenges particularly when “emerging digital learning technologies” are in early stages of discovery and implementation. We have limited the scope of emerging technologies as those that provide “digital learning experiences” and then to only a selection of those with significant research foundations. Otherwise, the entire scope of educational technology would be open for consideration. We have thus selected only a handful of emerging topics, leaving it to future updates of the handbook to include things such as robotics, wearables, artificial intelligence, and social media innovations. These newest technologies have the potential to transform learning by accelerating ubiquitous use of technology at scale, promoting the personalization of learning and introducing peer-based interactions into the data stream for continuous computation-led improvements.

To introduce this section, we briefly focus on a broad topic that underpins research on the knowledge base of games, simulations, and emerging digital learning technologies that are increasingly producing big data and the potential for learning analytics. This foundational field – educational data science – shares techniques and research concerns with emerging practices in assessment that utilize big data from digital learning experiences.

Larger flows of data available today about what the learner is doing while making decisions and interacting with digital learning materials is expected to continuously drive research into games, simulations, and other highly interactive technologies into the future (Behrens et al. 2011; Gibson 2012; Gibson et al. 2011; Quellmalz et al. 2012). For example, as artificial intelligence becomes integrated into a common cloud-based toolset and gives rise to a new group of practices in learning technologies, many of the same underpinnings of big data: gathering and cleaning massive amounts of data, pattern discovery, analysis and meaning making will continue to drive knowledge, classroom practice, and the continuous improvement of learning designs. The focus on big data provides an opportunity to point out that as the fields of games, simulations, and emerging technologies mature, educational data science (EDS) and learning analytics are keys to the future of research and the improvement of practice. Understanding EDS and learning analytics are thus two critical starting points for educational leaders, practitioners, and researchers.

Educational Data Science

The terms “educational data science” and “educational data scientist” have recently emerged within learning analytics and educational data mining communities, fields which themselves emerged as communities in the early 2000s (Baker and Yacef 2009; Romero and Ventura 2007). Naomi Jeffrey, contributing to a 2013 panel discussion at a “Learning Analytics and Knowledge” conference (Buckingham Shum et al. 2013) noted:

The educational data scientist must dive from Learning Analytics (LA) into Educational Data Mining (EDM) and resurface: exploring the real world, proposing meaningful measures, modeling the data, visualizing the output, sharing the technique and automating the process.

We can see in this formulation that there are *processes* (e.g., diving and resurfacing) as well as *techniques* (exploring, proposing measures, modeling, visualizing, sharing) being used to understand learning via big data derived from digital learning experiences.

Educational data science (EDS) is perhaps best viewed as a complex multifaceted collection of sciences aimed at understanding learning and teaching in the digital age. We can characterize the field as scientific inquiry based on data in an educational cloud framework that seamlessly supports formal and informal learning through a layered set of services that supply infrastructure, platforms, and software as services. Key to the EDS processes is the learner log, a trail of information about learning actions in their contexts. EDS also sits at the intersection of three foundational sciences of educational theory in the digital age – cognitive neuroscience, individual and social psychology of learning, and computational science, including data engineering. Aspects of the field of learning sciences, for example, emerge in the connection of cognitive science to the psychology of learning. Educational technology research often sits in the junction of educational psychology and computational science; and in the intersection of cognitive and computational science sits ergonomics (i.e., human-computer interfaces) and artificial intelligence.

A digital media learning framework has been proposed for understanding and assessing learning in the era of big data and cloud resource learning environments (Gibson 2010; Gibson and Webb 2013) founded in three research pillars: (1) evidence-centered design (Mislevy 2011; Mislevy et al. 1999); (2) theories of performance assessment (e.g., Clarke-Midura et al. 2012; Gibson and Webb 2015; Westera 2014); and (3) Unique affordances of immersive digital media learning environments (e.g., Gibson 2013; Ifenthaler 2010).

As noted in (Webb et al. 2013) concerning evidence-centered design (ECD):

The ECD framework (Mislevy et al. 2003) was developed by members of the National Center for Research on Evaluation, Standards, and Student Testing in the USA and has been applied to the design of a range of different types of computerized assessments including adaptive assessments, games, simulations (Rupp et al. 2010; Shute 2011), and portfolios (Gibson 2010). ECD is a four-staged assessment development framework that includes domain analysis, domain modelling, operational processes and the delivery system. The ECD framework makes explicit the interrelations among substantive arguments concerning domain models, validity, assessment designs and operational processes (Mislevy et al. 2003). The framework has diagnostic capabilities and provides for opportunities for stakeholders to view estimated competency levels, examine the evidence on which these judgements were based and to use this information for educative, formative purposes if appropriate

The ECD framework can be used in the planning and development processes of digital media learning experiences to guide ideation, construction, and then later, the EDS analysis of learner behaviors within a designed learning experience. The framework captures the foresight and intentions of designers and helps a team to embed data collection of evidence that can be used to characterize what a user knows and can do within that planned environment. It provides a road map for analysis of behavioral logs, for example, where the computer documents the actions and contexts of learner behavior. The ECD framework is made operational through

three interacting models – the student, task, and evidence models, which have been extensively discussed in the literature (Mislevy et al. 2004, 1999; Rupp et al. 2010).

Reflecting on educational data science from the standpoint of performance assessment and the aforementioned ECD evidence framework, a critical issue is the intention of the learner as actor in the setting – not only what knowledge and capability he or she is exhibiting but what was the understanding of the context, prompt and urgency of acting in a particular way which produced that evidence (Kopainsky et al. 2010). Documenting and supporting the learner’s intention is a critical challenge for the future study of impacts of emerging technologies.

The chapters of this section of the Handbook present an introduction to some of the breadth of the fields of games, simulations, and emerging technologies and underlying ideas just introduced. Perhaps easiest to implement are serious games and simulations, whether constructed for specific teaching purposes or not; so three chapters provide frameworks for thinking, raising key questions, and understanding their potential for learning and teaching. Rising quickly in educational research now are emerging practices with makerspaces and MOOCs and these each have a devoted chapter.

Introduction to the Chapters

In ► [Chap. 59, “Guiding Questions for Game-Based Learning”](#) by Karen Schrier, the capability of games to simulate intricate systems, invite collaboration and cooperation, and show people how to think through problems in new ways, uncover new truths and consider new perspectives is supported by a set of guiding questions for classroom teachers. The narrative provides a brief overview of game-based learning, shares approaches to using games for education, and identifies six characteristics or elements that should be considered when deciding whether and how to use and create games for learning. The chapter also reviews the key questions and challenges that need to be weighed when deciding whether and which game to use in educational settings.

To promote teachers ► [Chap. 60, “Evaluating Games for Classroom Use,”](#) author Katrin Becker focuses on three needs. First, educators need confidence that games embody or support sound pedagogy. Second, educators need to be able to evaluate games for their potential as learning objects. Finally, educators need concrete models of classroom use of games. The chapter provides an evaluation model that can guide a structured analysis of a game for potential classroom use and a sampling of instructional strategies adapted for teaching with games.

In ► [Chap. 63, “Educational Opportunities for Immersive Virtual Reality,”](#) Rick Ferdig, Enrico Gandolfi, and Zachary Immel examine existing recent research on the promise and the pitfalls of immersive virtual and augmented reality tools for educational outcomes. After providing concise definitions, the chapter then summarizes existing educational research on immersive virtual simulations. The chapter ends with a call for future research looking at key areas like special needs, potential negative long-term effects, training for

teachers and students, and exploration of key concepts like embodied cognition, computational thinking, self-tracking, spatial reasoning, and situational/individual interests within immersive virtual reality.

In a companion chapter, ► [Chap. 64, “Educational Opportunities for Augmented Reality,”](#) Gandolfi, Ferdig and Immel collaborated again to review research that highlights the current and potential impact of augmented reality in PreK-12, higher education, and professional development settings. While initial findings suggest use of the emerging technology can lead to increased engagement, the research synthesis offers a primarily theoretical argumentation for its PreK-12 implementation.

In ► [Chap. 61, “Toward Creator-Based Learning: Designs That Help Student Makers Learn,”](#) Chen-Chung Liu argues that contemporary educators have been advocating that teaching and learning in schools should go beyond knowledge acquisition. A critical challenge is how to help students learn like expert creators who constantly display active engagement and personal autonomy, and who are keen to collaborate with others. Recently, construction-to-learn activities have received even more attention than before. The maker movement has been seen in many educational settings. However, the setup of makerspaces does not necessarily guarantee a positive impact on students’ learning. Too much emphasis on the hardware tools may blur the educational focus and the merits of maker activities. The chapter summarizes and presents studies related to construction-to-learn activities which support students in their learning as creators. It revisits the key design principles of learning systems based on the needs of student makers: “supporting students to express their imagination,” “facilitating endless remixing,” and “low-threshold/high-ceiling.” Design examples and research findings are presented to hopefully shed light on the design of maker activities which can continuously engage students in construction-to-learn activities.

Vanessa Chang, Christian Gutl, and Martin Ebner discuss, in ► [Chap. 62, “Trends and Opportunities in Online Learning, MOOCs, and Cloud-Based Tools”](#) for primary and secondary education. The narrative begins by discussing the evolution of traditional classroom to online learning, followed by background on MOOCs and related research including those that are directed at K-12 teachers and students. The chapter discusses learning at scale with the MOOCs experience and the use of cloud-based tools (CBT) to create content for learning purposes and to provide teachers with increased flexibility to select their preferred learning tools and media to meet their own classroom needs and objectives. The chapter summarizes experiences, case studies, and examples that illustrate where these forms of technology-enhanced learning are heading.

Games · Game design · Educational games · Game-based learning · Serious games · Digital games

Introduction

In the free online game, *Spent*, players make choices as an unemployed single parent who needs to make it to the end of the month without running out of money (Roussos and Dovidio 2016). For instance, players may be asked to decide whether to give their child lunch money rather than pack a lunch or pay for the treatment of their pet’s illness, put it to sleep, or let their pet suffer, each of which have varying financial and social consequences. The educational goal of the game is to reduce prejudice against the poor and to enable players to “walk in the shoes” of someone who is poor, helping to enhance empathy and care (Roussos and Dovidio 2016).

However, when Roussos and Dovidio tested *Spent*, they found that not only did empathy and positive attitudes *not increase* after playing the game but, for some players, *negative attitudes* toward the poor actually increased after playing *Spent*. People who were already more likely to feel like poverty was a result of choices that are personally controllable had even greater negative attitudes toward the poor after playing *Spent*. Roussos and Dovidio suggest that these results were due partly to how *Spent* was designed as a game, in that the players could control their choices and its consequences and make the right choices to survive a month. Thus, players believed that likewise people who face real-life financial struggles should just make better choices. For those players, playing *Spent* decreased empathy for the poor; however, watching a video of the game being played did not have the same effect, because agency over one’s choices was removed (Roussos and Dovidio 2016). On the other hand, the game raised \$7,000 for a homeless shelter and enhanced awareness of financial inequities for some players (Farber and Schrier 2017).

Spent failed to meet its educational goals for some of its target audience members. Just as with any instructional experience or activity, whether a conventional lecture or textbook, website, or game, there are strengths and weaknesses, unintended consequences, and serendipitous possibilities inherent in the design of the learning experience. The design of an experience, for example, may even matter more than the medium, in that a specific game (e.g., *Mission US*) may work for a specific educational need (e.g., developing historical empathy for middle school students), while other games would not, just like some textbooks are written appropriately for an audience or topic and some are not (Clark et al. 2016; Schrier 2016c).

Ke (2016) explains that there are typically two areas of learning that are supported by games: (1) skills, such as systems thinking, argumentation, literacy, and

computational thinking, and (2) domains of knowledge, such as health information or history (Ke 2016). In addition, games may support changes in attitude or affect, such as interest or curiosity for a topic or perspective (Squire 2011). Even for those skills and domain areas that games teach well, the same experience may not work for every student or set of conditions. Digital games are never one-size-fits-all solutions, and a successful activity in one classroom may not necessarily be transferable or scalable.

The primary goal of this chapter is to identify the main questions and tensions for researchers, practitioners, and policymakers to navigate when considering *why*, *how*, *when*, *who*, and *whether* to use and design digital games. What factors should be considered when designing, using, and assessing a game for learning? How do game designers balance fun and accuracy, immersion and transfer, facts and skills, and innovation and tradition in a game? Would a game be the most appropriate way to teach a particular skill, attitude, or topic?

First, the narrative provides a brief overview of game-based learning, shares approaches to using games for education, and identifies six characteristics or elements that should be considered when deciding whether and how to use games for learning. Next, the chapter reviews the key questions and challenges that need to be weighed when deciding whether and which game to use in educational settings.

What Is Game-Based Learning?

Game-based learning comes in many different shapes, sizes, genres, and styles and varies tremendously, from learning what it's like to be President of the United States in iCivics' *Executive Command* to understanding what it's like to be the parent of a terminally ill young son in *That Dragon, Cancer*. In general, game-based learning involves using games for some type of educational purpose – such as a non-digital card game that features historical figures, a digital drawing game that supports creativity, or a word puzzle game that teaches Spanish. Sometimes a game is a central part of a classroom lesson, such as a long-term assignment to craft a historical building like the Taj Mahal in *Minecraft* (Weitze 2016). Other times games may be a shorter activity that leads to further deliberation, such as using *The Migrant Trail* to kick off a discussion on immigration or using *Dys4ia* to reflect on gender identity and marginalization (Schrier 2014). Game-based learning could be as simple and straightforward as playing a “name remembering” game at camp or as complex as transforming an entire class module into an alternate reality game (ARG), such as Darvasi did to teach *One Flew over the Cuckoo's Nest* for his English students (Darvasi 2014).

We can formally define games, as Juul has done in *Half Real: Video Games between Real Rules and Fictional Worlds*, as having a “rule-based formal system; with variable and quantifiable outcomes; where different outcomes are assigned different values; where the player exerts effort in order to influence the outcome; the player feels emotionally attached to the outcome; and the consequences of the activity are optional and negotiable” (Juul 2005, p. 13). However, whether an

experience is fully “a game,” is gamelike, has some playable aspects, or is inspired by but is not actually a game does not matter as much as whether it is useful, effective, and appropriate for the educational experience, needs, audience, and context. As such, what it means to be “game-based learning” continues to evolve, and the role of information technology in creating, offering, and experiencing games is also varied and evolving. The word “digital” will not be used throughout the chapter, but it should be understood that the chapter will focus on digital game-based learning as key area in educational technology that has emerged since the last edition of the handbook. Despite the focus on digital games, however, many of the guiding questions and research can apply to all types of games, including non-digital ones.

Why Digital Games for Learning?

Over the past two decades, there has been an explosion in the use of, design of, and research on digital games and learning, with people using games in classrooms, museums, libraries, and after-school programs and even at home for educational purposes (Schrier 2016a). For instance, more games are being played in the classroom than ever before, with 74% of K-8 teachers using games and 55% of teachers using games at least once a week in the classroom (Takeuchi and Vaala 2014). The Entertainment Software Association found that 63% of American households have at least one person playing video games at least 3 h per week (ESA 2016).

Moreover, empirical studies have suggested the potential of using digital games for learning (Sitzmann 2011; Wouters et al. 2013), though there is little consistency among the methodologies used to measure effectiveness. (For example, many are case studies, were not randomized properly, or have small sample sizes (Crocco et al. 2016; Brom et al. 2016).) In a study with a large data set that uses quantitative measures, Crocco et al. analyzed the use of game-based lessons in English, Math, and Science courses (2016) against control (nongame lessons) courses. Their findings suggested that games correlated with increased enjoyment of learning and that enjoyment also related to deep learning and higher-order thinking, suggesting that games can support learning through increased enjoyment (Crocco et al. 2016). But seemingly in contrast, in a meta-analysis of the cognitive and motivational aspects of games for learning, Wouters et al. (2013) compared games to conventional instruction methods (skill and drill practice, lectures, reading, and websites). Their results suggested that the games were more effective in learning (from a cognitive perspective) and retention, but not in motivation (Wouters et al. 2013).

Another recent meta-analysis of game-based learning research, supported by a Microsoft/SRI International grant for GlassLab Research and conducted by Clark et al. (2014, 2016), found that digital games can support learning better than nongame conditions in terms of cognitive learning outcomes. The design of the game, rather than the medium of “games” itself, was more important to whether the environment supported learning (Clark et al. 2016). Thus, whether a game is successful and effective is complex and often relies on the design and the context within which it is used.

When rationalizing the use of educational games, proponents often mention the increasingly large number of people playing games and using games in learning. They may point to case studies of using games in the classroom (Farber 2015), books on games and learning (Gee 2003), or evangelists for games (McGonigal 2011). However, games have always been connected to learning. Play has always been a way that people learn about each other, connect, understand and share ideas, and contribute to humanity (Schrier 2016c). That said, games should not be used because they are trendy, popular, or *seem* like more fun than other activities. They should be used because they are the most appropriate design solution and contribute to the best experience for specific educational needs. The next section describes six different characteristics of games for learning that may be useful when deciding whether and how to use or design a particular game.

Game Elements to Consider

Educators and researchers have investigated key aspects of games that can contribute to learning. These include motivation, fun and engagement, social interactions, problem-solving, and story, as well as games as systems and tools, which will be outlined in the next sections.

Motivation

Motivation relates to how people decide what to do and why to do it and is defined as moving someone to do something, like play a game (Ryan and Deci 2000). Games, if well designed, can be motivating for players, which make them potentially useful for activating learning, though the relationship among motivation, engagement, games, and learning is complex (Wouters et al. 2013). Eseryel et al. (2011) investigated McLarin's Adventure, an educational massively multiplayer online game (MMOG) geared toward eighth and ninth graders, and their findings suggested that enhanced engagement in the game resulted in better learning outcomes. They found that providing appropriately timed and balanced challenges throughout the game experience related to more engagement and motivation in the game (Eseryel et al. 2011).

On the other hand, games are not automatically motivating. There are a number of challenges to consider. Game players may be pulled in many directions – school, extracurriculars, and family obligations – in addition to entertainment and other game choices. Educational games may not be as visually appealing, narratively engaging, or dynamically designed as their mainstream counterparts. Different types of motivations – intrinsic and extrinsic (Deci and Ryan 2000) – may have differential results in games and learning (Malone 1981). Ryan and Deci's (2000) self-determination theory explores two motivation types: intrinsic (e.g., driven by something inherently interesting) and extrinsic motivation (e.g., due to external factors or objects). Ryan and Deci's research generally suggested people were more likely to practice skills or acquire knowledge if they felt more connected to others, more competent, and had autonomy over their choices and behaviors (Ryan and Deci 2000).

Moreover, people may be motivated by different aspects of gaming. Yee and Ducheneaut's Quantic Foundry, a company that focuses on surveying game players to understand their motivations, found that men are more likely motivated by competition (e.g., rankings, match wins) and destruction (e.g., explosions, car chases, guns), whereas women are more motivated by fantasy (e.g., acting a role in another world) and completion (e.g., finishing missions, collecting). Younger players are more likely to be driven by competition than older (above 35 years old) players, who are more driven by completion and fantasy (Yee et al. 2016).

Fun and Engagement

Should learning games be fun first and educational second? Researchers are split on whether the pedagogical aspects of the game should be prioritized over fun (Ravyse et al. 2017) or whether games and simulations need to be entertaining to be useful, educational, or effective (Crocco et al. 2016; Ravyse et al. 2017). Some researchers point to the importance of fun in educational game design (Habgood and Ainsworth 2011), and most game designers prioritize fun as the top aim of any game (Koster 2004), although what actually counts as "fun" may not be the same for everyone, and the difficult challenges in a game (e.g. Papert's "hard fun") may be what is actually fun (Bogost 2015). Educators should ensure that the balance of fun and work, and entertainment and learning, is appropriately maintained for each student throughout the experience.

Csikszentmihalyi (1990) describes a type of engagement with games – which he calls "flow" – where the player is immersed deeply in the experience. Achieving flow may be integral to learning. Educators need to ensure that, even if players are deeply immersed in a game, they are also engaged in learning and able to transfer any new knowledge to nongame environments.

Moreover, games are sometimes framed as being fun and frivolous, and this perception matters in whether games are acceptable for educational purposes and whether they are taken as "serious" learning environments. If a game is perceived as too fun, players may not take the content seriously enough. In *Beyond Pleasure and Pain*, E. Tory Higgins (2012) describes a study where some participants were encouraged to have fun while learning the material, and other participants were told that the task would be tedious and serious. Participants were also divided by high and low importance: some received instructions that the task was of high importance, and others were told it was not. Those people in the "high importance and high fun" group actually had a lower performance than those in the "high importance and low fun" one. So, while we may expect fun to be motivating and enhance our performance, because people expect that learning will be serious and not fun, this ended up hurting performance (Higgins 2012). Educators need to set and monitor expectations, frame game playing experiences as learning experiences, and also reflect on the game afterward to ensure that students deem a game as highly important and serious, even if it is also fun.

Social Interactions

Not all learning is best accomplished with other people (or even other devices or tools, such as computers, or nonhumans), but when properly designed, games can be particularly adept at enabling social interaction, helping people connect, and expanding community. Some educational goals may benefit from the ways that games can help to support collaboration through a game or around a game (such as in the case of players actively sharing resources or tasks in forums or social media). “Many in-game and out-of-game practices acculturate users, such as problem solving together on a quest, engaging in debates and other social events, or participating on fan sites and blogs” (Schrier 2016c, p. 105, citing work by Steinkuehler, Jenkins, and Gee). Players (such as those of *World of Warcraft*) may develop shared norms and practices through these communities (Steinkuehler 2007) and may also engage in peer-to-peer mentorship (Steinkuehler and Oh 2012), which all contribute to epistemic learning, a type of learning in which people adapt to the vocabularies, tools, values, and norms of a community by participating in it (such as through games) (Shaffer 2006; Squire 2011). Feeling a sense of belonging and inclusion in a game community may also contribute to learning (McGonigal 2011; Schrier 2016c).

Social interactions can also motivate further game playing, problem-solving, and make each greater than the sum of its parts (Eseryel et al. 2014; Yee 2006). For instance, in a study, players who shared a computer while playing a game were more motivated and had higher learning outcomes, possibly because they had to articulate their ideas and moves collaboratively, helping to reinforce their learning and engage them in the game (Inkpen 1994).

When supporting social interaction, caution is warranted. Certain types of online gaming communities can also be deleterious and discourage or demotivate learning. Particular games and gaming cultures may be rife with bullying, harassment, and toxic communication and may feel exclusionary or demotivating. Competitive social interactions may be welcoming to some but not others. For example, in an exergaming study by Song et al. (2013), players who were already driven by competition were more motivated to play, but those that were not driven by this were less motivated to play (Song et al. 2013).

Not all games are designed to support social interaction, whether informal sharing outside of the game or intense collaboration or competition within the game (Schrier 2016c). To enhance learning, educators and researchers are encouraged to think about how to appropriately add a social dimension, such as using social media, wikis and blogs, or journaling with pair-share groups.

Problem-Solving

Games at their core involve problem-solving or the process of finding solutions to problems (e.g., avoiding enemies in *Super Mario Run* or collecting enough Pokémon creatures in *Pokémon Go*). The game serves as a manifestation of a “problem space” (Jonassen 2000), where the game’s rules and boundaries constrain and encourage

certain solutions to be created in that space. Games may be particularly effective for practicing problem-solving because they can enable players to experience cause and effect by observing what is rewarded or punished within the game (Schrier 2016c). Players can test out hypotheses about how to solve a particular game's problems (e.g., avoiding enemies in *Super Mario Run*), such as through trial and error (e.g., jumping and seeing what happens), in-game tutorials (e.g., watching an example of jumping over enemies), educated strategies (e.g., trying jumping because it worked in the original *Super Mario Brothers*), or observing other players (e.g., watching videos of other people playing the game). Gee explains how games spur players to go through a cycle of questioning and probing the world, which he calls the "probe, hypothesize, reprobe, rethink cycle" (Gee 2003, p. 90). Games can also serve as microworlds, where players can iteratively push on a game's boundaries and explore causes and effects, which helps players test out solutions to problems (Papert 1993).

Games have been credited in honing players' problem-solving skills, such as by encouraging alternate paths, providing stories or analogies, or encouraging the sharing and deliberation of different perspectives among players. Games can help people move beyond functional fixedness or being fixated on the typical problem and solution. But games are not necessarily appropriately designed for all types of problem-solving, and problem types need to be matched to game play, audience, and contexts (Schrier 2016c).

Story

Not all games have or need an explicit story or narrative, but those that do can be particularly motivating for some players, such as those that are driven by fantasy (Malone 1980; Yee 2006) and immersion. Malone discusses fantasy as a key motivator for games, for instance, and uses Walt Disney World to illustrate how children experience fantasy worlds, see themselves in fantasy roles, or fulfill wishes through play (Malone 1980, 1981).

Story can work in different ways. People may be motivated to experience, complete, or co-create a story or narrative experience (Schrier 2016c). Shum et al. describe how story can help situate data and elements of a problem to provide meaningful context and illustrate its human dimensions (Shum et al. 2012). Providing a story context for a problem can also help by showing new perspectives or reframing the problem so people do not get stuck applying conventional or ineffective problem-solving methods. Story can also help make abstract concepts and problems more personally meaningful and relevant (Schrier 2016c). Teachers can also have students write their own stories about playing the game or even expand on the characters or interactions in the game. However, not all games need to have a significant story, and not all students will be motivated by story elements (Yee et al. 2016).

Games as Systems and Tools

Real-world concepts and topics, whether related to economics, history, ethics, literature, anthropology, or biology, require authentic tools, models, and epistemologies

to interact with them. To act like a scientist, for instance, you need to be able to use real-world scientific data and study real-world organisms or physical properties. You need to use tools and processes such as microscopes or mass spectrometry. You need to understand how scientists know and interact with the world, the typical language and terms used, and norms and values of the profession. Biological processes, such as photosynthesis, and social policies, such as immigration, are often not straightforward concepts but complex “living, breathing” social, cultural, economic, political, and scientific systems with many interconnecting parts, which, to be fully understood, need to be embraced holistically and systemically.

Likewise, games themselves are dynamic systems that can help situate meaning and simulate the complexity of various concepts, skills, and issues. “Players enter and explore within a game world, which is a deliberately designed system based on a set of rules, assumptions, and values” and which is further influenced by the addition of human players, their game play, the communities that emerge, and their own unique activities (Schrier 2016c, p. 39). While games cannot possibly simulate or model every corner of a dynamic system, they can realistically reimagine aspects of complex processes, skills, actions, and information within an authentic context, situate learning, and bring people together (Schrier 2016c).

Games can also function as tools by which to authentically explore systems and topics and to practice particular skills, attitudes, and perspectives (Shaffer 2006). For example, participants in *Foldit* can use authentic 3-D models of proteins, just as scientists would, and players in *Reverse The Odds* use real images of cancerous tumor cells to make judgments and classifications. Furthermore, players can design and co-create games as tools to help construct their own understanding of various topics, such as by making a game that models healthy interpersonal behaviors or designing one that authentically reflects gravity on the moon.

Guiding Questions for Studying and Using Game-Based Learning

This section explores various tensions, challenges, and questions to consider when studying the impacts of, or implementing, games for learning.

What Are the Goals?

A primary challenge in designing, using, and assessing games for learning is establishing goals and ensuring that both educational goals and game goals are appropriately matched. Weitze (2014) describes game goals as “objectives . . . what we strive for . . . [and are] fundamental to games” (p. 226). In a game, there are immediate, pragmatic goals (e.g., finish a level) and sub-goals (e.g., jump over an obstacle). There is also an ultimate game goal, ultimate outcome (Fullerton 2014), or end result needed to complete, accomplish, or reach to win the game. In a well-designed game, players know that they have reached game goal(s) through in-game

feedback, such as points, rewards, trophies, badges, unlocked levels, or progression of some kind (Weitze 2014).

Learning or educational goals, on the other hand, relate to a measurable change in skills, knowledge, abilities, information, attitude, feeling, and/or connection (Weitze 2014). In particular, curricular goals concerning knowledge, skills, and attitudes relate to those aspects of a curriculum that need to be covered or taught in a given activity, module, and/or time frame (Weitze 2014). Students and teachers may determine when learning goals have been reached through a combination of assessments, such as exams, completion of assignments, reflection exercises, observation of behavior, progression to more complex activities, or the successful application of learning to real-world processes (Weitze 2014).

As may be apparent, game goals, educational and curricular goals, are not necessarily the same and may diverge significantly. When designing games for learning, all relevant goals should work together appropriately and be “concrete. . .challenging but achievable. . .rewarding. . . balance[d] in the short- and long-term” (Weitze 2014, p. 231; Whitton 2009). Weitze describes a number of methods for orchestrating goals, such as the Q Design Pack for Games and Learning (Salen et al. 2011) and Smiley-Model (Weitze and Ørngreen 2012). For instance, in the Smiley-Model, designers can use the game goal, rules, choices, challenges, and feedback to intertwine with the learning goal (Weitze 2014).

Who Is the Audience?

Another key consideration is understanding the audience: who are the learners, what is their current skill level and expertise, what is their prior experience with games and gaming, and what do they enjoy learning, playing, and doing?

First, consider what motivates learners in terms of the games they want to play. Bartle (1996) describes four different player types (killers, achievers, socializers, and explorers). Achievers care about meeting goals and rising above challenges (similar to achievement in learning). Explorers want to discover the virtual world and push boundaries; socializers want to interact with others; and killers want to compete, show off, and wield power (Richard 2014; Bartle 1996). Building on this model, Quantic Foundry identified distinct player motivations for digital games, such as competition, destruction, challenge, story, and design, and four clusters of motivations for board games (e.g., conflict, strategy, immersion, and social fun) (Yee et al. 2016). Likewise, Radoff (2011) considers how different types of feedback may motivate a player. Quantitative feedback may be points, badges, monetary rewards, or leaderboard statistics; qualitative feedback may be stories, smiley faces, strengthened bonds, jokes, gifts, or character development (Richard 2014; Radoff 2011). Vandenberghe (2012) began to match the “Big Five” personality types to elements of play, such as novelty (openness), challenge (conscientiousness), stimulation (extroversion), harmony (agreeableness), and threat (neuroticism) (Richard 2014).

Thus, knowing what drives and motivates a learner can help with matching that individual to the correct type of game or learning experience. Beyond considering

player motivation types, players can also be matched based on hobbies, interests, or personality and just as with any learning experience, their “reading ability, learning curve, cognitive ability, learning style, and physical ability, as well as tactile desires” (Richard 2014, p. 209) – though all factors do not need to be simultaneously considered to make an appropriate match.

Other audience factors to consider include the accessibility of the game, the game’s technology, and the culture that emerges from and around the game (Richard 2014). Gaming cultures emerge from or around a game and may include political or cultural views expressed in the game; or implicit biases or values may be negotiated through the game. For instance, does the game support an inclusive learning environment or will players feel marginalized by a game’s genre: representations of race, sexuality, or gender? Does each player and player type have an equitable chance of engaging in the experience and attaining its goals?

What Is the Context for the Game?

The context of the game – how it is played, where it is played, with whom it is played, and how the game is framed – all affects its success, efficacy, and acceptance as an educational experience. Gee distinguishes between the little “g” game and big “G” Game. “Everything in-game is the game, with a small ‘g.’ The context around play is part of the Game, with a big ‘G.’ That is, it is not only the physical environment around the game but also the virtual environment,” as well as the learning context (Simkins 2014, p. 268, citing Gee 2012). Rarely should a game be viewed as a stand-alone activity (just the “g”); rather, it should be considered as part of a larger learning experience alongside other types of interactions, activities, lessons, topics, exercises, and assessments, as well as in relation to the broader environment and communities surrounding it (the big “G”).

Factors related to the educator can affect the success of a game in a classroom, such as a teacher’s beliefs and attitudes about games, their professional development and training, and the teacher’s prior experience with games and game-based learning (Groff et al. 2016). Teachers, for instance, may have trouble deciding whether a game is appropriate for a particular educational need or whether the content within the game is accurate and design effective (Kirriemuir and McFarlane 2004; Groff et al. 2016). Moreover, educators may not have the necessary game literacy (Zimmerman 2008) or design understanding to look more deeply into of the game and understand how it works; what values, misconceptions, or biases it may express or magnify; or how students may cheat, hack, bully, or otherwise transgress in the game (Consalvo 2007). They may not know how to question or interrogate the game with students even if they have a lot of experience with a particular game.

Another important consideration is the physical place where a game is played. Playing a game in a dinosaur museum, where students are able to also see bones, preserved tails and features, or teeth up close, is different than playing a game about virtual dinosaurs in a classroom or at home. Playing a location-based mobile game as a pair while walking around the site of the Battle of Lexington (as with

Schrier's *Reliving the Revolution* (Schrier 2014) is different than sitting at a computer, virtually walking around a historic site (as with *Mission US* or *Past/Present*).

Moreover, the type of support that is provided also matters. A busy after-school program, with only one teacher to support many individual student needs of different ages, is a different environment than a small preschool classroom with three teachers who can collaboratively guide a game. An outdoor camp game for high school students that involves physically exploring a large forest may need different types of support than an improv game for college theater students. A game needs to be shaped to the context and needs different types of facilitation to enforce any boundaries, rules, and norms.

The communities that emerge around and within games also affect the context through which a game is played (Kafai and Fields 2009; Steinkuehler 2007; Shaffer 2006). Jenkins et al. describe "participatory cultures," where people are actively creating, reconfiguring, revising, and reconstituting media and collectively participating in worlds such as games, where they are creating new avatars, story lines, or fan materials (Jenkins et al. 2006). The spaces where participants, players, and fans interact may be sanctioned by the game designers or even unsanctioned, and this affects the context of the game.

Thus, just as with any educational activity or experience, educators and designers must consider the dynamic and evolving interaction among students, place, expertise, educator, community, and other factors. Continuing to evaluate and reevaluate the context, and adjusting the experience, is part of the new role of the teacher-as-designer of learning experiences with games.

Practical and Technological Considerations

Practical and technological factors such as cost of the game, length of setup, time of game play, platform and technology used to create and play the game, length of class period or educational experience, and technology available to the students all make a game more or less feasible for learning. These pragmatic considerations need to be fixed or acted upon before moving to other considerations, such as curricular fit or audience's needs. If the technology itself does not work or cannot be accessed, we cannot even consider how to include it for educational use.

Certain platforms may be better at teaching and encouraging particular skills or interactions. For instance, a networked game (such as a console or browser-based game that has multiplayer options) may support certain social interactions in a virtual world, whereas a mobile or non-digital game may encourage real-world social interactions. On the other hand, a single-player computer game may be better at investigating individual performance on a skill or concept, depending on its design.

The platform used also has implications for accessibility, inclusion, context, equity, design, and learning in general. *Minecraft* accessed from an in-class private server may provide a safer "walled off" environment than playing on an open server with virtual strangers. Students with different sensory needs, neurotypes, or abilities

may be affected negatively by an intense virtual reality game, one with too many players, one that requires rapid hand or physical movements, or one that does not involve tactile interactions, depending on needs.

The length of time for completing a game can vary widely. Although longer games may be difficult to incorporate into classroom or more structured learning environments, the payoff for an extended experience with the game may be valuable. Groff et al. note that “Although more work may be involved to leverage these games successfully, they also offer the potential of developing 21st century skills, such as problem solving, decision-making, planning, strategy, and collaboration” (2016, p. 23, citing Klopfer et al. 2009).

Students may also be able to work with teachers, researchers, or designers to create games. For instance, younger students may use programs such as *Scratch*, *GameStar Mechanic*, or *Minecraft* to create or modify games as part of an assignment (Nolin 2016). Older and adult students may use Construct 2, GameSalad, Unity, Unreal, Twine, Metaverse AR, or ARIS to create games (see Nolin 2016; Chen 2016 for more details on each platform).

Curricular Considerations

The curricular objectives and domains of knowledge covered by a game can also affect its design and use. For instance, the educational objectives of a game, and any curricular needs of the learning experience, affect the need for accuracy in the game, the capability for authentic practice, level of literacy needed to play or learn from playing, skill development possibilities, support for creative and critical thinking, as well as the way domain knowledge can be applied within and beyond the game.

The extent to which game accuracy and precision matters, for example, depends on the game and learning goals and the types of skills, facts, topics, themes, approaches, or attitudes you aim to teach. When teaching students how to manage resources or to consider broader history themes, such as the balancing of resources toward religion, culture, military, and economic growth, then the COTS game *Civilization* may be appropriate and would not necessarily need to maintain a high accuracy to real historic events (Squire and Barab 2004; Squire and Durga 2006). Too much detail or connection to the real world in certain contexts may stifle the flexibility, creativity, and experimentation needed to learn a particular concept. What works well in real life or even in a book or video may not perfectly translate to a virtual space or non-digital gaming environment.

For instance, in *Mission US*, students can explore different moments and events from history, such as the Revolutionary War or the Underground Railroad (Schrier 2014; Farber and Schrier 2017). Enabling an authentic practice of relevant skills, such as argumentation or perspective-taking, may be more important than providing historically accurate or overly realistic scenarios (Schrier 2014).

Likewise, games can enable interaction with authentic scientific tools and models to help teach computational and technical skills (including “problem solving, algorithms, modeling, and abstraction” (Werner et al. 2014, p. 38a). Other games may

provide opportunities for dialogue or discourse or even musical, artistic, and physical interactions to learn relevant skills and behaviors. For instance, Kognito creates dialogue-based games, where players work through practice conversations (such as about a family member suffering from PTSD or about a doctor working with a family on healthy eating behaviors).

Assessment and Evaluation

One of the most important and challenging aspects of using and designing a game for learning is understanding whether it is effective, accessible, and useful for students, meets educational needs and goals, and teaches the appropriate skills, concepts, attitudes, or topics. Simkins (2014) recommends three questions that need to be considered to help in shaping any assessment plan: what are the learning goals of the game, how is the game played (mechanics, elements, game goals, game play), and what is the context of play? Assessment of games in learning is similar to other types of educational assessment, with pros and cons for different methodologies. Gibson and Webb (2013) argue that assessment should move from summative types to assessments that are “continual, diagnostic, and formative” and consider the “personal growth of the student, impact on social issues, and cultural importance” (p. 17).

Quantitative methodologies focus on measuring with a goal of replicating, verifying, and comparing results across and between students (Simkins 2014). Simkins describes some possible quantitative methodologies such as pre- and post-game examinations or eye tracking of what students are doing in a game. Qualitative methodologies “involve collecting data on what people are doing within their context. . .[could] involve a very close read of the actions, speech, practices, and behaviors. . .[and the] environment, social, cultural, and physical” context (Simkins 2014, p. 279). The Department of Education (DoE) also suggests the benefit of collecting and making use of student-learning data in real time so that educators and schools can make more effective, data-driven decisions and can better support differentiated learning, accessibility and greater feedback, inclusion, and transparency (USDOE 2010).

There are different aspects of games that can be assessed, such as whether in-game goals were completed, whether learning goals were reached, whether game play was effective in supporting goal completion, and how the in-game and out-of-game context encouraged learning. Any assessment is affected not only by the learning attained but also the context of the game and assessment(s) given, the students/people being assessed, the person providing the assessment, and other factors (Simkins 2014). Assessment does not need to take place outside of the game (such as through an exam or paper written using concepts or skills used in a game). The game itself can incorporate assessment through its play. For instance, the DoE describes how a virtual world, River City, assessed student scientific inquiry and communication skills in situ (USDOE 2010; Dede 2009).

Assessment and reassessment are part of any well-designed game because players need feedback to know if goals and tasks are complete. The fact that the player has

reached particular goals in a game could be in itself a useful assessment of the player's status and learning needs. For instance, Gibson and Webb (2013) identify specific types of assessment that may be relevant to games, such as investigating students' decisions in a game, commenting on peer students' game creations, and/or responding to a prompt through the creation of a game or interactive project. In other words, the act of playing and/or interrogating the game is a form of assessment.

Balancing Needs and Perspectives

Game design is a series of trade-offs and mini-solutions to an enormous number of questions that need to be weighed, such as designing flexible game play versus maintaining strict accuracy or enabling deep immersion in the game versus ensuring the ability to transfer learning to outside contexts. The decision about what type of game to use – for example, whether commercial-off-the-shelf (COTS) entertainment games or those focused on educational purposes – may also be rife with further questions and consequences. When representing an event from history or a physics property in a game for additional examples, there are a seemingly infinite number of ways to simulate something, with give-and-take decisions among many different constraints, such as accuracy, resources, expertise, time, platform needs, audience needs, game play desires, etc.

Choosing whom to include on a decision-making or design team may also involve trade-offs in budgets, technological limitations, resources, and expertise. For instance, educational games often include educators and researchers on their teams alongside game designers such as *Mission US: For Crown or Colony* (Schrier 2014; Farber and Schrier 2017). Many big-budget entertainment-focused games use large teams of people such as designers, developers, artists, musicians, and storytellers, whereas games specifically made for education often have smaller budgets, less resources, and fewer people (Schrier 2016c). Strong teams for educational game development combine expertise in game development, storytelling, art, and design, as well as in education, curriculum development, subject-area expertise, and assessment. Different stakeholders and perspectives need to work together to collaboratively decide how to navigate practical, creative, and educational tensions and questions while also meeting goals, standards, and metrics.

The Future of Games and Learning

This chapter brings up a number of questions relevant to game-based learning. Yet, the answers are not always obvious and will continue to evolve alongside technological, cultural, social, and economic changes. For example, expensive, immersive technologies such as those related to virtual reality are growing in use alongside cheaper and DIY (do it yourself) technologies, such as *Arduino*, *Raspberry Pi*, and *littleBits*, which will increase the types of digital and highly interactive educational experiences educators can create, as well as alter who has access to these types of

experiences (Schrier 2016b). Likewise, robots and robotics, as well as wearable technologies, interactive displays, context-aware technologies, and connected objects (“the Internet of Things”) are starting to be used within or alongside games to teach and support learning. For instance, students are learning how to program using robots and other interactive objects and technologies, which could also be used to create and support game play (McGill 2012).

Mobile and tablet usage is becoming more widespread, though inequities still exist, and knowing which educational apps and games to access and how best to use them in educational settings will require additional research and experience. Large data sets (big data and learning analytics) are also being used more frequently for predicting behavior and assessing learning – both in games and in other types of educational activities. The increased usage of data will affect the types of questions that will get asked as well as the types of methodologies and approaches available for considering, using, and studying games and learning. A new divide – the data divide – has been emerging (Boyd and Crawford 2012) between those who can use, analyze, and maintain the data culled from educational games and those who cannot. Ethical questions (such as those related to data use, privacy, transparency, equity, accessibility, and algorithm creation) need to be considered alongside pedagogical and design questions.

In addition to teaching content areas and topic-related skills (e.g., math facts and literacy), other types of skills have also become vital, such as computational thinking, twenty-first century and civic-minded skills such as argumentation, perspective-taking, media literacy and media fluency, and identifying biases. Game-based learning may be another way to show students how to separate fact from fiction, understand and evaluate viewpoints, and analyze information (Schrier 2014).

Finally, educators need to find innovative ways to engage students in solving real-world problems and creating new knowledge. Educators can use games also to help uncover solutions to real-world complex issues, such as poverty, war, or climate change. Games, and their ability to simulate intricate systems, invite collaboration and cooperation and show people how to think through problems in new ways, may help people uncover new truths, and consider new perspectives. Game-based learning has the potential to not only help people acquire knowledge but also to reveal new understandings of humanity, our world, and our past, present, and future.

Abstract

To promote teachers choosing and using games in the classroom, educational leaders, researchers, and practitioners must address three needs. First, educators need confidence that games embody or support sound pedagogy. Second, educators need to be able to evaluate games for their potential as learning objects. Finally, educators can benefit from concrete models of classroom use of games.

K. Becker (✉)
Mount Royal University, Calgary, AB, Canada

This chapter provides a brief introduction to game-based learning pedagogy, an evaluation model that can guide a structured analysis of a game for potential classroom use and a sampling of instructional strategies adapted for teaching with games.

Keywords

Digital game-based learning · Game-based pedagogy · Learning with games

Introduction

Digital games are being used more and more often as teaching resources in the classroom (Habgood and Ainsworth 2011). One way to build confidence that games do indeed embody sound pedagogy is by connecting the technology and design with “classical” learning and pedagogical theories that predate games. When a game has been chosen as a potential candidate for use in the classroom, it should then be evaluated with respect to how well this particular game embodies relevant learning theories, as well as more practical concerns such as the game’s connection to the curriculum and whether or not there is adequate teacher support. The criteria that make a game suitable for use in the classroom are varied. Jim Gee states that games for education must be re-playable and immersive, that they must build expertise and identity, be transdisciplinary, allow for different trajectories of expertise, and more (Gee 2012). These are worthy goals, but it is unclear that they are always necessary, and some argue that they aren’t even always desirable. An educational game can also be “an elegant experience that encourages and enables the target player to achieve the intended learning goal(s)” (Heeter 2013). Ultimately, a lesson must be built around the game to be used, and providing strategies for that can determine whether a game is more or less likely to be used than some other technology in any given context.

Games and Learning Theories

What theories and models underpin educational game design and use? Wu and colleagues performed a meta-analysis of studies on the learning theories foundational to digital game-based learning and found a variety of learning theories (Wu et al. 2012). They grouped them into four categories: behaviorist, cognitivist, humanist, and constructivist approaches to which social learning can be added as a fifth.

1. **Behaviorism** holds that behavior can be shaped by associating a desired response with a specific stimulus (Watson 1925). This category includes Skinner’s operant conditioning (Skinner 1938), Thorndike’s connectionism (Thorndike 1910), and Gagné’s conditions of learning (Gagné 1965).
2. **Cognitivism** holds that learning is affected by the workings of the brain and how people think. This group encompasses Bartlett’s schemata (Bartlett and Bartlett 1995); Piaget’s cognitive development (Piaget 1951); Weiner’s attribution theory

- (Weiner 1974); Collins, Brown, and Newman's cognitive apprenticeship (Collins et al. 1987); and Sweller's cognitive load theory (Sweller 1988).
3. **Constructivism**, which holds that learning is actively constructed and linked to existing knowledge by the learner (Bruner 1960). This group consists of Latour's actor-network theory (Latour 1996), Bruner's discovery learning theory (Bruner 1961), Leont'ev (1978) and Luria's activity theory (Luričiiia 1976), and Papert's constructionism (1980).
 4. **Humanism**, which claims that learning must involve the whole learner and their environment. Finally, this category includes Kolb's experiential learning (Kolb and Fry 1975), Maslow's hierarchy of needs (Maslow 1943), Deci and Ryan's self-determination theory (2000), and Csikszentmihalyi's flow theory (Csikszentmihalyi 1991).
 5. **Social learning**, which is said to occur in social contexts, such as those including the physical presence of other people, but it can also be mediated by technology. See Bandura's social learning theory (1977), Vygotsky's social development theory (1934), Vygotsky and Cole's social constructivism (1977), and Lave's situated learning theory (Lave and Wenger 1991).

Choosing Games

Information from the scholarly connection between theories of teaching and learning and the design of learning games can be used to help choose games for use in the classroom, but there remain some key questions that also need to be addressed, such as whether to use a game specifically designed for learning or to adapt a commercial off-the-shelf (COTS) game.

Commercial off-the-Shelf (COTS) or Serious Games?

A serious game is one designed for purposes other than or in addition to pure entertainment (Sawyer 2003). This includes but is not limited to educational games. While there is growing acceptance of the use of educational games, COTS games are not as well accepted, often with good reason. Using a COTS game in a formal learning context is, in most cases, analogous to an "off-label" use. Teachers use commercial off-the-shelf games knowing that this is not what the games were designed for, and so it is important to recognize that the efficacy of these games will inevitably come from a well-matched pairing of learning design outside of the game and directed or goal-oriented play within the game. In other words teachers need to make sure that the games they choose and use are going to meet teaching needs.

Assuming the content of the game matches with the learning objectives, COTS games can have some advantages that educational games don't. COTS games are often richer in terms of the worlds and environments; they are made with substantially larger budgets, so they are bigger, often with celebrity voices and music. This can have a positive impact on both motivation and acceptance. Some of the smaller

casual games can be useful in supporting the learning of a single concept or skill. They often have many levels with short rounds, making it possible to incorporate them as a supplement to a lesson without having to be the “feature attraction.”

On the other hand, it can be difficult to identify COTS games that map onto the curriculum well enough to justify the time spent using them. Assessment, while it is something many COTS games are very good at, tends not to be the kind of assessment teachers can readily apply to formal educational contexts. Finally, many commercial games are not free, and though they may be less expensive than a textbook, they do often assume that players will have access to the latest hardware and that is often not possible in a formal educational environment.

Serious games, especially those designed specifically for use in formal educational environments, often have learning objective-based assessments, classroom or other group licensing arrangements, and clear ties to known curricula. On the other hand, many educational games still lack those qualities that make COTS games “good.” For example, they often look good but fail to hold the players’ interests. This phenomenon relates to the decorative media trap, which is the mistaken notion that a game that looks good must also be good (Becker 2012a). The analytical model outlined in the next section provides a way to analyze games, both COTS and serious, that allows teachers to see where the game excels and where it is lacking. It also provides a way for games to be compared against each other.

The 4PEG Game Evaluation Model

The 4PEG (four pillars of educational games) evaluation model (Becker 2016) allows teachers and others to perform a structured analysis of games to assess potential classroom use. The pillars are:

Gameplay – there’s really no point in using an educational game unless it also works as a game. This pillar assesses the game *as a game*. It attempts to answer the following questions: How does the example measure up as a game? Is it fun? Is it interesting? Is it aesthetically pleasing?

Educational content – whether this game has been created specifically for learning or purely for entertainment, this pillar addresses the requirement that the game have identifiable educational content. It attempts to answer the following questions: How are there one or more recognizable educational objectives to be found in this game that are discernible either from the game itself or from the accompanying support materials?

Teacher support – in order to be truly useful in the classroom, games must have sufficient teacher support so that teachers are not always required to build lessons from scratch. There must be adequate teacher support to make it viable for use in a formal setting.

Balance of categories – the final pillar is based on the “magic bullet” model (Becker 2012b) to determine how well are the various learning elements balanced in the game.

Fig. 1 4PEG rating sheet

A rating sheet for the 4PEG model (Fig. 1) consists of 20 elements that can be graded on a scale of 0 (missing) to 5 (excellent). The scores for these individual elements are then summed to give a number between 0 and 100 as well as an average score for each pillar. In the following sections, the 4PEG model is discussed in detail.

Gameplay

Gameplay ratings are intended to assess the quality of the example as a game independent of its potential as an educational object. Gameplay is rated according to six criteria intended to provide information that will indicate whether it is likely to be a good fit for learning purposes:

- Content and originality:** Overall, is the game appealing?
- Game mechanics:** What can the players do in the game? A high score represents that the game mechanics complement the intended use of the game.
- Game progression:** The transitions between levels or progression from start to end should go from simple to challenging and should be smooth and appropriate for the game.

Artistic design: Is the visual design appropriate for the game? Is it a good fit for the kind of game it is and for its intended purpose?

Set, settings, characters, and costumes: Do the surrounding environment and the characters in the game work in harmony with each other to create a coherent experience?

Audio: Is the audio track appropriate for the game? Is the music necessary to the game? Can it be easily switched off?

Educational Content

This pillar addresses the quality and extent of the educational potential in the game considering 11 aspects.

Instructional strategies: An instructional strategy is a plan for what will happen during the course or lesson. What kind of strategy is being used in the game to help people achieve the educational learning objectives? For example, a guessing game or drill and practice may be appropriate for learning anatomy, but not for understanding the dynamics of Mendelian genetics.

Instructional design: Instructional design is the process of creating instruction through the analysis of learning needs and the systematic development of learning materials. Merrill's *First Principles of Instruction* (2002) is used as the benchmark against which the instructional design component of the game is measured.

Problem: Does the game engage learners in solving real-world problems, or if not, are the problems ones that can be applied to real-life problems?

Activation: Does the game activate existing knowledge as a foundation for new knowledge?

Demonstration: Does the game demonstrate new knowledge to the learner?

Application: When the player learns something new in the game, is the learner provided with opportunities to use it within the game?

Integration: Does the game help learners integrate new knowledge into the learner's world?

Objectives: This category rates the extent to which the game supports the objectives as determined someone doing the rating, who, prior to testing the game in the classroom, is making a reasoned judgment. The goal is to assess whether or not the game provides the necessary "raw materials" to address valued educational learning objectives.

Integration: In a serious game, it is essential that the educational learning outcomes be part of the required interactions of the game. It should not be possible to get through the game while ignoring the learning objectives.

Accuracy: Does the game contain accurate information? The facts associated with the educational learning objectives should be correct, and the needed concepts and principles should be clear.

Assessment: Is the in-game assessment relevant to the educational learning objectives? In some games a losing score can sometimes be just as valuable for meeting educational objectives as a winning one; on the other hand, the actions required to achieve a positive score may have little to do with what players are supposed to be learning (Gopin 2014).

Teacher Support

The level and quality of easily accessible teacher support is assessed considering four elements.

Teacher’s guide: Teacher’s guides should be clear, well-organized, and easy to locate. Support materials should include such things as: a description of gameplay, content description, any special permissions or skills required to install or run, and installation and execution processes.

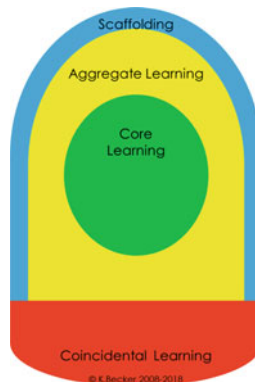

Plug n’ play: Do the support materials include lesson plans with thorough instructions for using the game in the classroom or other target environment? It should not require a large time investment to make it “teacher-ready.”

Supplementary resources: Additional information specifically for teachers, such as background on the game and the topics it addresses, ways to use the game, and where to get help, should be complete and readable.

Community: Is there a community where teachers can go for help, support, to share ideas and experiences, and explore ways to use the game?

Balance of Categories

Learning with games can be classified as a balance of four categories of learning, termed here as the “magic bullet” aspects of a game for learning (Becker 2008a). The categories include the learning that is required in order to win the game, other designed content, and unintended learning both external to and coincidental to the game.

Aggregate learning: Aggregate learning includes all that CAN be learned, as deliberately designed by those who created the game.

Core learning: Core learning is that which MUST be learned in order to achieve a given goal. It will almost always be a subset of the first category and includes only those items that are necessary in order to win or get to the end.

Scaffolding: This category includes learning that happens outside of the game: in fan sites and other social venues. This category also includes “cheats.”

Coincidental learning: The final category includes all other things we can learn. These are not necessarily designed into the game, although sometimes designers may hope that players choose to take these up.

The model includes an additional layer of contexts that are specific to educational contexts, so each kind of learning mentioned above becomes a subcategory of one of the following components:

Operational: Game controls, game mechanics, and other overhead depending on how the game will be used.

Educational: How does the teacher plan to use the game?

Elective: Any elements of the game that don't fit into one of the other two categories.

The balance pillar contains four key perspectives in which each rating is determined by how well the balance of the elements fits the type of game it is and its intended use and audience.

Overall balance: How well do the four magic bullet categories of learning match the game's intended use?

Aggregate vs core: Is the balance of things students can learn versus things they must learn appropriate for the intended use of the game?

Operational vs educational: Is the time spent learning to play the game appropriate for the game's intended purpose?

Educational vs discretionary: Is there an appropriate balance of learning and engagement?

The variety of categories in each of the pillars provides a detailed analysis of the game's strengths and weaknesses. A low game score may be tolerable if it has a high content and support rating. Alternately, a low support rating may not be important if the teacher has the experience and the time to develop custom materials.

Designing Game-Based Lessons

While there are a growing number of people who talk about using games in the classroom as an instructional strategy (Salen 2008), it can still be hard to find information on instructional strategies that use games. This can be a significant barrier as insufficient time, lack of tech resources, difficulties finding games that fit the curriculum, and not being sure how to integrate games in a teacher's teaching can all contribute to a teacher's reluctance to use games in the classroom (Molin 2017). Support in the form of strategies such as those in the following sections can help encourage some teachers to try using digital games that might otherwise avoid them.

Beyond Content: Games as Prompts for Thinking

Although we have largely focused on games as content, there are other ways to use games in the classroom. The author has outlined 15 different ways to use games in the classroom in some detail elsewhere (Becker 2016). The following is a brief summary of seven of them:

1. Content – the content of the game directly addresses some curricular need.
2. Example – the game is an example of or an artefact that supports what is being taught.
3. Inspiration – games can be used as inspiration for creative writing, for construction, as examples of scenarios, as role models, and counter-role models.
4. Art – some games have a unique artistic style that is worth studying.
5. Medium – the constructionist approach to learning focuses on making a game about the topic or concept being taught.
6. Literature – games can offer unique perspectives on narrative, and some can be studied as literature.
7. Environment – a game can provide an environment for an activity or part of a lesson.

Instructional Strategies

Instructional strategies shape the actual things teachers do in the classroom to bring planning to fruition. The following six ideas are a few examples of strategies that can incorporate games:

CROWN Closure Technique

CROWN is a closure technique that encourages students to reflect on the completed lesson (Jacks 2005), which can be applied to the entire lesson that uses the game, only the game, or to one part of the lesson or game.

C = communicate what you learned.

R = reaction.

O = offer one sentence that sums up what the whole lesson was about.

W = Where are some different places you could use what you have learned?

N = note how well you did today.

Collections

Many games allow players to collect items of various sorts. This strategy uses those collections as the source of projects, presentations, or writings related to the learning objectives. Players can be directed to gather collections of items that fit specifically with some concept or topic they've been given.

Data Analysis

Students can use games to gather data for analysis and graphing. In a multiplayer game, students can create and design surveys to conduct within the game. For example, in a game where players can choose human or animal avatars, players could record how many characters of each type they have come across in a certain period of time and then ask those characters why they chose the characters they did. In a single player game, other data can be collected. For example, when you plant flowers in *Animal Crossing*, they turn brown after a time and need to be watered. Players could record plantings and when the flowers turn brown along with the locations and then analyze the data to see if any patterns emerge.

Field Logs

Field notes or logs typically include written notes, comments, and reflections as well as sketches and maps. When gaming, players can imagine themselves as observers or researchers in the field and make notes about their “time in the field” for later analysis, reflection, and comparison.

Find the Fib

Groups of students write two true statements and one false statement and then challenge other groups or even the teacher to “Find the Fib” (Rowan 2013). As a game-based learning strategy, the statements will come from the game. Many games take liberties with various aspects of reality in order to make the game more playable, intuitive, or entertaining. Players can find two things within the game that are true and one that is false. For example, the relative sizes of some of the characters may not be to scale, or time might pass differently. There may be facts in the game that are incorrect. “Find the fib” is a way to get students to think critically about what they are seeing and experiencing in the game, and it can also provide a way to highlight specific learning goals.

Through the Eyes of the Enemy

Students consider alternate perspectives and gain empathy by trying to view the situation through the eyes of the antagonist in the story (Rowan 2013). Games are especially good at facilitating this kind of strategy as it is often possible to play “as the bad guy” in a game, and this can lead to interesting insights. Even when that is not possible, in a game that has an antagonist, it is possible to explore how the interaction might look from the perspective of the antagonist.

Lesson Plans

Along with assurances that good games embody sound pedagogy and suggestions for how to use games in the classroom, lesson plans for teaching with games can be adapted to contain distinct elements such as the following:

Game Description and Objectives

Identify how the game connects with learning outcomes and instructional objectives. List all topic and content-related materials and resources that you and the students will need in this section. Are there things that need to happen before the lesson begins? What do the students need to do?

Other Materials and Resources

List the resources necessary to use the game. If the students will need anything in addition to what the teacher needs, include that to make sure it is available on their devices. The resources that are specific to the game should be listed separately from other resources for the lesson and might include such things as a 4PEG review of the game (see above discussion) and any community websites, instructional manuals, teacher guides, or other documents related to the game. If the game gets used in another teaching context, the operation information need not be duplicated.

Lesson Activities

Describe what students will do before playing the game (pregame), during the game (in-game), and after the game (debriefing or post-game).

Pregame

How will students' interest in the topic be fostered? It's unwise to assume that they will automatically be interested, simply because they are using a game.

How will students' prior knowledge of the topic be revealed?

Do they need time to learn how to play the game before beginning the activity?

What about students who already know how to play the game or those who have never played video games?

How will they be prepared to attend to the objectives during play?

In-Game

What sequence of activities will the student experience?

What will the teacher do?

What will the students do?

What will students do who finish early?

How much time will each activity take?

What about clean up?

Will the teacher guide them through their play session, or are they playing on their own?

Debriefing

How will the play session be ended?

Where will students "reconvene" for the debriefing? The debriefing should help students reflect on or summarize what they have learned.

How will the lesson be ended? The closing should be linked to the instructional objectives.

Here are some additional questions to ask:

- What specific content is covered in the game and what is missing?
- Does it provide an overview of the topic (breadth), or does it focus on a particular aspect of it (depth)?
- Will the game be a single play for one lesson or be used across multiple lessons?
- Are there factual or conceptual errors or misleading information in the game? How are those going to be addressed?
- Are there alternate viewpoints in or around the game that can be used?
- How will gameplay be managed?
- Does the game allow saving at a particular point and then sharing the progress?

Conclusion

Choosing and using games in the classroom can make use of many techniques already recognized as sound pedagogy grounded in learning theory. Connecting teaching with games to good instructional practice, while not necessarily easy, brings a potential payoff that includes highly engaged students who are excited to learn. Furthermore, assessing games and sharing insights as well as support materials can move practitioners toward game-based learning pedagogy as a positive new teaching tool in their educational toolset.

The three-pronged approach to helping teachers evaluate and incorporate digital games as described in this chapter addresses a variety of needs and concerns that teachers often have when considering the use of digital games in the classroom. However, like every other new technology that has been applied to formal education, it will take time for games to gain acceptance and be seen in the same light as more traditional methods (Salen 2008). The body of research continues to grow rapidly (Chung-Yuan et al. 2017), and the field is still a young one, but with more specific studies of game use in the classroom as well as research on best practices for design and development, this incarnation of game-based learning in formal education looks to be more successful and lasting than the “edutainment era” of the 1980s and 1990s.

Abstract

Contemporary educators have been advocating that teaching and learning in schools should go beyond knowledge acquisition. A critical challenge is how to help students learn like expert creators who constantly display active engagement and personal autonomy and who are keen to collaborate with others. Recently, construction-to-learn activities have received even more attention than before. The maker movement is occurring in many educational settings. However, the setup of makerspaces does not necessarily guarantee a positive impact on students' learning. Too much emphasis on the hardware tools may blur the educational focus and the merits of maker activities. This article summarizes and presents studies related to construction-to-learn activities that support students in their learning as creators. It revisits the key design principles of learning systems based on the needs of student makers: "supporting students to express

Maker Movement and Pitfalls

In recent years, the development of various DIY production tools has made it possible for users to fabricate their own objects based on their own needs. As envisioned by Hod Lipson, our life will become science fiction as many imaginary parts such as coffee cups and houses can be printed out with 3D printers (Lipson and Kurman 2013). Due to the availability of such DIY production tools, construction-to-learn activities have received even more attention than before. The maker movement began with Neil Gershenfeld’s fabrication stations where individuals were empowered to use diverse types of tools to fabricate objects based on personal needs (Gershenfeld 2005). Since then, different types of “fab labs” have been installed at different educational institutions. The maker movement has been seen in many educational settings. It represents a phenomenon whereby people enthusiastically are engaged in maker activities to develop creative products with kits such as 3D printers or laser cutters (Halverson and Sheridan 2014). It has been advocated that such maker activities may be reinventing our schools as they transform learning into an active process. Maker activities fulfill several important pedagogical principles. Firstly, students are creators rather than consumers, and thus the engagement in such activities is generally based on enthusiasm. Furthermore, the activities are self-directed because makers have to solve unexpected problems in the process of making products. The products they create are a demonstration of what they have learnt to do (Dougherty 2012).

To facilitate construction-to-learn activities, many makerspaces have been set up in different places such as universities and libraries. The makerspace is a physical location where construction tools such as 3D printers, laser cutters and saws are made available. Students can gather there to work on projects together (EDUCAUSE Learning Initiative 2013). They can also share resources and knowledge in the makerspace. The makerspace is even more important for novice makers than for proficient makers as they can get help from others. Therefore, many K-12 schools and universities have been setting up makerspaces to implement maker activities on campus.

The maker movement may shed light on how learning activities should be designed to engage students in active learning. For instance, students can be engaged in practices in which they must apply tools/technology to build objects, showcase their creativity, and learn with others. Recent enthusiasm for the maker movement is

the result of the availability of DIY tools on the market, and thus many schools are now equipped with 3D printers in the makerspace for diverse educational purposes. However, schools and educators should be aware of the potential pitfalls of simplifying the implementation of maker activities as the installation of makerspaces. First, the setup of makerspaces does not necessarily guarantee a positive impact on students' learning. Too much emphasis on the hardware tools may blur the educational focus and the merits of maker activities. Maker activities risk becoming mere skills training for the DIY tools while failing to fulfill any educational merits. Second, educators may see the maker activities simply as assembling tangible objects according to existing menus, without considering the creativity principles embedded in them. Third, as the making process is usually conducted in the physical makerspace, the social practice may be constrained at a certain level without the possibility of stretching students' creativity to a higher level.

In this vein, this chapter aims to clarify the implementation considerations of maker activities based on a series of studies related to construction-to-learn activities (Burton et al. 1984; Harel and Papert 1991; Kiili 2005; Knobel and Lankshear 2008; Liu et al. 2011, 2014, 2016). Such creator-based learning aims to foster creator mentality in classroom learning practice and features three significant creativity principles during the learning practice: supporting students to express their imagination, facilitating the remix process, and low-threshold/high-ceiling. These three principles are particularly important for the design of maker activities as they could be helpful in avoiding the three pitfalls of the current maker movement and in extending the maker activities to become a creativity development process.

Supporting Students to Express Their Imagination

The first principle for implementing maker activities is to support students to express their imagination while engaged in the activities. Imagination is considered as the core of creativity and one of the elements of students' engagement in the learning process. Imagination, according to the Oxford dictionary, is "the faculty or action of forming new ideas, or images or concepts of external objects not present to the senses." It is the key component of human creativity based on Finke's Geneplore model of creativity (Finke et al. 1992). The Geneplore model asserts that creativity involves the generation of new ideas followed by the exploration of the detail of the new ideas. However, current teaching practice does not put much focus on how students' imagination can be integrated into learning.

To overcome the constraints of the current maker activities, the study by Liu et al. (2011) proposed the notion of an imaginative construction game to motivate students to learn by supporting them to build a product based on their imagination. This construction game relies on the basis of constructionism which posits that students construct knowledge most effectively in a context where the learner is participating in constructing a product that is visible to the audience (Harel and Papert 1991). Construction is the basis of maker activities as it motivates students to learn by engaging them in constructing an object visible to the audience. With the help of

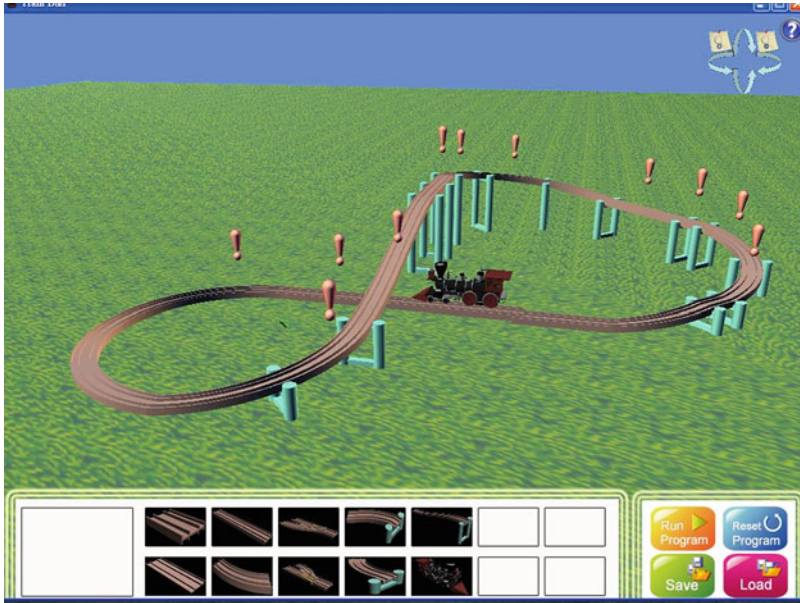

Fig. 1 An imaginative construction game supporting students to build and program rail systems

various kinds of production technologies such as Logo or Scratch, students must discover and analyze information as well as build knowledge in order to construct an entity.

The imaginative construction game illustrates two design considerations that may be helpful in implementing maker activities: production tools supporting students to express their imagination and simulation of students' imaginative ideas. Examples of such imaginative construction games include SimCity wherein the players must imagine, build, and manage a city. Such games may facilitate the achievement of educational objectives because they enable the players to exercise their imagination and analyze ideas. Therefore, the study by Liu et al. (2011) developed an imaginative construction game, namely, Train B&P (Train Build and Program it, see Fig. 1) based on the constructionism framework. Students can construct a railway model with the simulation in the same way they can with real toy trains such as Tomica trains. However, they can design imaginative rail systems that overcome the physical constraints of the real toys with such an imaginative construction game.

The imaginative construction game highlights the design consideration of enabling students to simulate their imaginative ideas before building them. It has been extensively advocated by researchers that computer simulations can facilitate discovery learning as they model complex system in the real world and allow students to explore, experiment, and exercise their ideas (de Jong and van Joolingen 1998). The constructionist approach to learning also highlights such computer simulation as one important means of enhancing in-depth learning while constructing or analyzing a product (Shneiderman 2000). If students can interactively initiate and

test their ideas while constructing a product, they are more likely to be engaged in the learning activity.

Train B&P enables students to write computer programs to build the railway model as a means of learning to code. Train B&P provides two simulation functions to help students simulate the rail models they built in the 3D environment. The first simulation is the physics engine embedded in the game. The engine simulates the movement of a train in a physical environment considering gravity, speed, acceleration, and friction. The second simulation is the program compiler that simulates the behavior of the programs students built. The program compiler allows the students to visualize the behavior of railway models in a virtual environment. In this way, students' imaginative ideas can be tested in order to improve their designs.

The results of the study suggested several implementation considerations for maker activities. It was found that the imagining-and-constructing activity significantly promoted students' intrinsic motivation to learn. Furthermore, the visualization and simulation tools also balanced the students' challenge and skills perceptions, thus significantly improving their flow perception during the learning process. The students were motivated to apply multiple problem-solving strategies including trial-and-error, learning-by-example, and analytical reasoning strategies while constructing products. Therefore, embedding students' imagination and helping them to simulate their imagination with proper tools may be necessary to go beyond the reproduction of existing products and to promote the maker activities to a level of creativity.

Facilitating Endless Remixing

The term "remix" originally referred to the audio-editing techniques used to create a new mix of an existing song. It has now been expanded to the generation of various types of artefacts such as articles and images (Knobel and Lankshear 2008). It is believed that remixing is the basis of human creativity. Creativity through remixing is a process of creative synthesis through which innovative ideas are obtained through a series of synthesis of existing ideas (Harvey 2014). Creativity is shaped from using the existing ideas or artefacts in three forms: making unfamiliar combinations of familiar ideas (combinational creativity), noticing new things in old spaces (exploratory creativity), and making new thoughts possible by altering the rules of the old spaces (transformative creativity) (Boden 2015). The core principle of the remix process is the endless hybridization process, whereby individuals create new entities using existing artefacts (Lessing 2008); remixing is therefore a pathway to creativity. Figure 2 displays how the remix process takes place in social contexts. Students may donate their products to a social platform, while others may retrieve and rework them to generate new products. They can work together to combine their ideas to generate new, innovative products. As they retrieve, understand, and amend existing artefacts, they can not only improve their understanding of the artefacts but also improve their quality (Liu et al. 2014). Such a process is helpful to implement the socio-constructivist viewpoint of learning which suggests that individuals' ideas

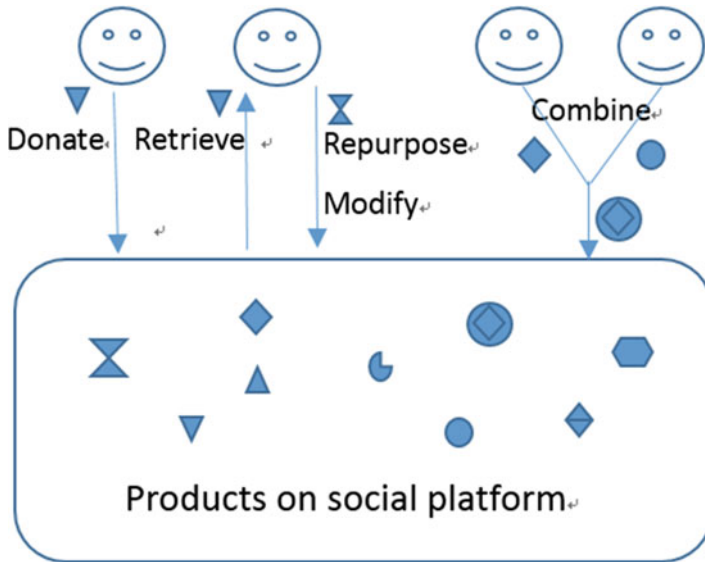

Fig. 2 The remix process in the construction-to-learn activities

are improved through social interactions (Roschelle et al. 2005; Shaw 1995). Therefore, individual capacity can be enhanced by the remix process.

However, remixing is not valued in schools. For instance, using material on the Web or others' work in assignments is regarded as plagiarism (Norman 2001). The main reason is that students do not understand the social value and manners of the remix process. Students often simply copy others' work without attributing credit to the original contributors when doing value-added remixing. Having acknowledged its potential downside, researchers have been increasingly applying the principle of the remix process to promote creativity in various construction activities. Some of the activities are closely related to maker activities. For instance, the remix process has been utilized to improve the learning of programming (Kafai 2016; Vasudevan et al. 2015; Liu et al. 2014). In the remix process, students do not learn to code from scratch. Instead, they learn to code by reworking the code generated by others. The analysis of exiting codes is an integral process of the learning of coding. Therefore, such a remixing is the core process of open-source development in which students join together to understand and pursue productive integration of code written by others (Kafai 2016). The remix process is also used by educators to develop students' storytelling ability (Liu et al. 2017), and artworks (Knochel and Patton 2015). During the remix process, students create new artefacts through modifying, repurposing, or combining available materials, instead of starting from scratch. Since students do not need to do everything by themselves, these materials therefore act as important scaffolds to help novice students participate in creativity activities (Liu et al. 2014; Vasudevan et al. 2015).

The remix process may therefore be helpful in terms of improving creativity in maker activities as it provides a mechanism of endless hybridization to make new

artefacts from using existing ones. The study by Liu et al. (2017) has demonstrated how the remix process facilitated the creation process of digital storytelling. The remix process in the study became an imaginative re-creation activity in which students integrated or interpreted existing intellectual works with their imagination to create new works. Such an imaginative re-creation activity is deemed as an essential function of novel reading to imaginatively re-create the perspective about the novel for oneself (Bruni 2016). Liu and his colleagues' study (2017) found that students applied various approaches to add value to the existing model stories such as scene enrichment, character enrichment, and emotional expression enrichment, which are also important quality drama and story features. Their survey of students' perceptual feedback also supported the argument that the remix process is effective in terms of maintaining students' sense of interest and curiosity as well as enhancing their confidence in developing creative products.

Such a remix process may also enhance social creativity in the maker activities. It strengthens the "transactivity" of the social activities, denoting the degree to which students reciprocally build their works or argumentation based on those of their peers (Weinberger 2011). In the study by Liu et al. (2014), they experimented with how students developed code through modifying peers' code work as a means of learning to program. Through the remix process, individuals' coding works were enhanced, as several remixes could be derived from a single original work. Such a remix process has been applied in the programming community in Scratch (Monroy-Hernández and Resnick 2008).

However, the remix process in social settings may encounter the social dilemma of knowledge sharing. This dilemma denotes the phenomenon that individuals simply try to maximize individual payoff (Cabrera and Cabrera 2002). To implement the remix process, students need to share their work with peers, and then value-added hybridization can possibly occur. However, the sharing of individual work may decrease the sense of ownership of the work, and thus refusal to share becomes the most beneficial strategy (Dawes 1980). As the initial condition of remixing is to share individual work, there arises a need to resolve this dilemma in order to encourage work sharing in the maker activities (Liu et al. 2014).

In this regard, the study by Liu et al. (2014) suggested that, with proper mediation, the remix process can significantly improve participants' attitudes regarding the derivative works, the satisfaction level of the remix outcomes, perceptions of peer interaction, and the sense of work ownership. They recommended that the Creative Commons (CCs) (<http://creativecommons.org/>) mechanism may be a potential approach to increasing individuals' responsibilities and motivating them to participate in the remix process. Traditionally, individuals cannot copy, use, modify, or distribute a work developed by others unless the author of the work give permission. Such a constraint on intellectual properties significantly limits the creative use of these properties. The CCs was thus proposed to work as a flexible mechanism that accelerates the remix process as it makes it possible to use others' intellectual property in a more flexible form. For instance, under the share alike license of CCs, individuals allow others to modify their work and then to distribute the derivative works, also under the share alike license. The study by Liu et al. (2014)

suggested that the CCs mechanism provides students with a reliable tool for mediating the remix process as it increases the willingness to share individual works as a source of remix. The CCs can significantly improve participants' attitudes toward the derivative works, the level of satisfaction with the remix outcomes, perceptions of the peer interaction, and the sense of work ownership. One of the objectives of the maker activities is to develop students' creativity literacy. Therefore, educators may consider the CCs mechanism as useful for students to experience, understand and model the social creativity process to prepare them for future creativity.

Low-Threshold and High-Ceiling

The English poet Samuel Taylor Coleridge coined the phrase "suspension of disbelief," indicating that the audience tends to overlook the limitations of a medium. This notion pointed out that readers tend to suspend their judgement about the quality of a literature creation. Due to such a tendency, a writer can use such "suspension of disbelief" to make an illusion that people like his/her creation (Böcking 2008). This notion has been referred to as the novelty effect (Clark 1983) in the use of technology in education. The current enthusiasm of the maker activities may have been the result of the effect of suspension of disbelief. Educators and students tend to overlook the challenges and limitation of maker activities in schools. According to the literature (Clark 1983; Hur and Oh 2012), very soon the enthusiasm will decrease when the novelty effect of the maker movement wears off.

Educators and researchers should ask the question during the implementation of maker activities: Do the technologies we are using in the maker activities really engage students in learning, or are we using students' ignorance or lack of knowledge to promote suspension of disbelief? The question should also be applied to all researchers using technologies to support other learning scenarios. The DIY tools such as 3D printers and other hardware devices may trigger students' curiosity during their initial encounter with them. However, their curiosity may soon fade if the maker activities do not sustain their interest in persistently participating in the activities. It is suggested in the literature that students' enthusiasm in learning activities is not a static process (Herrington et al. 2003) but that it changes according to the challenge and skill levels (Kiili 2005; Liu et al. 2016). The game design principle may shed light on the ways to address this temporal issue. Game design principles suggest that game systems need to be tuned to persistently engage students in a flow state from a lower to a higher level of challenge throughout the whole game process (Kiili 2005). Therefore, one of the principles to persistently engage students in maker activities is the low-threshold but high-ceiling principle (Myers et al. 2000). More specifically, the low-threshold feature of the technologies or maker activities should enable novice students to easily participate in the activities. At the same time, the high-ceiling feature has to allow students to work on increasingly sophisticated products. This is similar to the choice of Lego for children of different ages. For children under 3, they need large Lego blocks because they are easier to manipulate, thus making it easy for them to participate in Lego building activities. However,

children over 7 will not be interested in such big blocks. They need more complex building blocks to work on complex products.

The low-threshold/high-ceiling principle was initially coined to address the pedagogical guidelines for developing complex abilities (Burton et al. 1984). The principle is critical to sustaining students' engagement as it helps to achieve a sense of balance in students' challenge and skills perception in the maker activities. Such a balance is an essential condition of flow (Csikszentmihalyi 1975). In other words, to sustain students in a prolonged maker activity, the activity should afford students a high level of freedom so that they can exercise their imagination and regulate their activity to achieve the imaginative and challenging goal.

The low-threshold principle is critical to enabling novices to participate and to build their confidence in the maker activities. Through proper design, the threshold of the technologies can be lowered to support novice students to participate in maker activities. Tangible programming blocks such as AlgoBlock (McNerney 2004), for example, provide facilities for children to learn to code computer program. Such an easy-to-manipulate programming blocks are a potential approach to addressing the low-threshold principle. In programming activities, children may encounter cognitive barriers that significantly hinder young children's participation in the programming activities. The programming blocks provide tangible interfaces between the children and computer to support them in the creation of codes without needing complicated computer skills. In addition to the technology approaches, educators need to be aware of the pattern of students' engagement in using a certain technology and to take appropriate pedagogical approaches in order to address important temporal pedagogical considerations to achieve the high-ceiling principle.

Regarding the pedagogical approaches, the study by Liu et al. (2016) identified several types of disengagement that hindered their long-term engagement in the maker activity and derived pedagogical approaches to solve the disengagement. In their study, a making-my-digital-book activity was implemented to help third graders learn English from model stories. This was a self-directed learning activity in which the students freely created their digital stories based on the model stories with drawings and their own oral narrations without direct teaching (Fig. 3). The activity lasted for 2 years, from 2013 to 2015, and thus sustaining student engagement became a critical issue.

Liu and his colleagues (2016) identified that students' engagement dynamically changed over time. When triangulating students' engagement perceptions with their creation activity, Liu and his colleagues found mainly two reasons for disengagement: wearing off of the novelty effect and repetition. Regarding the wearing off of the novelty effect, during the students' first encounter with the creation activity, they showed a high level of engagement. However, they soon showed the first disengagement as they had no prior experience of similar creation activities and encountered difficulties creating digital stories. The novelty effect faded off soon. Liu and his colleagues also discovered that this disengagement could be easily reversed by the teacher's guidance that helped them accomplish their first story. Such a reverse of disengagement echoes the importance of the low-threshold principle. Educators need to arrange activities to enable the novice students to participate and shorten the period of disengagement due to the wearing off of the novelty effect.

Fig. 3 Students learn to create multimedia stories with drawing and oral narrations

The other reason for the students' disengagement in the creation activity was the repetitive nature of the activity. Such repetition is necessary for the long-term learning process of certain subjects such as language learning. In the study by Liu et al. (2016), the students experienced disengagement again over a longer period of participation in the creation activity. As they kept repeatedly creating and publishing stories during this phase, such repetition caused disengagement. Regarding such disengagement, Liu and his colleagues suggested that social activities that promote the awareness of the higher standard of stories were necessary to reverse the disengagement. When the students noticed the high-quality stories that some others published in the class sharing activity, their awareness of a higher standard of multimedia stories motivated them to improve the quality of their stories. Such a result suggests that educators should have a mechanism to keep students aware of the increasing standard that they should achieve to fulfill the high-ceiling principle. With this standard in mind, students are more likely to work on increasingly complex products to avoid repetition disengagement.

The studies above shed light on the implementation of low-threshold/high-ceiling maker activities. Scaffolding for novice students can shorten the disengagement due to the novelty effect. Setting up increasingly higher standards for maker activities is also a necessary pedagogical approach to continuously engage students in the maker activities in a long-term program.

Conclusions and Future Directions

Maker activities may fulfill the notion of creator-based learning. This is a way of learning by creating something new and meaningful. In contrast to instruction-based learning, creator-based learning is open-ended, rather than fixed scope, therefore requiring students to explore a domain by themselves to pursue long-term learning goals. Students have to expand their creativity, curiosity, and imagination and collaborate with others in order to create. The creator-based learning needs to integrate multiple competencies such as technology, science, art, and language. We

believe that such creator-based learning is helpful for cultivating the minds of makers and preparing students to become lifelong learners.

Maker activities have great potential to transform current education practices into creator-based learning. Learning can become a construction process rather than a knowledge acquisition process. However, to avoid their pitfalls, the implementation of the maker activities should consider the educational principles and promote the educational values of the activities. We have conducted a series of studies to investigate the ways to implement such creator-based learning.

This chapter summarizes our studies regarding creator-based learning and illustrates how the three principles may be used to implement maker activities. Firstly, integrating students' imagination in the maker activities promotes students' intrinsic interest in learning and persistently motivates them to apply multiple problem-solving strategies. Secondly, the remix process improves social creativity in maker activities as it provides a mechanism of endless hybridization which strengthens the "transactivity" of the social activities. During the remix process, students reciprocally build their works or argumentation based on those of their peers. Thirdly, the low-threshold/high-ceiling principle is necessary to enable novices to participate and build their confidence in the maker activities and to build increasingly high standards to improve the quality of the products they make.

We have deliberated three design principles to implement creator-based learning. However, there are still many open issues that need to be addressed in the implementation of maker activities in schools. Firstly, how maker activities can be leveraged in the school curriculum. As maker activities often involve multiple disciplines including science, technology, engineering, art, and mathematics (STEAM) and require a long period of implementation time, how creator-based learning can be aligned with the school course schedule needs further exploration. In particular, pedagogical approaches that leverage the contrast between the openness of creator-based learning and the structured learning format in schools should be necessary to help teachers implement maker activities in schools. The second issue is the assessment of learning performance in creator-based learning. Learning assessment is normally conducted within a constrained and rigid framework. Such a framework contradicts the open and creative nature of creator-based learning. How assessment schemes can be implemented in creator-based learning to assess students' learning and creativity performance needs further investigation. In particular, how the assessment and creativity and learning can be synergized to support the development of both creativity and knowledge in certain domains is a critical issue.

Other future works that should be addressed include how curiosity may play a role in creator-based learning and how curiosity can be triggered and measured in maker activities. Regarding the remix process, it is necessary to resolve the social dilemma of knowledge sharing to promote social learning in the maker activities. Gathering information on these issues through further studies can help obtain a thorough understanding of creator-based learning, which would inform educators and researchers in their design and pedagogical decisions on the implementation of maker activities in schools.

Abstract

Online learning, in particular massive open online courses (MOOCs) and cloud-based tools, is on the move. This chapter takes a deeper look at opportunities and possibilities that might be provided to K-12 education through these emerging tools. The chapter summarizes experiences, case studies, and examples that illustrate where technology-enhanced learning is heading.

Keywords

Online Learning · MOOCs · Cloud-Based Tools · K-12 learning and teaching · Cloud services · Technology-enhanced learning

Introduction

Technology is everywhere and it is intertwined in learning and teaching. At the start of the new millennium, Prensky (2001) stated that there are radical changes in the way students learn and how teachers would teach in the twenty-first century. Public schools in the United States provide at least one computer for every five students (Herold 2017). In Australia, every three students have access to one computer (Fogarty 2015). As evident in today's digital era, the use of enabling technologies has increased exponentially, and all educators – K-12 teachers, college professors, and administrators – must be well-equipped to follow the growth. Today's students are technology-driven (Nagler et al. 2014, 2016; Oblinger and Oblinger 2005) with many growing up with mobile devices, smartphones, laptops, tablets, and fast internet access; and they are more inquisitive while aspiring to learn in a formal, collaborative, and social setting (Conole et al. 2006; Margaryan et al. 2011; Bullen et al. 2008). In this regard, K-12 teachers and administrators must embrace new teaching and digital strategies taking into account aspects to incorporate both formal and informal learning. It is becoming clear that teaching and learning in the twenty-first century are vastly different to teaching and learning in previous centuries. In this context, the experts polled in the NMC Horizon Report 2016 K-12 agreed on the long-term trend of “redesigning learning spaces to accommodate more immersive, hands-on activities” which indicates that online learning and virtual reality are important emerging educational technologies (Adams Becker et al. 2016).

As educational technology permeates our society, teachers and administrators must now be aware of and learn to take advantage of enabling learning technologies and tools that influence the learning environment ecosystem and can be used to drive student engagement and motivation to learn. In addition, this global transformation has demanded that teachers learn new teaching skills and administrators adopt new operating models in response to technological changes.

Learning and teaching technologies have evolved from chalkboards, correspondence or on-air classes, overhead projectors, photocopiers, calculators, films, and videos to portable computers, microcomputers, whiteboards, personal digital assistants, learning management systems (LMS), the Internet, iPads, tablets, social media, wikis, and blogs – and the list of innovations has continued into the twenty-first

century. In particular, the introduction of LMS and the arrival of the World Wide Web in the 1990s changed the dissemination of learning experiences. Coupled with the use of Web-based applications, collaborative and constructivist learning emerged with the first use of bulletin boards (Maurer and Scerbakov 1996). The advent of Web 2.0 technologies introduced e-Learning 2.0 (Downes 2005), and this saw the rise of collaborative online learning, followed by the integration of mobile technologies (Ally et al. 2014) and cloud computing. With mobile computing devices and networked technologies and the mass consumerization of smart devices, some schools have implemented bring your own devices (BYOD) initiatives, and others have implemented one-to-one (1:1) computing programs. Today, online learning such as massive open online courses (MOOCs) includes teaching and learning for mass audiences (e.g., several MOOCs have more than 25,000 students learning together). Currently, there are research studies that are investigating the use of wearable technologies and sensors (Wong et al. 2015) and virtual reality technologies for learning and teaching (Spitzer and Ebner 2016). One of the newest emerging trends is the availability of a makerspace where creative thinking skills are exercised in a collaborative work space infused with computational imaging and other new capabilities (Schön et al. 2014; Adams Becker et al. 2016). Some of the new skills needed in the makerspace include how to use 3D printing, laser cutting, 3D modeling, and robotics. More recently, cognitive computing (e.g., IBM Watson) has introduced the concept that technology can understand, personalize, interact, and emulate or think like a human (IBM, 2017) and may be used to support online learning.

As important developments in educational technologies continue to emerge, K-12 teachers and administrators need to embrace the use of enabling technologies in *the world of connected instruction* (Smith 2014) to improve learning and teaching in schools. New teaching models utilizing technology-enhanced learning encourage students to be active learners allowing them to be both consumer and co-creator of contents. The future trends and opportunities in learning for K-12 point to new potential in the field of MOOCs and online learning. Although some work has been published on MOOCs and K-12 (e.g., Canessa and Pisani 2013; Ferdig and Pytash 2013; Ebner et al. 2016), many K-12 teachers and administrators may not have yet encountered the practical and pedagogical benefits of MOOCs in the K-12 domain (Ferdig and Pytash 2013). Adams Becker et al. (2016) identified difficult challenges in adopting teaching innovations into mainstream practice due to financial and organizational issues.

The aim of this chapter is to raise awareness about the emerging potential within primary and secondary education for the use of cloud-based tools in MOOCs and online learning. The chapter begins by discussing the evolution of traditional classroom to online learning, followed by background on MOOCs and related research including those that are directed at K-12 teachers and students. More specifically, this chapter will focus on learning at scale with the MOOCs experience and the use of cloud-based tools (CBT) to create content for learning purposes. The aim of introducing CBT is to provide teachers with increased flexibility to select their preferred learning tools and media to meet their own classroom needs and objectives.

Evolution of Online Learning

The evolution of online learning can be seen as following a five-stage process (Ebner et al. 2013). Stage 1 includes traditional teaching in lecture halls or classroom without the use of any technology. In today's most common stage 2, teaching is supported with technology; for example, with the use of overhead projectors or simple online services. Stage 3 includes the assistance of a LMS or similar online-based information systems, where teachers provide learning contents and learning tools such as discussion forums. Stage 4 adds blended learning approaches (e.g., using both face-to-face and online learning interactions) where some teaching shifts to the online setting as an activity to be engaged by the student prior to or after the classroom. Stage 5 is a mature stage where all teaching and learning takes place entirely through interactive student engagement in the online setting. In this stage, access to learning can be open access and unrestricted.

The concept of online learning at stage 5 prospers with the advancement of Internet capabilities. Subject content for online learning can be developed and presented using videos, audios, and graphic elements. To encourage student engagement in an online setting, courses can be taken synchronously in real time using webcams or chat rooms and asynchronously through discussion boards and peer-to-peer learning.

As the learning reaches stages 4 and 5, teachers may incorporate the use of mobile technologies to increase student motivation and engagement in the classroom. Incorporating bring your own devices (BYOD) into the learning activities can help teachers transform and enrich their teaching methods into project- or enquiry-based activities (Sharples et al. 2014). Teachers may create online activities such as voting and polls or ask questions via clickers on their smart devices. Students like to use and have control over their smart and personal devices, and they may be engaged to do a learning task and complete the classroom task.

In recent years, MOOCs have paved the way for personalizing learning at scale. MOOCs are primarily free, interactive online courses available to anyone who has Internet access and wants to take the course. MOOCs have already made their mark in higher education at a global scale, with many top universities offering MOOCs on well-known platforms such as edX, Coursera, FutureLearn, Udacity, and others. More recently, cloud-based services are incorporated into MOOCs as these services have a selection of engaging activities such as simulations and graphic programming environments (MOOCMAKER 2016a).

MOOCs are also making their way into K-12 education and there are immediate benefits of doing this. With the use of interactive digital tools and other services, MOOCs may be used as an effective strategy to disseminate knowledge and basic literacy to masses of people; conduct outreach to primary education students; supplement existing content to make it more interesting, engaging, and informative; and engage students in diverse peer-based learning outside the walls and other barriers of the classroom and community. Moreover, MOOCs can foster self-regulated learning skills (Neuböck et al. 2015). With these potential use-cases in mind, K-12 teachers and school administrators must be well-prepared to understand

and utilize the Internet, cloud services, social media, and visualization technologies. To be able to create effective and engaging courses at scale, teachers must explore and engage in the use of various learning technologies and tools to address varying learning challenges to gain maximum educational outcomes.

Massive Open Online Courses (MOOCs)

Overview

Over the last two decades, technological inventions and changing attitudes of society have resulted in new forms of open and massification of education. Open source and cloud-based tools as well as open education resources have provided freely available courses to anyone without restrictions. Although open education resources such as the MIT OpenCourseWare program can be tracked back to 2002 (see <https://ocw.mit.edu/>), George Siemens and Stephen Downes raised the awareness in 2008 by offering an online course called “Connectivism and Connective Knowledge” which was open to the public and attracted more than 2000 participants. The new concept of involving a large number of learners without any restrictions became known as massive open online courses or MOOCs. Since then, MOOCs have become increasingly popular. MOOC research has grown, and top educational institutions now offer hundreds of MOOCs to millions of people. In 2011, Stanford University offered the MOOC “Introduction to Artificial Intelligence” and reported some 160,000 enrolled users. For 2016, some 6800 courses from more than 700 universities and some 58 million users have been reported (Class Central 2016; MOOCMAKER 2016b) which shows how open education has scaled up since the first introduction of MOOCs.

Types of MOOCs

The first MOOC offered by Siemens and Downes (n.d.) followed the connectivist theory known as cMOOC. The role of a cMOOC is used to refer to a MOOC that is designed to connect learners, to share and learn from one another. Another type of MOOC is called xMOOC which is normally offered by university-based platforms and is modeled on traditional “stand, deliver, and test” higher education teaching methods. Rosselle et al. (2014) classified three types of MOOCs based on five dimensions: (1) learning goals, (2) choice of resources, (3) organization of learning activities, (4) organization of individual and group work, and (5) collaborative co-production.

- **cMOOC.** This type of MOOC is designed based on the connectivist approach and provides learners with the flexibility and openness for all the above dimensions.
- **xMOOC.** This type of MOOC is based on the idea of using a centralized learning management system, and the courses are designed by a set of defined activities incorporating some or all five dimensions listed above.

- **iMOOC.** These types of MOOCs follow an investigative approach in the instructional design. iMOOCs are restricted in terms of learning goals and the organization of the learning activities. However, such MOOCs give learners freedom to select learning resources and organize group work for collaborative co-production.

In the last few years, another type of MOOC builds on the same open infrastructure and technologies but with restricted access is called a Small Private Online Course or SPOC (Fox 2013).

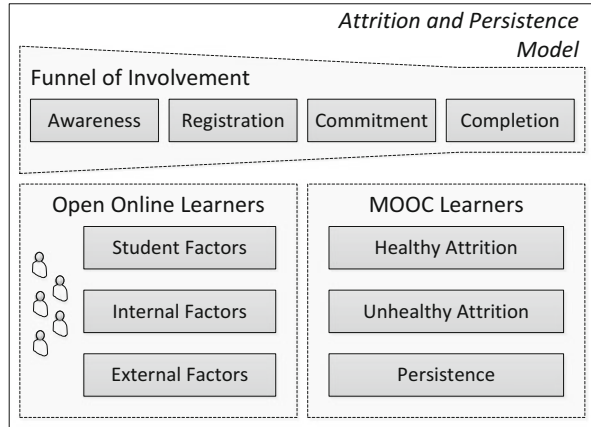

Characteristics of MOOCs

MOOCs are most often associated with open-access courses accessible to anyone, anywhere in the world. Learners have the opportunities to advance their knowledge and skills through formal learning as well as in lifelong learning settings. This setting allows learners from around the world with diverse social and cultural background to collaborate, interact, communicate, and work with one another. The MOOC environment also provides opportunities to those who cannot access traditional and formal learning due to financial constraints, geographical barriers, time, and other factors.

A successful MOOC course is typically highly engaging with lots of activities with contents that are presented in videos and rich media sources such as the use of graphics, images, games, infographics, slide deck, and course handouts. Quizzes and assignments are generally used to test the learners' mastery of the course. In order to motivate and engage with learners, gamification and simulation approaches may be considered as innovative features. MOOCs can be designed as self-paced, instructor-led, or a mixture of both methods. Where possible, a self-paced course is attractive in that it allows learners the freedom to work through activities at their own pace. Related to this, MOOC courses with succinct activities and shorter duration can also help to keep the learners motivated and committed to complete the course. With instructor-led courses, resources must be carefully planned, and sufficient facilitators or tutors need to be assigned to participate in discussion forums and respond to learners' questions. Learning activities should also be designed in a way that encourages learning in groups. A good mix of self-assessment, peer assessment, and automated assessment that provides useful feedback can guide the learners throughout the learning activities. The MOOC must also be designed in such a way that will allow learners to track their progress, and there is also the ability to take notes in the MOOC itself.

Since most MOOCs allow for global reach and are scalable, learners can come from all over the globe with different levels of education, varying technical and computer literacy, and diverse metacognitive skills. Depending on the way the MOOCs are designed, there can be a mismatch of the level of difficulty of the course and expectations of the learners. This generally leads to issues of high dropout rates. Detailed insights of learners' behavior and intentions when they are enrolled and of

Fig. 1 MOOC learners attrition and persistence model

those who are committed to finish the course must be considered. Most MOOC learners reached thus far have tended to be lifelong learners whose primary motivation is to learn about topics that interest them. Thus, many may only complete the learning content without completing any assessments. While educators in a traditional setting treat high attrition rates as a failure, this may not be true for MOOC completion (Gütl et al. 2014b). Research on attrition in MOOCs by Gütl et al. (2014a) reveals that learners who generally enrolled in MOOCs fall into three main categories. There are those who may only access the learning content without completing all the activities. There are other learners categorized as “completers,” and finally, there are others characterized as “persistence” learners who intend to complete all five dimensions as listed in Rosselle et al. (2014). Depending on the learners’ goals, course completion is not necessarily a measure of success. Figure 1 depicts a holistic model for learner attrition and retention in a MOOC (Gütl et al. 2014a).

MOOCs: Applications in Primary and Secondary Practice

MOOCs can be used for different purposes in K-12 education. Currently, teachers have successfully integrated online experiences such as MOOCs into the classroom by supplementing their teaching. Teachers may use part of the learning activities in the MOOCs to supplement their teaching. Students themselves can also enroll in the MOOCs independently. In some schools, educators have used MOOCs to discover career opportunities (Ferdig and Pytash 2013). Teachers have also enrolled in MOOCs for their own professional development, and some countries have requirements for continued professional development for teachers. One such example of a MOOC that is developed to help teachers continue professional education is the “Analytics for the Classroom Teacher” (see <https://www.edx.org/course/analytics-classroom-teacher-curtin-x-0>) MOOC offered by Curtin University on edX platform.

There are ample opportunities for both teachers and students with K-12 learning with MOOCs. As learning in MOOCs is primarily self-regulated learning, teachers

may need to guide students of how to use the MOOCs (Neuböck et al. 2015). Schoolchildren tend to “learn by doing,” and with a greater focus on science, technology, engineering, and mathematics (STEM) education, there are a number of examples that show motivated students watching videos to learn about physics or mathematics. Some students also follow videos to learn how to program small applications, a common practice among young people using YouTube videos to learn almost anything at anytime. Some MOOCs are built with gamification features that further motivate students to complete certain tasks. Some interesting development and successful applications are listed below:

- As part of the STEM education, STEM-MOOCs exist for students with the age range of 13–15. The conceptual and practical experiments of STEM are conducted via videos. Early research with the tracking of students’ performance showed students can benefit by having guided online learning (Khalil and Ebner 2015). Teachers can certainly supplement part or all of the STEM education into the classroom.
- To increase interest in programming especially for young learners age 10 and above, there are MOOCs that will teach both teachers and students to code. For example, a MOOC on Pocket Code was implemented offering step-by-step “How-To Program” videos to program a first mobile application. The core concept of the MOOC follows the principle of open learning outside the classroom to attract students to learn basic computer science knowledge.
- In partnership with Google Australia, the Computer Science Education Research Group at the University of Adelaide developed a series of K-10 MOOCs on Digital Technologies for STEM curriculum (see <http://csermoocs.adelaide.edu.au/moocs>). These resources are freely available for teacher’s education and professional learning (Falkner et al. 2015).
- In 2014 another MOOC for schoolchildren has also been offered, called the “the circle.” Over 40 videos were produced embedded in a special didactical approach. Keeping in mind the seamless learning approach, students get a master plan of how the videos can be used to learn the topics. This MOOC uses elements of gamification, and at the conclusion of each topic, students can collect stars to signal their completion and achievement (Föbbl et al. 2016).
- In 2016, Microsoft created a series of MOOCs to guide K-12 school and education leaders to develop teachers, enhance classroom teaching, and improve student engagement and learning outcomes. The aim of the MOOCs is to improve leadership in K-12 education and to drive transformational changes in the innovative digital schools.
- There exist a number of MOOCs on calculus, biology, statistics, and computer science, and teachers can certainly integrate the course materials as a “flipped classroom” concept and to augment their curriculum.
- Finally, teachers who may learn new skills about upcoming MOOC topics will benefit from this form of professional development. For example, there are MOOCs about incorporating 3D printing, vinyl cutting, and programming robots that teachers can use in the classroom (Ebner et al. 2016).

Cloud-Based Tools and Services

Overview

At the beginning of the new millennium, the Web, which was originally designed mainly for the consumption of information, has transformed into a participatory Web. Information consumers have become more actively involved in creating and remixing and repurposing existing contents in their role as information “prosumer.” The second period of the Web, called Web 2.0, has introduced new paradigms of Web development and browser capabilities for interactive and dynamic content management. These concepts have further evolved and combined with early distributed computing into cloud-based services and tools.

Generally, *cloud computing* is defined as “a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources [. . .]” (Mell and Grance 2011). Most common cloud services are Infrastructure as a Service (IaaS) providing computational infrastructure such as storage and processing power, Platform as a Service (PaaS) offering platforms hosting software, Software as a Service (SaaS) offering the actual applications and services, and Backend as a Service (BaaS) allowing the outsourcing of the server components for Web and mobile applications (Armbrust et al. 2010).

Cloud Services in Education

Cloud services can provide great value and impacts in various learning and teaching settings, from individual self-directed learning scenarios to group learning activities in MOOC environments. In particular SaaS, for cloud-based tools (CBTs) or cloud-based Web applications and services, can offer attractive opportunities for institutions, teachers, and students. Internet users who grew up with modern media consume and apply such tools and services for most activities in their daily life.

CBTs provide several opportunities in modern learning settings and are scalable at individual and massive online learning levels. There are four distinct types of scenarios which can be concluded from the above:

- ***Outsourcing of resources.*** Applications with high resources on computational power, memory load, and storage capacity can be accessed outside the learning environment, such as video streaming, simulations, and virtual worlds.
- ***Scaling up resources.*** In the case of massive online learning experiences, it is difficult to predict when learners will access the online materials. Cloud services can guarantee scalability and elasticity by “on-demand” provisioning of resources.
- ***Accessibility.*** CBTs can provide tailored access to services, e.g., to mobile devices, which might vary from responsive design to streaming services for simulations and game-based environments.
- ***Alternative learning experiences.*** A variety of existing CBTs and Web-based services may provide alternative and engaging learning experiences for learners and instructors.

Types of Cloud-Based Tools and Services

A rigorous literature study and review of existing CBTs and Web services has been conducted as part of the *MOOC Maker* project (MOOCMAKER 2016a). The project has revealed a wide range of tools and services. The classification of cloud-based applications discussed in the remainder of this section is an adapted version of the original structure of the *MOOC Maker* project (MOOCMAKER 2016a).

- **Course design and authoring tools.** This class of tools can support instructional designers, content authors, and teachers in creating and maintaining learning content. Examples of the online tools included Udutu (<http://www.udutu.com>), EasyGenerator (<https://www.easygenerator.com>), and Elucidat (<https://www.elucidat.com>).
- **Content creation tools.** Unlike the above group of tools, this class of tools supports both teachers and students in the creative process. A number of tools exist to support media, such as text, images, diagrams and charts, videos, animations, and presentations. Illustrative examples include Google Docs (<https://docs.google.com>), Gliffy (<https://www.gliffy.com>), and Emaze (<https://www.emaze.com>).
- **Collaboration tools.** This group of applications enables students to work together with their peers and communicate and share information with their peers and instructors. Cloud-based services for synchronous and asynchronous communication include WhatsApp (<https://www.whatsapp.com>) and Facebook (<https://www.facebook.com>). Examples for collaborative content creation cover a broad range of application scenarios, such as mind map creation and sharing by MindMeister (<https://www.mindmeister.com>) or storytelling by Storybird (<http://storybird.com>). Illustrative examples for content sharing include social bookmarking such as Delicious (<https://del.icio.us>) and for scientific papers and citations Mendeley (<https://www.mendeley.com/>).
- **Hands-on tools.** The focus of “hands-on tools” is for activities for active engagement that can be administered individually or in a team. This includes 3D simulations and virtual reality, such as in physics TEALSim (<http://web.mit.edu/viz/soft/visualizations/tealsim/>) or in medicine BodyViz (<http://www.bodyviz.com/>), or supportive programming environments like REPL.IT (<https://repl.it/>) or Blockly (<https://developers.google.com/blockly/>).
- **Assessment and feedback tools.** This group of tools comprises assessment of knowledge and skills as well as provision of feedback and guidance. This might be as simple as quizzes like Quizlet (<https://quizlet.com/>) and Automatic Question Creator (AQC) (Höfler et al. 2012) or managing the marking process using ClassMarker (<https://www.classmarker.com/>). Related to assignments are tools to check for plagiarism and services such as PlagTracker (<http://www.plagtracker.com/>) can be used.
- **Knowledge and auxiliary services.** For background information and knowledge related to the learning content, a number of services are available through the use of open content repositories and encyclopedias such as Global-Geography

(<http://global-geography.org/>). In order to work on assignments, document repositories can be used along with spell checkers or dictionaries like LEO (<http://www.leo.org>).

- **Learning management and support tools.** This group of tools helps teachers and students to keep track of the teaching and learning activities which include news and time management tools such as TalentLMS (<https://en.talentlms.com/>)¹. Self-guided learning support may also be included (Nussbaumer et al. 2015), and motivational aspects can be designed using gamification such as GameEffective (<http://www.gameeffective.com/>).

Remixing of Cloud-Based Tools and Services

CBTs enable teachers and students with high flexibility to support learning activities by using a wide range of existing tools. The concept can give learners the freedom to select preferred tools for a particular task. Although this would scale up in terms of the number of users and the variety of tools available, it also introduces a higher complexity in terms of integration of multiple tools. This includes the configuration and management of roles and features according to the learning tasks and ownership of content and archiving of created deliverables.

For modern and engaging learning activities, it is preferable to combine two or more of the CBTs according to pedagogical objectives. Take as an example a task in second language training where collaborative writing tools are enriched with capabilities of spell checking and a thesaurus provided by other CBTs. Generally, learning orchestration identifies the capacity to combine two or several tools and adapt features to support specific learning goals. Such complex functionalities require an orchestration of CBTs on a granular level of tool interaction, data exchange, and intervention. It also calls for unified user interfaces in the integrated learning environment, abilities of assessment, and role management (Hernandez Rizzardini and Gütl 2016).

Seamless integration of CBTs can also support the creation of *cloud education environments (CEE)*, a powerful unified learning environment for enhanced educational experiences. This requires full control over the educational experience by role definitions and corresponding management of those roles, authority over resources created, easy initial steps for the integration of a new tool, and configuration for the use of CBTs to be adapted for specific learning tasks. Ideally, new CBTs should be automatically integrated without any programming effort and be used in the CEEs. (Hernández Rizzardini 2015).

Generally in online education and in the context of CEE, the following technical aspects need to be considered (Hernández Rizzardini 2015):

- **Authentication.** This aspect includes user and group management and single sign-on on all platforms and CBTs.
- **Content packaging.** The reuse and exchange of learning assets are covered by content packaging mechanism.
- **Data definition.** This aspect focused on schema (in XML or any other format) for describing the content structure.

- **Data transport.** This covers aspects regarding how data are transferred among systems.
- **Launch and track.** This addresses information how content and tools can be launched and tracked.
- **Metadata.** This aspect deals with the data attributes and corresponding values to describe, search, and retrieve learning content and services.

Over the years, many standards and specifications for educational interoperability have become available covering one or more aspects listed above and discussed in detail in Aroyo et al. (2006) and Hernández Rizzardini (2015). Learning environments and middleware systems exist to support teachers, administrators, and practitioners to create and manage their own learning experiences on CBTs. Responsive Open Learning Environments (ROLE), a European project in the FP7 program, aims on a personal learning environment (PLE) by utilizing Web-based tools and technologies. ROLE provided technical infrastructure which enables learner groups to assemble widgets and services in PLEs (Hernández Rizzardini 2015). Research has also been conducted, and a middleware has been developed to integrate CBTs without programming effort by adopting recent technologies, such as JSON-LD and Hydra (Hernández Rizzardini 2015; Hernandez Rizzardini and Gütl 2016).

Cloud-Based Tools: Applications in Practice

Cloud-based tools are increasingly adopted in learning experiences, from formal learning in school and at university settings to vocational training and lifelong learning. It can be found in a wide range of learning settings, from individual learner's usage to the scale of MOOC environments (Anshari et al. 2016; MOOCMAKER 2016a). In the remainder of this section, two examples are introduced.

The first example is based on the middleware introduced in the previous section and covers one successful example of how cloud-based tools can be integrated and widely used for open learning settings in a MOOC environment (Hernández Rizzardini 2015). Galileo University built the virtual learning environment Telescope on top of the LRN learning platform (<http://dotlrn.org/s>) specifically designed for MOOCs. Additionally, the middleware for CBT integration has been used to offer various types of tools for learning purposes. The cloud learning activities orchestration (CLAO) system as reported in Hernández Rizzardini and Gütl (2016) enables teachers and MOOC coordinators to select specific CBTs, manages features on fine-grained levels, and configures graphical appearance within the virtual learning environment Telescope. In a pilot study, the setup has been used to offer the "cloud-based tools for learning" MOOC. Learning activities have been designed as xMOOC and include the following CBTs: Google Docs (<https://docs.google.com/>) as text editor, Cacao (<https://cacao.com/>) for creating diagrams and flowcharts, MindMeister (<https://www.mindmeister.com/>) as mind map tool, SlideShare (<http://www.slideshare.net/>) for sharing presentations, and Educaplay (<https://www.educaplay.com/>) for assessment and feedback activities.

Two thousand and forty-five users from Latin America enrolled in the course. Findings revealed that the effort of integration of the middleware for CBT integration and CLOA system for CBT orchestration was low compared with the effort on integrating on a tool by tool basis. In terms of performance, middleware and integrated CBTs were able to scale up with more than 2000 students enrolled in the course. The MOOC course designer and teachers are able to set up the learning activities and attach CBTs and configure features and appearance in the virtual learning environment.

In order to gain insights on motivational aspects and cognitive learning strategies of the students, the Motivated Strategies for Learning Questionnaire (MSLQ) was applied (Pintrich and García 1993). Students' attitudes on the value of using CBTs show a high intrinsic and extrinsic goal orientation as well as task value. The findings reveal a high-control self-belief and self-efficacy for learning, and the perceived level of anxiety in using CBTs was on a medium level. The metacognitive self-regulation in the MOOC settings was perceived as high, and elaboration and organization have been identified as the most relevant cognitive strategy in the MOOC setting (Hernández Rizzardini 2015).

The second example illustrates the integration of a hands-on tool into the edX platform used as learning and assessment activity. Physics simulations of electrostatic and electrodynamic phenomena, available in MIT's TEALsim (Dori and Belcher 2005; TEALsim 2017), were integrated in the MOOC platform. This example illustrates the CBT application in a formal learning setting for university students but is also easily adaptable for learning experiences in school education.

Seven simulations have been ported using the Google Web Toolkit (GWT) (Adam et al. 2013) and converted from the stand-alone Java application into a Web-based tool built on HTML and JavaScript to be used as extra activities in a university course in physics. Findings reveal that the hands-on tool was hardly used by the students. In order to improve the situation, it was decided to tightly integrate the tool in the learning activities to increase the application of the tool for assessment activities (Zeleznik 2015).

EdX (<https://www.edx.org/>) is one of the major MOOC platforms, which provides a variety of features, functions, and tools to create and run courses and analysis of user behavior. It also provides a JavaScript-based interface "jsinput" (edX 2017) to integrate external tools and exchange data between edX and the external tools. The TEALsim simulations have been integrated in such a way that a set of exercises can be personalized and configured for each student. The corresponding set of data controls the initialization of the tool for the hands-on experiences. Any interaction with the simulation is captured and sent back to the edX platform. Data are used for learning analysis and feedback in the learning phase. This setup enables the designer of a MOOC to specify a range of exercises for each of the students and also keep track of their performance. It also defines specific assessment activities which can be used to grade the performance of the students. This simulation and visualization scale up for a high number of participants in a MOOC course (Zeleznik 2015).

Research has indicated that learners are motivated and have positive attitudes toward using CBTs. They expressed excitement when using a variety of tools as they

are exposed to interactive ways of learning. With the positive learning experience, learners gained improved performance in the course. A minor drawback is the time to be familiar with several of the CBTs. To overcome this, training and tutorial videos should be provided to guide the learners while they are using the tools.

Embedding Online Learning, MOOCs, and Cloud-Based Tools Infrastructure in Schools

School stakeholders such as teachers and administrators who are embedding the opportunities presented with MOOCs and CBTs must follow three key areas to plan for a seamless implementation. The areas are (1) networked and technological infrastructure, (2) security and privacy, and (3) bring your own devices (BYOD) strategy. With the technology infrastructure, sufficient network bandwidth must be available to support the transfer of a large amount of data from various devices, applications, and data on servers. Robust network infrastructure supporting data movement from access device to data center is crucial in ensuring a seamless learning environment. Internet usage will increase in the school environment from learning and teaching activities, to administration functions. The bandwidth usually will virtually increase in every aspect of K-12 education, and connectivity must be reliable. High-speed connection that supports fast response times is critical to ensure students are connected as and when they need to use any applications via the Internet. Students and teachers alike expect the same rapid response when they connect to MOOCs and CBTs. Likewise, they would require powerful laptops, tablets, or desktops. Single or same sign-on is a capability that facilitates all integration on MOOCs or CBTs. Users will expect ease of access to multiple resources in the cloud without having to use different logins and credentials.

In terms of security and privacy, schools are required to comply with regulations governing the security of private information. As such computer and information security is of particular concern to schools as they maintain confidential information about students ranging from academic records to health information. Schools must derive information communication technologies (ICT) principles and governance. ICT security compliance standards exist to support schools and mitigate risks. Some of the principles include user authentication using proven cryptographic methods; privacy capabilities including data encryption, data anonymization, and mobile location privacy; single sign-on login capability; access protection to prevent third parties from accessing data; access to IT disaster recovery plan and data centers; and secure cloud-based data backup and storage.

BYOD programs will continue to have greater interest for school teachers and administrators. As technology continues to advance, students will increasingly want to use their devices at school. When BYOD are integrated in learning and teaching in the classroom, BYOD can offer many opportunities. BYOD also bring many challenges, in particular the issue of equity, fairness and access. Students may not own a smart device, and if they do, the data usage may be restricted (Sharples et al. 2014). Schools may have to provide more re-charging power stations and consider

the school's wireless infrastructure when encouraging the use of BYOD in classrooms. Schools will have to set clear guidelines to manage BYOD in the classroom environment, for careful and appropriate use, security and equity issues (Sharples et al. 2014).

Conclusion

It is clear that the twenty-first-century learning and teaching needs are very different to those of previous centuries. In the twenty-first-century classroom, in addition to imparting knowledge and skills, the advancement of technologies has allowed teachers to be facilitators of student learning. Teachers must supplement their traditional classroom teaching with new teaching strategies to engage their students in learning using a variety of instructional methods following different pedagogical approaches aided with technology. Students can be active participants if the classroom curriculum is designed in such a way that promotes active engagement, and this can be done by incorporating modern technologies in the curriculum.

Teachers and administrators can upskill by enrolling in MOOCs that are relevant and applicable to their role. Teachers also have greater flexibility of selecting CBTs for specific learning activities, and they have the opportunities to embed CBTs in the classroom. Teachers can also design their courses with greater interactive and stimulating learning experiences. From the technical and organizational point of view, online learning, MOOCs, and CBTs are highly scalable and widely accessible. Resources and applications can be accessed and used without a high payload. As discussed in this chapter, technology and software tools play a big role in developing learning activities for students in the modern-day classroom settings. With the effective use of technology and services such as CBTs and MOOCs, students can learn twenty-first-century skills of collaboration, creativity, critical thinking, and problem-solving (Crockett 2016). Advancement of technologies offers teachers with greater teaching methods and opportunities in the classroom. Some of the characteristics and features that teachers play in the twenty-first century with use of the technologies include the following:

- Student-centered: With this, teachers are focused on each student's needs, and with technology, students will play an active role in their learning with teachers facilitating in the classroom (Crockett 2016).
- Computing devices: Computing facilities and BYOD are readily available in the twenty-first-century learning. With the availabilities of cloud-based services and other resources such as MOOCs, teachers are able to create more engaging learning activities.
- Active learning: Students are encouraged to be active learners. With the availability of engaging learning activities, students are able to work independently or work collaboratively in teams. This will give students the ability to master a skill at their own pace or work, enquire, and research together with teammates.

- Collaborative learning: With computing devices, students will be able to work in group projects and solve problems in groups (Rotterham and Willingham 2009). With their smart devices, students are also able to work outside of classroom in synchronous and asynchronous modes.
- Connect: Students are able to connect with those students who would like to work on the same topic and perhaps those who are able to work together given time constraints.
- Adaptive learning: As students are at different stages of learning, teachers may be able to adapt and personalize the learning according to the student's abilities. There exist a variety of software tools that will enhance the learning of their students (Rotterham and Willingham 2009; Palmer 2015).
- Innovate: Teachers can continue to innovate and try new ways to teach and engage their students. In addition to the available tools, services, and resources for formal learning, teachers may also teach using social media and incorporate outside of classroom teaching.

As MOOCs and CBTs are maintained and upgraded automatically by third parties, a major drawback resides with the sustainability of the courses and tools (Rotterham and Willingham 2009). Administrators must have strategies, policies, and guidelines to manage the networked and wireless technologies, the implementation of BYOD, security, privacy, and technology equitable access to all students. Of greater importance is that administrators and school leaders must provide professional development to teachers and to communicate with parents of the expectations with the use of technologies and educational materials.

Acknowledgment This chapter has been partly supported by the MOOC Maker Project, and findings, in particular on cloud-based learning, have been incorporated in this work. Graz University of Technology and Curtin University of Technology are gratefully acknowledged for supporting the research visits of Christian Gütl to support this research.

Abstract

This chapter provides an overview of immersive virtual environments (IVE) in education with an emphasis on immersive virtual reality (IVR). A companion chapter in this volume focuses on a second type of IVE called augmented reality (AR). First, definitions are provided, focusing on concepts such as immersion, fidelity, presence, and simulations. Second, a review of research is presented for IVR that highlights the current and potential impact in PreK-12, higher education, and professional development settings. Findings suggest the use of IVR can lead to increased engagement. However, the synthesis also points to a relative dearth of published research for PreK-12 implementation. The chapter ends with a call

Introduction

A historical review of the implementation of technologies for education would show a rather slow transition from radio to television to the personal computer. However, once the personal computer reached its tipping point in modern society and in classrooms around the world, the speed of innovation seems to have increased exponentially with seemingly endless possibilities. For example, researchers and educators have recently examined the potential role of games and simulations, mobile devices and applications, haptics and touch devices, coding, and robotics.

Perhaps the most recent, cutting-edge implementation has come from the area of immersive virtual environments (IVE). Notable new and standard names in the educational use of such technologies have included *Second Life*, *Active Worlds EDU*, *Google Glass*, *Microsoft HoloLens*, and *Oculus Rift*. The purpose of this chapter is to examine a specific type of IVE known as immersive virtual reality. The chapter begins by providing concise definitions. It then summarizes existing educational research, focusing on the promise and pitfalls of immersive virtual tools for teaching and learning. The chapter concludes with a call for more research to further explore the value and benefits of VR for PreK-12 teaching and learning.

Defining IVE and IVR

A critical first step in defining virtual reality research is to further define the concepts of *immersive virtual environments* and *immersive virtual reality*. Entire volumes have been written attempting to best describe these concepts; a cursory overview will not give justice to the deserved and lengthy conversation. However, it is critical to set the stage for these terms to focus this review.

People began using the term *virtual reality* consistently in the 1960s (Freina and Ott 2015). Since that time, people have begun to further delineate the concept by describing both non-immersive and immersive VR. “The former is a computer-based environment that can simulate places in the real or imagined worlds; the latter takes the idea even further by giving the perception of being physically present in the non-physical world” (Freina and Ott 2015, p. 1). There has been significant use of

immersive VR (IVR) for professional development, entertainment, research, and higher education. Although much of the work of IVR originally happened in cave automatic virtual environments (CAVE; Cruz-Neira et al. 1993) or with full head-mounted displays (Shibata 2002), newer technologies like *Oculus Rift*, *PlayStation VR*, and *HTC Vive* are changing how researchers and educators are thinking about IVR installations.

Immersive virtual environments (IVE). Immersive virtual realities can include newer forms of augmented reality such as *Google Glass* and *Microsoft HoloLens*. As such, the term here is broadened to *immersive virtual environments*. An immersive virtual environment would best be considered as a set of digital tools used to provide an alternative habitation that centralizes the user experience to immerse him or her within its virtual boundaries. IVE also utilize input systems (e.g., motion controllers), artificial intelligence routines (e.g., interactions between the virtual setting and the player's input), mechanics, and aesthetics (Freina and Ott 2015). In theory, IVE could use all five senses to accomplish this task; "most VR environments today do not actually address all of them but usually focus on two: sight and hearing" (Freina and Ott 2015, p. 3).

The concept of immersion is what helps delineate IVE from other simulations. Most of the existing research further depicts this notion of immersion by using the concepts of *fidelity* and *presence*. Fidelity describes the ability of the simulation to mirror what is being simulated (Alexander et al. 2005; Riva et al. 2007). For instance, digital medical scenarios, flight simulators, and virtual driving machines can all be evaluated for fidelity based on how closely they mirror real-world environments. This is often referred to as fidelity of display, which examines vividness or the sensory quality of the virtual setting (McMahan et al. 2012).

Display fidelity is a useful concept, but measuring it becomes more complex when the virtual environment does not easily mirror real-world environments. As such, researchers also examine interaction fidelity or the exactness of real-world interactions being reproduced in the environment (McMahan et al. 2012). Interaction fidelity helps measure how naturally users are able to act in the virtual environment and consequentially perceive an agential incorporation (Calleja 2011).

In addition to fidelity, researchers also examine immersion by measuring presence. At its broadest definition, presence refers to being in the "here and now" (Calleja 2011). Mestre (2005) argues presence was defined as a "psychological state experienced as a consequence of focusing one's energy and attention on a coherent set of stimuli" (p. 2; also see Slater and Wilbur 1997). However, the author pushes the definition to address ecological validity, suggesting that it goes beyond just the interface to include sensory and motor behavior. There is an obvious connection between the two concepts as a high fidelity can improve presence. Both are critical to addressing immersion as a distinctive quality of IVE. There are two types of IVE: the first, addressed in this chapter, is *immersive virtual reality*. The second is *augmented reality*; it is addressed in the augmented reality chapter (► Chap. 64, "Educational Opportunities for Augmented Reality" by Gandolfi et al.).

Immersive virtual reality (IVR). Immersive virtual realities attempt to replicate a source reality like a medical examination or a flight path. IVR is typically represented by simulations that go beyond simple sight and sound. This may include

empowering sight and sound with 3D or a 360-degree perspective. IVR also uses iconic input systems that help support the correspondence between reality and virtuality. Iconic systems provide opportunities for the user to interact with the environment in natural, gesture-based manners or through tactile augmentation. The degree to which the simulation emulates the source (its fidelity) is related to its effectiveness. The challenge, of course, is using IVR for situations that do not have a well-framed origin or reality (e.g., a fictional reality).

IVR applications often address conditions of severe difficulty or impossibility. These conditions include space (e.g., being in other places or spaces instantly), time (e.g., historical or futuristic), ethics (e.g., creating a reality without ethical and moral implications or consequences), safety (e.g., creating a reality with no or limited risks and dangers that would exist in reality), situation control (e.g., taking untrained or young learners into risky situations), and realism (e.g., being involved in an environment that does not exist or in an environment about which few facts are known). In these environments, designers and educators have the opportunity to create a new reality with their own rules and scripts.

Crecente (2016) provides an important historical perspective on the development of IVR (see Crecente's publication for a detailed explanation of how these advancements contributed to our present perspectives of VR writ large). Milestones include:

- 1958 – Sensorama.
- 1966 – Ultimate Display (first HMD).
- 1975 – Videoplace (precursor of CAVE).
- 1978 – LEEP (extreme wide-angle stereoscopic optics system).
- 1979 – Aspen Movie Map (precursor of Google Street View).
- 1982 – Wired Globe.
- 1980s – Jaron Lanier starts to work on multi-person VR simulators and avatars and invents the concept of “virtual reality.”
- 1992 – VR movie *Angels* – first VR movie (by Nicole Stenger).
- 1992 – Virtual fixtures (see AR).
- 1993–1998 – Osmose/Ephemere (VR controlled with breathing and balance).
- 1995 – first CAVE.
- 1998 – CABIN and COSMOS – similar to CAVE (Michitaka Hirose).
- 2003 – Bravemind/use of VR for rehabilitation and psychological resilience (Albert Rizzo, USC's Institute for Creative Technologies).
- 1997–present – the use of VR for social experiments and tests (Mel Slater, Event Lab).
- 2010 – Kinect.
- 2012 – *Oculus Rift*.
- Today (2018) – Vive, PlayStation VR, Oculus Touch.

There are a number of educational opportunities within IVR. For instance, IVR has been created to share lectures (*LectureVR*, <http://immersivevreducation.com/lecture-vr/>), to share learning spaces (*AltSpaceVR*, <https://altvr.com/>; *Frooxius*, <http://frooxius.com>), to tell stories (*AlchemyVR*, <http://www.alchemyvr.com/>), to

visit national parks (*Google National Parks*, <https://artsandculture.withgoogle.com/en-us/national-parks-service/parks>), to improve health education (*Embodied Labs*, <http://www.embodiedlabs.com>), to learn and teach architecture (*ImmersiveVR*, <http://www.immersivevr.it/en>), and to teach and learn (*VREP*, <http://vrep.org>; *PublicVR*, <http://publicvr.org>).

A Review of Research on PreK-12 Immersive Virtual Reality (IVR)

Given its relative infancy, there are not a tremendous amount of published research articles on using IVR in PreK-12. However, there are a plethora of descriptive articles. For instance, Samsung completed a survey (Bolton 2016) asking educators about VR. They suggested that science, social studies, and history are key areas of potential benefit from IVR. A majority of survey respondents said they would be eager to use the tools (93%), thought they could improve learning (83%), stated they would increase student understanding of learning concepts (77%), and indicated VR would improve motivation (84%).

Other descriptive articles depict research or development projects in process both in and out of PreK-12. These contributions focus on new degrees (e.g., Connor et al. 2015), novel projects for robotics (e.g., Crespo et al. 2015), new theories about motion tracking (e.g., Fominykh et al. 2014), the potential of VR for urban planning (e.g., Nguyen et al. 2016), VR for health (e.g., Randall et al. 2016), and various other aspects of VR for teaching and learning (e.g., Häfner et al. 2013; Ip et al. 2016). Finally, there are articles that list IVR tools (e.g., Brown and Green 2016).

The research that does exist on IVR for PreK-12 learning is promising. For instance, Bower et al. (2016) studied the use of virtual worlds for cooperative learning and copresence with preschool teachers. The majority of participants considered the virtual world useful for communication, teamwork, and copresence. Chan et al. (2016) used a CAVE-like system for visual arts education. Students reported an overall positive experience but suggested that viewing other students' work in VR was difficult due to viewing issues and the focus on a single user. The study did provide additional evidence that VR could be useful for comprehension and inspiration. Ip et al. (2016) also used a CAVE while working with children with autism as they transitioned from kindergarten to first grade. Children had successful outcomes related to emotion recognition, affective expression, and social reciprocity (see also Lorenzo et al. 2013, 2016).

Some of the IVE research compares technologies. For instance, Fabola and Miller (2016) deployed various VR devices (e.g., *Oculus Rift*, *Gear VR*, and *Google Cardboard*) in teaching cultural heritage. Their results demonstrated that headset-based virtual reality systems stimulate young pupils' interest in learning history more than screen-based virtual reality systems. Passig et al. (2016) created a teaching intervention for first and second grades in which strategies for solving problems were combined with a variety of technologies including IVE. The authors reported data that suggested teaching in a 3D IVR environment contributed to the children's cognitive modifiability more than in the other groups in the Analogies Subtest of the Cognitive Modifiability Battery (CMB).

Not all of the research compared IVE to non-IVE and not all of the research outcomes were positive. For instance, Ke and Carafano (2016) presented an assessment of *Astronaut Challenge*, an immersive flight-simulation-based learning program. The authors suggested that the higher level of the sensory immersion in a simulation-based learning environment may foster task engagement and procedural practice but not collaborative conceptual processing. Ritz and Buss (2016) noted the potential for cognitive overload that can occur when using CAVEs in education.

A Review of Research on Non-PreK-12 Immersive Virtual Reality (IVR)

There are a number of other studies outside of PreK-12 that provide further evidence of the promise of IVR in PreK-12. Studies have demonstrated:

- VR can be more effective than video training for laparoscopic surgery (Alaker et al. 2016).
- IVR can be a useful tool for exploring and measuring concepts; in one study, it was adopted to understand the relationship between paranoia and self-confidence (Atherton et al. 2016). In a separate study, it was used to examine paranoid ideation, anomalous experiences, self-confidence, self-comparison, physiological activation, and behavioral response (Valmaggia et al. 2016).
- IVR can be exploited to study social interactions by changing variables and creating new situations; however, realism in immersion makes those environments more convincing (Bombari et al. 2015).
- *Oculus Rift* may potentially have a higher degree of immersion compared to *Google Cardboard* and a standard 3D TV when exploring heart rate and simulator sickness (Chessa et al. 2016). *Oculus Rift* was also shown to be engaging and motivating and lead to a greater sense of presence and immersion in virtual operating rooms (Kleven et al. 2014).
- VR training along with visual feedback, tactile feedback, and robot actuators can improve motor control with paraplegic patients (Donati et al. 2016).
- VR applications reduced operating room risks and surgery time by improving planning and organization (Pelargos et al. 2017).
- 3D VR can increase immersion, usability, amazement, and excitability in users; however, it can also lead to increased nausea (Hupont et al. 2015).
- Individuals consider the use of a head-mounted display more socially acceptable if the device is being used to support a person with a disability (Profita et al. 2016).
- VR can lead to higher levels of presence and involvement in the instruction of computer graphics for engineering and architecture courses (Moreira et al. 2016) and with airplane simulations (North and North 2016).

- IVR can be more effective compared to other forms of instruction due to the ability to engage multiple senses (Webster 2016).

In sum, there are research studies that demonstrate positive outcomes of using IVR in PreK-12 education. There are also a variety of studies outside PreK-12 that provide convincing evidence of the need to continue to explore new IVR applications for teaching and learning. However, it is critical to return to the point that simply integrating IVR into PreK-12 experiences does not translate into automatic gains. There are conditions under which these positive outcomes have occurred. Unfortunately, many IVR applications are implemented blindly and without a clear focus (Karutz and Bailenson 2015). Additionally, accessibility and usability are still barriers to successful implementation (Riva and Wiederhold 2015).

IVR Development Tools for K-12 Integration

Due to its relative novelty, IVR development tools are still emerging. There is also a mild danger in listing specific tools as innovations are introduced and/or disappear daily. However, there is value in at least describing some current tools so that educators and developers may begin to explore personal, curricular, and research-based implementations of VR in K-12 teaching and learning. This list includes but is not limited to:

- *StorySpheres* (<https://www.storyspheres.com/>) facilitates embodied storytelling by allowing users to add audio content to 360° sphere images.
- *InstaVR* (<http://www.instavr.co/>) supports the creation of IVR content and experiences for the most popular headsets; it includes an intuitive authoring interface.
- *Viar360* (<https://www.viar360.com/>) is an online platform for editing immersive stories by including interactive hotspots in 360° videos.
- *Wonda VR* (<http://www.wondavr.com/>) shows similar features as other VR tools with triggering mechanics, multiple paths and timelines, and an accessible drag-and-drop interface.
- EON Reality provides a development suite for educational experiences in IVR (<https://www.eonreality.com/applications/augmented-virtual-reality-education/>) spanning instructional games and hyper-detailed simulations.

There is also a possibility of using free (for noncommercial use) game engine tools like *Unity3D* and *Unreal Engine*, which embed several add-ons and tutorials for developing IVR environments (e.g., <https://unity3d.com/learn/tutorials/s/virtual-reality>). These require advanced technical skills; however, their flexibility and potential seem limitless. There are also guidelines, tutorials, and materials available online.

Conclusion

The first goal of this chapter was to further define immersive virtual environments (IVE) and then explicate examples of IVE: immersive virtual reality (IVR). (A companion chapter in this section focuses on augmented reality.) The second goal was to conduct a literature review on the topic to determine what the field knows and what researchers still need to learn – particularly about implementation into K-12 settings.

Most of the research on IVR is in higher education or outside of education with examples like rehabilitation, exposure therapy, and simulation training (e.g., Flores-Arredondo and Assad-Kottner 2015). The consensus among most researchers is that IVR will have more potential pedagogical exploration (and potential value) now that prices of technology are decreasing and the availability of resources is increasing. There is significant research on both fidelity and presence and how they impact the user experience of immersion. From a practitioner's perspective, there are a limited number of articles on how IVR can be successfully implemented into PreK-12 settings. Research is clear that implementation as stand-alone activities has not been as successful as using IVR as a supplement to other learning strategies.

There are several opportunities for future research and practice within IVE for IVR:

1. *Researchers need to explore accessibility in IVR.* Theoretical and empirical articles for IVE related to accessibility are very limited. This form of research should explore accessibility both as a delivery mechanism (e.g., who has access and can use it) and as a topic of exploration (e.g., can IVR serve those with disabilities?). Future applications could explore individualization, integration, and navigation through space and with various interfaces.
2. *Researchers and practitioners need to further explore how to educate teachers and students in the use of IVE for learning.* There has not been a significant amount of research on preparing PreK-12 instructors in the use of IVR or AR. The same is true for students (for an exception, see Wei et al. 2015). The latter is disconcerting; faculty and teachers often assume that because students have access to tools, they automatically know how to use them for learning.
3. *The field needs more pedagogical reflection.* Much research has been devoted to the hardware and software aspects of IVR. From a practitioner's perspective, there needs to be more models of how IVR can be successfully implemented into PreK-12 settings (O'Shea and Elliott 2016; Radu et al. 2016). This is particularly true for content that has yet to be explored (e.g., a majority of the work has been on science or in informal settings like museums and parks).
4. *Researchers should explore further notions of embodied cognition* (Gallagher and Lindgren 2015). At its core and in relation to this context, embodied cognition is the notion that a learner uses body and sensory involvement as a cornerstone to interaction with content (e.g., Shayan et al. 2015). The relationship between cognition and haptics is thus worthy of continued exploration.

5. *Researchers and practitioners should further explore concepts like computational thinking, spatial reasoning, and situational/individual interest.* A significant amount of the existing empirical research in IVR has explored content acquisition or concept change in areas like motivation and perception. Although how students perceive or are motivated because of IVE is interesting, there are deeper psychological and pedagogical concepts worthy of exploration (e.g., computational thinking and spatial reasoning). One of the challenges facing IVE is the novelty effect. Researchers and developer will need to explore how they can capitalize on this situational interest – a “focused attention and the affective reaction that is triggered in the moment by environmental stimuli, which may or may not last over time” (Hidi and Renninger 2006, p. 113). Research could help practitioners and developers understand how to help students move from situational interest to individual interest (Chen et al. 2016) before the novelty wears off.
6. *The field needs a deeper understanding of big data and the relationship to the quantified self (or self-tracking)* (Neff and Nafus 2016). Engagement with IVE tools will undoubtedly create more data. How researchers and practitioners can get access to this data will be critical. Given the relationship between mobile devices and AR, there will likely be new opportunities for users to monitor themselves in real environments. Helping users become aware of the data they are creating (or co-creating) will be an important pedagogical accomplishment.
7. *Researchers need to further explore the negatives of IVE.* No technology is perfect; no educational technology creates perfect learning environments or solely positive outcomes. As with any new innovation, most of the early adopters have focused on the promise and potential of such tools. Although these advocates need to be commended, the field also needs research to understand the short-term and longitudinal positive *and* negative effects of using IVE. Early indicators suggest that physical outcomes (e.g., nausea) and cognitive overload may be risk considerations. There are also concerns about the potential negative instructional aspects that could be exponentially increased by developers and pedagogues who wish to implement IVE simply because it is the latest cool tool.

Abstract

This chapter provides an overview of immersive virtual environments (IVEs) in education with an emphasis on augmented reality (AR). A related Chap. 63, “Educational Opportunities for Immersive Virtual Reality” focuses on the other main branch of IVE. The chapter begins with an attempt to clarify and define terms. Then, a review of research is presented for AR that highlights the current and potential impact in PreK-12, higher education, and professional development settings. Findings suggest that use of AR can lead to increased engagement. However, the synthesis also points mostly to theoretical argumentation for AR’s PreK-12 implementation.

Introduction

The purpose of this chapter is to examine a specific type of immersive virtual environment (IVE) known as augmented reality. A full explanation of IVE as well as a discussion of the other type of IVE – immersive virtual reality – can be found in a companion ► [Chap. 63, “Educational Opportunities for Immersive Virtual Reality”](#) (Ferdig et al.). The chapter begins by providing concise definitions. It then summarizes existing educational research on augmented reality. The chapter concludes with a call for more research in how AR can be used to support learning in PreK-12 education.

Defining Augmented Reality

A critical first step in exploring and discussing augmented reality research is to further define the concept of *augmented reality*.

Augmented reality (AR). One type of immersive virtual environment is called *augmented reality*. AR can be defined as computer-mediated scaffolding of a real environment. Freina and Ott (2015) proposed that AR provides a view of a physical, real-world environment whose elements are integrated with computer-generated sensory input. Persefoni and Tsinakos (2015) suggested that AR lets one experience the world with virtual objects without losing a sense of reality.

AR is often delivered by headsets (e.g., *Microsoft HoloLens*) or through mobile applications (e.g., *Pokemon Go*), although it could also be delivered in situ (see Gallagher and Lindgren 2015). Mobile delivery of AR has gained popularity because of the geolocation abilities of smartphones as well as the ubiquity of cellular devices across socioeconomic status, gender, race, ethnicity, and age.

An interesting question for AR is to further define what is getting augmented. In some situations, this could be a context. For instance, a device can help you learn more information through location tags, images, sounds, videos, and other content over existing landscapes like parks, playgrounds, streets, and classrooms. AR can also be used to augment objects such as books, trees, or even medical equipment. Functions of AR include visualization (e.g., seeing inside the human body), supplementing information (e.g., seeing medical charts next to a person), transformation (e.g., seeing what an object or place looked like historical or will look like in the future), or creation (e.g., adding additional information like trees or houses to existing environments). These additional augmentations can be static, dynamic, or even interactive (Cuendet et al. 2013).

Arth et al. (2015) provided a detailed and evolutionary perspective on the development and implementation of AR. A brief timeline of key historical events

includes (see <http://www.augment.com/blog/infographic-lengthy-history-augmented-reality/>):

- 1990 – The concept of AR was created in 1990 by Tom Caudell, a Boeing researcher.
- 1992 – Virtual fixtures (i.e., an overlaid virtual layer on a real one) were invented by Louis Rosenberg. This technology had a significant impact on AR development.
- 1994 – The first AR theatrical dance, *Dancing In Cyberspace*, was staged by Julie Martin (real performers danced among virtual objects).
- 1999 – The NASA X-38 spacecraft was developed with the hue-saturation-value (HSV) system, which used the AR Battlefield Augmented Reality System developed by the American Government with the intent to harness AR on the battlefield.
- 2000 – The open source ARToolKit was created (<https://artoolkit.org/>) allowing the development of AR applications from the bottom.
- 2013 – The Volkswagen Mobile Augmented Reality Technical Assistance (MARTA) app was published highlighting the commercial potential of AR.
- 2014 – Google Glass for consumers was made available, and Magic Leap technology was announced.
- 2016 – Pokémon Go/HoloLens developer licenses were released.

There are a number of educational tools related to AR. For instance, *ARToolKit* (<http://artoolkit.org>) includes tracking libraries for developing AR applications (further details follow below). *AR Sandbox* (<https://www.nps.gov/lavo/learn/news/ar-sandbox.htm>) is an augmented sandbox at the Lassen Volcanic National Park that makes visible and interactive concepts related to topography and watersheds. With the app *AR-Calgary Zoo* (<https://www.calgaryzoo.com/events-activities/special-events/dinosaurs-alive/prehistoric-park-augmented-reality-experience>), the Calgary Zoo allows its visitors to see animated dinosaurs in specific locations through their mobile camera. *Eco Mobile* (<http://ecolearn.gse.harvard.edu/ecoMOBILE/overview.php>) is a mobile experience that supports science teaching outdoor. The Smithsonian National Museum (<http://naturalhistory.si.edu/exhibits/bone-hall/>) has added an AR layer to some of its collections. *Augthat* (<http://augthat.com>) facilitates the inclusion of AR content in classroom activities and lesson plans. The *Quiver* suite (<http://www.quivervision.com/apps/quiver>) targets young learners with AR activities that bring to life real drawings. Finally, *Agents of Discovery* (<https://agentsofdiscovery.com>) is a mobile educational platform that enriches real environments with science-related contents and missions.

AR vs. VR. There is a resulting question of the relationship between VR and AR and whether they overlap or if there are extreme or ideal conditions of either. Arguably an ideal virtual reality would be an environment that harnessed the empirical senses (e.g., touch, smell, sight, sound, balance, orientation, etc.) to create a situation where the user could not tell the difference between the virtuality and reality. An ideal augmented reality would be one where all senses are also employed

but where the user cannot tell whether the object is real or augmented. Both these extremes are utopian, but innovations are increasingly pointing to them by covering more and more senses and patterns. Both point to the same result of delivering an empowered reality by improving normal experiences (according to several parameters and for various goals); both undertake different paths to get to that result (see Shayan et al. 2015; Karutz and Bailenson 2015; Gallagher and Lindgren 2015). Perhaps what separates them (for now) is the reality they are augmenting.

Milgram and Kishino (1994) highlighted this distinction as a continuum between the two extremes of physical environment and virtual environment. When a mediated environment is close to the former, we have an augmented reality; when the latter is in charge, an augmented virtuality takes place. Anything in between would be considered a mixed or blended reality. The reflection begs the question of whether one is augmenting reality or augmenting virtuality. It also asks researchers, educators, and developers to consider if time will eventually make these distinguishable immersive environments indistinguishable – or at least more blurred in their definitions.

A Brief Review of Simulation Research

IVEs (immersive virtual environments) are all simulations of one form or another, but not all simulations are IVEs. Such a distinction suggests that research on IVEs such as AR requires direct empirical research. However, it is worth beginning a review of the research by looking at simulations, as they set the stage for what we already know about using simulations more broadly.

Merchant et al. (2014) defined simulations as “interactive digital learning environments that imitate a real-life process or situation (...) [and] allow learners to test their hypotheses of the effects of input variables on the intended outcomes” (p. 30). Sitzmann (2011) further defined educational simulations as “instruction delivered via personal computer that immerses trainees in a decision-making exercise in an artificial environment in order to learn the consequences of their decisions” (p. 492).

Research has been conducted on the use of simulations both in and outside of PreK-12. Within K-12, D’Angelo et al. (2013) found that simulations can be positively used when learners are interacting with models. This is particularly true when those models are difficult to observe in real life. Merchant et al. (2014) completed a meta-analysis and found that simulations were useful when students were assessed immediately after the instruction. Simulations were also found to be more useful when integrated as practice sessions rather than stand-alone activities. Finally, Sitzmann (2011) discovered that gaming simulations increased post-training self-efficacy, declarative knowledge, procedural knowledge, and retention. The most positive outcomes occurred when students were actively involved, when students could access the simulations whenever they wanted, and when they supplemented learning rather than serving as stand-alone activities.

It is critical to note that the findings presented here and throughout this chapter do not set the stage for asking whether simulations or IVEs work or fail to work.

Research has already provided evidence that the more important question is to examine the conditions under whether these tools work (Ferdig 2006). In PreK-12 research, simulations worked under certain conditions; the same is true for the research on simulations outside of PreK-12. For instance, Alaker et al. (2016) found that VR simulations as a part of medical training supported laparoscopic surgery (e.g., shortened operation times). Chan et al. (2013) reviewed the literature for neurosurgery and came to the conclusion that as a curriculum supplement, simulations improved realism and training outcomes. Finally, Kincaid and Westerlund (2009) observed that simulations offered a safe environment for learners. Simulations not only provided more frequent feedback and assessment, but they also helped instruction by improving cooperative skills and reducing human error. In sum, simulations do not always work, but there is substantial evidence that there can be positive outcomes when implemented carefully and in conjunction with other education efforts because they promote learning by doing, problem-solving activities, and alternative settings to inhabit.

A Review of Research on PreK-12 Augmented Reality (AR)

Similar to the research on IVR, there are a number of articles published that describe practical and empirical research projects on AR in teaching and learning environments (Wei et al. 2015; Clark and Clark 2016). For instance, within PreK-12, projects have been created to teach elementary students about geometry and spatial cognition (Radu et al. 2015). AR projects have also been developed to teach about wildlife conservation (Phipps et al. 2016), to teach science in informal environments (Zimmerman et al. 2015), and to explore the role of multiuser AR environments (Noor and Aras 2015). Outside of K-12, projects have been created to use Kinect to explore cultural heritage (Bostanci et al. 2015; Pacheco et al. 2014), to use AR to guide visitors in museums (Djebbari et al. 2014), to teach about parks and historic places (Gordon et al. 2016; Kelling and Kelling 2014; Martínez-Graña et al. 2016), and to help learners understand anatomy (Jamali et al. 2015).

There are also articles that simply describe the promise of AR in education. Gallagher and Lindgren (2015) stated that AR could be useful because it affords metaphor use and full body movement. Kidd and Crompton (2015) suggested that AR allows educators to create authentic and engaging environments that are rich and student-centered. They are some of the few authors who discuss concerns about accessibility and the potential of AR for disabilities research. Kysela and Štorková (2015) claimed that AR could make history and tourism instruction more engaging and situated. Persefoni and Tsinakos (2015) argued that the potential of this technology is promising due to visualization (what cannot be seen) and discovery (being pushed to explore). Wu et al. (2013) added that location-based AR could address the difference between formal and informal learning and therefore could provide ubiquitous, collaborative, and situated learning.

Finally, there have been several literature reviews completed that are directly related to the use of AR in education. Most recently, Akçayır and Akçayır (2017)

found an increase in the number of AR studies in the last 4 years. They provided evidence that the biggest advantage of AR is enhancing learning achievement. However, challenges include usability and technical issues from connectivity problems in outdoor activities to accessibility of the user interface. Antonioli et al. (2014) also found promise for AR but noticed that most of the published work was related to student or teacher reactions and less about actual outcomes and dealing with challenges like cognitive load (see Dunleavy and Dede 2014). Bacca et al. (2014) highlighted AR implications for learning gains, motivation, interaction, and collaboration but raised concerns about superimposed information and users paying too much attention to virtual information.

Although there is value in reviewing these analyses, there is also insight that can be gleaned from looking directly at the studies to learn more about AR in PreK-12 education. For instance, a large percentage of the published research on AR in education has provided evidence of the importance and potential of using AR for science learning. For instance Techakosit and Wannapiroon (2015) directed an heuristic evaluation (n:9 experts) of an AR science laboratory finding that it significantly supported science literacy. Chang et al. (2013) examined socioscientific issues (SSI) and determined that AR could support student learning through presence, immediacy, and immersion; they also suggested that this may lead to more informed decision-making. Cheng and Tsai (2013) also explored science learning and advanced concepts like mental models, spatial cognition, situated cognition, and social constructivist learning which might be used to stage more effective interventions.

Fleck et al. (2015) used AR to support astronomy learning. Their research provided evidence that the combination of both real and virtual objects lowers abstraction levels of young learners. Furio et al. (2015) successfully adopted AR to improve motivation related to learning the water cycle (although learning outcomes were arguably the same). Huang et al. (2016) developed an AR-based botanic garden that successfully improved both learning outcomes and positive emotions related to learning about eco-discovery. This was a similar finding to Kamarainen et al. (2013) who improved learning and peer cooperation related to environmental issues. Echeverría et al. (2016) created an AR collaborative game about electrostatics and found positive outcomes in terms of engagement, usability, and knowledge.

Chiang et al. (2014a) focused on inquiry-based learning activities. Their AR experience was tested with 57 fourth graders, and results showed that the proposed approach is able to improve the students' learning achievements. Attention, confidence, and relevance were also perceived higher in comparison with the control group. Laine et al. (2016) demonstrated increased positive reception of science learning using context-aware games focused on storytelling. Finally, Lindgren et al. (2016) worked with immersive AR and reported significant increase in targeted comprehension due to the whole-body activity affordance of the interactive system.

Content growth wasn't limited to science learning; there were also research studies reporting improved performance in mathematics using AR. For instance, Sommerauer and Müller (2014) found that a mathematics AR exhibition is more effective than a non-AR one in terms of knowledge acquisition and retention tests.

Many of the empirical articles also addressed concept rather than solely content growth (Yilmaz 2016). For instance, Chen et al. (2015) found improved engagement with elementary students when using AR. Chiang et al. (2014) were able to provide evidence of knowledge construction behavior growth when harnessing AR. Cuendet et al. (2013) showed how AR could give teachers opportunities to more dynamically engage and be more flexible with students. Di Serio et al. (2013) used AR with middle-school students and showed increased motivation in comparison with traditional course lectures.

A Review of Research on Non-PreK-12 Augmented Reality (AR)

There are a number of other studies outside of PreK-12 that provide further evidence of the promise of AR in PreK-12. Studies have demonstrated that:

- AR can be used to improve students' laboratory skills while they build positive attitudes toward this type of environment (Akçayır et al. 2016).
- AR applications like *Pokémon Go* can increase physical activity and user health benefits and potentially reduce social withdrawal (Althoff et al. 2016; Tateno et al. 2016).
- AR-based tours can improve visitors' sense of place, their involvement, and their overall learning (Chang et al. 2015; Harley et al. 2016).
- AR experiences can affect user satisfaction and engagement with theme park settings, content, service, and overall quality (Jung et al. 2015).
- Google Glass as an example of an AR implementation can successfully help visitors connect with and learn about art (e.g., paintings; Leue et al. 2015).
- AR can support participation reinterpretation of public spaces (Liao and Humphreys 2015).
- Students positively perceive the use of AR in their learning (Martín-Gutiérrez et al. 2015).
- AR can support collaboration and teamwork while still keeping a strong sense of reality (Majorek and du Vall 2016).
- The use of AR can facilitate immersion and involvement in museum experiences (Mason 2016; Shirai et al. 2015).
- AR was found to increase integration and safety in situations where humans were interacting with robots (Michalos et al. 2016).

To summarize, there are a number of articles directly related to PreK-12 education that provide both theoretical and empirical support for the use of AR in education. As with IVR, access to hardware could be a potential constraint, particularly in lower socioeconomic status schools. There is a growing body of research evidence outside of PreK-12 that could positively impact both the implementation of AR in PreK-12 as well as future research in this area. The caveat to all of this research, however, is that this is not simply a case where implementation equates to learning outcomes. Not all AR experiences are positive. O'Shea and Elliott (2016) summarize:

There are several causes for the relative lack of ‘good’ AR technologies for learning. As with most things in education, problems begin with lack of resources. (. . .). Another issue (. . .) is limited infrastructure within educational settings. (...) Also, the technology itself is still at a nascent level. (. . .) Perhaps the most difficult barrier to overcome, though, is the fact that most AR experience designers lack knowledge of learning pedagogies, methodologies and strategies. (pp. 106–107)

AR Development Tools

Despite its brief history, AR development tools are getting more and more popular, allowing educators to create and design their own AR applications and materials. The leading program is the previously mentioned open source *ARToolKit*, which is a software development kit (SDK) of tracking libraries that allow users to build AR applications by supporting different devices and technologies (e.g., real time AR, headsets). Released in 1999 and currently owned by DAQRI, *ARToolKit* is powerful but requires technical skills to be mastered. Other options include:

- *TaleBlazer*, which is a free online development platform (<http://taleblazer.org>) creating mobile location-based AR experiences. Developed at the Massachusetts Institute of Technology, this program is based on the creation of virtual agents that can be placed in a real environment’s spots guiding and interacting with the user by displaying additional content, from videos and pictures to prompts and quizzes.
- *FreshAiR* (<http://www.playfreshair.com/>) is a mobile-oriented editor for adding an AR layer to real environments, from national parks to university campuses, by harnessing geolocation mechanisms. It is possible to create and include locations, media content, specific triggers, assessment items, and even roles within the augmented space. Therefore, chains of action and conditions can be designed personalizing and enriching the user experience.
- With *HP Aurasma* (<https://www.aurasma.com/>), users can upload whole assets and augmented elements (the so-called auras – images, videos, 3D creations, websites, animations) in their surroundings in relation with real objects, sharing and personalizing the exposition and collecting resulting data and analytics.

Regardless, it should be noted that given its relative infancy, this type of software constantly changes and evolves; therefore, researchers and educators should continue to monitor creation and development tools in order to maximize their efforts.

Conclusion

The first goal of this chapter was to further define and explore research within IVE: augmented reality (AR). The second goal was to conduct a literature review on the topic to determine what the field knows and what researchers still need to learn – particularly about implementation of AR into K-12 settings.

A majority of the research on AR in PreK-12 education is theoretical in nature (e.g., case studies, position papers, and project presentations). The existing empirical research focuses heavily on science education, “settings” research (e.g., parks, museums, etc.), and on user experience of perceptions and motivation. There has also been a recent surge of interest in how AR can support collaboration and teamwork. The amount of research that does exist may grow due in part to the popularity of mobile-based applications like *Pokémon Go* and tools such as *ARToolKit*.

According to these findings, some highlights can be outlined spanning future directions for research and instructional practice in PreK-12 education:

1. *Current research is significantly descriptive as its core* with an emphasis on validating researchers’ products rather than deploying a more objective perspective. Broader, deeper, and more longitudinal studies are needed to expand the educational scope of AR. This could include comparing different applications and learning environments as well as exploring its use in varying subjects or with diverse populations.
2. *AR is not currently usable by everyone.* More efforts are required to inform accessibility and usability issues and concerns within AR experiences in education. Such a dimension may make a difference in instructional scaffolding and supporting students with special needs and specific learning styles and preferences. For instance, customization features may be a key criterion for future development
3. *Lack of pedagogical design.* Pedagogical explorations targeting AR are still somewhat rare; yet we know implementation requires awareness in terms of planning and preparation. Therefore, researchers and experts need to formulate proper professional development strategies for educators and practitioners embracing software selection and reference rubrics. This will support moving beyond the novelty effect of AR to support instruction and cognition (e.g., knowledge retention).
4. *AR content is usually harnessed – and not created – by educators.* This situation could lead to weakened educational potential in terms of learning outcomes and curriculum integration (see Merchant et al. 2014). Therefore, teachers should start to explore development tools (see an example list in this chapter) for shaping their own media experiences aligned with their instructional activities. Understandably, there is a risk in learning something that is constantly evolving and that is still characterized by a narrowed educational focus (several AR programs used in education do not have explicit instructional purposes).
5. *AR is not a perfect technology.* A clear focus on AR weaknesses should be explored and documented in order to help prevent implementation issues and frustrating experiences. For instance, using AR applications outdoor can entail connectivity problems and concrete risks for the learner (e.g., being aware of his/her surroundings). Moreover, AR in the classroom may foster distraction rather than engagement if not implemented properly.
6. *Holograms need to be deepened with a renovated focus on education.* Holograms are an exciting and potential crucial component of AR; their importance will

increase with devices such as *HoloLens* and *Magic Leap*. Therefore, their impact on instruction needs to be analyzed, from cognitive load measurement to engagement effects and emotional reactions. Further explorations can inform their role in collaborative tasks and formal (or informal) learning settings.

7. *The AR context needs to be sufficiently considered.* Despite AR having a broad range of application, the context of use represents a fundamental variable needed to maximize its educational potential (especially in informal learning). Designing effective AR applications depends on the interplay with the context itself, from environment traits (e.g., Where are the augmented objects placed and in relation with what?) to social dynamics (e.g., Is the student/user alone? Is the teacher with him/her? Are group activities planned?) However, it is still an overlooked aspect in several studies about this technology.

Section XI

Issues and Challenges Related to Digital Equity

Section Introduction: Issues and Challenges Related to Digital Equity **65**

Thérèse Laferrière and Paul Resta

Abstract

This section is devoted to digital equity, and its evolving nature. Seven chapters are included in this section. Considering IT as a potential agent to social inclusion, authors devote much attention to the issues, challenges, and strategies involved in moving toward digital equity. Ways in which teachers and teacher educators can pay attention to digital equity when using IT in education are identified.

Keywords

Information and communication technology · Digital divide · Learning environment · Social inclusion · Knowledge divide

The question as to whether the digital divide is decreasing or increasing is a matter of the point of view one takes. It depends on the object and approach of the researcher. For instance, Van Deursen (Communication Science) and Helsper (Economist) (2015) claimed they found a link between Internet usage and widening inequality. Meanwhile, from an educational perspective, Hohlfeld et al. (2017) have results suggesting that Florida schools have improved on several indicators related to the

digital divide. Dolan (2016) looked at the evolving complexity of the digital divide. Efforts to reduce the digital divide gap are many and cover a large spectrum (e.g., using technology to support at-risk students' learning (Darling-Hammond et al. 2014); smart partnerships to increase equity in education (Leahy et al. 2016)).

In this section of the handbook, there is acknowledgement that digital equity does not escape the long-standing issues and challenges identified by equity research (e.g., gender, racial/ethnic, urban/rural, social class, learning disabilities). But instead of arguing that IT widens the gap between sexes, economic groups, ethnic groups, and countries, the contributing authors consider IT as a potential agent for social inclusion. Therefore, they devote much attention to the issues, challenges, and strategies involved in moving toward digital equity and the ways in which teachers and teacher educators can pay attention to issues of equity when using IT in education.

There is also an acknowledgement that those who contribute toward digital equity face significant issues and challenges at the national, regional, and local levels. Level one issues regard access to the Internet and to digital technologies and resources. Level two issues pertain to the uses of IT in teaching and learning. Knowing that IT is playing an increasingly critical role in preparing a new generation of students with the knowledge and skills needed to be successful in a knowledge-based global society (OECD 2017), the co-editors of this section chose to give more visibility to the issues and challenges faced in the United States and Canada than they did in the previous edition of this handbook. The rationale is that those who are still concentrating their efforts on level one issues will have to face, sooner or later, level two issues and challenges. The chapters of this section are thus aimed at informing.

Bringing together recent developments, this section includes two updated chapters from the original 2008 handbook and five new chapters. The introductory ► [Chap. 66, "Issues and Challenges Related to Digital Equity: An Overview,"](#) is updated by Resta and Laferrière. The five types of access, which delineated each of the five dimensions of digital equity identified in the first edition of this handbook, are updated with new research-based issues, challenges, and informed strategies. The chapter points to the new digital literacy demands placed on education systems while also continuing to underscore the challenges and need for basic literacy that allow individuals to access information and use IT to create value for their communities.

Warschauer and Xu, who wrote the ► [Chap. 71, "Technology and Equity in Education,"](#) aim to create a broad picture of the relationship between technology and equity in primary and secondary education by summarizing research literature on socioeconomic status, racial/ethnic, and gender differences related to technology. Technology access, use, and outcomes are considered. They stress, however, that the differences in access and usage that affect the disparities in outcomes remain inconclusive.

Penuel and DiGiacomo point to relational equity in ► [Chap. 70, "Organizing Learning Environments for Relational Equity in New Digital Media."](#) They define "organizing for equity" as the act of attending both to the distribution of access to digital tools and opportunities to learn about and with them, as well as to the advantages such access and opportunity provide. Organizing for "relational equity"

is about working to foster relations in which *all* participants' sensemaking is taken up and brought into joint activity in equally valued ways. The chapter identifies key principles for organizing learning environments that employ new digital media to promote relational equity and provides two examples of such environments.

With ► [Chap. 72, "Advancing Equity Through Educational Technology: Promising Practices for Adoption, Integration, and Use in K-12,"](#) Zielezinski and Darling-Hammond focus on how digital tools can be used to support underserved and under-resourced students. They submit that with increased access to technology on the horizon, educators stand at a crossroads. These researchers put forward the following challenge: Do educators continue with the status quo or attempt to use the rising technology levels to support those students who need it the most?

► [Chapter 69, "Learning Differences and Digital Equity in the Classroom,"](#) written by Treviranus, also addresses digital equity in the classroom for students with learning differences by attending to the role of technology in the provision of equitable education for the full diversity of students. The chapter points to the evolving opportunities and challenges that information technology in the classroom presents to students with learning differences and their teachers. It also highlights the benefits to all students of designing the classroom experience for students with learning differences.

Resta, Shonfeld, Yazbak Abu Ahmad, and Wallace are the co-authors of ► [Chap. 67, "Information and Communication Technology Revitalizing Cultural Identity and Diversity."](#) They propose that technology can be used to help revitalize cultural identity, language, and knowledge within marginalized groups. For instance, they exemplify how ICTs can be applied by indigenous peoples to strengthen and reinforce indigenous cultural identity, knowledge, and culture and to provide more culturally responsive learning resources and environments for their children. They include other examples and models from across the globe.

Finally there is ► [Chap. 68, "A Sociocritical Perspective on the Integration of Digital Technology in Education,"](#) written by Ntebutse and Collin. They argue for the relevance of socio-critical perspectives on digital equity in education and put forward such a perspective on the integration of digital technologies in education, including foundations and research lines.

Abstract

The chapter addresses two main concerns: Digital equity for social inclusion and digital equity in education. Five dimensions of digital equity are identified: (1) access to hardware, software, and connectivity to the Internet; (2) access to meaningful, high quality, and culturally relevant content in local languages; (3) access to creating, sharing, and exchanging digital content; (4) access to educators who know how to use digital tools and resources; and (5) access to high-quality research on the application of digital technologies to enhance learning. Issues, challenges, and informed strategies are pinpointed on the basis of what digital-divide and digital-equity research says.

Keywords

Social inclusion · Digital divide · Access · Digital tools and resources · Knowledge divide

Introduction

Digital equity is a highly challenging social justice goal. Stewart (2000) stressed that geographical, generational, cultural, and pedagogical issues and challenges combine to expand, or limit, school learners' participation in the determination of both individual and collective life chances. Physical access to devices is the first step in moving toward digital equity but, according to Gorski (2009), one that defines too narrowly the term digital divide. Referring to Light (2001), Gorski (2005) argued that a digital divide exists when a group's access to digital technologies and resources differs along one or more dimensions of social, economic, cultural, or national identity. In the first edition of this chapter, we adopted the following definition of the digital divide: "Situations in which there is a marked gap in access to or use of ICT devices" (Campbell 2001, p. 1). We retain it here while being aware that the meaning of the term keeps evolving.

In its 2015 resolution on the overall review of the outcomes of WSIS (The World Summit on the Information Society (WSIS) of the United Nations Educational Scientific and Cultural Organization (UNESCO) in Tunisia in 2005 stated: "*We underline* the importance of removing barriers to bridging the digital divide, particularly those that hinder the full achievement of the economic, social and cultural development of countries and the welfare of their people, in particular, in developing countries" (WSIS 2005, p. 1, article 10)), the United Nations General Assembly (2015) expressed five major concerns: (1) existing digital divides prevail and new divides emerge; (2) the ubiquitous use of ICT must be based on new levels of confidence and security; (3) the rights of individuals must be protected equally online and offline; (4) the progress brought in by ICT should be measured not only in economic terms but also in terms of the realization of human rights and freedoms; and (5) to serve as a development enabler, ICT must be grounded in ethical foundations. These concerns apply to many fields, including education.

In education, progress regarding physical access to digital technologies and resources (first-level divide) has revealed, as in other fields, second-level divides related to skill and usage patterns and production (The gap that separates the consumers of content on the Internet from the producers of content.) (Attewell 2001; Hargittai 2002; Solomon et al. 2003). Now third-level divides are surfacing, ones that will bring new challenges to those professional educators guided by the principle of equality of opportunity. According to Van Deursen and Helsper (2015), third-level divides are “disparities in the returns from Internet use within populations of users who exhibit broadly similar usage profiles and enjoy relatively autonomous and unfettered access to ICTs and the internet infrastructure” (p. 30). The authors report that their findings suggest that “the Internet remains more beneficial for those at the highest education levels, with higher social status, not in terms of how extensively they use the technology but in what they achieve as a result of this use for several important domains” (p. 46). Therefore, they claim they found a link between Internet usage and widening inequality.

Access to the digital infrastructure and technologies remains a challenging first-level issue for all countries. For instance, in the country that spends the most for student education, (In 2010, The United States spent more than \$11,000 US dollars per elementary student and more than \$12,000 US dollars per high school student. See <http://www.cbsnews.com/news/us-education-spending-tops-global-list-study-shows/>) 11.6 million students do not have the Internet access they need for digital learning (EducationSuperHighway 2017). Nonetheless, attention is, and must be, increasingly devoted to second-level divides. For instance, the National Education Technology Plan (US Department of Education, Office of Educational Technology 2016) emphasizes that digital use divide is the new challenge for teachers and learners. In its 2017 update, NETP articulates a vision of digital equity for reaching equity in learning.

This introductory chapter provides a conceptual framework for understanding issues and challenges related to digital equity. For Warschauer (2004), “digital solutions” do not come without consideration of the complex factors, resources, and interventions required to support social inclusion. Challenges and informed strategies related to each of five dimensions of the digital divide are identified. Issues and challenges are also discussed in detail within each of the seven chapters of this section.

Conceptual Framework

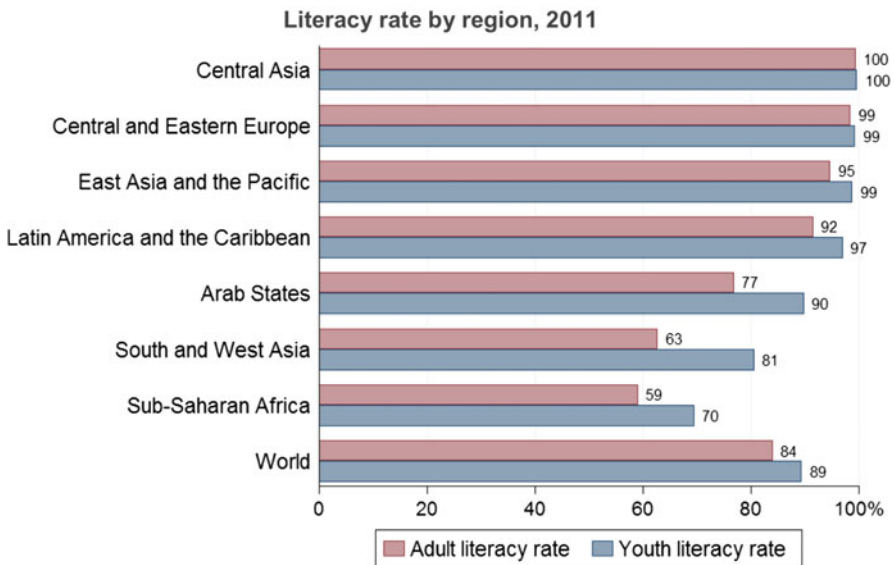

First and second-level digital divides set forth an alarming divide – the knowledge divide. Knowledge societies are becoming the aspiration of both Northern and Southern countries. Institutions and citizens are faced with an exponential growth in basic and applied knowledge: the world knowledge base doubles every 2–3 years, with similar growth trends in information on the Internet. With an increasing flow of information, national economies grow more internationalized. There is a social demand for higher levels of education as technology is reducing the need for

many types of unskilled or low-skilled workers (Johal and Thirgood 2016). Digital labor is beginning to be studied for the design of better digital work experiences (Bucher and Fieseler 2016). The main assumption here is that the access and the use of the Internet and digital technologies are critical elements for individuals to participate and derive the benefits of a global knowledge society. Therefore, the conceptual framework that follows is built around two concerns: digital equity for social inclusion and digital equity in education.

Digital Equity for Social Inclusion

The growing efforts to move toward digital equity are fueled by the prospect that digital exclusion will add to social and economic exclusion of individual learners and citizens and, on the broader scene, whole populations. A requisite for participation in the global knowledge society is basic literacy. Literacy levels vary greatly across gender, nations, and the world (Fig. 1).

The fact that almost two-thirds of illiterates are women limits women’s access to IT (UNESCO 2013). In the digital equity section of the 2008 edition of this handbook, a whole chapter was devoted to gender (Looker 2008). Another individual difference that impinges upon literacy and access to IT, even in developed countries with a high level of Internet penetration, is visual impairment and other disabilities. The visually

Fig. 1 Literacy rates by region and gender. UNESCO Institute for Statistics, Literacy data (2013). Available at http://uis.unesco.org/sites/default/files/documents/fs26-adult-and-youth-literacy-2013-en_1.pdf

impaired individual requires adaptive technology (Treviranus and Roberts 2008). In this second edition, Treviranus (► Chap. 69, “Learning Differences and Digital Equity in the Classroom”) focuses on the needs of specific groups. Although the basic literacy or “print divide” remains an important issue in many parts of the world, the digital divide has become a growing concern in education, one based on the recognition of the strong relationship between education and socioeconomic development.

Digital Equity in Education

There are efforts being made throughout the world that attempt to put the potentials of IT in the service of education (Charania and Davis 2016; Gonzales-Perez 2014; Yuen et al. 2016). These efforts exemplify individual and/or collective emancipation (basic skills, twenty-first-century skills) through access to information or people, and to IT-supported content creation, including knowledge creation.

For such emancipation to occur, however, educators must understand that digital equity is more than access to computers and connectivity. The remaining of this chapter is structured around the following five dimensions of digital equity that we identified in the first edition of this handbook:

- Access to hardware, software, and connectivity to the Internet
- Access to meaningful, high quality, and culturally relevant content in local languages
- Access to creating, sharing, and exchanging digital content
- Access to educators who know how to use digital tools and resources
- Access to high-quality research on the application of digital technologies to enhance learning

Issues, Challenges, and Informed Strategies

This section presents issues, challenges, and informed strategies related to the five dimensions of digital equity.

Access to Hardware, Software, and Connectivity to the Internet

Issues

Internet providers are conscious of the value of their goods, and consumers want an affordable price, reliability of service, and speed. However, in the Southern hemisphere, there are great numbers of individuals who are disadvantaged. Geographical location matters a great deal when it comes to digital equity (Cleary et al. 2006). Although the Internet is spreading at a much faster rate than electricity, the latter is still missing in some rural areas of the world. The International Telecommunications Union (ITU 2003) states that the Internet infrastructure is now in place on all

continents. According to Internet World Stats (June 2016), Asia has now half the number of Internet users (Fig. 2), and an Internet penetration level of 45.6% (Fig. 3). North America remains the region with the highest level (89%) of Internet penetration whereas Africa has the lowest (28.7%).

Looking at the distribution of people online worldwide (Fig. 4), one cannot help thinking that the digital equity goal is a far-reaching one. Contrary to radio, television, or print, computers are more complex, and this very factor keeps citizens from using them, including ones who are literate, wealthy, and living in the city.

Challenges

Cost. The cost of hardware, software, and connectivity to the Internet remains a continuous challenge. In developed countries, those connected to the Internet require increasing bandwidth for audio and/or video use. Exemplars of new limits reached are as follows:

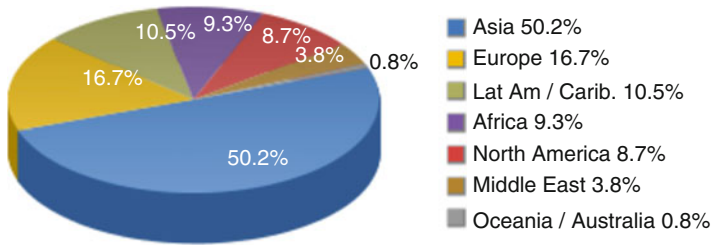

- Internet connectivity is slow when students are asked to download a document at the beginning of a period.
- Early-adopter teachers less time than previously at the computer lab as more teachers are taking students to the computer lab.
- A suburban school in a wealthy city finds it difficult to keep up with the demand for bandwidth created by the 500 computers used by students during class time.
- A small student team from a remote rural school can hardly hear students from another school with whom they are doing a learning project because the latter students are part of a large school whose three computer labs take almost all of the available bandwidth.

Developing countries would be facing similar issues except that IT keeps improving. Leapfrog initiatives are expected as hardware costs are coming down (e.g., 25% per year in increased power and lowered costs), and wireless technologies are growing rapidly in number and range (e.g., WiMAX, Google's project LOON (<https://x.company/loon/>)).

Technology Leadership. "While many countries have broadband policies in place and many Ministries of Education have called for broadband in all schools, progress towards reaching these goals is irregular and difficult to track..." (Broadband Commission for Digital Development ITU and UNESCO 2013, p. 14) (See also Fig. 5).

The level of the ICT infrastructure was found to be the most probable predictor of technology-leadership profiles assumed by Turkish principals (Banoğlu et al. 2016). In their study, the authors refer to ISTE's (2009) five indicators of technology leadership: (1) visionary leadership, (2) digital-age learning culture, (3) excellence in professional practices, (4) systemic improvement, and (5) digital citizenship. Technology leadership is the key challenge on the part of educational administrators, including school principals or master teachers, even after the early stage of IT integration to teaching and learning (Dexter 2008).

Informed Strategy

The societal passage from print to digital information is now well underway. Understanding the importance of broadband in education as part of a nation's strategy to prepare students with the twenty-first-century skills is key. ITU's, UNESCO's, and OECD's publications are remarkable sources of information for keeping oneself informed regarding global developments regarding digital technologies and bandwidth. While computers keep growing in interactive functionalities, countries can build capacity through dialogue and the development of partnerships between the governmental, educational, and the private sectors.

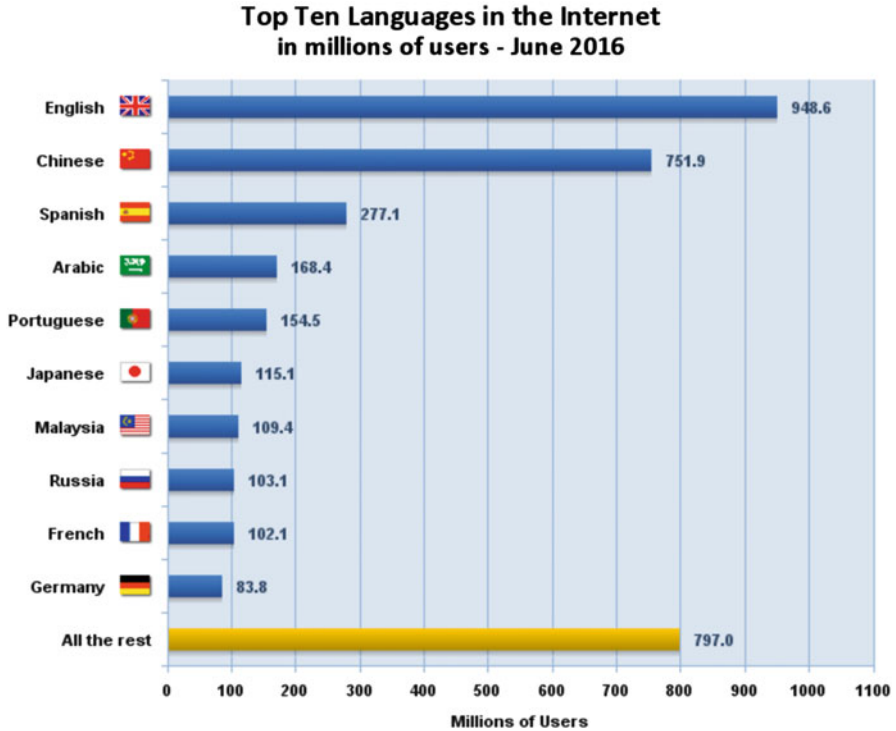

Access to Meaningful, High Quality, Culturally Relevant Content in Local Languages

Issues

The Declaration of Principles adopted at the World Summit on the Information Society (WSIS, Geneva, 2003, Article 1) highlighted “[the] common desire and commitment to build a people-centered, inclusive, and development-oriented Information Society, where everyone can create, access, utilize, and share information and knowledge.” The impetus behind the Geneva Summit was the growing awareness of the digital divide. IT should be turned into “a digital opportunity for all” according to the Summit's Declaration of Principles and Plan of Action (UNESCO 2001). And Ronchi (2009) provided a broad overview of the issues of the e-culture and digital heritage (e.g., virtual museums issues and achievements, cataloging, digitizing, publishing, and sustainable exploitation of cultural content).

Although the Web offers vast resources that are of value to education and lifelong learning, which are increasing every day, it must be recognized that the quantity of information available on the Surface Web (i.e., what is normally considered the Web) is small compared to information on the Deep Web (i.e. resources stored in databases, and not in an HTML format). The Deep Web represents the part of the Internet (4% is often mentioned when one searches on the Surface Web) that is inaccessible to conventional search engines and, consequently, to most users on the Web. The content available in the Deep Web is over 500 times greater than what is available on the Surface Web, that is, the approximation referred to by Kumar and Mishra (2015, p. 137). They observe that the Deep Web is growing more rapidly than the Surface Web in all major sectors, including education. They argue for hidden data indexing, given the necessity for the public to access the Deep Web.

When one looks at the language of the users of the Internet today (Fig. 6), the dominance of the English language remains a major issue but the Chinese language is growing rapidly compared to all other languages on the Web. Web content in Chinese was only 3.9% in the first edition of this chapter. We stated: English has become the world's lingua franca through globalization.

UNESCO has taken notice of the importance of access to content and promotes open Educational Resources (OERs) that are defined as follows:

any educational resources (including curriculum maps, course materials, textbooks, streaming videos, multimedia applications, podcasts, and any other materials that have been designed for use in teaching and learning) that are openly available for use by educators and students, without an accompanying need to pay royalties or licence fees. (Commonwealth of Learning and UNESCO 2015, p. 5)

The Commonwealth of Learning and UNESCO (2015) identify four policy issues for making more effective sharing and use of OERs:

1. *Provision in policy of clarity on intellectual property and copyright* on works created during the course of employment (or study) and how these may be shared with and used by others.

2. *Human resource policy guidelines* regarding whether or not the creation of certain kinds of work (e.g., learning resources) constitutes part of the job description for staff and what the implications are for development, performance management, remuneration, and promotion purposes.
3. *ICT policy guidelines* regarding access to and use of appropriate software, hardware, the Internet and technical support, as well as provision for version control and back-up of any storage systems for an institution's educational resources.
4. *Materials development and quality assurance policy guidelines* to ensure appropriate selection, development, quality assurance, and copyright clearance of works that may be shared (pp. 16–17).

In an attempt to better understand educators' perceptions of collaborative OER development, Pirkkalainen et al. (2017) find that "emotional ownership" is a barrier to collaboration: "The stronger one's attachment to the ideas, the less unlikely one would engage in sharing or building new resources and related practices in a collaborative manner based on it. Thus, the educator becomes more hesitant to share that idea with others" (p. 127). Moreover, their findings also show that "increase in reputation and status in the network" does not seem to influence the intention to share knowledge. Emotional ownership becomes an enabler rather than a barrier "when working in a trusted environment with peers" (p. 129).

Challenge

Trust is key to collaboration, and the open online environment is both a place of opportunity and uncertainty for content producers. Cultural preservation and development through the creation of digital content in local languages, a major challenge confronting many countries across the globe, is enabled by affirmative culturally oriented actions such as declarations, conferences, and publications (e.g., International Symposium on the Measurement of Digital Cultural Products, Montreal 2016; Linked Heritage Cultural Digitisation Conference 2013; Ronchi 2009). There are also projects such as Europeana (<http://antennalab.org/project-europeana-access-to-culture-and-heritage-in-the-digital-age/>), the European SchoolNet (<http://www.eun.org/>), SchoolNetAfrica (<http://196.1.95.39/schoolnet/english/index.htm>), and the eGranary Digital Library (<https://www.widernet.org/eGranary/>) that are developing and/or providing access to high-quality educational content in local languages.

Informed Strategy

The use of open educational resources (e.g., open courseware initiatives, Carnegie Mellon Open Learning Initiative, MIT OCW, UNESCO), Creative Commons (some rights reserved), and open source software (e.g., Apache Open Office, G Suite (email, drive, group, etc.), GIMP, Nvu, Tux Paint, Open Source Initiative) for individual and community empowerment is the employed strategy. For instance, Native Americans have engaged in the digital repatriation of sacred or important artifacts that reside in national or regional museums. Indigenous communities are now able to use technology to develop educational resources and materials that

reflect the language, culture, history, and resident knowledge of indigenous communities to help support culturally responsive teaching and learning in schools serving native children (Resta et al. 2004). The Broadband Commission for Digital Development ITU and UNESCO (2013) recommends the use of OERs to “accelerate free access to knowledge and facilitate the adaptation of content to local needs and languages” (p. 10).

Access to Creating, Sharing, and Exchanging Digital Content

Issues

The Geneva Declaration of Principles, which was adopted at the World Summit on the Information Society (WSIS 2003, p. 1), foresaw “an [...] Information Society, where everyone can create, access, utilize and share information and knowledge.” The rapid growth of digital libraries and repositories is not without issues and challenges related to access to content but here the emphasis is on access to content creation opportunities. We understand the above quote from the Geneva Declaration to be an incentive toward the democratization of content creation, one to engage school learners through collaborative ventures and the recognition of students’ voices, and ability to learn, create, and disseminate under the guidance of their teachers.

UNESCO (2011) promoted three teacher competencies – technology literacy, knowledge deepening, and knowledge creation. They are all necessary for content creation. The knowledge-building principles put forward by Scardamalia (2002) include one on the democratization of knowledge, meaning that primary and secondary school students are to be considered capable of knowledge creation. This is an advanced form of participation that may be exercised during both primary and secondary education. Robles Morales et al. (2016) address the relationship between digital participation and the digital participation divide: “The first concept refers to the use of the Internet to produce cultural goods that are subsequently shared on a global scale; the latter, refers to the inequalities generated by the uneven distribution of these creative uses of the Internet in a given population” (p. 97).

Challenge

This knowledge-building approach (Scardamalia and Bereiter 2006) has implications for education, culture, and democracy. It requires trust in school learners’ capacity to produce content of value for their classroom-based knowledge building community. It also requires a less normative approach to the digital equity problem, one that takes advantage of local circumstances and expertise to make contributions to one’s community and to other networked communities. The Knowledge Society Network (<http://ikit.org/ksn.html>) provides numerous exemplars of knowledge creation through the use of the same suite of digital tools.

Informed Strategy

The democratization of knowledge must be pursued at both ends, that is, both in access to knowledge and access to opportunities to create knowledge. Web 2.0

applications and user-created content are more available than they were in 2008. Both teachers and students have the right to produce as well as reproduce knowledge. In areas where there is a lack of content in local languages, teachers, teacher educators, elders, and students may use IT tools to create content that reflects their culture and resident knowledge. A global problem is a growing loss of local languages. Although media and technology have largely contributed to the loss of local languages, they may also be used to help preserve them. During the Four Directions Project, back in the nineties, a number of indigenous communities had very few fluent speakers of the native language. Teams of teachers, students, and elders worked together using digital technologies to develop audio recordings of the elders and to develop associated books and other materials to help students learn their native language. To be aware that social skills, as well as sociopolitical attitudes, may prevent the digital participation divide (Robles Morales et al. 2016) is part of the strategy we suggest.

Access to Educators Who Know How to Use Digital Tools and Resources

Issues

The relevance of IT to teaching and learning has been argued from the perspective of twenty-first-century skills, and now assessment methods and tools are unfolding (e.g., Griffin and Care 2015; OECD 2017). Innovation in teaching refers to new modes of delivery (e.g., learning object repositories), including online courses (see <http://opentraining.unesco-ci.org>), new approaches to learning (e.g., Bransford et al. 1999), and new pedagogies (OECD 2015). When education systems plan to innovate through the use of digital tools and resources for teaching and learning, they face the issue of teacher development. They can rely on a minority of innovative teacher educators and teachers willing to take risks (see Cuban 2001). The US National Education Technology Plan (US Department of Education, Office of Educational Technology, 2016) stresses the “digital use divide” that is now prevailing. Rather than recognize the immense potential to do things differently, teachers often use technology in accordance with old instructional practices, doing the same thing as before, but a little more quickly, a little more frequently, or a little better. Teachers who are transforming their primary or secondary classrooms into blended learning environments by combining onsite and online learning activities – the “flipped classroom” is the buzzword – are beginning to see it as “the new normal.” To expand beyond this group, however, continues to pose significant challenges (Cuban 2001; Selwyn 2013) and stresses the need for leadership and administrative, collegial, and pedagogical support.

Challenge

IT partnerships that include universities, schools, and sometimes governmental agencies are challenging but instrumental for capacity building in the use of digital tools and resources: see, for instance, Lating’s (2006) study on hybrid e-learning for rural secondary schools in Uganda. Partners face coordination and collaboration

challenges. Passey et al. (2016) argue that third-party providers have to better ground their initiatives in local education systems to face the sustainability challenge of innovation with digital technologies.

Informed Strategy

In many instances, teachers are not able to realize the full potential of information and communication technologies to enhance the teaching–learning process because of lack of comfort and competency in using the new tools for learning. Thus, to achieve digital equity requires the provision of high quality and sustained professional development for teachers. This may be accomplished in a number of ways such as providing online learning and professional development resources for teachers and building online and onsite communities of practice (see Looi et al. 2008; Turcsányi-Szabó 2008), including for preservice teachers (De Neve and Devos 2017; Hall 2017). Another strategy would be to network teachers such as in eTwinning, a European-wide teacher network that has become “an incubator for pedagogical innovation in the use of Information and Communication Technologies (ICT) for cross-border school collaboration and for formal and informal teacher professional development” (Vuorikari et al. 2015).

Access to High-Quality Research on the Application of Digital Technologies to Enhance Learning

Issues

Effective uses of digital technologies to enhance learning are what governments, school principals, teachers, and parents want to see for evidenced-based decision regarding IT. High-quality research is often considered to include quantitative studies involving large numbers of participants, prepost testing associated with short-term experimentation, and a control group (gold standard research). Even such research, however, may be misleading. For instance, Archer et al. (2014) reassessed inconsistent outcomes presented in three previous meta-analyses, and found that training and support were mediating factors. They suggested that “researchers include implementation factors such as training and support, when considering the relative effectiveness of ICT interventions” (p. 140).

There is also an emerging trend toward ethnographic studies involving in-depth observation and/or analysis of a small number of subjects. The so-called gold standard research provides descriptive low-end information on what is being applied on a large-scale basis whereas the latter provides higher-end but small-scale information growing out of detailed observations or interviews with limited generalizability. Both types of research have value provided they are done according to the highest standards of rigor for both types of research.

Challenge

Innovation requires both the use of well-established research approaches as well as the development of new research strategies to better understand the complex

environments and interactions in learning with the new digital technologies. Design research (Collins et al. 2004; McKenney and Reeves 2012) is especially conceived to these ends. The process is collaborative (university-based researchers and classroom-based teachers); it takes context into account and reinvests in the next iteration lessons learned as well as questions arising from the preceding iteration. Research is still needed for monitoring level 1 divide issues and challenges (access to Internet and digital tools and resources – Pittman et al. 2008), level 2 divide issues and challenges (uses of digital tools and resources; barriers and enablers of personalized learning or collaborative practices; learning outcomes as innovative practices are put into place – Terry et al. 2016), and level 3 divide issues and challenges (extended access to families, support services and communities of practice – Katz and Levine 2015; advantages of alternate certifications for students – Collins and Pea 2011; collateral benefits of being online – Van Deursen and Helsper 2017).

Informed Strategy

In places where the digital divide is the most pronounced, there is typically also a lack of access to high-quality research. One strategy for fostering research in these settings is through the creation of networked communities inclusive of experts, competent teachers, beginning, and prospective teachers (Hall 2017). This may also involve multi-institution collaborations to support innovative and enduring onsite/online experimentation with digital technologies (see Laferrière et al. 2015).

Conclusion

This introductory chapter provides an overview of the global challenge of the digital divide and the critical strategies that must be addressed to move toward digital equity. The major issues and challenges also appear and are discussed within specific contexts in each of the following chapters. In a rapidly changing, technology-based, and knowledge-based global economy, it is important to understand where we are now and how far we have to go to reach the WSIS goals of a global information society. As daunting as the task may be, the effects of doing little or nothing to move toward digital equity can only result in the greater social and economic exclusion of people and greater instability across the globe.

Abstract

Technology may be used to help revitalize cultural identity, language, and knowledge within marginalized groups. This chapter demonstrates how ICTs can be applied by indigenous peoples to strengthen and reinforce indigenous cultural identity, knowledge, and culture and to provide more culturally responsive learning resources and environments for their children. It includes examples and models across the globe that illustrate the ways that ICTs can be used as a tool to strengthen cultures and to foster understanding and respect for cultural differences and our common humanity. Governments are encouraged to work with universities and indigenous organizations to engage in similar initiatives and to establish policy structures that will enable indigenous peoples, and other unique cultural communities to work in partnership with ministries of education and universities, to provide culturally responsive learning opportunities for their children through the use of ICTs.

Keywords

Digital equity · Cultural diversity · Cultural identity · Indigenous knowledge · Indigenous identity · Cultural practices · Cross-Cultural understanding · Grandma stories

Introduction

This chapter focuses on the ways that technology may be used to help revitalize cultural identity, language, and knowledge within marginalized groups. This is as opposed to the thought that information and communication technology (ICT) leads to globalization and destroys cultural identity. Each of the initiatives described in this chapter offers evidence of the powerful ways that ICTs are being used across the globe to strengthen cultures and to foster understanding and respect for cultural differences and our common humanity.

Cultural Identity and Diversity

In an effort to understand the impact of ICT on cultural identity and diversity, we need to look at the meaning of these terms. Culture is defined as “institutions, communications, values, religions, genders, sexual orientations, disabilities, thinking, artistic expressions, and social and interpersonal relationships” (Baruth and Manning 2012). Cultural identity refers to a person’s sense of belonging to a particular culture or group. This process involves learning about and accepting traditions, heritage, language, religion, ancestry, aesthetics, thinking patterns, and social structures of a culture. As noted by UNESCO, “The current era of globalization, with its unprecedented acceleration and intensification in the global flows of capital, labor, and information, is having a homogenizing influence on local culture.

While this phenomenon promotes the integration of societies and has provided millions of people with new opportunities, it may also bring with it a loss of uniqueness of local culture, which in turn can lead to loss of identity, exclusion and even conflict. This is especially true for traditional societies and communities, which are exposed to rapid ‘modernization’ based on models imported from outside and not adapted to their context” (UNESCO 2017).

There is also concern about the ways that globalization contributes to the growing loss of cultural diversity. Cultural diversity encompasses the numerous cultural characteristics embraced by an individual as well as by a collective body. Cultural diversity has been defined as “the array of differences among groups of people with definable and unique cultural backgrounds” (Diller 2015).

Diversity is defined as “the condition of having or being composed of differing elements” (n.d.). Cultural diversity is complex because culture is not fixed and is constantly developing. Victor Frankl said, “When we are no longer able to change a situation, we are challenged to change ourselves” (Frankl 1942). Historical events and migration are just a few factors that have served as the impetus for change. The evolutionary nature of culture in the world is often a source of conflict within and among cultures sharing the same space and resources, which is due in part to the presence of subcultures that arise as change occurs. For example, the United States, as a whole, shares an American culture, which expresses freedom, equality, and entrepreneurial spirit as shared values of all persons residing in the country. However, there are subcultures within the United States that demonstrate behaviors, values, and beliefs, which are distinctly different from the dominant culture. Individuals identifying with the subcultures share common experiences, history, religion, regional affiliation, economic status, and values that may not appear in the dominant culture (Baruth and Manning 2012; Diller 2015). For example, first and second generation Asian Americans may embrace the dominant culture’s entrepreneurial spirit but hold fast to the ceremonial customs for marriage and religion derived from their homelands. Cultural diversity enables us an opportunity to see the world through the multiple lenses provided by the uniquely different individual surrounding us.

ICTs and the Erosion of Culture Identity

Globalization has contributed to erosion of cultural identity and nowhere is the effect most evident as among indigenous peoples across the globe. As is the case for all people, technology has often had unforeseen and unwanted consequences. ICTs may be used to reinforce and accelerate the dominance of Western-based modes of thought, culture, and learning strategies. Media such as television, radio, films, and computer games have resulted in massive and continuous exposure of many indigenous youth to non-indigenous cultural values and information with few opportunities for reinforcement of their own cultural identity, heritage, and language. As a result, “After hundreds or thousands of years of development and evolution, we are facing the disappearance of unique human cultures and their intellectual heritages.” According to UNESCO Atlas of the World’s Languages in Danger (UNESCO 2016),

there are approximately 3000 endangered languages across the globe. The loss of language contributes to the loss of cultural world views, knowledge, and identity (UNESCO 2017; United Nations 2007). It is estimated that approximately 600 languages have disappeared in the last century and they continue to disappear at the rate of one language every 2 weeks. Up to 90% of the world's languages are likely to disappear before the end of this century if current trends are allowed to continue (UNESCO 2017).

Television has also directly contributed to many societal ills of indigenous peoples including loss of indigenous cultural identity, lack of community involvement, disrespect toward others, violence, and obesity. It has also interfered with or replaced traditions that are held as sacred in Indigenous cultures. In addition, it has contributed to negative portrayals and images of indigenous peoples, further leading to their degradation and exclusion within the larger society (Mander 1991).

Elders are concerned that their children are losing ability in oral traditions and songs. They are concerned that ICTs can alter verbal communication and memory constructs while failing to build memory skills that indigenous peoples need to learn songs and dances about their culture (Leuthold 1999).

The Use of ICTS to Revitalize Indigenous Cultural Identity and Knowledge

There are examples of the ways ICTs, when appropriate and under the control of indigenous peoples, can be supportive of their language and cultural identity while also opening new doors and career opportunities through the development of ICT skills and knowledge. ICTs can also be used to extend learning opportunities to indigenous students who live in remote and isolated areas. The following are a few examples of the ways ICTs may be used in culturally responsive ways.

Examples of Ways ICTs Can Support Indigenous Identity and Cultural Diversity

There are many models across the globe that show how ICTs can be applied by indigenous peoples to strengthen and reinforce indigenous cultural identity, knowledge, and culture and provide more culturally responsive learning resources and environments for their children. A few examples include as follows.

The Four Directions Project: An Indigenous Model – United States

The Four Directions project involved 19 schools serving indigenous children in all parts of the United States. It demonstrates the benefits of indigenous communities partnering with private and public universities and other organizations to explore

ways ICTs can be used to help develop culturally responsive curriculum. Features of this program included:

- Restructuring curricula to incorporate local cultures and values
- A strong school-home and school-community focus
- Collaborating across sites through on-site training, online tutoring, and cooperative teaming
- Creating networked “virtual communities” of indigenous teachers and students
- Encouraging life-long learning by extending technology support to communities surrounding project schools
- Maintaining a network database of culturally appropriate teaching, assessment, professional development, and student-created resources

As the core of this project, each school developed an advisory team consisting of students, parents, teachers, paraprofessionals, elders, and other community members. The teams developed authentic learning tasks that were relevant to students and drawn from the unique cultural context of each indigenous community. These tasks were then developed into “thematic cycles,” central components of core curricula that allowed the presentation of subject matter within a cultural context and integrated the cultural theme into other subjects. All members of the team, parents, and community members, including elders, were involved in the development of curricula and in the evaluation of the project and its relevance to the traditions of the community. Targeted curriculum areas included art, mathematics, science, social studies, economics, geography, language arts, and fine arts (Allen et al. 2002).

Teacher Education in Sub-Saharan Africa (TESSA)

The principal purpose of Teacher Education in Sub-Saharan Africa (TESSA) research and development network is to improve the quality of, and extend access to, teacher education in Sub-Saharan Africa. TESSA brings together teachers and teacher educators from across Africa. It offers a range of materials (Open Educational Resources) to support school culturally based teacher education and training. Currently, 12 African countries are actively engaged in TESSA activities and more than 700 African academic teacher educators have participated in the TESSA process including authoring and adapting the core TESSA study units. The TESSA study units for primary teachers have been adapted to ten country contexts and are available on the TESSA website in Arabic, English, French, and Kiswahili. All TESSA study units contain a series of activities that participating teachers can carry out in their classrooms. Guidance handbooks have been created for teacher educators to help integrate and make effective use of study units in their courses. It has served 500,000 teachers and teacher educators in 19 teacher education programs have benefitted from their engagement with the TESSA resources (WISE 2017).

Honey Bee Network: India

The Honey Bee Network comprises a comprehensive multimedia/multilingual database of primary educational resources in native languages as well as information relating to new innovations and ideas, including, horticulture, biodiversity, and herbal medicine. In the same way that honeybees thrive on pollen from flowers, the Honey Bee Network is designed around the principle of information and knowledge sharing for the common good. Just as taking nectar away from flowers does not make them poorer, the objective of the Honey Bee Network is to enrich the lives of the people who share their innovations and ideas by helping them realize the value of their knowledge. By facilitating the cross-cultural and multilinguistic exchange of ideas, the Honey Bee Network provides an opportunity to tap into the creative component of indigenous knowledge systems. Unlike the more developed segments of urban society, the creativity of knowledge-rich peoples in rural and isolated areas goes largely unseen, because they lack the necessary channels of sharing their ideas with the wider polity. By providing publicly available access points (e.g., kiosks) in remote villages throughout India, the Honey Bee Network affords these geographically disadvantaged peoples an opportunity to share their creations and ideas with their peers in other parts of the country and the global community (Honey Bee Network 2017).

Project Multimedia Systems for Ethnographic Materials, Apoyo Para el Campesino – Indígena del Oriente Boliviano (APCOB) – Bolivia

APCOB, Apoyo **P** for the **C**ampesino-Indigenous of the **B**oliviano **O**riente, is a non-governmental humanist organization founded in the year 1980. The mission of APCOB is for the indigenous peoples of the Bolivian East to participate in society and in the national State by exercising their rights and articulating their development proposals within the framework of their culture (APCOB 2017). An important part of its mission is to:

- Investigate, recover, and enhance the knowledge and cultural practices developed by indigenous peoples to help strengthen their culture.
- Inform and make known to the national society the different aspects of history and culture of the indigenous peoples of the lowlands of Bolivia to contribute to the democratization of the country within the framework of interculturality.

APCOB has worked with indigenous organizations and other NGOs in Bolivia to build a vast collection of multimedia materials of indigenous knowledge about culture and economic practices in Bolivia. The project uses a variety of multimedia applications including video, audio recordings, and images to develop school materials about their indigenous cultures for use in primary and secondary schools. The materials are used to enrich subjects such as history, geography, culture, and languages and are also used for teacher training. Efforts are underway to integrate the materials in the national curriculum and to include this initiative as part of the Bolivia ICT policy for the education sector (IICD 2016).

Thailand Initiatives to Address the Digital Divide and Revitalization of Indigenous Knowledge

Thailand has a very high literacy rate of 93.5% as of 2014 (Kasichainula 2016). It also has a significant urban-rural digital divide. During 2005–2014, computer users increased both in urban and rural areas. In urban areas, computer users rose from 35.5% of the population in 2005 to 47.8% in 2014, while those in rural areas rose from 19.7% to 30.4%, representing a significant but narrowing urban-rural gap (Malisuwan et al. 2016). The national *Digital Thailand* plan includes four phases to eliminate this gap and develop Thailand into a fully digital country.

The *Thai Learning Technologies 2010* report (Ainley et al. 2010) notes that technology can be used to strengthen Thai knowledge and culture by providing wider contact with Thai culture so that people can access heritage sites that they might not be able to visit and have access to other resources central to Thai and indigenous culture. It recognizes that formal education provided in school does not provide sufficiently for learning about Thai culture. Many people who are capable of transferring this special knowledge are not widely available and are aging (Kaewdang 2000). Their knowledge and skills need to be made accessible using technology (Trankansuphakon and Khamphonkul 2006).

There is recognition of the challenges in using digital technologies to revitalize indigenous culture and knowledge. As noted by Oppeneer (2010), there is concern that when misapplied, the consequences of ICT can be to bring mass media, popular culture, and global languages that can potentially conflict with local traditions. Mander (1991), for example, describes the rapid negative impact of mass media on indigenous culture within a Native American community in Northern Canada. However, as noted in the earlier sections (e.g., Four Directions Project), there are ways to use digital technologies in appropriate ways that help support the continuity of indigenous language and culture.

The Inter-Mountain Peoples Education and Culture in Thailand (IMPECT) (Saenmi and Tillmann 2006) uses digital technologies to support cultural identity and knowledge. An example of their approach is the “Footholds in the Hills” project. The initial phase of the project emphasized the collection of local knowledge and forms of cultural heritage in conjunction with the communities. This collection and selection process served as the basis for the development of a series of media for cultural knowledge transmission involving the community to support implementation of teaching activities. The following four areas were identified as essential for successful implementation:

- A multi-faceted understanding of community life and inter-community relationships
- Techniques and training in formal and nonformal teaching for elders and customary knowledge experts
- Participation of community members and community groups to maintain and sustain interest and motivation
- Interrelation between effective work on cultural knowledge transmission and early childhood development and solving wider community problems

The IMPECT approach provides an example of how digital technologies and media may be used to enable and empower indigenous communities to move toward self-determination and to create the conditions for the continuity of indigenous peoples lives and cultures in modern states.

Technology, Education, and Cultural Diversity Center (TEC) Program and Cultural Identity: Israel

The TEC at MOFET and Kibutzim College in Israel has been a leader in the use of technology to support cultural diversity and cross-cultural understanding. The center develops and implements a collaborative learning model based on advanced technologies for teachers, preservice teachers and pupils from different ethnic groups and religions, yielding constructive dialogue and cooperation between diversified groups, and eventually tolerance and mutual respect (Shonfeld et al. 2013).

The collaborative learning model of advanced internet technologies is implemented within small teams from diverse cultures by the educators of the participating groups, progressing gradually from on-line communication (written, oral, video) to face-to-face interaction. Through collaboration in joint assignments over a period of 1 year, team members get to know each other, develop mutual respect, eliminate stigmas, and reduce mutual prejudices. The in-service educators then implement the program in public schools, and thus serve as major agents of social change, having influence on generations of students. Research has shown that the TEC Model yields outstanding results and its impact (Walther et al. 2015).

Each year, the TEC center more than doubles its activities (TEC 2017). More colleges and schools join the project and more courses are offered. Research shows that the program is making a big difference in attitudes to technology and to other cultures (Magen-Nagar and Shonfeld 2017; Hershko and Shonfeld 2017). In addition, other countries in the world are using the TEC model. Since 2005, tens of thousands of Arabs and Jewish teachers, students, lecturers, and pupils have worked together on yearlong projects. The center provides a social network in three languages – Arabic, Hebrew, and English – for safe online collaboration, as well as a “virtual Island” where Arab and Jewish children can meet online using avatars to talk and carry out activities together. It is unique in that it brings together Arabs not just with secular Jews but also with religious Jews where fear and mistrust is the greatest. The activities of the center have created a ripple effect on the parents, the other teachers in the school, other pupils and the whole community. The fruit of all these projects is represented in the annual TEC International Online Day.

In 2017, “Grandma’s Stories” was the theme for the TEC International Online Day where thousands of children, teachers, preservice teachers, leading scholars, renowned researchers, and policy-makers from different cultures locally and internationally connected to discuss/present grandma’s stories and to interact together in protected online and virtual environments. The universal term Grandma’s Stories may have different interpretations in different cultures. It may refer to her wisdom stories, or that her tales are something from the past and thus are not valid today, or it may refer to the healing cooking recipes she always offers for every disease/ailment.

For most people, grandmother's tales, stories, and recipes are viewed as the cure for everything. Grandmothers have a special charm and magic. For most children, even though their mothers may know a lot, grandmothers always have the answer for everything! Grandmothers across the globe always make time for their grandkids, share wisdom, show patience, give joy, and, of course most of all, they give love and affection (see URL: <http://www.mofet.macam.ac.il/tec/tecdays/eng/Pages/default.aspx>).

The TEC Center's goal is to assimilate the model of online cooperative learning in the school system to change preconceptions, prejudices, negative opinions, and stereotypes that affect Arabs and Jews, and religious and secular Jews in Israel, from an early age. The program's goal is to develop intercultural relations in cyberspace, connect young children in the school system, and start a discussion that will lead to understanding between the different cultures in Israel's divided society.

As a preparation for taking part in TEC International Online Day, the students are asked to write a family story or any piece of knowledge, as prose or a poem, they have heard from an older family member, like their grandparents. The story must be significant to them in forming their identities. Prior to the participation of the TEC college students in the TEC International Day, the diverse groups share a google doc where each member writes about his/her cultural identities within their multiple identities and they discuss it together.

Conclusion

The above are examples of the ways that ICTs can be used as a tool to revitalize culture and to foster cross-cultural understanding. Such efforts are critically needed to prevent the further loss of local and indigenous cultural knowledge and resources that contribute to the cultural richness of our world. Concrete actions at multiple levels could use the affordances of modern technologies to preserve cultural richness. For example, governments could work with universities and indigenous organizations to engage in similar initiatives and to establish policy structures that will enable indigenous peoples, and other unique cultural communities to work in partnership with ministries of education and universities, to provide culturally responsive learning opportunities for their children through the use of ICTs. By doing so, they will help the indigenous and local cultures in their countries to fully participate in knowledge societies (World Summit on the Information Society 2003). Various cultures, having been diminished in previous centuries, now have a new opportunity to expand knowledge of their values and inherent specialties via the Internet and to share with everyone their diverse culture and colorful native customs. This is the way ICT may help revitalize and support cultural diversity and cultural identity.

Abstract

This chapter aims to present what could be the contribution of a socio-critical approach for the benefit of digital equity in education. It begins with the presentation of the main issues of digital equity in education. It continues with the presentation of the need and the foundations of that socio-critical approach on digital technologies in education and ends with the main lines of research aligned with such a perspective.

Keywords

Sociocritical perspective · Digital technologies · Digital equity · Integration · Education

Issue of Equity in Education

According to OECD (2013, p. 15), equity in education can be seen through two dimensions. The first dimension is **inclusion**, which means “ensuring that all students reach at least a basic minimum level of skills. Equitable education systems are fair and inclusive and support their students to reach their learning potential without either formally or informally pre-setting barriers or lowering expectations.” The second dimension is **fairness** which “implies that personal or socio-economic circumstances, such as gender, ethnic origin or family background are not obstacles to educational success.” In that case, an **equitable education system** can be considered as “high performance among students from all backgrounds, rather than as small variations in student performance only” (OECD 2016, p. 6).

Besides this OECD definition, the Glossary of Education Reform proposes a definition which is centered on the fairness dimension: “In education, the term **equity** refers to the principle of *fairness*. While it is often used interchangeably with the related principle of *equality*, equity encompasses a wide variety of educational models, programs, and strategies that may be considered fair, but not necessarily equal. It has been said that “equity is the process; equality is the outcome,” given that equity – what is fair and just – may not, in the process of educating students, reflect strict equality – what is applied, allocated, or distributed equally” (Online, <http://edglossary.org/equity>).

Even if this definition presents only one dimension of the OECD definition, it adds an element that does not appear in it. That is the difference between equity and equality, suggesting that the first is a process whereas the second is an outcome. As a process, equity in education is complex and should be analyzed regarding the different levels of the social ecosystem in which education takes place and where inequalities and inequities occur. These levels are the following ones: the micro-system (e.g., inequities in families and classes), the mesosystem (e.g., inequities in a milieu where schools are located), and the macrosystem (e.g., societal inequities). Indeed, researchers in sociology of education clearly explain the process of reproduction of social inequalities in the social environment where learning and development occur. According to the French sociologist Duru-Bellat (2006), social inequalities become educational inequalities by the fact that they are drawn from: (1) the unequal environments through which children develop; (2) the differentiated socializations that cause unequal preparation of children for school requirements and inequalities in cognitive development and general skills; and (3) parental educational practices marked by material or cultural inequalities of families. These inequalities extend to the school setting, which then becomes the place of production of inequalities and hierarchies, and generates differences in the learning contexts. As consequences, within the school, the outputs of learning are not of the same value and lead to social inequalities of employment, income, and career. By the way, the vicious circle of inequalities has other facets, such as the fact that socioeconomic inequalities determine political inequality in terms of participation, representation, and influence (International Council of Science (ISSC), the Institute for Development Studies (IDS) and UNESCO 2016).

Apart from this introduction, which provides a general explanation of the factors that may affect equity in education, this chapter focuses on digital equity in education. This is one of the main challenges that education systems face because digital inequities reinforce pre-existing inequities at the different levels of the social ecosystem in which learning and development happen (Gorski 2009). It is therefore important to develop a sociocritical perspective on digital technologies in education in order to unmask these different forms of digital inequities that work for the benefit of dominant relationships and against the principles of equity, inclusion, and social justice.

Relevance of the Sociocritical Approach on Digital Technologies for the Foundations of Digital Equity

The relevance of the sociocritical approach of digital technologies in education is based on the observation that research on digital educational uses has mainly focused on teaching and learning in an institutional context (Bayne 2014; Erstad et al. 2013; Ito et al. 2013), in particular with a view to measuring their impact (Eynon 2012). Without calling into question the relevance of these studies, a growing number of researchers are calling for a better understanding of the digital era in education in terms of its dynamic relationship with educational actors in the social and cultural contexts within which this relationship takes place. From a pedagogical point of view, the sociocritical approach of digital education makes notice of the profound changes currently under way in learning (Le Douarin 2014): on the one hand, mobile digital technologies are increasing across educational and noneducational contexts (Erstad 2012); on the other hand, the boundaries with leisure, socialization, family, or work are increasingly porous (Sharples et al. 2006). This offers an opportunity to develop pedagogical and didactic innovations aimed to better link learners' out-of-school digital practices with the use of technologies in formal learning contexts. In doing so, it highlights fundamental contemporary issues such as lifelong learning, which is a growing professional demand, and digital inequalities that explain why individuals do not benefit from it in the same way (Bukodi 2017). As such, it helps to create the conditions for digital equity. As Resta (2011, p. 1) said, "Technology has transformed all aspects of society, including the teaching-learning process. It is critical that specific groups within our society not be excluded from the benefits of these new developments. Not only must digital equity continue as a priority goal of all nations, but efforts to move toward digital equity also must be mobilized, focused, and coordinated to prevent the development of a permanent underclass in global society."

Although the sociocritical approach has multiple origins (De Munck 2011) and is not uniform and homogeneous (George 2014), it has been widely developed in the disciplines concerned with the relations between technique and society. It also appears sometimes implicitly and always heterogeneously in the work of several researchers working in the field of digital education (Albero and Thibault 2009; Beynon et al. 1989; Bruillard 2011; Bulfin et al. 2015; Chaptal 2003; Collin et al. 2015; Cuban 1993; Dieuzeide 1982; Jacquinet 1981; Moeglin 1993; Selwyn 2010).

Foundations of the Sociocritical Approach for Digital Equity in Education

Three main premises can be considered as the basis of the sociocritical approach to digital education. First, the sociocritical approach is based on the main premise that students develop a “first” relationship to digital technologies in an out-of-school context as digital technologies are part of the family environment in developed countries. It is also now well established in the sciences of education that children do not arrive in school deprived of all representations and practices with regard to ways of being and behaving. For example, many works (e.g., Penoup 1999) show that students have an initial relation to writing before writing becomes the subject of learning in the school context. Thus, Barre-de-Miniac (2000) defines the relation to writing as the set of “conceptions, opinions and attitudes, with more or less great distance and more or less great involvement, but also values and feelings attached to writing and its learning and uses” (p. 13). The “relation to” is forged by each student on the basis of his own experiences (e.g., essays, failures, successes, self-interest) as well as in collective experiences (belonging to various social and cultural groups) in a complex interlacement. “The social and cultural groups in which students move develop the writing uses and their associated values which contribute to the development of the relationship to the writing of each individual and interact with different variables taken [...] from the standpoint of singularity” (Barre-de Miniac 2000, p. 14). Like in the case of the relation to writing, the sociocritical approach on digital technologies in education considers that students have prior representations, access, uses, and digital skills which will continue to develop in a concomitant manner with classroom-based uses of digital technologies.

The understanding of this relationship to digital technologies, constructed in an out-of-school context, leads to two other premises. First, the out-of-school context remains throughout the students’ schooling, the main context within which they construct their relationship to digital technologies. As such, several studies show that students’ access and digital use occur much more frequently outside school than at school (Buckingham 2007; Eynon 2008; OECD 2010), the latter struggling to take over digital technology (Cuban 1986; Leask 2011; Maddux and Johnson 2012; OCDE 2011; Underwood and Dillon 2011). The notable difference between out-of-school and school contexts leads some authors to speak of a new digital divide opposing the formal technology use at school and the many ways (e.g., formal, informal) learners are using them in their daily lives (Buckingham 2007). The extracurricular context is thus coconstitutive of the students’ relationship to the digital technologies since: (1) a great majority of students begins to develop that relationship at varying degrees before school, with accessible tools at home; (2) the out-of-school context remains the main context for students’ access and digital use. From this perspective, we argue that the school context, given its current low level of IT integration, plays a secondary role in the construction of students’ relationships to digital technologies. This interpretation requires a careful consideration of how one’s relationship to educational digital uses is built out of school. The results of the study reported by De Haan (2004) may be reported here. In this study, three competing

hypotheses to explain variations in digital skills among students were tested: (1) **the hypothesis instruction**, which postulates that variations in digital skills are due to differences in computer equipment in schools and to the quality of digital skills; (2) **the selection hypothesis**, which states that variations in digital skills come from the general intellectual skills of pupils (which are the basis for students' selection by schools in the Netherlands); (3) **the social background hypothesis**, which states that digital skills vary essentially according to the sociocultural profile and context of the students. The results of the study indicate that only social origin could explain the variations in digital skills between students.

The third and final premise assumes that this first relationship to digital technologies, constructed in an out-of-school context, can impact students' learning and subsequent socio-professional development. Although this relationship remains to be clarified, several studies have already established links between the variable students' digital uses and their ability to benefit from them for educational and other purposes (Hargittai 2002; Livingstone and Helsper 2007). An OECD (2010) study on data from the 2006 Program for International Student Assessment (PISA) concludes that the academic performance of students is more strongly correlated with their digital uses in nonformal contexts than in school context. It is therefore possible to think that the relationship developed by students with regard to digital technologies in an out-of-school context offers more or less potential for learning and therefore influences their willingness to learn with digital technologies in school context.

To sum up, the sociocritical approach to digital education in education is based on three main premises rephrased here: (1) students have a digital relationship growing out of their individual experiences and their belonging to sociocultural groups; (2) this relationship to digital technology develops mainly in out-of-school contexts, both before and during schooling; (3) it is likely to influence their willingness to learn with digital, especially in the school context.

Anchored in education, the sociocritical approach is particularly concerned with the educational relationship that students develop, to varying degrees, toward digital technologies. On the basis of these premises, the proponents of the sociocritical approach postulate that students' digital educational uses can only be fully understood if their sociocultural context and profile are taken into account. Selwyn (2010) is explicit on this point by stating that "whilst perhaps not immediately apparent to the observer of a classroom setting, it would be foolhardy to attempt to explain any aspect of education and digital technology in the twenty-first century without some recourse to these wider influences [the social 'milieu' of technology use]" (pp. 67–68). Hence, it is important to analyze digital inequalities in education by considering their roots in the broad sociocultural context in which learners evolve, both in institutional and extrainstitutional contexts of learning (Gudmundsdottir 2010; Brotcorne and Valenduc 2009; DiMaggio et al. 2004). As an illustration of this, Gudmundsdottir (2010), who conducted a study in South Africa, explored factors influencing the digital divide in four schools in Cape Town, South Africa. Among those schools, three were for disadvantaged learners whereas the fourth was for privileged white students. The results indicated that even if all these schools use

technologies in their curriculum delivery and despite substantial efforts made by educational authorities to increase ICT access for learners and teachers in public schools in Cape Town, digital equity has not been reached when digital competence for different groups was compared. “The differences in ICT skills were affected by learners’ opportunities outside of school to access and use computers. . . the vast differences in learners’ access and use outside of school are highly connected to wider social inequalities within society” (p. 98). The results of this study also show that the problem of digital equity cannot be apprehended by isolating it from the sociocultural context taken in the very broad sense and which secretes inequalities.

Main Lines of Research for the Sociocritical Approach

As the sociocritical approach addresses the sociocultural dimensions that contribute to shaping students’ relations to digital technologies, it necessarily implies a critical posture, which is in line with the work of the Frankfurt School (Friesen 2008). This critical posture assumes that “all knowledge, even the most scientific or commonsensical,” is historical and broadly political in nature (Friesen 2008, online). In a somewhat schematic way, it is based on two key principles (Bayne 2014; Buckingham 2007; Friesen 2008, 2013; Warschauer 1998): (1) The first places the object of study in its sociocultural context and in its historical evolution, on the assumption that no object of study is approached in a neutral and objective way; (2) The second brings to light the power relations and multiple and contradictory interests of a political, economic, social, or other nature that shape the object of study and the knowledge related to it. The aim of the critical posture is not to denounce the interests of some at the expense of others, but to start from this “state of affairs” in order to develop a complementary or alternative knowledge that takes into account social, economic, and cultural aspects, and ultimately aims at social justice.

Based on these two principles we suggest four important lines of research. The first line could be the **Contextualization of the digital technologies in the historical filiation of the technical objects that have penetrated education**. In this perspective, it is important to understand the extent to which digital tools should be placed in the long history of technical objects in education. The second line of research would deal with the **Contextualization of digital technologies in the economic, political, and ideological logics** that privilege certain values and purposes rather than others, and which are more or less compatible with the missions of the school. With this line of research, it should be important to understand the motivations and interests underlying the integration of digital technologies in education and grasp to what extent they serve the educational goals.

The third line of research should focus on the **Contextualization of the digital technologies in the daily life of the educational and para-educational actors, as social individuals linked by relations, roles and norms that vary according to the interlocutors, the places, the social classes, and ethno-cultural belongings**. For example, the research should focus on how digital technologies contribute to reconfiguring or maintaining educational roles, the school form, the relationship to

knowledge, and the time and place of teaching and learning. It should also analyze the extent to which digital uses in institutional context are in continuity or in discontinuity with the noninstitutional digital uses of educational actors. This line of research is important when we take into account the profound changes induced by digital technologies in learning and in the relationship between educational actors.

Finally, given the complexity of the issues raised by digital technologies, the fourth area of research for the sociocritical approach to digital education should be the **Contextualization of digital technologies in relation to the disciplines concerned by the understanding of the relations between technology and society**, while specifying the educational issues that are specific to this field of study. The question that could guide research should be, for example: What are the interdisciplinary contributions to the understanding of the relationship between technical objectives and education?

Conclusion

The purpose of this article was to present what could be the contribution of a sociocritical approach on the integration of digital technologies in education to the understanding of issues related to digital equity in education. In order to do this, we began with a brief presentation of the main issues of equity in education. We then demonstrated the need for a sociocritical approach to grasp the contours of digital equity in education and we presented the foundations of this approach. Finally, we presented the main lines of research that we believe are fundamental for the sociocritical approach of digital education to advance knowledge in the field of digital equity in education. We believe that this approach is indispensable to complement learning methods that seek to reduce digital inequalities and thereby promote digital equity.

Abstract

This chapter addresses digital equity in the classroom for students with learning differences, as well as the role of technology in the provision of equitable education for the full diversity of students. The chapter discusses the evolving opportunities and challenges that information technology in the classroom presents to students with learning differences and their teachers.

To meaningfully understand this topic requires an understanding of the complex context, the forces at play, and their relation to students with learning differences. Among the forces at play are policies, regulations, the accessibility movement, technical trends, instructional design strategies, educational publishing, open education resources, pedagogical trends, quality control approaches in education, and governance of formal education. The chapter highlights the benefits to all students of designing the classroom experience for students with learning differences.

Keywords

Inclusive design · Inclusive education · Accessibility · Open Education · Equity · Diversity · Inclusion

Introduction

Todd Rose (2015) in his book *The End of Average* amasses evidence that there is no average or typical student and that we all have learning differences. We are each a jagged, variable, and evolving set of characteristics and skills. There is no one that fully conforms to the collective notion of average and individually we rarely conform to our notion of our typical selves.

Despite this insight, our formal education systems are still largely based on the industrial model of education: attempting to create standardized learners by socializing conformity and then rating, ranking, sorting, and thereby assigning the destinies of students. If our aim is to produce a standardized learner, learning differences become a problem.

Other fields view diversity as a necessity for survival, not a problem. Our formal education system lags behind in recognizing the benefits of diversity. Economists and natural scientists have long understood the importance of diversity and diversification for dynamic resiliency and innovation. Even corporate cultures have integrated the insights of researchers such as Scott Page that diverse perspectives make for better planning, problem solving, prediction, and innovation (Page 2007).

Students identified as having disabilities are at the extreme edges of the jagged scatterplot of difference. We assign the label of “disabled” when it is either impossible or extremely difficult to conform to standard expectations. As such these are the students that most feel the effects of educational inflexibility. Conversely, they may

also be the greatest impetus for greater systemic adaptability, to the benefit of all students (Treviranus 2016).

What Is Disability?

Conventional views of disability frame disability as an absolute and personally defining trait and thereby divide the world into people with disabilities and people without disabilities. This is reinforced by services or exemptions for people with disabilities, which require certification of disability status (e.g., individual education plan, wheelchair accessible parking, funding programs for assistive technology; see <https://www.ssa.gov/disability/professionals/bluebook/listing-impairments.htm>). A definition of disability arising from the design domain contests this binary view. The definition frames disability as a mismatch between the needs of the person and the environment, product, or service offered. In the realm of education, this would be a mismatch between the needs of the learner and the learning experience offered. This implies that anyone can experience a disability if presented with a design that does not match their needs (Treviranus 2014a).

Given that needs are personal and diverse, this also implies that it cannot be determined whether something is accessible until one takes into consideration the unique needs of the individual, their context, and their goals. Accessibility is relative and evolving. All students potentially face barriers to learning. Like barriers faced by students with disabilities, these can be seen as a product of a mismatch between the needs of the learner and the learning experience and environment. Learning needs that affect learning can include:

- Sensory, motor, cognitive, emotional, and social constraints
- Individual learning approaches
- Linguistic or cultural preferences
- Technical, financial, or environmental constraints

Using this framing, an accessible learning experience is a learning experience that matches the unique, diverse, and evolving needs of each student.

Formal Education System and Impetus for Change

Our formal education system is a highly complex system of systems, in part constructed to buffer or resist external influences for change (Treviranus 2016). The classroom itself is a complex system with connections and dependencies to many other nested and overlapping complex systems including the school administration, educational authorities, the digital technology industry, the publishing industry, parents, the local community, policy frameworks, and sources of funding. Any fundamental change of the

education system to adapt to learning differences at the edges of the jagged spectrum of student needs must take these nested and entangled systems into account.

Education as a Human Right

The formal education system has encountered many forces for change over the last 50 years. One precarious force is a nearly global commitment to education as a human right (e.g., the Salamanca statement with 95 nations as signatories, the Convention on the Rights of Persons with Disabilities (2007)) (Ainscow and Cesar 2006; United Nations General Assembly 2007). The commitment has yet to be kept. The response has been varied. One compromise has been to create segregated, separate systems of education for students with extreme differences. This has been countered with the social justice demand for integration (Dixon 2005). The integration argument comes from the perspective of students that are excluded, but an equally cogent argument can be made from the perspective of the mainstream in that segregation denies the majority the positive influences for diversification, flexibility, and adaptability. All students are different and benefit from education designed to support and nurture that difference. Society benefits when that difference can be leveraged to create more choices, provide more perspectives, find new competencies, and see innovative approaches not considered before.

Digitization and Global Connectivity

Another hugely disruptive force, which has demonstrated the change-resistant nature of our formal education system, is the move to digitization and global connectivity. Beyond the buffer of our classroom walls, digital technology and connectivity have significantly changed the reality, or future, students are to be prepared for by education. Formulaic and standardized skills can be taken over by machines, computers generally have more accurate factual memories than people, and mechanistic calculation can be left to computing (National Research Council (U.S.). Committee on Defining Deeper Learning and 21st Century Skills et al. 2012). At the same time collective, distributed production has never been easier, expertise is publicly available, and we are drowning in unfiltered information. Reduction through a popularity and affinity filter appear to be our primary means of synthesizing information and dealing with growing complexity; this has resulted in rising populism, tribalism, and social fragmentation (Treviranus and Hockema 2009).

Currently, there is a dawning understanding that as a society we need collaborators, critical thinkers, and the skills and characteristics that machines do not address. One of these characteristics is the fostering of divergent skills, combined and thereby multiplied, to address the complexity of our current global reality (Weigel 2002). Our formal education systems appear to be structurally biased against answering this challenge. A positive transfer effect, of the demand to accommodate students with learning differences, may be to disrupt this structural bias and stretch our education systems to support and even foster diversity. Redesigning education to address the

needs of students with learning differences logically benefits all students and society as a whole. Disability, often occupying the outer edges of difference, crosses all cultural, geographic, political, economic, age and divides and touches all lives. Accessibility for students with disabilities is in everyone's interest.

The Opportunities and Challenges of Digitization and Global Connectivity

For students with learning differences, digital systems and computer-mediated learning provide both an opportunity and a risk. If designed correctly these systems can unlock previously inaccessible learning experiences and overcome many barriers to access. However, if not designed inclusively, these systems amplify and speed disparities between students that have digital equity and those who don't. These systems then not only feed into vicious cycles of exclusion but also exponentially amplify their effects.

Opportunities

When computers are configured to enable alternative means of presentation and alternative means of control, they act as powerful translation devices for students and teachers who cannot use the standard means of accomplishing academic tasks. Visual information and text can be translated into speech, sounds, or tactile signals: through screen readers, refreshable Braille displays, or haptic interfaces, for example. A variety of voluntary actions can be translated into the equivalent of keyboard and mouse/trackpad input. These voluntary actions might include speech, pointing with your head or foot, or activation of switches through discreet movements of any body part, including blowing or sipping, and contracting muscles, or even through repeatable patterns of brain activity read by an electroencephalogram (EEG) device. For students who face barriers to traditional modes of engaging in academic activities, computers thereby act as a path to speaking, writing, reading, experimenting, manipulating learning materials, and researching (Alper and Raharinirina 2006).

Digital content is far more flexible and mutable than print. Many students experience what has been termed a "print impairment" that makes access to traditional printed curriculum difficult or impossible, including students who:

- Cannot see print
- Have difficulty seeing print because of the size and contrast of standard print materials
- Have difficulty decoding text
- Cannot hold and manipulate a physical book or page

Digital learning materials, if designed correctly, offer many advantages (Thomson et al. 2015):

- Text can be translated to speech for students that cannot see or decode text (e.g., students that are blind or have dyslexia).
- Content can be magnified, spaced, and presented in higher contrast for students that have difficulty seeing.
- Distracting materials or complexity can be reduced or hidden for students that have difficulty with focus.
- Manipulation and navigation of content can be controlled through available alternative voluntary actions (e.g., head movements, vocal command, puff or sip, for students with paralysis or reduced dexterity).

Networks and global connectivity can connect students, teachers, and parents, who have minority or outlying needs, with connections to others that share these needs. Global connectivity can also reduce redundant production of learning material variants (e.g., a text description of a visual graph or a text caption of a video). Global networks have been used to crowdsource and cooperatively create alternative formats such as captions of audio in videos for students that have difficulty hearing (<http://amara.org/en/>).

Rapid prototyping tools allow the rapid customization of physical materials and tools. These include holders, handles, stabilizers, switches, buttons, and device casings to make controls easier to hold and manipulate (Buehler et al. 2014). Internet of things' sensors, monitors, and actuators enable the creation of smart environments that can be responsive to diverse personal needs (e.g., controlling light, heat, and security) (Domingo 2012).

The major caveat to all these disruptive opportunities is *if* designed correctly. The systems and their associated practices must be designed to support human diversity. To accomplish any of these potentially liberating functions, digital systems must support the flexible transformation, augmentation, and replacement of both presentation (e.g., visual, through speech and sound, or tactile), and means of control, and the integration of scaffolds and supports. The design must acknowledge that humans are diverse, not typical or average.

Risks and Challenges

Since the emergence of personalized computers and the ubiquitous proliferation of network connectivity, there have been numerous trends that have both threatened and promoted support for human diversity in the socio-technical ecosystem.

Some of the most change-resistant systemic threats are associated with traditional market models. A competitive market compels a producer to strive to address the largest customer base and to protect their hold on their market share through proprietary practices. Proprietary practices hamper interoperability, excluding anyone who does not fit into the constrained boundary of the customer majority.

Supporting human diversity requires interoperability between the various components or parts in the socio-technical ecosystem (Treviranus 2014a). The range and extent of diverse human requirements demands a plurality of developers and suppliers. The original designer, developer, and producer cannot be expected or relied

upon to anticipate or address all of the diverse human requirements. In as far as digital systems are modular and “mashable,” new, unanticipated, alternative interfaces or user experiences can be added, or the existing ones can be adjusted or augmented. This requires open, transparent, commonly agreed upon protocols or open interoperability standards for software and hardware and open data formats. These provide the common meeting place from which the human interface can diverge.

Entities at the margins of a domain are the first to feel the effects of problems within a domain. Such is the case for the alternative computer access system (or assistive technology) producers at the edge of the digital market. Most mainstream applications and devices are designed to address the needs of a typical customer. Assistive technology is relied upon to bridge the divide between the needs served by the standard product and the needs of people with disabilities. For students who can't use a standard computing device, they must acquire both the standard device and an assistive technology that more closely fit their unique needs.

The producers of these assistive technologies face two major challenges. Because they are serving a customer base that is more diverse than any other (the only common characteristic of disability is difference), if they do their job well, they will have a relatively small customer base for any one design. At the same time, they need to ensure that their product will interoperate with all of the applications, browsers, operating system utilities, and peripherals on the computing device their customers use. This means interoperating with a huge variety of frequently updated applications that may be mashups of many components, with difficult to determine provenance. To make matters worse, most of the developers of these mainstream applications are reluctant to share information about how to interoperate with them. As a result the alternative access system industry is struggling, causing a limited supply in even the most well-resourced countries. Because of limited supply, and public funding rules that restrict funding to only qualified vendors and products, alternative access systems available to students with disabilities are relatively expensive. The systems frequently suffer from interoperability problems, meaning that many functions or applications are not available to students that rely on alternative access systems. Because of the technically and economically difficult market, there is a decrease in the alternatives available to students with needs at the edges of this already marginalized group, such as students that have severe motor limitations. As a result, it may cost more than ten times as much for students with disabilities to get online (Khetarpal 2014). Digital access is getting less expensive, faster, more reliable, more multifunction, and more ubiquitously available for students that can use mainstream products. The opposite is often true if you have a disability and cannot use a standard access system. This produces a broadening technology gap that compounds the disparity these students already encounter.

Promising Trends

One promising trend that circumvents some of these limitations is when the manufacturers of the standard products include and integrate assistive technology features directly into their products. Examples of this include the availability of screen reading functions in touch screen devices, voice recognition as a standard feature,

and word prediction or character disambiguation in on-screen keyboards (Brunet and Ramachandran 2016). Another promising trend is the availability of open-source assistive technologies. This is especially beneficial to students in the many countries that do not have an assistive technology industry (Ptolomey 2011).

Another very promising trend is the adoption of inclusive design as a corporate-wide design strategy, as has been exemplified by Microsoft Design (<https://www.microsoft.com/en-us/design/inclusive>). Microsoft is leveraging the insights and innovations inherent in designing for and with people with disabilities to improve their products overall. The design team has adopted and advanced the inclusive design toolkit of the Inclusive Design Research Centre as an enterprise-wide strategy (Kuang 2016). The trade press has suggested that this has helped to make Microsoft “cool again” (Anderson 2016).

The ease of copying, which digital systems afford, has acted as a disruptive counterforce to proprietary systems that cater only to the typical consumer. This has created “zero marginal cost” markets for many commodities, including books and music, or replication and mass production with negligible cost after the first instance of a product (Rifkin 2014). New market models, which leverage the diversity and innovation that comes from openness and interoperability, have emerged in the form of platforms that leave the creation of variants to the world at large (e.g., IOS apps, Android, YouTube, etc.). These provide ecosystems that enable diversification of designs, but also means of finding variants that fit unique needs.

The Promise and Challenges of Open Education Resources

This market tug-of-war has played out in the education domain in the form of competition between established educational publishers and nascent openly licensed education resources or open education resources (OER). OER provide greater equity for disadvantaged regions globally and students who are economically disadvantaged. OER are openly licensed to support what are referred to as the “5R Permissions of OER,” the right to:

1. Retain and make your own copies
2. Reuse in a wide range of ways
3. Revise, adapt, modify, and improve
4. Remix by combining two or more
5. Redistribute to share your contributions with others (Lumen Learning 2014)

OER thereby offer the potential to create many variants and choices to match the variability and diversity of student needs. This same latitude and variety is not available to mass-produced, copyright-protected traditional publishing.

Students who require alternative formats (and their parents and support services) report spending inordinate amounts of time and energy addressing digital rights management (DRM) restrictions that prevent the creation of variants and lock out the opportunity to translate from one modality to another (Whitehouse 2008). While hard-won exemptions to DRM restrictions for students with print disabilities

have been granted in certain markets (e.g., the Marrakesh Treaty) (Fitzpatrick 2014), the burden to prove that a student has a disability and the parallel supply chain that is required to acquire an alternative format textbook result in an onerous process for an already taxed student and their support system. The open licenses of OER would circumvent this complex and difficult means of acquiring accessible learning material.

The most acrimonious battlefield has been in the United States where educational publishing has been an extremely lucrative and well-entrenched market. In the primary and secondary grade market, large textbook publishers are aided by a highly competitive “textbook adoption” framework that structures competition for public funding in such a way that large profits are guaranteed to the winning textbooks and other choices are left with little support (Petrides et al. 2011). Textbook adoption was enacted to promote, protect, and curate the quality of textbooks that receive public funding. The design of the curriculum and textbook ecosystem then further entrenches this competitive advantage by granting management of textbook clearinghouses to these same winners in the adoption contest, thereby granting further advantage to the dominant publishers. Students with disabilities have been used as a “pawn” of sorts in this battle. To understand the complex role that students with disabilities have played in this struggle requires an understanding of regulatory frameworks that support accessibility.

Accessibility Regulations and Laws

Accessibility, or design that works for people with disabilities, is a precarious value: most people agree that it is important, but it is one of the first things to be compromised when other pressures arise, such as time and budget constraints. To protect this precarious value, progressive public institutions and governments have been compelled to create laws, regulations, and policies that oblige accessibility. However, laws, regulations, and policies are very blunt instruments. They are most effective in changing behavior when compliance can be easily tested using consistent, objective measures. Creating clear, concise, objectively testable criteria inevitably requires reduction and compromise. It does not lend itself to enumerating the broad, complex spectrum of diverse needs. Thus certain needs are inevitably left out or compromised.

The Web Accessibility Initiative (WAI) of the World Wide Web Consortium (W3C) is the primary manifestation of the movement for digital equity for people with disabilities (<https://www.w3.org/WAI/>). The Web Content Accessibility Guidelines (WCAG), one of three foundational sets of WAI guidelines, are embedded in laws, regulations, and policies in many jurisdictions around the world. The WAI has produced and maintained three sets of guidelines:

1. **Web Content Accessibility Guidelines or WCAG 2.0** (Caldwell et al. 2008) define how to make web content more accessible to people with disabilities. The guidelines are divided into four overarching principles:
 - **Perceivable** – Information and user interface components must be presentable to users in ways they can perceive. This means that users must be able to perceive the information being presented (it can’t be invisible to all of their senses).

- **Operable** – User interface components and navigation must be operable. This means that users must be able to operate the interface (the interface cannot require interaction that a user cannot perform).
 - **Understandable** – Information and the operation of user interface must be understandable. This means that users must be able to understand the information as well as the operation of the user interface (the content or operation cannot be beyond their understanding).
 - **Robust** – Content must be robust enough that it can be interpreted reliably by a wide variety of user agents, including assistive technologies. This means that users must be able to access the content as technologies advance (as technologies and user agents evolve, the content should remain accessible).
- Although the WCAG guidelines address barriers to accessibility in web content, they can be applied to all digital content. WCAG also includes useful techniques and documents that demonstrate how to develop accessible multimedia content. Following these guidelines removes barriers to content and user interface transformation, making it possible to personalize Web-delivered learning resources.

2. **The User Agent Accessibility Guidelines (UAAG) 1.0** (Jacobs et al. 2000) and 2.0 in draft (Allan et al. 2010) guide

developers in designing user agents that make the web more accessible to people with disabilities. User agents include browsers, browser extensions, media players, readers and other applications that render web content. A user agent that follows UAAG 2.0 will improve accessibility through its own user interface and its ability to communicate with other technologies, including assistive technologies.

3. **The Authoring Tool Accessibility Guidelines (ATAG) 2.0**

Richards et al. (2015) provide information to web authoring tool developers about how to design tools that will produce accessible web sites as well as how to design authoring tools that have accessible interfaces. The purpose of these guidelines is to make it easier for web developers to produce accessible content even when they are not aware of or motivated to follow accessibility guidelines and to enable individuals with disabilities to participate in the construction of web content. Authoring tools that comply with the seven guidelines of the ATAG document can support accessible web authoring through prompts, alerts, checking and repair functions, and help files and automated tools. Additionally, the authoring tool will be accessible to authors with disabilities. The goal of ATAG is to encourage development of accessible web content that reaches a broader, more diverse audience as well as enable individuals with disabilities to participate fully in web culture as active creators of content.

The Challenge of Enforceable Regulations

The simplest, most easily enforced, interpretation of accessibility is an absolute definition. Any relative framing leaves room for subjective interpretation and

compromises compliance testing and enforcement. This creates a dilemma in the global community that supports digital inclusion for people with disabilities. Absolute criteria inevitably compromise or negate accessibility for individuals at the edges of the jagged spectrum of human needs or individuals that don't fit established categories of needs (e.g., individuals with multiple disabilities, individuals with disabilities that don't as yet have an associated advocacy group). These individuals are therefore, also, most vulnerable to exclusion. On the other hand, relative criteria are largely impervious to enforcement. One approach to addressing this dilemma is to require interoperability, open standards, and open formats and thereby protect the opportunity for diversification and enable the creation of variants. However, for companies that view accessibility as merely a legal risk and rely on closed, proprietary business practices, this demand for openness is seen as something to lobby against. The struggle for greater accessibility through regulations then becomes a battle of influence between established industry and advocates for excluded consumers.

Laws, regulations, and policies are also slow to change. Therein lies a further dilemma for legally enforced digital inclusion. The pace of change in the digital domain is unprecedented. Survival within the digital market requires constant innovation and responsiveness to this change. Laws that constrain freedom of movement within this environment are seen as hostile to innovation and corporate survival. Many strategically wily corporations have walked the fine line of obstructing regulations without the public appearance of hostility to accessibility and the associated public relations mistake of showing lack of concern for people with disabilities (Stienstra et al. 2007).

Diversity-Supportive Regulatory Design

Ironically, therefore, movements to legally enforce digital inclusion have been pushed to support inflexibility and to oppose innovation. To support diverse learners requires flexibility. To address unmet needs requires innovation. Several promising alternative regulatory designs have emerged, but these have not received the popular support that prescriptive accessibility checklists have received. One reason may be that popular support favors simple, literally graspable concepts rather than nuanced and indirect strategies.

Legislative strategies that are supportive of diversity and innovation include:

1. Providing a process to validate new strategies that achieve equivalent accessibility as the criteria in a regulation. This would facilitate innovative advances and would also provide a mechanism for updating the regulations.
2. Giving priority to strategic pivot points, or common meeting places that enable divergence and diversification, such as requiring open interoperability standards that allow alternative access systems to more easily connect, and open formats that can be played on a variety of browsers and players.
3. Regulating a process that results in inclusive design rather than requiring a specific outcome. This would encompass prioritizing regulations that require

that the tools used to create digital content and interfaces support designing for diversity. This approach would have the advantage of requiring compliance and understanding from a much smaller group of legally obligated entities, namely, the developers of authoring tools rather than the myriad of web content authors. An example of this strategy would be to give priority within the global Web Accessibility movement to authoring tool guidelines that represent the process, in contrast to web content guidelines that represent the outcome or product.

Compounding the phenomenon that popular support favors simple and direct ideas is the tendency to also favor immediate or short-term rewards. This combination may cause the bias against systemic interventions. System-wide interventions are more diffuse but afford far greater and more lasting impact. These interventions include:

- Requiring education and training of future producers and suppliers to include an understanding and competency in designing for diversity
- Ensuring that currently excluded individuals can participate not only in the consumption but also in the production of knowledge and products
- Requiring the participation of diverse perspectives in decision-making bodies that influence socio-technical directions

Aligning Open Education Resources with Accessibility

The legislative compromises that the accessibility field has had to make, to create regulations that can be broadly understood and enforced, has meant that the accessibility movement has become misaligned with the OER movement. OER are a potentially powerful ally that favors diversity and the innovation that is birthed by variability in education. The OER ecosystem boosts flexibility and the more long-term systemic growth that supports the emergence of designs that span the spectra of human diversity. As far as OER provide a means to create a rich array of choices, and a process for finding satisfying choices for the full diversity of students, the OER ecosystem will offer more inclusive and long-term digital equity in education. The largely unregulated, organically organized, opportunistic OER production effort, however, does not naturally lend itself to absolute criteria. Publishers that see OER as a threat have used this to their advantage and have claimed that the adoption of OER in formal education systems should be disallowed because they do not adhere to accessibility laws. A simple response, which has yet to be formally articulated by the adjudicators of this struggle, is that compliance with accessibility requirements should be judged at the system level rather than the individual resource level. Thus if the pool of resources offers options for the full diversity of learners, it is compliant with the accessibility requirements, and each resource does not need to meet all the fixed criteria. This would reduce the compromise that students, which don't fit defined categories or criteria, need to make. It would also support the innovation that comes from diversification.

This however requires a system that matches the diverse individual requirements of students with a satisfying resource or learning experience. Resourceful parents, educational assistants, and teachers have been attempting to perform this function. OER portals such as OER Commons (<https://www.oercommons.org>) and GOORU (<https://www.gooru.org/welcome/>) have begun to integrate search features that stretch to the edge requirements of students with disabilities.

The FLOE Project (<http://www.floeproject.org>) is helping to provision the OER ecosystem with an infrastructure or platform to deliver a learning experience that matches the needs of students with learning differences. FLOE aims to use the platform model to pool and share reusable resources and supportive tools that enable a growing, diverse global community to create a rich pool of learning experience variants. To achieve this ambitious goal requires OER resources that are amenable to reuse a large, diverse pool of OERs. If the default OER is inaccessible to a specific student, the inclusively designed system would either:

- (a) Transform the resource (e.g., through styling mechanisms)
- (b) Augment the resource (e.g., by adding captioning to video)
- (c) Replace the resource with another resource that addresses the same learning goals but matches the learner's specific access needs

To achieve this functionality requires:

- Utilities that help learners discover, explore, refine, and declare their learner preferences (thereby also supporting learning to learn and metacognition)
- Markup, metadata, or algorithmic means of locating resources that match specific learner needs or preferences
- A private and secure means of storing and transporting personal learner preference files from one learning experience to the next
- A matching service that can reconfigure, augment, or search and find a resource that matches a learner's preference specifications
- Supports to help OER producers to create reconfigurable resources and provide helpful metadata regarding the learner preferences the resource can match. Ideally these supports should be embedded in the tools used to create OER

The FLOE Project has created the necessary pluggable building blocks that are being integrated into projects that deliver OER. Fortunately these steps are not foreign to the OER effort but can be seen as impetus to advance the OER agenda as a whole. However this approach is helped by conceptual and practical adjustments in both the OER and accessibility communities. The approach requires that the OER community:

- Fully adopt and support the principles of cumulative authoring, derivative works, reuse, and repurposing that is already a part of the OER mantra
- Improve learner-focused resource discovery and the prerequisite labeling

- Promote an authoring attitude that lets go of the tight control on a fixed presentation or rendering
- Invest further in a learner-centric approach to resource design
- Commit to support open interoperability standards for both file formats and programming/scripting environments
- Support open source tools with open communication protocols to enable interoperability with assistive technologies
- Improve portability or device independence of resources

The accessibility community must:

- Adjust the interpretation and implementation of accessibility legislation and policy to judge accessibility by the ability of the system (rather than each resource) to address the individual needs of each student; notably this does not require that the letter or spirit of existing legislation be changed, only the interpretation and implementation
- Recognize that OER are a viable alternative to the complex, confounding, and deeply entrenched Digital Rights Management conundrum that is consuming so much accessibility effort and passion
- Let go of the focus on equivalent content and focus on equivalent learning
- Recognize that in the digital realm it is possible and effective to shift from a one-size-fits-all to a one-size-fits-one approach to providing universal access

A growing community of interest in OER accessibility, including the FLOE Project partners, supports this shift in both communities through practical tools, advocacy, and education.

The following diagram provides an overview of the FLOE process and infrastructure (Fig. 1):

FLOE leverages an international interoperability standard called AccessForAll. This is expressed both as an International Organization for Standardization (ISO) standard (ISO/IEC 24751) (http://www.iso.org/iso/catalogue_detail?csnumber=41521) and an IMS specification (IMS AccessForAll) (Jackl et al. 2004). AccessForAll supports a common language for describing personal needs and preferences (or student accessibility requirements) and a common language for describing resources that might match the needs and preferences.

Diversity-Supportive Pedagogy

Several pedagogical movements assist in the changes required by the individualized AccessForAll approach to learning design. AccessForAll and FLOE are well aligned with pedagogical models that support accessibility and equity such as Universal Design for Learning (UDL) (Rose 2000) and differentiated learning. UDL promotes three principles:

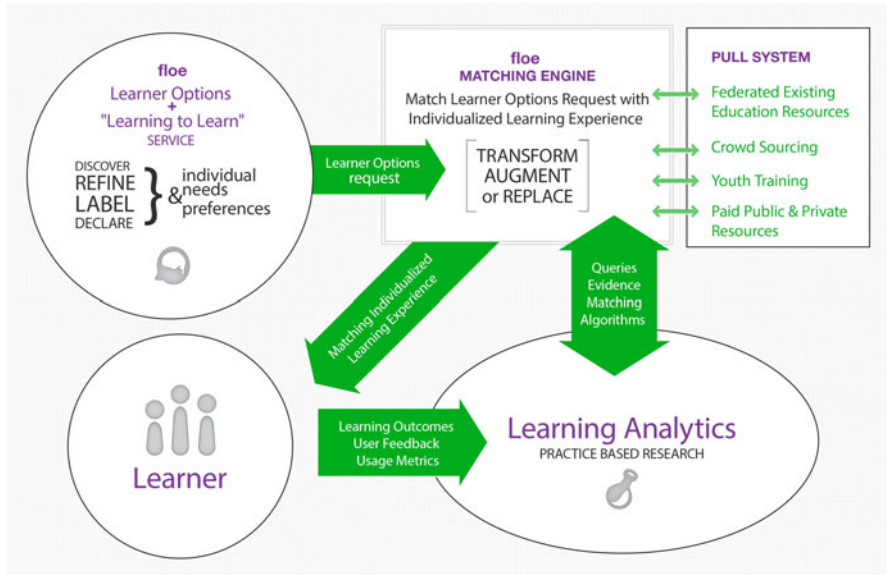

Fig. 1 The FLOE ecosystem enables the learner to refine their understanding of their needs and preferences, request a matching resource, and provide feedback regarding the match provided. This feedback provides important evidence regarding what works for learners who are outliers

- Principle I: Provide Multiple Means of Representation (the “what” of learning). This addresses perception, language, expressions and symbols, and comprehension
- Principle II: Provide Multiple Means of Action and Expression (the “how” of learning). This addresses physical action, expression and communication, and executive function
- Principle III: Provide Multiple Means of Engagement (the “why” of learning). This addresses recruiting interest, sustaining effort and persistence and self-regulation

FLOE can be said to be the network-enabled instantiation of these pedagogical frameworks.

Personalization

Projects such as FLOE, which implement AccessForAll, are also aligned with diversity-supportive e-learning trends toward personalization. Both are promoting one-size-fits-one education rather than one-size-fits-all education and the rejection of mass, “cookie-cutter” education. The trend to personalization is in part motivated by evidence that better learning outcomes are associated with personalized learning (Beetham and Sharpe 2007).

The label of personalization has been used to cover a broad range of very different initiatives. These initiatives differ in the following ways:

1. What is personalized, including the:
 - Path or sequence of steps to achieving a learning outcome, including repetition of specific items
 - Pace or how much time is devoted to each part
 - Personalization of the content used, including using local information, a favorite topic (e.g., teaching math using dinosaurs), using first and second languages at the same time, etc.
 - Presentation of the content including the style of text, magnification, color contrast, spacing and layout, density of content, etc.
 - Modality of delivery including video, audio, text, images, immersive content, etc.
 - Degree and type of interactivity, including games, quizzes, collaborative exercises, etc.
 - Form of pedagogy used, including constructivist, didactic, experiential, project based, problem based, collaborative, competitive, etc.
 - Form of motivation, including external feedback, internal feedback, affinity topics (e.g., trains, panda bears, or currently popular personalities), peer support (e.g., buddy system)
 - Form of social support, including peers or instructor
 - Scaffolds provided, including prompting, calculators, dictionaries, thesaurus, etc.
2. What kind of learning trajectory or plan is supported? This could include the following forms of planning:
 - Predetermined by education authority or instructor
 - Self-guided by students themselves
 - A formal and constrained trajectory
 - A responsive and opportunistic learning plan
 - A life-long learning plan that has no terminus
3. Who decides what and how things are personalized? This could include the following strategies:
 - Machine intelligence makes the decisions based on fixed algorithms or adaptive algorithms (and either informs the learner or does not inform the learner).
 - Educators or teachers control the factors to be personalized.
 - The learner is informed about the choices and what has worked for them and decides what is personalized and how it is personalized.
4. What data is used to guide personalization? This includes:
 - Personal data for each student
 - Representative data from previous students or a pool of students
 - A combination of representative data and personal data
5. Who the data is presented to? This includes:
 - The machine intelligence engine and company creating it
 - The students and learners themselves through dashboards and visualization tools
 - The teachers and educators

Metacognition, Smarter Machines, and Smarter Students

Projects such as FLOE differ from mainstream personalization initiatives in one important respect. Personalization initiatives are often used as a *raison d'être* for applying artificial intelligence to education. Adaptive education systems make data-backed decisions regarding the learning design that will bring optimal results for a student (Schunk and Zimmerman 2008). The FLOE Project is guided by the ethos that students should become experts in their own learning and that students should be able to experiment and draw conclusions about what works best for them. The FLOE Project asserts that machine learning should not supplant student metacognition, self-regulation, and self-determination but assist students in making informed decisions about their own learning requirements. FLOE and similar projects also support students in developing their own learning plan.

Becoming an expert in your own learning requirements rather than leaving this up to a data-driven inference engine is better suited for students who are outliers (Treviranus 2014b). Research, including big data and learning analytics, aspires to draw generalizable conclusions that can be applied to the majority, or a large prescribed group, with predictable results. The veracity of the conclusions depends upon an accurately representative group of “subjects,” and the accuracy of predictions depends upon statistical power through numbers. By definition these generalizations do not hold true for learners who are outliers. This is in large part due to the fact that there are no representatives that meaningfully reflect the unique interconnected complexity of requirements to be represented, let alone a large enough group of representatives to garner conclusive results. The only viable alternative is to represent yourself and to iteratively discover and refine your understanding of your own learning requirements with the help of supportive facilitators or tools. Tools can support this discovery by measuring and presenting “small” (personal) and “thick” (contextualized) data about the conditions under which you learn best for a given context or learning goal, allowing you to refine these conditions and monitor the results (Welles 2014). Taking from models in sports and gaming, students can hone their learning performance.

Quality Control

Prescriptive quality standards, especially centrally controlled determination of quality, are often an impediment to more diversity-supportive inclusive design of formal education. Ironically, safeguarding equal access is frequently used as the motivation for centrally imposed quality standards (Goldberg and Cole 2002). Unfortunately this removes self-determination from teachers and students and restricts leeway for diversification and thereby customization and personalization or designing for diversity. However, common education standards such as the US Common Core can be used to provide useful descriptive metadata regarding the learning goals met by a learning resource (Achieve n.d.). When this is combined with accessibility metadata or metadata regarding the accessibility requirements met by the resource,

this Common Core metadata can be used to find learning resources that address personal needs and also achieve an equivalent learning goal.

New Challenges for Inclusive Design

The tension between a one-size-fits-one and a one-size-fits-all “checklist” approach to accessibility and inclusion becomes even more complicated as learning resources become more interactive, multimodal, immersive, and collaborative. This is especially the case for learning experiences that do not translate easily from one sensory modality to another. It can often be argued that a legally accessible learning resource is not an equitable learning resource.

For example, a text description of an interactive science simulation is not an equivalent learning experience and is not likely to achieve the same learning outcome. A real-time sonification of the simulation that matches the student’s personal mental models and codification of sounds would be far more equitable. A partnership between the University of Colorado’s PhET project and the Inclusive Design Research Centre is developing a framework for sensory translation from vision to sound (real-world audio combined with speech) that enhances the experiences of the simulations for all students (<https://phet.colorado.edu>). The IDRC is also developing a means to express charts and graphs through sounds. Students can choose a sound codification system that makes the most sense to them (e.g., a long tone for tens, followed by short sounds for single digits to indicate the size of a pie slice; see <http://floeproject.org>). Both the DIAGRAM Center in the United States and the Inclusive Design Research Centre in Canada are exploring the use of 3D printing to create tactile models for individuals that cannot see images (<http://diagramcenter.org>). Both initiatives are also exploring the combination of audio and touch, whether it is tactile graphics and audio in the case of the DIAGRAM Center or haptic artifacts and effects (e.g., flow of river, extrusion of province or state to feel the boundaries better, effect of elastics to indicate latitude and longitude) combined with audio for maps and geographic information in the case of the IDRC (Treviranus 2000).

A text caption of an evocative piece of music is not as instructive as the original. A visualization of the music accompanied by vibration, such as provided by the “Emotichair” developed at Ryerson University, is much more equivalent for someone that is deaf (Karam et al. 2010). The Emotichair project translates sound to vibration and provides a means of composing vibro-tactile music, thereby enhancing the experience for both Deaf and hearing students.

A text description of an immersive environment is not equivalent to exploring the space. A responsive 3D soundscape that can be explored, with speech labels that can be selected according to the student’s interests, would be far more equitable. These are experiences that are being explored by a number of museums including the Virtual Museum of Canada (<http://www.virtualmuseum.ca>).

One currently unsolved challenge is interactive collaborative experiences in which the collaborators each have different preferences or requirements. This can

be resolved if the collaborators are remote as they can each have a personalized view of the interaction, but becomes more difficult if collaborators are sharing an interface. The Canadian Museum for Human Rights (<https://humanrights.ca>) has implemented multi-touch tables in which each zone can adapt to the needs of the user, but the overall experience continues to be collaborative. Another very promising practice is to enlist peers to provide and refine translation. This works best if it is supported in the collaborative interface.

Inclusive Life-Long Learning

Socio-technical trends and the inevitable transformation of work require a rethinking of education. Education suited to emerging realities inevitably includes radical diversification and continuous refreshing of competencies only achievable through life-long learning. To supply this diversified and perpetual education requires self-guided learners. However, the structural barriers to an approach that supports students in fully taking control of their own learning are many. Education itself has a history of paternalism and the belief that students do not know what is best for them. Students who have disabilities or students who are at risk often face a strange duality of infantilization or demonization. Either there is an added layer of protection or assumed vulnerability and incapacity or the students are distrusted and blamed for failure (especially students who face mental health issues or invisible disabilities or who don't "respond to treatment") (Epp 2003). Any understanding of the students' "condition" is usually hidden from them.

Our systems of education must also recognize the beneficial role of mistakes and failure. Using failure and error as a tool for learning is rare. Learners with disabilities are often protected from failure. In education failure is viewed as deterministic; it is used to predict all future performance, putting students further at risk.

Standardizing, establishing norms, and corraling and guiding performance through measurement (e.g., bell curve) or statistical evidence are inextricably fused with the values and aspirations of formal education. Individualization would lead to divergence and would reduce control. The individually chosen approach would not conform to the target metrics set up for formal education systems, causing systemic disruption to established reward systems (e.g., student awards, educator promotion, and institutional ranking). It is uncertain at what point formal education systems would be willing to risk devolving quality control to the student and supporting each student in refining their own learning performance.

However, an established phenomenon in inclusive design is that designing for the margins benefits the majority (Jacobs 2002). A mass approach to education has many casualties. All learners are multifaceted and unique. The systemic advantages of diversity are well documented. Like all relatively free-form discovery, the necessary diversification of education and divesting of control to students is an evolving, messy, risky process requiring trial and error, play, mistakes, failure, and patience. Students at the periphery are practiced in navigating this type of terrain.

Conclusion

Evidence and exemplary models are mounting that resoundingly support the principle that designing for students with learning differences and stretching to make room for a diversity of perspectives in our formal education system benefits all students and society as a whole. To successfully serve the purpose of preparing all students to meet their full potential and become prosperous, self-guided contributors to our global community, formal education systems must undergo a significant culture shift. Students with learning differences may be the impetus that pushes our complex system of education to make room for diversity to the benefit of all.

Abstract

This chapter theorizes the notion of *relational equity* in the context of new media-supported learning environments. Drawing upon examples from multiyear investigations into the social organization of learning activity in an elementary afterschool program in Colorado and an adolescent music and journalism production program in California, we outline an emerging framework for how to organize learning ecologies in ways that encourage more symmetrical relations among adults and youth across various lines of difference. In articulating design principles at the

level of the technology tool, the social interaction, and the broader learning environment, this chapter offers empirically grounded insight for those interested in organizing learning opportunities with new digital media in expansive and equitable ways. Further, it makes visible how attention to (in)equity must not constrain itself to one place, space, or time – cognizant of the ways in which power operates through a multiplicity of relations and processes that serve largely to reproduce inequality in society. It is with this understanding of power that we foreground the ways that new educational technologies might reorganize social relations in educational practices in schools and the community, with careful attention to how such technologies might change the normative yet deeply entrenched relations of power and privilege that exist in contemporary societies.

Organizing Learning Environments for Relational Equity with New Digital Media

Within educational research and practice, the notion of *equity* is broadly conceived of as the measure of fairness and opportunity within a given interaction, activity, or institution. Distinct from *equality*, a concept which falls short due its guiding assumption of a level playing field (Chang 2012; Carter and Welner 2013), equity in education is about recognizing and attending to the unequal ways in which opportunities, spaces, policies, and/or systems are distributed. It also takes into account how this distribution provides advantages for dominant individuals or groups within particular societies and political economies while marginalizing nondominant individuals or groups. In the field of educational technology research, organizing for equity thus means attending both to the distribution of access to digital tools and opportunities to learn about and with them, as well as to the advantages such access and opportunity provide.

The access to valued digital tools and contexts to learn with them that members of some social groups enjoy is a function of the operation of power. Power, as we understand it, is not the property of an individual or an institution, but rather operates through a multiplicity of relations and processes that serve largely to reproduce inequality in society. As articulated by Foucault (1978), power is “omnipresent,” that is, “not because it has the privilege of consolidating everything under its invincible unity, but because it is produced from one moment to the next, at every point, or rather in every relation from one point to another” (p. 93). It is with this understanding of power that we foreground the ways that new educational technologies might reorganize social relations in educational practices in schools and the community, with careful attention to how such technologies might change the normative relations of power and privilege that exist in societies. These relations today do not exist in a single public sphere, but in multiple “networked publics” (Varnelis 2008), that is, within different online and face-to-face places where we interact with others.

Organizing for “relational equity” is about working to foster relations in which *all* participants’ sense-making is taken up and brought into joint activity in equally

valued ways (DiGiacomo and Gutiérrez 2015). Working toward relational equity requires more than just attending to the unequal ways that social hierarchies of power structure social institutions and social interactions (The Politics of Learning Writing Collective 2017) – it requires that those in positions of relational power continually reflect and reposition themselves in activity in ways that trouble the unequal status quo. It also proceeds from the understanding that contemporary educational settings are organized in ways that privilege the experiences and knowledge of some while marginalizing, and often oppressing, those of others (Moll 1998). For example, contrary to a widely circulated rhetoric of equal opportunity within educational practice, racialized relations between a predominantly White teaching population and a largely Latina and Black student population continue to shape and delimit learning opportunities for Brown and Black youth (Matias and Zembylas 2014; Nasir 2012). Especially within our contemporary local and global climate of heightened racism, xenophobia, and nativism, we understand relational equity as integral to creating the conditions for young people to take on increased responsibility, to shape the production of knowledge, and/or to contribute authentically to the *telos* of learning activity.

Our chapter defines key principles for organizing learning environments that employ new digital media to promote relational equity, and we describe two examples of such environments. Both environments – perhaps not by chance – are out-of-school learning contexts, where young people participate by choice, where there is a purposeful effort to position young people as capable producers of knowledge, and where race, class, and disparities in access to resources and opportunity are focal within the design of the learning environment. In these environments, young people collaborate with peers and adults and use digital tools to play, make, or produce new meanings and imagine new ways of relating and being together. In this way, the kinds of learning supported allow adults and youth to use digital tools in ways that promote relational equity.

Defining Relational Equity

Relational equity is evident when educators design experiences that enable youth to discover new goals and possibilities through joint engagement with peers and adults in tasks where they make, produce, and critically reflect on new understandings of themselves, the world, and their relation to the world. Relational equity is *consequential* (Beach 1999) to the extent that these activities of making, production, and critical reflection also change people's relation to the world. To be sure, working toward relational equity does not free us from being a part of relations of power, but by critically reflecting on our relation to the world, we make what is taken for granted something human-made and malleable.

In a learning environment characterized by relational equity, expertise is brought and shared, as well as made together. People develop new forms of expertise by observing others performing tasks competently and pitching in to ongoing activities led by others (Rogoff 2014). The expertise needed in the learning environment is both related to the task at hand – whether that is making a new app or creating a social media campaign – and interactional. Interactional expertise entails know-how with respect to

different ways to organize joint work successfully, which includes eliciting and making good use of expertise available in the environment (Edwards 2011). Sometimes, how people's expertise is relevant to a task is not apparent to others in a group, because we tend to rely on privileged categories of expertise, and we view people through these lenses. We are less likely to see easily – except when we collaborate to create new knowledge together and produce it unexpectedly – the expertise of others whose knowledge is not typically valued (McDermott and Raley 2011). Environments characterized by relational equity are counter-normative, that is, they challenge relations that typically exist in schools between teachers and students. As lead organizers of learning activity through lectures, assignments, or adult-led discussions (Gutiérrez et al. 1995), teachers often struggle to organize learning activity in more symmetrical and equitable ways. Transforming such relations requires a conscious attention to and reflection on asymmetries of power to which we have become accustomed in typical teaching and learning environments (Jurow et al. 2012).

Relational Equity and Learning with New Digital Media

This chapter focuses on relational equity in the context of learning with new digital media. To us, the term *new digital media* encompasses not only applications people use to compose, compute, draw, animate, and produce digital artifacts but also the digital locations where people can share artifacts with others, read or experience what others have produced, and obtain content that they remix for themselves. It contrasts with traditional educational technology applications primarily in the degree to which the notion of “producer” and “consumer” is blurred. Jenkins (2006), following Toffler (1980), calls the new user a “prosumer,” which is part of what he sees as a new, participatory folk culture in which participants reshape media content to serve their own personal and group interests.

In this sense, learning with new digital media involves *production for others*. In the process of producing things for others, people imagine audiences whose thoughts and actions they hope to influence and whose responses will shape their own assessment of what they have produced. Critique inheres in the process of production, as learners “produce these imaginary contexts by conjuring hypothetical scenes, responses, and consequences for the decisions made within the process of production (Soep 2006, p. 754). Further,

Learning is, in its manifestation through critique, a way of making. Young people in critique are constantly producing contexts for learning, producing situations in which they need to act and judge. And they are constantly reorganizing their environments in ways that extend their situated cognition beyond a given here and now – a video shoot in an alley within a crisis of choreography, an e-mailed refusal to make changes to a poem – into a future beyond that moment. (Soep 2006, p. 754)

Below, we describe how production with new digital media can support relational equity, as well as the pedagogical foci that support this aim.

Supporting Discovery of New Goals and Possibilities for Relating to Others

One of the ways young people can learn in production is through experimenting with different tools for producing new digital media content. Video production has long been a means to support youth in both developing new skills they might apply in the workforce and as a means of finding new means for self-expression (Goodman 2003). Today, audiences for video can be reached more broadly through a wide variety of free sharing platforms, and young people are using digital video to share visions for social change, attempt to change broad social norms, and influence policies at the local, state, and national level (McDermott et al. 2015). These platforms are relatively easy to use, but there remain advanced skills in production that have value to youth in the marketplace, if they have opportunities to develop those skills (Soep 2014).

A wide variety of new materials associated with the “Internet of Things,” in which a variety of “smart” objects are networked together, enable young people to discover entirely new forms of self-expression. For example, “BlockyTalky” is a set of hardware and software that enables learners to create their own networked devices that can perform different tasks and that bridge the digital and material world (Shapiro et al. 2014). Through using these tools, youth can learn introductory principles of programming, robotics, and setting up digital communication networks. Collaborative design with BlockyTalky enables very different possibilities for interaction and for promoting equity than production with laptop and desktop computers, where keyboards are the primary means by which young people can share in the effort. Multiple interfaces and devices enable very different configurations of young people, even challenging us to define and measure “equity of participation” in new ways (Deitrick et al. 2016).

Supporting the Development of Expertise for Co-producing New Media

Some of the pedagogies for developing new media expertise are “school-like” in that they involve learners in acts of interpreting and making sense of texts and multimedia products that others have produced, or even acts of “overt instruction” (The New London Group 1996, p. 86). For example, young people might engage with case studies of how others have managed or mismanaged their digital identities (Soep 2014). They might receive instruction and practice in how to evaluate critically different information they find on the Internet (Britt and Aglinskis 2002). Young people might, as part of a course, be asked to “remake” a media product in a way that frames it critically, that is, makes clear how that product reflects or helps reproduce unequal relationships in society (Garcia et al. 2013).

There are other ways that young people can develop expertise in new media production. Young people can learn through legitimate peripheral participation (Lave and Wenger 1991) in ongoing professional activities, for example. That is a form of learning akin to an apprenticeship in which people contribute from the

periphery to tasks that are part of a larger set of interlocking practices. From a relational equity standpoint, what is critical is that such apprenticeships are not exploitative: learners must have the opportunity to move flexibly and easily into new roles within activity and gain access through apprenticeships to valued networks (O'Connor 2003). There needs also to be an expectation that those in organizing roles learn from apprentices; that learning helps the relationship grow and transform over time into a clearly mutualistic one.

Another pedagogy that is particularly valuable for promoting relational equity is that of joint work. In joint work – as opposed to apprenticeship learning – youth and adults work side by side on goals that they mutually decide upon. For example, young people working side-by-side with adults on issues related to student voice might become fluent in communication tools and discover through their use of those tools to perform joint action how different groups use such tools to their advantage and to maintain power when others threaten it (Goldman et al. 2008). Or, by working side by side with adults to study issues of concern to them, youth may learn different aspects of social inquiry, including sophisticated forms of data analysis that can help them with arguments that persuade others to take action to address those concerns (Penuel et al. 2004).

How New Digital Media Can Support Alternative, More Equitable Participant Structures

New digital media technologies, with their emphasis on low barriers to entry, joint production, and shared, networked connection and expression, are well positioned to support alternative participant structures in learning activity with the potential for more symmetrical participation among adults and youth (Resnick and Rosenbaum 2013). Encouraging in-the-moment research using smartphones or tablets, for example, can support teachers in organizing for side-by-side learning on topics of interest to youth (DiGiacomo 2017). And inviting youth to share out their work by posting it on designed social media platforms not only encourages a sense of community by making visible the contributions of all participants but promotes opportunities to reflect, remix, and extend one's own thinking (Nacu et al. 2014). According to Barron et al. (2014), many tools for production today are free and give students the ability to create designs that previously could only be created by trained professionals. Used in this way, new media tools can serve in the development of alternative means for distributing youth work, as well as support the development of more equitable participant structures among adults and youth.

Arrangements That Help Adults Follow and Support Youth Initiative Rather Than Lead

Working toward relational equity requires purposeful attention to the spatial organization of activities and interactions, including the ways in which material and physical artifacts are engaged. Pedagogical arrangements organized to allow the

adults and youth to be at the same height while engaging in activity, while manipulating a material medium large enough to allow for the simultaneous work of multiple hands, can serve to amplify and multiply the contributions of the youth in shaping the course of ongoing activity. For example, ensuring that the shortest participant's hands are able to reach the string lever and view the path of the moving marble on a Rube Goldberg machine might be a small but significant way of spatially ensuring that the youth's position within the activity remains equally valued throughout (Schwartz et al. 2015).

In the next section, we present two examples of projects that illustrate how new digital media can support relational equity in intergenerational learning environments. One focuses on teens and young adults and the other on preservice teachers and elementary-age students. Both are out-of-school programs, where – in our view – it seems possible for more equal teaching and learning relationships between youth and adults to emerge from joint activity.

Youth Radio: Amplifying Youth Voice Through Critical Engagement with Media

Youth Radio is an organization that prepares young people for communications and technology careers while also supporting critical forms of civic engagement supported by digital media. Youth in the organization develop and produce radio stories, blogs, online articles, and video. Though based in Berkeley, California, the organization has affiliate programs across the United States and operates bureaus in Los Angeles, Atlanta, and Washington, DC. The stories that youth develop appear in different media: on National Public Radio and American Public Radio programs, in periodicals, and on Youth Radio's website. In addition, youth in the organization's Youth Radio Interactive program have produced interactive websites and mobile applications that focus on issues of concern to youth and their communities.

By all accounts, Youth Radio is a successful program in promoting relational equity through its partnerships with media outlets and community-based organizations. The largely low-income participants not only experience individual academic success – 97% graduate from high school and 87% go on to college – but graduates have also gone onto successful communications careers and employment within the broader organization itself. Youth Radio's youth-driven stories have won acclaim and prizes (including the prestigious George Foster Peabody Award for journalism) for their critical examination of issues such as teen prostitution and hazing of gay military personnel. Their stories reach an audience of 30 million people, according to the program's website.

Through Youth Radio's different classes, internships, and jobs for youth, youth encounter professionals in radio, video, and music production, interactive application design, media studies, journalism, and education. These professionals act as teachers within programs, as production and story editors, and as mentors who broker youth access to further opportunities to develop academic and career skills. They engage young people in what Soep (2014) calls different "forms of know-how"

that enable young people to use activities of production to “achieve desired effects on issues of public concern” (p. 51). These include using interactive storytelling to get the public’s attention and influence viewpoints; designing platforms that invite members of the public to engage with issues in particular ways; identifying, interpreting, and representing data relevant to those issues; managing self-disclosure on the web; and mobilizing peers.

Youths’ exposure to new media-related expertise isn’t limited to what is available from adults in the program. Youth learn from near peers who have graduated from basic programs and become teachers in advanced classes. In addition, youths’ stories put them in the community, asking questions and developing new expertise through their interactions with informants. In researching stories, digital media figure prominently. For example, in one of the award-winning stories focused on the hazing of a young gay sailor in the Navy, youth used a social media site for veterans and military personnel to locate the young man. They used social media as part of dissemination, adding materials to a website they could not use in the radio story to allow people to deepen their understanding of the issues raised in it.

The project’s pedagogy can’t help but be critical, given their commitments to supporting youth-driven storytelling. Youth stories inevitably push up against more traditional power relations that limit youth voice and access. As Soep (2014) describes it, when youth knowledge

reflects unfavorably on powerful people, utilizing it can require sophisticated knowledge of everything from computer programming to stats to design principles to techniques for sweet-talking or bamboozling one’s way into networks that have every reason to block youth. (p. 32)

Youth knowledge has a privileged place in Youth Radio. For radio spots, youth pitch stories that are rooted in their own interests and experiences. The form, tone, and angle of stories are all shaped by youth participants. The tone and angle of stories often cut against the grain of mainstream media portrayals of youth. The youth perspective explicitly “unsettles standard media conventions” (Soep and Chávez 2010, p. 56). Importantly, the adult guides in the setting are well aware of the challenge that youth’s voice presents, that is, the ways that hearing youth voices on radio challenge the privilege that adult perspectives on youth institutions like schools have in most media accounts.

But adult expertise also shapes stories as they evolve. The process of story development itself helps to surface and develop expertise. It involves multiple occasions of what Soep and Chávez (2010) refer to as “collaborative framing,” in which youth and adults shape one another’s ideas as together they “confront obstacles, challenges, and unexpected curves in a story’s developmental trajectory” (p. 57). Adults are especially helpful in guiding youth to help them anticipate audience responses and the potential impact of their stories on both listeners and the people they interview. Adults may also use their institutional positions, relationships with others, and past experience to help youth navigate difficult positions. For example, Youth Radio producers helped one interviewer assert their right to

interview a student on a school site in the face of principal opposition. They made sure the student understood their rights ahead of time and how to present themselves as youth journalists seeking a fair, balanced account of a local movement to opt out of taking standardized tests.

The participant structures explicitly support side-by-side learning of youth adults in the process of story development. Youth facilitate editorial meetings, and adults have to request permission of youth facilitators to speak or comment. Youth pitch story ideas, while adults help them clarify their perspective and develop it. Because the stories have to do with youth culture and lives, adults often find themselves in the position of “learner” rather than teacher, lacking knowledge that youth have and that is essential to story development. Pitching stories based on topics of their choosing, young people in Youth Radio are “in a strong position to contribute knowledge informed by their own experiences, their social networks, and their research into wider social trends and public policy” (Soep and Chávez 2010, p. 50).

Another way in which adults follow – rather than lead – youth in Youth Radio is through the pedagogy of youth-led inquiry. Youth conduct investigations for stories, with suggestions from adults along the way. Through these investigations, youth develop initial ideas that often reflect personal opinion and experience into more multi-perspectival stories. In the process, they learn to “contextualize their own experiences” and how to situate stories within “wider debates that circulate around them” (Soep and Chávez 2010, pp. 63–64). They learn what it takes to convince others and themselves of the truth and value of a story through the process of investigating a story. Leaders within the program acknowledge that positioning youth in this way challenges power relations in the broader society, where youth are often positioned as learners not teachers and consumers of news rather than producers of it.

El Pueblo: A University-School Partnership Focused on Equity

El Pueblo is a maker-oriented afterschool program in the Denver suburbs that serves predominantly Latina, elementary-age students. Offered as an option for the students 3 days a week within the school’s broader afterschool programming, El Pueblo is designed as playful learning environment that invites the young people and their adult guides to jointly engage in new media-supported activities such as digital storytelling and game design, as well as in making and tinkering activities like squishy circuits and scribbling machines. At El Pueblo, the adult guides are undergraduates from the nearby university who are enrolled in an upper division Educational Psychology class (most of whom are preservice teachers) and who are required as part of this course to attend the practicum afterschool site once a week. El Pueblo is an example of a university-school partnership aimed at supporting relational equity through its theoretically grounded approach to side-by-side learning as well as its strategic inclusion of digitally supported activities that allow for immediate feedback in activity.

In the Educational Psychology class, the undergraduates' coursework involves extensive engagement with sociocultural and critical theories of learning and culture (e.g., Vygotsky's theory of human development and Freire's pedagogy of the oppressed). Through a combination of lectures, discussions, reading and writing assignments, and hand-on activities, the instructors of the course encourage the undergraduates to examine their oft-unexamined assumptions about the practices of teaching and of learning, including how conceptualizations of culture intersect with issues of power and privilege within social relationships (Gutiérrez and Vossoughi 2010; Gutiérrez and Jurow 2016). The undergraduates are challenged to consider how these social relationships, constituted by discourse and the organization of interactions over time, mediate learning opportunities for young people. In particular, given the demographic of the El Pueblo practicum site (predominantly Latina, low-income children from and predominantly White, middle-class adults), the undergraduates are asked to critically reflect on the ways in which their own social positionality at the site vis-à-vis the children and other adults serve to both promote and delimit opportunities to learning meaningfully through joint engagement in site activity.

At El Pueblo, the undergraduates are also encouraged to consider the social organization of the activities in which they are participating with the youth. This means paying attention to the ways in which the spatial, material, and physical properties, as well as discursive practices, of the activities themselves both afford and constrain more or less equitable social engagements and pedagogical arrangements among the youth and adults in activity. The course instructors promote this type of attention in part by allowing time in class for the undergraduate themselves to think about how learning activities are designed by watching instructional videos and using a "social organization of learning" worksheet to document spatially the organization of material, physical, and discursive artifacts of the learning environment, alongside noting how these arrangements intersect with children's participation in activity.

By making the relationship between the undergraduates and the youth at El Pueblo an explicit object of analysis and design, El Pueblo attempts to lay bare the multiple levels of power and privilege that tend to inhere in traditional teacher-student relations in educational settings, in particular those among largely White teachers and students of color who attend the program. In so doing, the course-practicum experience works toward relational equity in one way by unearthing the human-made and malleable nature of such historically rooted relations in an attempt to reorganize them toward more equitable ends.

The course instructors of the Educational Psychology class encourage the undergraduates to leverage innovative designed learning activities that bring together insights from "making and tinkering" (Vossoughi and Bevan 2014; Vossoughi et al. 2016) and "scalable game design" (Repenning et al. 2015; Her Many Horses 2016). The learning affordances of certain making and tinkering activities, such as "squishy circuits" and "scribbling machines," have been documented to promote relational equity at El Pueblo due to the in-the-moment "material and relational feedback" of the activities (DiGiacomo and Gutiérrez 2015). In the case of 'squishy

circuits' (see Johnson and Thomas 2010), as youth work together to create a circuit through the manipulation of insulating and conductive molding clay, LED lights, and wires, they receive immediate feedback regarding the viability of their design thinking, which supports their sense of ability and accomplishment in the STEM-related activity. At the same time, the immediate feedback stemming from the materiality of the activity itself makes room for the adult guides working with them to not only provide as-needed assistance but to witness the ingenuity in the moment of the youth's tinkering process (see also Resnick and Rosenbaum 2013).

In a purposeful attempt to position the youth as producers, rather than consumers, of the activities in which they engage, El Pueblo provides students with the opportunity to engage in practices of scalable game design. Cognizant of the racial disparity in access to and participation in high-quality computer science opportunities, Her Many Horses (an El Pueblo graduate researcher and site support) encourages the youth at El Pueblo to create their own video games by using the AgentCubes platform for game design. With the in-the-moment material feedback of the platform, the youth and adult guides are able to readily see the movement of the designed agents and their paths on the computer screen. And to increase autonomy over time on the part of the youth in the design process, Her Many Horses designed a web-based scaffolding tool that made the design process even more concrete and visible. As a result, the youth "not only completed the design process but also accessed much of the information that would help them to make their games" (Her Many Horses 2016). In this way, scalable game design serves as an activity at El Pueblo that promotes relational equity by working to shift the agency and responsibility in STEM activity design and action toward the youth.

Looking to the Future: Organizing for Relational Equity at the Community Level

In this chapter, we have outlined the importance of attending to relational equity when engaging with new digital media in educational practice. Cognizant of the "social hierarchies of power" that shape how learning ensues in and outside of the classroom (Philip et al., 2017), we argue for the need to explicitly organize learning environments in ways that continuously privilege the knowledge, experiences, and sense-making of those whose social identities have been historically marginalized. In particular, we have suggested the following considerations for creating the conditions for relational equity to emerge in new media-supported practices: attention to pedagogical arrangements, participant structures, support for the development of youth expertise, and space for the reimagining of social relationships. And in highlighting the cases of Youth Radio and El Pueblo, we have shown the ways in which programs can embody, through their design, aspects of relational equity.

The organization of these learning environments are ones that – despite being out-of-school environments – require similar kinds of efforts as designing classroom-based environments. They do not attempt to reorganize relations at the community or citywide level. Some emerging uses of digital media do in fact support broader efforts

to promote more equitable relations and address historical inequities associated with the operation of power related to class and race in cities. Below, we present one such example in closing our chapter as an illustration of how the concept of relational equity might be applied at the community scale and in the context of contemporary movements to create more “smart and connected” cities and communities.

The example we offer for the potential of community-level transformation is the *Chicago City of Learning*. The Chicago City of Learning is a citywide partnership in which more than 170 organizations engage young people in roughly 4000 out-of-school learning activities. The partnership’s website enables youth and their families to identify activities based on their interests. The website is also used to recognizing youths’ accomplishments in these activities, recording digital badges such as “Science Research,” “Robot Instructions,” and “Peer Mentor.”

A key aim of the Chicago City of Learning is to promote more equitable distribution of and access to learning opportunities across the city. To that end, researchers are mapping the locations and diversity of learning opportunities in each of the neighborhoods in the city. The partnership, for its part, is beginning to use these data to identify where there are “learning deserts” (Pinkard et al. 2016) and where new kinds of programs might be offered to support young people’s interest discovery and development.

The Chicago City of Learning is exciting, because it shows the possibility for enhancing access to programs like Youth Radio and El Pueblo and for transforming the relations among programs. Ultimately, young people should have the opportunities not only to find programs like the ones we have highlighted nearby, but they should also know where they can develop advanced skills and connect with new people who share their interests across the city. The Chicago City of Learning partnership is intended to do just that.

Like the Chicago City of Learning effort, our chapter has been purposefully *utopian*, in that we point to ways that digital media largely might – but does not reliably or broadly at present – support relational equity in learning environments. We have envisioned a possible world in which youth produce new media tools and content side-by-side with adults to transform relations among groups in society and work toward more just social futures. We recognize that there are many obstacles to transforming social relations in inequitable societies and in political economies that regularly reproduce race, gender, and class-based hierarchies. But we think efforts to organize technology-supported learning environments ought to offer alternative visions for the future, rather than simply prepare people to live in and with inequity.

groups. Regarding usage, youth groups differ in the manners and the extent digital technologies are used at schools and outside of schools. Since there is a wide range of technologies available and groups' usage pattern varies among forms of technology, it is challenging to summarize a single trend of inequality of technology usage. Regarding outcomes, how the differences in access and usage affect the disparities in outcomes remains inconclusive. The challenge for the reader in consuming studies on outcomes of technology is that what is often reported as a result of using technology may in fact just be that two broad factors – technology and learning – are observed to go together but may not cause one another. The technology use may affect learning, or other factors, such as SES, may shape both learning and technology use.

Technology access · Technology usage · Achievement gap · Twenty-first-century learning skills · Educational equity

Introduction

The development and diffusion of information and communication technologies (ICT) is having a profound effect on contemporary education, which adds new elements to the long-standing issue of educational equity. In many countries, the issue of educational equity typically centers on the disparities of academic achievement among groups of students, especially groups defined by socioeconomic status (SES), race/ethnicity, and gender. Therefore, when examining the relationship between technology and educational equity, research generally focuses on whether technology may exacerbate or ameliorate the achievement gaps or have no effect.

There are two existing perspectives regarding this relationship. On the one hand, technology access and usage in education are unequal across SES, racial/ethnic, and gender groups. Groups with lower academic achievement are generally less likely to access and use technology and thus may benefit from technology to a lesser extent than their more advantaged peers. This unequal access and usage may result in amplifying existing educational inequality. On the other hand, if deployed effectively, the affordances of technology in providing scaffolding and enhancing engagement can help facilitate learning of students with lower achievement, thus ameliorating educational gaps. Both perspectives are supported by a wide range of research. This seemingly conflicting evidence may result from methodological differences in the studies. For example, studies may be conducted in different contexts with diverse segments of the population and diverse forms of technology or interventions. Therefore, results generated from one study may not hold true in another context.

This chapter aims to create a broad picture of the relationship between technology and equity in K–12 education by summarizing research literature on SES, racial/ethnic, and gender differences related to technology. We organize our review around the framework of technology access, use, and outcomes (cf. Warschauer and

Matuchniak 2010). Research concerned with the inequality of access and usage of technology is generally descriptive, articulating the patterns of technology access and usage among different groups. Studies focusing on the inequality in outcomes prioritize the examination of the causal impact of technology access and usage upon a youth's learning. The challenge for the reader in consuming these kinds of studies is that what is often reported as a result of using technology may in fact just be that two broad factors – technology and learning – are observed to go together but may not cause one another. The technology use may affect learning, or other factors, such as SES, may shape both learning and technology use.

Access

The notion of technology access encompasses two components: physical access to digital devices (e.g., computers, tablets, the Internet) and access to digital content. Physical access to a device is a necessary first step for digital equity, but studies also have suggested that access to content that is both of high quality and educational value is a secondary concern. In this section, we will first examine the gaps in the two forms of access among SES, race/ethnicity, and gender groups and then link these gaps to the related social factors, both in home and school environments.

Access at Home

Home access is defined as a student having access to digital technology at home, regardless of whether it is a shared item in the household. However, despite the steady progress that has been made in boosting home technology access for minority and lower-SES households around the world, access remains unevenly dispersed, even within developed countries.

For example, in the USA, the overall home computer and Internet access divide as well as its evolution over time is well documented by several national reports, among which is the National Telecommunications and Information Administration (NTIA) report, based on the Current Population Survey (CPS). The NTIA report provides the most robust evidence on this issue. In the latest released report, household computer and Internet access continued to show an unbalanced pattern, with Asian or White, higher-SES, metropolitan households more likely to have access than their counterparts (File and Ryan 2014). This finding is consistent with common assumptions, as well as other nationally representative surveys (e.g., Anderson 2015). When longitudinally comparing the NTIA reports over a period of 15 years, we can see that as the technology access rate increases steadily across all groups, the gaps between more advantaged and less advantaged groups are narrowing but remain substantial (White House Council of Economic Advisers Issue Brief 2015).

Among those with Internet access at home, the conditions of access differ, ranging from access to broadband connections to relying solely on a cell phone data plan. Broadband offers Internet speeds fast enough to facilitate full interaction

with advanced online platforms, while online activities via circular data plan are usually constrained by slower speeds. According to a report by Pew Research Center, for 7% of American youths, cell phones are their only means of accessing the Web (Pew Research Center 2015a). Those who are younger, of lower financial status, and with less education are more likely to fall into this category. Blacks and Latinos are also more likely than Whites to lack other means of accessing the Internet. However, on the positive side, the dramatic increase in smartphone penetration has helped bring the Internet in some form to those who lacked home Internet access (Connected Nation 2013).

While economic constraints tend to be viewed as the primary reason for the divides in home technology access, other social factors also play a critical role in this issue. For example, some literature emphasizes the importance of social support for technology access (DiMaggio et al. 2001). Many immigrant households may lack social networks that would enhance their opportunities to acquire digital access. In contrast, individuals with many friends and relatives who own computers and use the Internet are more likely to do so as well, because their network can help them acquire necessary technology skills, and they have greater return in using technology due to their large social network online. As Ono and Zavodny (2008) pointed out, these network effects to some extent explain why the divides in technology access reflect or even exacerbate the existing social inequality.

Examining inequality in the amount and quality of content available via home digital devices, it is generally hypothesized that youth groups who are more likely to access digital devices tend to be exposed to richer digital content. However, as it is implausible to comprehensively measure the volume and quality of the content a youth may access from their device, most existing research focuses on measuring the access to specific forms of content. For example, recent research has noted an “app gap,” which refers to inequality of accessing educational applications on smartphones or tablets (Prensky 2012). These applications are frequently assumed to be beneficial for children. According to a study by Common Sense Media (2013), while wealthier parents load their children’s iPads with brain-boosting educational apps, less advantaged parents rarely do so. This divide may reflect parents’ perceptions about the value and role of technology. Lin et al. (2012) believed that lower-SES parents may have less confidence in teaching or regulating their children with digital technologies, thus leading to a lower likelihood of equipping their digital devices with educational content.

School Access

Technology investment in schools worldwide has increased substantially in the last two decades, on the rationale that digital access and usage improve learning. However, school divides in technology access have not yet been eliminated. Internationally, the gap in school technology access between developing countries and developed countries is, not surprisingly, large. While school technology access rates have almost reached saturation in some developed countries, such as the UK,

Canada, and New Zealand, many developing countries are just beginning to introduce computers and Internet connections in schools. Within developed countries, gaps are narrowing but still exist. In the USA, for example, high-poverty schools still have fewer students per Internet-connected computer than low-poverty schools, and underrepresented minority students are less likely to have technology access at school than their White counterparts (Snyder et al. 2016). At the same time, only 16% of schools in poor counties (i.e., with county-level median household income less than \$35,000) have high-speed Internet connection, whereas the percentage for schools in wealthier regions (i.e., with county-level median household income more than \$35,000) is almost four times higher at 62% (Connected Nation 2013).

Similar to home access, school technology access is supported or constrained by economic factors as well as socio-technical contexts, often in ways that heighten educational inequity. Previous lessons have shown that, by merely increasing access to technology, schools may still not be able to take advantage of these facilities (see, e.g., Warschauer et al. 2011). For example, the Los Angeles public school system undertook a \$1.3 billion effort in 2013 to give each teacher, administrator, and 640,000 pupils an Apple iPad preloaded with educational software. This program was seen as a way to boost the city's low-income students, who had limited access to digital education tools at schools until the program. However, the program did not achieve its original goal and soon resulted in a breakdown. After an investigation, the US Department of Education (2016) identified a lack of district-wide instructional technology strategy and insufficient instructional support of technology as among the causes of the failure. Recommendations made in the report include the following:

Require each school to create a clear but light-weight Instructional Technology Plan aligned to individual school improvement goals. . . this plan should ideally include input from all stakeholders and be posted publicly for parents and community input. Pilot approaches for integrating technology professional development as part of the districts' overall professional development strategy.

These recommendations reinforce the complexity of technology integration, which goes beyond simply equipping schools with technological resources.

Usage

What is more critical of course than mere access to technology, both inside and out of school, is whether and how it is used. This is also often related to issues of SES, race/ethnicity, and gender.

Out-of-School Usage

The majority of youths from all SES backgrounds and racial/ethnic groups find ways to use digital technology. According to the research from the Organisation for

Economic Co-operation and Development (OECD), in 2012, disadvantaged students spent at least as much time online as their wealthier peers, on average across 40 OECD countries. However, despite the equivalent time spent online, different groups are found to use different devices and in different ways. Higher-SES teenagers were more likely to use the Internet to search for information or to read news rather than to chat or play video games (OECD 2016). This finding resonates with a survey in the USA, which found that lower-SES youths use technologies more for leisure rather than for learning-related activities, which is substantially different from those with higher-SES backgrounds (Rachel 2012).

This raises the question of whether more time using digital media adds or subtracts educational value. Researchers put forth the concept of the time-wasting gap, which refers to the disparity of time spent online for pure leisure by different population groups. This gap may produce negative effects for the youths who use technologies: the more time spent online, the less gained. Traditionally marginalized groups are believed to be more prone to this situation. Therefore, it is important to take the quality of technology usage into consideration. This is typically discussed around three common types of out-of-school technology usage: media consumption and creation, communication, and video gaming.

Content Consumption and Creation

Children consume content via digital devices in various ways, including viewing videos, browsing websites, listening to music, and reading eBooks. Among these activities, viewing online videos takes primary position. According to multiple sources, the average viewing time for teenage children of online videos may be up to an average of 3 h daily. However, not all groups spend the same amount of time watching videos. A study surveyed 2000 teenagers and discovered that those with low family income and low parent education levels tended to watch online videos 1 h more than their better-off peers (Common Sense Media 2015). Possible detrimental effects of video watching include distraction from time available for reading or studying, as well as negative effects from problematic programming, such as media portrayals of drinking and alcohol advertising.

Children also use a variety of tools to create content, including blogs, websites, videos, fanfiction forums, and programming. Researchers view the practices of content creation as a knowledge construction experience, in which children develop their skills as well as creatively engage with information. However, again, differences exist among groups. Lower-SES youths, while avid content *consumers*, appear to spend less time than higher-SES counterparts in content creation (Pew Research Center 2005; for a more recent study of college students, see Hargittai and Jennrich 2016). Differences in technology access and usage as well as motivation appear to be the factors that underlie and perpetuate differences in online content creation (Blank 2013). This gap in content creation could contribute to social inequality, both by limiting minority youth's opportunity to gain important skills that are necessary in the contemporary workplace and also by rendering their voice and opinions less likely to be heard by the public.

Communication

Digital technologies are seen by teenagers as a tool for social networking with their friends. Communication encompasses a range of older and newer forms of Internet communication such as sending email, instant messaging, blogging, going to chat rooms, and social networking communication. How children use online communication tools varies on two levels – whether they use particular tools or not and in which activities they engage. The variation in these two levels correlates with children’s backgrounds to some extent.

Facebook is shown to be the most popular of all the social media platforms among teenagers, and background characteristics do not seem like a strong indicator of whether or not they use Facebook. However, the activities performed do vary along socioeconomic and racial/ethnic lines. Junco (2013) demonstrated that students from lower-SES environments were less likely to use Facebook for communication, connecting, and sharing, i.e., the exact types of activities for which Facebook was created. Another study revealed that lower-SES students were less likely to engage in classroom-related academic collaboration on Facebook than their higher-SES peers (Khan et al. 2014).

Concern thus arises that lower-SES students may not be able to take full advantage of online social networks to help strengthen real-world connections with friends and schools, as they perform activities that are less communication-oriented. Another contrasting view is that lower-SES students, with less social capital in the real world, may benefit from the virtual network more than their better-off counterparts. Relatedly, Wohn and colleagues studied the role of Facebook in the college application process of high school students. The authors found that, for first-generation high school students, Facebook use was associated with higher feelings of efficacy, thus facilitating their college application emotionally and practically. However, Facebook did not provide the same degree of help to students who had at least one parent who graduated from college (Wohn et al. 2013).

Video Gaming

Video games are pervasive among most teens – and, for boys in particular, video games serve as a major venue for the creation and maintenance of friendships. The amount of time teens spent on gaming varies little by family income, education, or race/ethnicity. However, nuances in gaming preferences and behaviors still exist among groups. First, SES appears to play an important role. A study in which 200 high schoolers were surveyed showed that nearly half of the low-SES students preferred sports-themed video game consoles, whereas only 20% of high-SES students reported this preference (Andrews 2008). In contrast, high-SES students were shown to be more likely to engage in literacy practices related to the games they played (e.g., view screenshots, use walkthroughs, post scores), while low-SES students rarely performed these activities (Andrews 2008). Additionally, higher-SES students appeared to be more likely to use networked games to connect with their in-person friends than their less well-off peers (Pew Research Center 2015b). This finding resonates with the results from other studies: higher-SES people tend

to take better advantage of digital technologies for socializing and building relationships.

Regarding gender differences in gaming preferences and behaviors, in sharp contrast with boys' avid interest in gaming, girls generally reject being identified as "gamers." Among girl gamers, the majority reported favor for casual games with fewer challenges. In contrast to the majority of boys, who favored the sports genre, very few girls reported that they enjoyed these games (Andrews 2008). Some scholars suggest that high-challenging video games favored by boys may potentially foster interest for STEM careers, especially in computer science and engineering, or similarly develop technology skills helpful for those careers.

Usage in School Settings

Despite teenagers' frequent home usage of technology, their school technology usage is not paralleled. In most OECD countries, more than 80% of 15-year-olds use computers frequently, yet a majority do not use them much in school, even though most schools are equipped with computers and Internet access (OECD 2010). Among the schools using technology frequently, the ways in which they implement technology into instructional activities differ. It is generally believed that poorer schools tend to use technology for drill and practice activities, whereas in higher-SES schools, technology is exploited fully to enhance students' problem-solving skills (Warschauer and Matuchniak 2010). For example, findings from a recent study showed that students attending low-SES schools were given more limited opportunities to use technology to engage in student-centered critical thinking learning activities, compared with their counterparts in higher-SES schools (Lee 2013). And while computer-based writing and revision is viewed as a valuable activity for enhancing academic achievement (see, e.g., Warschauer 2011), the 2011 US National Assessment of Educational Progress (NAEP) found that only 33% of students who are eligible for free or reduced price lunch use computers very often for writing assignments in school, according to their teachers, compared to 51% of students who are not eligible for the national school lunch program.

The disparity in technology use patterns between higher-SES and lower-SES schools is believed to be a result of the interplay of economic conditions, teachers, social dynamics, and institutional culture differences. Among these factors, the most examined by researchers is teachers' knowledge, including their knowledge of using technology and the knowledge of integrating technology into teaching. First, the computer skills and knowledge of teachers are important determiners of the efficient use of technology. Since teachers in poorer schools are reported to receive less technology training, they may possess lower proficiency in using technology than teachers working in wealthier schools (National Education Association 2008). Second, teachers' knowledge in integrating technology matters. Teachers in poorer schools may have limited opportunities to understand how to use technology in ways that engage students in discourse with peers to collaboratively solve problems (see discussion in Kitchen and Berk 2016). As a consequence, students in these

schools often work in isolation from their peers on digital devices, resulting in limited opportunities to develop their reasoning and conceptual understanding collaboratively.

In addition to the role of the teacher, technical support is another factor that influences technology use. Technical problems, such as slow network performance and inadequate computers, can make it difficult to use technology in classrooms, thus frustrating teachers. In a qualitative study comparing technology use in low-versus high-SES schools, Warschauer et al. (2004) found that high-SES schools tended to invest more in hiring full-time technical support staff than low-SES schools. Additionally, in high-SES schools, technology facilitators were selected from teaching staff, who received intensive in-service technology training. These facilitators provided technical and pedagogical support to their colleagues. Student aids were also trained to help in classrooms. These groups were facilitated by clear channels of cross-communication and coordinated effort. Low-SES schools in this study were less likely to have the same degree of interconnected support networks.

Outcomes

Important outcome measures from technology use include student attitudes, traditional school achievement measures, and twenty-first-century learning skills. A number of studies have looked at the relationship of technology access and usage to these outcomes, but frequently using non-experimental designs that are unable to identify the *causal* effect of technology access and usage from other unobserved differences across students and schools. Therefore, while reviewing these studies, we should keep in mind that the true impacts of technology access and usage on student outcomes may be over- or underestimated.

Attitudes Toward Technologies

As computer technology becomes ubiquitous in schools and the workplace, attitudes toward technology may be as important as skills in using a specific device. Individuals who view computers positively, and are confident about their ability to use computers, will be more likely to learn whatever new skills are required by future technological developments.

There is considerable interest in the literature in studying the influence of gender on technology acceptance. Generally, most of the earlier studies conducted before 2005 showed that males held a more positive attitude toward technology than females. These gender differences in attitudes may be caused by many factors. For example, some research has also suggested that the masculine image of the computer deters females from benefiting from technology, as this has made them less confident or more anxious (Culley 1988). However, a recent research has revealed changing attitudes among female computer users. Dündar and Akçayır (2014) studied 183 high school students in Turkey and found a lack of support for gender

differences in attitudes toward computers. This lack of gender differences in attitudes toward computers could be attributed to the increased use of computers for teaching and learning in schools or in other settings. Females may have been socialized differently in today's digital era to become more comfortable with computers, which may serve as a good starting point to remove barriers to technology training.

Several studies examined differences in attitudes across SES and race/ethnicity groups. The "digitally disadvantaged" groups have been found to have similar beliefs in the usefulness of technology as their more privileged counterparts. Generally, youths believe that they can benefit from interacting with digital technology. For example, English language learner (ELL) students are reported to have high interest in using Facebook, Twitter, and text messaging for literacy learning purposes. These results may reflect their motivation to improve their English language skills through multiple exposures across multiple contexts, since these students typically do not have access to English in their home environment (Li et al. 2015).

Academic Achievement from Home Usage

A large body of research focuses on whether using new technology can help students acquire mastery of academic content. It is common practice for most researchers to use traditional school achievement measures to answer this line of related questions, due to the clarity of these outcome measures as well as their high level of acceptance among educators and the general population. These studies take one of two emphases: either examining the impact of technology availability (e.g., whether a computer is available at home) or the impact of technology use. Since youths can perform a wide array of activities on computers or tablets, the research on effects of technology use generally focuses on a more specific kind of activity such as Facebook use and video gaming, rather than vaguely asking the effects of "computer usage."

The results on the impact of home technology access are inconclusive. A few studies find significant positive effects on various educational outcomes such as grades, test scores, and cognitive skills (e.g., Fairlie et al. 2010), while an almost equal number of studies find evidence of modestly sized to significant negative effects of the use of home computers on educational outcomes (e.g., Vigdor and Ladd 2010).

Regarding whether home technology access may benefit underrepresented students' learning, one field experiment study that offered low-income high school students the opportunity to own home computers provides a compelling test (Fairlie and London 2012). Fairlie and his colleague conducted a randomized control experiment with 1,123 students in grades 6–10 attending 15 schools across California, USA. Although the experiment substantially increased computer ownership and usage without changing school technological environments, the research found no evidence that home computers had an effect (either positive or negative) on any educational outcome, including grades, test scores, credits earned, attendance, and disciplinary actions. A follow-up survey was conducted to provide information on several less-commonly measured intermediate educational inputs and outcomes such

as homework effort and time, receiving help on assignments, software use, and computer knowledge. Consistent with the previous findings, access to a home computer did not yield any impact on these measures. This result indicated that computer ownership alone is unlikely to have much of an impact on short-term schooling outcomes for low-income children.

Another line of study regarding the association between different forms of technology use and academic achievement also finds mixed results. This may be because different forms of technologies each have their own unique affordances and thus generate different effects on users. Common themes explored by the researchers include video gaming, social media, and digital homework. Generally, nonacademic usage of technology (e.g., passive gaming, SNS) negatively relates to academic achievements, while home technology usage for educational purposes (e.g., serious gaming, accessing to educational information) is reported to have positive effects on academic performance (Biagi and Loi 2013).

Only a handful of studies investigated the effect of home technology usage on minority, low-SES teens. Jackson et al. (2006) conducted a longitudinal study to examine the impact of home Internet use on low-income family teenagers' academic performance. Participants were 140 teenagers, mostly African-American (83%), mostly boys (58%), and mostly living in single-parent households (75%) in which the median annual income was \$15,000 or less. During the 2-year study, participants' Internet use was continuously recorded, including time spent online, numbers of domains visited, and numbers of emails sent. Findings indicated that children who used the Internet more achieved higher scores on standardized reading tests and higher grade point averages (GPA) than did children who used it less.

Academic Achievement from School Usage

Studies on the effects of school technology usage are more likely to adopt experimental design than those on home technology usage. Most existing literature is based on non-nationally representative samples and tests the effect of a specific kind of technology/intervention. Since these studies are highly contextualized, the results may not be interconnected. Several meta-analysis reviews have attempted to depict a broad picture from these mixed studies. For example, Zheng et al. (2016) reviewed 65 journal articles and 31 doctoral dissertations published over a period of 15 years (2001–2015) in order to examine the effect of one-to-one laptop programs on teaching and learning in K–12 schools. Based on a subset of these studies that met the requirements for meta-analysis, they found an overall significant positive average effect on academic achievement with effect size of 0.16. Significant positive impact on achievement was also found in the subareas of English, writing, math, and science.

Another important question is whether the use of laptops by diverse learners helps bridge the achievement gaps among student groups. The positive impact of school technological programs on disadvantaged students was identified in a number of studies (see, e.g., Warschauer et al. 2014). However, these positive goals for at-risk

learners are not achieved in all programs. For example, a study in the USA explores the impact of one-to-one computing on student achievement in Ohio high schools as measured by performance on the Ohio Graduation Test (Williams and Larwin 2016). The sample included 24 treatment schools that were individually paired with a similar control school. Overall, examining the full sample, student performance and content-specific achievement in math, reading, science, social studies, and writing were not significantly affected by the introduction of the one-to-one program. However, when broken down into demographic groups, the results show that Black students in the treatment group performed lower than their peers in control groups.

These contradictory results initiate further investigations into the reason why technology access and usage generate distinct impacts on disadvantaged learner populations. Wenglinsky (2005) noted that “the drill and practice” activities favored in low-SES schools tend to be less effective, whereas the constructive integration of technology disproportionately found in high-SES schools achieves positive results. The author argues that it is not whether the schools use technology, but rather how they use it that makes the great difference. If used appropriately, technology does have the potential to enhance low-achieving students’ learning through various pathways.

Some studies offer insight into how to maximize the benefits of technology for disadvantaged students. For example, some have found that when students are engaged in content creation projects involving technology, they demonstrate stronger engagement, self-efficacy, and attitudes toward school, thus enhancing their academic achievement (see, e.g., Sadik 2008). This may especially benefit disadvantaged students. Content creation projects include a wide array of activities such as engaging in multimedia content creation to communicate ideas about the material they are studying by creating reports, graphic representations of data they have researched or developed, websites, slides presentations, video production, digital storytelling, and other means. Darling-Hammond et al. (2014) described a technology-rich classroom for at-risk students, in which the teacher used one-to-one computers with wireless Internet connection to engage students in “word processing, spreadsheet, database, web page production and presentation software in a variety of contexts” (p. 9). Results showed that the students in this particular classroom ultimately outperformed other higher-tracked classes in their school in the state tests. According to the authors, the process of content creation allows students to develop their personal and academic voice with the scaffolding of technology. Due to their affective involvement with this process and the novelty effect of the medium, students are more engaged than in traditional assignments.

Citing research by Reeves (2004) and others, Warschauer (2011) argues that informational writing is a critical level for improving academic achievement among at-risk students and that technology-based writing instruction is thus especially valuable for promoting educational equity. He and his colleagues provide evidence from school districts with technology-based writing forms that have helped bridge performance gaps (Warschauer et al. 2014; Zheng et al. 2013).

Twenty-First-Century Learning Skills

Knowledge of core content is necessary, but no longer sufficient for success in postsecondary institutions and workplaces. Higher education and information economics place increasingly high value on people who can use their knowledge to communicate, collaborate, analyze, create, innovate, and solve problems. It is widely believed that technology use plays a pivotal role in helping students develop these so-called twenty-first-century skills. This broad concept can be categorized into three related skill sets: information, media, and technology skills; learning and innovation skills; and life and career skills. Even though we conceptualize twenty-first-century skills as a separate ability from traditional academic achievement for our discussion, these two components are highly correlated.

Ritzhaupt et al. (2013) provided a comprehensive examination of gaps in the three components of twenty-first-century skills among student groups. In this study, a large sample of students were asked to complete a performance-based assessment of digital literacy skills. Five domains were assessed: technology operations and concepts, constructing and demonstrating knowledge, communication and collaboration, independent learning, and digital citizenship. Results showed that high-SES and White students outperformed their counterparts in all domains. It is hinted in the study the divides in twenty-first-century skills may stem from different patterns of school technology use and out-of-school use among student groups.

In school settings, well-implemented technological programs are believed to facilitate acquisition of twenty-first-century skills. In a large-scale laptop program, for example, more than one-third of students reported using laptop from once a week to several times daily to gather and evaluate information, solve real-life problem, and visually present or investigate concepts. Warschauer (2006) interviewed teachers, students, and parents; conducted observations in the classrooms; and analyzed student work. He suggested that these kinds of learning activities may help enhance students' twenty-first-century skills and have important implication to other technology-based interventions.

Another question is whether low-SES schools provide students with equitable supports for achieving such skills compared with high-SES schools. A study demonstrated that students in lower-SES schools had less digital resources, used technology less frequently, and had more limited technical support and service, so as their teachers (Hohlfeld et al. 2008). These differences provided evidence of the existence of the divide in technology literacy among K–12 schools.

Youths could also develop their twenty-first-century learning skills from using technology in out-of-school environments. As at school, whether or the extent to which technology use can help enhance such skills depends on what kinds of activities youths perform with technology. Ito and her colleagues found that some youths are “geeking out” in interest-driven activities, which refers to an intense commitment or engagement with media or technology (Ito et al. 2009) and mastering sophisticated skills such as media literacy, creativity and innovation, communication and collaborations, and initiative and self-direction. Ito's interviews revealed some of the factors that may contribute to what she termed “information magic,” including

adequate access to technology, high levels of commitment, and “an advanced media ecology that is finely tailored to youths’ interests” (p. 69).

Unfortunately, not all youths benefit from these kinds of digital activities at the same level. There has long been a concern that girls are not gaining the same knowledge and skills about technology that boys are, because of differential attitudes toward technology and use at home. Fields et al. (2014) mapped out the gender difference in the online Scratch community, by far the largest online informal programming community primarily for young programmers aged 11–18, where they post Scratch programs that they create, view and comment on each other’s work, and seek and provide help on forums. Drawing on a random sample of 5,000 youth programmers and their activities over 3 months in early 2012, Fields and his colleagues found that girls only represented one-third of all registered members on the Scratch site. The authors then classified the users into four different levels (i.e., beginner, intermediate, advanced, experience) based on their programming work. Girls were dramatically less likely to reach advanced and experience levels than boys. Additionally, since low-SES and minority children are reported to use technology in a less sophisticated way outside of schools (see discussion in Warschauer and Matuchniak 2010), we believe these groups may be less likely to gain technology skills from the usage than their counterparts.

Conclusion

The research reviewed above hints at the complexity of equity issues intertwined with the rapid expansion of digital technology and its impact on students’ access, use, and outcomes. Regarding access, it is clear that gaps in home and school technology access are narrowing but still persistent across SES and racial/ethnic groups. Regarding usage, youth groups differ in the manners and the extent digital technologies are used at schools and outside of schools. Since there is a wide range of technologies available and groups’ usage pattern varies among forms of technology, it is challenging to summarize a single trend of inequality of technology usage. Regarding outcomes, how the differences in access and usage affect the disparities in outcomes remains inconclusive. The lack of concrete conclusion may partially be due to the inherent difficulty of causal inference – that is, to prove access and usage of technology *causes* the change of students’ learning outcomes. Additionally, the majority of existing literature concerned with outcomes is based on non-representative small samples and tests the effect of a specific kind of technology/intervention. The mixed findings are thus highly contextualized and noncomparable.

Future research is needed to offer deeper understanding of the relationship of technology and equity. First, descriptive research which only examines SES, ethnic/racial, and gender differences in access and use is important but not sufficient. The inequalities have been confirmed. The future task should be to understand the reason for these inequalities as well as the possible approaches to alleviating the inequalities, other than merely describing the problems. For example, how family contexts or school contexts influence teenagers’ technology usage patterns may be an

interesting question to explore. Second, to understand the outcomes of digital technology access and usage, it is crucial to have more studies with rigorous design, such as experimental research (e.g., random assignment, natural experiment) or longitudinal research. Third, researchers may want to further investigate the possible different effects of technology access and usage across SES, racial/ethnic, and gender groups, which may shed light on how technology may contribute to the achievement gaps.

Abstract

School technology access has become an issue of international priority. With increased access to technology on the horizon, educators stand at a crossroads. Do they continue with the status quo or attempt to use the rising technology levels to support those students who need it the most? The work in this chapter aims to contribute to this dialogue in two ways. First, it introduces the Digital Learning Ecosystem as an empirically grounded framework that provides a holistic perspective of the mutually interdependent variables shaping a technology-enabled learning environment. In addition to proposing the Digital Learning Ecosystem, this chapter continues the tradition of identifying and sharing promising research-based practices that are empirically linked to improved learning outcomes by underserved students.

Introduction

For many years, educators, researchers, and policy makers have looked to technology as a tool for closing the achievement gap. However, the results of various technology initiatives have failed to provide the silver bullet that proponents anticipated. As often as not, the introduction of technology into classrooms has failed to push the needle on student outcomes. Furthermore, the wide variability within and between classroom, school, and district technology access and use is consistent with notions of a growing digital divide (Gray et al. 2010a, b; Zielezinski and Darling-Hammond 2016) which serves to further the achievement gap rather than fix it. Beyond school walls, disparities in hardware ownership, Internet access, and access to community-based resources contribute even more to the troubling lack of digital equity and educational opportunity in the USA (Madden et al. 2013; Purcell et al. 2013; Barron et al. 2010). For many years, the focus has been on increasing access to technology to reduce the digital divide, and while addressing access is an essential element of this effort, increased access alone is not sufficient for improving educational outcomes for underserved students. Once *access* is granted, we must consider how technology can be *used* to support learning by those who need it the most.

To further develop the understanding of how digital tools can be used to support underserved and under-resourced students, we conduct a comprehensive literature review, taking into account more than 50 studies, white papers, reports, and reviews primarily published between 2003 and 2013 (Zielezinski and Darling-Hammond 2016). The focus of this work was on underserved, under-resourced, and underprepared students who have been placed at risk by the organizations that serve them and societal structures in which they live, specifically students in grades 6–12 who have been labeled as minority, low-SES, low achieving, or not on track to graduate. Moving forward, use of the term “underserved” in this chapter will refer to students with one or more of these social markers (This is not intended to be a comprehensive definition of “underserved.” Instead it is the operational parameter used to delineate the scope of the studies reviewed.). In this chapter, we first introduce and describe the research-based framework called the Digital Learning Ecosystem that we developed for understanding technology use in schools. Next, we share the key findings from our comprehensive literature review (This chapter is adapted from an extensive literature review (Zielezinski and Darling-Hammond 2016) and US policy brief (Darling-Hammond et al. 2014). See the original literature review for methodological details and additional research-based examples of promising practices for digital equity.). We end the chapter with a synthesis of findings and conclusion.

Conceptual Framework and Methodology

The Digital Learning Ecosystem (see Fig. 1) was developed in our review process and is based on an in-depth analysis of 23 highly relevant reports and reviews that synthesize the findings from over 2,000 empirical articles about technology for

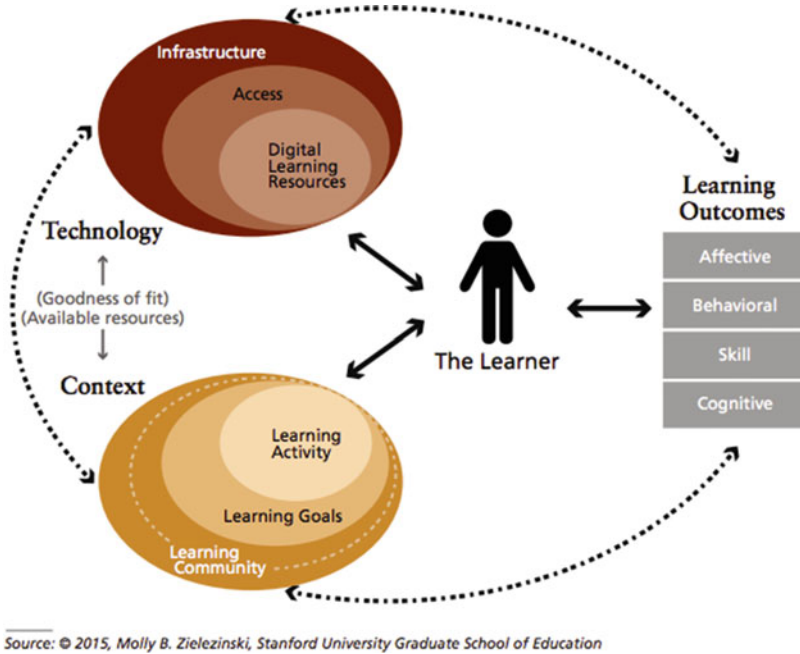

Fig. 1 The Digital Learning Ecosystem. (Source: © 2015, Molly B. Zieleszinski, Stanford University Graduate School of Education)

learning (The initial 23 reports and reviews synthesized literature on digitally mediated learning for students in grades 6–12 but were not limited to literature specifically reporting outcomes for minority, low-SES, and underprepared students. This collection was used specifically to develop the Digital Learning Ecosystem as a frame for analyzing factors that influence learning with technology. Later, the literature search for empirical works specifically reporting outcomes for minority, low-SES, or underprepared students in grades 6–12 yielded 34 studies. These articles were coded and analyzed. Results of this analysis are presented in the findings section.). Taken as a collection, these reviews illustrated that learning outcomes are the result of interactions among numerous variables within a given learning environment. No single variable can ensure a desired outcome because learning environments are complex systems governed by sets of mutually interdependent elements. The Digital Learning Ecosystem is a representation of the most critical elements as revealed in the research as they pertain to learning outcomes for students using technology. In the coming section, each element of the Digital Learning Ecosystem is introduced. In the subsequent section, this ecosystem is used to frame the findings from the review of a decade of empirical work about underserved students learning with technology.

The ecosystem was designed with the learners at the center. What learners bring to their learning environments – their previous experiences, content knowledge, skill

level, technological literacy, and social emotional state – plays a distinct part in mediating the outcomes of a learning activity. These outcomes are often narrowly conceived in terms of academic achievement, but our analyses indicated that this idea is somewhat shallow (Ritzhaupt et al. 2011; Beltran et al. 2006; Barron et al. 2010). Instead of solely academic outcomes, learning outcomes can be considered across four domains: academic, affective, behavioral, and cognitive. We determined that two major spheres of influence shape the learners' experience and outcomes: the technology and learning contexts.

When considering technology as a context, the most influential elements are related to infrastructure, access, and the specific features of a digital tool. Infrastructure refers to the “back end” of the technology setup. This includes categories such as bandwidth, servers, storage, and data hosting models. Access refers to the hardware used in the learning environment but also includes the model for access, which describes the organization of the learners and devices as well as the time, place, and frequency of access to this device. In schools, common models for access include one-to-one stationary computer labs, mobile computer labs, and bring your own device (BYOD).

Infrastructure and access are closely related, and each provides a set of enabling (or constraining) circumstances surrounding the use of technology in service of various learning outcomes. Each also plays a part in either limiting or extending the success of a particular digital learning resource. Digital learning resources can be characterized in terms of the platform or application being used and the specific features of that digital tool. These features influence the way content is presented, stored, and revisited, as well as whether and how information is manipulated or shared. The features of a digital tool make visible a wide variety of design specifications that shape a learner's experience with a digital tool and thus influence the resulting outcome.

Considerations about technology alone are not sufficient for drawing conclusions about the potential effectiveness of technology. The learning context is equally relevant and thus constitutes the other major sphere of influence in the Digital Learning Ecosystem. As with technology, the learning context is also subdivided into three categories: the learning community, the goals and objectives for learning, and the actual activities that learners engage in as they are using the digital tools. Fig. 2 delineates the aspects of the learning context at each of these levels as they commonly appear in the literature.

The technology and the learning contexts interact to provide a unique set of conditions for learning. Learners' previous experiences and beliefs shape their responses to these conditions dictating patterns for interaction and engagement. Together, these variables constitute a distinct experience for each learner, and the experience in turn enables a wide variety of outcomes that come to be associated with the use of particular digital resources. This ecosystem is more evolved than the binary conceptions of technology for learning common at the end of the twentieth century. The early years of the digital divide were characterized in terms of having or lacking access, and little information was collected or reported about the details of use. Even now, it is common for researchers to report on some but not all aspects of

Fig. 2 Learning contexts in the Digital Learning Ecosystem. (Source: © 2015, Molly B. Zieleszinski, Stanford University Graduate School of Education)

the Digital Learning Ecosystem as it is presented here, and there is little explanation given for what is included and what is left out.

The major benefit of the ecosystem approach is that it makes clear the need to understand outcomes for learners with regard to the multiplicity of variables that impact both the learners’ experiences and the potential outcomes associated with technology use. We cannot assume that the success of digital learning activity in one classroom will generalize to success in another classroom without also understanding details about the technology, the learning context, and the desired learning outcomes.

In the remainder of this chapter, the ecosystem is used as a frame for presenting the findings from the literature about technology use and learning by underserved students. Each finding points to a specific variable in the Digital Learning

Ecosystem, offering details from the literature on how it can be leveraged to best support learning outcomes for underserved students. **When considering these levers for change, remember that strong alignment among all the elements within the Digital Learning Ecosystem in a given context supersedes any of the specific practices listed below.** The potential for achieving the positive outcomes associated with these practices decreases when there is poor alignment between a given practice and the other elements within the ecosystem – and likewise increases when a practice is clearly aligned with the available technology, specified context, characteristics of the learners, and desired learning outcome.

Findings

Technology in Context

When considering technology in the learning context, the most critical elements are infrastructure, access, and features of the digital learning resources available to the learners. Several key recommendations are presented below given the potential of each to set the stage for learning and development by underserved youth. In the research reviewed, learning and development include cognitive gains, skill development, increase in desired behavior, and positive changes in student affect.

Underserved students benefit from opportunities to learn that include one-to-one access to devices. One-to-one access refers to environments where there is one device available for each student. There is wide variation within one-to-one environments, including the time spent using devices, the overall availability of devices (e.g., whether the students can bring them home), and the quality of the instructional materials used on the device. While this variation can be profoundly influential, the literature supports the notion that students often benefit from opportunities to learn when there is at least one device per student (Grimes and Warschauer 2008; Maninger 2006; Ritzhaupt et al. 2010, 2011; Shapley et al. 2009). For example, Grimes and Warschauer (2008) studied “the implementation of a one-to-one laptop program in three diverse schools in California. The program was carried out in one largely Hispanic low socioeconomic junior high school, one largely Asian–American high-SES K–8 school, and the gifted program in a medium-SES elementary school” (p. 305). Their findings indicate that a majority of teachers found the laptops to be useful for learning by “at-risk” youth and that low-SES students demonstrated significantly higher gains in mathematics as compared to the high-SES students in the laptop program. Regardless of SES, the one-to-one laptop implementation increased students’ likelihood to engage in the writing process, practice in-depth research skills, and develop multimedia skills through “interpretation. . . and production of knowledge” (p. 319).

High-speed Internet access is needed to prevent user issues when implementing digital learning. Digital learning often requires Internet access, and this need is growing with the proliferation of online audio and video resources. Kim and Lee (2011) found that underprivileged students participating in blended and

online courses reported that a faster Internet connection would have improved their learning experiences. Grimes and Warschauer (2008) found that when students were given one-to-one laptop access as well as access to the Internet at school, they made use of this at least several times per week: “We witnessed online information access by students for three main purposes: to provide background knowledge, to facilitate ‘just in time’ learning, and to support research projects” (p. 317). Fast and reliable Internet access allows teachers and students to support learning in real time.

Underserved students benefit from digital activities designed to promote high levels of interactivity and emphasize discovery. The design of technology tools allows for different types of interactions between the learner and the technology. In the literature, designs that support certain types of interactions repeatedly demonstrated support for learning by underserved students. Several design considerations that promote interactivity and exploration are presented below.

First, underserved students benefit from technology interactions designed to promote high levels of interactivity (Bos 2007; Callow and Zammit 2012; Elam et al. 2012; Figg and McCartney 2010; Watson and Watson 2011). The level of interactivity refers to the amount and type of interactions permitted between learners, technology, and content, where a high level is characterized by frequent opportunities to manipulate, examine, and create new content in a variety of forms. For example, in one study, students measure the heart rate of their peers during various activities and use this to generate and test hypotheses. In another, students used handheld GPS devices to participate in a scavenger hunt. Using interactive approaches such as these has been found in several studies to be successful in helping low-income students pass state competency tests (Bos 2007) and master complex new materials (Hannafin and Foshay 2008).

Second, underserved students benefit from technology interactions designed to emphasize discovery and exploration rather than direct instruction (Bos 2007; Harness and Drossman 2011). For instance, a design that includes features of technology that “generate fluency, [and allow students to] create and modify representational forms is used to develop the dimensionality of a quadratic function through exploration, problem solving, and through making and exploring virtual environments” (Bos 2007, p. 356). Students who were allowed to explore the concept of quadratic functions in this study significantly outperformed those who learned via lecture and note-taking. In this example, students constructed understanding by working directly with graphs and tables. Afterward, they answered guided open response questions to help further develop their understanding of quadratic functions and checked this understanding through dialogue with other students (Bos 2007). Experiential learning such as this allows students to develop their own understanding through exploration prior to direct instruction. This strategy is augmented when combined with built-in opportunities for students to synthesize and apply what they are learning, for example, by engaging in face-to-face or digitally mediated dialogue with peers and teachers, capturing emerging knowledge through written reflection, or completing other informal formative assessments.

Third, underserved students benefit from technology environments that allow the learner to engage with data and complex content and represent thinking in multiple

forms. Technology tools and their specific features and affordances structure the interactions students have as they engage in digital learning activities. Such features and affordances can be leveraged to provide learners with opportunities to engage productively with their peers or directly with content. In the literature, highly interactive tools that promote data analysis (Bos 2007; Elam et al. 2012; Grimes and Warschauer 2008; Marino 2009), engagement with complex content (Bottge et al. 2006; Samsonov et al. 2006), and opportunities to convey understanding in multiple forms (Bos 2007; Callow and Zammit 2012; Hall and Damico 2007; Marino 2009; Watson and Watson 2011) repeatedly demonstrated support for learning by underserved students. For detailed examples of these strategies from the cited literature, see Zielezinski and Darling-Hammond (2016).

Learning Context Sphere

The context sphere consists of the learning community, the learning goals, and the learning activity. While there is some overlap between the digital resources considered in the previous section and the learning activity presented in this sphere, there is a distinction. Discussion of the digital resources in the technology sphere is related to the specific design of the technology, while the learning activity has more to do with the choices about using technology to meet certain lesson objectives and goals within a learning environment. Within this sphere, three major recommendations were identified that show promise for stimulating active participation in effective digital learning activities for underserved youth.

Underserved students benefit from learning activities that focus on the development of higher-order thinking skills (such as problem-solving, making inferences, analyzing, and synthesizing) and twenty-first-century skills. These should be prioritized over activities that target basic skill development (such as memorizing facts and applying rules). Consistent with the literature on technology for learning by the general population of all K–12 students, the literature regarding underserved students reveals that digital learning supporting problem-solving and other higher-order thinking skills has more positive effects than digital learning opportunities that emphasize the development of basic skills (Barley et al. 2002; Bos 2007; Ringstaff and Kelley 2002; Wenglinsky 2005). Warschauer and Matuchniak (2010) conducted a literature review about the equitable use of and access to technology by various learner populations concluding that “the drill and practice activities favored in low-SES schools tend to be ineffective, whereas the uses of technology disproportionately used in high-SES schools achieve positive results” (p. 205).

Warschauer and Matuchniak (2010) utilize differences in standardized test scores across low- and high-income schools as evidence to support the idea of prioritizing digital learning opportunities that focus on higher-order thinking over those that focus on basic skill development. Another instance of this in the literature comes from a study of 48 “at-risk” high school mathematics students in Texas. In this experiment, students spent 55 min per day, working through six lessons that

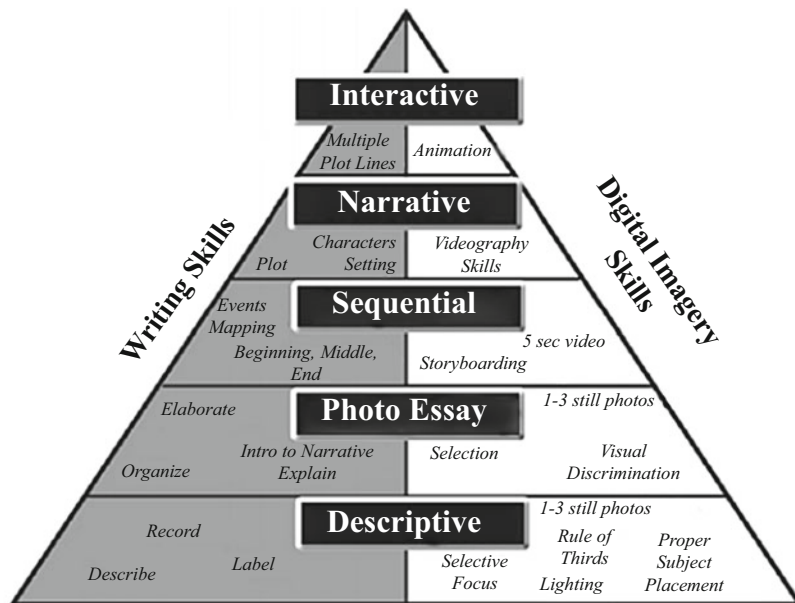

followed the cycle: “engage, explore, explain, and elaborate” (p. 356). Through this cycle, students utilized simulations to manipulate information on interactive graphs and tables. They followed an exploration and were prompted to explain and elaborate on certain phenomena they observed. Students who engaged in this intervention outscored those learning in more traditional forms. The authors conclude that “results are deeply embedded in the core of the learning process and the necessity to create an environment that involves all students in high level thinking skills and to promote problem solving versus a more drill-practice approach” (Bos 2007, p. 366).

These examples point to the utility of simulations and digital games for the development of higher-order skills. The literature also indicates that these are useful for promoting twenty-first-century thinking skills and brain development (e.g., working memory and vocabulary development). Specifically, educational games have been linked to skill and concept development for underserved students (Alloway 2012; Ritzhaupt et al. 2010, 2011). Ritzhaupt et al. found that students who played single and multiplayer games demonstrated an increase in motivation, interest, and self-efficacy (and potentially academic achievement). Others have noted the importance of using digital learning environments (such as games and simulations) with features that are appropriate for the students’ prior knowledge and skill level (Marino 2009; Samsonov et al. 2006).

Underserved students benefit from learning activities that draw on culture and community, specifically activities that integrate culturally relevant practices, foster student development of expertise, and highlight this expertise by providing opportunities for students to share their knowledge and skills with authentic audiences. Digital learning activities that were connected to the learners’ cultures and communities were more successful than those that were not culturally relevant. One form of cultural relevance was observed when students engaged family and community members in authentic content creation tasks such as creating a family movie (Figg and McCartney 2010). Another form of cultural relevance was seen when Hall and Damico (2007) provided African-American 10th, 11th, and 12th graders with interest-driven opportunities to create representations of their thinking about local social justice issues, prioritizing cultural relevance by encouraging students to make use of language that they were typically asked to suppress but is common within their communities.

Meaningful activities foregrounding culture and community were observed with respect to authentic audience, opportunities for communication, and the development of student expertise. In one study, peers, family, and community members were mobilized to act as an authentic audience for students’ multimodal presentations. Parents enjoyed authentic opportunities to communicate with their children about learning (Figg and McCartney 2010). Additionally, authenticity was created through opportunities that honored students’ roles as experts, for example, the provision of opportunities for the teacher to learn from the students and opportunities for parents to see children as experts (Figg and McCartney 2010).

This project conducted by Figg and McCartney (2010) was culturally relevant because the students were asked to “draw upon oral or biographical family history,” making them each experts in their own topic (p. 54). This cultural relevance was

Source: © 2005, Candice Figg (as cited in Figg & McCartney, 2010).

Fig. 3 The model of digital storytelling. (Source: © 2005, Candice Figg (as cited in Figg and McCartney 2010))

successful in part because of the well-designed, highly scaffolded structure of implementation. Another way this project was a model for culturally relevant activity is through the active involvement of family and community members as participants and audience members. Fig. 3 outlines the process of scaffolding in terms of writing and digital imagery skills. Stepping the students from the bottom to the top of this pyramid over a 2-week period allowed them to become active and engaged daily writers. Another way this project was a model for culturally relevant activity is through the active involvement of family and community members as participants and audience members. Students were asked to participate alongside a very important person or people (VIPs) from their life, such as a parent, grandparent, or close member of their community. VIPs committed to several sessions where their students taught them computer skills while working on the project and presented the final versions of digital stories they had created. The presence of the VIPs and the opportunity for real conversations between VIPs and students raised the stakes for students by invoking community as an authentic audience. This combination of cultural relevance, scaffolding, and authentic audience led to improvement in students' writing skills, motivation, and interest.

With the rise of the networked world, neither culture nor community needs to be local anymore. Students can and often do identify with a number of cultures both on- and offline. Each of these subcultures has digital and/or face-to-face audiences that

can be mobilized as students prepare to share their developing expertise. For example, imagine a student that creates a Minecraft how-to video, posts this on YouTube, and links to it within a Minecraft community forum post. This student is invoking a form of cultural identity and honing her skills by putting her emerging expertise on display to be evaluated by an authentic audience. These are the types of interest-driven activities that connected youth regularly engage in today (Ito et al. 2013). As such, relevant cultures and communities, rooted in either the digital world or local context, can have powerful transformative potential when integrated within learning activities. These types of authentic activities can be leveraged in formal learning environments more frequently as a way to increase engagement and support learning by underserved students.

Underserved students benefit from learning activities that provide them with opportunities to drive their own learning. These include learning opportunities that allow students to become content creators. This type of student agency was featured in several different studies and included the use of technology to provide students with a choice of instructional materials and allow them to become active agents in their learning (e.g., making decisions about how a task was done) (Watson and Watson 2011). Similarly, technology was used to allow students the freedom to determine the structure and framework of learning tasks when engaged in multi-modal content creation (Hall and Damico 2007). Finally, technology was used to promote agency in the context of choices about whether or not to use the technology at all (Edmonds and Li 2005).

In a study by Hall and Damico (2007), African-American high school students attended a precollege summer course focused on digital media construction. The course was aligned to standards put forth by the International Society for Technology in Education and was focused on meaningful creation of digital texts by students. In this case, students were able to drive their own learning on multiple levels. First, students, working in groups of four or five, “were encouraged to explore a social justice problem related to their respective communities” (p. 82). Thus, they were given the choice to engage in a topic that was both relevant to their community and interesting to them. The student teams next exercised agency in the project by choosing to make either a website or an iMovie. The course provided the students with the skills and resources necessary to complete these learning activities *and* offered a choice as to which path they pursued. Finally, students were given complete authority over their plans for completing the project. This included the way the work was divided among the team, their design choices, and the order in which various parts of the project were completed. By the end of the summer program, instructors were facilitating student-driven learning rather than directing it.

Activities like this one that involve students as content creators show promise in terms of student engagement, self-efficacy, and attitude toward school and learning. In a number of studies, students engaged in content creation projects demonstrated improved engagement, self-efficacy, attitude toward school, and skill development (Bottge et al. 2006; DeGennaro 2008; Elam et al. 2012; Figg and McCartney 2010; Hall and Damico 2007; Lang et al. 2009). Content production can take a number of forms. For instance, students might engage in multimedia content creation that

communicates their ideas and thoughts about culturally relevant themes and events (Figg and McCartney 2010; Hall and Damico 2007; Watson and Watson 2011). This may be accomplished through video production (Cohen et al. 2012; Harness and Drossman 2011), digital storytelling (DeGennaro 2008; Figg and McCartney 2010), or other forms.

The cases detailed above are clear illustrations of the way content creation might look as a single ongoing project. An alternative example comes from Lang et al. (2009), who worked with 55 Latino adolescents on a number of shorter content creation projects. In this study, students attended 16 2-h sessions that met weekly. Within these sessions, each student had a computer and engaged in original content creation projects, such as the production of posters using Broderbund's The Print Shop software that advertised positive traits about a student's ethnic group. In another lesson, students were asked to create materials for a business they envisioned themselves starting. They used software such as Microsoft Excel to track expenses, The Print Shop to advertise to potential employees, and Microsoft FrontPage to mock up a website for their business. Although this instantiation of content creation differs in terms of scope, it shares common characteristics with the earlier illustrations, including cultural relevance, interest-driven activities, structured choices, and student agency within the learning activity. Historically, these types of activities are associated with large projects, but the underlying characteristics could be designed into much smaller content creation projects such as blog posts, comments on articles, article annotations, social shares, tweets, or even emails. For content creation to support learning outcomes, the scope, task, and digital tool must be well aligned to the other elements of the Digital Learning Ecosystem. When these elements are well coordinated and scaffolded, underserved students benefit from the opportunity to drive their own learning, create original digital content, engage meaningfully with content knowledge, or hone their digital literacy skills.

Synthesis of Findings

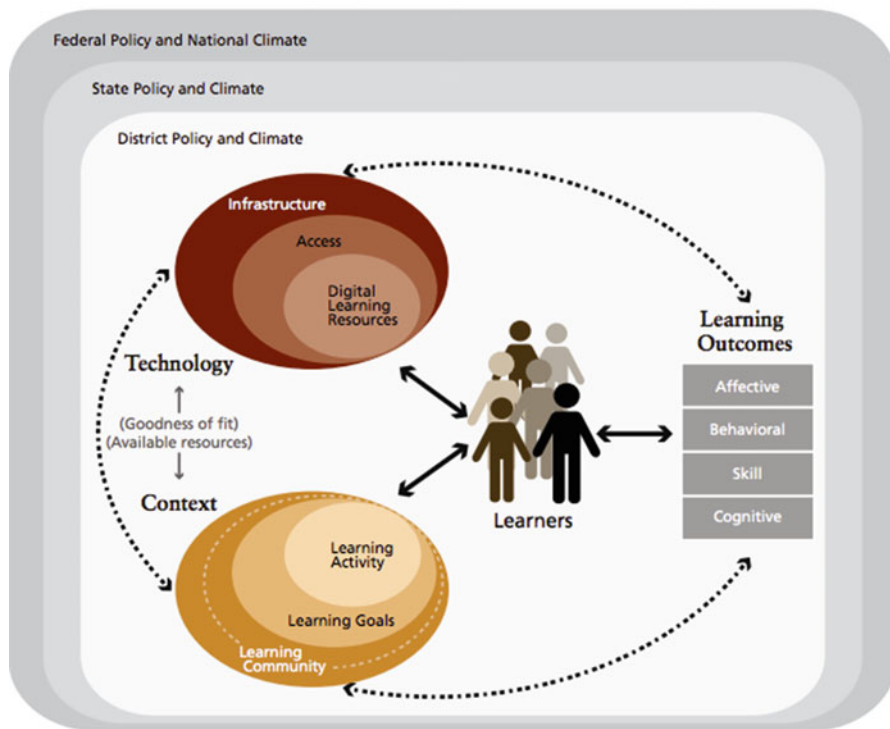

School technology access has become an issue of international priority. With increased access to technology on the horizon, educators stand at a crossroads. Do they continue with the status quo or attempt to use the rising technology levels to support those students who need it the most? Research on technology for learning by underserved students has revealed that patterns of technology use and access vary along socioeconomic and demographic lines. Underserved students use technology to practice basic skills far more frequently than others, and these types of drill and practice activities contribute little to actual learning. Additionally, evidence indicates that these students experience stronger learning benefits from tasks that promote higher-order thinking skills. These are not, however, the types of opportunities that underserved youth commonly experience (Warschauer and Matuchniak 2010). These findings indicate that educators who continue with the status quo are likely to reinforce patterns of inequity, not solely in terms of access to technology but also in terms of how the technology is used. Although issues of equitable access are far

from resolved, the rising tide of technology access necessitates a new wave of dialogue dedicated to identifying and disseminating promising practices for technology use that support learning by underserved students.

The work in this chapter aims to contribute to this dialogue in two ways. First, it introduces the Digital Learning Ecosystem as an empirically grounded framework that provides a holistic perspective of the mutually interdependent variables shaping a technology-enabled learning environment. The application of this framework has both benefits and limitations. A major benefit of the Digital Learning Ecosystem is that it provides a detailed picture of the variables that are present when students are learning with technology. In this framework, we begin to see how these interconnected elements collectively mediate student outcomes. As such, the framework can be applied in either research or practice. As a research tool, the Digital Learning Ecosystem can be used to frame inquiry and situate findings. In practice, it can be used to support strategic planning, preparation, or evaluation. As districts, schools, and teachers prepare to use new digital tools or transform their existing digital practices, they can use the Digital Learning Ecosystem to identify elements within their systems that are strongly aligned and those that need additional support.

The limitation of this framework is that it fails to take into account variables that were not highlighted by the researchers and educators within the studies reviewed. Examples of missing variables include peer interactions as well as district, state, and national policies. Each of these variables influences the learning environment, which in turn impacts the outcomes for learners. Fig. 4 depicts the Digital Learning Ecosystem version 2.0, which has been lightly revised to depict peer interactions as an additional variable that influences digital learning. This limitation can be mitigated if we consider the Digital Learning Ecosystem to be a living artifact that must be updated and revised based on the shifts in the larger educational landscape. Future waves of scholarship, widespread changes in educational practice, the evolution of new technologies, and the way these technologies are adopted in schools will all shape future iterations of this framework.

In addition to proposing the Digital Learning Ecosystem, this chapter continues the tradition of identifying and sharing promising research-based practices that are empirically linked to improved learning outcomes by underserved students. This chapter provides abridged outtakes from a more extensive review of the literature conducted by Zielezinski and Darling-Hammond (2016). The review indicated that in terms of technology, best practices for supporting underserved youth include one-to-one access to devices and high-speed Internet connectivity. Additionally, technology tools that promote student engagement with data and provide a variety of interactions with complex content in multiple forms were identified as features of digital learning resources that support underserved students. These resources best support learning when they promote high levels of interactivity and allow students to discover insights about complex concepts (rather than receiving direct instruction on the concepts). These recommendations for infrastructure, access, and digital learning resources were evident in literature published between 2003 and 2013. Given the rapid technology evolution cycles and the shift in national adoption patterns, this list

Source: © 2015, Molly B. Zielezinski, Stanford University Graduate School of Education

Fig. 4 The Digital Learning Ecosystem 2.0. (Source: © 2015, Molly B. Zielezinski, Stanford University Graduate School of Education)

of promising practices in the technology sphere should not be considered comprehensive or final.

The recommendations from the review related to context have slightly more staying power because the rate of change for formal learning environments is far slower than a technology evolution cycle. In the literature related to the learning context, Zielezinski and Darling-Hammond (2016) found positive outcomes for students when digital learning activities were used to support the development of higher-order thinking skills, when learning activities drew on relevant culture and community, and when students were drivers of their own learning, developing expertise and creating original content. These contextual features broadly frame the types of learning activities and learning objectives that guide all aspects of instruction, not just the moments that integrate technology. Successful long-term adoption of these kinds of objectives and activities is partially dependent on their alignment with other elements of the learning context, including but not limited to the curricular ideology and values of the school community, teachers' beliefs and experiences related to technology, classroom culture, and the time available for the activity.

Conclusion

Finally, conclusions in the review were informed by studies of specific students at a particular place, in a particular time, using a particular technology. Each study accounted for some, but certainly not all, of the factors that enabled or limited success for underserved students, and no single study provides detailed information about all of the variables in the Digital Learning Ecosystem. So, for those who seek to apply these recommendations, remember they are not an instructional manual for digital learning. Instead, they are merely guidelines intended to stimulate thinking and mobilize change. As we endeavor to use technology to support learning by underserved students, we must remember that the most immediately relevant beacons always come from within. Data about what is working and what is not working in your classroom, school, or district are more relevant and up to date than any academic article or national report. Interpreting these data within the Digital Learning Ecosystem can shed light on the multiple factors enabling or limiting student success as digital tools are utilized in new ways. There is utility in knowing what are widely considered to be promising practices, but these are only the starting point. The end point is when you find what works for the students who you work with and the technology available to them – especially if what is working today is preparing these students for the world they will encounter tomorrow and the one they will inherit in the years to come.

Section XII

Paradigms for Researching Information Technology in Education

Section Introduction: Paradigms for Researching Information Technology in Education

73

Margaret J. Cox and Joke Voogt

Abstract

Research and development of IT in educational settings is intertwined with the design of the IT tools themselves and influenced by policy makers and other stakeholders. This section presents the key paradigms for researching information technology (IT) in education, taking account of the challenges which need to be addressed while the teaching and learning environment is forever evolving and expanding because of the increasingly diverse IT tools and resources. Each chapter addresses different research methods and approaches, all of which have implications for designing effective research investigations, which will help to inform and shape the policies and practices of stakeholders in education.

1101

This section presents the key paradigms for researching information technology (IT) in education building on the evidence from the previous edition of the Handbook in 2008 (Cox 2008). Current research challenges now include the varying access to IT beyond the school boundaries, the changing sensory perceptions of the learners, the diversification of human computer interfaces, the mobility of the learner, and the effects of IT tools on teachers' and learners' expectations. The last Edusummit (Lai et al. 2017) identified the importance of the control of the individual learner in adapting to the digital world and the relationship between formal and informal learning. All of these have implications for designing effective research investigations which will help to inform and shape the policies and practices of stakeholders in education.

In this chapter (► [Chap. 74, "Researching Information Technology in Education: Meeting the Challenges of an Ever-Changing Environment"](#)), Cox considers the research challenges to take account of the new knowledge and knowledge representations which are accessible through dynamic, mobile, and diverse computing technologies. Evidence from this chapter shows a shift from research involving using IT resources in formal classroom settings to research across contexts between school and home and learning with personalized mobile devices. Based on the roles and interactions among researchers, policy makers, and practitioners, the chapter concludes with considering the scalability and sustainability of research methods and outcomes through recommending strategies which will consolidate research outcomes and underpin future policy and research decisions.

An important approach to researching IT in education is the use of meta-analyses which occur in many subjects ranging from medicine, law, and science to education. Extensive previous studies, reviewed by Liao and Lai in ► [Chap. 75, "Meta-analyses of Large Scale Datasets: A Tool for Assessing the Impact of Information and Communication Technology in Education,"](#) provide a brief description of the meta-analysis research method, a synthesis of meta-analysis studies of the impact of IT in education, and an identification of what kinds of evidence outcomes can be achieved through meta-analysis. They conclude that meta-analyses enable educational researchers to deliver generalizable answers to basic questions of policy and therefore practice and the consequent effective uptake of IT.

In ► [Chap. 76, "Researching the Design and Evaluation of Information Technology Tools for Education,"](#) Bruillard and Baron, investigating IT tools for education, distinguish three genres: (1) software tools for learning specific subjects, (2) learning platforms such as MOOCs for distance learning, and (3) digital resources. Behind all these tools, they observe a strong tension between individualized instruction and the intention of offering collaborative usage of general tools and individualized instruction and collaborative usage of general tools, where users have a certain margin of freedom. They conclude that evaluating education software, resources, and platforms supports an extreme diversity of approaches. To be effective, it should include different criteria: functional compliance, interactional conformity, and hedonic quality. Finally, it is important to reaffirm the key role of teachers, helping them to develop their agency in the field of educational resources, empowering them, and accepting them as collaborative partners.

In ► [Chap. 77, “International Large-Scale Computer-Based Studies on Information Technology Literacy in Education,”](#) Fraillon discusses recent developments in international large-scale studies of IT literacy-related achievement with a focus on their shared necessary attributes and the associated challenges with operationalizing these attributes in the test instruments. Two key attributes addressed are (i) that the test contents reflect real-world use of IT and (ii) that the tests make use of the dynamic functionality and multimodal opportunities afforded by the computer-based environment. The chapter concludes with recommendations of possible future directions in large-scale international studies related to IT literacy.

An important challenge for researching IT is how to measure the impact of emerging technologies and their integration into learning and teaching. This is addressed in ► [Chap. 78, “Measuring the Impact of Emerging Technologies in Education: A Pragmatic Approach”](#) by Cukurova and Luckin. They argue that traditional impact evaluations in education have to be reconsidered within these more diverse contexts. They present a pragmatic approach which focuses on the suitability of the proposed evaluation methods and the types of evidence rather than on the hierarchy of these methods and evidence types. They conclude that all types of evidence during impact evaluations of emerging technologies should be generated from intervention trials and case studies and existing literature should be leveraged at different innovation stages of emerging technologies.

In ► [Chap. 79, “Looking Back, Moving Forward: Impact and Measurability of the Use of Educational Technology,”](#) Pachler and Turvey present a critical review of the various historical analyses of the impact of technological interventions in education in order to identify the gaps in educational research and the challenges posed for researchers. These include teachers’ often limited knowledge of IT affordances and therefore the vagueness of teachers’ actual uses of IT resources in their teaching and often a failure to understand how learners think. They conclude with a call for methodological perspectives that are not confined by paradigm but that are able to bridge and integrate research paradigms in order to respond to the complex sociocultural ecologies within which digital technologies are implicated.

These anomalies and misunderstandings about research results imply that there needs to be a much clearer identification and classification of what constitutes researching IT in education and what can be relied upon to inform other researchers, practitioners, and policy makers. Hence the justification for this section of the Handbook aims to enlighten the reader on these challenges.

Abstract

This chapter considers the challenges which need to be addressed by those researching IT in education. Evidence from the first Edition of the handbook and many meta and individual studies published since 2008 reveal changing methodological approaches to address the increasing diversity of IT in continuously changing educational contexts. These include research methods to take account of the new knowledge and knowledge representations which are accessible through dynamic, mobile, and diverse computing technologies. The discourse uses Entwistle’s evaluation framework to help researchers identify the range of factors which have an impact on the quality of learning consequent to the use of educational innovations in formal and informal settings. Evidence from this review shows a shift from research involving using IT resources in formal classroom settings to research across contexts between school and home, computer-based learning devices to learning with personalized mobile devices.

Introduction

This chapter reviews the evidence to date reported in the literature about researching IT in education. Building on this evidence, it identifies the challenges of researching the new knowledge and knowledge representations which are accessible through dynamic, mobile, and diverse computing technologies. Comparing the evidence with the previous version of a similar review published in the first edition of the handbook in 2008 (Cox 2008), 10 years on, there are still many of the same limitations and challenges facing those involved in educational research in this field (► Chap. 79, “Looking Back, Moving Forward: Impact and Measurability of the Use of Educational Technology” by Pachler and Turvey in this volume). However, more recent research shows that there is a better and growing understanding of the complexity of conducting research in technology enhanced learning (TEL) (e.g., see San Diego et al. 2012; Cox et al. 2013; Huber et al. 2016; and Herodotou 2018), whose studies are discussed in more detail later in this chapter.

Rather than give a definition of the meaning of IT in this chapter, it is probably, I would argue, more helpful to show what affordances are and have been provided by IT resources for teaching, learning, and understanding over many decades and how these have influenced research agendas (see Table 1). In many countries and across eras, the IT resources made available in schools have been determined by government priorities and initiatives and what has been produced for society as a whole rather than led by the teachers’ perceptions of the potential to enhance learning or by teachers’ choices (Webb and Cox 2004; Cox et al. 2013; Brinda et al. 2016). As a consequence, the research methods and approaches have often been influenced by key outcomes wanted by policy makers rather than investigating the actual learning potential of a new IT resource.

As was shown in the previous edition (Cox 2008), the early research and development of IT in educational settings was intertwined with the design of the IT tools themselves and the research focus was on measuring the impact which these had on students’ learning leading to a consequent improvement of the design (Reeves 2008). There was little awareness and realization of the impact on learning which such additional influences might have, such as teacher intervention, student

Table 1 Technological developments for education and the focus of research into teaching and learning (Cox 2013a)

Dates/era	Technological developments	Development of IT in education and focus of <i>research</i>
1950–1967	Large scale main-frame valve-based analogue computers. Miniaturization of electronic components (transistors and diodes) and circuitry leading to the large scale digital computer. Increase in memory/processing capacity.	Subject based drill and practice programs for use with small groups of pupils. <i>The impact on pupils' learning and evaluating educational software.</i>
1968–1970	The introduction of the Internet – ARPANET ^a seeding the international networks of computers and subsequent online learning, social media 20 years or so further on.	Remote access to schools and universities to widen the use of subject specific software, <i>comparing learning with subject specific software to learning with traditional resources.</i>
1971–1974	Creation of JANET ^b – UK network of computers, and real-time interactive computers. User graphics on-line computer terminals. Internet connections for some schools. Remote access to computers from different locations. Forerunners of desk-top computers: e.g. Hewlett Packard, Horizon.	Remote access to educational software programs from universities to schools. Individual computer work-stations. <i>The impact on learning and evaluating educational software.</i>
1975–1979	Miniaturization of computers. Production of small desk-top computers with 32k of memory and graphics. Move from tape-based storage to disk based storage of large computer programs. Prestel/Teletext: commercial and educational information provided on-line.	Educational graphic simulations, expanding range of educational software. Changes in the IT subject curricula. <i>The impact on learning and the requirements for teacher training.</i>
1980–1984	Fibre optics facilitating fast and large-scale communication Modems in schools providing wider remote access. Range of input and output devices for education, e.g. concept keyboard/ graphics tablets, touch screens, speech input and output	Large range of drill and practice and simulation software available to schools. <i>The impact on pupils' learning, attitudes and uptake by teachers and schools.</i> <i>Effectiveness of teacher training.</i>
1985–1989	Microsoft windows launched. More powerful cheaper personal microcomputers. Invention of the World Wide Web by Tim Berners-Lee (http://en.wikipedia.org/wiki/Tim_Berners-Lee). New external storage devices: CD-ROM: Interactive video; plug-in memory cards.	More diverse range of educational software, including modelling software and some access to the Internet and WWW. International school collaborations. <i>The impact on learning, uptake by teachers and schools, and collaboration amongst learners.</i> <i>International comparisons.</i>

(continued)

Table 1 (continued)

Dates/era	Technological developments	Development of IT in education and focus of <i>research</i>
1990–1999	Lap-top computers. Spread of wireless computer technologies: networks; air-mouse; video-conferencing. Mobile phones. Interactive whiteboards. Personal Digital Assistants (PDAs).	School/home uses of IT. Pressure on IT resources for teaching IT as a subject and teaching with IT. Whole class teaching with IT. Organisation of learning with IT and online. Individualised learning. Informal education. School priorities and level of integration. <i>Theories underpinning educational change.</i>
2000–1904	Further increases in processing and storage of personal computers. Wide cheap access to the Internet and the World Wide Web. Virtual learning environments (VLEs).	More powerful educational software. Curriculum dilemma for teachers in schools between using office software (word-processing etc.) and educational bespoke software. <i>Researching online courses and assessment. Networked learning.</i>
2005–1909	Web2, Wikis, VLEs. Thin clients. Thin client technologies in schools. Haptic devices for use in education. Development of molecular computing technology. Widespread access to wireless networks. Web2 technology - Social software environments: e.g. Wikipedia, Second Life	Digital literacies and agendas, relative benefits of different IT resources in school and home. New representations. Changing focus of human computer interactions. <i>Impact on formal/informal learning. Changing teacher-learner-external expert relationships.</i>
2010–2012	Graphics portable devices: I-phone; Blackberry; I-pad; Satnav; MP3-players; E-books; Social software: Facebook, Blogs; Twitter; social bookmarking; One World TV. Integration of mobile technologies with social software.	Mobile learning, Blended learning, <i>Research to understand the levels of immersion in technologies. Impact of social software on learning scope and agendas.</i>
2012–2018	Touch technologies; haptic devices; Integration of different HCI interfaces.	Learning with touch devices. <i>Researching sensory perceptions; interface between different learning modes and experiences.</i>

^aARPANET – Advanced Research Projects Agency Network created in 1969

^bJANET – Joint Academic Network

cooperation; students' digital literacy skills, new ways of interacting with learning resources and so on which could be happening within any IT learning experience. Alongside these earlier developments were evaluations of the effects of using IT on students' IT skills and abilities. It was decades before the majority of the research community became aware that researching IT in education needed to acknowledge the ways in which IT is used in and out of schools, online, and in many different contexts.

Table 1, modified from previous similar tables (e.g., Cox 2008, 2013a) shows the types of IT resources which were available to educators and therefrom the focus of past research studies. As a result of the previous review of the effectiveness of research designs and methods across different educational contexts, the recommendations identified in the previous edition of this chapter (Cox 2008, p. 959) were:

1. “Any investigation should be clear about what types of IT are going to be used and design measures to match the specific IT type to the teaching and learning outcomes.
2. Research studies should take account of the nature of the knowledge representations likely to be experienced and not limit the research to assumptions about traditional subject material knowledge representation.
3. Research into the impact of IT resource types on learning needs to take account of the pedagogical beliefs and practices of the teachers involved.
4. In-depth case study investigations are required to measure the quality and extent of the teaching and learning experience.
5. The ways of measuring the impact of IT on education need to take account of the different factors which may need measuring in addition to attainment and learning gains.
6. Large-scale national and international studies should include case studies to find out the level and depth of IT use and experience to inform the quantitative data.”

As is now well known, investigating the impact of IT on students’ learning therefore involves measuring the effects of IT on generic and specific skills and knowledge, the effects of group and collaborative learning, taking account of human computer interfaces and the changing nature of knowledge presented and the role of the teacher. The remainder of the chapter addresses new challenges which, although researched by several in the last few decades, have become more prominent now because of the ever-changing IT environment in society permeating what was once a fairly controlled and understood formal educational system.

Complexity of the Learning Experience

Following from the earlier research discussed in the previous edition of the handbook “An important word of warning for teachers and researchers which came from many of the earlier studies between 1975 and 1995 is that *what* the students learnt was often not *what* the teachers and researchers had anticipated them learning” (Cox 2013a, p. 24.). There are many reasons for this which have become more significant as IT continues to pervade all aspects of society. A useful framework developed by Entwistle (1987) for teaching and learning at university level is still applicable today and is also relevant to primary and secondary schools. This framework, although developed 30 years ago, has been used by many researchers to construct a comprehensive and inclusive research strategy. It shows the more obvious factors which influence students’ learning as well as those at an institutional level. This framework,

Educational Evaluation Framework

Factors affecting learning experiences (Entwistle, 1987)

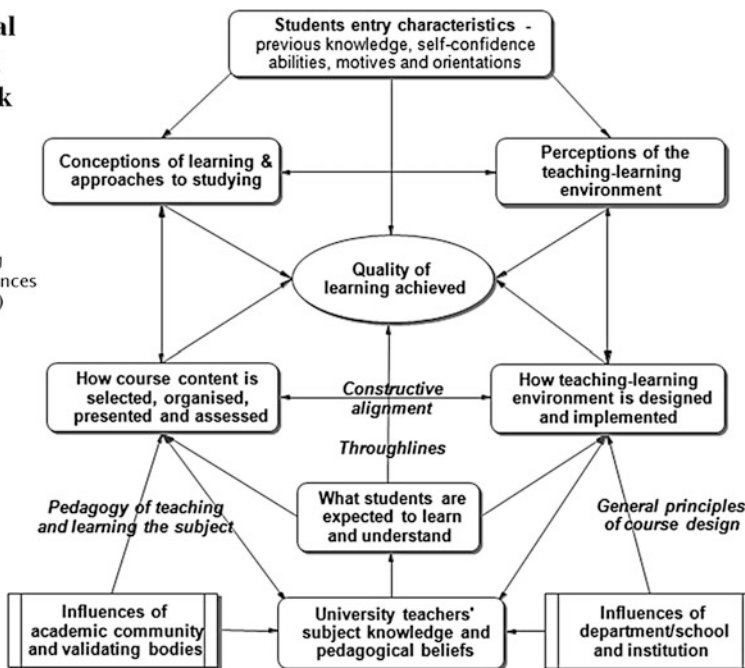

Fig. 1 Evaluation framework showing key influences on students’ learning within a formal institution (Entwistle 1987)

shown in Fig. 1, was developed from a meta-analysis of over 250 research studies of the quality of the student learning based on a range of measures and the different variables which will influence the actual learning achieved.

Many of the variables shown in this framework are also relevant to researching any educational innovation but have added complexity and significance when considering the digital environment and the teachers’ and learners’ own expertise and familiarity with it. If we consider each of these in turn related to past research, it helps us to identify the methodological approach which might best fit researching IT in complex learning environments.

1. *Student entry characteristics.* When measuring the impact of using an IT resource on students’ learning in a formal setting such as a school, research which additionally measures the students’ previous knowledge, not only acknowledges the need to measure subject or topic conceptual understanding but now more than ever needs to know about the students’ IT literacy skills. These might include how to interpret knowledge presented in new formats through the use of computer screens, diverse IT applications, e.g., spreadsheets, simulations, skills at using personal devices such as social networking tools, instant messaging, taking pictures with cameras to access relevant information (Looi et al. 2014a), and motives and orientations (Romero-Hall et al. 2016).

2. *Conceptions of learning and approaches to studying.* According to Entwistle's Framework, the quality of the learning achieved will also depend upon the students' conceptions of learning and approaches to studying. In a recent study by Iten and Petko (2016) of 74 children from five primary schools playing the learning game AWWWARE, the authors measured the anticipation of the pupils towards the learning activity (serious game). The results of pre- and post-tests were analyzed using multiple linear regressions. The results showed that "anticipated enjoyment played only a minor part in students' willingness to learn with serious games. Of greater importance was the students' expectation that the learning game would be easy and instructive." (p. 151.). However, this study like many others measured the children's attitudes towards the learning activity through online questionnaires using Likert scales for such statements as "Ease of use," "simplicity to use," "fear of use." Many earlier research studies (e.g., see Cox and Marshall 2007) have shown, however, that such constructs eliciting the pupil's opinions often do not measure the deeper attitude of learner's conceptual understanding and approaches to studying which we need to know to determine these effects on the quality of learning.
3. *Perceptions of the teaching and learning Environment.* It is already well established that how teachers perceive the IT resource's contribution to learning is dependent upon the teachers' IT literacy, their pedagogical content knowledge and their perceptions of the students' responses to the learning activity and so on. (Webb and Cox 2004). These factors are becoming even more complex now with students able to use their own devices to study subjects being taught in school with very limited control by the teacher. The consequences of this eclectic mix of learning resources is that the teacher's perception of the learning environment may differ from that of the actual learning environment and therefore be more evasive to the researcher attempting to measure its impact.
4. *How course content is selected, organized, presented, and assessed.* Although recent research shows that there is a growth in the use of IT resources in formal learning settings, there is still a large variation in the way in which the same resources might be selected by different teachers, different integration within the curriculum, and how the learning may be assessed (Voogt 2008). A recent study by Wang (2017) investigated the learning effects of different instructional methods by two teachers who were using the Interactive Response System (IRS) with two different teaching methods: learner as leader, and teacher as leader. They found that the students' learning resulting from both organized learning strategies supported previous research which showed that IRS improved learner's engagement. In the majority of educational settings, it is still the case that for formal education, the course content is often preselected for a body of students while the IT resources are an additional extra. (e.g., see Passey 2015; Cox et al. 2013). This provides a significant challenge for researchers investigating the effects of an IT resource on students' learning across several classes or schools, because the same resource may be used differently by each teacher being studied.

5. *How teaching-learning environment is designed and implemented.* With the growing use of personal mobile devices (tablets, laptops, mobile phones, etc.) and online learning, it has been argued that the control of the prepared curriculum and standardized content is in many countries and schools a passing phase (Sakamoto 2002; Cox and Niederhauser 2013). The actual use of the teaching-learning environment is becoming fluid, more determined by the scope and extent of IT use than by an accepted set of materials chosen by the teacher/course leader. A review of just one issue of the *Journal of Computer Assisted Learning* for example (*Journal of Computer Assisted Learning* 2017) includes research articles on the use of tablets, blended learning environments, Web activities, automated learning, video instruction, and computer simulations. This diverse range of research foci shows a trend in what kinds of IT resources are now being used in schools.
6. *What students are expected to learn and understand* – In the previous handbook edition, decades of evidence (Cox 2008) showed a potential mismatch between the teacher’s expectation of the concepts and processes their students would be learning (through the use of an IT environment) and the actual learning which might occur. This is because, frequently, the teachers are mostly accustomed to using more traditional teaching resources and methods and are unfamiliar with the different interactions and educational challenges offered by an IT environment. As said previously, “*what the students learnt was often not what the teachers and researchers had anticipated them learning*” (Cox 2013a). Even a decade later, it is still difficult for researchers to measure the impact of IT use on students’ learning because as Entwistle (1987) has shown over 30 years ago, not only is what is learnt affected by what each student expects to learn but what the IT resource affordances provide.

The remaining three variables identified by Entwistle in his framework: *Influence of the academic community* (in the case of this handbook would be confined to the formal settings); *teachers’ subject knowledge and pedagogical beliefs*; and *influences of the department/school and institution* have been extensively addressed in the previous handbook edition (Voogt and Knezek 2008). Previous reviews of large-scale international studies, e.g., Plomp et al. (2009) include evidence of the effects of policies on practices in over 30 different countries. These previous studies support Entwistle’s claim that the quality of students’ learning will also be influenced by the ethos, emphasis and facilitation of the educational communities within which their learning is taking place.

Numerous studies previously reported confirm the significant influence of teachers’ subject knowledge and pedagogical beliefs on the quality of students’ learning (e.g., see Webb and Cox 2004). Even more than a decade on it is still difficult to measure this when trying to evaluate the contribution of IT to students’ learning. In conclusion, the previous substantial published research literature into the influence of the school on students’ access to appropriate, relevant, and beneficial IT resources (e.g., see Voogt and Knezek 2008) and teachers’ professional development (Desforges 1995; Cox 2013a) and those discussed above confirm the importance of

the range of variables identified by Entwistle (1987), and the significance for researchers in considering these influences when planning research in IT in education. The remaining sections of this chapter address the most recent challenges we have to face in achieving research designs and outcomes which will be scalable and sustainable across different contexts and communities.

Evolution and Diversification of IT Resources – Shifting Sands

In spite of the limitations caused by not enough account being taken of Entwistle's factors in many previous studies, there are those reported in the literature which have addressed many of these influences and shown that the impact of diverse types of IT resources on students' learning can have a positive impact on learning gains within formal and informal settings (Cox 2008, 2013a; Huber et al. 2016); on students' motivation (cf. Gardner et al. 1993); attitudes and perceptions (Christensen and Knezek 2008; Romero-Hall et al. 2016). However, each study has often involved different research methods, different types of IT resources, and different educational settings. These differences present various research challenges when attempting to measure the precise nature of students' learning as a consequence of the affordances of the specific IT resources being used. Furthermore, these diverse approaches often make it difficult to generalize and apply these findings on a larger scale (see the section below on [Scalability and Sustainability of Research Methods and Outcomes](#)).

As discussed in the previous section and shown in Table 1 above, the IT resources used in educational settings (formal and informal) are often driven by those used in society as a whole and the last 50 decades show that these continue to diversify and become more individualized. Not only can all pupils in a school in a developed country bring their own devices (BYOD, e.g., mobile phones) to school and be encouraged to use them in their lessons, but such mobile devices can complement traditional learning resources and other IT resources (e.g., searching for information online) (e.g., see Mehdipour and Zerehkafi 2013). These opportunities have been researched in settings ranging from traditional science field work to changing the curriculum to an enquiry-based curriculum which would need mobile devices such as phones to collect data in the field. Wu et al. (2012) conducted a meta-analysis of 164 studies (most of which were in higher education) of mobile learning from 2003 to 2010 with an increasing number being found in 2010. The primary research method to measure effectiveness of these 164 studies was through survey methods followed by experimental research. However, evidence from the first edition of this handbook (Marshall and Cox 2008) have shown that surveys do not reliably measure the learning effectiveness because as is shown in Fig. 1, many of the variables which influence the quality of learning have not been accounted for. This is especially true for mobile learning studies which involve learners in different settings. For an extensive review of mobile learning in this handbook see Soloway and Norris (► [Chap. 53, "Section introduction: Mobile learning"](#)).

One of the conclusions from Looi et al.'s study, referred to earlier, was that "With mobile technology, science inquiry can be extended into more authentic contexts,

such as field trips to a park, woodlands, and a museum, and other home-based activities” (p. 102). The challenge posed for researchers in this ever-changing IT environment is not only investigating the level of use and integration within the curriculum but the personal individual skills of each pupil using such devices.

A further complication for researchers especially when consolidating previous international evidence and comparing new results with those published by others is that the actual curricula in which such innovative uses might take place will differ by content and approach from one country to another. It is therefore difficult to generalize and scale up the results for wider implications. For example, in the extensive research into Mobile learning reported by Looi et al. (2014b) and the earlier review of trends in mobile learning reported by Wu et al. (2012), they advocated being able to scale up an innovation by transforming their national science curriculum in Taiwan into an enquiry-based science curriculum. Although this is an obvious appropriate use for mobile technologies for measuring and controlling science data in schools in the laboratory and in the field, it is hardly new in many Western countries. The importance of such field work was concluded by Woolnough (1994) more than 20 years ago from the results of a survey of over 6000 students (16–18) and science teachers of their attitudes towards studying science in schools. He found that learning activities which involved collecting scientific data in the field encouraged students both to study science at school and to pursue it in a career. These results reveal another challenge for researchers which is that, when reviewing previous research published internationally, in order not to repeat unnecessary investigations, a proposed research study needs to be founded on extensive knowledge of the evidence to date of the context and national curricula as well as the research objectives identified by the affordances of the IT environment itself.

Researching Across Boundless Contexts: Informal and Formal Learning.

If we refer back to Table 1 above and the previous discussions, we can see that even in the 1970s, some people in mainly developing countries had access to personal desk-top computers in the home and Internet access in the later 1970s. Mobile phones were coming into use in the 1980s. There were early research studies into the personalized informal use of computers for learning with the focus mostly on learning specific science or mathematics concepts using dedicated educational software. Later reviews reported an increasing use of informal learning for homework (Hallam 2004) and in more recent years linking school and home IT use for learning (Pachler and Redondo 2005; Cox 2013b). Much of this earlier research was reporting on the uses of IT in the home by learners rather than finding out the impact on the quality of their learning.

From the plethora of research reports already published (e.g., see Badri et al. 2017), the range of technologies available in society will continue to change and the use of these outside formal settings is very difficult to measure accurately. An earlier review of informal learning with technology outside school by Sefton-Green (2004) identified

these challenges for researchers: it “is conceptually difficult because there is no one simple science of learning, no one set of shared rules to which all researchers in the field would point to begin to describe how informal learning might take place. At the present time, for example, researchers in ‘education’ continue to struggle with the challenges of combining psychological and sociological approaches to an understanding of learning. The conceptual challenge of defining children’s learning outside schools is also particularly problematic as most literature in this field is oriented towards the implications of informal learning for the formal sphere.” (Sefton-Green 2004, p. 8). Over a decade later a more recent review by Lai et al. (2013, p. 422) of blending student technology experiences in formal and informal learning with more diverse and powerful personal learning devices confirmed the earlier review concluding that “we know very little about how it (informal learning) can best be supported by mobile technologies and applications.”

Although, for many decades the main research objectives for funded research has been linked to formal educational settings which in the majority of countries would be schools mostly funded by national governments, the widespread use of technologies outside schools can no longer be ignored. It is necessary to accommodate the greater granularity across the increasingly leaky formal and informal boundaries which educational technologies encompass. A recent review conducted by Working Group 2 of Edusummit2017 (Lai et al. 2017) provided four key strategies for researching the impact of informal learning using technologies:

- Develop technologies to enable learners to capture and reuse their learning experiences (e.g., the SCROLL system in the context of language learning)
- Develop technologies to support critical thinking
- Conduct more evidence-based studies to understand the relationship between formal and informal learning
- Design studies that capture rich data on student use of technology outside formal institutions (e.g., ethnographic, walkthroughs). (ibid. p. 30).

In order to identify approaches that can be adopted by researchers investigating the impact of informal uses of technology on learners, the first stage is, as it has always been with traditional learning, to identify the research objectives. However, for research objectives which include trying to measure the impact of IT on the quality of learning specific to informal learning, there are three main considerations which need to be addressed:

1. The loss of control of how learners in schools are using IT beyond the school (Cox et al. 2013).
2. The changing sensory modes of learning and thereby perceptions due to the IT interfaces leading to changes in use of our anatomical sensory organs: (sight, sound, smell, touch, and taste: see the following section).
3. The changing IT literacies of the learners brought about by knowledge being learnt in new forms of representation: new ways of learning (see the following section).

2 and 3 above apply equally to formal and informal settings although the increasing use of various devices by learners will impact upon how they learn and conduct their learning beyond the experiences they used to have when their learning was once mostly controlled by teachers.

New Knowledge; New Representations; New Modes of Learning

Prior to the 1960s, the dominant way of learning for over a century was through reading books and other texts and listening to teachers. This mostly involved students applying visual reading and listening skills. For science subjects, other sensory modes of learning have also been used for experimentation, such as smelling, listening (to various sounds), and touch (haptics) (e.g., see Perkins et al. 1995). Haptics and its application have become more dominant in the last decade and is widespread across mobile devices such as touch-phones and tablets. Other specific haptics simulators have long been the norm for pilot training and other professional skills but are now expanding in use in formal sectors of education at school level (e.g., Webb et al. (2017) and in many health care courses in higher education (e.g., see Quinn et al. (2015).

Herodotou (2018) conducted a literature review of the use of tablets with children, the main focus of the 19 studies being to measure the effects of the use of mobile technologies on learning. “The great majority of the 19 studies included in this review examined cognitive effects of mobile devices on young children, relevant to mainly literacy, science and Math, and reporting positive outcomes. There is a lack of studies examining possible impact of mobile devices on children’s social and emotional development and a need for gaining a fine-grated understanding as to why observed effects have been identified” (Herodotou 2018, p. 8). A small number (4) of these studies considered the changes in the new and different ways the children might be learning due to the haptic interface with the tablets they were using by also measuring changes in their fine motor skills.

Another review of the use of tablets in schools by Haßler et al. (2016) of 33 studies showed that the main affordances investigated were related to the multiple features of the resources, such as the camera, microphones, and easy access to dictionaries and screen readers and the benefits of their portability. However, they found that few of these studies investigated the effects of these affordances on learning outcomes but only on learners’ uses of the technologies. They concluded that “Researchers investigating what it is about tablets that supports students to learn should seek to establish ways in which the technology can be used more effectively than other similar devices to promote learning in the classroom” (Haßler et al. 2016, p. 23).

From the results of these reviews and many other studies, it is clear that there is still a lot of uncertainty about the interaction between the different senses which learners may be using and how this will affect the learning outcomes. For more than a decade, as was also discussed in the first edition (Cox 2008), researchers have been aware of the need to improve our understanding of the relationship between knowledge and how it is conveyed and experienced by the learner through interfacing with the

technology (Hindmarsh et al. 2014). Before haptics began to pervade IT technologies, it was already a significant challenge. For example, if we consider touch screens used by children (see Herodotou's meta-analysis summarized above), the research methods used to measure their learning need to include measuring the changes to the learners' fine motor skills as reported in some of the studies out of the 19 reviewed. Furthermore, "The interactive and social features of touch screen media suggest new forms of prosocial behaviour that merit examination including understanding what characteristics of the media or of certain applications might affect emotional competences, how children might relate to application characters and exhibit empathy or accepting or rejecting others. Moreover, given the play-like character of mobile applications in early years, it might be fruitful to examine how interaction with such technologies relates to children's imaginary play, their understanding of the distinction between fantasy and reality, and the extent to which interaction with this new media enriches their imaginative and creative capacities" (ibid. p. 9).

A recent study on the use of touch screens by children conducted by Piotrowski and Krcmar (2017) measured the effects of hot spots on children's haptic uses of the tablet, their verbal responses, attention, and story comprehension. They found that the children showed less attention to the story being told with the use of hot spots, yet recorded similar content afterwards as the control group who read the story without the use of the tablets. From the range of results obtained, the researchers concluded that "Given the full-scale adoption of tablet computers into many schools it is crucial to consider how children use and respond verbally and haptically to tablets when educational information is presented to them. Furthermore, a better understanding of how the timing of hotspot use influences comprehension may allow digital story-book creators to tailor more to children's comprehension needs" (Piotrowski and Krcmar 2017, p. 333).

Evidence from these recent studies and those previously reported in the first Edition show that there has been some progress made by researchers from the Human Behaviour and Human Computer Interface domains in recognizing the need to take account of the learners' gross and fine motor skills which will affect their interactions with haptic devices and consequent learning. However, there is still no common agreement on taxonomy of touch or on the effects of immersion within the IT medium and transfer of knowledge to other domains. The most promising approach to take account of new representations and interfaces is to incorporate the body of knowledge from the psychology field when identifying the objectives of a research study and the expertise of haptic cyberneticists to help in the identification of the affordances of these complex learning environments (e.g., see San Diego et al. 2012; Hindmarsh et al. 2014).

International Significance and Applicability

As can be seen in Table 1, access to IT resources has expanded with the reductions in cost and the diversification of types of IT technologies. As a result of national government IT in education policies, there have been many national and

international large-scale studies investigating and comparing the uptake of IT in education (mostly at the school level) (Kozma 2003, Law et al. 2008; Plomp et al. 2009, Voogt and Knezek 2008, Fraillon et al. 2014), which have provided evidence of the factors which promote or inhibit the uses of IT in education.

The methods used in these large-scale studies include school and teacher questionnaire surveys across countries, specialized IT tests and standardized tools for analyzing the results (► Chap. 77, “International Large-Scale Computer-Based Studies on Information Technology Literacy in Education” by Fraillon). However, the data provided by each country will be influenced by the national interpretations, the political priorities, and the local methods for collecting the data. Furthermore, many of these large-scale studies do not always specify what is meant by IT and what is understood nationally. Although great care may be taken in the design of questionnaires for example to cover this diversity of IT resources, schools and teachers themselves have been seen to differ significantly in their interpretation of the meaning of IT which therefore influences their responses to such questionnaire surveys. There still remain ambiguities across such results because of these factors and more work needs to be done to identify which data collection methods can provide the most reliable and robust results.

Scalability and Sustainability of Research Methods and Outcomes

In the 1960s, research into IT in education was initially focused on the effects on students’ learning because the main purpose for using IT was to enhance existing teaching and learning practices or to present the existing curriculum in different ways. It was assumed that results which showed evidence of a positive impact on students’ learning would gradually be adopted by other teachers and educational establishments. However, 50 years on, we have seen many promising technological applications in education decline in use (see Table 1 and Cox and Marshall 2007), e.g., the QUERTY keyboard, the use of LOGO in primary schools, the use of integrated learning systems, simulations in science teaching, and many others. One of the main reasons for the lack of sustainability of use of specific technologies in education has been due to teachers being persuaded by policy makers to adopt it initially and they have therefore never claimed ownership for their own teaching innovation. The factors shown in Fig. 1 and the body of research into the pedagogies and roles of teachers (e.g., Desforges 1995, Law 2008) has for many decades found that innovations particularly IT are often only used by innovative teachers in schools where the Head-teacher/principal has a strong policy for professional development and innovations in the curriculum.

Earlier large-scale international studies and meta-studies conducted in a time when the range of IT resources in schools was more limited and much less mobile have provided results which still could be generalized and thereby scalable. However, such studies did not always take account of the learning contexts and the effects of stakeholders on the uptake of new technologies which influences the interpretation of the results in relation to specific local, national, and cross-national contexts. In conclusion, 10 years on, there continues to be evidence that, in order for IT

innovations in education to be sustainable, teachers need to feel ownership of the technology and require detailed knowledge of the nature of IT tools, their different representations, and the ways in which they may contribute to learning and knowledge. These factors therefore need to be taken into account by educational researchers in order for them to be able to design appropriate research methods to measure their impact and the relationship between learning and the types of IT media being used by the learner (Khenissi et al. 2016).

The review conducted by one of the working groups of Edusummit2017 (Lai et al. 2017, pp. 71–76) focussing on the sustainability and scalability of educational research, identified three challenges for researchers, practitioners and policy makers (p. 73–74) which need to be adopted if we are to build on research in the past and present to *sustain* an innovation over time and *scale* up the use of an innovation into other contexts, domains, cultures and across nations. Challenge 1 recommends that productive partnerships need to be established among all stakeholders to build capacity of IT use in schools. Research programs need to be co-designed so that policy makers need to claim ownership of the research results and thereby take responsibility for policies based on research outcomes. Challenge 2 is that research approaches should be identified that are sustainable and scalable and where relevant support sustainability and scalability. Challenge 3 is that successful integration of technology should be founded on evidence from the research literature rather than on isolated policy driven initiatives.

Challenges to Researching IT and Solutions

In this chapter, I have identified the key challenges which researchers face in an ever-changing IT environment. These include having a prior understanding of the following:

- The affordances and reach of the IT learning environment be it a specifically designed educational resource used within the formal classroom or a personal device being used outside of the classroom in an informal setting
- Organization of courses, curriculum, in which IT resources might have a central or peripheral role, and interactions in learning between formal and informal education
- Student and teachers' digital literacy skills and how these encompass new knowledge: new representations and new modes of learning when IT resources are being used
- Evolution and diversification of IT resources and the effects on the complexity of the learning experiences and the loss of control of the teacher
- Scalability and sustainability of research methods and outcomes at a local, national, and international level

Figure 2 below shows how these challenges and associated factors and influences are related, complementing the earlier educational framework shown in Fig. 1 developed by Entwistle (1987). It takes into account the innovation being IT

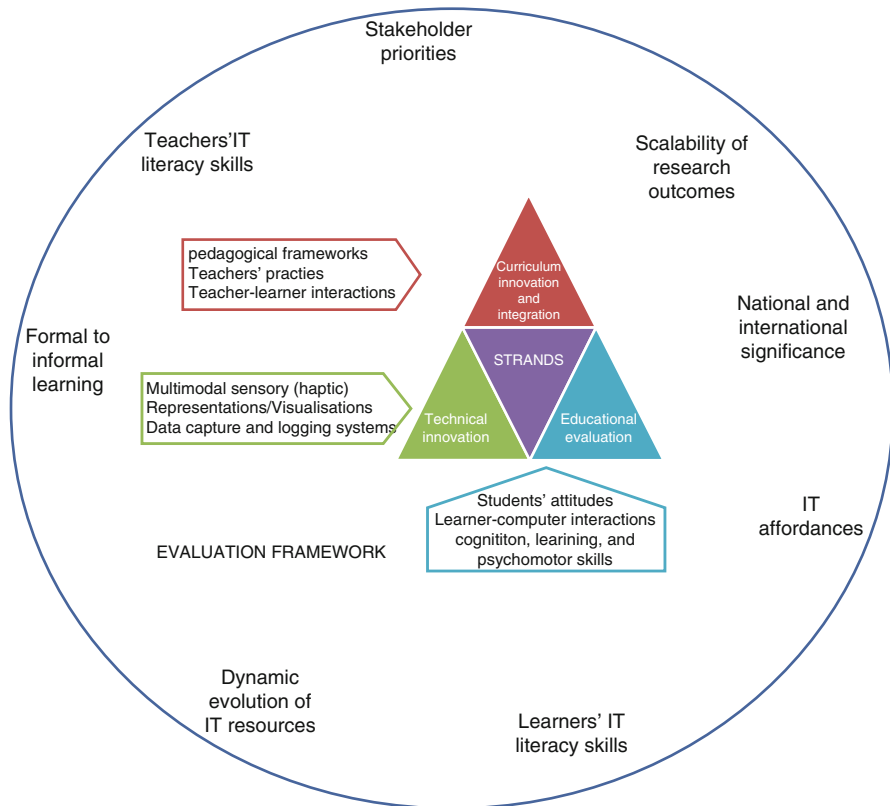

Fig. 2 Evaluation framework for researching IT in education

resources (E-learning) and the consequent integrated and multi-methods research approach which is needed.

In considering the long-term strategies and effects of researching IT in education, Pachler and Turvey (► Chap. 79, “Looking Back, Moving Forward: Impact and Measurability of the Use of Educational Technology” in this volume) identify research principles (p. xx) which they believe will “act as a catalyst for sustainable methodological innovation that progresses the field of educational technology research.” They recommend that there should be a “call for far-sighted innovation that resists becoming confined by methodological or pedagogical paradigms.”

In the 10 years since the publication of the first edition, there have also been calls from research teams to devise strategies which will ensure appropriate methodologies and a sustained body of experts interacting with policy makers and practitioners to ensure that the challenges we face identified in this chapter can be adequately addressed and can achieve sustainability and scalability. Figure 3 shows a framework initially produced by Cox and Niederhauser (2013) and further developed by Cox et al. (2013) which identifies the wide range of roles and interactions among

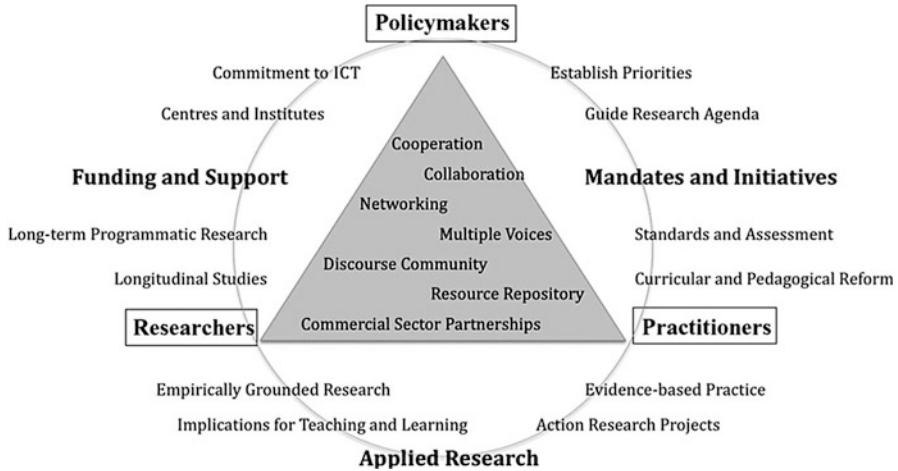

Fig. 3 Roles and interactions among researchers, policy makers, and practitioners (Cox et al. 2013: p. 482)

researchers, policy makers, and practitioners which need consideration when researching IT in education. As has been discussed in this chapter, in order for the field of researching IT to have the most effective and long-term impact on innovation adoption in education, research studies need to have relevance and meaning for practitioners and policy makers. Otherwise, the outcomes often fall on deaf ears of policy makers and teachers or wither on the vine of disinterestedness and stagnation.

Technology changes society and thereby changes the goals of education. Therefore, important considerations for policymakers include: how technology is changing the ways we learn, and the educational institutions that support that learning, how research practices can be intertwined with cultural differences, national priorities and global agendas; and what is the nature of technology use that improves education and will be likely to support its transformation? Success (for researching IT) will require cooperation, collaboration and a shared vision with all stakeholders contributing to the greater effort (Cox et al. 2013, p. 485).

Abstract

This chapter focuses on the types of research questions that might be answered by using meta-analysis in the area of information communication technology (ICT) in education and the strengths and weaknesses of such meta-analyses. The chapter is divided into four parts: (a) brief description of the meta-analysis research method, (b) synthesis of meta-analysis studies of the impact of ICT in education from 1988 to 2017, particularly focusing on 2007–2017, (c) identifying what kinds of evidence outcomes can be achieved through meta-analysis, and (d) discussion of the strengths and weaknesses of meta-analysis in ICT in education and what are the most reliable methods to obtain accurate evidence about the impact of ICT in education.

The Meta-analysis Research Method

In the first edition of the *International Handbook of Information Technology in Primary and Secondary Education*, Liao and Hao (2008) showed that meta-analysis is a useful research method to synthesize research outcomes in the field of technology in education. Meta-analyses apply statistical methods to the treatment of quantitative representations of study outcomes. In this respect they differ from more qualitative reviews of research findings (e.g., literature reviews) or informal reviews (e.g., “vote counting”). For a definition of Meta-analysis and an extended discussion of the advantages and criticisms of meta-analysis as a research method, we refer to the first edition of this Handbook (Liao and Hao 2008).

The present synthesis focuses on two eras, from 1988 to 2017 because prior to 1988 Walberg (1983) and Roblyer et al. (1988) had done a wonderful job to synthesize studies in computer-based instruction (CBI) before 1988. There is no reason to repeat their works. However, since 1988 new instructional technologies such as e-learning, web-based learning, and m-learning have continually developed. In addition, new approaches to synthesize large-scale datasets advanced. It is important to see the impact of these new approaches to students’ learning. We first summarize two periods which are also covered in the first edition of the Handbook (see also Liao and Hao 2008): 1972–1986 – the early days of technology in education – and 1988–2006 when the Internet became widely available for education. Then we extensively present and discuss the meta-analyses published in the 2007–2017 timeframe when mobile learning became widely available in schools. The chapter concludes with a discussion of the final period up to the present day and the changes since 1988.

Review of Studies of Meta-analysis on Information Technology in Education

According to Anderson et al. (2001), the revision of Bloom’s taxonomy of learning domains can be categorized in three domains: cognitive, affective, and psychomotor domains. The learning outcomes of studies in the field of information technology (IT) can also be characterized within this framework. Most meta-analyses in IT focused on students’ cognitive outcomes (e.g., academic achievement, or problem-solving ability); some meta-analyses assessed students’ affective outcomes (e.g., attitudes toward learning, or interest in specific domain); and a few meta-analyses evaluated students’ psychomotor outcomes (e.g., social skills). In the present review, we used this framework and grouped the overall effect size of collected meta-analyses into cognitive, affective, and social skills aspects.

The Period from 1972 to 1986

Many studies regarding the impact of IT in education have been published since the 1970s. These large numbers of published studies enabled educational researchers to conduct studies of the meta-analysis method itself. Walberg (1983), for example, introduced and illustrated the methods of research synthesis and summarized the substantive findings regarding teaching and areas of instructional technology (IT in education). On the other hand, Roblyer et al. (1988) reviewed 26 research studies between 1972 and 1986 to assess the impact of computer-based instruction (CBI) on students' learning. However, the reviews from this period did not reach similar conclusions, and only a few clear agreements were found among the findings of these various reviews. Nearly all the reviews during this period seemed to yield evidence that computer-based treatments offered some benefits over other instructional methods (Roblyer et al. 1988).

The Period from 1988 to 2006

In the first edition of the *International Handbook of Information technology in Primary and Secondary Education* Liao and Hao (2008) presented a review of meta-analyses published between 1988 and 2006. Their review included 44 meta-analyses and were grouped into two categories: 30 meta-analyses for computer-assisted instruction (CAI) and 14 meta-analyses for distance education (DE). The results showed that when combining the effect sizes (ESs) of both CAI and DE together, the overall ESs were 0.29 and 0.06 for the cognitive aspect and affective aspect, respectively.

The further analysis was to compare the different effects between K-12 and other students (college and higher education) for both CAI and DE meta-analyses. For CAI, the ESs were almost identical for K-12 and non-K-12 students on every aspect (0.41, 0.15, and -0.02 for the cognitive, affective, and social skill aspects, respectively). However, for DE, the results showed that the ESs of non-K-12 were higher than those of K-12 for the cognitive (0.06 for K-12 and 0.19 for non-K-12) and a bit higher for the affective aspects (-0.09 for K-12 and -0.03 for non-K-12) of DE. This can probably be explained by the fact that at the time DE in this period was much more used in higher education than in K-12 education (see also ► [Chap. 49, "Virtual Schools: A Global Perspective"](#) by Davis and Ferdig, this volume).

In sum, there were 30 meta-analyses comparing CAI with conventional instruction in terms of students' cognitive achievement. About 90% (27) of the meta-analyses indicated that students whose teaching was supplemented with CAI performed better than students without CAI. Five meta-analyses investigated the affective variable, attitude. Two of them indicated that students using CAI had a better attitude toward learning than did students without CAI, and two studies indicated that there was no significant difference between the two modes. Only one meta-analysis compared students' social skills when using computerized testing with those when using paper-and-pencil tests. The results indicated that a slight

reduction in impression management happened because of computerized testing and a slight increase in self-deceptive enhancement happened because of computerized testing, when comparing computerized testing with paper-and-pencil or face-to-face administration (see details in Liao and Hao 2008, pp. 1023–1027).

For the 14 meta-analyses comparing DE with traditional face-to-face instruction, 57% (8) of the meta-analyses indicated that DE students slightly outperformed traditional students on examinations. Thirty-six percent (5) of the meta-analyses concluded that there was no significant difference between the two modes, and 7% (1) of the studies summarized that traditional students had better achievement than remote distance learning students. In addition, three meta-analyses investigated the affective variable, attitude, and concluded that either traditional students had better attitude toward instruction than did remote students (67%) or students had no significant preference to any mode of instruction (33%) (see details in Liao and Hao 2008, pp. 1023–1027). However, the ages and therefore maturity of the students differed among those k-12 students compared with adult students in higher education, one of several variable differences not addressed in these comparisons.

The Period from 2007 to 2017

The meta-analysis presented in the remaining part of this chapter includes 45 studies published between 2007 and 2017. These studies were grouped into five categories: (1) Computer-assisted instruction (CAI): CBI, CAI, information and ICT, and teaching or learning with Intelligent Tutoring Systems (ITS); CAI is used as a general term here. (2) Distance education (DE) and Internet technologies: Tele-courses, online learning (synchronous or asynchronous), and courses utilizing the media of online computer-mediated communication belong to this category; DE is used as a general term here. (3) Multiple technology (MT): meta-analysis might include studies utilizing all kinds of tools related to educational technology. (4) Game-based learning (GBL): digital game-based learning and computer-based simulation; GBL is used as a general term here. (5) Mobile-learning (ML): mobile learning, and ubiquitous learning; ML is used as a general term here.

The overall ES for CAI were 1.06 for the cognitive aspects, while most meta-analyses did not report affective outcomes and psychomotor skills. Table 1 lists the meta-analyses included in the present period reviewed in this chapter. The overall ES are given as a footnote to the table. The fact that the overall ES of 1.06 is much higher than the ES in the period of 1988–2006, which is 0.41, is because the 5 meta-analyses conducted in Turkey (Camnalbur and Erdogan 2008; Demir and Basol 2014; Dýnçer 2015; Tekbiyik and Akdeniz 2010; Yesilyurt 2010) all reported high ESs. That raises a question whether the effect of CAI may differ for students in different countries.

Further analyses were completed to compare the different effects between K-12 and other students for CAI meta-analyses. Seven out of 11 studies displayed overall ESs for students in all grade levels, three studies presented overall ESs for postsecondary students, and two studies (Liao 2007; Tekbiyik and Akdeniz

Table 1 Overall effect sizes for 11 meta-analyses of CAI versus non-CAI instruction

Author(s)	Number of studies	Effect size	Subject matter	Grade level
Abraham (2008)	11	C = 0.73	Language (L2)	Postsecondary
Camnalbur and Erdogan (2008)	78	C = 1.05	NA	All
Chiu (2013)	16	C = 0.75	Language (L2)	All
Demir and Basol (2014)	40	C = 0.9	Math	All
Dýnçer (2015)	26	C = 1.21	Math and science	All
Larwin and Larwin (2011)	70	C = 0.57	Statistics	Postsecondary
Liao (2007)	52	C = 0.55 Elem. = 0.41 Juni. = 0.85 High. = 0.23 Univ. = 0.82	All	All
Kulik and Fletcher (2015)	50	C = 0.66	All	All
Sosa et al. (2011)	45	C = 0.33	Statistics	Postsecondary
Tekbiyik and Akdeniz (2010)	52	C = 1.12, Elem. = 1.43 Seco. = 0.79 Univ. = 1.06	Science	All
Yesilyurt (2010)	25	C = 3.84	Math and science	All

Note. The overall effect size of the cognitive aspect is 1.06 (K-12 = 0.74; postsecondary = 0.61) NA data not available, C cognitive achievement.

2010) specifically reported ES for each grade level. The overall ESs for K-12 and postsecondary students are 0.74 and 0.61, respectively. The overall ES for K-12 was mildly higher than those of postsecondary students. Regarding the subject matter, 8 of 11 studies focused on specific subject matters: two studies on L2 language, four studies on mathematics, science, or both, and two studies on statistics. In total, there were 11 studies comparing CAI with conventional instruction in terms of students' cognitive achievement. All studies indicated that students who learned with CAI performed better than students without CAI.

Nine meta-analyses categorized in DE were included in this period. The overall ES for DE was 1.07 for the cognitive aspects while most meta-analyses did not report affective outcomes and psychomotor skills. Table 2 lists the meta-analyses included in the present period. The overall ES are given as a footnote to the table. Three studies (Kim and Kim 2013; Mothibi 2015; Voutilainen et al. 2017) utilized e-learning as instructional tools, while 2 studies (Lin et al. 2013; Lin 2014) applied CMC in learning L2 language. The fact that the overall ES of 0.92 is much higher than the ES in the period of 1988–2006, which is 0.17, is because that one meta-analysis (Voutilainen et al. 2017) reported a very high ES of 5.24.

Table 2 Overall effect sizes for 9 meta-analyses of distance education and Internet technologies versus non-Internet-based instruction

Author(s)	Number of studies	Effect size	Subject matter	Grade level
Jahng et al. (2007)	20	C = 0.023	All	Postsecondary
Kim and Kim (2013)	8	C = 0.301	NA	All
Lin et al. (2013)	10	C = 0.33	Language (L2)	NA
Lin (2014)	59	C = 0.44	Language (L2)	All
Means et al. (2009)	45	C = 0.2 K-12 C = 0.17 Non-K-12 C = 0.204	All	All
Mothibi (2015)	15	C = 0.712	NA	Postsecondary
Roberts (2011)	59	C = 0.777	All	Postsecondary
Shachar and Neumann (2010)	125	C = 0.257	All	Postsecondary
Voutilainen et al. (2017)	10	C = 5.24	Nursing education	Postsecondary

Note. The overall effect size of the cognitive aspect is 0.92 (K-12 = 0.17; postsecondary = 1.40) NA data not available, C cognitive achievement

Further analysis was to compare the different effects between K-12 and other students for DE meta-analyses. Five of nine studies presented overall ESs for postsecondary students, and only one study (Means et al. 2009) reported ES for each grade level. The overall ESs for K-12 and postsecondary students were 0.17 and 1.4, respectively. The overall ES for postsecondary students was much higher than those of k-12. Overall, there were nine studies comparing DE with non-Internet-based instruction in terms of students' cognitive achievement. All studies indicated that students who utilized DE as learning technology performed better than students without DE.

Multitechnology (MT) includes all types of computer-based tools (Schmid et al. 2014), ranging from early computer-assisted instruction (CAI) or computer-based instruction (CBI), to simulations, or computer-mediated communication, to the Internet or Logo (Li and Ma 2010). Meta-analyses gathering studies utilized more than one instructional technology were categorized into MT.

The overall ESs for MT were 0.36 and 0.19 for the cognitive and affective aspects, respectively. Table 3 lists the meta-analyses included in the present period. The overall ES are given as a footnote to each table. Further analysis was to compare the different effects between K-12 and postsecondary students for MT meta-analyses on both aspects. Four of nine studies presented overall ESs for K-12 students, two studies presented overall ESs for every grade level, and three studies reported ES for postsecondary students. The overall ES for K-12 (0.42) was slightly higher than those of postsecondary (0.32) on cognitive aspect, but both achieved small to moderate ES. However, for affective aspect, the overall ESs for K-12 (0.18) and postsecondary (0.2) were almost identical and reached small but positive ES. On the

Table 3 Overall effect sizes for nine meta-analyses of multitechnology versus conventional instruction

Author(s)	Number of studies	Effect size	Subject matter	Grade level
Bernard et al. (2014)	117	C = 0.33	All	Postsecondary
Borokhovski et al. (2016)	45	C = 0.35	All	Postsecondary
Chauhan (2017)	122	C = 0.55	All	Elementary
Grgurović et al. (2013)	37	C = 0.26	Language	All
Lee et al. (2013)	58	C = 0.42, A = 0.18	All	K-12
Li & Ma (2010)	46	C = 0.28	Math	K-12
Liao et al. (2007)	48	C = 0.45	All	Elementary
Schmid et al. (2014)	1105	C = 0.27, A = 0.2	All	Postsecondary
Tamim et al. (2011)	25	C = 0.35	All	All

Note. The overall effect size of the cognitive aspect is 0.36 (K-12 = 0.42; postsecondary = 0.32). The overall effect size of the affective aspect is 0.19 (K-12 = 0.18; postsecondary = 0.2). *NA* data not available, *C* cognitive achievement, affective achievement

subject matter, only two studies (Grgurović et al. 2013; Li and Ma 2010) focused on language and mathematics. In summary, there were nine meta-analyses comparing MT with conventional instruction. All studies indicated that students who learned with MT performed better than students without technology on cognitive aspect; two studies (Lee et al. 2013; Schmid et al. 2014) examined the affective outcome and concluded that K-12 ES was trivially lower than those of postsecondary students.

Computer games are designed under a set of agreed rules and constraints (Garris et al. 2002). The purpose of game-based learning (GBL) is not to entertain the player but to use the entertaining quality for training, education, health, public policy, and strategic communication objectives (Wouters et al. 2013; Wouters and van Oostendorp 2013). On the other hand, in general, a simulation is defined as a computer program which relates cause and effect together. When it comes to an instructional purpose, it enables students to bridge the gap between reality and abstract knowledge (Lee 1999). Although GBL and instructional simulation have slight differences in terms of goals, rules, and design features, they all share the idea of providing users with an enjoyable virtual environment to enhance learning motivation. Meta-analyses investigating the effect of GBL or simulation were categorized into GBL.

The overall ESs for GBL were 0.45, 0.44, and 0.35 for the cognitive, affective, and social skill aspects, respectively. Table 4 lists the meta-analyses included in the present period. The overall ESs are given as a footnote to each table. Further analysis was to compare the different effects between K-12 and postsecondary students for GBL meta-analyses on three aspects. Ten of 13 studies reported overall ESs for every grade level, two studies presented overall ESs for postsecondary students, and only one study (D'Angelo et al. 2014) reported ES for K-12 students. The overall ES for

Vogel et al. (2006)	32	C = 0.13 A = 0.59	NA	All
Wang and Tseng (2011)	21	C = 0.58	NA	NA
Wouters and van Oostendorp (2013)	29	C = 0.34	All	All
Wouters et al. (2013)	39	C = 0.29 A = 0.26	All	All

Note. ^atwo meta-analyses reported in an article

The overall effect size of the cognitive aspect is 0.45 (K-12 = 0.67; postsecondary = 0.59)

The overall effect size of the affective aspect is 0.44 (K-12, NA; postsecondary, NA)

The overall effect size of the social skill aspect is 0.35 (K-12, NA; postsecondary, NA)

A affective achievement, C cognitive achievement, S social skill, NA data not available

K-12 (0.67) was mildly higher than those of postsecondary students (0.59) on cognitive aspect, but both achieved moderate ES. However, for the affective and social skill aspects, the overall ESs for both K-12 and postsecondary were not available. Regarding the subject matter, two studies (Brydges et al. 2015; Cook 2014) specifically focused on the health profession. In summary, there were 13 meta-analyses comparing GBL with conventional instruction. All studies indicated that students who learned with GBL performed better than students without GBL for the cognitive aspect. Five studies investigated the affective outcome and one study analyzed the students' social skills (Clark et al. 2016). The GBL forms of instruction all showed positive and moderate effects over conventional instruction.

Mobile devices such as Personal Digital Assistants (PDAs), tablet PCs, mobile phones, and e-book readers offer features of portability, social connectivity, context sensitivity, and individuality, which desktop computers might not offer (Chinnery 2006). Mobile learning (ML) integrates electronic learning (e-learning) materials

Table 5 Overall effect sizes for three meta-analyses of mobile-learning versus non-ML instruction

Author(s)	Number of studies	Effect size	Subject matter	Grade level
Lee et al. (2014)	44	C = 0.54	Languages	NA
Sung et al. (2015)	45	C = 0.53 A = 0.55	Language	All
Sung et al. (2016)	110	C = 0.52 Kinder = 0.1 Elem = 0.66 Middle = 0.51 High = 0.39 College = 0.6 Adults = 2.47 Mixed = 0.08	All	All

Note. The overall effect size of the cognitive aspect is 0.53 (K-12 = 0.42; postsecondary = 1.54) The overall effect size of the affective aspect is 0.55 (K-12, NA; postsecondary, NA) *A* affective achievement, *C* cognitive achievement, *NA* data not available

with mobile devices (Lee et al. 2014; Sung et al. 2016). Meta-analyses investigating the effect of ML on students learning were categorized into ML.

The overall ESs for ML were 0.53 and 0.55 for the cognitive and affective aspects, respectively. Table 5 lists the meta-analyses included in the present period. The overall ESs are given as a footnote to each table. Further analysis was to compare the different effects between K-12 and postsecondary students for ML meta-analyses on both aspects. The overall ES for K-12 (0.42) was much lower than those of postsecondary students (1.54) on cognitive aspect, but both achieved moderate to very high ES. However, for the affective aspect, the overall ESs for both K-12 and postsecondary students were not available. In total, there were only three meta-analyses comparing ML with non-ML instruction. All studies indicated that students who learned with ML performed better than students without ML on cognitive aspect; one study (Sung et al. 2015) investigating the affective outcome also showed positive and moderate effects over non-ML instruction.

Evidence Outcomes Achieved Through Meta-analysis on Information Technology in Education

According to Cohen (1988), an effect is said to be small when $ES = 0.2$, medium when $ES = 0.5$, and large when $ES = 0.8$. In the period of 1988–2006, when both CAI and DE were combined, the overall mean ES for the cognitive achievement was 0.29, and 0.06 for the affective aspect. These results suggest that students with technology integrated into learning activities slightly outperformed those students without using technology for learning. With regard to the affective aspect, technology seems to have a trivial impact on student learning in the 1988–2006 time frame. In addition, in the same period, when comparing K-12 and non-K-12 settings, CAI appear to be equally effective for both K-12 and non-K-12 students' performance, but DE was more effective for postsecondary than K-12 students.

Table 6 Summary of overall ES for each category of ICT in Education in 2007–2017

Category	Cog. ES	Aff. ES	Sc. ES	Cog. ES for K-12	Cog. ES for PS	Aff. ES for K-12	Aff. ES for PS
CAI	1.06			0.74	0.61		
DE	0.92			0.17	1.4		
MT	0.36	0.19		0.42	0.31	0.18	0.2
GBL	0.45	0.44	0.35	0.67	0.59		
ML	0.53	0.55		0.42	1.54		
Overall mean ES	0.67	0.39	0.35	0.48	0.89	0.18	0.2

Note. *CAI* computer assisted instruction, *DE* distance education, *MT* multitechnology, *GBL* game-based learning, *ML* mobile learning, *Cog.* cognitive, *Aff* affective, *Sc.* social skill, *PS* postsecondary

However, in the period of 2007–2017, when combining all 5 categories of technology (i.e., CAI, DE, MT, GBL, and ML) together, the overall mean ESs for the cognitive, affective, and social skill achievement were 0.67, 0.39, and 0.35, respectively, which are much higher than those in the previous period. The results from this period point out that students learning with technology performed much better in all three aspects than those students without using technology. The summary of overall ES for each category is presented in Table 6. Furthermore, when comparing the effects of K-12 and postsecondary for the cognitive aspect, postsecondary students (overall mean ES = 0.89) seemed to benefit more from learning with technology than K-12 students (overall mean ES = 0.48). Regarding the affective aspect, the overall mean ESs were 0.18 and 0.2 for K-12 and postsecondary students, correspondingly; students in both levels were almost identical. Moreover, when comparing the effects of different technology applications in education, the overall mean ESs for cognitive aspect were CAI = 1.06, DE = 0.92, MT = 0.36, GBL = 0.45, and ML = 0.53. CAI and DE appeared to be the most effective technology for learning. For the affective outcomes, the overall mean ESs were MT = 0.19, GBL = 0.44, and ML = 0.55. ML was considered to be the best choice.

A detailed discussion about the evidence of outcomes achieved through meta-analysis on information technology in education in the period of 2007 to 2017 is given below.

There are 11 meta-analyses focused on CAI published in this period. Among them, seven studies were for all grade levels, three studies for postsecondary students, and two studies (Liao 2007; Tekbiyik and Akdeniz 2010) reported separate ESs for K-12 and postsecondary students. Liao's meta-analysis involved 52 studies (134 ESs) from Taiwan. The overall ES was 0.55 and the ESs for elementary, junior, high, and university students were 0.41, 0.85, 0.23, and 0.82, respectively. According to the earlier meta-analysis by Cohen (1988), the effects of ESs ranged from small to large, and the most effective ESs were for junior and university students, and the most ineffective ES was for high school students. Tekbiyik and Akdeniz's meta-analysis involved 52 studies (65 ESs) on students' academic achievement in science education from 2001 to 2007 in Turkey. The overall ES was 1.12, while the ESs were 1.43, 0.79, and 1.06 for elementary, secondary, and

university students, respectively. These ESs are interpreted as large. The study also found significant differences in effectiveness for different grade levels; the most effective grade level was elementary (4th–8th), followed by the university level. The most unproductive effects were the high school (9th–12th) level. Based on the findings of Liao and Tekbiyik et al.'s studies, CAI do have different effects for different grade levels.

One interesting finding is that five meta-analyses conducted in Turkey (Camnalbur and Erdogan 2008; Demir and Basol 2014; Dýnçer 2015; Tekbiyik and Akdeniz 2010; Yesilyurt 2010) all reported high ESs. The study by Yesilyurt even achieved a very high ES of 3.83. The high ESs from these studies raised a question whether the effects of CAI may vary when applied to students in different countries. Studies of this question will require further clarification of the exact relationship between CAI and educational policy or culture of that specific country.

In comparing DE with traditional classroom instruction in this period, DE students have noticeably higher gains in cognitive outcomes than those who are being taught conventionally. Among nine meta-analyses, only one study analyzed by Means et al. (2009) reported separate ESs for k-12 and non-k-12 students, and the effects were all small, based on Cohen's criteria. The fact that only one out of nine meta-analyses in this period specifically examined the effects of DE on K-12 students seemed to suggest that DE is perhaps not appropriate for K-12 students and that it is not an integral part of the curriculum delivery. In addition, five meta-analyses used postsecondary students as the sample and reported quite diverse effects; the ESs ranged from 0.023 (Jahng et al. 2007) to 5.24 (Voutilainen et al. 2017). The study by Voutilainen et al. was particularly for students in a nursing school, and the other four meta-analyses did not specify any subject area. Although the ES of 5.24 is unusual in meta-analytic research, the wide range of ESs seemed to suggest that the effects of DE may differ when applied to different subjects.

In comparing multitechnology with conventional instruction, students who used multitechnology showed better gains in both cognitive and affective aspects. In K-12 setting, the benefits of multitechnology were greater among elementary students compared to secondary students (Li and Ma 2010; Lee et al. 2013), and the role of learning strategies was found to be important whether with a constructivist approach (Li and Ma 2010) or project-based learning (Lee et al. 2013). To investigate whether the use of multitechnology can help elementary students achieve better learning, Liao et al. (2007) analyzed 48 studies. They showed a positive result ($ES = 0.45$) and concluded that the effect of CAI may vary over different subject matter, individual learning is better than group learning, and that computer simulation had the highest ES comparing to web-based learning or CAI. Chauhan (2017) used 122 studies resulting in 215 ESs, which confirmed that the technology had a medium effect on learning effectiveness of elementary students.

In a much earlier study by Clark (1983), after reviewing several meta-analyses of CAI, his results suggested that the effects of new media on instruction were due to a novelty effect, because the ES was reduced when treatment lasted for longer periods of time. Liao and Bright (1991) also reported this novelty effect in their meta-analysis of programming on students' cognitive abilities. However, the results of

Chauhan's study, more than 25 years later, found that ESs for studies in which the duration of treatment was over 6 months or less than 1 week were equally high, indicating that novelty effects may not be a factor affecting the impact on learning, which counteracts the previous viewpoint of the novelty effect.

Three meta-analyses categorized in multitechnology and used in postsecondary all tried to answer the "big question": does technology work? Schmid et al. (2014) examined Richard Clark's claim about the nature of the relationship between technology and pedagogy, Bernard et al. (2014) focused on the blended learning, and Borokhovski et al. (2016) emphasized the impact of designed interaction treatments and contextual interaction treatments on student learning outcomes. The results of these studies are all positive in both cognitive and affective aspects.

Grgurović et al.'s (2013) meta-analysis concentrated on the effects of computer assisted language learning (CALL) in all education levels and reached some conclusions. First, research of CALL tends to use in higher education and the need for research in K-12 is urged to better understand any potential differences. Second, in comparing the various conditions of technology use, second/foreign language instruction supported by computer technology was at least as effective as instruction without technology. However, when comparisons between CALL and non-CALL groups were made in rigorous research designs, the CALL groups performed better than the non-CALL groups, as indicated by a small, but positive and statistically significant weighted mean effect size of 0.257. (Grgurović et al. 2013).

The overall ESs for GBL were 0.42 and 0.44 for the cognitive and affective aspects, respectively. All studies concluded that students learning with game-based computer resources performed better than students without game-based learning. However, the evidences show research interests diverse among different GBL studies. In an attempt to resolve the dispute of which educational technology results in the highest cognitive gain for learners, Vogel et al. (2006) investigated 32 studies and conducted a meta-analysis to decipher which teaching method, games and interactive simulations or traditional, truly dominates and under what circumstances. Their results concluded that games and interactive simulations are more dominant for cognitive outcomes. When students navigated through the programs themselves, there was a significant preference for games and interactive simulations. However, when teachers controlled the programs, no significant advantage was found and when the computer dictated the sequence of the program, results favored those in the traditional teaching method over the games and interactive simulations. Examining the relationship between two forms of simulation, pure and hybrid, and two modes of instruction, presentation and practice, Lee (1999) analyzed 19 studies and concluded within the presentation mode that the hybrid simulation is much more effective than the pure simulation. Simulations are almost equally effective for both presentation and the practice modes. If the hybrid simulation is used, specific guidance on how to use the simulation seems to help students to perform better, whereas when students learned in the presentation mode with the pure simulation, they showed a negative attitude towards simulation.

Wang and Tseng (2011) synthesized 21 studies and analyzed how media were used to support GBL. The ES of 0.58 indicated that students who learned with games

can obtain better learning effects than those who learned without games. Wouters and Van Oostendorp (2013) examined 29 studies to test if instructional support enhances learning in GBL. The overall ES was 0.34, suggesting that instructional support in GBL environments improved learning. Additional analyses revealed that the learning effect became largest when learning of skills was involved and when the instructional support aimed at the selection of relevant new information.

To investigate whether serious games are more effective in terms of learning and more motivating than conventional instruction methods, Wouters et al. (2013) analyzed 39 studies and concluded that serious games were more effective in terms of learning and retention, but they were not more motivating than conventional instruction methods. D'Angelo et al. (2014) researched the effects of computer simulations on science, technology, engineering, and mathematics (STEM) and concluded, on average, that simulations had a positive effect on science achievement. Additional findings revealed that learners using serious games learned more when the game was supplemented with other instruction methods, when multiple training sessions were involved, and when players worked in groups (Wouters et al. 2013).

Examining the impact of GBL in K-12 or higher education settings, Merchant et al. (2014) concluded that an elaborate explanation type feedback is more suitable for declarative tasks, whereas knowledge of correct response is more appropriate for procedural tasks. Students' performance was found to be enhanced when they played games individually than in a group.

Theory-driven meta-analysis examines the correlation between theory and GBL. Drawing from social cognitive theory and the cognitive theory of multimedia learning, Gegenfurtner et al. (2014) examined how design characteristics in digital simulation-based learning environments moderate self-efficacy and transfer of learning. The findings indicate that high levels of user control result in higher estimates of self-efficacy and transfer and that offering assessment feedback after rather than during training led to higher efficacy beliefs and transfer. Brydges et al. (2015) evaluated the effectiveness of interventions designed to support trainees in self-regulated learning (SRL) activities in the simulation-based training context and found that interventions including SRL supports were associated with small benefits compared with interventions without supports on both immediate posttests and delayed retention tests. To find out whether interactive cognitive complexity theory claim that simulation games are more effective than other instructional methods, Sitzmann (2011) analyzed 55 studies and the result showed posttraining self-efficacy was 20% higher, declarative knowledge was 11% higher, procedural knowledge was 14% higher, and retention was 9% higher for trainees taught with simulation games, relative to a comparison group. Cook (2014) re-analyzed the results of a meta-analysis of simulation-based education (SBE) to determine the necessity of replication research studies. The result showed some replication is necessary to obtain stable estimates of effect and to explore different contexts.

The cognitive effect of ML for language learning has been shown to be effective (Sung et al. 2015; Lee et al. 2014). Adults and school children had similar beneficial effects, integrating mobiles with multiple learning strategies produced better

learning achievement, using mobile devices for vocabulary or mixed language skills produced better effects, and using mobiles produced better learning achievement for L2 learning than for L1 learning (Sung et al. 2015). As for which subject matter has better effects with the integration of M-learning, Sung et al.'s (2016) meta-analysis has shown that social studies had a high ES, while professional subjects, such as science, language arts, and mathematics, had medium effect sizes.

In addition, Sung et al. (2016) found the effects of ML were varied for different grade levels. Young children achieved a high ES on learning achievement, while adults and secondary-schools had medium ESs. As for the answer of novelty effect, no conclusion is yet able to be made, since the results have not been consistent (Sung et al. 2015; Sung et al. 2016).

Meta-analysis on Information Technology in Education: Potential and Limitations

As has been shown in this chapter, meta-analysis as a research method helps to make sense of the available evidence about the impact of technology on student performance. With a carefully conducted meta-analysis, the findings of quantitative studies in the field of technology in education can be synthesized and presented in terms of effect sizes. One should keep in mind that meta-analysis has the ability to reduce sampling error by synthesizing effect sizes estimates across multiple primary studies and it cannot reduce sampling error to zero (Schmidt and Oh 2013). A second-order meta-analysis defined as the quantitative synthesis of the results of apparently similar meta-analyses may be able to reduce the sampling error from multiple meta-analyses. As such meta-analysis provides a more robust picture of the effect of technology integration on student performance compared to traditional teaching and learning methods. Such information might help policy makers and industry to decide whether their investments are worth the effort. The strength of meta-analysis is it can answer the big question of what makes learning effective; however, numbers have their limitations as has been shown, for example, in the comparisons presented in this chapter between K-12 results and students in higher education learning through DE (distance education). Therefore, meta-analysis as a research method in the field of technology in education is not the only way to get insights into the impact of technology use in education (see other chapters in this section). Meta-analysis falls short when the aim is to understand the reasons behind the numbers. Experimental designs and qualitative studies are more informative when “why” or “how” questions need to be answered and an in-depth analysis of the types and extent of IT in education being used by the teachers and learners.

A keyword search using the term “meta-analysis” performed on Proquest and set the periods from 1960 to 1988, 1988 to 2006, and 2007 to 2017 result in 686, 49,888, and 244,271 studies, respectively. The increasing number of studies across decades and various academic discipline confirms the fact that meta-analysis has become a highly accepted and focal approach for reviewing large-scale quantitative studies.

As in the first edition of the Handbook we conclude with quoting Bangert-Drowns' (1986, p. 398):

Meta-analysis is not a fad. It is rooted in the fundamental values of the scientific enterprise: replicability, quantification, causal and correlational analysis. Valuable information is needlessly scattered in individual studies. The ability of social scientists to deliver generalizable answers to basic questions of policy is too serious a concern to allow us to treat research integration lightly. The potential benefits of meta-analysis method seem enormous.

Abstract

Concerning IT tools for education, we can distinguish (1) software tools for learning specific subject matters (e.g., simulation and discovery tools), (2) learning platforms, including MOOC platforms for distance learning but also used in hybrid contexts, and (3) digital resources (Wikipedia and Wikimedia, new interactive textbooks, video capsules, etc.). Behind all these tools, we observe strong

tension between the desire to individualize instruction and the intention of offering collaborative usage of general tools, where users have a certain margin of freedom. If the analysis of big data appears as a new Eldorado for education, we have to be aware of incompleteness or spuriousness of data and faulty interpretation of results: number of different types of data (behavior, physiology, etc.) are collected and made accessible, interpreting them is difficult, and much research is still needed. Concerning design processes, a wide spectrum is observed: companies, start-ups, communities, and groups. An interesting link between teacher communities of practice and open educational resources can be underlined. Evaluating education software, resources, and platforms supports an extreme diversity of approaches. But it should include different criteria: functional compliance, interactional conformity, and hedonic quality. Finally, it is important to reaffirm the key role of teachers, helping them to develop their agency in the field of educational resources, empowering them, and accepting them as trusted partners.

Context

In the past two decades, IT tools for education have evolved quite a lot. As was prophesied by Norman (1998), computers have tended to be replaced by *information appliances*, mobile and massively online, while digital resources have come to the fore, at least in developed countries, which have sufficient technical infrastructures and low connection costs.

In these countries, what has changed is that in society at large, virtually anyone with any specific interest can find very quickly an answer to any question, simply by asking some search engine on her mobile device. What this person will later do with the information (i.e., believe it, cross-check it, forget it, etc.) is another matter. Overall, as described many years ago (e.g., Berger 2001), online environments may be used for learning everywhere, well beyond the school and its formal organization, in an informal way (see, e.g., Cox 2013; Dabbage and Kitsantas 2012).

For many persons, computer tools are just like an extension of their body. As a consequence, the classical opposition between anthropocentric and technocentric approaches tends to disappear. For example, the Google search bar offers no real affordance, but as soon as one encounters a sort of search bar, she believes it functions exactly as she thinks Google is functioning (without really knowing how). Correlatively, there is an overall tendency to expect that tools can be directly used, without any specific learning. This is an illusion: those tools, improperly considered as intuitive, function as long as their use is directly in line with previous uses of devices having similar functions and based on the same metaphors and gestures.

Among these environments, only a fraction has been designed with the explicit aim of guiding learning toward explicit learning outcomes; a special case being Massive Online Open Courses (MOOCs) and MOOC-like environments; see section “[Platforms for Distance Learning in Education, Also Used in Hybrid Contexts](#)” below.

Furthermore, let us highlight a very important distinction: users interact with devices that are more or less secretly split between what resides within the user’s information appliance and what is processed and stored on some remote platform running very sophisticated algorithms profiling the user in order to adapt its message to her.

Within the school, things have also evolved. Teachers have learned to cope with the fact that students have access to alternative sources of information and knowledge and use a wide range of software tools, few of them being directed toward learning. Many learning platforms (Claroline, Moodle, MOOC platforms, and so on) have also appeared and are used to disseminate contents. But the role of these platforms is not limited to diffusion, there are adding other features: recording and analyzing data, proposing diagnostics, and suggesting interventions.

Since educational IT tools represent much more than computer-assisted instruction, the question of designing and evaluating IT tools for education has to be reframed. We propose to distinguish three great classes of such tools.

1. *Software tools* used in the study of the different subject matter and specialized software systems prescribed or selected by teachers and acting either for monitoring students’ progress or as simulation and discovery tools, providing new user experiences (e.g., virtual reality).
2. *Learning platforms*, including MOOC platforms (Coursera (<https://fr.coursera.org/>), EdX (<https://www.edx.org/>), FUN (<https://www.fun-mooc.fr/>), Iversity (<https://iversity.org/>), MiriadaX (<https://miriadax.net/home/>), FutureLearn (<https://www.futurelearn.com/>), etc.), often used in distance education.
3. *Digital resources* of various granularities that may either be directly used by teachers to illustrate their courses or be prescribed to students. This idea of resource has known a huge development in the past two decades, under an extremely wide range of forms: Wikipedia and Wikimedia, new interactive textbooks, video capsules, shared curricula designed by individual teachers or associations of activists, etc.

We shall now analyze these different current forms of IT tools for learning and teaching.

From Software Tools to Digital Resources

The three categories we have distinguished above raise similar issues. For each of them, there is a strong tension between, on the one hand, the desire to *individualize instruction*, implying the implementation of hidden devices tracking the user

activity and trying to orient it, and, on the other hand, the intention of offering *collaborative usage* of general tools, where users have a certain margin of freedom, up to a certain degree.

Nowadays, the illusion to be in control is very common: tactile and audio interfaces are so user-friendly. The very old issue of the balance for initiative and control between the user and the machine, explicitly stated in the 1960s about *adaptive learning* (Pask 1966) and at the beginning of the 1970s by Carbone (1970), comes again to the fore. What are the respective responsibilities of the user, the teacher (or the tutor), and the system?

Software Tools for Learning

“Software tools” is a term covering a reality that has taken other names in the past 50 years. Originally, what came first in the 1970s was computer-assisted learning (CAL), with many studies about systems allowing teachers to write courseware or contribute to its development (e.g., see Bork 1972; Cox et al. 1988; Reeves 2008).

Then, developing in the 1980s was the movement of artificial intelligence and expert systems which first appeared in the beginning of the 1970s, posing difficult problems of modeling, both the domain to be studied and the student (Bruillard 1997). One of the key principles adopted then was overlay models and the implementation of expert systems having a knowledge of the field to be studied and, as far as possible, of the pedagogical issues linked with the field, including the design of buggy models, able to offer understandable explanations to learners (see Van Lehn 1990; Bruillard 1997). But it has also been found, at least in scientific subjects, that the students’ conceptualizations may have nothing in common with the expert one, consequently requiring designers to take into account students’ conceptions and scientists’ conceptions as well (Kattmann et al. 1996; Niebert and Gropengiesser 2013).

From the beginning of this century, things have evolved. Firstly, with the dissemination of online facilities, the idea of guiding the student along an optimal path for solving problems has given way to the idea of providing her with a dashboard of information about how she was situated, both in a progression and relatively to other students.

Then, toward 2010, things changed again. After the diffusion of MOOCs and the pervasive presence of “big data,” a new interest for adaptive learning has arisen. This time, software is no longer propelled by a *symbolic* artificial intelligence, operating from databases of facts and rules, but on the operation of neural networks able to perform “deep learning” and to mine huge heaps of data reflecting more or less accurately learners’ activities and providing some kind of classification of their actions.

This process has been fuelled by the dissemination, at least in industrialized countries, of connected mobile tools having limited processing capacities and small screens but allowing anybody to access information and redact small messages anywhere. Once again, what users see of these devices is only one face of the system, the local one, a remote platform processing most of the data.

On the other hand, a large *panoply* of software tools is now available in most subject domains: e.g., dynamical geometry software in mathematics, GIS (geographic information system) in geography, and more generally, applications using geolocation, CAeX (experimentation assisted by computers) in natural sciences, lexicographic tools in literature, databases in history, and so on. Research (see below) has shown that these tools allow very interesting experiments, but a recurrent problem is to lure students into meaningful activities lasting long enough for them to build new knowledge.

For example, Dorey's work (Dorey et al. 2013) about the three-dimensional visualization of molecules shows the existence of a sort of *saturation* effect. Using such software in interesting ways requires an understanding of some underlying concepts, and teachers in secondary schools have not enough time to ensure that students will get acquainted with them. So, in this case, activities are mainly limited to guided tours (see also Webb and Cox 2004).

A lot of hope is currently linked to the *gamification* of learning activities, which foster the design and use of games qualified as *serious*. Although the use of role-playing games and simulations has been incorporated into educational tools for more than 40 years pioneered by, among others, SAGSET (*the Society for the Advancement of Games and Simulations in Education and Training*) founded in 1970, the use of these is becoming more mainstream with the more powerful IT technologies. The idea is to engage students in challenging and meaningful activities. This is not exactly a new idea, since computer games and simulations have existed for a very long time as indicated above. But it has received more recent support from theories such as those expressed by Csikszentmihályi (1990) about the interest of creating lasting states of "flow," sometimes called "optimal experience." The school context (time and space constraints) makes it however generally difficult to practice games within the school, outside of specific situations (kindergarten, sports, etc.).

Overall, as shown in the diagram (Fig. 1), the degree of guidance exerted by software environments has tended to decrease along the years, the tendency being that almost any software has been used as educational software (even if, with the revival of adaptive teaching, it could reverse the curve).

Perhaps one of the most important phenomena of the past decades has been the development of distance education, relying on specific platforms.

Platforms for Distance Learning in Education, Also Used in Hybrid Contexts

A steady development of generic learning platforms has occurred in the past 20 years, a few of them such as Moodle, currently dominant, setting a standard. Offering numerous functionalities, more than any singular teacher or academic might want, they are content independent. Therefore, they allow developers and users to perform all the tasks expected in distance education and even more since they are also currently used to support learning in secondary schools but implement a view (and even a philosophy) of what education should be.

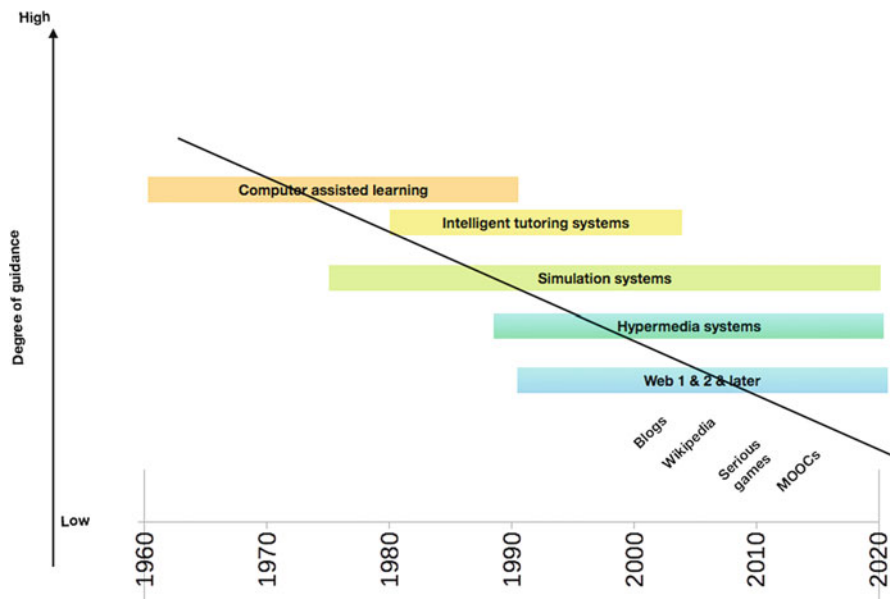

Fig. 1 A global decreasing trend over time of the guidance exerted by software

The success of MOOCs, since 2011, is changing the rules. This very notion of MOOC has evolved. In a seminal paper, Daniel (2012) analyzed an opposition between cMOOC (connectivist MOOC) and xMOOC (supposed to adopt a transmissive approach). This distinction is now less valid. In fact, three common elements, beside the generalized presence of short video capsules, may always be found in those kinds of systems: distance learning using online resources (in particular short videos), social networks, and more or less strict temporal frameworks.

The ability of being a self-directed learner has often been highlighted, and, roughly speaking, participants in MOOCs, in their majority, have had, prior to their enrollment, at least a bachelor degree, even if it is not required (Reich 2014).

Although forms of distance education are developing in secondary education, MOOCs currently have a limited role in it. However, considering them as one of the contemporary forms of books (Bruillard 2017) leads to surmise that they might gain an important place. In particular, a discernible trend exists around MOOCs with cultural aims or for helping students choosing high school itineraries, in a perspective of preparation for higher education.

An interesting observation is the relatively high proportion of teachers in the public attending MOOCs. In surveys about MOOCs hosted by the edX platform (MIT and Harvard), one-third of people say they are or have been school teachers, and 20% of them teach the same subject (Chuang and Dean 2016). This suggests that MOOCs might become a significant vector for teacher development.

Most of all, MOOCs have forced researchers to cope with big data (number of registered students, number of clicks, log files, etc.). Along with a surge in interest for “deep learning” and other applications of neural networks, a new perspective is emerging, sounding like an oxymoron: *adaptive massive personalized learning*, based on the alliance of brute force and sophisticated algorithms applied to big data.

Digital Resources

Using resources for learning is not exactly something new, since J. Dewey himself introduced as early as the beginning of the twentieth century (1916) the idea that learning was related to the presence of resources.

Among those resources, textbooks have traditionally occupied an eminent place. The huge spread of the Internet is considerably changing the landscape. Many high-quality resources, up-to-date, precise, aesthetic, well-designed, and so on may be found on the Internet, the problem being for users to recognize which resources have a high quality.

Furthermore, with the growing obsolescence of the classical truth regime in schools (postmodernist view) and the need of proposing quantities of activities to students, the teacher’s role is more complex, requiring more and more resources. These are of very different formats: texts, pictures, videos, animations, and so on. These resources may be considered as educational by opportunity (not created for educational purposes, but used in educational context) or by destination (specifically designed for education).

The action of teachers working with resources depends upon their degree of pedagogical freedom. Teachers collect resources and, most of the time, rearrange them for their students, composing something new from several sources, according to their choices and priorities. Investigations have shown that their sources may be very different. It may be other colleagues, who sell online their previous preparations (Abramovich and Schunn 2012), or free resources, either from the public sector or from some association or institution (including Wikipedia). They may also come from the market, even if teachers are rarely the clients (Baron and Zablot 2017). In a context of abundance, curation (Bhaskar 2016) becomes a key process that is very time-consuming.

In a current research project aiming at documenting the way teachers design, search, select, edit, and reconstruct educational resources (ReVEA (see <http://www.agence-nationale-recherche.fr/?Project=ANR-13-APPR-0006>) – teaching and learning with lively resources), we have identified four key processes:

1. Inheritance and transmission (getting resources from university preservice training or from colleagues)
2. Participation (sharing and codesigning resources)
3. Collection (storing and organizing educational materials)
4. Establishing trusted networks (persons and places, as websites) (see Bruillard 2016)

Big Data, at the Risk of Mirages and Spurious Interpretations

A series of discreet changes has been accumulating in the past 20 years and has finally produced a dramatic evolution that obliges us to reconsider the issues of designing and evaluating software. Most IT environments now collect lots of data linked to the user's activity. Much hope has been invested in the possibility of mining those data in order to produce interesting results that might help designing software and evaluating its effect on learners.

The diversity of these data is huge: log files, written interaction between students on platforms (in particular on forums), performances on tests, data from eye-tracking devices, and so on. The challenge is to extract automatically information from these data in order to inform humans (designers, teachers, students) to take pertinent decisions. The only way to do this is to apply algorithms reducing the complexity and providing a profile. There are no technical problems to obtain results in real time since broadband allows one to divide the tasks between networks of computers in the cloud that have the ability to treat really large sets of data.

The results are flabbergasting, as anyone, having used platforms like Google, Amazon, Facebook, Twitter, and the like, has realized.

The most known domain of application is marketing, where profiles allow, for example, to target advertisements and to propose purchases adapted to the clients' needs (as they have been guessed by the system). However, in other sectors such as the government, relying on statistically based predictions raises many issues (see Rouvroy 2009 for a political analysis).

We are going to focus here on educational issues and will not analyze the general case of risks toward privacy; i.e., the fact that in such algorithmic intermediations, the person tends to disappear behind the profile, the phenomenon of "vendor lock-in," nor the fact that many dangers exist (OECD 2016).

In education, the main problems encountered in basing decisions on the results of algorithms are twofold: (1) incompleteness or inaccuracy of the data and (2) faulty interpretation of the results.

We assume that the algorithms themselves are classical (pertaining to well-documented classes like computation of similarities between nodes in a graph and the like). But it may be that other computational engines be employed, with the ongoing surge of new forms of artificial intelligence.

Incompleteness or Spuriousness of Data

If data are numerous, how can one be sure they are complete and that their quantity is a guarantee of their quality? What they generally reflect is behavior or rather a small part of behavior. To what extent does this behavior correctly reflect learning activities? To what extent does it reflect the activity of one person? For example, it is well-known that, due to material problems or to a pedagogical will, some activities are led in groups of students. How then, to distinguish between the different actors?

On the other hand, it has been remarked for a very long time that the duration between different user's actions is hardly a time on task. In most cases, also, data will ignore teachers' interventions, which always are to be considered when one intends to understand the effect of an instrument. In some cases, data may therefore be spurious.

These issues have massive consequences: algorithms will always reduce the data they ingest to a smaller set, and they will classify them and highlight some results. But the final quality will fundamentally depend upon the relevance of the input they receive.

There is also another very deep problem. Often, results are based on the computation of correlations. This may be useful but correlation is by no means the same as causality and correlations are likely to be spurious. As Calude and Longo (2016) explain, basing themselves on research from the world of mathematics: "the bigger the database which one mines for correlations, the higher is the chance to find recurrent regularities and the higher is the risk of committing such fallacies" (p. 15).

Faulty Interpretation of Results

Once data are classified and profiles established, and supposing that results correspond to something real, how to interpret them? And what do they actually represent? What can be analyzed from them: learning processes or user's behavior?

The situation here is not quite the same if interpretations are to be made by humans or by software. The first case generally poses no problem except when the finality of processing the data is questionable. Take the case of text processing software or spreadsheets. For many years, when installing this kind of software, network managers could tick a box, allowing the software to transmit the data to the enterprise. Has this permitted the improvement of users' experiences and progress in their appropriation of the software? Or rather has it allowed the enterprise to adapt its offer to users' behaviors?

Human decision is crucial. To give an example mainly concerning higher education, popular software chasing plagiarism in students' work (that function very well on the average) often return for each submitted text a flag (green, orange, or red) and a score of plagiarism. Everyone having had to mark copies knows that caution is in order and that a careful inspection may reveal situations where there is in fact no plagiarism. This problem also exists in secondary education, but in this case class sizes are sufficiently small for teachers to control individual productions, and this provides them with a good opportunity to intervene in work processes rather than judge only one outcome.

The case of MOOCS is illuminating. An important literature has explored the massive data retrieved from learner traces (Reich 2014). The initial intention was to try to understand the phenomenon of dropout rates and to find mechanisms to encourage persistence, that is, to keep participants as long as possible, which is more a marketing perspective than a learning one. It was found that the best dropout prediction was registration behavior (Cisel 2016) and the kind of participation in

discussion forums (strong participation is a good indicator of persistence). A/B testing was also used, good opportunity in massive courses (see, e.g., Kizilcec et al. 2014), but the results are always difficult to interpret without a thorough knowledge of the participants, as in most large-scale quantitative surveys.

It should be noted that new instruments can be used to capture data of a new type: eye movement and attachment points, pulse, blood pressure, cerebral activity, etc., but this requires special conditions. This constrains the activity of the learners, making interpretation of the collected data sometimes problematic.

For investigating complex visual displays, eye-tracking certainly is a very important technique (see Van Der Schoot et al. 2008). Research opens up complementary perspectives, allowing, for example, to study the differences between experts and novices in reading behaviors (Knight et al. 2014). But it is still hard to use.

To summarize our previous remarks, even though we are entering a new era in which a large number of different types of data (behavior, physiology, etc.) are collected and made accessible, interpreting them is difficult, and much research is still needed. The classical techniques of the human sciences remain still topical in order to understand the actors and their activities.

A Wide Spectrum of Design Processes: Companies, Start-Ups, Communities, and Groups

About Design Principles

Analyzing design processes is difficult. Which design process? Designing a textbook or computer software follows very different paths, and according to the large spectrum of resources, software, and so on as elaborated above, it is impossible to pick a typical design process.

Therefore, studying the methods and data for designing IT tools is not an easy task. The classical chain of design for new products has been profoundly modified these last years. Successive stages of production, starting from initial ideas and leading, after engineer work, to a final product sold on the market, are no longer the norm. There is not one norm, one standard and situations vary: what is common between, let us say: (1) a large company aiming at selling a serious game targeting a large audience, which gathers a large team of computer scientists, 3D designers, and content specialists; (2) a small team in a medium-sized enterprise in charge of delivering an upgrade of an e-learning resource about selling a new product; and (3) a small group of teachers preparing a course on some topic by assembling resources they have collected in different places?

While a few large companies have for decades dominated the textbook market, the explosion of educational resources has brought in new players: companies specializing in educational software, young start-ups in the Edtech field, but also teachers' associations. Now, traditional school publishers have to deal with IT companies and invent new common processes. The financial rules are also new. In the textbook market, authors' fees are paid after first sales or first purchases. Now,

they have to take more risk at the beginning or let small companies take risks until a new product seems likely to have some commercial success. In this market, the users are not always the buyers and this poses specific problems. At least two levels have to be considered: the teachers are not always the final users but have a role of both prescribers and assistants (choosing parameters, choosing or developing examples, helping students). The students are generally “captive” end users.

In the IT business, users have traditionally been associated with designers from the early stages of design. But there is a new tendency to distribute products that have not been completely finalized, which are quickly brought to market with the aim of obtaining rapid returns of use in order to direct the rest of the process. Ascending design, crowdsourcing, loop between design and use, continuation of design in use, etc., are key processes. Agile software development is now a current way of producing apps (applications) for different platforms. The methods of contextual design, based upon contextual inquiry (Beyer and Holtzblatt 1998), now take into account a much richer and more complex context of use, inviting designers to immerse in the user context (Holtzblatt and Beyer 2015, p. 74).

Probably, only a fraction of the digital environments is produced by companies using a kind of industrialized approach, at least at this moment. Outside the professional publishing sector, much is improvised. People design in an incremental way without following strict rules; teachers bring their own touch and keep on refining their resources. Resources are also directly assembled by teachers, starting from elements they borrow (and sometimes buy) from a variety of sources.

The design process is therefore manifold. Many teachers redistribute the resources they have produced, either in a market (Abramovich and Schunn 2012) or freely. In France, Quentin and Bruillard (2009) have analyzed the activities of communities of activist teachers. For example, Sesamath, a small teacher association (around 80 members), has been able to create a lot of software tools and free textbooks for Grade 6–10 (<http://www.sesamath.net/>). Compared to traditional publishers, this small association was able to distribute drill and practice tools which can be freely used by teachers and students at school or outside schools, providing teachers with student learning data collected during their activities, even outside the school. In 2012, more than one million lower secondary school students were registered by their teachers, according to Sebastien Hache, one of Sesamath co-founders (<http://www.vousnousils.fr/2012/01/16/sebastien-hache-un-collegien-sur-quatre-est-inscrit-a-notre-dispositif-labomep-519918>). Sesamath products were used by a majority of mathematical secondary school teachers.

Communities of Practice and Open Resources on the Rise

This is typical of a rise of new IT resources based on non-capitalistic values: free software, open educational resources, copyleft and creative commons, etc. The idea is to support an education that may be freely accessed, reused, modified, and shared. This movement is developing in higher education (Unesco 2015; Downes 2007; OECD 2007). It seems also to gain impetus in primary and secondary education.

In a country like France and most probably in other countries where teachers are well organized, many teachers have a mentality of hackers, with strong values concerning education, considering that the necessities to adapt their teaching to their student needs are more important than copyright laws. The profession of faith of the Sesamath association is quite explicit (<http://www.sesamath.net/blog/index.php/2013/04/20/quelle-est-la-philosophie-de>) and illustrated below.

The profession of faith of Sesamath sheds light on the philosophy of association. In particular, Sesamath defends a number of values: solidarity, respect, openness (Sesamath comes from Sesame Math), and sharing. The provision of free and modifiable content on the Internet (under a free license) and also the collaborative work between teachers (including different cycles or countries) are means to serve these values. Sesamath places its action in a public service perspective and considers the educational resources it generates as common goods that can be used by all.

In order to develop its activities, Sesamath sets up partnerships (e.g., with publishers) that extend its activities, but seeks to remain as independent as possible, and as close as possible to the users of its resources, who can participate at any time in the improvement of these commons.

Quentin and Bruillard (2013) have described the functioning of some online teacher networks: between personal interest and depersonalized collective production and between the sandbox and the hive. The hive, which characterizes highly productive collectives underpinned by strong shared values, has very binding and explicit rules that do not allow the user to see their production processes. The sandbox, on the other hand, has collectives with flexible and implicit rules and publishes all their interactions, allowing the diffusion and legitimation of teaching practices.

The model of the commons is therefore a very good framework to analyze what is going on here. Beyond the so-called tragedy of the commons – misuse, purposeful, or not – that might diminish or destroy the common benefits shared by all users, open governance practices, meeting the openness criteria recommended by Elinor Ostrom and her colleagues, could be interestingly developed (Ostrom and Basurto 2011). One can imagine a more collective teaching profession, able to manage educational resources as “commons” in the sense of common goods (Buck 1985). Innovation commons (Allen and Potts 2016) will perhaps develop as a new way of implementing innovations, in a bottom-up vision.

Evaluating Educational Software, Resources, and Platforms

The same complexity is encountered about evaluation. Evaluation of what: Learners' outcomes? Acceptability? Parents' advice? Market evolution? Evaluation for what purpose? Evaluation based on which data? There is an extreme diversity of

approaches. But it is possible to describe briefly some general elements and focus on exemplary cases.

Often, research results are obtained by comparing the performance between pre- and posttests for different groups studying under different conditions (Cox and Marshall 2007). From this point of view, there is an abundance of research results, which are often indecisive or not on agreement between them, suggesting that hidden variables play an important part in the results. We would like to quote here a reflection we made 10 years ago: There are many examples of systems that had worked well in an experimental context and that did not work later, in ordinary classroom practice. “What is worse, history shows that examples of ‘best’ or even ‘good’ educational practice, which are indeed absolutely necessary, are seldom infectious by their own virtue” (Baron and Bruillard 2003, 2007). Reeves (2008) showed the importance of evaluating software in real schools with actual teachers. In sum, the context plays a crucial part and several planes intervene: technical and usability. So the analysis may be carried in terms of several forms of compliance.

As previously explained by Reeves (2008), whatever the products, the first level is technical evaluation: does the product do what it is supposed to do, without error? Then, as products are essentially interactive, a set of criteria released by ergonomists specify the expectations. Coutaz (2013) analyzes these criteria in terms of compliance. The first is *utility* or *functional compliance*. The second, *usability*, is characterized by its *interactional conformity*. The third is the *hedonic quality* often named *user experience*, to designate a subjective experience, the meaning and the value that an individual attributes to a system, but also its perceived utility and usability. Coutaz adds contextual conformity (compliance), the importance of the context of use being recognized for a long time in interactive systems design.

Concerning productions such as *serious games or simulations*, other forms of compliance need to be considered. Firstly, fidelity or conformity to the functioning of objects of the real world is essential. But even low-fidelity systems may be efficient (Toups et al. 2011). In fact, the impact of instruments can be only evaluated contextually, depending on educators’ choices.

Secondly, compliance with educational objectives must be verified. For example, in order to succeed in the game, is it the targeted knowledge that is implemented? If another path is possible than the one expected, what does it help to learn? For sure, teachers can do an interesting job even with poor software, provided they devise a way to illustrate pedagogical aims. But an issue exists and caution is in order since, among existing games, some have a dark side, with questionable and unethical features. For example, Zagal et al. (2013) pinpoint some debatable issues found in common games, such as “playing by appointment” (being obliged to follow the game time schedule), “paying to skip,” “paying to win,” “impersonation” (when the software pretends somebody else sending you a message), encouraging antisocial behavior, and even games with a purpose, where the software traps users in pursuing another goals. As they put it: “It is one thing to invite someone to play a game and tell them that they may learn something in the process and another to try to trick them into learning something” (p. 6).

Beyond these characteristics, it is essential to have access to the models underlying the games or the simulations: this is a critical issue in education, because the

elements underlying these systems have to be verified and need to be accessible. It is critical for educators to be confident that educational software and resources correspond to what is acceptable in their educational system. Perhaps even this is a point for which educational authorities should give a label in order to avoid what might be called hidden defects.

Another form of conformity to be taken into account is linked to the specific cultures of the different contexts: linguistic cultures, national or local cultures, cultures of a community, etc. Numerous studies have been led (see, e.g., concerning gender issues, Bruegilles and Cromer 2009) on the representations of minorities in textbooks and are relevant to interactive products.

On this point, even if it is the duty of authorities (scientific or hierarchical, sometimes religious in some countries) to certify acceptable educational resources, the process of legitimization carried out by peers is essential. The fact that others have been able to use a product and recommend it is a guarantee of utility and usability. This form of legitimation is very important in communities of teachers because it lowers the risk of trying new things in the classroom.

As far as noninteractive products are concerned, the example of the evaluation of Wikipedia articles is enlightening. The elements offered by Wikipedia, with the history of the successive versions, through the discussions and models of editing and automated processes of correction are very rich. But if all these data are searchable, their analysis takes time, and there is still no visual summary that provides effective information. The quality labels self-assigned by Wikipedia are most often the only ones available (see https://en.wikipedia.org/wiki/Wikipedia:WikiProject_assessment).

Discussion

As we have tried to explain, designing and evaluating IT tools for learning have evolved quite a lot in the last decades, and research is facing a brand-new situation: IT tools are everywhere in the life of students, and most of these tools may be used for learning purposes, but not necessarily in line with current educational standards.

The perspective on IT tools for learning has changed with the spread of learning contexts occurring outside of the school, either at a distance, in the home, or anywhere, and having often a nonformal character. The notion of learning resource has tended to supersede the concept of computer-assisted learning, and instructional design has given way to learning design (Baron 2011).

Furthermore, the design of IT tools and resources is often subordinated to existing general purpose platforms, like Moodle, EdX, or similar systems. These platforms actually play an important role in the design of courseware and also of diverse resources. Processes of design are often makeshift or artisanal, with limited range (at best a group of teachers united by some proximity).

Regarding evaluation, research consistently shows that it is pointless to evaluate IT tools without taking into account the educational context in which learning activities are taking place. Much depends upon who is prescribing or suggesting

the interest of using a particular tool; much depends upon the kind of learning design that has been incorporated and is being implemented in educational activities. To summarize, what matters are the situations set up by teachers and even a bad product may be useful in a particular context. Educational assessment refers to the situations set up and only indirectly refers to the tools used.

This view has profound implications, highlighting the importance of allowing teachers to develop their agency in the field of educational resources. This implies to empower them and to accept them as trusted partners.

Abstract

The first international large-scale study in Information Technology (IT) literacy was conducted in 1987, and a broad range of studies that assess IT literacy and related areas of digital learning have followed. This chapter discusses recent developments in international large-scale studies of IT literacy-related achievement with a focus on their shared necessary attributes and the associated challenges with operationalizing these attributes in the test instruments. Two key attributes addressed are: (i) that the test contents reflect real-world use of Information and Communications Technology (ICT) and (ii) that the tests make use of the dynamic functionality and multimodal opportunities afforded by the computer-based environment. Challenges associated with these attributes include ensuring that the individual tasks within each assessment are independent of each other, maintaining a standardized test-taker experience, providing test-takers with plausible feedback from the computer-based environment, and maintaining construct validity. Examples are discussed of how the common challenges in creating

Information technology · Information technology literacy · Information and communication technology literacy · ICT literacy · Large-scale assessment · Computer and information literacy · Digital literacy

Introduction

In 1960 the IEA Pilot Twelve-Country Study collected assessment data from 13-year-old students in five areas: mathematics, reading comprehension, geography, science, and nonverbal ability. The authors suggested that the study “may well be described as an unusual addition to the literature of education” (Robinson 1962, p. 5) and differed from other studies in comparative education in that it sought to “introduce prominently an empirical approach into the methodology of comparative education, a field that has, in the main, relied on cultural analysis as its chief mode of enquiry” (Foshay 1962, p. 6).

This chapter examines recent developments in international large-scale studies that seek to research achievement outcomes relating to digital or ICT literacy (ILSA-ICT). The focus of this chapter is on large-scale studies that are computer-based, and consequently, it is important to make the distinction between those studies that use the computer as a vehicle for test-takers to demonstrate their proficiency in a given discipline (such as in science, reading, or mathematics) and those studies which measure digital or ICT literacy-related outcomes (see Fraillon et al. (2013) for further discussion of this distinction). While, at face value, the distinction might be clear, there will always be some lack of clarity around the edges of the domains where ICT-related skill such as navigation on web-pages, running an application, making evaluative judgments around the credibility of information, or using information ethically may be regarded as within the scope of both a subject-based discipline and a broader digital literacy. This chapter begins with a brief history of ILSA-ICT-related studies before focusing on the methodological issues associated with designing and conducting computer-based performance assessments ILSA-ICT.

The Beginnings of Large-Scale International Studies Relating to ICT

International large-scale assessment relating to IT began with the IEA Computers in Education study (COMPED). The study was conducted in two stages between 1987 and 1992 (Pelgrum and Plomp 1993; Pelgrum et al. 1993). Stage 1 was a descriptive survey of computer use in elementary, lower secondary, and upper secondary schools. Stage 2 was conducted in two parts. The first part was a follow-up of Stage 1. Part 2 “was intended to study the relationship between policy, practice and

outcomes with respect to computers in education” (Pelgrum et al. 1993, p. 1). Stage 2 included a 30-item Functional Information Technology Test (FITT) that was completed by students using pencil and paper with a further optional short computer programming test (Anderson 2008, p. 70; Pelgrum et al. 1993) (A more detailed description of COMPED can be found in Pelgrum and Plomp (2008)).

In 2003 the results of a feasibility study, commissioned by the OECD, on the inclusion of ICT (information, communication and technology) literacy in PISA were released. For the study, ICT literacy was defined as: “*the interest, attitude, and ability of individuals to appropriately use digital technology and communication tools to access, manage, integrate, and evaluate information, construct new knowledge, and communicate with others in order to participate effectively in society*” (Lennon et al. 2003). The study included a pilot administration of computer-delivered assessment tasks of ICT using a “toolbox of ICT user interface components assembled for the study” (Lennon et al. 2003, p. 14) as well as computer delivered questionnaire materials for students. Data were collected from students in Australia, Japan, and the United States. The study concluded that conducting tests of ICT literacy as part of the PISA suite was “both feasible and worth doing” (Lennon et al. 2003, p. 10), although the authors acknowledged that it would be challenging and recommended a “phased approach” (Lennon et al. 2003, p. 12) to the implementation so that the inevitable (known and unknown) hurdles could be overcome along the way. Even though the assessment of ICT literacy has not yet become part of the PISA suite of assessments, the ideas explored and articulated in the feasibility study can be clearly seen in contemporary large-scale assessments of ICT literacy. In particular, the essence of the definition of ICT literacy as having a focus on digital information literacy skills, and the application of computer-based *real-world* (also referred to as “authentic”) contexts for applying ICT literacy has continued to be fundamental to large-scale ICT literacy assessment.

The IEA Second Information Technology in Education Study (SITES) was conducted across two modules (SITES-M1 and SITES-M2) with a follow-up survey referred to as SITES 2006. Data collection was in 1998–1999 for SITES-M1 and in 2001 for SITES-M2. SITES did not include a direct assessment of student performance. In SITES-M1, data were collected from principals and technology coordinators in 26 countries (or education systems). SITES-M1 focused on school management and the support for the use of ICT in schools, ICT infrastructure, staff development, and support regarding the use of ICT and school objectives with respect to ICT (Pelgrum and Anderson 1999). SITES-M2 built on the work of SITES-M1 with a view to exploring innovative pedagogical practices relating to the use of technology. Innovative classrooms within schools were identified in participating countries according to a common set of selection criteria. Data were collected from the schools and classrooms across 28 countries. These were qualitative case-study data collected from multiple sources including interviews with administrators, technology coordinators and innovative teachers, focus groups with a range of school community members, administration of selected SITES-M1 questions, classroom observations, and review of school documents. SITES-M2 reported on analyses of 174 case-studies (Kozma 2003). SITES 2006 sought to

investigate the extent to which innovative pedagogy using technology was present in classrooms and how the presence of innovative pedagogy related to contextual factors at the school and system levels (Law et al. 2008). Questionnaire data were collected from school principals, technology coordinators, and teachers of mathematics and science in representative samples of schools in 22 participating countries.

Recent Developments in International Large-Scale Studies Relating to ICT

In the 1990s and early 2000s, the uncertain availability of suitable computing technology, including Internet connectivity, was regarded as a risk and likely barrier to the implementation of the computer-based performance assessments in large-scale international studies. Around that time, the most widely accepted technical option to ensure collection of standardized computer-based performance data was for test-takers to be provided with computers configured for the testing. An example of this is the Programme for International Student Assessment (PISA) Computer-Based Assessment of Student Skills in Science. Data were collected in 2006 from 15-year-olds in three countries using laptop computers loaded with purpose-built software (OECD 2010). In many contexts, the cost and administrative complexity of facilitating such delivery were regarded as too great to make computer-based data collection viable. However, ongoing improvements in Internet connectivity, increases in the affordability, and prevalence of digital devices and increasing agreement about the importance of digital literacy-related competencies have led to the development and implementation of large-scale international studies that include computer-based collection of performance data.

Five preeminent large-scale international studies that include computer-based tests of performance relating to ICT literacy are: the IEA International Computer and Literacy Study (ICILS), the IEA computer-based component of the Progress in International Reading Literacy Study (ePIRLS), the OECD Programme for International Student Assessment (PISA) Digital Reading Assessment, the Assessment and Teaching of twenty-first Century Skills (AT21CS), and the OECD Programme for the International Assessment of Adult Competencies (PIAAC).

ICILS

ICILS investigated differences among and within 21 education systems countries in computer and information literacy (CIL) (see also ► Chap. 6, “Students and Their Computer Literacy: Evidence and Curriculum Implications” by Ainley in this Handbook). Computer and information literacy is defined as:

an individual's ability to use computers to investigate, create, and communicate in order to participate effectively at home, at school, in the workplace, and in society. (Fraillon et al. 2013, p. 18)

The ICILS assessment framework describes CIL as comprising two strands, each specified by a number of aspects.

Strand 1, collecting and managing information comprises:

1. Knowing about and understanding computer use
2. Accessing and evaluating information
3. Managing information

Strand 2, producing and exchanging information comprises:

1. Transforming information
2. Creating information
3. Sharing information
4. Using information safely and securely (Fraillon et al. 2013).

ICILS focused on variations in CIL between and within countries and student and school factors that were related to those variations (Fraillon et al. 2014). The study took place in 2013 and involved almost 60,000 Grade 8 students in more than 3,300 schools. It was delivered using USB drives and could be run on school computers. In addition data were gathered from teachers from each school, principals, and ICT-coordinators. National research coordinators coordinated information procured from national experts about policies for the use of ICT in education. A second cycle of ICILS data collection, including some new CIL test content and an optional (at the country level) test of computational thinking, is being conducted in 2018.

OECD PISA Digital Reading Assessment 2009

In 2009, PISA included an assessment of digital reading. This was completed by subsamples (36,500 students from 3277 schools) of the national samples of 15-year-old students in 19 countries. Students answered additional computer-based questions to assess their capacity to read digital texts (OECD 2011). Digital texts included dynamic windows and frames, hyperlinks and networks, multimedia, and augmented reality and provided for engaging with on line discussion and social networks (OECD 2011, pp. 34–35). As a consequence, although the processes to obtain meaning from digital texts were similar to those for reading print-based texts, digital reading was argued to include additional skills because readers had to construct their own paths through digital texts and had greater opportunities to engage with text by adding comments to blogs or responding to email messages (Mendelovits et al. 2012). Navigation was also regarded as an important skill in digital reading.

IEA ePIRLS

IEA ePIRLS was conducted in 2016. It is a computer-based assessment of reading literacy for fourth grade students that could be completed as an optional (at the country level) extension to PIRLS (Mullis et al. 2017). The ePIRLS reading literacy assessment was completed by almost 74,000 students in 14 countries (with a further 12,000 students in two benchmarking participants) (LaRoche and Foy 2017). The tests were delivered mostly by USB drives (with some delivered on Local Area Networks (LAN)) that as for ICILS contained all required software resources to be run on computers. ePIRLS measured student reading comprehension of electronic informational texts. This includes the application of comprehension skills and strategies that largely “parallel those assessed in PIRLS” (Muillis and Martin

2015, p. 24) but with the inclusion of navigation skills (such as clicking on links or tabs to navigate to web-content) and dynamic text stimulus (such as animations). In ePIRLS, questionnaire-based data relating to the context in which students were learning to read and reading were also collected from students, teachers, and principals.

The Assessment and Teaching of Twenty-First Century Skills

The Assessment and Teaching of twenty-first Century Skills (ATC21S) is a project that sought to define the capacities that needed to be developed so that people progressing through school would be better prepared for life in modern society (Griffin and Care 2015). The emphasis was on formative assessments for teachers to use, and the focus was on students aged between 11 and 15 years (Griffin et al. 2012). Two areas that involved digital technology were included in the assessment. One of these was an assessment of collaborative problem solving that utilized computer technology (Hesse et al. 2015; Care et al. 2015). The other was an assessment of learning in digital networks (Wilson and Scalise 2015). The construct “learning in digital networks” was seen as comprising four strands:

- Functioning as a consumer in networks
- Functioning as a producer in networks
- Participating in the development of social capital through networks
- Participating in intellectual capital (i.e., collective intelligence) in networks (Wilson and Scalise 2015, p. 59).

OECD PIAAC Problem Solving in Technology Rich Environments

The OECD Programme for the International Assessment of Adult Competencies (PIAAC) provides internationally comparable measures of three sets of skills: literacy, numeracy, and problem solving in technology rich environments (PSTRE) (OECD 2013). It provides national estimates for people aged 16–65 as well as relationships with a range of characteristics. The most recent cycle was conducted in 2011–2012 and involved around 166,000 adults in 24 countries or subnational regions. Twenty of those countries or regions administered the PSTRE assessment (OECD 2014).

The focus of the assessment was intended to be on the cognitive skills required to access and make use of computer-based information to solve problems rather than on the application of computer skills. The PIAAC assessment was delivered on laptop computers to test-takers in their homes as part of an integrated computer-delivery platform. The PSTRE assessment involved a series of problems set in realistic computer environments. Test-takers had to solve each problem using the information and tools that were accessible in simulated computer environments. A range of applications was provided, such as an Internet browser and web pages, common applications, such as e-mail, word processing, and spreadsheet tools and special applications such as a room-reservation system. The problems involved different levels of complexity, numbers of steps, levels of inferential reasoning,

and requirements for the evaluation of the relevance and credibility of information (OECD 2013, p. 86).

Attributes of Large-Scale International ICT-Related Performance Assessment Instruments and Their Associated Challenges

Mendelovits (2017) suggests that the demands of good large-scale assessments are that they:

1. Ensure construct validity (i.e., measure what they purport to measure)
2. Are fair to all test takers (i.e., there is no disadvantage or advantage to any given sub-group of test-takers)
3. Balance the claims of various stakeholders
4. Balance the demands of reporting changes over time with the capacity to innovate.

This section contains a discussion of the attributes of ILSA-ICT in the context of their unique characteristics and the challenges that these bring to bear. The challenges are discussed in terms of the necessary compromises that exist when balancing the demands of large-scale assessments suggested by Mendelovits (2017) and the desirable attributes of the performance assessments. Ultimately, in most cases, there are trade-offs between achieving the ideal characteristics and managing the conceptual and operational limitations in the instrument design and delivery. How these trade-offs influence instrument design is also discussed in this section, with a particular emphasis on how the trade-offs are managed in ICILS.

Reflecting Real-World Use

Characteristics

A common expectation of ILSA-ICT performance assessments is that they require test-takers to complete tasks that reflect plausible real-world use. In the case of computer-based assessments of digital reading, there is an expectation that the digital texts will be multimodal and contain standard navigation features (such as hyperlinks and website tabs) but in addition will address content and contexts that participants could typically expect of digital texts based on their real-world experience. ePIRLS, for example, used only informational text types, whereas the paper-based version uses both informational and literary texts (see Mullis and Martin 2015) and the PISA digital reading assessment included digital environments relating to real-world contexts such as a job search website (OECD 2011). The AT21CS assessment of learning in digital networks used real-world school-based contexts such as a peer-to-peer second language learning environment (Griffin and Care 2015).

In ICILS, the real-world applicability of the tasks is represented through the implementation of a test design using 30-min “modules” in which test-takers complete a sequence of tasks based around a common theme. Each module involved a number of discrete tasks that were to be completed as a lead-up to a final large task. The large tasks were typically communication tasks using some form of productivity software (such as a poster maker or presentation software). For example, in one module, students set up an online collaborative workspace to share information and then selected and adapted information to create an advertising poster for an after-school exercise program (An annotated video demonstration of this module can be viewed at: <http://www.iea.nl/icils-past-cycles>.) (Fraillon et al. 2014, p. 18).

The ICILS Assessment Framework describes three broad types of task included in the test modules. These are:

1. *Information-based response tasks* that are similar to those that could be delivered in a static format on paper but using the slightly richer format available for the computer-based environment.
2. *Skills tasks* that have test-takers complete single-action (such as clicking on a link) or multiple-action (such as changing the settings on a web-page).
3. *Authoring tasks* that require students to edit or create information products using purpose-developed computer applications (such as text editors or presentation display software). These tasks are typically open, in that test-takers are free to explore the functions of the software, undo, redo, and continue to edit features without restriction (Fraillon et al. 2013, pp. 36–42).

The ICILS assessment instrument includes both *point in time* assessments of knowledge, understanding, and skills and *real-world performance* skills. Typically, the information-based response tasks and skills tasks described above assess *point in time* knowledge understanding and skills and the authoring tasks assess *real-world performance* skills.

Challenges

Maintaining Local Independence of Tasks and a Standardized Test-Taker Experience within the Real-World Testing Context

There are a number of challenges in instrument development in ILSA-ICT associated with maintaining a real-world experience in the computer-based performance assessment while keeping the integrity of a large-scale standardized test-taking experience.

The first relates to maintaining local independence of scores obtained from individual tasks or items. Large-scale international proficiency assessments are typically scaled using Item Response Theory (IRT) (Berezner and Adams 2017), and local independence of items is an assumption common to all IRT models (Finch and Jeffers 2016). Empirical analyses of the data collected in large-scale assessments can be conducted to identify the existence and magnitude of local dependencies, and decisions can be made about how to treat them if and when they are identified (see for example Fraillon et al. 2015, pp. 161, 162). The focus of this chapter is, however,

on instrument design, and consequently this section will describe the potential that using of real-world contexts in ILSA-ICT has to create local dependency in test materials and explain how test design can try to minimize the impact of local dependency on the quality of the data obtained from the tests.

From the perspective of instrument construction, local independence means that the experience of completing any given item (and consequently the response to any given item) on a test is not influenced by or related to a test-taker's experience of completing any other items on the test. In its simplest form, a violation of local independence (i.e., local item dependency) would take place when the answer to a given item is somehow provided in another item. In most cases considerations of local independence are more subtle than this. For example, local item dependency can exist in a set of items that refer to a common stimulus in which a test-taker's broad engagement with or comprehension of the text may exert a common influence on the test-taker's capacity to manage all the items relating to the stimulus. Local dependency can also occur in criterion-based scoring of individual pieces of work (such as in the assessment of a piece of writing or some other artifact) if the individual criteria are somehow mutually dependent, dependent on the same attributes of the work, or if judges' ratings on more than one criteria in a piece of work are influenced by their overall impression of the quality of the work.

The ILSA-ICT described earlier typically use clustered items (testlets) that include some real-world stimulus materials referenced by more than one item. In the PISA Digital Reading Assessment (DRA) and ePIRLS, the reading stimuli are electronic web-style texts with multiple pages. In PIAAC and ATC21S, there was a range of digital stimuli to which the tasks referred. In each of these cases, there was a trade-off between maintaining the real-world presentation of the stimuli and the potential for this real-world presentation to introduce some local dependency. Typically, the aim is for the individual items to address clearly different skills and aspects of the relevant constructs and also to reference a range of different parts of the stimulus texts. In this sense, as long as test-takers are dealing with the individual items on their merits, it is reasonable to assume that the items are not conceptually interdependent.

In ICILS, a similar approach is taken to the general design of the individual performance tasks. In many cases, the overarching context in which the tasks are being conducted is not directly relevant to the performance skill that is being assessed. Students may, for example, be asked to click on a hyperlink or reformat some text. In these cases, the real-world context of the module theme is unlikely to be the cause of local dependencies. However, each ICILS test module relies on an internal narrative structure that has test-takers working towards a final goal. Test-takers may, for example, first search for some information, then evaluate the usefulness and credibility of information from a variety of sources, then reframe selected information (such as create a diagram to represent a sequence of events in text) before they begin to create their information product using the resources they have assembled along the way. While this represents a typical real-world sequence of events, it introduces methodological challenges relating to standardization and local dependency in the test design.

In order for the test to be fair to test-takers, it is necessary that the initial state of each individual task be the same for each test-taker. The challenge to this in ICILS is that in the natural narrative of a real-world ICT task, one builds a repository of resources in sequence with the outcome of each task affecting the starting point of the next. This introduces a natural local dependency. For example, a sequence of tasks could ask test-takers to:

- (i) Enter a search term in response to a given research question
- (ii) Identify the most relevant website from the search results;
- (iii) Find a relevant piece of information from a website (from within a set of competing and irrelevant information)
- (iv) Copy and paste the information into a presentation (including an accurate citation)
- (v) Reformat the information to match the presentation style

Table 1 shows the sequence of example tasks described above with a suggested standardized initial state for each task, a summary instruction to test-takers, and the outcome space of possible responses.

The sequence of tasks and outcomes shown in Table 1 illustrates the challenge that the real-world context applied in ICILS creates in managing standardization and avoiding dependencies between items. If the sequence were to be completed in an unstandardized real-world environment then the character string generated as a search term in (i) would affect the search results shown in (ii). The selection of the search result in (ii) would affect the nature, presence or absence of the information shown in (iii). Whether or not the participant could execute the copy and paste in (iv) would then influence whether or not it was even possible for any reformatting to be conducted in (v).

Table 1 Sequence of tasks in an assessment of ICT Literacy

Task	Standardized initial state	Summary task instruction	Outcome space (ignoring nonresponses)
(i) Enter search term	Search engine search field available	Generate a search term	Any character string
(ii) Select search result	Predefined set of search results displayed	Select the best search result	Selection of any one of the predefined set of displayed search results
(iii) Locate relevant information	Predefined web-page presented	Select relevant information on the web-page	Selection of anything on the web-page
(iv) Copy and paste specified information	Predefined information selected on page	Copy and paste information to presentation file	Execution of any available command
(v) Reformat text	Predefined text displaying in presentation	Reformat text	Execution of any available command

In order to maintain standardization and to minimize the potential for item dependency, ICILS adopted two essential design features. Firstly, all tasks began with a fixed, predefined state, and in many cases this state showed the “best” response to the preceding task (or tasks). So in the example shown in Table 1, the search results shown for task (ii) were in response to the “best” possible search term for task (i) regardless of what the test-taker had completed in task (i). Similarly, the text that was displayed in task (v) was the copied and pasted text from task (iv) which in turn was the “best” text selected in task (iii). The initial state of each task was independent of what had been completed by a test-taker on any previous task. Having each task begin in a fixed predefined state ensured standardization and also removed one source of item dependency – the potential for a test-taker’s performance on a previous task influencing his or her performance on the next.

However, this solution in of itself created the possibility that as test-takers moved from task to task, they would see the “best” response to earlier tasks. Some test-takers may then want to go back to an earlier task and change their responses to better match what they saw later in the test (i.e., to correct their earlier responses). In order to account for this second potential source of item dependency, the decision was made to allow test-takers to progress only forward through the test and so that once they had completed an item, they were not able to return. The PISA DRA adopted a similar approach. However, it is of course possible that some test-takers may develop insights into how to complete subsequent tasks through the process of being provided the “best” responses to earlier tasks regardless of whether or not they can return to complete them. This would, somewhat ironically, be a situation in which the attempt to remove item dependency created some dependency. Ultimately the design decision must be based on which of the possible design alternatives will most likely *minimize* item dependency and yet retain the real-world context, and some compromises may need to be made as part of this decision.

A further compromise relates to the feedback that test-takers receive from the computer during the assessment. One feature of working in the computer-based environment is that typically one receives immediate feedback from the computer about whether or not one has executed a command correctly. For example, when a user tries to change a font to bold, the user immediately can see whether or not the command has been executed correctly. In the previous section, the three broad categories of ICILS task were described (information-based responses, skills tasks, and authoring tasks). In the design of ICILS, deliberate decisions were made about the feedback that test-takers would receive when they completed each type of task. The CIL construct includes the execution of generic and fundamental skills and the expression of knowledge about how computers work and of “using information safely and securely” (Fraillon et al. 2013, pp. 22–23). In ICILS, these types of knowledge, skills, and understanding are tested using the information-based response and skills tasks.

When students complete information-based responses, they receive no feedback. While this is typical of any assessment that is scored at a later time, it is unlike typical “real-world” computer use experience. When test-takers complete skills tasks in ICILS, they also do not receive any feedback from the system about whether or not

they have correctly executed the task. Continuing the example from above (changing font to bold), in ICILS if a test-taker was instructed to change selected font to bold then, as soon as the test-taker had executed a command (any command), they would receive feedback from the system to indicate that an action had been recorded. The test-taker would not “see” the font change (although in subsequent tasks it would show as bold regardless of what the test-taker had done in this task) but would be offered the opportunity to try again (once) or move to the next task. In this case, the real-world authenticity of the skill assessment is compromised in favor of collecting information about the *point in time* skill execution of the test-taker. In contrast, the ICILS authoring tasks, in which test-takers work in an open software environment, support the full experience of trial-and-error skill application, review, and revision that is typical of computer use. ICILS was designed to include both task types as a way of collecting data on both test-takers’ *point in time* knowledge and the *real-world performance* skills as they relate to CIL.

A further challenge brought by the real-world approach in ICILS is in the scoring of large tasks. ICILS is the first large-scale international study to use analytic criterion-based scoring of test-taker products. The decision to include information products in ICILS was made in order to incorporate the real-world contexts in which CIL is typically expressed. The two critical challenges in using the analytic criterion-based scoring system were to maximize standardization of scoring across countries (although this is a challenge in all international studies, the potential impact of differences was exacerbated in ICILS by the application of multiple criteria to each large task) and to minimize the impact of dependency across the analytic criteria within each task. The mitigation for each of the two challenges was largely the same. Firstly, a rigorous “train the trainer” scoring training model was implemented in a similar way to that conducted in most large-scale international surveys (see for example Turner 2017). Secondly, the analytic criteria were devised independently and specifically for each task. The criteria within each task were designed to be independent of each other by assessing different aspects of the work. In broad terms, there were criteria that typically related to the quality of the information content in each task (such as the adaptation of information from sources, or targeting to a specified audience) and those that related to the visual presentation of the work in the context of the typical design conventions for the software environment (e.g., poster, presentation, or website). The conceptual hierarchy in scoring layout referenced the degree to which the individual layout features were applied in ways that supported or enhanced the communicative effect of the work.

Optimizing Use of the Computer-Based Environment

Characteristics

An implicit demand of computer-based testing is the expectation that the computer-based testing system will make use of the dynamic and multimodal opportunities afforded by the computer-based environment that are not available in static paper-based testing. ILSA-ICT performance instruments are designed with this expectation

in mind and typically attempt to maximize the potential offered by the computer-based environment.

One explicit expectation is that the computer-based assessment will make extensive use of the computer-based functionality that is typically available to users when using similar software in their day-to-day computer use. For example, when working in a browser-based web environment, typical available features include navigation between pages using a variety of means: using the back and forward arrows, clicking on hyperlinks, clicking on or opening new tabs, direct entry of addresses into the address bar (including by copying and pasting), bookmarking pages, and using the history function in the browser. The assessment design needs to include careful consideration of which functions should be included in order to ensure that the environment is fit for purpose. In PISA DRA and ePIRLS, for example, the available navigation features are typically limited to those that are most commonly used when reading digital texts (back and forth arrows, clicking on tabs, or links). In ICILS, the CIL construct is broader and includes execution of a range of navigation skills. In this case, decisions around which options are available are determined in part by what skills are being assessed. For example, if the skill being assessed is to navigate to a site when provided the URL as plain text, then entering the URL into the address bar of a browser is a necessary available function. In assessments where specialized ICT skills are not essential to the construct, there is greater opportunity to restrict the functionality of the system without compromising test-takers' capacity to demonstrate their achievement. In ICILS, decisions must be made about how the inclusion or exclusion of software features relates to measurement of the CIL construct.

A further expectation in the optimization of the computer-based assessment environment is that the test-takers' capacity to engage with the test content will be independent of operating systems and devices. For example, even though all the ILSA-ICT described in this chapter require test-takers to navigate a web-based environment, none assume that navigation is being tested in relation to one particular web-browser or operating system. In ICILS the position is most complex because the CIL construct includes (explicitly and implicitly) the application of a broad suite of commands. In addition to basic navigation and editing, test-takers are expected to work with a range of types of productivity software tools and web-based data resources, in particular in the execution of their skills for the purpose of communication. Across all studies, the common solution is to use purpose-developed (or adapted) applications that make use of generic commands that reflect interface design conventions common across operating systems, software applications, and devices.

Challenges

Achieving Standardization Across Platforms and Devices

ILSA-ICT are expected to make use of the unique features the computer-based testing environment and yet remain operating system and device independent. This provides significant test design and technical challenges. As described previously, one test design solution is to create an environment in which test-takers make use of

generic commands that can reasonably be expected to be equally familiar to test-takers of equal ability regardless of their experience with particular software systems or devices. However, while this solution is generally suitable for dealing with different software systems (including operating systems), it becomes more problematic across device platforms. As the rapid rise of tablet technology is only relatively recent, the full extent of their impact on large-scale assessment is as yet unknown. Increasingly, however, there is an expectation that tablet devices be used to deliver assessments. The two biggest challenges to this are: the screen size that is available on smaller devices, such as some tablet devices or netbook computers, and differences between the suitability of tablet devices and computers with external keyboards for undertaking some specific tasks.

All ILSA-ICT instruments incorporate some form of test taking interface (that typically allows test-takers to navigate between tasks, monitors progress, and gives an indication of the time available/remaining). While the design of these interfaces varies across ILSA-ICT, they typically are a constant feature on the visible screen and take up some screen space. The remaining screen space is used by the test content (stimulus and items/tasks). Even though smaller screens may be able to display accurately the test interface and content, there is a point at which the absolute screen size becomes so small that it may interfere with a test-taker's capacity to manage the content and compromise standardization of the test experience. Test-takers using smaller screens may need to scroll more than those using larger screens and text and screen content may be difficult to read or manipulate on small screens. In most ILSA-ICT, there are specifications for the minimum permissible screen size. The problems associated with screen size are exacerbated on tablet devices used without an external keyboard. On-screen keyboards may obscure assessment content or at least reduce the available screen space to display the test contents. Typically in ILSA-ICT there is a requirement to make use of an external keyboard for all devices.

Maintaining Construct Validity Across Platforms and Devices

In ICILS, there is a further issue relating to construct validity if the assessment were to be delivered on tablet computers. The performance test includes the need for students to create and communicate using productivity tools, and currently there are questions about whether tablet devices are used in the same way as conventional computers (or even at all) for the completion of larger productivity or communication tasks. Haßler, Major, and Hennesy (2016) following an extensive literature review of reported use of tablet computers in schools suggest:

Unsurprisingly, certain technologies are more appropriate for particular tasks than others and this is also true when considering uses for tablets: for example, keyboards, larger screens and specialized software (perhaps only available for certain operating systems) may be needed to support specialized tasks such as extensive writing, mathematical constructions and computer programming. (Haßler et al. 2016, p. 148)

The above conclusions have significant impact on the conceptualization and design of large-scale international studies which focus on digital literacy (such as

ICILS, PIAAC PSTRE, or AT21CS). In these cases, in addition to resolving technical issues associated with achieving standardized delivery across devices, there are questions of whether construct validity can be maintained on tablet devices if tablet devices are not typically used or suitable for given tasks that remain within scope of the assessment contracts.

Balancing Test Delivery Infrastructure Requirements with Test Content and Validity
At a technical level, there is a trade-off between the available delivery infrastructure (web-based, server-based, or locally run on USB or from the local hard drive) and the standardization, security, and richness of content that can be delivered. In this case, the trade-off includes multiple parameters. While the concept of Internet-based delivery is inherently appealing, it brings with it risks associated with reliance on local users' Internet connectivity and speed. Furthermore, without some intervention on local devices (to create a consistent set up across devices and to prevent or monitor use of other applications), the level of standardization of user experience and security of Internet delivery must be assumed to be relatively low. This relates to a further trade-off between the degree of standardization and level of security and the amount of work that needs to be done to set up devices to support testing. Typically, greater standardization of test-taker experience and test security in a given assessment are commensurate with higher necessary levels of local configuration of the test-takers' devices (see Walker 2017 for a discussion of issues relating to computer-based delivery of large-scale assessments).

Test content development is also influenced by the delivery infrastructure. Rich multimedia including streamed video, for example, makes high demands on bandwidth and may not function well if delivered using the Internet to a number of test takers concurrently in a given location. Consequently, the inclusion of rich media in an assessment may only be feasible if a local delivery option is being used. Audio could technically be included in a test instrument, but this places further demands on the delivery technology. In ILSA-ICT, these issues are further complicated by the significant variation in available infrastructure across countries. The typical approach in ILSA-ICT is to adopt a strategy that balances some innovation in test design with a design that caters to the lowest quality expected delivery infrastructure.

Future Directions in Large-Scale International Assessment

United Nations Sustainable Development Goal target 4.4 is by 2030 to “substantially increase the number of youth and adults who have relevant skills, including technical and vocational skills, for employment, decent jobs and entrepreneurship” (UN 2016). Indicator 4.4.1 under this goal is the “proportion of youth and adults with information and communications technology (ICT) skills, by type of skill” (UN 2016). This is a formal recognition of the current and ongoing value of digital ICT-related skills. In this section, the future direction of ILSA-ICT is considered in terms of current trends in the area, necessities, and the challenges they may bring.

In order to remain relevant and useful, international large-scale assessment must remain up to date with developments in digital technologies and their use. This is a particular challenge when considering the speed with which change occurs, and the challenge is manifest in design choices around assessment content, choices relating to delivery and in the ongoing conceptualization of the constructs that are being assessed.

The inclusion of DRA in PISA and ePIRLS in the PIRLS assessment suite were responses to changes in technology and the increasing prevalence of computer-based reading. The restriction of ePIRLS to include only information text types was a deliberate decision in light of the types of electronic texts that Grade 4 students can be expected to read. As technologies develop, it is plausible, for example, that the text types in large-scale international assessments of computer-based reading may expand to reflect changes in reading behaviors. It is also plausible that they may not. Such decisions need to be made carefully and strategically in light of data about patterns of use and whether these represent enduring reflections of changes in reading as a construct.

Previously in this chapter the relationship between tablet device use and the measure of computer and information literacy in ICILS was discussed. This is one example of a challenge that changes in technology can bring to the measures of digital literacies. The imperative solution in this case is to determine what is “core” to the digital literacy discipline and what is peripheral to a domain in the context of how it can be assessed and how changes in technology may affect assessment. In ICILS, the core skills relating to information literacy in the digital context, which had their roots in the 2003 PISA feasibility study, are the ones that have endured. However, ICILS 2018 has included computational thinking as an optional international assessment in response to increasing interest and formal application of this domain within countries. This is a response to changes in the field, not as a result of changes in technology but rather as part of the natural evolution of priorities and thinking in the domain.

Stage 2 of the COMPED study conducted over 25 years ago included the FITT with domains that relate closely to those covered in computational thinking. The ICT processes that were first determined as having international applicability in the PISA feasibility study represented a shift in focus of the domain away from computing towards information literacy using the Internet and computers (now digital devices) as tools. While this thinking dominated the domain in the first decade of this century, recently there has been a shift of interest to include computational thinking as a domain worthy of curriculum definition (see, for example, Angeli et al. 2016), teaching, and assessment (see, for example Bocconi et al. 2016). With an eye to the future, one must determine whether the current resurgence of interest in computational thinking will be sustained, with computational thinking joining a lasting core of ICT-skills, or whether it is peripheral to a central core. Decisions about how to work with computational thinking now and into the future are simply contemporary examples of the general principle that it is important to monitor and evaluate what is core and what is peripheral to IT-related domains in the context of continuous and rapid technological change.

Changes in technology can, however, continue to influence the core constructs of interest. For example, in the past decade, collaboration and social media-supported publishing have become significantly easier and faster. With relatively little technical skill, it is possible for users to publish information in the public domain. With this technological development, there has been consequent broadening in the focus of the assessment of safe and ethical computer use to include the user as an information producer and publisher as well as a consumer. This has resulted in a broadening and shift in emphasis of constructs covering this aspect of the domain.

As technologies develop, policies evolve, and device use changes, the fundamental questions that need to influence the planning and development of large-scale international assessment of IT-related literacy relate to the relevance, scope, and anticipated longevity of the changes. Those changes that relate to core issues in the domains and that are likely to be sustained are the ones that need at the very least to be incorporated into the design of future large-scale assessments.

Abstract

The evaluation of emerging technologies is important for their impacts to be effectively integrated into learning and teaching settings to bring the best benefit to learners and teachers. Educators, learners, parents, and policymakers alike, therefore, need reliable methodologies for evaluating the effectiveness of such emerging technologies. However, the impact evaluations of technology in education are challenging. This challenge is more significant for emerging technologies, as change is the essence of emerging educational technologies. Therefore, the value of traditional impact evaluations in education requires being reconsidered within this context. Here, we present a pragmatic approach to measuring the impact of emerging technologies in education which focuses on the suitability of the proposed evaluation methods and the types of evidence rather than on the hierarchy of these methods and evidence types. The approach has two main steps. First one is the creation of a clear theory of change to identify outcome measure(s) and assumptions that are behind the expected impact of the emerging

Evidence-informed practice · Emerging technologies · Impact evaluation · Pragmatism · Evidence

Introduction

The impact of technology on learning and teaching is often at the forefront of demands, particularly from those who dictate the funding available to pay for technology within education systems. This is not an unreasonable request and there is merit in impact evaluations of educational technologies including emerging technologies. Nevertheless, as has been shown in numerous meta-level investigations (see for instance Cox et al. 2003), evaluation of the impact of technology on educational outcomes is a challenging task. This challenge is even greater when evaluating emerging technologies. This is at least partially due to the connotation that, in traditional impact evaluations, evidence regarding the impact of an intervention is considered as *a shield against change*. The generation of scientifically robust evidence about the impact of an educational technology can be therefore taken as a message for the stakeholders of this technology to standardize it and scale it up. *However, change is the essence of emerging technologies*. Measuring the impact on educational outcomes is certainly a necessity if we are to increase our confidence in our educational technologies for their potential to meet their expected outcomes. However, particularly in the case of emerging technologies, the evidence generated from impact evaluations might rather be used to provide “informed change” instead of a justification for standardized practice and manuals for implementations.

This fundamental difference between emerging technologies and more traditional educational interventions is important and it must be taken into account in the discussions about and designs of studies to evaluate the impact of emerging technologies. In the context of emerging technologies, the value is in the careful consideration of different types of evidence as well as robust methods to generate them. In this chapter, we will focus on two key particularities of emerging technology interventions, and based on these, we will suggest a pragmatic approach to evaluate the impact of emerging technologies.

Defining Emerging Technology

When simply defined, particularly within the context of education, emerging technologies are those that have the potential to change the current state of affairs in education. Emerging technologies include but are not limited to virtual reality implementations (Merchant et al. 2014), augmented reality implementations

(Dunleavy and Dede 2014), mobile learning devices (Crompton et al. 2017), physical computing tools (Katterfeldt et al. 2018), Internet of things hardware with sensors (Cukurova et al. 2018), and technologies that allow collaborative learning at a great scale (Cress et al. 2016). Change is at the core of these technologies not only because they evolve by time, but also arguably their *raison d'être* is to transform the learners' current experience. Therefore, the change is not only in the educational technology that is aimed to be evaluated, but also in the learners' experience of the interventions through which the impact of the technology will be evaluated. When change is such fundamental to emerging technologies, how can we measure their impact in a robust and meaningful manner? Next, we will go through the notion of evidence-based education and how evidence is being generated to measure impact in more traditional educational settings with the purpose of presenting the (in)compatibility of these ideas to the nature of emerging technologies.

Evidence-Informed Emerging Technologies in Education

The notion of impact and the demand to be shown that something really “works” requires evidence of some kind of influence or effect of the educational technology on their users. In educational technologies, as well as in education broadly, often this evidence of effect is measured in terms of learner attainment (see for instance Cox and Abbott 2004). Measuring impact on student attainment might be considered as somewhat narrow, and increasingly there is a recognition of the value of illustrating effects on a much wider range of outcomes. The previous edition of this book presents some of these examples such as those relating to emotional well-being (Ainley et al. 2008) or motivation (Cox 2008). Regardless of the type of outcome measured to show the impact, high-quality evidence that relates to the potential of an educational technology to achieve its expected learning outcomes and the information regarding the process of how these learning outcomes can be achieved is key for impact measurements.

Although there are some concerns regarding the centralization of such evidence as the only source of input for decision making on which to base educational practice (see, for instance, Biesta 2007), it is hard to argue against the potential value of evidence to inform and improve practice (Petty 2009). Recently, interest in effectiveness evidence in educational practice and policy has increased globally (Buck and McGee 2015; Greany and Maxwell 2017). For instance, in the UK, the department for education invested a £125 million founding grant to Education Endowment Foundation in 2011 aiming to improve evidence-based practice in education. Department for International Development is preparing an approximate £20 million investment to create a global research hub to form a global “what works” evidence hub to catalyze effective innovation in the education sector. This initiative aims to provide decision-makers with evidence to harness the transformative potential of educational technology – to deliver better learning outcomes for all (DfID 2017). Similarly, in the USA, 2015 Every Student Succeeds Act encourages the use of an educational practice

that meets evidence standards from experimental or quasi-experimental evaluation studies. Fundamentally, these initiatives point out that educational policies and practice should be chosen based on evidence on their effectiveness (Slavin 2017).

Governmental initiatives as mentioned above lead to discussions around impact and evidence in primary and secondary education practice with an emphasis on “what works,” suggesting that practice should implement teaching methods that are presented to be effective at maximizing learning outcomes by research (Hattie 2008). However, despite the significant amount of academic interest and policy focus as well as the resources directed to educational technology’s impact, it is still a significant challenge to generate and identify robust evidence on the effects of technology in education, particularly for emerging technologies.

After decades of research in the field of technology in education, there are still significant questions waiting to be answered that relate to the impact of technology on students’ learning (Cox 2008). There are various reasons behind this lack of robust and reliable evidence regarding the effects of technology in education.

As categorized by Cox and Marshall (2007), these include issues that relate to different assumptions about how learners think; the broad range of technology types and their varied uses leading to different effects; curriculum design and implementation-related variance of technology adoption and use; problems of the pedagogical approaches of the teachers; and issues that relate to the identification and use of research instruments as well as the interpretation of results generated from their use. In addition, it can also be argued that there are other challenges that are more practical in their nature such as the lack of investment and interest from educational technology companies in measuring the impact of their products on educational outcomes, strategic challenges such as the lack of cross-sector learning and multidisciplinary collaboration in educational technology research and practice (between developers, designers, entrepreneurs, educators, and academics). To exemplify the first point, for any pharmaceutical product to be available in the market, it has to go through a very strict evaluation process and impact trials. Yet, educational technology products can go straight into the market as soon as they are developed without any evaluation of their impact on their expected educational outcomes, or identification of their potential detrimental effects. To make it clear, we do not have any purpose of comparing medicine as a discipline to education; however, the point we are making is that, at the moment, there is a great uncertainty around the impact of educational technologies on their expected outcomes, and this should be decreased to a certain extent through appropriate impact evaluations. This approach would be unacceptable, unethical, and illegal in various disciplines including medicine, agriculture, engineering, or architecture. However, yet it appears to be acceptable in educational technology contexts. The demand regarding the decreased uncertainty around the impact of educational technologies would also encourage educational technology producers to be more interested in and invest into impact evaluations. Regarding the second point, efforts to ensure that promising research has at least some chance of being “translated” into useful products are explicit in many other disciplines (see for instance <https://www.elsevier.com/connect>). On the other hand, attempts to create a shared understanding between the key stakeholders

in educational technology, including technology developers, academia, and educators, are extremely rare (see for instance <https://educate.london>).

It is clear that generating evidence about the impact of educational technologies is a challenging enterprise. Furthermore, evaluating the impact of emerging technologies, which is the particular focus of this chapter, is even more challenging. In this chapter, we discuss two main reasons for this argument. Firstly, compared to more mature and established educational technologies, it is more challenging to explicitly diagnose and identify the actual educational “problem” specific to the contexts of emerging educational technologies, which also makes outcome measure(s) and their relationship to the expected impact hard to identify. However, transparency of interventions in terms of outcome measures, their definition, and contextual factors is fundamental for the emergence of evidence in educational research (Cukurova et al. 2017). In some cases, the solutions created through the emerging educational technology do not relate to any particular educational outcome which would be the key outcome measure of the impact evaluation of the emerging educational technology created. This leads to the result that neither the emerging educational technology interventions created nor the evidence of their impact on certain outcomes has much value for practitioners and policy-makers. Evidence presented in previous reviews (see, for instance, Cox and Abbott 2004) shows that likely effects of technology interventions on learning are often present *only when* outcome measures are closely linked to the actual expected learning outcomes of the technology.

Secondly, there has been a tendency in recent educational research to move towards experimental research designs that aim to generate evidence to inform teaching practice while undervaluing other types of research approaches (see for instance Slavin 2017). This movement towards positivist research methodologies in education has led to heated debate over the last few years about the way in which evidence in education is perceived, and the relationship between research and practice in educational research (De Bruin 2015), with much discussion focusing on how to generate a positive relationship between educational research and teaching knowledge and practice (Pampaka et al. 2016). Here, we argue that due to the ever-changing dynamic nature of emerging educational technologies, the traditional methods of more positivist impact evaluations, such as randomized control trials (RCTs), should *not* be considered as *the only* solution. Such research methods require mature practices, long-term implementations, and big sample sizes which are all problematic to satisfy for emerging educational technologies. In measurements of emerging technology impact, it might be a more appropriate approach to collect evidence in an iterative and adaptive process, disseminating findings as they evolve, and contribute to the maturation of both technology and its implementation in particular educational contexts. After such maturation of technology and its implementation has been reached, the value of more positivist approaches becomes more apparent in the impact evaluations. Traditional positivist impact evaluations cost a significant amount of resources, and they require long treatment periods to be meaningful. They do have a great value for more established interventions, which are refined with pilots and early research that use postpositivist approaches with both qualitative and quantitative data. However, for emerging technologies, their value is

open to criticisms. Here, we will argue that small-scale rapid cycle evaluation type of investigations might be more appropriate for most of the emerging technologies until they reach a certain level of maturity.

Transparency of the Intervention and Identification of the Outcome Measure(s)

As we mentioned above, the diagnosis and identification of the actual educational “problems” specific to the contexts of emerging educational technologies is a challenging but a necessary step in impact evaluations. This challenge might lead to the omission of key contextual factors and clear outcome measures for the impact evaluations of emerging technologies. The omission of contextual factors is hard to understand when one considers that a wide range of research has illustrated that it is impossible to understand how people work or learn without also taking into account the people and artifacts that make up their context (Nardi 1996). Although the term context is probably the term that is used most frequently within educational research papers to index the circumstances in which learning takes place (Cole et al. 1996), it is still a complex concept with its various definitions and interpretations by educational researchers. It is very difficult to “pin-down” in a way that enables context to be used as the basis for informing the practice of teaching and learning. However, the context has been subjected to two principal conceptions: the first conceptualization is “that which surrounds,” which is open to the criticism that context is portrayed as a container rather than part of the same situation. The second conceptualization requires that we interpret mind in a relational way: “as distributed in the artefacts which are woven together and which weave together individual human actions in concert with and as part of the permeable, changing, events of life” (Cole et al. 1996). In this chapter, our interpretation and use of the word context are similar to the latter conceptualization of context. In this sense, context is a reflection of the interactions that the learners have experienced with multiple people, artifacts, and environments. This interpretation of context includes a range of factors such as the learning tasks and the learning interactions of social constructivist learning processes, as well as its relatively simplistic interpretation as being that which surrounds learning and learners. It is sadly true that the treatment of context in educational studies, particularly when it is considered in this broader sense described above, is “under-examined, under-theorized and under-developed” (Gulson and Symes 2007). Context is often so poorly reported within the educational technologies research literature, that a sustainable and systematic manner in measuring emerging technology impact in primary and secondary schools evades the research community. The omission of contextual information from much educational technology research devalues the impact of this research both on the practice of educators and on the practice of policy-makers (Cukurova et al. 2017).

In the past, due to limitations of technology and its use in education, impact evaluations were often completed through straightforward questions such as “what are the effects of this physics teaching software on students’ understanding of the

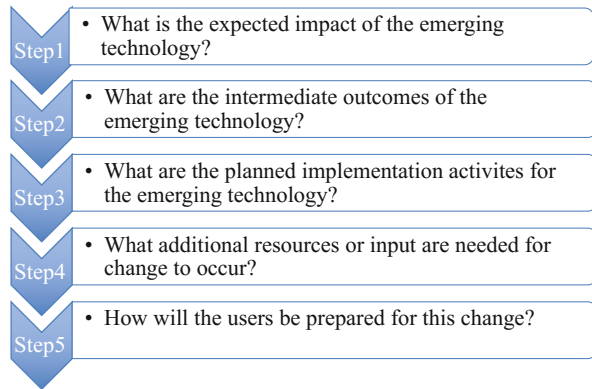

concept of gravity?” or “Is there an impact of students’ understanding of chemical bonding after engaging with this simulation?” etc. The evaluations were also undertaken with traditional methods such as pre- and posttest evaluations (Cox 2008). However, in the case of emerging technologies, the aim is often to transform students’ experience of traditional education. Therefore, what exactly this experience involves, including the expected outcome measures and contextual factors, should be clearly defined as the initial step of the impact evaluation process. If we take the position that the context is the sum of one’s experiences, then the context in which the impact measured should be as transparent as possible in order to be able to clearly identify the outcome measure(s) which will be investigated during the impact evaluations of emerging technologies. The complex design of emerging educational technologies requires much more understanding of human-computer interactions (Cox 2005) as well as the wider learning context in which they are being implemented.

Emerging technologies vary enormously, and multiple researchers have made it clear that the design and use of an educational technology plays a big role in its impact on educational outcomes (see for instance Reeves 2008; Pilkington 2008). Not all emerging technologies are equal in their potential to afford efficacy. Any kind of impact evaluation in educational technology research, therefore, also requires detailed knowledge of the nature of the evaluated technology, their different representations, and the ways in which they may contribute to learning (Pilkington 2008). There could be various methods to bring this transparency of the emerging technologies and their contexts, next we will present one of them.

A Theory of Change for Emerging Technologies

Change is the essence of emerging educational technologies. This change involves changes in the technology as well as the changes in the experience of learners. According to the theory of change, until a change occurs, a state of equilibrium exists in which any forces that might drive change are equal to the forces that are resisting change. For change to happen, the balance in the equilibrium needs to be upset (Fullan 1983). This imbalance can be achieved either by strengthening the driving forces behind the change or by removing the barriers that resist the change (Fullan 2001). In the context of emerging technologies, a theory of change can essentially be represented as a diagram that explains how an emerging technology might have an impact on its users. It should mainly outline all design features that an emerging technology has, the ultimate impact that it aims to have on its users and all the potential outcomes that lead or contribute to this ultimate aim. A theory of change diagram is very useful in impact evaluations as it enables one to identify the steps that are necessary to take in order to reach the expected educational outcomes as well as the assumptions taken for granted between those steps. It also ensures that these outcomes may actually lead to emerging technology’s overall impact and that the impact is measurable. The transparency that a theory of change brings into the problems that an emerging technology aims to tackle in education is the first step to take for impact evaluations. There are five main steps of creating a theory of change (Fig. 1):

Fig. 1 Theory of change diagram steps for emerging educational technologies

Step 1: This step can be considered as the identification of the expected primary impact of the emerging technology. In other words, to what issue in education this emerging technology product might provide a solution to? One of the key challenges here is that impact should be measurable, and ideally, the impact should be the direct impact of the emerging technology that can be observed in realistic timescales. There is no point in creating multiple impact scenarios that are not specific to the emerging technology; therefore, the impact should ideally be one to three bullet points that are specific.

Step 2: These intermediate outcomes lead to the overall impact and can be defined as the expected change/benefit that your users of the emerging technology will experience. These also should be measurable; however, unlike impact, these outcomes should be comprehensive in order to be able to explain all expected changes the users will experience as part of their engagement with the emerging technology.

Step 3: There is great evidence that the activities, in which the technology in education is being used, affect the expected learning outcomes (Cox et al. 2004). Activities in which the emerging technologies are being used might range from using what are essentially traditional methods with only small interaction with the technology to more fundamental changes in the teaching and learning practices. For instance, a natural language processing artificial intelligence (AI) tool (such as Amazon Alexa) can be used by a teacher as part of her teaching practice, essentially as a handy dictionary to define unknown words that might emerge during her teaching activities. However, it could also be used as part of students' group activities in which students talk with the AI agents in order to improve their pronunciation, motivated to be understood by the natural language processors of the AI agents (Underwood 2017). Clearly, the impact evaluations of these two interventions with the same technology would be significantly different. Therefore, in impact evaluations, clear explanation of the implementation activities of the emerging technologies is very important. Activities may comprise everything that the emerging technology does for its users and everything that users do when they are using it as part of the intervention.

Activities should only include things that influence the users directly, not operational tasks that are done in advance of the teaching and learning activities or that might impact the user in an indirect manner. As part of a theory of change, activities and their outputs need to be linked to intermediate outcomes identified in step 2. It is useful to draw arrows indicating this potential causality on a theory of change.

Step 4: There are often other resources needed to use the emerging technologies – other than the technology itself. These could include access to the Internet or other software or hardware requirements. Likewise, other inputs, such as particular skills or training, might need to be present for successful implementation of the emerging technologies in education. It is important to bring transparency to these resources as part of a theory of change.

Step 5: In addition to making sure the users have the resources and skills necessary, there might be many other challenges with the process of change, especially in education. It is important to consider these when planning for impact evaluations, as they would affect the size of the impact. This step is particularly useful for the interpretation of impact measurements as well as the process of it. A few issues to consider are presented below;

- (a) **Readiness for change:** Change in education is a slow process, compounded by the fact that many educational practices have not changed in decades. Ensuring that the users of the emerging technology are ready for the change, in terms of understanding and accepting the need for the change, is vital for its impact.
- (b) **Urgency or need for change:** When processes and practices are so intertwined, it is often difficult for participants to understand why change is necessary. Clear explanations and data that demonstrate why the change is positive and necessary can help convince stakeholders of the need for change.
- (c) **Learning anxiety:** Participants need to feel that the conditions are safe for a change. One way to combat this anxiety is to include practice phases as part of the implementation so that participants can test the change and iron out mistakes.
- (d) **Implementation dip:** There is good evidence that confidence in using technologies is vital for impact on educational outcomes (Condie and Munro 2007). When people realize that they are required to learn new skills and that they are not as confident in the new practices as they were in the old, an implementation dip occurs. This is a decrease in both performance and confidence during the change process. The implementation dip is to be expected, especially in education, and requires coaching and other support to help people through this transition.

A Pragmatic Approach to Impact Evaluations

Impact evaluations of any emerging technology require the generation of evidence regarding any effects arising from an educational intervention that involves that

emerging technology. However, views about what constitutes “evidence” may vary considerably among and between stakeholders. For instance, although most educational technology developers would present quotes from their users as evidence of the impact of their product or service, such anecdotal instances would not impress most academics. This variance brings more confusion into the already complex endeavor of educational technology practice and decreases the likelihood of employing evidence-informed practices in educational environments. When the discussion is on measuring impact, evidence is often categorized in four groups as elaborated below (Hoeken 2001). It is important to note here that the type of evidence does not necessarily reflect the quality of the evidence and different types of evidence have different advantages and disadvantages (Marshall and Cox 2008). Different types of evidences’ quality are judged with different criteria, and different types of evidences are more appropriate for different research purposes and contexts. Exploration of the quality criteria for different types of evidence is outside the scope of this chapter (for further information please see O’Leary 2004). Nevertheless, the point that requires to be made here is that each type of evidence should be judged with appropriate evidence quality criteria and a type of evidence’s appropriateness should be considered for specific questions and within particular research contexts.

Types of Evidence

There are four main categories of evidence: anecdotal, descriptive, correlational, and causal evidence.

1. **Anecdotal evidence** is evidence from personal statements or claims based on one or more people’s personal experiences. When compared to other types of evidence, anecdotal evidence is generally regarded as limited in value due to a number of potential weaknesses regarding the evidence quality measurement values such as subjectivity. Therefore, it is hard to argue about the impact of emerging technologies using only this type of evidence. However, anecdotal evidence can be considered within the scope of the scientific method as long as it satisfies some of the quality of evidence criteria (auditable and transparent), empirical and verifiable. Often the real value of anecdotal evidence is in its potential to indicate the potential context in which an emerging educational technology can be effective. For instance, in a recent case study, Perry (2015) investigated the potential impact of a new augmented reality-based mobile learning tool which was created for first-year University French students in order to bridge the gap between gaming and education through quest-based learning. As part of the study, volunteers were sought from first-year University level French-language classes and a total of 11 students participated in the study. Based mainly on student excerpts, the study concludes that game-based mechanics can be positive motivators for learners. While this study provides an interesting piece of evidence that could be used as a supplement to a larger body of evidence, it is too limited in scope and sample to stand on its own. However, it addresses several benefits and limitations of the emerging educational technology

investigated via a case study, and it offers theoretical and practical implications that will shape the future more targeted studies. For instance, the evidence generated from the case study is used to shape further analysis of student interactions with each other and their interactions with the tool in order to provide a comprehensive analysis of the emerging technology's use and its impact on student motivation.

2. **Descriptive evidence** stems from the summary of characterizing individuals and groups who use a specific emerging technology and depicting events, processes, trends, or relationships that emerge from users' interaction with an educational technology resource. This type of evidence can provide more insight into effectiveness; however, the main criticism of this type of evidence is that it does not control the other variables that could potentially have an impact on the results generated (Marshall and Cox 2008). Educational technology research and commercial documents are replete with such evidence (see, for instance, Beraza et al. 2010).
3. **Correlational evidence** is the identification of the relationship between a condition or initiative and a specific outcome. When the results show correlations, these might be due to the intervention or another causal factor. The correlation results, therefore, cannot answer why questions, yet they are still very useful for evidence-informed predictions.

For instance, Bakker et al.'s (2015) longitudinal study, which is conducted over 2 years, includes a much larger sample size than the aforementioned case study (719 pupils from 35 primary schools) in order to examine the effectiveness of computer "mini-games" in primary education. Such game applications can barely be considered as an emerging technology; however, due to lack of longitudinal research on emerging technologies, potentially due to aforementioned dynamic nature of these technologies, we will use this example here. This work is labelled as a controlled longitudinal study. The three groups researched included pupils who used the computer games at home, with no in-school discussion, pupils who used the games at home but discussed them in school, and pupils for whom the games were played in school as a part of the mathematics curriculum. The study found that the games were most effective in improving the multiplicative skills of students who used them at home with follow-up at school.

In designing this study, researchers considered several meta-analyses of the use of technology in mathematics education and included a control group so that the variation between the control group and experimental groups could be attributed to the influence of the technology intervention (in this case, the mathematics mini-games) (Bakker et al. 2015). Due to its relatively large sample and somewhat controlled nature of the study, it provides a nice example of correlational evidence and its value in terms of providing a relatively high level of confidence in the results generated. Even so, the researchers point out the fact that this study cannot be generalized beyond the sample and experimental conditions used here. One of the reasons for this is that their sample was not representative of Dutch schools as a whole, due to the dropout in participation they experienced from their original sample size. Also, the students were not

distributed randomly into groups which brings doubts about the equivalence of students in control and intervention groups in terms of potential confounding factors such as their motivation and confidence.

4. **Causal evidence:** Strong causal analysis can only be achieved by ensuring that the only difference between the group that receives an educational technology intervention and the comparison group is the intervention itself. Many guidelines for evidence-based practice indicate that the best-quality evidence comes from randomized controlled trials (RCTs). RCTs assign large numbers of subjects into either a control or a treatment group by chance. The treatment group then receives the educational technology intervention being tested and the control group does not. An RCT is one of the strongest forms of design for an impact evaluation in general, because it establishes whether a specific intervention caused an outcome or not. Evidence of the causality of an intervention is relatively rare in educational technology research, particularly that involving emerging technologies. In order to exemplify this type of evidence, we will have a look at the research conducted by Miller and Robertson (2011). The main objective of their research was to create a large-scale study that examined the impact of the use of computer games in schools on pupils' mental computation skills and mathematics self-concept. In this study, they collected data from 634 primary pupils across 32 schools in Scotland. Pupils were randomly assigned at a school level to experimental or control conditions. In the experimental schools, pupils spent 20 min per day for 9 weeks on a mathematics brain training game. Control schools simply progressed with normal activities in mathematics classes.

The Miller and Robertson study found significant gains in both groups from the pre- to posttest periods of the research, but the gains of the experimental group were 50% greater than the control group in terms of accuracy and twice that of the control group in speed. In contrast to the previously cited longitudinal study, the authors of this research asserted that their findings can be generalized. However, even in this case of strong evidence, it is worth to mention that the findings would only apply to a restricted part of the curriculum that is investigated in this research. Furthermore, Stern (2015) argues one can draw conclusions from a causal inference based on an RCT that a specific intervention led to an increase in expected learning outcomes. However, when it becomes evident that the same intervention does not always lead to the same learning outcomes in all places, people start to ask "why?" Another important issue in emerging technologies research is that it is hard to recruit large numbers of participants that are needed to achieve the statistical power required to iron-out various differences between individuals. Regardless, RCTs are an essential part of impact evaluations due to their power to generate reliable causal evidence.

5. **Meta-level evidence:** The confidence in evidence studies increases through their meta-level analysis. For instance, Li and Ma (2010) reviewed studies on the impact of technology in general and on the mathematics learning in primary and secondary classrooms. From existing literature, the authors identified 46 studies encompassing 36,793 learners. Nearly all studies were well controlled, using a random assignment of students to either experimental or control conditions. In

their analyses of preexisting research, the authors found statistically significant positive effects of the use of technology on students' achievement in mathematics, as well as several other findings that numerous reviewed studies have in common. However, Bakker et al. (2015) note one of the challenges with this meta-analysis is that it only looks at "computer technology" in general, rather than a specific intervention, and thus is difficult to apply the results of such a metalevel evidence into specific emerging technologies. In addition, as also argued by the authors, "It is impossible for any meta-analysis to evaluate the design quality of the programs used in primary studies" (Li and Ma 2010, p. 235). Due to the challenges of identifying individual emerging technologies from review studies and the lack of details about the design quality of the technologies in primary studies, values of such metalevel investigations in practice are limited. These issues emphasize the value of a clear theory of change in impact evaluations (see section "[A Theory of Change for Emerging Technologies](#)").

It is also worth to make it clear that meta-level evidence does not have to come from quantitative studies (see for detailed discussion Noblit and Hare 1988). For instance, Tondeur et al. (2012) reviewed 19 qualitative studies that focused on strategies to prepare preservice teachers to integrate technology into their lessons. In their synthesis, they explain key themes explicitly related to the preparation of preservice teachers (e.g., using teacher educators as role models, learning technology by design, scaffolding authentic technology experiences), and conditions necessary at the institutional level (e.g., technology planning and leadership, co-operation within and between institutions, training staff). The meta-level evidence generated then used to create an overarching model that explains the relationship between these factors. More extensive meta-studies are also discussed in ► [Chap. 75, "Meta-analyses of Large Scale Datasets: A Tool for Assessing the Impact of Information and Communication Technology in Education"](#) in this volume.

It is increasingly clear then that different types of evidence in impact evaluations of emerging technologies have different advantages and disadvantages. Therefore, relying on one study or one type of evidence is unlikely to provide enough reliable evidence to judge the impact of an educational technology. Unfortunately, for most traditional experimental methods, once the generalization has been made, the assumption, particularly among practitioners, is that the result will occur regardless of the means of getting there, both in terms of the context and the process. This results in issues that even though well-established evidence regarding the impact of emerging technologies on various learning outcomes exists, it is hard to argue that the evidence would be strong under every contextual factor or even so, its strength would be the same (Cukurova et al. 2017). In addition, as argued by Kelly et al. (2008) emerging technology interventions should respond to new knowledge emerging from recent research studies. This is not common in more traditional educational research and might even be considered as unproductive. However, given the pace of change in emerging technologies, it is not always easy for researchers in the field to get satisfying support from the findings of the effectiveness of previous interventions investigated. As one potential solution to this, Ann Brown (1992) discusses strategies to transform

schools into communities of learning and interpretation where students are provided opportunities to take charge of their own learning and calls for new and complex methodologies to capture the systemic nature of learning, teaching, and assessment in their own contexts. Such approaches to empowering other stakeholders of educational technologies rather than relying only on researchers in impact evaluations might potentially be valuable for measuring emerging technologies' impact in primary and secondary education (see for instance <https://educate.london>). Similarly, more recently, Design-Based Implementation Research (DBIR) aims to organize research and development that addresses the challenge of creating effective, scalable, and sustainable policies and programs in education. The approach argues that continuous close connection between researchers, teachers, and their local education districts is fundamental for effective implementation of educational interventions (Coburn et al. 2012).

Multiple sources of evidence are needed in order to strengthen the argument that a particular technology intervention will be successful under a variety of conditions. Both quantitative and qualitative sources of evidence are valuable for the statistical power of their large sample sizes (correlational and causal evidence) and the explanatory power of more in-depth questioning (anecdotal and descriptive evidence). It would be premature if decisions were taken about whether or not to implement an intervention based on one type of evidence only. A more holistic approach is needed in order to reach a complete picture regarding the impact of emerging technologies in education. All evidence types may shed light on why an intervention of an emerging technology succeeded or not and in what circumstances. Rather than arguing about the overall superiority of one particular type of evidence or research approach over others, perhaps a more important questions to ask are what type of evidence is the most appropriate for a particular emerging technology innovation? and how can we design and implement interventions that might help us generate this type of evidence? Such questions are particularly important in domains with little prior research (Cobb et al. 2003) which is, by definition, is the case for emerging educational technologies.

Innovation Stages of Emerging Technologies

The spiral above was developed by Nesta (2016) to capture the different stages of the innovation process, and it can be used to identify different innovation stages of emerging technologies. As argued by Nesta (2016), different stages of innovation would require different types of evidence. For instance, initial stages of exploring opportunities and challenges, as well as generating ideas, it would be beneficial to focus on literature reviews and design principles, identifying what has worked or failed in the past in different contexts and using this evidence in the design decisions made for the emerging technologies. These design principles and lessons can help both developers and users of emerging educational technologies follow strategies that are more likely to have an impact. During the developing and testing stage, rapid cycle evaluations that would generate anecdotal and descriptive evidence would be beneficial, whereas at making the case stage it would be beneficial to

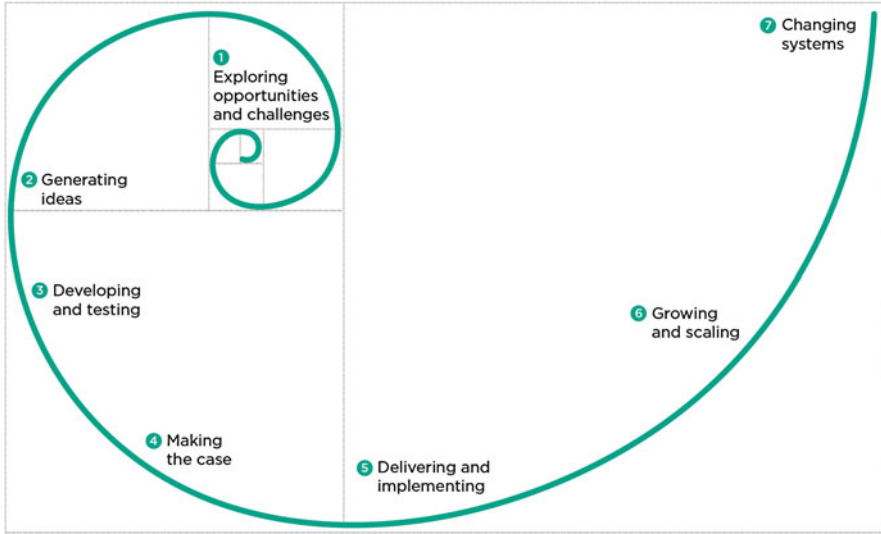

Fig. 2 Innovation cycle as presented in *Using Research Evidence: A Practical Guide* (2016)

undertake impact evaluations that would generate some correlational evidence. Once an emerging technology reaches certain level of maturation through these stages, during the delivery and implementation stage, it would require causal evidence that would show causal impact. On the other hand, growing, scaling, and spreading stage would require bigger scale experimental evaluations. System-level change can only be provided through multiple big scale evaluations from various contexts and clear implementation manuals that would ensure impact in multiple places. It is interesting to note here that by the time an emerging technology reaches to system changing level, or even the growing and scaling level, it would have reached a certain level of maturation so much so that its emerging nature would be questioned (Fig. 2).

The approach put forward by Nesta considers evidence in a holistic manner and recognizes the value of different types of evidence at different stages of emerging technology innovation. It contrasts with the more traditional approach of considering evidence types in a hierarchical manner, in which causal research evidence is considered as “gold standard” and other types of evidence are undervalued. We argue for the synergy of evidence types and research methodologies to generate different types of evidence during impact measures of emerging technologies. This position is based on the view that kite-marking a certain technology as “effective” based on “gold standard” causal evidence and encouraging its scaling might be a futile approach for emerging technologies. As mentioned in the introduction to this chapter, emerging technologies are constantly evolving and being implemented in different contexts with different populations. Therefore, the value of previous experimental evaluations for an emerging technology is limited. In addition to this, meaningful big scale positivist evaluations of emerging technologies are expensive

and they take a long time to be completed. There are various research methodologies that can produce *valuable indicators of the potential impact*, and they should be encouraged before encouraging researchers, emerging technology companies and users for such big scale evaluations.

Conclusions

Emerging technologies have a vitally important role to play in any change management in education. Emerging technologies can also disrupt and bring about unexpected change, the consequences of which must then be managed. Either way, the evaluation of these emerging technologies is a key part of the way in which their impacts are effectively integrated into learning and teaching settings to bring the best benefit to learners and teachers. Artificial Intelligence technologies for use in education are a good example of an emerging technology that will inevitably bring change. Educators, learners, parents, and policymakers alike, therefore, need reliable methodologies for evaluating the effectiveness of such emerging technologies.

Discussions about the impact of emerging educational technology should focus on the suitability of the proposed evaluation methods, and it should focus on the types of evidence rather than on the hierarchy of these methods and evidence types. Different impact evaluations have different purposes. It is therefore important to recognize that any research design and methods can only meet the requirements of a subset of the possible evaluation purposes. We, therefore, argue for an approach that focusses on the identification of the specific research questions that are appropriate for the educational issues that are relevant to the context of the intervention to be evaluated. Finding the right research method to generate the right type of evidence is of crucial importance. Impact evaluations of emerging technologies should be considered as a process, rather than as a one-off case if we are to progress to a more productive way forward in evidence-informed educational technology discussions.

In this chapter, we have introduced an approach that can be adopted as one potential process of measuring the impact of emerging technologies in education. Our approach has two main steps. First one is the creation of a clear theory of change to identify outcome measures and assumptions that are behind the expected impact of the emerging technology intervention. Second is the identification of the type of evidence and methods to generate it that are the most appropriate for the current innovation stage of the emerging technology. We argue that the more traditional approach of generating causal evidence through empirical research studies and argue for the “effectiveness” of an intervention in order to scale it might not be a productive approach for emerging technologies. Rather we suggest that during impact evaluations of emerging technologies all types of evidence both generated from intervention trials, case studies, and existing literature should be leveraged at different innovation stages of emerging technologies.

Abstract

In this chapter, we carry out a critical review of the various historical analyses of the impact of technological interventions in education. The purpose is to analytically explore and learn from some of the methodological limitations and strengths of the approaches adopted to measure and capture the impact of educational technology. This retrospective examination is then used to explicate methodological design principles that can increase the use and value of research evidence regarding the impact of educational technology. understanding the impact of digital technologies in and on learning is inherently problematic. It is exacerbated by the continually developing nature of digital technologies and their formal and informal boundary crossing. We posit methodological design principles that are sympathetic to the fact that evidence of the pedagogical application of digital technologies is both borne out of, and brought to bear in, complex and dynamic contexts that are mediated by, and impact upon, the various ways in which technologies are appropriated for educational purpose. The chapter concludes with a call for methodological perspectives that are not confined by paradigm, but are able to bridge and integrate research paradigms in order to respond to the complex sociocultural ecologies within which digital technologies are implicated.

Keywords

Educational technology · Impact · Methodological innovation · Design principles

Introduction

This chapter presents the case for a nuanced and qualitative understanding of the impact of digital technologies on learning; that is, an understanding that complements but also recognizes the limitations of the quantitative turn seen globally with the proliferation of large datasets or quantitative meta-analyses of education interventions.

The concepts of measurability and impact are inherently problematic in education. This is exacerbated when focusing on technology-supported learning, due to the continually developing nature of digital technologies and their crossing of boundaries between formal and informal contexts (Voogt and Knezek 2008; Cox 2013; ► Chap. 74, “[Researching Information Technology in Education: Meeting the Challenges of an Ever-Changing Environment](#)”). It is necessary to frame any discussion of impact and its measurability, in a way that enables us to learn from critical debate surrounding methods and what they do or do not afford. Otherwise, we simply run the risk of being confined by methodological paradigms and learn little of any consequence. Conceptualizing impact merely as a post hoc concept or measure of “what works” is problematic. Impact in the field of education, we contest, is not an abstract or singular entity that can be isolated from context and adequately measured post hoc; rather impact is borne out of constituent action(s) carried out by sentient agents with and without technologies in a sociocultural ecology of factors, giving rise to pedagogical and methodological tensions and opportunities (Turvey and Pachler 2016). Even in the realm of physical matter and materials, designers and engineers work with tolerances because of the range of variable factors at play in any context. There is merit in looking back historically at methods for measuring impact in technology supported learning with a concern for how we design contingencies for future desirable impact, in new and emerging contexts.

With these concerns in mind, we structure the first half of this chapter around a retrospective critical examination of some of the various historical analyses of the impact of technological interventions in education. Our concern is to look back in

order to move forward in terms of what we can learn from the methodological approaches adopted, their limitations, and their innovations. We acknowledge that we are unable to offer a fully comprehensive review of the literature but a pragmatic and valid starting point. In the second half of the chapter, we identify four methodological design principles based on key lessons from the evidence of impact and methodological approaches taken. Our concern here is to examine emergent research paradigms in the field of technology-supported learning and what methodological design principles can be identified to improve the reliability and validity of the data and evidence for sustainable innovation in the field of educational technology. Again, we acknowledge that this will fall short of a comprehensive review, but we believe a genealogical approach focusing on some of the methodological innovations, enables this chapter to make a valid contribution to the debate, and knowledge surrounding the issues of measurability and impact where digital technologies are used to mediate learning.

Looking Back

Defining Terms and Parameters

At the outset of this diachronic review, it seems necessary to touch briefly on definitional matters. In the literature, many terms are used, often interchangeably, to discuss technology use in educational contexts such as, among others, IT, ICT, new technologies, digital technologies, and educational technology. To underscore our interest in learning, we use the term “educational technology” here and its definition by the Association for Educational Communications and Technology (AECT):

“Educational technology is the study and ethical practice of facilitating learning and improving performance by creating, using, and managing appropriate technological processes and resources.” (Januszewski and Molena 2008, p. 1)

Another important precursor to evaluating the impact of educational technology and the quality and findings of related research is to clarify the purposes of underlying work in the field. Pachler (2009, p. 2) argues that a discussion about the appropriateness of research methods needs to take into account the specific aims, objectives, and questions posed by individual researchers and research projects. He references Kjeldskov and Graham (2003) who delineate the following research purposes for the field of human-computer interaction: understanding, engineering, reengineering, evaluating and describing. Judgments, therefore, about specific pieces of educational technology research arguably need to be made in terms of the appropriacy of the chosen methods relative to the underlying epistemological and ontological framing, the intended aims, and objectives as well as research questions. This is in line with advice given in a recent paper by Twining et al. (2017) who set out to address the problem of the imbalance in the number of quantitative and qualitative papers

published by highly ranked journals. They deduce a set of guidelines for the design, implementation, and reporting of qualitative research. Their paper includes the recommendation to be clear about the theoretical stance underpinning the research, and to ensure it aligns across methodology, design, methods, instruments, data, and analysis.

In contextual terms, it is important to bear in mind when examining the available research that a key policy driver behind the integration of technology over recent decades has been the perceived need to compete at a system level internationally in the wake of the increasing importance of global comparisons such as PISA. As a result, research in the field is often judged in terms of its ability to inform policy decisions.

The focus on efficacy, i.e., impact, in turn, is very much a result of the growing importance of accountability and financial exigency in education. It also reflects the significance of spending normally associated with and required for technology-supported educational interventions at an organizational (class, school) or system (local authority/district, state/national) level. And, in the wider policy arena, recent decades have seen an increasing emphasis on evidence-informed decision making which, in turn, can arguably be seen to have led to persistent educational reform programs. These have often included technology-supported interventions and innovations.

Identifying the Gaps

The use and efficacy of educational technology research has been a topic of considerable interest to researchers for some decades and, consequently, a large number of studies have been published in the field. As Cox and Marshall (2007, p. 59) note, despite the efforts of generations of researchers from a range of perspectives, several questions about the long- and short-term impact of technology on students' learning remain and unambiguous answers are elusive. An important omission from existing studies can be seen to be "major policy analyses that encompass a wide range of settings and look for commonalities and differences as a result of systemic conditions" (ibid, p. 60).

Particularly important findings from education technology research arguably are that very specific uses of ICT have the most impact on attainment (Cox and Abbott 2004) and that teachers' knowledge about their subject and of pupils' understanding of the subject influence the effect of educational technology on attainment (Cox et al. 2004); this has clear implications for generalizability of research findings:

"The effect on attainment is greatest when pupils are challenged to think and to question their own understanding, either through pupils using topic-focused software on their own or in pairs, or through a whole-class presentation." (p. 3).

Thus, it is of particular concern that many research papers in the field appear to lack a clear description of how teachers and/or students are using technology as well as valid and reliable measures of their use of technology for teaching and learning. As Bebell et al. (2007) point out, measuring the use of technology by teachers has

become increasingly difficult in view of the growing complexity and dispersal of technology (p. 4) and much research limits itself to focusing on technology access as a proxy (p. 3).

Bebell et al. (2007) report a widely held view among researchers and others that much of educational technology research is methodologically weak. Weaknesses, according to them (p. 2), include limitations in the way technology use is measured with poor alignment between prior achievement and control groups, and paper-based assessment with insufficient sensitivity to detect changes in learning. These weaknesses are also compounded by a failure to account for hierarchical structures of schools that “mediate the relationship between technology use and achievement” (p. 13).

Reeves and Oh (2016) provide a more recent overview of goals and methods of educational technology research. They categorize the goals of educational technology research as follows: theory development/synthesis, exploratory/hypothesis testing, descriptive/interpretivist, critical/postmodern, design/development, and action/evaluation (p. 2).

In their review of available research, Cox and Marshall (2007) draw attention to considerable difficulties with assessment and evaluation tools owing to their rootedness in particular educational paradigms, ones that “usually fail to examine the cognitive processes which students employ to reach their goals” (p. 61) with instruments and evaluation processes which often have only a poor match with the inherent goals of the technology-supported interventions they are used to measure. They go on to identify the following five problems with educational technology research (pp. 62–68) which, they argue, need to be addressed in order to provide robust and reliable research results:

- A failure to understand how learners think
- A problem with identifying actual types of educational technology use contributing to learning gains
- A lack of knowledge about the kinds of curriculum implementation and classroom settings that are most influential
- The variability in teachers’ knowledge and pedagogical use of educational technology
- A lack of match of learning objectives and the learning outcomes being measured

Jenkins (2009, p. 274) posits that educational technology research often fails to provide significant insights into how students interact with the learning tools and how new knowledge has developed through the use of technology. She highlights the gap between knowledge and understanding as being significant, for knowledge is “more readily captured with traditional methods of evaluation” whereas, “understanding, given its emergent nature, is more elusive” (p. 276).

Among other areas, Kirkwood and Price (2014) identify difficulties in attributing causality and the types of evidence gathered. They note, and rightly in our view, that whilst quantitative measures of student interaction might be comparatively easy to collect, they do not necessarily contribute a lot to our understanding of how

participation in collaborative processes can promote qualitative developments in learning (p. 24). Kirkwood and Price also make the point that technology-based interventions often necessitate, or are accompanied by substantial curricular changes and that it is often not clear what led to improvements and/or gains made.

Latchem (2014, p. 9) draws his readers' attention to the fact that educational technology research tends to be carried out by individuals or small groups working in isolation and that work in the field would benefit from multisite, multiperspective, cyclical collaboration into a larger number of similar interventions at different stages of development across different sectors. He recommends the development of indicators that are designed to capture the immediate, short- to medium-term, and longer-term positive improvements in the learning and lives of those involved (p. 9).

In their review of educational technology research, Ross et al. (2010, p. 18) conclude that because of the significant diversity of approaches to educational technology research, it is very difficult to offer "even a characterization of the field today" and they note the importance of a wide range of research approaches including:

- Highly controlled basic research studies of cognitive processes relating to the interaction with computers
- Descriptive and evaluative studies of how learners use educational technologies as tools
- Context-specific design-based studies focusing on how particular technologies operate in particular environments
- Applied research focusing on solving specific problems

Aggregation, Opportunities, and Limitations

In order to critically evaluate a large body of research evidence, meta-analyses and systematic reviews have become popular in educational, social science, and medical research. This also applies to the field of educational technology. While different methodological approaches to such reviews exist, they tend to share the purpose of combining the results of comparable studies and improve the power of small or inconclusive studies. According to Pérez-Sanagustín et al. (2017), meta-analyses can bring together insights from a wide range of settings and help "identify gaps in current research and formulate a research agenda that poses new ideas and directions for future investigation in the field" (p. A2). They cannot, however, improve the limitations of original studies such as a lack of quality of original reporting.

Examples of recent meta-analyses and literature reviews in the field of educational technology research include:

- Higgins et al. (2012), who conclude that "taken together, the correlational and experimental evidence does not offer a convincing case for the general impact of digital technology on learning outcomes" (p. 3);

- ICF Consulting (2015), who come to the view that there is conclusive evidence that educational technology can support attainment in general and in math and science in particular; that there is indicative evidence that it can support attainment in literacy and that it can close the attainment gap between groups; and that there is promising evidence that educational technology can provide assistance to overcome challenges faced by some learners, employability skills, and knowledge of career pathways, improved communications with parents and time efficiencies for teachers (pp. 3–4);
- Kirkwood and Price (2014), who identify several desired enhancements to learning and teaching in higher education through technology: operational improvement (increase in flexibility and accessibility), quantitative change in learning (increased engagement and attainment), and qualitative change in learning (promotion of reflection, deeper engagement, and richer understanding) (p. 14);
- Livingstone (2012), who offers up three forms of critique of the claims made in support of educational technology: an “analytic critique,” which requires a skeptical analysis of claims made as a result of which she concludes that the “jury is still out” on whether educational technology supports learning; an “explanatory critique” which asks about competing theories and alternative explanations; and an “ideology critique” exploring technology in relation to the societal configurations in which they exist (pp. 20–21).

A recent report published by the OECD in 2015 provides an international comparative analysis of digital skills acquired by students. It concludes that there is a lag between the promise and reality of technology in schools and that “their impact on student performance is mixed at best” (p. 3). This by-and-large reflects the findings of an earlier review by Luckin et al. (2012) who found that often the impact identified is relatively modest in scale and that the focus tends to be on how educational technology supports existing practices rather than on transforming them (p. 9). While Luckin et al. conclude that “much existing teaching practice may well not benefit greatly from new technologies” (p. 64), they also claim to have found proof that educational technology can work, i.e., that different technologies can improve learning by augmenting and connecting proven learning activities, by putting learning first (p. 63).

The key gaps in the literature identified by Pérez-Sanagustín et al. (2017, p. A12) are:

- A preponderance of quantitative research
- A lack of research from different parts of the world
- A gap with regards research from the humanities, natural, and “formal” sciences
- A lack of preschool studies
- Studies which lack a focus on teachers’ pedagogical actions with limited value
- Only few studies involving participants in their design
- A need to increase sample sizes in research with objectivist approaches
- A lack of private sector funded studies

The field has also seen the publication of a second-order meta-analysis by Tamim et al. (2011), which provides an overview of 37 of 60 or so meta-analyses published since 1980 capturing some 1050 primary studies out of a total of 1250 or so primary studies covered by meta-analyses with nearly 110,000 participants. It helpfully sets out the codebook developed for the study covering inter alia information about the identification of studies, contextual, methodological, and analysis features. This data is important to ensure transparency and comparability.

Theoretical Positioning

In addition to exploring the efficacy of research methodology, an important antecedent of determining the impact of educational technology is how learning is defined and what the purpose of education is. Depending on one's conceptualization of learning, different uses and affordances of technology will come to the fore which are susceptible to different types of measurements and instruments. A focus on basic skills and the recall of content, for example, can normally be measured fairly efficiently through standardized tests to determine attainment gains linked to educational technology. If, however, learning is viewed more in line with Kalantzis and Cope (2004, p. 46), as conditions of belonging and transformation, i.e., engaging the learner's identity and taking them on a "journey into the unfamiliar," or with Kirschner (2006, p. 11) as interaction-based and dialogic, standardized tests become problematical as measures of attainment gain linked to technology use.

In her critical reflections on the literature, Livingstone (2012), for example, references the work of Turkle (1995, p. 35) who characterizes the modernist to postmodernist transformations brought about by the emergence of the internet, which she characterizes as a shift "from a culture of calculation" to a "culture of simulation based on tinkering and experimentation," much less concerned with hierarchical structures or rules (p. Livingstone 2012, p. 17). In such a paradigm, different ways of measuring learning gain are required.

One strand of educational technology research has focused on barriers to and enablers of the integration of technology into formal education. In their overview of related research, Hew and Brush (2007, p. 241) identify the relationship and interaction between what Ertmer et al. (1999) have called first-order (lack of resources, institution, subject culture, assessment) and second-order (attitudes and beliefs, knowledge, and skills) barriers.

Shortcomings in teacher preparation and development, and teachers' pedagogic beliefs and knowledge, are issues identified by several studies as an important barrier in effective technology uptake, as are integration strategies.

Scardamalia (2006) outlines three areas where technology can be seen to have the potential to contribute to depth of understanding: computer-assisted instruction; simulations, games, and laboratory instruments; and discourse.

With the emergence of mobile technologies, learning environments characterized by one-to-one computing and bring-your-own-device (BOYD) have increasingly become the focus of research. Alas, often the same limitations apply to these

emerging research fields that we diagnosed for traditional educational technology research: they tend to be undertheorized, i.e., do not tend to build on explicit or sufficiently robust conceptualizations of key concepts such as clear definitions of learning and learning gain; are small-scale, short-term, one-off and “piecemeal” rather than large-scale, longitudinal, and cumulative; are qualitative rather than mixed mode or quantitative; are descriptive or exploratory rather than correlational, quasi-experimental, or randomized mixed-mode; are over-reliant on self-reported perceptual data; and are often characterized by weak documentation of research methodology (see e.g., Hew and Brush 2007, p. 246).

Ross et al. (2010, p. 24) stress the importance of educational technology research achieving a balance between rigor, what they call “internal validity,” and relevance, what they call “external validity” in order to be able to help tackle “real-world” educational problems. Internal validity, they argue, enables the drawing of valid conclusions about the causal effects of one variable on another and external validity enables the generalization of results to conditions of interest. They further suggest that randomized controlled trials can maximize internal validity but can be liable to low external validity (p. 25).

A number of studies appear to point toward the dependency of efficacy of educational technology on its integration in teaching programs. In order to understand the most effective way of designing new teaching programs utilizing educational technology, Bai et al. (2016), for example, carried out a clustered randomized controlled trial. According to Sibbald and Roland (1998), randomized controlled trials are the most rigorous way of establishing cause and effect between an intervention and its outcome as well as its cost effectiveness. One key advantage can be the reduction in selection bias by random allocation to treatment or control group of participants once subjects have been checked against eligibility criteria for participation.

Crook et al. (2010, pp. 7–8) identify two broad forms of impact research: relatively short-term studies focusing on particular educational technology supported practices in a rather unsystematic way which they call “contained interventions”; and “system-wide” interventions, which focus on large-scale adoption of educational technology. Both, they argue, are characterized by methodological and interpretative challenges and can lead to unjustified skepticism about the value of investment in educational technology. Given the complexity of sites of teaching and learning, Crook et al. argue for a broadening of the definition of impact and related research that yields a better understanding of learning practice and outcomes. To achieve this, they call for “research that documents the reported experience of integrating technology into ongoing practices of teaching and learning, as they are pursued at the classroom level” but also within the broader ecology of educational practice as even “piecemeal approaches disturb the larger ecology of teaching, not just the ecology of individual lessons” (p. 8).

The impact of educational technology is predicated on increasingly sophisticated technology being integrated into complex education systems and ecologies as well as the perpetual obsolescence of technologies making replication studies difficult. The growth in personal ownership of devices adds further complexity and leads to a

diffusion of the technological infrastructure involved in many research projects. In turn, this impacts on the locus of control with an increase in user agency and use in informal contexts governed by different social and cultural practices than that of formal education settings and a decrease in influence on the research context by the researcher (see e.g., Pachler 2009, p. 3; Pachler et al. 2010). Therefore, research and evaluation models are required that reflect this complexity. This can involve the recasting of the role of learners into coresearchers. Technology can be seen to “disappear” more and more by virtue of its integration and by being embedded further and less visibly into our physical and social world (Bruce and Hogan 1998). Consequently, what is needed, we argue, are approaches to educational technology research that capture the complexity of technology-based interventions at a micro (classroom, program), meso (institutional), and macro (system) level from multiple perspectives rather than a dogmatic application of particular research designs. Jenkinson (2009), for example, argues the case for design-based research to capture the “messy” elements of technology interacting with the educational endeavor, because of the collaboration between researchers and practitioners it affords.

Recognizing the increasing complexity of technology use in educational contexts, in part as a result of technological transformations and the increasing affordances of educational technologies, VasabØ and Gudmundsdottir (2014, p. 2) problematize how best to research networked learning within multifaceted technology environments. They ask what research designs to use, how to interact with the key stakeholders, how to capture and understand interaction between contexts and across different dimensions, and how meaning is made in and across physical places and virtual spaces. Their questions, coupled with Crook et al.’s (2010) analysis and the shortcomings we have identified above, point toward the need for a paradigm shift in educational technology research to which we turn now.

Moving Forward

To identify the character of such a paradigm shift, we consider four research design principles that could help shape this shift and increase the efficacy of research attempting to measure the impact of educational technology. The principles we outline here are by no means extensive but we believe what is most important is that they are rooted firmly in the methodological lessons emerging from past educational technology research and motivated by the need for a progressive framing of sustainability in educational technology research. As Bachmair and Pachler (2015, p. 1) argue, there is a need for both pedagogical and methodological practices associated with educational technology to establish the “ability to maintain innovation over time and to become embedded into mainstream practice.” This can only come from methods that offer the potential for increased understanding of the appropriation of digital technologies in the lives of both students and teachers across formal and informal boundaries. We also enter the caveat that although these design principles are numbered and discussed linearly in what follows, they are interrelated as our discussion of such will reveal. The following methodological design

principles could, we believe, act as a catalyst for sustainable methodological innovation that progresses the field of educational technology research. We express these principles thus:

1. Methodological and pedagogical interoperability should be prioritized, which means a call for far-sighted innovation that resists becoming confined by methodological or pedagogical paradigms.
2. The quantitative should be qualified, as far as possible.
3. Post hoc analysis should be accompanied by concurrent description and analysis.
4. Impact needs to be both defined broadly and also theorized rigorously, to understand and document the complex social cultural ecology into which educational technology is integrated.

We briefly outline these principles in more detail below.

Interoperability

We define interoperability as the ability of one methodological or pedagogical design or system to make use of another through, for example, the exchange of data or methods and can be seen to be inherent in meta-analyses which aggregate and synthesize data across various studies. But how might this be achieved across qualitative studies or between quantitative and qualitative research? Without such interoperability, it is impossible to envisage how educational technology innovation could be built upon and sustained. This is not to reject either positivist or interpretivist paradigms but to concur with others who call for methodological innovation in educational technology research (Jenkinson 2009; Crook and Garratt 2011; Cox 2013; Latchem 2014; Kirschner and Kester 2016). Indeed, Crook and Garratt (2011, p. 215) argue that critical reflection about methods, the ethical engagement with participants, and the significance of context can all be seen to emerge from the legacy of positivism, as can the conception of context as a “social ecology rather than a structure of causal relations that is more rigidly mechanical.” Such concerns and problems of methodological design are not confined by paradigm so why should the data or analysis that is generated be confined and how do we render such data and analysis open to reuse? There are, of course, no simple answers to such questions, but it is important to imagine and begin to design methodologies that are genuinely more complementary in the way they bridge established research paradigms to promote efficacy. As Kirschner and Kester argue (2016, p. 538), methodology should be free of “dogmas that split the world into quantitative, empirical positivists versus qualitative anecdotal ethnographers.”

In imagining more complementary and sustaining research methodologies whose methods, outputs, and outcomes lend themselves to greater levels of interoperability, our second design principle is invoked. There is a need for increased qualitative detail in datasets. Our retrospective review above found that methodological innovation is a necessary factor in being able to measure with increasing validity, reliability and

granularity, the impact that technology can have on learner outcomes. It also highlights that increased granularity in measuring impact often comes from a richer understanding of the qualitative conditions of the context. Such a view, we contest, necessitates the development of methodologies with greater granularity across the increasingly leaky formal and informal boundaries that educational technologies encompass.

Qualifying the Quantitative

There is an urgent need to qualify the quantitative if we are to design research methodologies that genuinely deepen our understanding of the complexities of learning with and through digital technologies. By “qualify” we mean to offer rich or sufficient qualitative contextual detail. Meta-analyses (see also ► [Chap. 75](#), “[Meta-analyses of Large Scale Datasets: A Tool for Assessing the Impact of Information and Communication Technology in Education](#)” by Liao and Lai) of the impact of various educational interventions, including those incorporating educational technologies, have gained favor with policy makers in recent years. They conveniently lend themselves to the relatively simple reporting of impact in the popular media and are also compatible with the global econometrics used to measure and make crude comparisons of the performance of international education systems. But what do they measure? (UNESCO 2014; OECD 2015). The key issues with meta-analyses and the experimental studies they synthesize, we argue, is a tendency to view their results and findings at face value and a failure, tendentially, in the experimental research studies they synthesize to adequately qualify the quantitative effect sizes they produce. Higgins et al.’s meta-analysis of educational technology interventions (Higgins et al. 2012) found that the introduction of digital technologies on average can offer “moderate learning gains” of approximately 4 months progress. Hattie (2009), using comparable methods estimates a similar potential effect size on average. But, the actual effect sizes of the different studies that Higgins et al. (2012) synthesized in their meta-analysis, vary significantly. Useful though these are, the only firm conclusion to be drawn is that digital technology can have positive, negative, or indeed little to no impact on attainment and learning. Similarly, Haßler et al.’s (2015) meta-analysis focusing on the use of tablet devices in schools highlights the significant problem of redundant findings or data when there is a failure to qualify the quantitative. Out of 23 studies, Haßler et al. (2015) found 16 reported positive learning outcomes, five no difference, and two negative learning outcomes. The authors make the important point that much of the research included in their review did not go beyond face value, stating that “a large proportion of identified research offers limited or no details of the activities that learners engaged in,” making it difficult to identify important contextual detail necessary in recognizing more or less effective use of the technology (Haßler et al. 2015, p. 151).

While there is increased availability and access to large quantitative data sets, singular or paradigmatically-confined approaches leave significant questions unanswered such as: how have people learned or not learned with the technology? And: are there significant characteristics of pedagogical design shared by those

interventions where educational technology has had a negative, positive, or no effect on learning? Similarly, how has the formal and wider informal context influenced this? One strand of the ImpaCT2 study (Somekh et al. 2002) complemented the quantitative analysis of the impact of educational technology through a rich picture of contextual detail using visual methods to capture important qualitative information pertaining to pupils' use of ICT in the home and broader community. This illustrates how questions of context and pedagogical design can only be addressed by invoking our third design principle that post hoc analysis should be accompanied by methods that also facilitate concurrent description and analysis.

Post Hoc and Concurrent Analysis

By concurrent analysis, we mean the analysis of data are as close as possible to the source of any educational technology-based intervention. Concurrent data affords greater insight and lends itself to reuse and further methodological innovation or analysis. Jenkinson (2009, p. 277) argues strongly that to answer questions about the numerous contextual and agent-centred variables influencing the impact of educational technology, there is a need for “quantitative and qualitative data sets that tightly integrate concurrent and retrospective” data-capture and analysis. The recent systematic review we referred to in the first half of this chapter (Pérez-Sanagustín et al. 2017, p. 12) claims studies that ignore what teachers do “are unlikely to be of much value.” We fully concur with this view but would extend this to include as full a range of contextual and agent-centred variables as possible such as, inter alia: dispositions toward educational technologies and learning, prior experience with the technology both formal and informal, how learners experience or perceive educational technology, and the subject in which it is being used. The more contextual and concurrent data (quantitative or qualitative) available, the more we can learn about the use of educational technology. This is particularly evident when comparing studies with greater and less scope.

For example, an area where limited methodological approaches are sometimes seen, is in some of the research into the use of mobile phones in schools. Beland and Murphy's (2015) research on mobile phone use in schools simply analyzed, post hoc, the correlation between schools who banned or allowed the use of mobile phones (gathered via a headteacher survey) and data from the National Pupil Database (UK) on examination performance. The only thing of potential significance from this is that impact appeared to vary according to the students' different and current levels of attainment. That is, the use of mobile phones in school appeared to have no positive or negative impact on higher attaining children but was negatively correlated with lower attaining children. The concurrent variable in this limited study allowed some small yet potentially significant insight to emerge with regards different student characteristics as a moderating variable. But the research tells us very little beyond this about the use of mobile devices as educational technology.

Contrast this with another recent meta-analysis (Chauhan 2017), which attempted to offer greater insight into the various correlations between the impact on learning outcomes and educational technology by differentiating a greater range of concurrent

moderating variables. Chauhan synthesized a number of international experimental studies ($N = 122$) via moderating variables such as subject domain, type of digital application, duration of the intervention, and learning environments. Identifying such concurrent moderating variables can support increased contextual granularity. For example, differentiating by subject domain, highlighted greater effect sizes reported for digital technology supported interventions in Science, suggesting subject cultures can also influence the impact of educational technology, although it should also be noted that there is a dearth of experimental research in the use of educational technology in subjects such as music and art. This still does not offer insights into the actual pedagogical designs and contexts in which Science teachers incorporated digital technologies across these studies. While the use of concurrent moderating variables offers the potential for greater granularity, it also raises questions regarding potentially significant concurrent variables not captured, such as teacher knowledge and pedagogical design, learner dispositions, and socioeconomic characteristics or wider contextual influences. It would seem prudent for future studies to develop an agreed standard in terms of what concurrent moderating variables (quantitative and qualitative) should be included as a minimum expectation in educational technology research. Such agreement could lead to the increased power of both statistical and qualitative meta-analyses as a more “robust and reliable taxonomy of the relationship between different ICT resources, teachers’ pedagogies, and students’ learning” (Cox and Marshall 2007, p. 68). But there is also a risk here that we make assumptions, which is why we invoke our fourth design principle that impact needs to be both defined broadly and also theorized rigorously, to understand and document the complex social cultural ecology into which educational technology is integrated.

Broadly Defined but Rigorously Theorized

The principle of embracing a broadly defined yet rigorously theorized conception of impact may seem paradoxical but, we argue, it is prudent to assume that as well as not knowing what we should know after decades of research (Cox and Marshall 2007), the constantly changing nature of educational technology means we also cannot assume we know what we do not know. Those at the forefront of appropriating educational technology formally into practice have valuable insights to contribute in this respect and participatory methodologies such as narrative approaches (Pachler and Daly 2009; Turvey 2012) and learning design (Laurillard 2012; Persico and Pozzi 2015; see also ► Chap. 38, “Teaching as a Design Science: Teachers Building, Testing, and Sharing Pedagogic Ideas” by Laurillard) are significant. As various studies have shown, the teacher is the most significant variable in the appropriation of educational technology (Harrison et al. 2002; Cox et al. 2004; Somekh 2007). From this perspective, design-based research methods such as those encompassed by the field of learning design are an important area of methodological innovation that can facilitate a bottom-up approach to measuring impact that, if rigorously theorized, can enable a greater understanding of the sociocultural ecology of educational technology. As Laurillard asserts (Laurillard 2012, p. 226),

the pace of change and the potential impact of digital technologies more broadly not only enable the treatment of teaching “as a design science, they also require it.”

Persico and Pozzi (2015, p. 244) claim that learning design “addresses the decision-making process of individual teachers.” Furthermore, innovations in learning design have attempted to synthesize the gap between quantitative and qualitative data by drawing on the ease of availability of online data (e.g., learning analytics) when learners engage in online platforms. The ease and speed with which such data can be available, combined with the computational processing power that can be used to provide teachers with data representations to inform their pedagogical designs, to some extent addresses our concern expressed in the third design principle regarding the bridging of post hoc and concurrent data analysis. Similarly, Mor et al. (2015, p. 221) encapsulate these design principles further in their defining of the focus of learning design which they claim is concerned primarily with “understanding how the intuitive processes undertaken by teachers and trainers can be made visible, shared, exposed to scrutiny” and improved further. That is, there is a concern with the micro and meso-level detail (qualitative and quantitative) influencing teachers’ actions and motivations involving educational technology, as well as improving the visibility, and therefore the reusability and interoperability of pedagogical processes.

However, promising as such approaches are, Persico and Pozzi’s (2015) note there is still the potential for misunderstanding with regards the use of educational technologies and pedagogical approaches. As they state, learning design research must guard against “producing a plethora of different representations, approaches and tools that are not interoperable” (Persico and Pozzi 2015, p. 245). While there is a need to broadly define impact, there is also a need for progressive focusing from the subjective toward a more objective shared understanding of the different kinds of impact that may emerge and how those more desirable impacts may be reseeded through appropriate and reusable pedagogical designs. This, we argue, can only come through understanding and articulating the various subjectivities involved as practitioners appropriate educational technology, a process that is facilitated significantly through dialogue and narrative. Narrative analysis, in particular, can support an inductive and iterative process that enables participants “to achieve a certain degree of consensual interpretation” (Pachler et al. 2009, p. 81).

The fields of learning design and narrative methodologies lend themselves to the rigorous scrutiny and theorizing of the impact of pedagogical practice with educational technology in ways that other methodological approaches often omit. In their paper on sustainability and innovation in mobile learning, Bachmair and Pachler (2015, p. 5) state that there is a need for “relevant knowledge about the practices of mobile learning” and that “we cannot succeed without objectified tools and operational implementation procedures.” Such knowledge and procedures cannot emerge from research designs that ignore or omit the need for carefully scrutinized and theorized pedagogical intervention and as Bachmair and Pachler (2015) go on to establish, hermeneutical research approaches that foreground intentional pedagogical intervention and professional dialogue have a significant role to play in addressing this issue.

It is beyond the scope of this chapter to give an in-depth review of learning design and narrative research methodologies other than to highlight the potential for innovation they offer. But this brief discussion also illustrates that the four design principles we have outlined are common concerns across various research paradigms. The challenge moving forward is how to shift out of the relative comfort zones that have been established in educational technology research in order to establish a more innovative and sustainable approach to impact and measurability in educational technology research.

Conclusion

The Programme for International Student Assessment (PISA) remains a globally influential dataset that lends itself predominantly to quantitative post hoc research analysis. Pérez-Sanagustín et al. (2017, p. 12) call for a need to “redress the balance between quantitative and qualitative research” as their systematic review of educational technology found only 55 out of 352 studies drew on qualitative methods over a period of 4 years. This rebalancing is an important step but we also ask: would such a rebalancing necessarily draw us out of our respective paradigmatic comfort zones, to achieve further sustainable methodological and pedagogical innovation? We argue that, together with redressing this balance, there is a need for further integration of paradigms and of quantitative and qualitative research designs. The latest cross-country analysis (OECD 2015) of the purported impact of digital technologies on students’ learning outcomes highlights further this need to qualify the quantitative through greater integration and innovation. It illustrates how face-value approaches to measuring impact that employ only post hoc instruments to find correlations or associations between technology take-up and school performance indicators simply raise more questions than they answer, without more detailed levels of granularity that complementary and concurrent qualitative data could afford. We concur with Alexander (2015) who questions this tendency to equate such measurable yet narrow proxies as attainment in education as the ultimate and only indicators of quality. Quantitative studies themselves illustrate that student characteristics and dispositions toward digital technologies, as well as teachers’ pedagogical decisions and motivations about digital technologies could well be the basis for the significant variability in their findings. But, such qualitative factors are not adequately captured or accounted for in many of the research approaches. Intervention, context, and impact **is**, we argue, too often conceived as a simplistic mechanical causal structure rather than a sociocultural ecology. Contemporary design-based approaches to research in this field are attempting to address the problem of measurability and impact of educational technology. Drawing out principles of design, based on a genuine attempt to learn the lessons of past educational technology research is, we believe, a useful and sustainable way forward for further innovation in research methodology.

Abstract

As an introduction to the section on “International Policies on ICT in Primary and Secondary Schools” an overview over the aims and content of the section is provided.

Keywords

ICT policies · Primary and secondary schools · International perspective · Section overview ICT policy section

The digitalization of practically all spheres of life has entailed significant developments on a global scale. In view of their responsibility to prepare students for what is commonly referred to as the digital age, educational systems have taken on a key role in imparting digital competencies and in using ICT for learning on future generations (Edwards 2012). In this respect, research revolves around the potential of technological developments to change or improve learning processes and support students' competencies to ensure the students' participation in a digitalized society. While the former aspect refers to the technological potential as well as to the meaningful integration of digital media into scenarios of teaching and learning, the latter addresses overarching concepts such as equity and successful participation. All

these issues are relevant for research as well as for policies towards ICT integration into schools, curricula, and school systems (Vanderlinde et al. 2012). While there is a broad range of knowledge on schools and on which factors contribute to adapting schools to the affordances of changes in the digital society, comparably little is known about the developments of educational systems and how it is affected by policies (Ball et al. 2012). Closing this research gap, the following section on “*International Policies on IT in Primary and Secondary Schools*” elaborates on this. The section pursues the section “*International and Regional Programs and Policies*” by Jef Moonen (2008) which is to be found in the first edition of the international handbook. Again, now in the scope of the second edition of the handbook, the following section brings together recent developments regarding ICT policies and how they affect teaching and learning with technology in schools from all parts of the world. The section consists of seven chapters. It describes and analyses the current state of research as well as developments concerning ICT policies in primary and secondary schools. By doing so, all chapters of the section refer to a set of core questions aiming to get an up-to-date impression of recent developments and results. Consequently, each chapter answers the following set of questions from the perspective of one of the seven regions in the world: How does policy deal with integrating ICT in teaching and learning in primary and secondary education and which trends as well as developments can be identified most recently? Which overall policy plans, strategies, and papers exist and what is characteristic of and common in policy documents of international organizations about IT and education? How useful and effective are these and in which range can one identify indications that certain policy measures are more successful than others? Which aspects can facilitate success and sustainability? All chapters close with an outlook on future developments and challenges.

The regions that are covered in the book are: Australia and New Zealand, Asia, Europe, Latin America and the Caribbean, North America, North Africa and the Middle East, and Sub-Saharan Africa.

In view of the multiplicity of educational systems around the world, it is not surprising that educational policies, in this case with regards to ICT, globally show a great degree of variation. This section therefore aims to provide an overview of features and characteristics the experts in the respective regions have figured out. The efforts made in the section were only possible through the work and contributions of the authors of the individual chapters which put together recent developments of ICT policies in their regions and present them in a systematic and most informative way.

One overall result of the section on ICT policies around the world is that cross-national as well as world-wide strategies and plans for different regions of the world influence national or regional strategies on integrating ICT into schools in different ways. In addition to the manifold national policies and initiatives, cross-national and world-wide strategies for the implementation and promotion of ICT and ICT-related skills equally have an effect on the perspectives on how and ways in which digital media are integrated into educational curricula.

Abstract

The use of ICT in primary and secondary education has gone through a number of different phases over the last decades. Alongside rapid technological developments and changes in pedagogical paradigms, ICT policies have proven to be one of the main driving forces behind the implementation of ICT in education settings. The following chapter examines the relevance of such policies, plans, and frameworks from an international perspective, focusing thereby on the primary and secondary school sectors. In doing so, it provides valuable insights into international ICT policies. Aiming to provide a holistic view, it presents analyses of cross-national international policies as well as cross-national policies

in different parts of the world. Given the multiplicity of education systems around the world, education policies regarding ICT vary considerably. Nonetheless, the analysis of cross-national studies uncovers a number of common core topics, directions, challenges, and potential future directions for ICT policies in primary and secondary schools. This compilation and examination of findings from international studies and their implications for ICT policies in turn reveal and reinforce the need for research-based and research-informed policies and strategies. The chapter concludes by collating the different lines of reasoning and developments and deducing potential directions for the development of powerful and responsible policies toward the use of ICT and its implementation in schools and school systems.

ICT policy · Current developments on ICT in education · Future challenges · National and international plans

Introduction

In view of their responsibility to prepare students for what is commonly referred to as the digital age, education systems have assumed a key role in imparting digital competencies to future generations. The core questions in this respect revolve around the potential of technological developments to change and improve students' learning processes and outcomes, thereby ensuring their participation in a digitalized society. While the former concerns both the technological potential and the meaningful integration of ICT into teaching and learning scenarios, the latter addresses overarching aims of education and education policies such as equity and successful participation in all areas of society. Education policies on the use and implementation of ICT in schools and school systems play a crucial role in this context. In contrast to the other chapters in this section, this chapter does not look at such ICT policies in specific regions of the world. Instead, it aims to provide a more holistic view on the scope and topic of ICT policies for schools and school systems by adopting an international perspective. In so doing, the first part of the chapter endeavors to characterize ICT policies by defining categories to describe and analyze them. The second part elaborates and discusses the role of ICT policies formulated by international organizations. Commonalities in ICT policies in different parts of the world are outlined in the third part of the chapter, which also elaborates on the key challenges addressed or to be addressed in ICT policies. Findings from international initiatives and studies on ICT in schools and the implications drawn for ICT policies bring research and policies together in the fourth part. The chapter concludes by emphasizing the key role that ICT policies play as drivers for educational change and pointing to the responsibility that education stakeholders and researchers have to improve primary and secondary education in the digital age.

Characterizing Educational Policies Toward ICT in Primary and Secondary Schools

Education policies focus on overarching decision and planning strategies as well as on setting goals for education systems. Ideally, they forge a bridge between education plans and practice, shed light on the necessity for change, and provide both the solutions and the means for meeting and overcoming current or future needs in education. Analyses of education policy look both at how it has evolved and how it has been implemented and evaluated (OECD 2017). Comparisons of education policies in individual countries have to review corresponding trends and actions on the student level, e.g., in terms of student outcomes (especially equity and quality), preparation for the future, evaluation and assessment, or the quality of improvements to schools. They also have to look at such trends on the system level, e.g., how education systems are organized in terms of governance and funding to deliver education policy (ibid.). When it comes to policies on the use of ICT in primary and secondary education, Moonen (2008) points to the potential impact of ICT-related evolution on education policy. Seen from this perspective, ICT policies aim to improve and optimize the impact of the use of technologies in schools at regional, national, and international level. Moreover, it is assumed that they take the socioeconomic, educational, and cultural context of their respective education system(s) into account (Kozma 2011; Roumell and Salajan 2016), an aspect that affects their substantive and strategic impact: “The diversity of the technological, pedagogical, and cultural situation in a region has, most probably, a profound impact on what kinds of policies can be possible” (Moonen 2008, p. 1077).

A look at ICT policies for primary and secondary education from a global and meta perspective reveals that education policies in general – and in particular those that address the use and implementation of ICT – are characterized by a number of different aspects:

1. *Target group*: Policies can be characterized by their target group, i.e., the group or actors in education and education systems that they deal with or to whom they refer. Education policies for ICT in schools most commonly relate to students’ learning culture and the organizational culture of schools (Ball et al. 2012). In order to have an effect on such cultures, policies may target education decision-makers, teachers, or school principals. They may also provide recommendations for curriculum development and thus function themselves as addressees (Vanderlinde et al. 2012).
2. *Authorship*: Policies can likewise be characterized by their authors and their corresponding background and philosophy. The different roles and formal positions of these authors (e.g., political stakeholders, political bodies, or nonprofit organizations) in the education system determine how a policy is aligned to the content of policy plans and how ideas, concepts, and aims are rationalized.
3. *Obligation*: The degree of liability and obligation characterizes the placement of the policy.

4. *Understanding of teaching and learning*: In the case of ICT policies, the way in which teaching and learning with ICT are understood differs and therefore constitutes a central characteristic of policies.
5. *Geographical scope*: Similarly, the geographical scope and radius of the policies or corresponding strategies can have an impact on their implementation.
6. *Timeframe*: The designated timeframe is likewise important for the success and sustainability of ICT policies. Defining this timeframe can be more challenging than it might seem: policymakers work in legislatures, and longer-term ICT policies require ideas that disregard technological developments. Although developing such ideas is a challenge, the resulting policies do appear to have greater potential to be sustainable. Technology-based policies tend to be more concrete and incorporate current or upcoming technological developments, which can be advantageous, especially when they meet the need of pedagogical ideas.
7. *Means*: Last but not least, the means needed to support the realization of education policy concepts and plans, e.g., support for schools, teacher professional development, and funding, can form part of ICT policies (and indeed should if they aim to be successful). Indeed, policies based on education programs in which resources are aligned with policy intentions seem to be more successful (Cohen and Hill 2001).

All in all, characterizing ICT policies by identifying their particular mind-set can help to understand and analyze them. However, the different characterizing aspects are not always documented (or at least evident) in all policy concepts and frameworks to integrate ICT into primary and secondary education. This has two main implications for their potential effectiveness. First, gaining a sound understanding of the concepts and the reasoning behind them remains a challenge, which in turn makes them difficult to realize as intended. Second, the lack of clarity regarding the different characteristics can diminish acceptance and purview by pedagogical actors, both of which are crucial aspects if education policies are to have an impact and induce change. Policies are deemed to have failed to have an impact in the classroom when they have no explicit links to teaching practice and teachers are unable to recognize their implications for teaching (Cohen and Hill 2001).

In light of the above, it can be concluded that all of the aforementioned aspects have to form part of (and be addressed by) an ICT policy if it is to be successful, forward looking, and productive. This assigns a high level of responsibility for education systems and societies as a whole to those who are in charge of developing ICT policies for school systems around the world. With such policies, policymakers fulfill the need to ensure alignment between the development of ICT in society, its integration into schools, and its use in teaching (UNESCO 2011a).

ICT Policies Provided by International Organizations

Responsibility and the sharing of expertise in formulating ICT policies for education and school systems are often assumed by international or regional organizations. Cross-national policies are important for providing social opportunities, e.g., by

facilitating social participation, prosperity, and social cohesion. This is especially relevant in the case of ICT policies, whose function is to provide general orientation in a world that is becoming more and more complex. Cross-national policies support countries and regions in the development of national or regional policies and thus enable the development of specific cross-national ICT policies (Moonen 2008). The actual purview of such policies depends not only on the core ideas contained therein but also on their legal range. Since most countries are members of international or at least regional organizations (e.g., UNESCO or the OECD), multinational plans are developed to cover interests that extend beyond a single country or region. In this regard, global institutions and organizations such as the World Bank (cf., e.g., Trucano 2016) or UNESCO have long shown their commitment to exploring the potential of digital technologies for student and teacher education alike, e.g., in terms of the opportunities they afford for e-learning or professional development. UNESCO, for example, already began developing ICT policies at a very early stage. Indeed, one of its core current papers describes a competency framework for teachers (UNESCO 2011b). The paper updates the 2008 UNESCO document on teacher standards and is aimed at “helping countries to develop comprehensive national teacher ICT competency policies and standards, and should be seen as an important component of an overall ICT in Education Master Plan” (ibid, p. 1). It contains a description of the rationales and overarching aims of the policy, statements regarding its understanding of ICT in education (e.g., the link between education and economic growth), and a clear and differentiated modular competence framework with indications for its practical application by different groups (e.g., school principals). The paper shows some of the typical characteristics of cross-national papers: it demonstrates expertise, elaborates on research findings and pedagogical experience, sets out concrete ways for implementation, but is non-binding, i.e., does not establish any obligation. Although the latter is not the aim of such a paper, this lack of obligation clearly restricts its implementation into education practice. As far as the categorization system for ICT policy papers (see above) is concerned, the paper refers (at least briefly) to all aspects apart from timeframe (aspect 6).

The analysis of education policies of the seven regions included in this section of the handbook (Australia and New Zealand, Asia, Europe, Latin America and the Caribbean, North America, North Africa and the Middle East, and Sub-Saharan Africa) mirrors the role that this and other cross-national policies play and how they have been transferred into practice – or at least how their ideas have been included in regional or national policy papers.

Commonalities and Challenges of Cross-National Regional ICT Policies in Primary and Secondary Education

Given the multiplicity of education systems around the world, it is not surprising that education policies, in this case with regard to ICT, also vary greatly. Although there appears to be a common understanding of the potential of ICT for learning, its use can still differ to some extent in pedagogical practice in line with the conditions and

needs of an individual region or country. Against this background, the following part of this chapter offers an overview of the main developments in this context in the abovementioned seven regions. In so doing, it considers recent developments in ICT and ICT policies, the relevance of cross-national strategies for individual regions, as well as the corresponding challenges and prospects. Elaborating on the insights and findings in the regional chapters in this section, the analysis contrasts developments and identifies core cross-national and cross-regional developments.

The contributions from the different regions indicate various recent developments and initiatives in ICT policies and implementation. One such development is the recognition and acceptance of the need for and benefits of a national ICT integration plan. While such plans and policies do, of course, differ in terms of their content, goals, and obligatory nature, the common thread that runs through them is an aim to reach all students within their education systems and enable all young people to participate in the digital age.

In Europe, for instance, many countries have already developed their own guidelines and projects. These include the “National Plan for the Digital School” in Italy, the “Digital Literacy Green Paper” in Malta, the “Lehrplan 21” [“Curriculum 21”] curriculum in the German-speaking cantons of Switzerland, the “Fit 21” program in Austria, or the nationwide “Bildung in der digitalen Welt” [“Education in the Digital World”] strategy in Germany (cf. ► [Chap. 87, “Information and Communication Technology Policy in Primary and Secondary Education in Europe”](#) by Ottestad and Gudmundsdottir). Such strategy papers either pursue the aims of rectifying lower than anticipated performance, e.g., in ICILS 2013 (Germany), improving resource availability (Denmark), and focusing on newly emerging competencies such as computational thinking (Czech Republic, Finland) or simply emphasize the importance of ICT for personalized learning (Estonia).

ICT has also been incorporated into national curricula in other regions of the world, where the strong economies in particular have set objectives for specific periods of time (ranging from a few years to over a decade). In Asia, for instance, Malaysia introduced the “Education Blueprint 2013–2025” to promote Internet access and support special needs, Singapore published its third “ICT Master Plan” (covering the period 2009–2014) to develop both collaborative and self-directed learning, and Thailand’s second “ICT Master Plan” (2009–2013) aims to improve thinking and problem-solving skills through ICT, as does the fourth phase of South Korea’s “ICT in Education Master Plan” (cf. ► [Chap. 82, “Information and Communication Technology in Educational Policies in the Asian Region”](#) by Yuen et al.). Taiwan’s 10-year infrastructure program, which was introduced in the 1990s, now includes digital literacy as an official curriculum component, demonstrating a trend to incorporate ICT into teaching and learning processes. This trend is likewise evident both in China’s three 5-year plans to enhance its ICT infrastructure and integrate ICT into school curricula as well as in Japan’s “Knowledge Construction with Technology 2010” initiative to transform didactic teaching styles with ICT. India’s “CLASS” studies and “ICT@Schools 2004” project view the decade from 2010 to 2020 as a period of innovation. Hong Kong has already moved beyond the ideal of integrating ICT into teaching and learning that was promoted in its third “IT

in Education Strategy” (2008–2013); its fourth strategy now focuses on the promotion of computational thinking (in analogy to the developments observed in other countries around the world).

In the Middle East and North Africa region, Kuwaiti and Jordanian approaches to ICT policy incorporate related skills at all levels of education (e.g., “National ICT in Education Strategy,” Kuwait, 2008), with both countries also taking their policies beyond the mere provision of indispensable infrastructure (► [Chap. 86, “Information and Communication Technology and Educational Policies in Primary and Secondary Education in the Middle East and North African \(MENA\) Region”](#) by Alayyar et al.). Jordan, as a role model for the Arab world for the implementation of digital media in the school curriculum, has developed a policy framework that is continuously updated to meet the requirements and challenges of the ever-evolving technological domain. Saudi Arabia, on the other hand, has adopted an approach that involves numerous annual ICT releases instead of a stand-alone ICT policy. Like their counterparts in Egypt, Saudi students only learn ICT skills in secondary school; such skills have not been made a priority in primary schools in these education systems. While the funds for purchasing the necessary infrastructure are available in Saudi Arabia, other countries have cut funding for technology in education. This is the case, for instance, in the USA, where the “Enhancing Education Through Technology (EETT)” initiative was dropped in favor of a modernized “E-rate” program that lays the foundations for digital learning in conjunction with the “National Educational Technology Plan.”

While some countries enact these policies at national level, others make a clearer distinction between states, provinces, or territories. In Canada, education remains a matter for the individual provinces, despite current national initiatives for online instruction. The province of Alberta, for example, has adopted the “Alberta Learning and Technology Policy Framework,” which specifies the following (and other) priorities: student-centered learning, research and innovation, professional learning, access, infrastructure, and digital learning environments (► [Chap. 84, “Information and Communication Technology and Educational Policies in the United States of America and Canada”](#) by Davis et al.).

Many countries in Latin America and the Caribbean have likewise initiated digital agendas, most notably Uruguay’s “Plan Ceibal,” which goes beyond equipping primary and secondary schools to also install computers in private homes (► [Chap. 88, “Information and Communications Technology and Educational Policies in Latin America and the Caribbean”](#) by Castillo-Valenzuela and Garrido Miranda). Other education systems in this region have paid particular attention in their ICT policies to the professional development of teachers, e.g., those in Argentina (“National Teacher Training Plan”) or Brazil.

While South Africa has made the integration of ICT a priority at all levels of schooling, other countries only have formal recommendations in place, the success of which varies greatly. The highest variance in the establishment of ICT policies developed and realized by national plans can be found in Sub-Saharan Africa (► [Chap. 85, “Information and Communication Technology and Educational Policies in the Sub-Saharan African Region”](#) by Tilya). Although all countries in

Sub-Saharan Africa have policies to guide the provision of education, not all of them have a policy on ICT in education. Those that do place particular emphasis on improving the quality of subject teaching and learning. One conclusion to be drawn here is that the most basic requirements (like ICT equipment and electricity) cannot be taken for granted in some of the countries in this region, resulting in poor conditions for digital learning. Their approaches to ICT are likewise manifold: ICT is taught as a school subject in Tanzania and Madagascar (from secondary school level), Kenya has developed an “ICT Trust Fund” to provide schools with the necessary equipment, while the Seychelles and Botswana both have an “ICT Master Plan” and a “Revised National Policy on Education” that includes digital media. In contrast, Burkina Faso and other countries in the region do not even have any formal recommendations in place regarding ICT in education.

Beyond the cross-regional trend to develop national ICT policy plans – be it with reference to overarching plans or not – some core ICT policy topics are common to many or even all regions:

1. Developing ICT infrastructures that reflect pedagogical aims, especially the fostering of one-to-one and BYOD (“bring your own device”) concepts, often in combination with personalized learning
2. Focusing on access, equity, and participation
3. Reaching all students and improving teacher training
4. Bridging and linking formal and informal learning
5. Integrating the aims of (subject-specific) learning with ICT with more general education goals such as creating a skilled workforce for the twenty-first century
6. Introducing new topics (e.g., computational thinking) and modernizing curricula
7. Pointing to new potentials such as those afforded by new forms of online learning and online assessment as well as to risks and more critical issues like data privacy

These overarching topics can be rationalized by the challenges that education regions face with regard to the integration of ICT in primary and secondary schools. Like the other aspects of ICT policies and strategies discussed above, the implementation challenges are manifold and differ across education systems. While countries in Sub-Saharan Africa lack the essential prerequisites of basic infrastructure, hardware, connectivity, and electricity, other regions face less substantial but nonetheless still complex challenges. In North Africa and the Arab countries, for instance, a major focus needs to be placed on the pedagogical integration of ICT into teaching and learning processes. This meaningful use of ICT, along with teachers’ digital competences and professional development, will likewise need to be a focus for further progress in Europe, Asia, and Latin America. The closing of the digital divide, both on a national and an international level, appears to be a global challenge in ICT policy and integration. The assessment of Latin American concepts points to a particular lack of coordination between global, regional, and national ICT policies, which can at times be contradictory or misaligned. Further emphasis should also be placed on personalized learning (e.g., in Australia, New Zealand, the USA, Canada, and Latin America) as well as on the responsible use of ICT, including issues of

cybersecurity (Asia) or privacy (the USA, Canada). The Asian contribution (► Chap. 82, “Information and Communication Technology in Educational Policies in the Asian Region” by Yuen et al.) also notes that a continuous measurement and evaluation of ICT literacy skills are imperative for improving student competencies and securing their participation in society. In contrast to the majority of the abovementioned education systems, Canada exhibits only minor issues in digital equity, while developments in the digital domain in Australia are largely “on track.” The less-developed education systems do, however, still need to pay more attention in this respect, yet not be oblivious to the fact that digital technology – and consequently the potential that is linked with its integration into the education system – is an ever-evolving, dynamic domain that requires constant attention, development, and evaluation through ICT-related policies.

Research-Informed ICT Policies: The Role and Impact of International Research Initiatives and Studies

If we look back over the last decades, we can identify different driving forces behind the implementation of ICT in formal education. Alongside the more ambivalent discussion of economic interests, technological innovations (cf. Pereira and Pereira 2015), the potential for pedagogical change afforded by ICT, and the transition to an information and knowledge society (with its associated need for new forms of learning and new competencies) all call for a modernization of schools and school systems. Beyond political, social, and economic interests and aims, research findings provide evidence-based knowledge that supports the need for changes in education. The EduSummIT (International Summit on ICT in Education) initiative’s 2013 working meeting focused, for example, on “research-informed strategies to address educational challenges in a digitally networked world” from an international perspective. It highlighted the relevance of basing ICT policy decisions on research findings and engaging in dialog with stakeholders and practitioners to interpret and turn these findings into pedagogical practice (Voogt et al. 2015). Two of the main findings were the need to identify what works (and what does not work) in the integration of ICT into education and to make research accessible to a broad range of stakeholders, thereby also improving the link between research and practice (EduSummIT 2013). Parallel to this, international studies have investigated ICT use in schools, hindering and supporting conditions in different levels of school and education systems and student achievement. The IEA’s SITES 2006 (Second Information Technology in Education Study, module 2006) and ICILS (International Computer and Information Literacy Study) studies and some sub-areas of the PISA (Programme for International Student Assessment), PIRLS (Progress in International Reading Literacy Study), and TIMSS (Trends in International Mathematics and Science Study) studies have together established a huge international information base for ICT policies (e.g., Plomp et al. 2009). On an international level, ICILS and PISA both formulate recommendations for a future-orientated development of schools and school systems which can be understood as guidelines for policies on

ICT in schools (Fraillon et al. 2014; OECD 2015). More specifically, some of the recommendations of ICILS 2013 (► Chap. 6, “Students and Their Computer Literacy: Evidence and Curriculum Implications” by Ainley; see summary on pp. 24–25) point to the fact that the knowledge, skills, and understandings described in the Computer and Information Literacy (CIL) scale can and should be taught. Moreover, and regardless of whether young people are considered to be digital natives or not, the findings show that it would be naive to expect relevant ICT competencies to materialize without coherent learning programs. The study also concludes that policy planning should focus on increasing teacher expertise in ICT use. At school level, endeavors to implement supportive collaborative environments that incorporate institutional planning focused on using ICT and teaching CIL in schools should be supported. Some regions have also taken up the findings of the ICILS 2013 study on a cross-national level. They form the basis, for example, of the European Commission’s ICT policy recommendations for EU member states (European Commission 2014). These recommendations, which include placing more emphasis on active teaching practices with ICT to equip teachers for effective pedagogical use of ICT, are directly addressed to policymakers. The commission also draws conclusions for its own future activities, e.g., follow-up work on a digital reference framework for learners and the development of a framework for educators (ibid).

While ICILS and PISA look at secondary schools, PIRLS and TIMSS address primary schools. Beyond their findings on reading achievement and primary school students’ competences in mathematics and science, the most recent cycles of TIMSS (2015) and PIRLS (2016) provide an international comparison and assessment of ICT use. Classroom reading activities with ICT (e.g., reading online) vary from country to country within and across regions and are related to reading competence in different ways. This could be an interesting conclusion for policymakers and one that might move education systems into the digital age. On average, students read digital texts (19%), apply strategies for reading digital texts (13%), critique texts on the Internet (17%), look up information (25%), research a problem (19%), and write something (17%) in classrooms on a weekly basis (Mullis et al. 2017). Nonetheless, and despite the fact that such findings supply highly interesting insights into and a comparison of education systems, their pedagogical approaches, and efforts, few conclusions have so far been drawn with regard to their implications for future developments.

While these and many other findings of the abovementioned (and other) studies are of considerable interest for policy decisions to improve school systems around the globe, the link between research and policymaking, with a few notable exceptions (Bundsgaard 2016; Eickelmann 2016), remains largely untapped.

Conclusion: The Potential of ICT Policies to Move Education Systems into the Digital Age

The speed at which digitalization is currently affecting all spheres of life and work is still not reflected in how ICT is used in primary and secondary education. Although there are huge differences in how education systems around the world embrace the

potential of ICT to improve student learning processes and achievement and how they can help to establish modern school systems that provide everyone with access to knowledge and education, ICT policies can nonetheless function as a catalyst for educational change (Kozma 2011). The challenges facing education systems vary in different continents, countries, or even regions within countries. Developing appropriate ICT policies is therefore extremely challenging. Nevertheless, such policies play a key role in making sustainable changes, thereby empowering young people to participate successfully and autonomously in the digital age. The contrast between the rapid pace of digitalization and the slow pace of development of sound and well-considered ICT policies for school systems will remain a dilemma that can only be resolved when policies include not only different types of technologies but also overarching education aims such as participation, equity, and twenty-first-century competences. In this context, the PISA study provides both an in-depth analysis of ICT-related topics and research-based knowledge for policymakers (e.g., OECD 2015). Indeed, the OECD (2015) referred to PISA 2012 findings when formulating its “implications for digital technology for education policy and practice.” These call on policy and practice to invest in skills to promote equal opportunities in the digital world, to raise awareness of the possible harmful aspects of internet use, to develop coherent plans (including teacher training) for the use of ICT in the classroom, and to learn from past experience to improve the effectiveness of future investments in technology.

Abstract

The chapter analyses the various policies towards ICT in primary and secondary education from the perspective of Asian region, where it is the world's most diverse region, and the most heterogeneous, especially for integrating and sustaining ICT across several domains, including education. Using the Knowledge Ladder framework, this chapter explores firstly the rationale for the development of ICT policies in Asia in terms of four types of education models. Over the past decade, we can observe that the development of ICT policies in Asia are mixed. In certain nations, e.g., Lao PDR and Vietnam, the policy priority areas of basic education focused on poverty alleviation, improving ICT use by teachers and improving training in ICT for students. In other nations such as Malaysia, Singapore, Thailand, Hong Kong, Taiwan, China, Japan, Korea and India the policy priority areas supported knowledge deepening, knowledge acquisition or knowledge creation. This chapter shows that recent ICT policies in the Asian

region have placed more emphasis on the development of students than of teachers. Other stakeholders such as parents are also included in the ICT policies in some Asian countries. From recent empirical research, we noted three main challenges: closing the digital divide, promoting the safe and responsible use of ICT, and measuring and evaluating ICT literacy skills. Finally, we also provide emerging perspectives for the development of ICT in education in Asia, namely alignment of local and international goals, student engagement in learning alongside social and leisure activities, and the context of Asian culture.

Asian region · Development of ICT policies · ICT in primary and secondary education · Knowledge Ladder framework

Introduction

National policies on information technology (IT) or information and communication technology (ICT) in education can serve several important functions. Strategic policies can provide a rationale, a set of goals, and a vision for how education systems can operate with the introduction of ICT and how students, teachers, parents, and the general population can benefit from its use in schools. These strategic policies can motivate, change, and coordinate disparate efforts to advance a nation's overall educational goals (Kozma 2008). For a sensible policy to improve the impact of ICT on education, Moonen (2008) suggested three main policy lines from a global perspective. First, basic knowledge and skills about ICT should become available in education. Depending on the level of development of a country, teaching ICT knowledge and skills, or supporting its daily use in schools, should be encouraged. Second, policy should support the creation and facilitation of informal teacher networks. Teachers should become equals with their pupils in terms of attitudes and skills toward ICT. Third, policy should facilitate the use of ICT for the new generation of pupils by maximizing Internet access, not only in schools but also in libraries, sport facilities, and homes.

What are the developments of ICT in education policies in the Asian region? Are they related to the policy lines as suggested by Moonen (2008)? This chapter seeks to review the developments of ICT in education policies in the Asian region by focusing on primary and secondary education. In general, there are three subregions: (1) Northeast Asia (China, Hong Kong, Mongolia, Japan, North Korea, the Republic of Korea, and Taiwan), (2) Southeast Asia (Indonesia, Myanmar (Burma), Thailand, Malaysia, Brunei, Singapore, Vietnam, Laos, East Timor, the Philippines, and Cambodia), and (3) South Asia (India, Pakistan, Nepal, Bhutan, Bangladesh, Sri Lanka, and the Maldives). Of course, this chapter cannot cover all of these countries, and instead explores selected countries from different subregions.

The International Telecommunication Union (ITU) ICT Development Index (IDI) is a unique benchmark of the level of ICT development in countries across the world. The IDI combines 11 indicators on ICT access, use, and skills, capturing key aspects

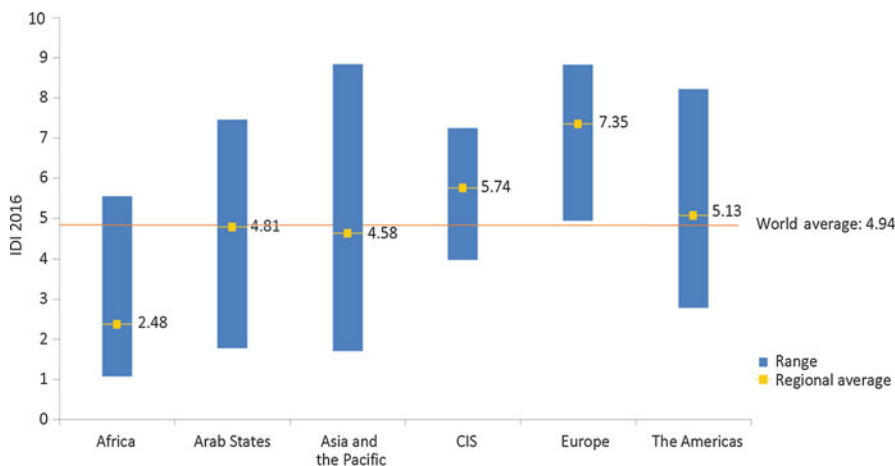

Fig. 1 IDI 2016 by region compared with global average (Source: ITU 2016, p. 44)

of ICT development in one measure that allows for comparisons across countries and over time (ITU 2016). IDI 2016, covering 175 economies worldwide and making comparisons to IDI 2015, highlights both progress and the persistent divides in the global information society. The 175 economies are grouped into 6 regions: Africa, Arab States, Asia and the Pacific, the Commonwealth of Independent States (CIS), Europe, and the Americas. The regional averages and ranges of IDI 2016 are presented in Fig. 1.

There has been greater improvement in the use of ICT than in its access. Nearly all countries improved their IDI values over the last year, but significant disparities persist between more- and less-connected countries. There is a strong association between economic development and ICT development, with the least developed countries at a particular disadvantage. The average IDI value rose by 0.20 points to 4.94 points (out of 10), with smaller increases at the top and at the bottom of the list. The gap between the highest- and lowest-performing countries – one measure of the digital divide – remained almost unchanged, at 7.76 points in IDI 2016. The Republic of Korea tops the IDI rankings in 2016 for the second consecutive year. The top 10 countries also include two other economies in the Asia-Pacific region and seven European countries (ITU 2016).

Table 1 presents the IDI rankings and values of 34 economies in the Asia-Pacific region. As this chapter does not refer to Australia and New Zealand, they are excluded in our discussion. The top 10 positions in the regional rankings for 2016 are almost identical to those for 2015, with China displacing Thailand in tenth place. The top seven economies in the region (among them the Republic of Korea, as the global top performer, Hong Kong, Japan, Singapore, and Macao) have IDI values above 7.5 and occupy the highest quartile of the IDI rankings. They are all high-income economies that have maintained high IDI performance ever since the first publication of the Index. These findings for the Asia-Pacific region reveal a greater

improvement in IDI values among middle-ranking countries than among countries in the top and bottom quartiles, suggesting that the Asia-Pacific region may be witnessing a reduction in the digital divide between developed countries and the majority of developing countries, alongside a worsening divide between the majority of developing countries and the least connected countries (ITU 2016).

In terms of ICT development, the Asian region is the world's most diverse region (IDI ranging from 1.73 to 8.84) and by contrast the most heterogeneous (ITU 2016). Especially for integrating and sustaining ICT across several domains, including education, the Asian region also exhibits significant economic disparity (UNESCO-UIS 2014). Thus, due to such differences and variations, it is a challenge to provide appropriate coverage, fair framing, and complete discussion of ICT in education policies in the Asian region.

Recent Developments on ICT in Asia

This section attempts to highlight the recent developments of ICT in education for some Asian countries as depicted in two comparative studies conducted under the auspices of the International Association for the Evaluation of Educational Achievement (IEA). In the late 1990s, the IEA decided to conduct the Second Information Technology in Education Study (SITES), which is an international comparative research program exploring the use of ICT in education. SITES 2006 was the third module in this program, and its aim was to provide a comprehensive understanding of how teachers teach, both generally and in situations when ICT is used, as well as how school- and system-level factors affect teachers' pedagogical adoption of ICT. A total of 22 countries were involved in SITES 2006, which included 5 Asian economies, namely, Japan, Taiwan, Singapore, Hong Kong, and Thailand (Law et al. 2008).

Most of the participating countries reported that the 5 years preceding SITES 2006 had seen an increase in the following pedagogies in their education systems: inquiry-based learning, individualized learning, collaborative projects, interschool collaboration, and international collaboration projects. The following discussion focuses on findings about school practices and conditions for pedagogy and ICT (Pelgrum 2008).

The trend analyses regarding the presence of lifelong learning practices as perceived by school principals suggest that the most noteworthy change between the SITES assessments of 1998 and 2006 was the increase in pedagogical practices involving information handling (searching for information, processing data, and presenting information). The results showed that the lifelong learning indicator was quite high in many systems, although there was variation across countries. Noteworthy are the relatively high scores of Chile (3.66) and Thailand (3.56) versus the relatively low scores of South Africa (3.31), Hong Kong (3.29), and Japan (3.28). In contrast, Singapore scored 3.52 and Taiwan scored 3.45 (Pelgrum 2008).

The results showed that although principals were promoting all three visions (traditional, lifelong learning, and connectedness), they tended to give less support to connectedness than to the other two factors. School leaders generally underscored the importance of using ICT with pedagogical approaches for lifelong learning. In some systems, school leaders seemed, for example, relatively inactive in terms of trying to influence the pedagogical practices of their teachers, while in other systems they tended to be much more active. ICT was recognized as a catalyst for change by a substantial number of school principals in some systems (e.g., Chile, Taiwan, Israel, Lithuania, Slovenia, and Thailand), but this was not the case in other systems (Catalonia, Finland, and Japan). In Asian economies, the percentages of school principals who recognized ICT as a catalyst for change were as follows: Thailand 77%, Taiwan 47%, Singapore 44%, Hong Kong 23%, and Japan 16%.

For staff development, in most participating education systems, hardly any, or only a minority, of the schools required teachers to be trained in areas involving new pedagogy and ICT. The availability of courses also differed substantially across education systems. Courses on pedagogical issues related to integrating ICT into teaching and learning were available in more than three-quarters of the schools in Taiwan, Denmark, Estonia, Hong Kong, Lithuania, Moscow, Singapore, and Slovenia. However, there were also quite a few education systems (Alberta, Chile, Finland, Israel, Italy, Japan, France, Norway, South Africa, and Thailand) where sizeable numbers of schools did not seem to have access to such courses.

In SITES 2006, school principals were asked to indicate the possible actions they had undertaken to address the issues relating to change management. Principals in most countries said they had set up security measures, allowed students to use school computers outside of school hours, limited game playing, and specified skills that students were expected to acquire. Measures restricting the number of hours that students could use computers appeared to be most prevalent in the Russian Federation and Thailand, but such measures were of little consequence in Denmark and Hong Kong. Many schools in Taiwan, Hong Kong, and Singapore took measures to provide laptops for teachers. For most Hong Kong schools, this was also the case with regard to students. Taiwan, Moscow, Norway, and Thailand implemented incentive schemes to encourage teachers to use ICT in their lessons, but Finland, Japan, and Slovenia rarely did so. Many schools in Hong Kong included parents in ICT-related activities, but France and Japan appeared disinclined to do so.

The International Computer and Information Literacy Study (ICILS) studied the extent to which young people have developed computer and information literacy (CIL) to support their capacity to participate in the digital age. CIL is defined as “an individual’s ability to use computers to investigate, create, and communicate to participate effectively at home, at school, in the workplace, and in society” (Fraillon et al. 2013, p. 17). ICILS also addresses the necessity for policymakers and education systems to gain a better understanding of the contexts and outcomes of CIL-related education programs in their countries. As an IEA international comparative study, the main ICILS 2013 took place in the 21 participating countries between February and December 2013. Only three Asian economies participated in ICILS 2013, namely, Hong Kong, the Republic of Korea, and Thailand.

Table 2 A summary of CIL results of Asian economies participating in ICILS 2013

Country	Average CIL score (standard errors)	IDI 2012 (country rank)	Student-computer ratios (standard errors)
Republic of Korea	536 (2.7)	8.57 (1)	20 (2.3)
Thailand	373 (4.7)	3.54 (95)	14 (0.9)
Hong Kong	509 (7.4)	7.92 (10)	8 (0.8)

Source: Fraillon et al. (2014, p. 96)

The following discussion focuses on some major findings of ICILS 2013 (Fraillon et al. 2014).

The CIL construct combines information literacy, critical thinking, technical skills, and communication skills as applied across a range of contexts and purposes. The variations in CIL proficiency (with the average CIL score ranging from 361 to 553) show that while some of the young people participating in ICILS were independent and critical users of ICT, there were many who were not. As the volume of computer-based information available to young people continues to increase, so too will the responsibility of societies to critically evaluate the credibility and value of that information. Table 2 presents the CIL averages, IDI rankings, and student-computer ratios of three Asian economies participating in ICILS 2013. It is worth noting that the achievement of the Republic of Korea is significantly higher than the ICILS 2013 average (500), whereas the achievement of Thailand is significantly lower than the average. As Hong Kong did not meet the sample requirements, no comparison was made.

Evolving technologies (such as social media and mobile technologies) are increasing the ability of young people to communicate with one another and to publish information to a worldwide audience in real time. This facility obliges individuals to consider what is ethically appropriate and to determine how to maximize the communicative efficacy of information products. Students were asked to report their performance of various activities at least once a week. Across the ICILS countries, one activity stood out from the others in terms of weekly use, namely, “communicating with others using messaging or social networks.” The cross-national average for this activity was 75%. Student percentages in several countries exceeded the ICILS 2013 average by more than 10 such points. These were Norway (89%), Poland (88%), the Slovak Republic (87%), and the Czech Republic (86%). Those countries where the respective percentage was more than 10 percentage points below the ICILS 2013 average were Korea (42%), Thailand (49%), and Turkey (56%). Hong Kong was 60%. Also, all three Asian economies were lower than the average.

When responding to the ICILS student questionnaire, students indicated how well they thought they could perform each of 13 computer-based tasks. The difficulty of the tasks ranged from “search for and find information you need on the internet” to “create a computer program or macro.” For the Asian economies, the national percentages of student confidence in performing the more difficult tasks were

Table 3 Internet access at home and CIL scores

Country	Students with internet access at home		Students without internet access at home	
	Percentages (standard errors)	Average CIL score (standard errors)	Percentages (standard errors)	Average CIL score (standard errors)
Republic of Korea	98 (0.3)	538 (2.6)	2 (0.3)	444 (14.5)
Thailand	57 (1.5)	400 (5.4)	43 (1.5)	339 (5.5)
Hong Kong	99 (0.2)	511 (7.4)	1 (0.2)	#

Subgroup sample size too small for reporting reliable estimate

below the ICILS 2013 average in general. To some extent, this observation raises a concern about Asian students as digital natives with a self-developed capacity to use digital technology.

Even though we can discern within the ICILS findings high levels of access to ICT and high levels of use of these technologies by students in and outside school (especially at home), we need to remain aware of the variations in CIL proficiency within and across the ICILS countries. Table 3 presents the percentages of students with/without Internet access at home and CIL scores of Asian economies. Obviously, there is a lower percentage of Thai students with Internet access at home.

Teachers' ICT use was greatest when the teachers were confident in their expertise and were working in schools that collaborated on ICT use (and that had few resource limitations). These were also the conditions that supported teachers' ability to teach CIL. For professional development activities, the most common form of participation involved observing other teachers using ICT. On average across the ICILS countries, 46% of teachers reported this type of participation. The countries whose teachers most frequently reported observing their colleagues' use of ICT were Lithuania (60%), Australia (57%), and the Republic of Korea (57%). In contrast, there were lower scores for Thailand (53%) and Hong Kong (41%).

Recent Developments on Policies on ICT in Asia

Over the decade from 2006 to 2016, there have been major developments regarding ICT policies in Asian countries. What drove these ICT policies? To understand the rationale for the development of ICT policies in Asia across this time frame, we draw upon Kozma's *Knowledge Ladder* conceptual framework consisting of four types of education models: basic education, knowledge acquisition, knowledge deepening, and knowledge creation (UNESCO 2011).

In the *basic education* model, the curriculum focuses primarily on basic numeracy and literacy skills with minimum use of ICT. If available, access to the Internet is used for administrative support, access to online content, and professional

development resources for teachers. In the *knowledge acquisition* model, the curriculum emphasizes a large number of facts and concepts within the school subject areas. ICT is used mainly to deliver instruction. In the *knowledge deepening* model, the curriculum stresses the understanding of key concepts within and across different subjects and their application to solve real-world problems. ICT is used to support collaborative projects and connect students and teachers outside normal school hours. Simulations and multimedia materials are used to support understanding of interrelated concepts, explore systems, and solve problems. In the *knowledge creation* model, the curriculum is responsive to student goals and contexts. It focuses on learning, inquiry, and the skills involving in creative and critical thinking. ICT is used to support knowledge sharing by students and teachers.

Over the past decade, we can observe that the development of ICT policies in Asia has been mixed. In certain nations (e.g., Lao PDR, Vietnam), the policy priority areas of basic education centered on poverty alleviation, improving ICT use by teachers and improving training in ICT for students. In other nations such as Malaysia, Singapore, Thailand, Hong Kong, Taiwan, China, Japan, the Republic of Korea, and India, the policy priority areas supported knowledge deepening, knowledge acquisition, or knowledge creation. We briefly describe the policies of these nine countries as follows.

Malaysia has an Education Blueprint 2013–2025 ICT policy, formulated by the Ministry of Education and the Multimedia Development Corporation (Malaysia Ministry of Education 2013). This Education Blueprint focuses on three priority areas: providing Internet access and virtual learning environment, augmenting online content, and maximizing the use of ICT for distance and self-paced learning. ICT is used to deliver instruction (knowledge acquisition) such as with EduWeb TV that provided 497 videos covering seven subjects for primary schools and 13 subjects for secondary schools. ICT was also used to support student understanding of interconnected concepts in STEM (Science, Technology, Engineering, and Mathematics) through robot-assisted secondary school programs. In Wave 2 (2016–2020) of the Education Blueprint, the Ministry of Education will focus on helping groups with specific needs such as under-enrolled schools, rural schools, and gifted students (Malaysia Ministry of Education 2013). The Ministry also aims to lower the student-to-computer ratios to a maximum of 10:1.

In Singapore, the country's third ICT Master Plan (MP3), implemented between 2009 and 2014, aimed to use ICT to develop students' proficiencies for collaborative and self-directed learning. MP3 was also designed to upgrade ICT infrastructure to support learning anytime and anywhere (Teo and Ting 2010). With MP3, bandwidth in schools was increased to 1GBPS, and 1-notebook-to-1-pupil schemes were implemented in more schools. Most recently, Singapore launched its fourth Masterplan for ICT in education (MP4) which aims to broaden the focus beyond self-directed and collaborative learning to develop knowledge (Educational Technology Division 2010–2015).

In Thailand, one of the key aims of the second ICT Masterplan from 2009 to 2013 was using ICT as a tool to improve student skills in thinking and problem-solving in conjunction with curriculum reform (UNESCO 2013). The Masterplan also aimed to

promote online communities for the sharing of student knowledge (knowledge creation) and develop ICT hardware, software, and assistive technologies to help students with disabilities.

In Hong Kong, the Third IT in education strategy “Right Technology at the Right Time for the Right Task” was implemented from 2008 to 2013 (Education Bureau 2012). This strategy aimed to integrate ICT into teaching and learning to improve student learning outcomes. A depository of curriculum-based learning and teaching resources was developed to provide teachers with relevant digital resources and pedagogical advice for use in primary and secondary schools. These digital resources mainly supported knowledge acquisition and knowledge deepening. The e-learning Pilot Scheme was also launched in 2010 which involved 61 schools. The e-learning Pilot Scheme aimed to promote student self-directed and interactive learning and accommodate the diversity of learners. Most recently, the Education Bureau launched the Fourth Strategy on IT in Education (ITE4) to promote students’ self-directed learning, problem-solving, collaboration, and competency in computational thinking (Education Bureau 2016). This clearly resonates with the education model of knowledge creation.

The Taiwanese government has been making significant investment in the research and development on e-learning since the 1980s. With the announcement of a 10-year program on building school ICT infrastructure in 1997, Taiwan officially started the promotion of e-learning in school education in recent decades with three stages. Building on the achievements made in the first and second stage, the Taiwanese government continued the third stage (2009–2014), focusing on the following aspects: addressing the development of twenty-first-century skills, making digital literacy an official curriculum component, and introducing a mobile learning program (Kong et al. 2014).

In China, new technologies are being widely advocated as effective instruments for erasing differences between learners and learning communities, particularly with regard to transplanting “modern” education into rural communities (Schulte 2015). In 2000, China’s Ministry of Education held a historic meeting on e-learning for school education that produced two important decisions: implementing the campus network construction project for enhancing ICT infrastructure in schools and offering ICT-related curriculum for K–12 students while speeding up the integration of ICT into school curricula. The results of this meeting guided the Beijing Municipal Commission of Education to outline e-learning strategies and policies across the three five-year plans on educational reform and development in the 2000s (Kong et al. 2014).

Japan launched its Knowledge Construction with Technology led by the Consortium for Renovating Education of the Future (CoREF) project in 2010 with the primary aim of transforming traditional didactic teaching styles to more collaborative and knowledge constructive approaches. The targeted learning outcomes for primary and secondary school students include promoting collaborative problem-solving skills through the Knowledge Constructive Jigsaw pedagogy (Miyake 2013).

The Republic of Korea tops the IDI rankings in 2016 among 175 economies worldwide (ITU 2016). With the fourth phase of ICT in Education Master Plan having reached its completion, the MOE announced the fifth phase of its five-year master plan (2014–2018). The overall aim of the fifth Masterplan for ICT in education is to develop students' twenty-first-century skills, improve problem-solving skills, and reinforce self-regulated learning (Han 2013). The MOE selected a total of 30 strategic assignments in areas including kindergartens, elementary schools, secondary schools, research and development, lifelong education, welfare, special education, public information infrastructure, and the creation of a healthy cyber culture.

In India, the National Policy on Education 1986, as modified in 1992, stressed the need to employ educational technology to improve the quality of education. The policy statement led to two major centrally sponsored schemes, namely, educational technology and computer literacy and studies in schools (CLASS) paving the way for a more comprehensive and centrally sponsored scheme: Information and Communication Technology @ Schools in 2004 (Government of India 2012). Recently, India's government announced 2010–2020 as the decade of innovation. This identifies reasoning and critical thinking skills as necessary for innovation and schools as the foundation of these skills. Ideally, affordable ICT tools and techniques can be integrated into classroom instruction starting at the primary stage so as to enable students to develop their requisite skills. Most of the tools, techniques, and tutorials are open domain and accessible on web (www.icbse.com/ict-education).

In addition to supporting knowledge acquisition, knowledge deepening, or knowledge creation, it is important to note that some ICT policies acknowledge the need to safeguard student interests and help students become responsible digital learners. For example, the Singapore Ministry of Education uses a Cyber Wellness framework to develop elementary and secondary school students' well-being when using the Internet. In 2009, the Singapore Ministry of Education, IDA, and Microsoft launched a Cyber Wellness Student Ambassador Program to promote positive peer influence through student-led activities (UNESCO 2013). Malaysia is another country that has two national programs to address cyber safety issues (UNESCO 2016): Cyber Security Awareness for Everyone (CyberSAFE) and Klik Dengan Bijak (Click Wisely). ICT is also used in teacher education programs in Asia. Many of these courses to some degree aim to equip preservice teachers with the relevant knowledge and skills to appropriately and effectively use ICT to develop learning resources that can enhance students' learning experiences. For example, the Korea National University of Education provided preservice teachers a *Theory and Practice for Instructional Media Development* course to help them develop visual, audio, and video animation materials (Kim 2013). Singapore offers preservice teachers a mandatory *ICT for Meaningful Learning* course which emphasizes how ICT can be used to support the following five dimensions: real-world knowledge, engaging students' prior knowledge, learning by doing, collaborative learning, and self-directed learning (Wong and Divaharan 2013).

Relevance of Cross-national and Worldwide Strategies and Plans for Asia

Policymakers can benefit from a large collection of resources that can aid them in policy formulation and implementation (Kozma 2008). Among these are works that list the current ICT policies of other countries, such as the *Cross-National Information and Communication Technology Policies and Practices in Education* (Plomp et al. 2008) and the *Meta-Survey on the Use of Technologies in Education in Asia and the Pacific* (UNESCO 2003). As suggested by Kozma (2008), UNESCO also has a policymaker's toolkit for ICT in education and a set of ICT standards for teachers. Also, the infoDev program at the World Bank has a variety of helpful knowledge maps, guides, and handbooks. Educational policymakers are in a unique position to initiate change as illustrated in the SITES Module 2 study of 174 ICT-supported innovative classrooms in 28 countries (Kozma 2003). With the collection of resources, policymakers can begin to craft and refine policies that can help ICT deliver on its promises and can build a community of like-minded policymakers (Schulte 2015).

The document – *Transforming Education: The Power of ICT Policies* (UNESCO 2011) – presents a conceptual framework known as the *Knowledge Ladder* (as described in the previous section) and makes recommendations that policymakers can use to craft policies and programs that unfreeze the current system and align it with the social and economic policies that move a nation toward an information economy and knowledge society. Within this context, ICT policies can be transformational.

Initial teacher training and professional development are important components of ICT in education policy. However, ICT in education policy can address much larger issues related to professional development, and they do so in a broader context of educational change, as does the *Knowledge Ladder* and the UNESCO ICT Standards for Teachers (UNESCO 2008). A significant challenge to Asian developing countries bringing more students into the education system is to increase the number of teachers. In many developing countries, ICT is being used to extend access to education for teachers, particularly those in rural areas. The UNESCO ICT in Education Toolkit Toolbox 3 provides helpful suggestions in this regard (UNESCO 2011). The *Knowledge Ladder* can also be used to examine policy goals and visions along with the other policy components such as related strategic programs and operational plans. These components include professional development, pedagogical and curricular change, assessment reform, school restructuring, and technological infrastructure comprising hardware, software, networks, and technical support.

As ICT adoption and use in the wider socioeconomic context of countries become more prevalent, it becomes clear that ICT adoption and policies in education are areas requiring further study. Demonstrating meaningful effects on learning and student outcomes in general is also needed to help policymakers effectively set national priorities and develop policies. The report – *ICT in Education in Asia* (UNESCO-UIS 2014) – examines the curriculum as fundamental to building a

culture of ICT use in education. This is followed by a comparative analysis of ICT integration across Asia by looking at four specific types of data: the use of ICT in policy and key curricular areas, ICT infrastructure and its importance to integrating ICT-assisted instruction, participation in programs offering ICT, and teaching and learning as they relate to ICT in education. These data provide a snapshot of ICT access and of basic usage of ICT in education across the vast region. The analysis, using the framework of e-readiness (UNESCO-UIS 2009), can effectively contribute to facilitating evidence-based policymaking for ICT in education.

Recently, the document – *A Policy Review: Building Digital Citizenship in Asia-Pacific through Safe, Effective and Responsible Use of ICT* (UNESCO 2016) – presented the results of a policy review that examined the national policies, initiatives, and efforts of member states in the Asia-Pacific region relating to the promotion of safe, effective, and responsible ICT environments and ICT use by children. In particular, the review focused on national education policies relating to fostering digital citizenship in schools and among students, teachers, parents, and caregivers. It is hoped that member states can – through knowledge sharing, communication, and collaboration – adopt best practices, model initiatives, and learn lessons, to develop policies that will ensure that their children are better equipped to benefit from the digital world.

Challenges and Relevance of Research for Policies on ICT in Education in Asia

Probably the most important strand of empirical findings that needs to be considered, when it comes to developing policies for ICT in education, is concerned with questions related to the impact of ICT. Does access to ICT help students learn their school subjects? How can we best use ICT to help students learn their school subjects? And how can we use ICT to foster students' ICT literacy? The answers help policymakers justify the large financial investments needed to integrate ICT into education systems.

Unfortunately, thus far the empirical findings on the contribution of IT to learning appear to be mixed. For example, on one hand, two studies conducted in the United States suggested a positive relationship between computer availability in schools and test scores (National Centre for Educational Statistics 2001a, b). On the other hand, a recent report by the Organization for Economic Co-operation and Development (OECD 2015) that analyzed PISA 2012 test data indicated no appreciable improvements in student achievement in reading, mathematics, or science in countries that had invested heavily in ICT for education, even after accounting for differences in national income and in the socioeconomic status of students and schools. Yet, students who used computers moderately at school, such as once or twice a week, displayed somewhat better learning outcomes than students who rarely used computers (OECD 2015). In addition, OECD (2015) found that students who spend more than 6 h online per weekday outside school hours reported feeling lonely at school and arrived late for school. Other studies have suggested that computer use does

increase student performance but this is due mainly to the use of computer at home rather than at school (Delen and Bulut 2011; Papanastasiou and Ferdig 2006; Spiezia 2010).

It is important for policymakers to note that the conclusions of these correlation analyses are limited because they cannot establish causality. Causality can only be determined by examining a substantial number of controlled experiments such as meta-analysis studies (UNESCO 2011). A comprehensive analysis of meta-analysis studies is beyond the scope of this chapter. We examined several recent and seminal meta-analysis studies including Cheung and Slavin (2013), Hattie (2009), Kulik (2003), and Means et al. (2013). The findings can be summarized as follows:

- In an analysis of 74 experimental studies, the results overall suggest that using ICT produces a positive effect size of 0.16 on mathematics achievement (Cheung and Slavin 2013). In particular, using ICT as a supplementary tool had the largest effect on mathematics achievement. Supplementary ICT tools (e.g., PLATO, Larson Pre-Algebra, SRA Drill and Practice) provide extra instruction to aid traditional classroom learning.
- In an analysis of 36 controlled studies, Kulik (2003) found that students who used computer tutorials in mathematics, natural science, and social science scored significantly higher on tests in these subjects. Students who used simulation software in science also scored higher.
- Hattie's (2009, p. 221) synthesis across 76 meta-analyses of computer-assisted learning found that computers are used effectively when (a) there is a diversity of teaching strategies; (b) there are multiple opportunities for learning such as deliberate practice and increasing time on task; (c) the students, rather than the teacher, is in control of learning (e.g., sequencing and pacing of instructional materials, choice of practice items, reviewing); (d) peer learning is optimized; and (e) feedback is optimized.
- In a meta-analysis of 23 study effects, Means et al. (2013) reported that students in blended learning conditions performed significantly better than students learning the same material through face-to-face instruction alone. In addition, available research evidence from nine comparison studies revealed that using prompts to help students perform self-reflection, self-explanation, and self-monitoring leads to more positive learning outcomes.

Taken together, these findings suggest the following implications. First, it is not sufficient to merely provide access to ICT in schools. Furthermore, the mere training of teachers does not seem to be sufficient. Therefore, to enhance the possible effect of ICT on students' academic performance, it is important for policymakers to address both the appropriate pedagogical use of ICT and the incentives for teachers to use ICT. The second implication is to consider proposing guidelines on Internet use. As mentioned, students who spend more than 6 h online per weekday outside of school hours reported feeling lonely at school and arriving late for school (OECD 2015). Consequently, what specific Internet use guidelines should policymakers in Asia consider? Currently, there is no single standardized policy on worldwide Internet use. Different countries have their own guidelines. The third possible

implication is to consider developing a policy for ICT use at home. Several studies have indicated that student learning can be improved upon when computers are used at home (Delen and Bulut 2011; Papanastasiou and Ferdig 2006; Spiezia 2010). This suggests that policymakers should think about providing students and their families with the financial support for computer purchase and Internet subscription (Spiezia 2010). Spiezia (2010) further recommended that teachers should ensure integration between the use of ICT at home (based on self-directed learning and exploration) and the use of ICT at school.

Also, there appear to be three main challenges toward ICT in Asia. Closing the digital divide is one of the main challenges of ICT in Asia. Given the disparity in terms of GDPs among the many various countries in Asia, it is not surprising that wealthier economies such as Hong Kong, Japan, the Republic of Korea, and Singapore have computers present in almost every household. However, more than half of students in Indonesia (74%) and Vietnam (61%) did not have a computer at home. It is important to note that the issues of digital inequity are also found in developed economies such as Hong Kong (Yuen et al. 2016a, b).

Promoting the safe and responsible use of ICT is a second challenge faced by countries in Asia. A recent UNESCO (2016) study surveyed selected Asian-Pacific countries and reported the following findings. Countries such as the Republic of Korea, Bhutan, Nepal, and Lao PDR did not have any education policies targeting students in the lower primary school level (e.g., 7–8 years old). There were no policies regarding cyber security skills or the ethical use of creative content, and there were no programs promoting appropriate responses to cyberbullying. Although the Fourth Strategy for IT in Education in Hong Kong included students' ethical use of IT as one of its objectives, it provided no overarching framework. Furthermore, while some countries (e.g., Korea, Japan, China, Bhutan, Bangladesh) have policies that focus on cyber security skills, the ethical use of content, and proper responses to cyberbullying for students between 13 and 18 years old, these policies were not monitored or evaluated (UNESCO 2016). Without a proper monitoring and evaluation mechanism in place, it is impossible to determine how effective these policies are. In addition, only 55% of participating countries in the study have policies regarding secure Wi-Fi, networks, and encryption at the secondary level, only 51% have such policies at the primary level, and only 48% at the early primary level (UNESCO 2016). This suggests that many schools are vulnerable to unauthorized access and malicious attacks (UNESCO 2016).

The third challenge is measuring and evaluating ICT literacy skills. Many nations in Asia recognize the importance of promoting ICT literacy skills among students. However, evaluation remains a challenge. How do we actually define ICT literacy skills? How should we measure and assess these skills? Currently, different countries have their own basic ICT standards. For example, in Singapore primary-level students are expected to search for information over the Internet, create a short document using a word processor, and create a short presentation with multimedia elements, while secondary-level students are expected to use functions for calculations in a spreadsheet, represent data using graphs and charts in word processors and spreadsheets, and communicate over the Internet, among other skills (Singapore

Ministry of Education 2009). Hong Kong's secondary-level students are expected to explain the basic components of a computer and how they work to perform computational tasks, describe concepts related to an operating system, explain the social implications of ICT, develop concepts related to structured programming, and create the simple constructs of a computer program, among other things (Curriculum Development Council and Hong Kong Examinations and Assessment Authority 2015). However, in the ICILS 2013, the three participated Asian countries had not consistently exceeded the average score for most items being tested. For example, in the items that tested students' ability to produce and exchange information, Republic of Korea, Thailand, and Hong Kong scored 57%, 30%, and 69%, respectively, while the average score was 66% (Fraillon et al. 2014, p. 77).

Emerging Perspectives for Developments in Asia

This chapter has shown that the ICT policies in the Asian region are related to Moonen's (2008) three main policy lines. However, recent policies have placed more emphasis on the development of students than of teachers. Other stakeholders such as parents are also included in the ICT policies in some Asian countries. We discussed implications of recent empirical research and noted three main challenges in the previous section. Furthermore, we provide emerging perspectives for the development of ICT in education in Asia.

The Internet has become a tool for bringing together the small contributions of millions of people (Grossman 2006). Nonetheless, the Internet remains largely untapped in education. To transform the Internet into a truly universal tool for development, policymakers must tackle not only the supply-side challenges of the Internet, including infrastructural deficiencies and high prices, but also the demand-side barriers that exist outside the ICT ecosystem (ITU 2016). This means that addressing broader socioeconomic inequalities is essential (Yuen et al. 2016a). Above all, students need to acquire not only the necessary digital skills but also other twenty-first-century skills, such as basic literacy and numeracy, communication skills, and critical thinking skills to exploit the potential of the Internet. In terms of ICT in education, policymakers must act as part of a larger Internet ecosystem to empower students and make Internet content easily accessible to disadvantaged groups. ICT policies must also be linked to investments in education to develop the necessary human skills and raise levels of education, thus bringing more people online (ITU 2016).

ICT has served as a lever for change in most Asian countries. Today, ICT leaders may use the *Knowledge Ladder* to make decisions about the number and location of computers, the type of network, the development of teachers, and the purchase of software. More importantly, the *Knowledge Ladder* may be used to position ICT as a lever for changing other components of education and, ultimately, overall change in the system in a way that supports broader development. As technology is introduced or expanded, policymakers may work with others in the education system and use the opportunity to coordinate changes in pedagogy, such as, with teacher professional development that includes training for how new technologies can promote

innovative teaching methods that advance development goals. For example, ICT policies in Singapore take ICT as a way of supporting pedagogical innovation and student-centered learning (UNESCO 2011). However, we need to consider the link between the alignment of local and international goals, such as the Millennium Development Goals, the World Summit on the Information Society, and Education for All (UNESCO-UIS 2009).

Fraillon et al. (2014) indicated that students were more confident in their digital competencies when they had high access to use ICT at home and at school. Confident students also tended to be positive about the effect of ICT on their work and leisure. The ICILS 2013 reported evidence showing that the pedagogical use of ICT is not simply associated with more abundant ICT resourcing. They observed that despite enhanced resourcing in the several years before the study, school use of ICT had not increased since 2006. This context enabled the study to draw attention to the lack of ICT policies in schools. From a sociocultural perspective, it is important to note that students' ICT use at home, either for learning or leisure, is a complex process of interaction between their intentions, objectives, attitudes, and the affordability of new technologies (Yuen et al. 2016a). The concepts of learning and leisure also need to be understood in the context of new digital practices (Drotner 2008). The blurring of ICT use in school and at home raises the issue of whether ICT in education policies need to consider enabling students to engage in learning activities alongside social and leisure activities.

ICT in education in Asia can be viewed from two different perspectives. The first reflects a development discourse that stresses the role of ICT in eliminating the digital divide by reaching the unreached and by providing support to those who cannot access essential infrastructure, trained teachers, and other educational resources. The second perspective adheres to an e-learning paradigm and is a response to the emerging knowledge society in which ways of teaching and learning are evolving at a rapid pace, thus fostering learner-centered educational environments that encourage collaboration, knowledge creation, and knowledge sharing. While countries are admittedly at different stages of integrating ICT in education, ultimately both perspectives will be increasingly relevant for countries in the Asian region (UNESCO-UIS 2014). However, it is important not to overlook Asian culture in addressing this dichotomy. Nisbett (2015) argues that all cultures in East Asia have roots in the Confucian tradition. The influence of the Confucian tradition is evident in Asian societies with different political structures, such as China, Hong Kong, Taiwan, and Singapore, and that such tradition may produce different positions and offer a cultural context for the development and implementation of ICT in education (Yuen et al. 2017).

influencing the integration of ICT in teaching and learning in primary and secondary education. Trends and developments are identified through the analysis of policy documents and published research to highlight differences and similarities between the two countries. The chapter indicates that both countries have introduced digital technologies in schooling in ways which reflect learning with digital technologies, and are shown to be influenced by international trends. Both Australia and New Zealand have been developing curriculum to guide the teaching of students to learn about digital technologies, through computational thinking and coding. A key challenge continues to be providing equitable access to opportunities for teachers and students to integrate digital technologies effectively into teaching and learning. However, New Zealand has a nationally funded policy of providing universal access to Broadband Internet to all schools which research has found to correlate with improved achievement in the primary years and similar infrastructure priorities were evident in Australia. A further challenge is building teacher capability with and dispositions about digital technologies for effective implementation of policies in both countries.

Introduction to ICT in Primary and Secondary Education in Australia and New Zealand

This chapter presents a summary of developments in relation to information and communication technologies (ICTs) in educational policies in Australia and New Zealand. Throughout this chapter, we use ICT and digital technologies synonymously and interchangeably and recognize that ICT and digital technologies are not values-neutral “tools” which can be merely integrated into existing curriculum, pedagogy, and assessment, but are viewed as new and emerging technologies which impact upon curriculum, pedagogy, and assessment.

Subsequent to outlining the contexts of schooling in Australia and New Zealand, recent developments in ICT in schooling in Australia and New Zealand are discussed. Those developments are framed within international trends, challenges, and developments in technology through reference to the *NMC/CoSN Horizon Report: 2016 K-12 Edition* (Adams Becker et al. 2016). Given the dynamic changes in technologies and the implications for policy, recent policy developments are then highlighted. These include policies which respond to challenges relating to infrastructure, governance, curriculum, and expectations for current and future teachers. Relevance of cross-national and worldwide strategies and plans for Australia and New Zealand are then presented, together with a discussion about the challenges and relevance of research for policies on ICT in education in Australia and New Zealand. The chapter concludes with some key perspectives and emerging themes about developments in Australia and New Zealand.

Contexts: Australia and New Zealand

As Sawyer et al. (2015) have noted, the contexts of both Australia and New Zealand today have been influenced by British colonization and settlements. They indicate, for example, as well as having the Union Jack and the Southern Cross on their national flags, both countries have inherited Westminster political institutions and that, when the process of federation began in Australia toward the end of the nineteenth century, there was some thought that New Zealand might become the seventh state, geographically separated by the Tasman Sea. Though this did not occur, Sawyer et al. (2015) explain that there has been significant policy transfer between the two countries which are democratic nations, but the two countries also differ in terms of their political architecture.

In summary, Australia and New Zealand each has a unique identity and context developed over time through a range of historical, social, cultural, political, environmental, and geographical influences. To illustrate, while acknowledging the influence of British settlement on the democratic systems on education policy and the aims and purpose of education is evident in both countries, this chapter will establish that the educational policy responses are uniquely different. Therefore, directly relevant in this chapter is the understanding that these contexts are being shaped by and responding to technological developments. For example, ICT presents educational challenges and opportunities for addressing issues associated with the geographical isolation which is a feature of both countries, as both Australia and New Zealand have diverse population demographics and are distant from other Organisation for Economic Co-operation and Development (OECD) countries. How each country has responded to those challenges and opportunities is discussed in subsequent sections of this chapter.

Schooling in Australia and New Zealand

To logically follow the previous section which provided a summary of the Australian and New Zealand contexts, schooling in Australia and in New Zealand is briefly discussed in this section. This provides the essential context for the subsequent discussion on recent developments in ICT in schooling in both countries.

Schooling in Australia

Essentially, there are three school systems – government, independent, and catholic schools, located in state (New South Wales, Queensland, Victoria, South Australia, Western Australia, and Tasmania) and territory (Northern Territory and Australian Capital Territory) jurisdictions. According to the Australian Bureau of Statistics (ABS 2016a), in 2015, the number of students enrolled in schools in Australia was 3,750,973. Government schools were the major provider (2,445,130 students – 65% of all students), while the remainder (1,305,843 students – 35% of all students) attended either independent or catholic schools. Of those students, 200,563 students (5.3% of all students) were Aboriginal and Torres Strait Islander students. In 2015, there were 9404 schools (ABS 2016b, c), consisting of 6639 government schools,

1737 catholic schools, and 1028 independent schools. There was a total of 301,572 full-time equivalent (FTE) teaching staff in 2015, consisting of 218,849 female teaching staff and 82,723 male teaching staff (ABS 2016c).

These data enable a sense of the scale and diversity of schooling, in terms of sectors and school systems, in Australia. States and territories largely have responsibility for schooling in Australia. This can be traced back to British settlement which resulted in separate colonies which became states when the Commonwealth of Australia occurred with federation in 1901. This has created some tensions between the Australian government and state governments in relation to national approaches to education, while recognizing and respecting state authorities and responsibilities. Examples of different schooling resulting from state education policy decision-making and within the different schooling systems (government, independent, and catholic) include different starting ages of students, variations in curriculum, variations in ICT policy, infrastructure and resourcing, and different expectations and pay scales for teachers. Furthermore, individual schools vary in terms of their autonomy and agency in ICT strategic planning, decisions, and practices.

Schooling in New Zealand

In October 2016, there were 796,993 school students enrolled across New Zealand's 2501 schools. The schools vary in size with 186 having fewer than 30 students and 118 with more than 1000 students (Education Counts 2016a). The majority of students (96%) are enrolled in state or state-integrated schools (government funded with a special character). Each school has its own curriculum developed from one or both national curricula documents, and the purpose of both the English medium and Māori medium versions is to "develop the competencies [young people] need for study, work, and lifelong learning and go on to realise their potential" (Ministry of Education 2007, p. 6).

New Zealand has a devolved schooling system. For state and state-integrated schools, the central government sets educational policy such as national curriculum, pays teacher salaries, and allocates funding to schools for operational expenses and buildings. The state funds centralized quality assurance through the Education Review Office and sets accountability standards that focus on literacy and numeracy for primary schools and qualification attainment in secondary schools. Within this framework each school is self-managing with autonomy to set strategic priorities, develop a school curriculum appropriate for their context drawing on the broad national curriculum and manage resources provided through the operational grant. Thus the state has broad guidelines for curriculum and pedagogical approaches, and each school applies these as appropriate to their context. This creates opportunities and challenges for each school to develop their own approach to the integration and teaching of ICT or digital technologies.

Challenges and Opportunities in Integrating the Regions into One Chapter

Given the differences and variations, for example, between jurisdictions, sectors, and school systems in Australia, this presents a significant challenge within this chapter in representing Australia as a single educational entity with a single set of policies.

This task is exacerbated when attempting to construct a discussion about both Australia and New Zealand. However, while, acknowledging this challenge and the limitations associated with this, there is a wonderful opportunity and great value in attempting to provide a comparative exploration of the developments in ICT in schooling in both countries, through considering their policies in ICT in education, the role of research, and emerging perspectives.

Recent Developments in ICT in Schooling in Australia and New Zealand

Fullan, in his William Walker Oration titled *Leadership in a Digital Age* at the 2015 Australian Council of Educational Leaders Conference, highlighted the three big forces now evident – technology, pedagogy, and change knowledge. He argued that “technology outstrips the others in dynamic movement. . .In any case traditional schooling is an outdated failure...The internal challenge is boredom; the external challenge is uncoordinated threat and opportunity” (Fullan 2015, p. 6). Thus, the discussion in this section initially examines trends, challenges, and technologies from an international or “satellite” perspective, highlighting recent trends, challenges, and developments in ICT schooling in Australia and New Zealand.

Trends, Challenges, and Technologies: Horizon Report

In examining international trends, challenges, and technologies, the *NMC/CoSN Horizon Report: 2016 K-12 Edition* (Adams Becker et al. 2016) identified key short-term, midterm, and long-term trends accelerating technology adoption in K-12 education, challenges impeding technology adoption, and important developments in educational technology over three time-to-adoption horizons. As displayed in Fig. 1, the horizons relate to the period from 2016 through until 2020.

In that report, references are made throughout to developments in Australia and New Zealand, such as the following examples:

- **Long-Term Trend: Redesigning Learning Spaces**
“The New Zealand Ministry of Education. . . .has published a set of guidelines and an assessment tool to help schools apply flexible learning spaces into redesigns and new constructions. All schools are required to comply with these standards...” (Adams Becker et al. 2016, p. 8)
- **Midterm Trend: Collaborative Learning**
“...students and teachers in New Zealand...are using platforms such as WhatsApp to establish an online partnership to bring forth a greater understanding and perspective of the importance of each culture to one another.” (Adams Becker et al. 2016, p. 12)
- **Midterm Trend: Deeper Learning Approaches**
“New Tech Network is working with over 100 schools, districts, and communities across the US and Australia to implement PBL in public schools and offer professional development in facilitating meaningful projects. . . .” (Adams Becker et al. 2016, p. 15)

Challenges	Trends				
	Short-Term (one year or less)	Mid-Term (two to three years)	Far-Term (four to five years)		
Solvable: Those that we understand and know how to solve <ul style="list-style-type: none"> ➢ Authentic Learning Experiences ➢ Rethinking the Roles of Teachers 	<ul style="list-style-type: none"> ➢ Coding as a Literacy ➢ Students as Creators 	<ul style="list-style-type: none"> ➢ Collaborative Learning ➢ Deeper Learning Approaches 	<ul style="list-style-type: none"> ➢ Redesigning Learning Spaces ➢ Rethinking How Schools Work 		
	2016	2017	2018	2019	2020
Difficult: Those that we understand but for which solutions are elusive	Developments in Technology				
	Near-Term (one year or less)	Mid-Term (two to three years)	Far-Term (four to five years)

Fig. 1 Trends, challenges, and technology developments in K-12 education (Adapted from Adams Becker et al. 2016, p. 2)

• **Short-Term Trend: Coding as a Literacy**

“Australian parliament members are working to ensure coding is taught at all primary schools. . .by 2020. (Adams Becker et al. 2016, p. 17)

Trends, Challenges, and Technologies: Australia

Key trends, challenges, and technologies in schooling in Australia include ICT resources in schools and the take-up of digital technologies, implications for curriculum, and the changing knowledge base of future and current teachers to develop and demonstrate technological pedagogical and content knowledge (TPACK) (Misra and Kohler 2006).

In relation to ICT resources in Australian schools, Thomson (2015) reported that “. . .on average, every three students have access to one computer, compared to the international mean of 18 per computer” (Thomson 2015, p. 12) and that there were little variations between jurisdictions, though this ranged from 1:1 ratio in the Northern Territory up to 4:1 in New South Wales. Almost a decade earlier, White

(2008) had also highlighted the substantial provision and take-up of and access to technologies by students in schools and in their homes. Importantly, White (2008) observed that major networking initiatives had been undertaken to improve technology infrastructure in Australian schools so that learning can be designed in the future that enables students to learn anywhere at anytime.

The implications of ICT for curriculum can be conceptualized according to two distinctive considerations in Australia. Firstly, it can be conceptualized as learning and teaching *with* digital technologies. That is, ICT enables teaching and learning experiences to be designed to enable students to access, share, revise, and create learning content using digital technologies. Secondly, it can be conceptualized as learning *about* digital technologies. This is evident through *The Australian Curriculum: Technologies Learning Area* (ACARA 2016a) consisting of two subjects, namely, *Design and Technologies* (ACARA 2016b) and *Digital Technologies* (ACARA 2016c), to be taught to all students from Prep to Year 10. Furthermore, *The Australian Curriculum* (ACARA 2016d) requires students to develop the ICT capability (ACARA 2016e) as one of seven general capabilities expected to be developed across all learning areas.

Both learning *with* and learning *about* digital technologies present new expectations for future teachers. This has been highlighted at the *Queensland Digital Technologies Summit 2016: Initial Teacher Education* (Finger et al. 2016). For example, the Digital Technologies Summit identified initial teacher education strategies (Finger et al. 2016) required for teacher graduates to develop the competencies *with* and dispositions *about* digital technologies required to demonstrate the Australian Institute for Teaching and School Leadership (AITSL) (AITSL 2011a, b) professional standards at the graduate level.

In relation to current teachers, Thomson (2015) drew upon the finding from the *International Computer and Information Literacy Study* (ICILS) (Fraillon et al. 2013) that the most problematic obstacle related to ICT skills of teachers. For example, in the ICILS, the Australian ICT coordinators who were surveyed reported that “75 per cent of Year 8 students attend schools in which the biggest problem reported was the lack of ICT skills among teachers” (Thomson 2015, p. 12). Consequently, there is evidence of increased attention, and research is evident in relation to TPACK in ITE programs and professional learning for teachers as technological knowledge (TK) is being considered important for teachers to develop and demonstrate, along with pedagogical knowledge (PK) and content knowledge (CK).

Trends, Challenges, and Technologies: New Zealand

Key trends, challenges, and technologies in schooling in New Zealand are summarized as being the development of learning spaces through redesigning physical spaces, Bring Your Own Device (BYOD) and mobile devices initiatives, the challenge of equity in relation to access to digital devices, implications for curriculum, and the use of data analytics.

As referred to in the *NMC/CoSN Horizon Report: 2016 K-12 Edition* (Adams Becker et al. 2016), the New Zealand government has prioritized modernizing of

school classrooms across the country, due to the age of existing classrooms, population growth, and the Christchurch earthquakes of 2010 and 2011. The development of *learning spaces* as opposed to classrooms has been a focus since 2010, underpinned by the notion that schooling in a digital age should look different to schooling in an industrial age (Ministry of Education 2015a). The changes in physical learning spaces are underpinned by the notion that teaching and learning at school should be differentiated and responsive to the needs of the students, rather than focused on a teacher delivering a one-size-fits-all curriculum (Ministry of Education 2015a). Increasing access to resources through digital devices can enable the implementation of student-centered pedagogical practices (Hannafin et al. 1997). The central funding of new or altered physical spaces in which teachers collaboratively teach cohorts of up to 120 students reflects the aim that teaching will be more personalized for the students. This is a significant trend in primary schools, particularly for children aged 8–12, with walls being knocked down between existing classrooms and teachers developing ways to work collaboratively. A similar trend is occurring in some secondary schools, with a number exploring flexible timetabling with longer scheduled classes and open plan spaces. These policy directions have not yet been evaluated.

A current trend in New Zealand secondary schools is the introduction of BYOD policies. The majority of secondary schools either allow or require students to bring a device which connects with the school's Wi-Fi for learning and make use of tools such as Google Classroom and subject-specific tools for learning (Johnson et al. 2014). This is complemented by the current ICT focus in New Zealand on the infusion of mobile devices within teaching and learning. In primary schools in New Zealand, mobile digital devices are more likely to be purchased or leased by the school with touch screens being used by younger children and netbooks by older children (Johnson et al. 2014). While some schools have a dedicated one device per student policy, the majority provide access to shared devices that children can use for learning. Interactive whiteboards continue to be utilized in some primary classrooms, although these appear to be losing popularity with the evolving pedagogy and availability of large flat-screens with functions such as Chrome casting.

A significant challenge is equitable access to digital devices for learning. Primary schools in low socioeconomic contexts purchase fewer devices than those in higher socioeconomic contexts. In some low socioeconomic contexts, trusts, such as Manaiakalani (Jesson et al. 2015), have been established to assist families purchase or lease netbooks for learning at home and school. However, equitable access to devices and the Internet at home across the country is a challenge in the current context.

A further challenge is teaching a curriculum that enables students to become digitally competent. ICT are embedded in the technology learning area of the New Zealand Curriculum (Ministry of Education 2007). Each school develops their own curriculum from the national document and determines the extent that computing and digital technologies are taught across the school. The teaching of coding is not explicit or required in the existing flexible national curriculum, although this is being introduced in 2018 (Ministry of Education 2017). In recent

years, coding clubs have been introduced to some primary schools as an option or extracurricular activity, and there has been a growth in robotics taught as part of the technology curriculum to 10–13-year-olds. Some primary schools have been exploring the teaching of computer programming, usually introduced by a teacher with a passion for coding (Falloon 2016).

Computing is offered as a subject in New Zealand secondary schools and can contribute to national qualifications for students in their final years at school. In 2015, out of 524 secondary schools, 79 taught computer science/programming, 242 taught computer studies, and 222 taught ICT. Less than 1% of students attending secondary school were studying computer science/programming (Education Counts 2016b). However, this may increase as a digital technologies strand within the national curriculum is being developed with an emphasis on computer programming for implementation in 2018 (Ministry of Education 2016b).

The use of data analytics is emerging in New Zealand schools. While data are predominantly used for accountability purposes, such as the evaluation of teacher and school effectiveness, the opportunities for broader use of digital data are being explored (Sutherland 2015). Teachers are increasingly using student achievement data to inform their teaching programs and pedagogical decisions, and principals are analyzing a range of digital data to inform school policy and decision-making. A challenge in developing the use of data is the availability of appropriate analytical tools and knowledge of how to maximize this resource.

Recent Developments in Policies on ICT in Australia and New Zealand

In this section, some of the recent developments in policies are discussed, within the context of understanding the contexts summarized earlier and the trends, challenges, and developments in technology.

ICT Policy Developments in Australia

ICT policy developments in Australia can be traced back to the 1980s as personal computers started to appear in schools and then revised as the Internet appeared during the mid-1990s. For example, in Queensland, Australia, the initial policy was *Computers in the Curriculum* (Department of Education, Queensland 1983) and was revised substantially with *Schooling 2001* (Education Qld 1997), which envisaged every classroom being connected to the Internet. More recent developments in that jurisdiction include the Smart Classrooms strategy designed to provide “direction for harnessing the learning and business potential of ICT now and into the future” (Qld Government 2016). That strategy is conceptualized according to four ICT eLearning drivers, i.e.:

- Working Digitally (e.g., OneSchool, OnePortal, Dream Factory) – outlines how schools use digital technology to move from traditional to transformational ways of working

- Developing Professionals (e.g., Digital Practice Guide, OneChannel) – articulates expectations for teacher and leader capabilities
- Enabling Learners (e.g., The Learning Place – Student Spaces and Staff Spaces) – focuses on addressing learners’ needs through effective learning environments
- Harnessing the Enterprise Platform (e.g., Managed Internet Service, Websites for Schools, Computers for Teachers) – focuses on the processes, systems, and practices to develop and maintain effective learning and business productivity (Queensland Government 2016)

Similar examples can be identified within the other jurisdictions, and more recent policy responses have tended to reflect dynamic, and often disruptive, transformational technological changes, such as the emergence of laptop programs, mobile devices, social media, and BYOD initiatives. Many policies and curriculum have needed to ensure that the implications of learning *with* and *about* ICT are appropriately responding to those technological changes. Moreover, these challenges have required a collaborative approach at the national level. The *Digital Technologies Hub* (Education Services Australia 2017) is a tangible example of a national approach in providing “learning resources and services for teachers, students, school leaders and parents” (p. 1), support “the implementation of quality Digital Technologies programs and curriculum in schools” (p. 1), and to leverage “events and activities offered by education jurisdictions, industry and other providers” (p. 1).

To illustrate, all Australian education ministers were signatories of the *Melbourne Declaration on Educational Goals for Young Australians* (MCEETYA 2008). This declaration sought “to achieve the highest possible level of collaboration with the government, Catholic and independent school sectors and across and between all levels of government” (MCEETYA 2008, p. 5). That declaration stated that, “In this digital age, young people need to be highly skilled in the use of ICT. While schools already employ these technologies in learning, there is a need to increase their effectiveness significantly over the next decade” (MCEETYA 2008, p. 5).

Subsequently, Lloyd et al. (2016) have noted that the Melbourne Declaration has led directly to the development of *The Australian Curriculum* (ACARA 2016d), which includes the ICT capability to be developed across all learning areas (ACARA 2016e). As discussed earlier, *The Australian Curriculum: Technologies Learning Area* (ACARA 2016a) has become an approved curriculum and includes *Design and Technologies* (ACARA 2016b) and *Digital Technologies* (ACARA 2016c) subject areas. They also refer to the *Australian Professional Standards for Teachers* (AITSL 2011a), which outlines expectations across four career stages – graduate, proficient, highly accomplished, and lead teacher. In referring to those *Australian Professional Standards for Teachers*, they acknowledge that while there is “no formal nationally-accepted ICT Professional Development Strategy for Teachers in Australia... many Standards can be demonstrated through the meaningful use of ICT in the classroom” (Lloyd et al. 2016, p. 25). Importantly, in relation to future teachers, all initial teacher education (ITE) programs in Australia must be approved and reviewed through program accreditation processes informed by those professional standards.

In summary, recent ICT policy developments in Australia find expression both at the national level and within jurisdictions, with significant implications for learning *with* ICT through the development of ICT capability across all learning areas and learning *about* digital technologies through the technologies learning area and its subjects, namely, Design and Technologies and Digital Technologies. In addition, informed by the *Australian Professional Standards for Teachers* (AITSL 2011a), there are expectations for current and future teachers to develop and demonstrate the efficacy to design and implement learning experiences for students to learn *with* and *about* ICT.

ICT Policy Developments in New Zealand

ICT policy developments in New Zealand have enabled technological innovation to overcome barriers of access to learning within rural New Zealand. Regional networks established in the 1990s, such as OtagoNet, have enabled the sharing of teachers and resources across schools for students attending rural schools (Barbour and Wenmoth 2013). This began as video-conferencing and has evolved to use a variety of ICT and a brokerage system whereby school networks can offer to teach a course and, in return, their students can access courses on the network. Urban networks such as the Wellington Loop have enabled the development of infrastructure and technical support across clusters of school (Barbour and Wenmoth 2013). These regional initiatives have informed current policy directions.

A national infrastructure development of laying fiber cable across the country included providing ultrafast broadband or rural broadband to every school in New Zealand by 2015 and the establishment of the *Network for Learning* (Crown Fibre Holdings n.d.). *Network for Learning* was established to manage the rollout of broadband to schools, and part of the function of this initiative has been to develop a repository or shared space, where teachers can share and evaluate digital resources. This innovation aimed to improve network capability and reduce geographical and socioeconomic inequities in Internet access between schools. Research suggests that the introduction of broadband is correlated to improved achievement in primary schools (Grimes and Townsend 2017). While the government developed the infrastructure to enable broadband access, the development of ICT policy for teaching and learning in New Zealand is the responsibility of the leadership or governance of individual schools; there are no national policies on how digital technologies should be used for teaching and learning apart from a brief statement in the national curriculum about how ICT can support teaching and learning (Ministry of Education 2007). The ICT policy developments are currently focused within and across groups of schools.

The devolved system of governance, introduced in 1989, included a model in which individual schools competed for student enrolments. This model sometimes skewed school-based decisions to consider the marketing potential or impact on the perceived image of the school to attract students and in some cases limited collaboration between schools who perceived themselves to be in competition (Wylie 2012). A current political direction in New Zealand is to increase collaboration across schools by encouraging networks of schools in a similar context to form

communities of learning (Ministry of Education 2016a). This national policy direction has implications for the development of ICT policies and sharing of resources across clusters of schools in a way that supports and enhances the earlier regional initiatives.

Both Australia and New Zealand have a strong history in distance education for rural and isolated students. E-learning is an area that is rapidly evolving and provided some pioneering work within the use of technologies for learning at school. A policy change on the horizon in New Zealand is the introduction of communities of online learning (COOL) schools (Ministry of Education 2016c). Currently, there is one national distance education school that is fully funded by the government that was originally established for the education of rural and isolated students, but over time the students enrolled have changed to include a wider demographic (Barbour and Wenmoth 2013).

Cyber safety is taught in most schools under the Health or Hauora learning area of New Zealand Curriculum (Ministry of Education 2007). This is embedded within learning about personal safety such as the “keeping ourselves safe” program offered by the New Zealand Police (New Zealand Police n.d.) and through advice and resources developed by NetSafe, an independent national organization (Netsafe n.d.).

In contrast to Australia, New Zealand does not have explicit accountability requirements for teachers to use digital technologies or ICT in their teaching practice. The professional standards which guide primary and secondary teacher evaluation for certification purposes have one reference, i.e., that teachers will “select teaching approaches, resources, technologies and learning and assessment activities that are inclusive and effective for diverse ākonga (learners)” (Education Council 2015, Criteria 9ii). However, it would be difficult to meet the range of criteria without using the digital technologies that are infused into the work of a teacher. For example, the professional standards state that fully certified teachers are able to “analyse assessment information” (Criteria 11) which in most schools would include analyzing digital data integrated into a student management system. Therefore digital technologies while not explicit within professional standards are implicit.

Relevance of Cross-National and Worldwide Strategies and Plans for Australia and New Zealand

The discourse about education within Australia has increasingly been influenced by international and jurisdictional comparisons being conveyed through, in particular, analysis of the performance of Australian students in the 2015 *OECD Programme for International Student Assessment (PISA)* (OECD 2016), *Trends in International Mathematics and Science Study (TIMSS)* (see Thomson et al. 2016), *International Computer and Information Literacy Study (ICILS)* (see Fraillon et al. 2013), the *National Assessment Program – Literacy and Numeracy* and the *National Assessment Program – ICT Literacy* (ACARA 2012). These will continue to be important, but a wider agenda is needed that encompasses a broader and deeper curriculum for young Australians than these areas measured by these testing programs.

New Zealand national policies are also influenced by international trends including student achievement in PISA and TIMSS. The development of learning environment policy is attributed to OECD reports (2006, 2013). The introduction of the digital technologies curriculum drew on curriculum developed and implemented in Australia and England (Bell et al. 2014). Strategies and plans at a school level are influenced from regional experiences and can reflect the unique context of the schooling environment (Barbour and Wenmoth 2013).

Challenges and Relevance of Research for Policies on ICT in Education in Australia and New Zealand

The interface between research, policy, and practice underpins research for policies on ICT in education. Research can provide guidance for informing policies in Australia and New Zealand in a digital age.

Challenges and Recommendations for Policies on ICT in Australia

Thomson (2015) appropriately asks the central questions: Where to from here? and “Is Australia on track to realise the aims of almost a decade ago, to ensure that ‘young people need to be highly skilled in the use of ICT’?” (Thomson 2015, p. 16). She highlights a range of comparative performances with other countries as well as historical data and trends to indicate that much has yet to be done to address differences in outcomes associated with socioeconomic disadvantage, challenges associated with attracting female students to ICT courses, and building student confidence in their ability to perform higher level ICT tasks. That is, Thomson uses research to critique policy in her suggestion that “Our education system could well be creating basically proficient ICT users but very few technicians, innovators or developers” (Thomson 2015, p. 16). In addition, she cited Livingstone (2015) who has argued that:

...for Australia to succeed in a digital age, we should be starting the digital education of our students in the beginning years of primary school, introducing skills such as computational thinking, problem solving and computer coding. This is a giant leap from where Australia is now, and will require determined policy and a great deal of teacher professional development (Livingstone 2015, cited in Thomson 2015, p. 17)

The recent developments in terms of curriculum and expectations for future and current teachers appear to be largely “on track” to meet the challenges. For example, the Digital Technologies (ACARA 2016c) requires teachers to implement a project-based learning approach in which students from Prep to Year 10 (5–15-year-olds) develop systems thinking, computational thinking, and design thinking to create digital solutions to real-world problems. Thus, in Australia, there is momentum and an appetite for key stakeholders to collaboratively enable future and current teachers to develop the competencies with and dispositions about digital technologies needed in a digital age (Finger et al. 2016). The interface between research, policy, and

practice in Australia requires focused attention on the role of research to inform both policy and practice, particularly in relation to ICT infrastructure and resourcing which provides guidance in relation to access and meaningful use of new and emerging digital technologies for teaching and learning, curriculum design, implementation and review, and building teacher capabilities for a digital age.

Challenges and Recommendations for Policies on ICT in New Zealand

A challenge and ideal in New Zealand is to have an equitable education system that narrows or closes digital divides (Starkey et al. 2017). While New Zealand students achieve comparatively well in the PISA research, there is a significant difference in academic achievement between advantaged and disadvantaged students (OECD 2016). These differences could widen given the current funding and devolved governance model within New Zealand (Wylie 2012).

While central policy has led to ultrafast broadband being made available to all schools, how this is used and the purchase of technology to access the Internet is decided independently at each school. Research has identified that schools with a higher proportion of disadvantaged students report spending more on digital technologies for student learning and less on teacher professional learning than those with a lower proportion of disadvantaged students (Johnson et al. 2014). The potential for digital divides to widen should be considered in educational policy and could be mitigated through targeted funding and curriculum design such as developing a profile of digital competence for learners and the deliberate teaching to enable all young people to leave school with the digital competence to be active participants in society (Starkey et al. 2017).

Perspectives for Developments in Australia and New Zealand and Emerging Themes/Perspectives

In Australia, learning *with* and *about* digital technologies is a useful conceptualization for understanding teaching and learning expectations for teachers and students and the design of curriculum discussed earlier in this chapter. Of direct relevance is *The Australian Curriculum: Technologies Learning Area* (ACARA 2016a), the *Design and Technologies* (ACARA 2016b) and *Digital Technologies* (ACARA 2016c) subject areas, and the ICT capability (ACARA 2016e) expected to be developed by students within all learning areas. It was established that these present new expectations for many teachers, as, for example, the *Digital Technologies* subject area is being introduced for the first time and is being mandated in Prep–Year 10. These developments in Australia are integral to the Science, Technology, Engineering and Mathematics (STEM) agenda in Australia. That STEM agenda and vision are being expanded to include digital literacy through concrete strategic planning, strategies, and funding support articulated in Australia's *National Innovation and Science Agenda* (Australian Government, Department of Education and Training 2016) termed *Inspiring all Australians in digital literacy and STEM* (Australian Government, Department of Education and Training 2016), which involves:

- Upskilling our teachers to be able to implement *The Australian Curriculum: Digital Technologies*
- Upskilling our students, through various computing and coding challenges, computer science summer school, and focusing on underrepresented students in STEM subjects, such as female students
- Facilitating partnerships with industry
- Digital Literacy School Grants, which schools and other organizations can apply for to facilitate the implementation of *The Australian Curriculum: Digital Technologies*
- Engaging in the early years, through providing funding of \$14 million over 4 years to promote positive STEM learning experiences with children aged 3–5 years
- Funding of \$112.2 million for *Inspiring all Australians in digital literacy and STEM* (Australian Government, Department of Education and Training 2016)

In New Zealand, all schools have reliable fast Internet access, and the focus is now on how digital technologies are integrated or infused into education (Ministry of Education 2015b). A review of STEM education and the resulting strategic plan (New Zealand Government 2014) has led to strengthening the place of digital technologies in the national curriculum which will place an emphasis on coding and computational thinking to be implemented in 2018–2019 (Ministry of Education 2017). The government has released contestable funding of 1 million dollars to support schools to pilot learning programs teaching coding to enable each school to consider how they might integrate this aspect of the curriculum into their technology programs. This places a significant challenge particularly within primary schools where teachers usually teach all aspects of a curriculum and have limited experience of computational thinking or coding.

Conclusion

To conclude this chapter, we emphasize the variation and similarities across the contexts within New Zealand and Australia and how this influences ICT policies. Both countries are influenced by international trends, and attention is given to their rankings within international tests, such as PISA and TIMSS. At the political and policy level, tensions and contradictions are evident in relation to this, for example, with some reductive policy advocacy more suited to an analogue world. Rather, we suggest that there are policy responses occurring in response to the dynamic opportunities and challenges presented by new and emerging ICT.

As outlined earlier, within Australia various national and jurisdiction policies are currently shaping how students learn *with* and *about* ICT. The last decade of curriculum developments in this regard has been largely informed by the *Melbourne Declaration on Educational Goals for Young Australians* (MCEETYA 2008), which involved collaboration between all education ministers and across all systems of schooling in Australia, i.e., state, catholic, and independent schools. Guided by that

framework and within the context of competitive federalism, *The Australian Curriculum* (ACARA 2016d) has been developed with a new *Technologies Learning Area* (ACARA 2016a) developed, consisting of the two subject areas, namely, *Design and Technologies* (ACARA 2016b) and *Digital Technologies* (ACARA 2016c). The various state and territory jurisdictions in Australia are at varying phases of implementing this. Furthermore, within *The Australian Curriculum*, the ICT capability is a general capability to be developed across all learning areas. The policy and curriculum implications in Australia also are reflected appropriately in expectations for current and future teachers articulated in the *Australian Professional Standards for Teachers* (AITSL 2011a). There are significant implications for upskilling Australia's teachers and students explicitly articulated in Australia's *National Innovation and Science Agenda* (Australian Government, Department of Education and Training 2016).

In New Zealand, national policies guide the development of infrastructure and individual schooling policies to enable the development of the use of ICT within teaching, learning, and curriculum. For example, a national policy prioritized the provision of fast broadband Internet connection to schools across New Zealand which created the context for increasing the use of the Internet within learning programs. Evaluation of this policy identified a positive correlation between the introduction of fast broadband and student achievement within primary schools (Grimes and Townsend 2017).

National policies in New Zealand do not specify which ICTs should be used for teaching and learning or how they should be used although the national curriculum does outline why they should be used (Ministry of Education 2007). Likewise, ICT use is not explicit in teacher standards; instead it is implicit as it would be difficult for teachers to meet quality assurance measures without using digital technologies. Therefore it is the responsibility of the individual school to make the decision about the use of ICTs for teaching and learning and justify their policies to the Education Review Office. Research from New Zealand that explores policy and implementation is focused on access to technologies which reflects equity concerns.

A current development within both New Zealand and Australian policy is the introduction of computational thinking and coding named as "digital technologies" as part of technology learning across levels within the respective national curricular. This is in the early stages of implementation with Australia ahead of New Zealand. The need for teacher professional learning has been recognized in both countries, and this is being supported through allocated funding. The outcomes of this policy have not yet been evaluated.

Key ideas from ICT policies and implementation in Australia and New Zealand include the importance of context when considering whether ICT needs to be explicit or implicit within policy. The provision of broadband Internet access appears to make a difference to student learning at the primary school level. The changing expectations of teachers and school leaders to prepare students to be active and successful citizens in the world today and in the future present both challenges and opportunities which require active collaboration of research, policy, and practice within and across both countries.

When we consider, with increased life expectancies, that students entering schools in Australia and New Zealand in 2017 are likely to complete their schooling in 2029, and some might be alive beyond this century, this is critically important policy work. There are significant implications for curriculum, in relation to learning and teaching *with* and *about* digital technologies, and for the professional expertise of a teacher in a digital age.

Abstract

This chapter reviews ICT and education policy in the United States and Canada; both countries have populations with diverse cultures, languages, socioeconomics, and ideologies. Generally local school authorities provide education, while state/territory and national bodies exert influence. Focus areas in this chapter include ICT infrastructure, protections for student data and privacy, data interoperability, personalized learning, online assessment, and updates to national technology standards and frameworks. In addition to evolving infrastructure, issues related to supporting “future-ready” learning, perhaps of equal importance, is the ongoing evidence-based evaluation of educational technology and effort to increase the pace and rigor of evidence associated with educational technology purchases and renewals by school districts. Some school systems are moving toward a competency-based education (CBE) model which often requires policy shifts. There is growing interest in exploring new models for teacher preparation and development as well as calls for increased personalization of student learning. Policy debates continue around the degree of equal access to technology that government should require, including whether parity should be required in terms of device age and availability, quality and availability of digital learning materials, and classroom bandwidth and whether the technology is being used actively or passively by students across all socioeconomic groups and across all schools. As policy makers grapple with the displacement of jobs and loss of employment due to advances in technology and continued growth in income inequality, they may turn to policies that encourage better alignment between K-12 education and the skills needed for future careers.

Introduction to ICT in Primary and Secondary Education in the United States and Canada

The socio-educational landscape in the United States and Canada can be characterized by geographically expansive countries comprised of states, provinces, or territories, whose educational realities and policies reflect socioeconomically,

culturally, linguistically, and ideologically diverse perspectives. In Fall 2016, according to the National Center for Education Statistics, approximately 50.4 million students attended public elementary and secondary schools in the United States (NCES 2016). In the United States (US) decentralized education system, generally kindergarten through 12th grade (K-12) schools are run under local control of a school board that is responsible for setting policy and serves as the authority of the district (or diocese) of schools. However, each state does influence what happens in schools through policies and practices in critical areas such as teacher licensure, high school (secondary) graduation standards and requirements, funding patterns, and legislation (Anderson and Dexter 2009).

The federal government has very little direct control over the nation's schools; education is controlled entirely by the states. There is no national curriculum for education, and schools only receive a small percentage of funding from the federal government. This is especially true at the elementary and secondary level, where about 92% of the funds come from nonfederal sources (US Department of Education 2017b). That means the federal contribution to elementary and secondary education is about 8%, which includes funds not only from the US Department of Education (USDOE) but also from other federal agencies, such as the Department of Health and Human Services' Head Start program and the Department of Agriculture's School Lunch program.

The US Department of Education (USDOE) is influential by making additional funding available for national initiatives, with an emphasis on evolving high-need focus areas, and by developing and disseminating educational plans and national reports and making critical recommendations. ICT policies and practices in K-12 education at the state and national levels follow the same pattern of local control influenced by state and federal funding opportunities and policy recommendations (Anderson and Dexter 2009, p. 698). Federal grants support focus areas like high-poverty schools; teacher professional development; science, technology, engineering, and mathematics (STEM); and programs focusing on English language learners, students with special needs, etc. Generally, national large-scale assessments are administered annually in content areas like mathematics and reading.

While there are similarities in the education systems in states across the United States, there are generally differences in curriculum, large-scale assessment, and accountability policies. To date, 42 states, the District of Columbia, and four territories have adopted the Common Core State Standards. Launched in 2009 by state leaders through their membership in the National Governors Association Center for Best Practices (NGA Center) and the Council of Chief State School Officers (CCSSO), the Common Core State Standards (CCSS) provide a set of shared goals and expectations for the knowledge and skills students need in English language arts/literacy and mathematics at each grade level, including the use of technology and media, so that they can succeed in college, career, and life. Though the states of Alaska, Indiana, Nebraska, Oklahoma, South Carolina, Texas, and Virginia are not presently adopting the standards at a state level (Common Core State Standards Initiative 2017), many of these state standards are similar in content to the CCSS. An additional effect of the wide adoption of the CCSS and similar

standards has been the ability to create digitally based assessments that allow results to be shared across state lines (ETS 2016, p. 4).

Canada constitutionally recognizes French and English as its two official languages. Canada's decentralized education system is the responsibility of the ten provincial and three territorial governments with approximately 4.74 million students attending public elementary and secondary schools in 2014–2015 (Statista n.d.). There is no federal department of education and no direct funding for public schools, with two exceptions: (1) the federal government does provide financial support for official minority language education in public schools. In the 12 provincial/territorial jurisdictions where English is the predominant and official language, this includes education in French and includes education in English in Québec where French is the official language. Under federal legislation, (2) the federal government is also responsible for funding the education of Aboriginal children of the First Nations living on reserves (Rich 2009, p. 120).

The differences in curriculum, assessment, and accountability policies in Canada's provincial and territorial education systems are influenced by the geography, culture, history, language, and specific needs of the diverse populations served. In the 13 jurisdictions, departments or ministries of education have curriculum departments and are responsible for the organization, delivery, and large-scale assessment of education at the elementary and secondary levels (Council of Ministers of Education Canada 2017). At the local level, elected school boards generally oversee the education system for districts, representing the interests of their constituents within the legal framework of the province or territory.

While there is not a federal department of education, the Council of Ministers of Education, Canada (CMEC) was formed in 1967 by the provincial and territorial ministers responsible for education, to undertake educational initiatives cooperatively and represent the interests of the provinces and territories with national and international organizations and federal and foreign governments. The CMEC provides a national voice for education, and, through the CMEC, the provinces and territories work collectively on a wide range of priorities at the elementary, secondary, and postsecondary levels (Council of Ministers of Education Canada 2017).

Recent Developments on ICT in the United States and Canada

Several recent developments in ICT in the United States and Canada focus on areas like infrastructure, protections for student data and privacy, data interoperability, personalized learning, online assessment, and updates to national technology standards and frameworks.

ICT Infrastructure in Schools

ICT infrastructure in the United States is supported by the federal E-Rate program, which was mandated by Congress in 1996 and implemented by the Federal

Communications Commission (FCC) in 1997, and has the goal of reducing the cost of Internet access for schools and libraries. Historically, the program was effective in providing basic connectivity to schools, but resulted in insufficient bandwidth in classrooms. Significant progress has been made in recent years in providing broadband to classrooms as a result of the modernization of the E-rate program (see section “[Recent Developments on Policies on ICT in the United States and Canada](#)”).

A robust technology infrastructure is essential to “future-ready” learning environments (USDOE 2016, p. 41). Having adequate bandwidth is essential for teachers and students to utilize digital content. Low bandwidth is extremely problematic when trying to stream interactive or media-rich content, especially under the demands of a 1:1 classroom environment. The CoSN (2016) Annual E-Rate and Infrastructure Survey Report, which documents infrastructure changes in the United States, finds that school systems are making substantial progress toward meeting the FCC short-term goal of 100 Mbps per 1,000 students with more than two thirds (68%) of school systems reporting that all schools in their system fully meet the minimum Internet bandwidth recommendations. This number climbs to 80% of school systems having three fourths of their schools at this immediate connectivity goal, representing a significant improvement from 19% in just 4 years across urban, rural, and suburban districts.

Given that the education system in Canada is decentralized, national reports synthesizing ICT policies and practices are intermittent. Some cross-national or national profiles of ICT policies and practices in education in Canada have provided summary data and illustrative examples from select provinces (Milton 2015; USDOE 2011). The International Experiences with Technology in Education (IETE) Report, for example, includes the following findings for Canada: (a) improving Internet connectivity in primary and secondary schools is a top priority in national efforts to improve education (e.g., SuperNet high-speed network project in Alberta provides broadband connections to the Internet for all public institutions, including schools), (b) Canada is one of the seven countries to report national initiatives to deliver online instruction for students (e.g., the Alberta Distance Learning Centre serves 30,000 elementary and secondary students with distance learning services, including fully online courses, and manages the province’s virtual school), (c) Canada is included in the eight participating countries to report the implementation of programs for using ICT for summative assessments, and (d) Canada was also one of the 17 of 21 countries that reported teacher technology standards in place in 2010 and also conducted some form of assessment of teacher ICT skills. Notably, Alberta was the participating province for this report (USDOE 2011, pp. viii–ix).

The British Columbia (2016) Education Plan also offers an illustrative example of efforts to improve infrastructure in Canadian schools. The Ministry continues to support quality technology-related learning through their next-generation network (NGN). “[The] initiative [is] transforming the Provincial Learning Network to a high-capacity, modern system that can grow and adapt to changing needs. The initiative will convert approximately 1,650 School District sites to the NGN over a period of three years” (p. 10).

Similarly, Ontario is improving access to high-speed broadband connectivity in schools across the province. In particular, infrastructure improvements focus on northern, rural, and remote schools to provide all students with reliable and equitable access to learning resources (Queen's Printer for Ontario 2017, para. 1). The \$50M initiative will move Ontario's schools toward equitable access to adequate broadband speed in three waves over the next 4 years (para. 5).

Protections for Student Data and Privacy

Protections for student data and privacy have also become a growing priority and concern in the United States and Canada (Government of Canada 2017; Library of Congress 2015). According to the US National Educational Technology Plan, the use of student data is crucial for personalized learning and continuous improvement. As stewards, schools and districts have an obligation to inform students and families about the kind of student data the school or third parties (e.g., online educational service providers) are collecting and how the data can be used (USDOE 2017b, p. 79).

The US Department of Education, along with other organizations (Library of Congress 2015), offers schools and families resources and examples, training, and other assistance in navigating privacy concerns in the United States and Canada (USDOE 2017b; Government of Canada 2017).

Data Interoperability and Standards

Increasingly, educators and other stakeholders have the need to enable data sharing through an existing or custom application program interface (API) or through a data export option. In order to be useful, the data need to be in a common format, and rules must be applied to map common data fields across the systems. Data interoperability frameworks have been established to ensure data are presented in usable formats. There are several examples of existing frameworks, resources, and organizational alliances that address the issue of data interoperability:

- The Schools Interoperability Framework (SIF) is an open data sharing specification that includes Extensible Markup Language (XML) for modeling educational data and service-oriented architecture for sharing the data between institutions.
- The Ed-Fi Alliance supports the creation of a common data standard for communication among educational tools and systems. Ed-Fi technology aligns with the Common Education Data Standards (CEDS) established by the National Center for Education Statistics (NCES) and works closely with other entities such as the IMS Global Learning Consortium to expand interoperability.

- Project Unicorn, a grassroots effort to improve interoperability in K-12 education, works with school systems and vendors to create a demand for secure interoperability.

Personalized Learning

Educators in both the United States and Canada have given increased attention to personalized learning (USDOE 2016; Milton 2015) which refers to instruction in which the pace of learning and the instructional approach are optimized for the needs of each learner. Learning objectives, instructional approaches, and instructional content (and its sequencing) may all vary based on learner needs. Technology can enable personalized learning or experiences that are more engaging, relevant, and student-driven (USDOE 2016, p. 7).

Additionally, all students deserve equal access to (1) the Internet, high-quality content, and devices when they need them and (2) educators skilled at teaching in a technology-enabled learning environment. When this occurs, it increases the likelihood that learners have personalized learning experiences, choice in tools and activities, and access to adaptive assessments that identify their individual abilities, needs, and interests (USDOE 2016, p. 30).

Personalized Student Learning

- Technology enables personalized pathways for student learning through active and collaborative learning activities. Clearly defined sets of learning outcomes guide instruction. The outcomes, and the aligned curriculum, instruction, and assessment, reflect the multidisciplinary nature of knowledge, prepare students for our participatory culture through attention to digital literacy and citizenship, and attend to general skills and dispositions, such as reflection, critical thinking, persistence, and perseverance.
- Leaders ensure that policies and resources equip teachers with the right tools and ongoing support to personalize learning in their classrooms.
- Teachers collaborate to make instructional decisions based on a diverse data set, including student and teacher observations and reflections, student work, formative and summative assessment results, and data from analytics embedded within learning activities, and software aided by real-time availability of data and visualizations, such as information dashboards. Leadership policy and teacher methods support student voice and choice in the design of learning activities and the means of demonstrating learning. Students frequently complete a series of self-directed, collaborative, multidisciplinary projects and inquiries that are assessed through a profile or portfolio. Technology is integral to most learning designs, used daily within and beyond the classroom for collaboration, inquiry, and composition, as well as for connecting with others around the world. In the classroom, teachers serve as educational designers, coaches, and facilitators, guiding students through their personalized learning experiences (USDOE 2017b).

Personalized learning has been widely discussed and advocated for in Canada as well. Authors of the C21 Canada report argue:

The well-tested methods of making change in education through incremental improvement are insufficient to the task of transforming schools into 21st century learning environments. We see the possibilities in many individual schools and classrooms – where personalization of the curriculum is the natural outgrowth of students’ interests and aptitudes; where students communicate with subject experts worldwide; where classroom discipline and culture are established by students because their work is interesting and valued by themselves and those they connect to. (Milton 2015, p. 6)

Online Assessments

Recent developments in next-generation online assessments and performance-based tasks are attempting to measure a broader array of high-order skills and competencies that include critical thinking, problem solving, and socioemotional skills (ETS 2016, p. 3–5). Vander Ark and Schneider (2012) suggest that “the adoption of internationally benchmarked college- and career- ready standards in literacy and numeracy (Common Core or equivalent) and the move to online next-generation assessments are two key indicators that a national movement is building” (p. 3). Moreover, Vander Ark and Schneider and a number of stakeholders contend that students graduating into [an] increasingly global, technology-rich knowledge economy will need an expanded skill set to succeed (p. 3). In addition to the creation of digitally enhanced summative assessments, online formative assessments continue to be developed and adopted to inform daily instruction (Molnar 2017).

According to the Ontario Ministry of Education (2016), the Education Quality and Accountability Office (EQAO) is “exploring technology-enabled assessment, beginning with the use of computer-based assessments as an alternative to paper-and-pencil tests, with the hope of moving towards more transformative-based assessments in the future” (p. 41).

Increased Accessibility

As technology-enhanced tools and curricular materials become more widely adopted, demand increases for accessibility features to be built-in from inception in order to meet the needs of more students. Many of these tools and curricular materials are being built using principles of Universal Design for Learning, a framework for the design of materials and instructional methods that are usable by a wide range of students. Specifically, “UDL design principles take a holistic approach to learning in which curriculum, procurement, the LMS, and policy work together to support the needs of all learners” (Gronneberg and Johnston 2015). Gronneberg and Johnston (2015) argue that though the aim of UDL is to provide full access to students with special needs, the approach “offers significant affordances for all students, allowing them to benefit from learning presented

through multiple sensory avenues and a variety of conceptual frameworks. Early research about the influence of UDL is positive, showing that it improves engagement and performance among all students” (p. 2).

Updates to Technology Standards, Competencies, and Frameworks

Significant work has been done to develop and update technology standards, competencies, and frameworks in recent years. There is now widespread consistency on the twenty-first-century competency foci (e.g., critical thinking, problem solving, digital literacy, digital citizenship) needed for students to be successful (e.g., CMEC 2011; ISTE 2007, 2016; Ontario Ministry of Education 2016). The widely used set of International Society for Technology in Education (ISTE) standards, for example, “emphasize ways that technology can be used to amplify and even transform learning and teaching,” rather than focusing on education technology tools, and work in concert to support key stakeholders (e.g., students, teachers, administrators) with clear guidelines as they rethink education and adapt to a constantly changing technological landscape” (ISTE 2016). The ISTE standards are student-driven and focus on student agency across respective focus areas, standard statements, and indicators. The focus areas are (a) empowered learner, (b) digital citizen, (c) knowledge constructor, (d) innovative designer, (e) computational thinker, (f) creative communicator, and (g) global collaborator. The recently updated ISTE Standards for Students (2016) provide an aspirational framework to leverage technology for learning transformation. A recent focus on digital citizenship is also evinced across ICT frameworks and standards (e.g., ISTE 2016; Hoechsmann and DeWaard 2015). In unpacking the ISTE Digital Citizenship focus, the standard “Students recognize the rights, responsibilities and opportunities of living, learning and working in an interconnected digital world, and they act and model in ways that are safe, legal and ethical” maps to four indicators (e.g., *students cultivate and manage their digital identity and reputation and are aware of the permanence of their actions in the digital world*).

Similarly, Hoechsmann and DeWaard (2015) describe digital citizenship as one of six core digital literacy competencies adopted by British Columbia from the ISTE Standards (Digital Literacy Competencies). In the Draft Digital Literacy Framework, this definition of digital citizenship is broken down into ten specific outcomes relating to (a) Internet safety, (b) privacy and security, (c) relationships and communication, (d) cyberbullying, (e) digital footprint and reputation, (f) self-image and identity, (g) creative credit and copyright, (h) legal and ethical aspects, (i) balanced attitudes toward technology, and (j) understanding and awareness of the role of ICT in society.

Additionally, the Council of Ministers of Education, Canada (2011) discussed how “provinces and territories are addressing the broad range of skills that [students] will need to be fully engaged workers and citizens in the knowledge society of the 21st century” (para. 9). Skills include critical thinking, information literacy, collaborative learning, and new modes of civic engagement. The C21 Canada (2012) seminal

report, *Shifting Minds 1.0: A 21st Century Vision of Public Education for Canada*, also offers a vision for education, guiding principles for the vision, seven competencies (the 7 C's) that all students need to succeed in the twenty-first century, and priorities for redesigning the public education system. The 7 Cs are (1) creativity, innovation, and entrepreneurship, (2) critical thinking, (3) collaboration, (4) communication, (5) character, (6) culture and ethical citizenship, and (7) computer and digital technology. The authors explain the focus of the paper "is systemic transformation. It explores the critical question facing school district leaders and government policy makers: How can innovative models of teaching that are emerging in some places become the new norm in all schools?" (Milton 2015 p. 8). The "shift" described proposes a shift away "from hierarchical policy-driven systems toward networks of strong, responsive, schools . . . [In] these transformed systems, leaders at the top empower leadership at all levels . . . The dual strategies of school improvement and innovation work together to hold the system in balance" (p. 8).

Recent Developments on Policies on ICT in the United States and Canada

In 2011, the US Congress defunded the Enhancing Education Through Technology (EETT) provision of the Elementary and Secondary Education Act (ESEA), which was the only dedicated federal funding source for educational technology. This program has provided states more than \$3.5B in dedicated funding of educational technology since 2002. This negatively impacted the ability for states to maintain educational technology expertise and capacity on the state level, leading to the elimination of a number of state level educational technology director positions, or the combining of those positions with other responsibilities. It also negatively impacted districts around the country who relied on these funds for district level personnel and support.

In 2015, with the passage of the Every Student Succeeds Act (ESSA), Congress reauthorized the *Elementary and Secondary Education Act of 1965 (ESEA)*, the primary legislation governing elementary and secondary education in the United States. In this law, EETT was consolidated and combined with 49 other programs into a single program called the Student Support and Academic Enrichment (SSAE) program. This program provides state block grants aimed at (a) providing all students with access to a well-rounded education, (b) improving school conditions for student learning, and (c) improving the use of technology in order to improve the academic achievement and digital literacy of all students. It is important to note that this program is focused on building educator capacity to use educational technology effectively and caps the dollars that can be spent on the direct purchases of hardware and software at 15% of total educational technology spending.

It is also important to note that, as clarified in a Dear Colleague letter issued by the Office of Educational Technology at the US Department of Education, funding from other provisions of the law may be used by states and school districts to pay for educational technology in many cases as long as the purpose of those purchases is in

direct support of the goals of those provisions of the law and abides by the particular rules associated with those programs (USDOE 2017a).

Another major recent development in federal policy in the United States is the modernization of the E-Rate program. In 2014, this program was updated to increase the overall spending cap to \$3.9B per year and also increase the priority of internal connections (i.e., WiFi in schools) while phasing out support for some services (i.e., pagers and voice). As a result, from a baseline level of 30% of school districts meeting the targeted bandwidth in 2013, as of January 2017, between 81% and 88% of school districts now meet the bandwidth goal. This dramatic change lays the foundation for widespread, reliable digital learning in US classrooms.

Through the National Educational Technology Plan (2017), the United States also seeks to provide a vision and a call to action to US schools for how they use technology for learning including calling for using technology to reduce equity gaps in both access and achievement. It also calls for a focus on the active use of technology by students as tools for them to explore, to create, to communicate, and to solve rather than more passive uses of technology (USDOE 2017b).

The US Department of Education and the US Department of Health and Human Services also issued a joint policy brief in 2016 on the use of technology by early learners. This brief differentiates between different kinds of technology use for early learners, going beyond “screen time” to discuss the purpose and manner in which the child engages. It encourages overall limits, but also encourages active learning with others, especially underscoring the importance of adults’ co-viewing with children to provide context and reinforce learning (USDOE & US Department of Health and Human Services 2016).

Alberta Learning and Technology Policy Framework

It is difficult to apply a broad brush stroke in the review of ICT policies and practices across Canada. Rather, reports have highlighted illustrative policies and practices from provinces like Alberta. Alberta’s updated (2013) Learning and Technology Policy Framework provides a roadmap that delineates five interdependent policy directions and respective outcomes (for students, teachers, administrators, and other school professionals) and actions at both the school authorities and Ministry of Education levels (Alberta Ministry of Education 2013):

- Policy Direction 1: Student-Centered Learning – Technology is used to support student-centered, personalized, authentic learning for all students.
- Policy Direction 2: Research and Innovation – Teachers, administrators, and other education professionals read, review, participate in, share, and apply research and evidence-based practices to sustain and advance innovation in education.
- Policy Direction 3: Professional Learning – Teachers, administrators, and other education professionals develop, maintain, and apply the knowledge, skills, and attributes that enable them to use technology effectively, efficiently, and innovatively in support of learning and teaching.

- Policy Direction 4: Leadership – Education leaders establish policy and governance.
- Policy Direction 5: Access, Infrastructure, and Digital Learning Environments – All students, teachers, and administrators and other education professionals have access to appropriate devices, reliable infrastructure, high-speed networks, and digital learning environments.

Relevance of Cross-National and Worldwide Strategies and Plans for the United States and Canada

Although educational plans and frameworks established at the global level have highlighted the need for generating ICT policies in education, such as the Organisation for Economic Co-operation and Development (OECD), this influence has not been enacted formally or fully in the United States and Canada perhaps due, in part, to a lack of comparable structures and coordination of ICT policies and structures (► Chap. 88, “Information and Communications Technology and Educational Policies in Latin America and the Caribbean” by Valenzuela and Miranda) in both of these countries. However, the United States and Canada have participated in developing promising frameworks like those described in the OECD study and attended the UNESCO (2015) Conference.

Innovation Imperative

OECD (2015) research from the Teaching and Learning International Survey (TALIS) found that an average of two thirds of teachers across the participating countries consider the school where they work “an innovation hostile environment.” This tracks with innovative learning environments being the exception rather than the rule in most education systems. They underscore, “a powerful learning environment and learning system will constantly be creating synergies and finding new ways to enhance professional, social and cultural capital with others” (p. 4).

Economic critique and educational critique, evinced in international discourse (OECD 2015), make a strong case for both innovation in and an urgency for systemic change in schools. When focusing on learning systems and innovation, OECD (2015) suggests many conventional frameworks are inadequate by themselves. OECD researchers conducted an international Innovative Learning Environments (ILE) study. The underpinnings of the study included three interrelated strands: “(1) research about the fundamentals of learning using international expert knowledge, (2) the study of a range of cases across many countries and education systems, and (3) the search for effective practices for change management and policy implementation” (p. 4).

The ILE study authors discuss the wide variety of contexts in the initiatives highlighted (e.g., some were organized or just supported by national ministries, some cover a small network of schools, some were based on digital technology, others addressed particular groups of learners). Despite the widely different contexts, there were some common threads shared: (a) culture change, (b) clarifying focus,

(c) capacity creation, (d) collaboration and cooperation, (e) communication technologies and platforms, and (f) change agents.

There are further examples of cross-national synergies and work with the United Nations Educational, Scientific, and Cultural Organization (UNESCO). The UNESCO (2015) Conference Report of the Canadian Delegation (2015) outlined several issues addressed. A delegation, comprised of close collaboration between the Government of Quebec, CMEC, Canada's Permanent Delegation to UNESCO, and Confederation of Canadian Unions (CCU), took an active part in the conference and achieved several objectives. The main issues addressed included:

- UNESCO's leadership role in implementing the new Education 2030 agenda
- The promotion of inclusive, quality education
- The promotion of global citizenship education
- The development of cross-sectoral policies and the engagement of all parties in the process, including youth
- Consideration of the various different forms of learning and the promotion of information technology
- The importance of promoting lifelong learning in education
- The use of existing structures such as national commissions, ASP.NET, and UNESCO chairs in the promotion and implementation of UNESCO *activities* (p. xx)

Challenges and Relevance of Research for Policies on ICT in Education in the United States and Canada

Equity and Access

Similar to the United States, Canada is geographically vast and has a tendency to have a concentrated population in large urban centers (Rich 2009). According to Rich, "this situation leaves a rural and often remote population located in coastal regions, mountain areas, the northern regions of the central provinces, and the Arctic" (p. 128). Canada's population is also culturally diverse encompassing the

original First Nation and Inuit inhabitants along with residents from successive waves of immigration (Rich, p. 128). Rich maintains that several factors – the vast geography of the country, the mix of large urban concentration and remote towns, and a linguistically diverse and multicultural population – present challenges for maintaining quality educational services. Rich further asserts these contexts position ICT as both a promise and a challenge. While technologies may help in removing some barriers (e.g., geographic), they can present a challenge "in terms of demonstrating that equity of access to and use of ICT enhances learning. (p. 129)

Notably, one can draw parallels from this context, to help unpack digital equity issues in the United States (Davis et al. 2007). Additional concerns in Canada include infrastructure issues (e.g., less access to high-speed Internet/broadband for rural schools).

While use of ICT in Canadian schools has been purported as a solution to some equity issues, far-reaching results have not been completely realized. Looker and Thiessen (2003) found that access at home and the level of skill in using ICT were lowest for Inuit, Mi'kmaq (a First Nation group in eastern Canada), and Black students in Canada and highest for Asian and White students (as cited in Rich 2009). More recently, "the CMEC reviewed results from OECD's 2009 Programme for International Student Assessment (PISA). Canada remains one of the few countries in the world where high PISA scores and high equity go together. Canadian students not only score in the top tier of participants; the gap between the highest- and lowest-performing students is relatively small (CMEC 2011). Additionally, according to the International Experiences with Technology in Education Report, Canada is exploring ways to better serve students at risk of not completing high school and English- or French-language learners (USDOE 2011).

Competency-Based Education

Some school systems are moving toward a competency-based education (CBE) model which often requires policy shifts. Competency-based education, as defined by the Council of Chief State School Officers and the International Association for K-12 Online Learning (Patrick and Sturgeis 2013), incorporates the following:

1. Students advance upon mastery, not seat time.
2. Competencies include explicit, measurable, transferable learning objectives that empower students.
3. Assessment is a meaningful and positive learning experience for students.
4. Students receive timely, differentiated support based on their individual learning needs.
5. Learning outcomes emphasize competencies that include application and creation of knowledge, along with the development of important skills and dispositions (p. 6).

According to a policy and political landscape published by KnowledgeWorks (Pace et al. 2015), many current accountability measures create barriers to full adoption of competency-based education such as state seat time requirements, lack of consensus on what constitutes proficiency, required assessments designed to measure grade-level knowledge rather than competency, and limited opportunities for students to demonstrate mastery in multiple formats.

Evidence-Based Evaluation of Education Technology

In addition to evolving infrastructure, issues related to supporting "future-ready" learning, perhaps of equal importance, is the ongoing evidence-based evaluation of

educational technology. Research by Digital Promise shows that school districts rely more upon peer recommendations than rigorous evidence when making educational technology purchases (Digital Promise 2014).

In a Digital Promise (2014) report, authors suggest that procurement, the process for discovering, evaluating, and acquiring classroom resources, processes can become a barrier to selecting and implementing high-quality ICT solutions, particularly when these practices were designed for print-based resources rather than modern technology. Several recommendations were made as a result of the survey findings:

- a) Better guidelines for conducting needs assessments and including end users in the process,
- b) Faster methods of evaluating products and better ways of sharing results,
- c) Simplified Request for Proposal (RFP) processes to ensure a level playing field and high-quality results,
- d) Pilot approaches that increase rigor and drive purchasing decisions without overburdening teachers,
- e) Incentives for providers to get results and show evidence, such as performance-based contracting and prizes,
- f) Websites with trusted information about edtech tools and district procurement policies and better ways to match providers and products with educators, and
- g) More research about funding strategies for acquiring ed-tech products. (para. 7)

Also worth noting, rapid-cycle technology evaluations have been effective for some school leaders. According to the Office of Educational Technology (OET), at the US Department of Education, “rapid-cycle tech evaluations are designed to assist school leaders in making evidence-based decisions regarding educational technology acquisitions. Traditional research approaches do not meet the needs of evaluating rapidly changing education technology. They 1) take too long, 2) cost too much 3) cannot keep up with speed of development, 4) are not iterative, and 5) serve a different purpose than most school leaders need. By the time a traditional research project is complete, new iterations of the app can make the research outdated before it is even published” (USDOE n.d., para. 1).

A number of commercial and open source tools have emerged to assist districts and schools with conducting rigorous rapid-cycle evaluations to collect essential evidence to use technology more effectively in teaching and learning (USDOE, OET n.d.). This is part of a larger effort to increase the pace and rigor of evidence associated with educational technology purchases and renewals by school districts.

Comprehensive Landscape Analysis Needed

A recommendation that came out of the National Educational Technology Plan (USDOE 2017b) in the United States is to create a comprehensive map and database of connectivity, device access, use of openly licensed educational resources, and their uses across the country. To understand the digital divide better and progress toward bridging it, researchers, state and local officials, and district administrators should work in concert with one another to test connectivity speeds in schools and

homes and to identify the kinds of devices to which educators and students have access and the ratios of devices to users within education institutions. The building of such a map and database would allow for the visualization of inequities of access and targeted interventions to alleviate them. In addition, the level of engagement with openly licensed learning materials should be made transparent as an indicator of progress toward equitable structures, cultivate innovation, and build capacity within the system to leverage technology in support of student-centered learning and system efficiencies.

Given that the responsibility for setting education policy resides at the provincial and territorial levels, it is not surprising that there is considerable variance across the 13 jurisdictions and geographic regions across Canada in terms of digital literacy policies and implementation programs. Hoechsmann and DeWaard (2015) explicate that approaches to implementing digital literacy and digital citizenship education differ across the country. They identify four main approaches used in implementation strategies: infusion, cross-curricular competencies, integration, and dispersion (p. 15). Table 1 highlights digital literacy and digital citizenship frameworks across the five geographic regions in Canada.

Perspectives for Developments in the United States and Canada and Emerging Themes/Perspectives

Deeper Learning

Vander Ark and Schneider (2012) suggest that great teachers and innovative schools are discovering ways to foster deeper learning for their students. But along with other scholars, they caution that it will not be possible to bring these opportunities to scale, without the necessary technology (Vander Ark and Schneider 2012; Dede 2014). They further assert that the adoption of college- and career-ready standards and the coordination of next-generation assessments create an unprecedented opportunity to advance readiness that can be realized by linking digital learning and deeper learning (p. 2). Among other insights, Vander Ark and Schneider identify three primary ways that digital learning promotes deeper learning:

- Personalized skill building in preparation for deeper learning (e.g., adaptive learning)
- Schools and tools that foster deeper learning (e.g., project-based learning networks)
- Extended access (e.g., access to quality courses and teachers online) (p. 1)

Dede (2014) also positions that we are now seeing digital technologies used in ways that promote deeper learning. Dede highlights two promising technologies in detail that have been widely researched in empirical studies: digital teaching platforms and immersive authentic simulations. He offers that an extensive series of

Table 1 Select digital literacy and digital citizenship frameworks in Canada

Geographic region	Digital literacy and digital citizenship framework
In the North	“Northwest Territories based their vision on five core competencies drawn into a holistic circle that unites community, home, workplace and school, and also individual life trajectories that include psychological (self), social (others) and spiritual dimensions as well as an acknowledgement of the physical context (the land). Brief explanations of each of the five core competencies set the directions of this twenty-first Century curriculum” (Hoechsmann and DeWaard 2015, p. 17)
To the East	“In Newfoundland and Labrador, twenty-first Century learning is oriented towards a strong vocational focus based on changing work futures. The [curriculum map includes] three domains: literacy; life and career skills; and learning and innovations skills. Significantly, “literacy” combines the traditional “three Rs” with ICT literacy. [The] direction for digital skill sets and mindsets are holistic and oriented to students’ needs in the classroom, community, and future workplace” (Hoechsmann and DeWaard 2015, p. 20)
Central Canada	“A growing trend in Canadian education is to move away from content knowledge curriculum outcomes in favour of competency-based outcomes. While this trend is not unique to Quebec (for example, Saskatchewan and BC have similar orientations), the Quebec Education Program (QEP) was the result of a major rethinking and reworking of the province’s curriculum and teaching guidelines. The QEP is based on a three-pronged vision: to provide instruction in a knowledge-based world; to socialize students in a pluralistic world; and to provide qualifications in a changing world” (Hoechsmann and DeWaard 2015, p. 15)
Out West	“Manitoba’s Literacy with ICT (LwICT) is a holistic and pedagogy-focused approach to integrating digital literacy into and across the curriculum that recognizes the fundamental shift that has occurred in communication and learning with digital tools, but makes a very explicit connection between traditional and digital literacy practices. “The meaning of literacy evolves with the times. Literacy is not only about reading, writing, listening, speaking, viewing and representing. It is also about developing literacy with information and communication technology (ICT). . . [which] means thinking critically and creatively, about information and about communication, as citizens of the global community, while using ICT responsibly and ethically” (Literacy with ICT Across the Curriculum: Definition and Purpose)” (Hoechsmann and DeWaard 2015, p. 24)
On the Pacific	“Adopted from the six competencies articulated in the 2007 ISTE Standards for Students, British Columbia’s Digital Literacy Framework provides another model for the development of a digital literacy curriculum that is comprehensive and concise. It includes: research and information literacy, critical thinking, creativity and innovation, digital citizenship, communication and collaboration, and technology operations and concepts” (Hoechsmann and DeWaard 2015, p. 26)

research studies have been conducted on their effectiveness and practicality. Dede proffers three recommendations: stay focused on reducing achievement gaps, build professional capacity to use digital tools effectively, and invest in research and development.

Building Professional Capacity

In addition, there is growing interest in exploring new models for teacher preparation and development to build professional capacity. Discourse has centered around how to best prepare and equip educators with the transformative skills and experiences needed to empower learners to use technology to its fullest potential and reduce equity gaps in achievement. Calls for increased personalization of student learning have been amplified in cross-national and national discourse in both the United States and Canada (USDOE 2017b; Milton 2015). Cator et al. (2014) remind us, “new adult learning models are creating the potential for personalized preparation and development pathways for teachers. As student roles change in a personalized learning environment, teacher preparation and professional learning should evolve accordingly” (p. ii).

Digital Use Divide

The digital use divide has been a growing concern. According to the 2017 NETP, “[c]losing the digital divide alone will not transform learning. We must also close the digital use divide by ensuring all students understand how to use technology as a tool to engage in creative, productive, life-long learning rather than simply consuming passive content” (USDOE 2017b, p. 21). Essentially, though there are notable exceptions, technology exposure for most students still needs to move from a focus on passive consumption to creation.

Augmented and Virtual Reality

Augmented reality (AR) is expected to take a more prominent role in education, as is virtual reality to a lesser degree. According to review of studies on AR (Bacca et al. 2014), augmented reality has been shown to improve learning gains, to increase motivation and student engagement, and to foster stronger collaboration skills. However, AR is still often considered an intrusive technology; students can pay too much attention to virtual information (p. 146). In addition to increased use of AR and VR for learning experiences, students will also likely need to learn how to create and manipulate augmented experiences themselves.

Scaling Out and Scaling Up

Both the United States and Canada face significant challenges in scaling innovation both out and up. Fullan and Donnelly (2013) in their discussion on the challenges in research on digital innovations recognize, for example, that the “field is currently characterized by either weak or undeveloped pedagogy, or strong technology and pedagogy connected to a small number of schools; that is, the best examples

tend to be small-scale exceptions that are not representative of the main body of schools” (p. 11). Further, they argue that “pushing the envelope in the direction of larger-scale reform will require the integration of technology, pedagogy, and system change” (p. 11).

OECD (2015) discusses micro-, meso-, and meta-levels that must be addressed when focusing on learning systems and innovation. According to a C21 Report, Canada faces challenges of scaling out and up as school districts pursuing “a change agenda along an improvement and innovation trajectory start where the opportunity presents itself because there is not a single (or simple) approach to create innovative schools across a whole system. . . . Leaders watch for the fine balance between the need for autonomy to innovate at the school level and the desire for systemic and sustainable improvement” (Milton 2015, p. 12). Milton (2015) discusses innovation further:

[c]reating the conditions for local innovations is relatively easy. Sustaining the innovations over time, and scaling them out to other schools, is much harder. Schools may, for example, get better at using technologies and may for limited subjects and time periods support interdisciplinary studies or facilitate collaborative projects. But without a disciplined approach to transformation, these innovations will not likely add up to a new way to do school every day for all students in every class. (p. 13)

Looking to the Future

As Canada and the United States expand their support of educational technology in schools, policy makers will encounter both challenges and opportunities. These include determining the proper safeguards for protecting the privacy of student data and determining the propriety of allowing private entities with profit motives to access and use this data, even when authorized by school officials and limited to specific purposes related to improving student outcomes. Also challenging will be constructing policies governing student assessments, including whether computer-based assessments should be a required format for gathering national data. Policy debates will also continue around the degree of equal access to technology that government should require, including whether parity should be required in terms of device age and availability, quality and availability of digital learning materials, and classroom bandwidth and whether the technology is being used actively or passively by students across all socioeconomic groups and across all schools in a given geography. Even as technology is used in more effective ways for learning, the debate will continue about whether policies should limit the amount of overall screen time students experience in school and, if so, by how much.

Some opportunities for policy makers include supporting expanded interoperability standards to make it easier for educators to gather data from multiple products into a single learning dashboard; reforming educational technology procurement policies to support the procurement of digital resources in lieu of paper textbooks and to require a demonstrated evidence-based for educational technology solutions before purchases are approved or renewed; supporting for the systematic use and

vetting of high-quality open educational resources (OER) in schools; expanding the applications of data systems at the national and regional level that provide comparative longitudinal information on learning gains across schools and demographics; supporting teaching approaches that elicit active learning, rather than passive learning, with technology; and implementing policies that help prepare learners to be responsible digital citizens in both digital workspaces and social realms.

Both Canada and the United States face particular economic challenges in the upcoming years that education technology could play a role in addressing. As policy makers grapple with the displacement of jobs and loss of employment due to advances in technology and continued growth in income inequality, they may turn to policies that encourage better alignment between K-12 education and the skills needed for future careers. Educational technology can support the necessary data, learning, and credentialing to create pathways from K-12 to college and career that align with long-term employment stability. Further, if personalized learning approaches can be designed to provide experiences that help students not only learn required material but also explore their personal interests, passion, and purpose, educational technology can be a powerful force in enabling a lifetime of learning and fulfilment.

Abstract

This chapter refers to policies toward integrating ICT in primary and secondary education from the perspective of Sub-Saharan Africa region. This chapter explores how recent development in ICT policy facilitates the integration of ICT in teaching and learning in primary and secondary education in the region. Varieties of strategies are in progress to ensure the technology is integrated into primary and secondary education. These strategies focus mainly ICT professional development for management and teaching and learning; electronic content resource development and distribution; access to ICT infrastructure; connectivity, community engagement; and research and development, though the emphasis vary from country to country. Moreover, trends show that different countries are at different stages of ICT adoption and use (UNESCO. (2004). *Integrating IT into*

education: A collective case study of six Asian countries. Bangkok: UNESCO). Majority countries are at emerging and applying stages in ICT adoption and use in education, with only Seychelles, Mauritius, and South Africa at infusing stage. The main challenges facing the region include lack of sufficient budget to sustain ICTs in schools, inadequate ICT infrastructure, untrained teachers and technicians on ICT integration, and ineffective coordination of ICT initiatives, which leads to unfriendly curriculum which does not specify where, how, and when to use ICT for educational purpose. However, low cost and proliferation of mobile technologies in the region have enormous potential to improve ICT use in education. In many countries, mobiles are the only channel for effectively distributing reading material, given the high cost of books and their distribution, especially in rural areas. In addition, mobiles offer interactivity, connectivity, and personalized content.

Introduction of ICT in Primary and Secondary Education in Sub-Saharan Africa

This chapter presents an overview of information and communication technology (ICT) and education policies in sub-Saharan Africa (the African countries south of the Sahara desert). The focus is on sub-Saharan Africa (SSA), not Africa in total, as Northern Africa is similar in many ways to the Middle East, and it is discussed in one of the chapters of this volume. According to the UN, SSA region consists of all African countries that are fully or partially located south of the Sahara. The region is full of tremendous promise as it is emerging out of decades of stagnation and now is the home of fastest-growing economies of the world. Since 2000, GDP per capita in SSA has grown by almost 5% per year, compared with 2.4% in the two preceding decades despite being one of the poorest regions in the world (Leke et al. 2010).

Given sub-Saharan Africa's historical legacy, most of the region's educational systems have been modeled largely on their European counterparts. Although sub-Saharan educational institutions have been modified partially to respond to local conditions, by and large, formal educational programs reflect the basic primary, secondary, and higher education structures and standards found in European countries. For most sub-Saharan countries, this meant that educational policy and the allocation of resources to education have taken place essentially through the public sector rather than through the private sector, at the national level rather than at the local level, and frequently through the coordination of educational policy targets with national development planning of one form or another (LeBel 2000).

Although all countries in SSA have education policies to guide how the provision of education throughout the country, not all countries in SSA have ICT policy in

education. Most sub-Saharan African countries with ICT in education policies are progressively integrating information and communication technologies (ICTs) into their education systems especially in primary and secondary schools with a particular emphasis on improving the quality of subject teaching and learning.

A recent report from the UNESCO Institute for Statistics (UIS) has found that, despite the development of ICT in education policies, the integration of technology in classrooms across sub-Saharan Africa remains insufficient to meet the needs of the twenty-first-century labor market (UNESCO 2015).

ICT in education is widely accepted as both enabling learning and preparing students for employment in a technology-rich workplace. But in sub-Saharan Africa, barriers – including a lack of effective policies, basic infrastructure (i.e., electricity, the Internet, computers, and mobile devices), financing, and teacher training – mean that the use of ICT in education is still at an embryonic stage in most countries (UNESCO 2015).

In the UNESCO report, the most pervasive barrier is the lack of electricity, especially in remote, rural areas where most of the primary schools are. ICTs are more likely to be found in urban schools, where access to electricity and the Internet enable computer-assisted instruction and online learning. In addition, Hennessy et al. (2010a) concluded that a primary barrier to ICT integration in SSA is teachers' "readiness and confidence" in using ICT.

Recent Developments on ICT in Sub-Saharan Countries

Although ICT integration in education is facing many challenges in SSA, the use of ICT, especially of mobile communications, has increased exponentially in other sectors of society in the past decade (Etzo and Collender 2010). Mobile communications are seen as the fastest-growing market, and the outlooks show large potential (World Resources Institute [WRI] 2007). Unavailability of electricity has been the biggest hindrance to the growth of ICT in the region, especially in remote and rural areas. It is becoming common to talk of a "mobile revolution" sweeping the region, with mobile phone use spreading quickly, geographically, and socially, accompanied by novel applications, impacting on other areas of economic life. The quick spread to some extent is caused by easy means to charge mobile devices without depending on electricity supply from the national grid. The percentage of the population having access to a mobile phone is already bigger than the share of the population having access to electricity. Mobile phones have spread quickly, not only addressing the huge demand for communication but also substituting for products like bank accounts, newspapers, entertainment, medical advice, and training, to which many people previously had no access (Aker and Mbiti 2010). Building the necessary connection infrastructure has considerably advanced, and digital devices are becoming more affordable. In 2009, sub-Saharan Africa began to see its first international submarine fiber-optic cable connections. They brought with them much faster and a bit cheaper, the Internet. The Internet still has to catch up with the mobile sector, but

there are encouraging signs that it will do so. The whole continent is ranked the last in Internet use, and most Internet access takes place on mobile phones (ITU 2016).

However, general literacy and digital skills across the population are generally low, and it needs to be improved in order for countries in the region to fully reap the benefits of the digitalization, and this is a more difficult challenge to tackle.

Albimana et al. (2016) found that mobile phone and the Internet have triggered economic growth in SSA region. They also found that except for financial development, human capital, institutional quality, and domestic investment were the main growth-enhancing transmission channels of ICTs use in the economy. Other studies have shown that there a number of initiatives to ensure ICTs are having an impact on many sectors of the economy, from access to basic amenities like electricity supply and clean water to financial transactions.

In SSA, few people have a bank account, and this gap has been filled by mobile transactions. In Kenya, for example, more than two-thirds of adult population use m-banking for transferring money, making payments in stores, paying bills, and making online purchases. Similar mobile money services have proliferated in SSA with varying degrees of success, but SSA remains the region in which mobile money is most widely spread (Aker and Mbiti 2010).

Agriculture is the largest sector of the SSA economy, the use of new digital applications has hugely benefited the farmers. Farmers' organizations are using a text message service or a mobile communication platform, to inform farmers about market prices and link them with potential buyers. Digital platforms are also used to provide practical information about growing methods, market trends, weather information, and warnings and advice about plant and animal diseases and in financial transactions related to agriculture (Aker and Mbiti 2010).

Mobile technology is hugely transforming the way health care is delivered in SSA, considering the region has an acute shortage of medical staff. Numerous projects have been developed, providing health information for pregnant women, advice to youth on sexuality, helping identify counterfeit medicine, helping with self-diagnosis and the search for a physician, and even in providing an e-learning and communication platform for medical staff (Fayoyin 2016).

Digital communications, especially social media and news platforms, are used to help improve governance, by enabling access to public information online, increasing transparency and accountability, and promoting better interaction between citizens and government to improve efficiency through provision and their services to citizens online, for example, tax collection and safely reporting cases of corruption. More and more SSA countries are using an electronic system of voter registration based on biometric identification (UNDP 2010).

e-Learning initiatives are certainly underway in many sub-Saharan African countries, particularly in higher education institutions. However, access to ICT remains deficient in many parts of SSA. Many schools are still not connected to the electricity grid, and digital devices are unaffordable to many children. Even when digital devices are made available to schools, they are not always used effectively as very few trained teachers with ICT pedagogy are available. ICT can provide a solution to the problem of shortage of teachers in schools, through the use of digital devices and platforms and

by overcoming physical distance. The mobile phones can improve access to education in the region, though promoting new learning is yet questionable (Valk et al. 2010).

The potential uses of ICT promise a transformative impact on economic, social, and political life, spurring development in numerous areas. If current trends continue, more and more people will see their life touched by these new technologies. It is also important to remain aware of the potential limitations of the new technologies, which cannot fully substitute, for example, for other major drivers of economic growth or for real teachers and schools.

Recent Developments on Policies on ICT in SSA Region

Efforts of reforms in sub-Saharan education systems are geared toward achieving United Nations millennium development goals (MDGs) and *Education for All (EFA)*. Neither the MDGs nor EFA provided concrete objectives or goals related to the role of ICT in education. Despite some progress, universal attainment of the goals remains distant. Nonetheless, education is the key to sub-Sahara's future, and if it is to do what is expected of it, technology has to be at the heart of it. The continent's education ministers adopted a 10-year plan in which science and technology teaching was to undergo reform at all levels of sub-Saharan educational systems (African Union [AU] 2006). The plan aimed at improving learning outcomes, promoting the use of indigenous knowledge, and encouraging more girls to pursue scientific careers. Science and technology education is seen as the most important tool in existence for addressing challenges to development and poverty eradication and for participating in the global economy. Technologies such as ICT are perceived and therefore employed to bring the plan to success.

In all regions of the world, the penetration of ICT in schools has led to a major transformation of the education landscape which brought about increase in economic productivity through digital economies, enhancing the delivery of public and private services and achieving broad socioeconomic goals in education, health care, employment, and social development.

The task for the education sector in SSA is therefore to identify ways of creating necessary conditions within the education system to maximize the benefits of ICT and thus support development. Proper acquisition of skills for productively transforming knowledge and information into innovative products and services will define successful knowledge economies and societies. Because knowledge and information have become the most important currency for productivity, competitiveness, and increased wealth and prosperity, nations of the region have placed greater priority on developing their human capital. The sub-Saharan governments at different levels are thus focusing on strategies to increase access to and improve the quality of education through ICT (United Nations Economic Commission for Africa [UNECA] 2003).

Mansel and Wehn (1998) noted that knowledge and human capital are essential to all aspects of development. They further observed that key to this form of development is to ensure that all people in a country have the ability to acquire and generate

knowledge. This is where information technologies become vital. They are the primary tools to enable the acquisition, generation, access, and use of knowledge that forms the bedrock of effective development. ICT needs to be enhanced by an ICT policy that ensures people are capable of using it to source and assimilate information and transform it into useful knowledge. ICT policy often defines broad strategies and approaches to issues; sometimes policies establish more specific actions. The rapid integration of ICT into learning environments raises many issues that demand the development of effective ICT policy. ICT policy issues are particularly diverse and challenging, in part because the rapid rate of change in the technology continues to create new possibilities for use and the need to find the best ways to implement them.

Zlotnikova and van der Weide (2011) proposed a framework for developing and improving ICT educational policies in countries of sub-Saharan Africa, as well as a tool for evaluation of ongoing ICT educational projects and success forecasting of future projects. The model has components and parameters. Components proposed are influenced by numerous parameters (economic, political, demographic, technological, and cultural).

Development and implementation of ICT policy in education have started in SSA though vary in emphasis and dimension from country to country. Some countries piloted ICT use in schools and trained teachers without an ICT in education policy, for example, Kenya, Uganda, and Tanzania, and later developed one. Others, for example, Mauritius, find it important to have the policy to serve as a framework and guide. Better economic advantages made South Africa spearhead developing and implementing ICT policies in its education system. Integration of ICT is a low priority when compared to other educational objectives in most SSA countries. Despite the development of ICT in education policies, use of ICT in education is still at an embryonic stage in most countries; the integration of technology in classrooms across SSA remains insufficient to meet the needs of the twenty-first-century labor market.

Relevance of Cross-National and Worldwide Strategies and Plans for SSA

Studies of ICT development in both developed and developing countries identify at least four broad approaches through which educational systems and individual institutions typically proceed in their adoption and use of ICT (Anderson and Van Weert 2002). Sometimes, the number of stages identified varies. However, there is a consensus that the introduction and use of ICT in education proceed in broad stages that may be conceived as a series of steps. These steps, termed emerging, applying, infusing, and transforming, are elaborated in Fig. 1:

- *Emerging*: In this initial phase, administrators and teachers are just starting to explore the possibilities and consequences of using ICT for school management and adding ICT to the curriculum. In this phase, ICT infrastructure is either donated or purchased by the school authority.

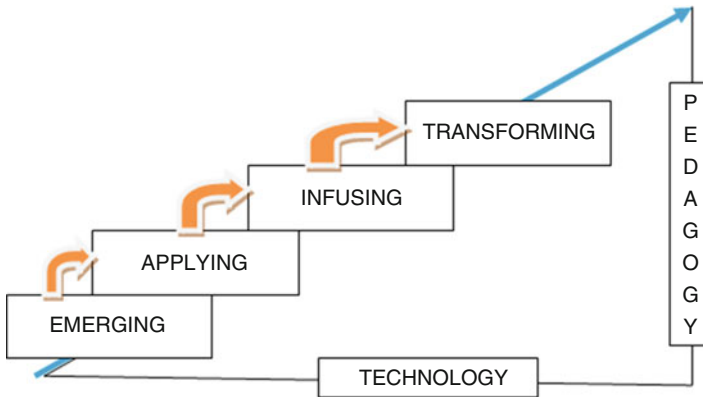

Fig. 1 Stages of IT development

- *Applying*: In this step, administrators and teachers use ICT for tasks already carried out in school management and in the curriculum. For example, schools adapt the curriculum in order to increase the use of ICT in various subject areas with specific tools and software such as drawing, designing, modeling, and application-specific tools.
- *Infusing*: It involves integrating or embedding ICT across the curriculum and is seen in those schools that employ a range of computer-based technologies in laboratories, classrooms, and administrative offices. ICT infuses all aspects of teachers’ professional lives in such ways as to improve student learning and the management of learning processes.
- *Transforming*: In the final stage, ICT becomes an integral though invisible part of daily personal productivity and professional practice. The focus of the curriculum is now learner centered and integrates subject areas in real-world applications.

The steps represent a continuum of approaches to ICT development. The continuum model presented can be mapped onto two interwoven tracks for the development of teachers’ capacity in harnessing information and communication technology with regard to (a) stages of ICT usages and (b) pedagogical usages of ICT as shown in Fig. 2.

Figure 2 shows the stages of ICT usages in terms of awareness, learning how, understanding how and when, and specializing in the use of ICT tools according to the stages of the proposed model:

In becoming aware of ICT – Teachers and learners become aware of ICT tools and their general functions and uses. Usually, the emphasis is on ICT literacy and basic skills.

Learning how to use ICT – It involves the use of general or particular applications of ICT and is linked with the *applying stage* in the ICT development model.

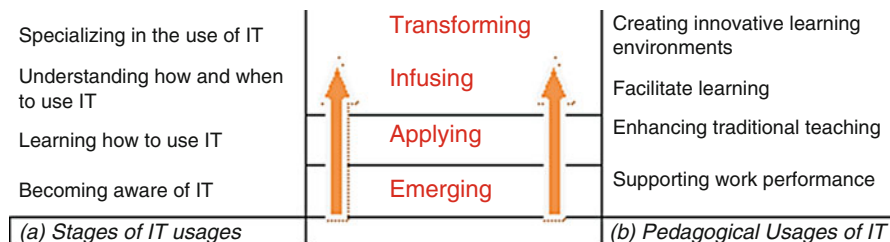

Fig. 2 Mapping the model

Understanding how and when to use ICT – It implies the ability to recognize situations where ICT will be helpful, choosing the most appropriate tools for a particular task and using these tools in combination to solve real problems.

Specializing in the use of ICT – It demands specializing in the use of ICT tools which occurs when one enters more deeply into the learning environment that creates and transforms the learning situation with the help of ICT.

Studies of teaching and learning in schools around the world identify four broad stages in the way the teachers and learners use ICT as a support for teaching and learning that have been broadly classified as supporting work performance, enhancing traditional teaching, facilitating learning using multimodal instruction, and creating innovative environments, according to the stages of the proposed model:

Supporting work performance – In this initial stage, teachers use productivity tools such as word processor, visual presentation software, spreadsheet, database, email, etc. to support their daily work performance.

Enhancing teaching – It entails techniques for integrating computer-based learning in the traditional instructional process through use and developing computer-assisted learning software and beginning to make use of such software in different disciplines.

Facilitating learning – It indicates the ability to recognize situations where various multimedia, simulation, and modeling software can be utilized for teaching and learning. Teachers learn how to choose the most appropriate tools to solve real-life problems.

Creating innovative learning environments – It involves specializing in the use of network-based resources to create a meaningful environment with rich and affordable innovative learning models. This occurs when one enters more deeply into the shared learning environment that creates and transforms the learning situation.

Countries in the sub-Saharan region are at different stages of ICT policy implementation, in terms of infrastructure, curriculum, content development, technical support, and usage of ICT in the teaching and learning process. In the typical sub-Saharan schools equipped with ICT, computers are often secondhand and are more frequently available for secondary education; electricity supplies are

unreliable; access to computer rooms is limited by the competing demands of teachers, students, and administrators; and Internet availability ranges substantially within the region. Owing to lack of training and familiarity with computers, teachers do not know how to browse effectively and find Internet materials and are not familiar with the educational software. These differences are not only varying from country to country but even within the individual countries. There are uneven developments from region to region, area to area, and even from institution to institution. National priorities and strategies for ICT implementation in education differ widely from system to system. Although there is variation in terms of the structure of education systems and other aspects of the economic and social context, there are also strong similarities in the pathways of change in terms of the goals of introducing ICT in education. Most countries have established formal recommendations to integrate ICT in at least some subject areas; the level and grades recommended for integrating ICT in curricula vary. For example, in South Africa recommendations for integrating ICT begin in primary education and cover all subjects and grades, whereas in Côte d'Ivoire and Zambia formal recommendations exist for some grades in primary education and then all grades in secondary education. In Tanzania, ICT is offered as a subject from primary to tertiary levels, while integration in a subject is mostly at secondary school level. Integrating ICT in curricula is least common in Gambia, Madagascar, and Sao Tome and Principe where they begin only at the upper secondary level. In Burkina Faso, Comoros, Guinea, Niger, and Togo, there are no formal recommendations at all for integrating ICT across subjects or education levels (UNESCO 2015).

In view of the abovementioned observations, a framework to be able to situate a country in its development of ICT in education policy is helpful. The framework might also be useful to show the interrelationship of various components of ICT implementation and in portraying how complex systems operate. The framework (see Table 1) provided by Moonen (2008) is used to situate the ICT in education policies of sub-Saharan countries. The status of ICT in African countries information to fill in the framework was gleaned from a variety of sources (Farrel and Shafika 2007; GESCI 2011; UNESCO 2015).

From Table 1 it is clear that only three countries in the region are without ICT policy. Equatorial Guinea and Guinea Bissau have a lot of uncoordinated ICT in education activities going on, initiated mostly by the private sector and civil society. Somalia has been without a stable government for the past 25 years. Since the transitional federal government (TFG) came into power, a lot of effort through various international organizations, notably UNICEF and the UNESCO, has been to increase primary school enrolment and improve access to postprimary education including technical, vocational, and higher. The seemingly healthy ICT infrastructure in the urban centers supports the use of ICT in schools (ITU 2006).

Almost all sub-Saharan countries currently have either ICT policies or ICT educational policies or both and have started to implement the policies either on an ad hoc or small project basis. In Botswana, for example, they have a revised national policy on education that emphasizes the importance of proficiency in computer use by students and their teachers. Also, the Ministry of Education has

Table 1 A summary of ICT implementation in sub-Saharan countries

pursued an aggressive roll-out campaign to equip all secondary schools with a fully networked computer laboratory with at least 20 computers and access to the Internet. Teachers are prepared for the integration ICT into, and across, the curriculum; heads of schools are also trained to support resourcing initiatives. In addition, computer-integration support officers are trained to pass ICT skills to their colleagues at the school level. ICT is taught as a subject and but is not examinable (Garegea and Moalosi 2011).

Tanzania started by ensuring teachers’ colleges gets equipped with basic ICT infrastructure, and all graduates from the colleges are ICT literate and have basic skills to integrate ICT in the curriculum (Mendes et al. 2003; Hennessy et al. 2010b). The college’s curriculum also supports the integration. Few public primary schools have ICT integrated into the curriculum though the curriculum has ICT as a subject. Few public secondary schools are supported with ICT infrastructure and the Internet. In Kenya, the government launched a multimillion ICT Trust Fund and committed to providing 2500 of the 3500 public secondary schools in Kenya with computers, but the challenge is employing the technology to improve student learning (Mwangi 2014; Hennessy et al. 2010b). In Nigeria, several initiatives by government, civil society, and the private sector managed to acquire hardware, but the challenge is its integration into the curriculum to benefit learners (Oshionebo and Ashang 2011). Similar stories are evident in other sub-Saharan countries.

Only Mauritius, Seychelles, and South Africa are barely in the infusing stage of policy implementation. The two islands are more advanced because of their small population and the more dynamic nature of the ethnic composition of the population. The main resource of Mauritius Island is human capital; the government is committed to making ICT the fifth pillar of its economy and also intends to convert the island into a “cyber island” (Eastmond 2006; Lincoln 2006), and ICT is used in most

schools from primary level. For Seychelles, the Ministry of Education has developed an ICT master plan (Ministry of Education [MOE] 2000) since the year 2000 with goals and strategies to use ICT. There are policies promoting the use of ICT across the system at both organizational and capacity building levels. The use of ICT in educational processes at schools and at higher education levels has become a main priority for the Seychelles government (Chisholm et al. 2004). South Africa, on the other hand, is a much bigger country, and her economic muscle enables integration of ICT in the curriculum to quite a high number of schools. The South Africa in e-education white paper (Department of Education [DOE] 2004) emphasized support ICT integration in teaching and learning and improved management and administration, competencies for teacher development in the integration of ICTs into the curriculum, connectivity, and high-quality content. The challenge that the country is facing is a digital divide between rural and urban schools.

Challenges and Relevance of Research for Policies on ICT in Education in SSA

At the beginning of 2006, 28 of the sub-Saharan countries had developed national ICT policies aimed at ameliorating the realization of national development goals (UNECA 2006). These policies were general in the sense that it was at the discretion of each government ministry to develop appropriate implementation strategies. ICT policy for education implementation strategy is vital for it to impact societies in the region by revolutionizing the learning and teaching processes, opening new learning opportunities and access to educational resources well beyond those traditionally available, and impacting curriculum development and delivery.

However several challenges impede the revolution. These challenges include inadequate ICT infrastructure, unskilled manpower, resistance to change by teachers, underfunding of the overall education system, over-dependence on the government for everything, ineffective coordination of ICT initiatives, and sustainability (Grant 2004; Tearle 2003).

In view of the abovementioned challenges, the ICT policies in education in sub-Saharan Africa must address at least five strategic objectives: ICT professional development for management and teaching and learning; electronic content resource development and distribution; access to ICT infrastructure; connectivity, community engagement; and research and development (UNESCO 2004).

Naidoo (2003) noted that attempts to integrate ICT into the education system entail the leadership of the government and the education ministry, working together with other relevant ministries. Leadership must have a clear vision of the mechanism that the government intends to use and to implement ICT. This vision then needs to be integrated with national policies. Walker (1989) observed three preconditions for a successful introduction of new information technologies into an education system, these being an appreciation by the government of the financial, resource, and operational requirements and the resulting consequences; a commitment by the government to give time and take responsibility for decision-making and

implementation strategies; and commitment to an integrated support service encompassing teacher and technician training, curriculum, and assessment, together with software and hardware provision. Such an approach helps to build ICT within a broader environmental context of the education system, covering economic and social infrastructure and policies and global market conditions.

Also reflecting this broad context, UNESCO (2004) proposed generic elements that any policy on ICT in education should cover. These are a careful analysis of the current context that the country finds itself in with respect to the type of society and economy that is being built and the education system necessary to contribute to it, research and analysis of international developments and trends in ICT use in education, and an outline of the key issues that need to be addressed, together with proposed methods of doing so.

From experiences in Asian countries, UNESCO recommends a holistic approach to ICT in education policy implementation. This considers crucial aspects such as the curriculum, assessment, ICT resources, professional development of teachers, research and development, and fund generation. Once policy and an implementation strategy for using ICT in the education system are developed, the next step is ensuring that the policy is integrated into the general education policy and other related policies.

The challenge of providing ICTs to sub-Saharan schools in order to enhance the quality of learning and teaching requires a significant investment. Research contribution in providing solutions on how to prepare school to accept ICT; procure and install technology; train teachers to use ICT; integrate it into the curriculum, content development, and management; and plan for continuous evaluation and research, provision of curriculum, and technical support and developing partnership is necessary.

There are success stories of ICT in education which research has contributed much and SSA can emulate. The Dutch Kennisnet Four in Balance model is one example. According to the model, introducing ICT for educational purposes has a greater chance of success if four basic elements – vision (how an educational institution envisages qualitatively sound and efficient education, how it intends to achieve it, and what ICT's role will be), expertise (the competencies that staff must have to make satisfactory use of ICT), digital learning materials (the information, educational content, and software used in an educational institution), and ICT infrastructure (the availability and quality of hardware, networks, and connectivity within the institution's education system) – are in balance (Ict op School 2004). In essence, successful introduction of ICT in education involves striking the right balance between vision, expertise, content and applications, and infrastructure. Having better technical facilities does not automatically lead to more computer use. Considering the human elements alone (e.g., making a vision explicit in a policy plan or receiving training) will not lead to the long-term use of ICT if the necessary technical facilities are not available at the same time. It is possible to strike the right balance between the human and technical elements of the stakeholders – teachers, school managers, and school boards – that work together. Since its creation, the model has proven its added value in the implementation of ICT in Dutch schools.

Another example is Enlaces network, a national information and communication technologies and education initiative designed as part of a series of programs to overcome inequity and quality issues of public education in Chile, by integrating teachers and learners into the knowledge society. It has provided basic infrastructure tools, connectivity, ICTs, and teacher training to a huge number of schools (Sanchez and Salinas 2008). Though the network results are limited in classroom learning, there are plenty of lessons to learn from it.

Perspectives for Developments in SSA and Emerging Themes/ Perspectives

According to Cambridge dictionary, development is the process in which someone or something grows or changes and becomes more advanced. Many SSA countries have seen some of the world's highest economic growth rates in the past decade, which has led to high levels of economic optimism for the future. The growth of economy should have been a sign of development, but real income growth has failed to keep pace with population growth and other related areas such as education, health care, poverty, etc. World poverty has decreased over the last few decades. However, in sub-Saharan Africa, the situation has not improved: In 1981 half the population lived on less than 1 USD a day, and in 2005 this was still the case. Today, the percentage of people living on less than \$1.25 a day in SSA (41%) is more than twice as high as any other region (such as Southern Asia, with 17%). Of all sub-Saharan African countries, just Mauritius saw a consistent drop in poverty rates between 1970 and 2003. In all other sub-Saharan African countries, poverty only improved in one or two aspects regarding chronic poverty or not at all (de Haan 2010).

Perhaps more surprising, however, sub-Saharan African countries perform poorly when it comes to converting their limited wealth into well-being (better life for their citizens), too. Although few countries like Ethiopia are doing very well in the conversion of economic growth into the improvement of the well-being of citizens, most are not doing so. Poor governance and corruption seem to be the stumbling blocks in achieving conversion of wealth to well-being. Africa is widely considered among the world's most corrupt places; a factor is seen as contributing to the stunted development and impoverishment of many African states. Of the 20 countries considered most corrupt in the world, 10 are in sub-Saharan Africa, according to Transparency International (2016), a leading global watchdog on corruption.

Though generally, the situation in SSA is bleak, the region is full of tremendous development promises. Emerging out of decades of stagnation, the region is now home to seven of the world's ten fastest-growing economies. The significant strides in sub-Saharan Africa's socioeconomic progress have helped to grow a vibrant middle class and propel technological advancements at a rapid pace. Lessons learned from countries performing well in the region clearly show that success in raising standards of living relies in large measure on a combination of four critical

factors: strong political commitment, disciplined prioritization of key objectives, well-crafted policies that reflect local realities, and effective systems for delivering change. In the landlocked nation of Ethiopia, novel approaches are driving significant improvements in providing primary health care for rural populations. At the same time, government policies in Ghana have made that country one of the region's most attractive investment centers and are contributing to the emergence of a robust information technology industry. And political stabilization in resource-rich Angola after decades of war has fostered major progress, including the rebuilding of the nation's infrastructure. These improvements illustrate an inescapable truth: governance matters. In fact, advances in governance constitute the single largest differentiator between the sub-Saharan African countries with the greatest improvement (Africa Economic Outlook [AEO] 2016).

The region has a potential which if well planned can be harnessed for future development. Africa is the world's most youthful continent. Today, nearly 50% of sub-Saharan Africans are under age 15. Africa's young people are the future leaders and will be the driving force behind sustainable growth across the continent. Over the next 20 years, as both infant mortality and fertility rates decline, sub-Saharan Africa will become the main source of new entrants into the global labor force. This is a trend with significant ramifications for both the region and the global economy. Under the right policies, the region could indeed benefit from a substantial demographic dividend, but the magnitude of that dividend will depend critically on the speed of decline in fertility rates and on the strength of accompanying policies. Hence, investment in education and training is essential in building an educated and skilled workforce and to encourage innovation (Africa-America Institute [AAI] 2015).

Education required in SSA region need to cater for local needs such as the provision of clean and safe water, health care, agriculture, etc. (which will eventually eradicate poverty) in addition to fulfilling twenty-first-century skills (Kamehameha Schools Research & Evaluation 2010) to be successful. This type of education will produce individuals who are critical thinkers, problem solvers, and skilled in information literacy, with mastery in a different kind of knowledge required in changing economies worldwide. The success of graduates from this education lies in being able to communicate, share, and use the information to solve complex problems, in being able to adapt and innovate in response to new demands and changing circumstances, in being able to command and expand the power of technology to create new knowledge. ICT will play a key role in this; hence good ICT policy in education and investment in ICT integration and teacher education is necessary.

Other possibilities to augment or complement education also exist. Rodríguez-Pose and Tijmstra (2005) proposed local economic development (LED) as an alternative approach to economic development in SSA region. LED is an approach toward economic development which allows and encourages local people to work together to achieve sustainable economic growth and development. LED helps to build up the economic capacity of a local area to improve its economic future and the quality of life for all. It is a process by which public, business, and nongovernmental sector partners work collectively to create better conditions for economic growth and employment generation.

Reflections and Future Steps to Improve the Introduction of ICT in Education

A phased implementation of ICT policy in education ensures that the implementation process is manageable and the development of best practices and lessons learned is gradual. The following factors are worth considering.

ICT infrastructure is the backbone of the ICT venture in education. Therefore it is important that sub-Saharan African governments mobilize support from telecommunications and ICT organizations and industry to promote affordable Internet connectivity and computer hardware and software. High costs of telecommunications prohibit schools from adopting ICT, especially in the rural areas. But technological innovation and the decreasing costs of wireless and other technologies, combined with progressive policy and regulatory environments, have resulted in the provision of telecommunication services to remote areas in Latin America, Central Europe, and Asia (UNESCO 2004). This is also possible for sub-Saharan Africa. In addition, the proliferation of mobile phone networks has transformed communications in sub-Saharan Africa. The mobile phone is fast becoming the PC of Africa. In many countries, mobiles are the only channel for effectively distributing reading material, given the high cost of books and their distribution, especially in rural areas. Mobile devices offer interactivity, the ability for readers to comment on content, to connect with other readers, and to publicly ask questions and receive support, and can deliver appropriate and personalized content, in ways that print books cannot.

The sub-Saharan governments need to be careful to avoid past failures of investment in computers and connectivity that emphasize on quantitative benchmarking based on rough indicators such as pupils per computer or investment in the technological infrastructure, investing in ICT infrastructure solely while forgetting developments in teacher training, content, partnership, and organizational and regulatory frameworks to promote participation of private providers in the development of ICT in education (Robertson 2003).

Having a comprehensive ICT policy in each of the sub-Saharan countries is something unavoidable if the region is serious about preparing future generations for a knowledge economy. On contemplating what is required of policymakers, the following ideas are put forward:

- The educational transformations associated with technology are that technology is not a mere ingredient that “boosts” teaching and learning. Rather, it is part of a collective project of educational communities, and the outcomes of that undertaking depend on a multitude of decisions at the local (schools) as well as the national and global level.
- Research input into the implementation process is important, but we need to reconfigure the systems of educational research and teaching so that we can respond more quickly and establish a more dynamic knowledge base on questions of ICT use in education. Through research, justification of continued investment of funds for ICT in education can then be

made, and educators, policymakers, educational researchers, and the public will know what can be gained by using technology in schools and at what costs.

- ICT has the potential to enhance access, quality, and effectiveness in education in general and to enable the development of more and better teachers in sub-Saharan Africa. Capacity building of the key transformers in this process, namely, teachers, is paramount to the success of ICT integration in the curriculum. Also, the focus needs to be on the integration of well-designed technologies in the context of meaningful, mindful inquiry projects, nonpresentational pedagogies, access to resources and tools, and adequate support for technological maintenance and pedagogical renewal.
- One of the phenomena of recent times has been the enthusiasm with which Africans have adopted mobile phone technology (BBC 2014). Lower smartphone prices are driving a digital revolution in Africa, allowing mobile phone users to access the Internet at unprecedented levels. In many countries, mobile phones are the only channel for effectively distributing reading material, given the high cost of books and their distribution, especially in rural areas. Nokia capitalized on the growing popularity of social networking in South Africa to launch MoMath, a mathematics teaching tool that targets users of the instant messaging platform Mxit in South Africa (SchoolNet South Africa 2012). The potential for transforming the continent's dysfunctional educational system is immense, as mobile phones – cheaper to own and easier to run than PCs – gain ground as tools for delivering teaching content. It is hoped that mediating education through social networking will help reduce the significant numbers of school-age African children who are not receiving any formal education. However, the mobile phone can be a disruption to teaching and learning, hence a need to promote responsible phone use in school. It is important to have a clear school policy on pupil phone use, to inform parents about this, and to explain the reasoning behind it. Policymakers need to seriously think about how to fuel the demand for ICT in their educational systems through mobile phone-facilitated learning in contributing to improving learning outcomes.

Conclusion

The level of development and culture in North Africa is more or less the same as Middle East countries.

Abstract

The chapter refers to policies toward information and communication technology (ICT) in primary and secondary education from the perspective of Middle East and North African region (MENA). The MENA region includes countries that vary in culture, language, religion and resources. Since it is quite difficult to cover the whole region, the researchers excluded some countries (i.e. Cyprus, Iran, Israel, & Turkey) that only share the geographical location with the other countries in the region. The analytical approach had been used to provide information on how policy deals with integrating ICT in teaching and learning in primary and secondary education in MENA region. Trends and developments are identified by analysing policy plans and strategies. Six main trends were identified in the region. The trends include using ICT in primary and secondary education to increase access to formal education, using ICT to improve teaching and to prepare students for future jobs, using data to align learning with job market, analysing performance for personalize learning, and utilizing online learning for learning and skills development. The most important finding of this section is that countries in the MENA region are willing to move forward the adoption of ICT in education by increasing their spending on planning and implementing ICT in education. However, the process of planning and implementation is not always successful due to different factors. The main challenges were: financial challenge, less attention given for the pedagogy behind ICT integration, resistance from actors, lack of cooperation, contextual challenges, technical challenges, and social and political challenges.

Keywords

ICT · MENA region · ICT policy · Primary education · Secondary education · K12 education · ICT integration in education

Introduction to ICT in Primary and Secondary Education in the Middle East and North African (MENA) Region

This chapter discusses information and communication technology (ICT) in primary and secondary education in 23 countries (Table 1) from the Middle East and North Africa, known as the MENA region. Some countries in the region share similar characteristics (e.g., language, culture, and religion), while other countries only have the geographical location as a common feature with the others. The aim of this

Table 1 MENA region

Number	Countries of the Middle East (ME)	Subregion	Countries of North Africa (NAR)
1.	Cyprus	Omitted	Algeria
2.	Iran		Egypt
3.	Israel		Libya
4.	Turkey		Morocco
5.	Bahrain	Arabian Peninsula	Sudan
6.	KSA		Tunisia
7.	Kuwait		Western Sahara
8.	Oman		
9.	Qatar		
10.	UAE		
11.	Yemen		
12.	Iraq	Fertile Crescent	
13.	Jordan		
14.	Lebanon		
15.	Palestine		
16.	Syria		

chapter is to cover ICT policies in education in MENA; since it is quite difficult to cover the whole region, we offer some guidelines and notes below to provide an overview of the region.

First, we excluded some countries as being part of MENA since their only connection is through their geographical location; these countries are Cyprus, Iran, Israel, and Turkey. Second, the remaining countries were grouped into three main regions based on similar characteristics such as sharing the same culture and geographical status. Those three regions, presented in Table 1, are (1) Arabian Peninsula countries (Bahrain, Kingdom of Saudi Arabia [KSA], Kuwait, Oman, Qatar, United Arab Emirates [UAE], and Yemen), (2) Fertile Crescent (Iraq, Jordan, Lebanon, Palestine, and Syria), and (3) North Africa (Algeria, Egypt, Libya, Morocco, Sudan, Tunisia, and Western Sahara).

Throughout the chapter, we tried to include various examples from MENA to support our claims. At the same time, the limited articles and research conducted in many of these countries limited our option of including examples of all countries in the region. So, we tried our best to include a variety of examples that represent different countries as much as possible.

Information and communication technology (ICT) in education was introduced in the MENA region as a result of national policies adopted by the governments with the help of international organizations (UNESCO 2013). Generally, in any educational reform, certain contextual challenges must be taken into consideration to effect any real change (Al Dakkak 2010). The MENA region possesses contextual factors which are unique to the region and which can affect ICT reform.

For any reform to work, there should be a strong commitment from the governmental leadership about the direction that needs to be taken (Al Dakkak 2010). The administrators must implement a long-term (5, 10, or 20 years) state-owned strategy regardless of the changes that may take place in the government and ministry (Al Dakkak 2010). Also, there should be clear plans to review, evaluate, and redesign the ICT policy and conduct real assessment and monitoring of what is happening inside the classroom. In addition, the decision-makers should address implementation steps or a road map of how ICT policy will be implemented inside the classroom. The involvements of the community's stakeholders, businesses, and parents in the reform process are important factors, and they help offer a clear vision and set standards and expectations that should be considered (Al Dakkak 2010).

The implementation and use of ICT in education lag behind in the MENA region (Chapman and Miric 2009). At the same time, in many MENA countries, children and youth learn more about how to use various ICT tools informally outside of the school system (UNESCO 2013). An example of mass usage of ICT that surpasses current capacity within the educational system and schools is the case of Egypt during the Arab Spring of 2011, when the youth efficiently used mobile devices and the Internet to communicate and organize the protest.

Recent Development of ICT in the MENA Region

Over the years, the MENA region countries have gone through many significant changes. One of these changes is the development and implementation of ICT. In this section, we consider the ICT implementations in the MENA region and present examples from specific countries in the region.

Introducing ICT/Computer Literacy as a Separate Subject

Kuwait, Jordan, Oman, and Qatar have specific objectives or courses at all three levels of primary and secondary education regarding the inclusion of basic computer skills (or computing) in their curricula (Alayyar 2011; UNESCO 2013). However, this is not the case in KSA, Egypt, and Palestine, where courses that cover basic computer skills are lacking in primary education. They are only introduced in secondary education (UNESCO 2013; Al Mofarreh 2016). While many children in KSA, Egypt, and Palestine may be learning informally how to use ICT, children who are the most disadvantaged economically or geographically will likely continue to be deprived.

ICT Infrastructure and Models for Incorporating ICT in Schools

In the case of Jordan, the first technological project, Education Reform for Knowledge Economy (ERfKE), is a 10-year project that was launched in Jordan in 2003 by the World Economic Forum. The schools and technology component of ERfKE has

been managed by the Jordanian Education Initiative (JEI) which has been operating to support and develop ICT integration in 100 Discovery Schools situated in and around Amman, the Jordanian capital (Ministry of ICT, 2012). In these schools, staff and students were introduced to an electronic curriculum delivered via an Internet-based learning platform called “EduWave.” In addition, schools were equipped with new computers, several Smart Boards, and data projectors that were installed in the classrooms (Abuloum and Qablan 2008).

In Bahrain, the King Hamad School of the Future (KHSF) project started in 2003 with 11 schools spread all over the 5 districts, and by 2010 all the schools in Bahrain became part of the project (Eqab 2003). Today, all schools in Bahrain have broadband Internet connections, equipped with at least one ICT suite. They also have data projectors and/or interactive electronic whiteboards in many classrooms (Lightfoot 2012).

Since 1999, all primary and secondary schools in Kuwait were equipped with at least 2 computer labs containing about 25–35 computers each, to teach computer literacy courses with Internet connection and data show (MoE 2008). The Ministry of Education (MoE) required all primary and secondary schools in Kuwait to have an accessible website on the MoE portal. Also, most schools have at least one computer in each classroom connected to the Internet with data shows, while some schools are equipped with a Smart Board and more recently with Wi-Fi connections in the school (moe.edu.kw 2015).

According to the National ICT Policy in education plan, primary and secondary schools in Egypt are required to have computer labs at the rate of 1 lab for every 15 classes and 1 computer, data show, and wide screen connected to the Internet for each class (Farid 2016).

The United Arab Emirates Department of Education has undertaken the UAE Vision 2021 for implementing computer-assisted learning. Part of this vision, the “Mohammad Bin Rashid Smart Learning Initiative,” will be introduced in four stages over 5 years. The initiative is designed to provide a single digital platform to support teachers, students, and parents (Galil 2014).

Use of ICT by Teachers and Students

To better evaluate ICT use in primary and secondary schools, it is important to look at the students and teachers’ access to technology. A good indicator of ICT use is the student-computer ratio in the classroom. According to a report published by UNESCO, the average number of students to computers at the primary school level in Egypt is 120 students to 1 computer, and in secondary school the number of students decreases to 25 students per computer, while in other countries such as Jordan, Oman, and Qatar, the average student-computer access is between 7 and 19 students per computer at the primary level, and it drops to 5 students per computer at the secondary level. The gap between Egypt and the other countries regarding students’ computer access shows how the MENA region is widely different in characteristics and resources. The disparity between the previous countries and

Egypt is enhanced when looking at the number of students who have access to computers connected to the Internet. In primary education in Egypt, every 441 students share 1 computer with Internet connection (Stamboliyska 2013).

In Egypt, it is obvious that the technology is not easily accessible in schools, which means that students' practice time is limited. On the other hand, countries like Jordan, Qatar, and Oman provide more initiatives to their students and teachers, encouraging them to be proficient in using ICT. Less or lack of access to technology leads to less practice for students, which leads to less experience with using the technology. It is also a sign that every teacher is responsible for teaching a large number of students with limited resources. Even though teachers may be interested in implementing and using ICT while teaching, it could be a challenge to do so with large numbers of students and limited access to technology.

Despite substantial success at creating and providing e-learning resources to schools, the common uses of these new resources do not yet align with the vision of use desired. The misalignment could be attributed to the fact that the traditional teacher-centered approach is still predominant in most schools in the region (UNESCO 2011a). For example, in 2011 in Kuwait, the use of ICT by teachers within the classroom was very limited. Computers were used predominantly for slide shows and YouTube to reinforce teaching. This practice is due to lack of teachers' training on how to integrate ICT into the classroom (Alayyar 2011; Alharbi 2012). However, Kuwaiti students are still able to acquire a high level of ICT due to the presence of computers and connection to the Internet in most homes (Alharbi 2012).

Teachers and students can achieve greater ICT skills when teachers integrate the ICT hands-on session into their classes so that students don't learn the skills in isolation. Integrating ICT skills into mathematics, science, Arabic, EFL, geography, and other subjects can help to provide a context for teaching these subjects (UNESCO 2011a, b).

Teacher Training About ICT

ICT training must be a central component in teacher preparation programs. The ideal teacher in a globalized world must be an expert in a subject area as well as an expert in the use of ICT in teaching and learning situations. Such teachers must be prepared to be active participants in integrated communities of learners (Misra 2012). In some developing countries, ICT training for teachers is based on developing computer literacy, which is considered an important component for integrating ICT in education. However, it is noteworthy that effective training should not stop at computer literacy, but should model effective teaching practices (Infodev Annual Report 2015). According to the literature, training that focuses only on ICT skills is insufficient for preparing teachers to integrate ICT in their lessons; thus, training should be more focused on the integration and use of ICT for certain contents with different pedagogy within a certain context (e.g., Koehler and Mishra 2005).

In Kuwait, for example, during the academic year 2000–2001, the Ministry of Education started facilitating and providing the International Computer Driving

License (ICDL) training course for in-service teachers to equip them with the practical skills needed for ICDL qualification. Later on, the MoE started to use incentives for teachers to encourage them to obtain the ICDL qualification or diploma (Alayyar 2011). Today, the ICDL diploma is a prerequisite for employment in public schools. The teachers suggested that ICT training should focus more on how to use ICT as a teaching aid and not only focus on acquiring ICT skills (Alharbi 2012).

The Jordanian education system adopted different strategies to prepare their teachers to meet the ICT educational policy by offering courses to improve the use of ICT in classrooms. Some of the offered courses are Word Links, Intel Teach to the Future ICDL, CADER, and iEARN. These courses are also aimed to improve teachers' ICT experience at three levels, which include ICT skills, pedagogical skills, and curriculum training (Alutaibi 2003).

In Egypt, most teachers need to earn the ICDL. They were trained to use ICT in preparing and conducting lessons by setting agreements with international companies such as Microsoft, Cisco, Intel, and Oracle. The agreement was made to help enhance the educational process through upgrading the programs and training teachers to use modern technology (Farid 2016).

Many educational systems considered ICT training courses as prerequisites for teachers' promotion and reward. However, there are no follow-up and monitoring efforts to gauge real practices. ICT policies and programs related to teacher training should be structured in a way that connects to specific classroom practices or engages teachers in a community of professional practice and ongoing development, policies that have proven to be effective in school reform (Cohen and Hill 2001). In the early phases of ICT introduction, teachers need training in the operation of hardware, software, and, to some extent, networking. As ICT use by teachers becomes more common, professional development shifts to pedagogical integration, creation of content, and development of shared knowledge and practice (Kozma 2011).

Recent Developments of ICT Policies in the MENA

ICT educational policy was defined by Kozma (2008) as "a rationale, a set of goals, and a vision for how education systems might [work] with the introduction of ICT and how students, teachers, parents, and the general population might benefit from its use in schools" (p. 1084).

In the MENA region, the first decade of the new millennium has seen policy initiatives which have promoted the use of ICT in schools in several countries (Chapman and Miric 2009). Policy makers in the region believe, like other policy makers around the globe, that access to ICT in education will help enhance learning and provide students with new sets of skills, will reach students in rural and remote regions, will facilitate and improve the training of teachers, and will minimize costs associated with the delivery of traditional instruction. These benefits will in turn help to create a skilled work force for the twenty-first century and enhance social mobility (UNESCO 2013).

The Jordanian education policy's main objective is to provide its citizens with the appropriate knowledge and skills to create a competitive economy in the global marketplace. Another goal is to maintain and extend the Jordanian society's security and stability. To fulfil the mentioned goals, Jordan has set the following objectives for its educational and strategic plan:

- Ensuring lifelong learning by restructuring the educational system
- Ensuring responsiveness of the educational system to the knowledge-based nation
- Accessing and utilizing ICT to maintain successful learning and system management
- Ensuring high-quality learning experiences

The ICT policy of Jordan focuses on incorporating both e-content and e-learning into several disciplines in all K-12 education. The Jordanian Educational Initiative is the foundation of innovation in expanding ICT through the curriculum for all grade levels in Jordan (UNESCO 2011a). The JEI has adopted policy for the use of open educational resources (OER), where it offers the public educational materials that can be accessed, used, and redistributed with an open license, at no cost, and with few or no restrictions (UNESCO 2013).

The Kuwaiti government believes that the controlled deployment of ICT in schools will create exciting possibilities for learners and teachers to engage in new ways of information acquisition and analysis, as well as new opportunities to create knowledge. ICT will enhance access to education and will improve the quality of education delivery in a more equitable way across the country. The government is therefore committed to a comprehensive program of rapid deployment and utilization of ICT within schools to transform the education system and improve the lives of Kuwaitis (National ICT in Education Strategy 2008).

In 2004, Kuwait developed "Kuwait's Strategy for Developing Education, KSDE, 2005–2025." This strategy was intended to improve the quality of public education by providing strategic guidelines for anticipating and managing existing and future concerns, challenges, and issues facing Kuwait's educational system in the twenty-first century. Among other principles, the strategy emphasized updating the curriculum to ensure the country's objectives and principles and incorporating advances in ICT in the education process. It is worth noting that the strategic document did not advise the MoE to undertake any sort of operational framework. Also, the fulfilment of the strategy was left up to the judgment of appointed ministers (AL-Refai et al. 2015).

The KSDE strategy was followed by a large total quality management (TQM) project by the MoE in 2009. The project was a result of the 2008 National Conference on Educational Development which recommended the reform of preuniversity public school education using TQM principles (AL-Refai et al. 2015). In 2008, the MoE issued the strategy of e-learning and, in 2009, started its implementation. The blended learning mode of e-learning was adopted through the e-learning strategy of the MoE in Kuwait, whose main objectives were to improve teaching and learning by introducing ICT, to increase student-centered learning, to create an environment for immediate interactions between learners and the teacher, to overcome the limits of time and place in the educational process, and to avoid the emergence of new generations suffering from technological illiteracy (moe.edu.kw 2015).

In 1999, Egypt adopted a National ICT Policy by the Ministry of Communication and Information Technology (MCIT). This policy concluded that the number one priority in Egypt is education. Both MCIT and the MoE are responsible for conducting the National ICT Policy in the area of education. The Egyptian policy uses ICT as a lever to reduce illiteracy and improve the education of its citizens by providing equal opportunities for learning regardless of age, gender, class, or geographical location (Stahl 2008). The ICT policy in education was formulated to a working plan that includes seven major points (Farid 2016), as follows:

- Integrating technology in schools.
- Introducing developed educational software.
- Providing electronic educational services, such as e-content for K12, and virtual classes for effective transmission.
- Establishing the infrastructure of the information technology by which information could be exchanged among schools, education directors, administration, and the ministry.
- Distance-training national net: Upgrading the use of videoconferencing and video streaming and equipping some classrooms with videoconferencing tools. Distance interactive learning is encouraged to test the abilities of those attending the videoconference training sessions.
- Training the educational cadres.
- Co-projects with donors, by using local or foreign loans and grants and setting agreements with international companies such as Microsoft, Cisco, and Intel to constantly upgrade the programs and regularly train teachers to use the ICT. Cooperating with the European Union, World Bank, US Aid, etc., to equip schools with technological equipment that will help in improving the educational process.

In the Kingdom of Saudi Arabia, there is a prolific list of implied rules/policies regarding educational policy in KSA. In addition, a variety of annual documents are released in relation to the implementation of ICT such as ministerial resolutions, administrative declarations, school memos, and curricular letters (Al Mofarreh 2016). However, there is neither a stand-alone policy for ICT nor a syllabus that incorporates ICT. Implementation at the school level is through pedagogy that relies predominantly on textbook use. There is neither a fundamental document nor an article that completely covers or strictly defines ICT policy. Rather, information regarding ICT is distributed through a general board of educational policy (Al Mofarreh 2016).

ICT Initiatives

In this section, the ICT initiatives that are emerging as new and potentially complementary ways to reform education in the MENA region are presented. The Brookings Institution (2016) identified six initiatives that are emerging in the MENA region, as follows:

Increasing Access to Formal Education

Countries in the MENA region have made great effort to increase access to formal education. However, in countries with limited budgets, governments are unable to effectively serve their populations, leaving youth with worse prospects than the previous generations. ICT can present an opportunity to complement the governments' efforts to scale up access to education. For example, Tabshoura is a free, interactive trilingual e-learning platform that intends to offer the complete Lebanese curriculum from kindergarten to grade 12 (The Brookings Institution 2016). Another initiative is Nafham ("We Understand"), a free online K-12 educational video platform launched in Egypt in 2012, on which teachers and users can post 5–15 min of educational videos on any topic covered in the public-school curriculum (The Brookings Institution 2016). Also, in Saudi Arabia, Khan Academy's videos were translated and made available to over 350 million users in the Arab world (Friedman 2015).

Using New Media

Most classes in MENA countries are still teacher centered, memorization based, and assessment focused. Using ICT tools for educational purposes has opened the space for students to be more active in the learning process (The Brookings Institution 2016). ICT also allows the learning process to be more customized to the needs of students through differentiated learning, thereby improving teaching and learning inside and outside the classroom.

The first such initiative to use new media in the MENA region was the Jordanian Educational Initiative in 2003 (The Brookings Institution 2016). Through partnerships with key global and local actors in the fields of technology and education, one of the JEI's goals was to integrate ICT in schools to improve students' outcomes and capabilities and better prepare them for the knowledge economy. The JEI's model involves improving schools' ICT readiness through providing hardware and software, training for teachers and school leaders, changing management, and offering digitized content and enrichment materials to improve student learning. JEI pilots a range of programs, applications, and games across K-12, focusing on English and Arabic literacy, math and sciences, computer programming, critical thinking, and other soft skills. (The Brookings Institution 2016)

Preparing Learners for Future Jobs

Youth in the MENA region need to be prepared to compete in the global market. They need to develop other skills, besides the core-subject knowledge, that are in demand among employers, such as collaboration, creativity, flexibility, communication, and foreign language skills (IFTF 2011). Today, high school graduates in the MENA region are weak in communicating in either or both Arabic and

English languages, which limits their ability to perform effectively and professionally at work. One way in which these skills can be strengthened is through the use of more creative, engaging, and personalized technological mobile and web application tools to develop their language learning. For example, Little Thinking Minds (Jordan), an interactive digital Arabic literacy program for young learners, is accessible via digital books and mobile applications. Another is Josoor Arabia (Egypt), a program that aims to promote Arabic-language content on the Internet. The program is implemented in collaboration with SchoolNet Africa and AGENT Consulting. A third example is AlHudHod (Jordan), a program for early learners that is taught using smartphone and interactive boards, facilitating Arabic literacy and teaching numeracy in ways that promote imagination and creativity.

Another skill that is critical to develop in the next generation of youth besides digital literacy is computer programming. Computer programming has grown in popularity across schools in parts of the MENA region, like Lebanon, Jordan, the UAE, and Kuwait (Knight 2015). Other similar private initiatives have also been launched, such as The Coding Circle in the UAE, Hello World Kids in Jordan, and Coded in Kuwait, which offer software coding courses to a variety of ages of children and youth.

Using Large Data to Align Learning with the Job Market

The ability to digitize information provides more comprehensive data for more effective decision-making and policy formulation by government, educational institutions, and industry leaders. Hence, the developed policies and programs aligned with the needs of the job market that can ease the transition for youth from education to work. This trend is primitive in the MENA region. However, given the high unemployment rates of youth in the region, technology could be used to leverage such data in creating medium- to long-term strategies to provide youth with better work prospects. Doroob, a new initiative in KSA, started in 2015. Based on the needs of the job market, Doroob offers training opportunities to unemployed youth who are not sufficiently trained to fulfil future jobs. It offers a range of free online accredited professional development certificates to prepare youth at three levels: (1) career readiness (ICT and English language classes), (2) job-specific training (in hospitality, accounting, retail, information technology, fashion, and more), and (3) on-the-job training.

Adopting New Metrics and Performance Analytics

When it comes to assessing and personalizing learning, ICT can provide formative assessments to ensure that students and teachers identify learning gaps of each individual in real time. ICT can help administrators and teachers monitor students regularly and provide opportunities for remedy if they are failing. In the context of

the classroom, it offers teachers the flexibility to alter online content or incorporate new innovative materials and programs that provide personalized support to address the specific learning needs of students at different academic levels. There is a growing investment in learning management systems – online platforms for administering, documenting, tracking, reporting, and communicating within schools. In 2012, the government of UAE launched the Mohammed Bin Rashid Smart Learning Program, the most ambitious effort in the region, which aims to integrate technology across most of the country's public schools, giving students from grades 6 to 12 their own tablets (The Brookings Institution 2016).

Offering Open Online and Blended Learning

There is a great demand for lifelong learning, including up-skilling and on-the-job training that can be facilitated by using ICT. Introducing blended online learning for students in primary and secondary education helps prepare them to integrate this technology in the future. Examples of blended online learning initiatives are the Nafham, Tahrir Academy (Egypt), and Tabshoura (Lebanon), which complement the national curricula in their respective countries by providing lessons using online media.

Relevance of Cross-National and Worldwide Strategies and Plans

The whole world is connected somehow; whenever something happens in one part of the world, it affects the other parts of it. The influences could be small or big, economic or political, and social or environmental. Globalization influences education quality and decisions; especially ICT has a huge influence on schools' curricula, planning, and implementation. Educators and ICT planners must be able to "think globally and act locally" when planning education due to the influence of the international culture on education (Misra 2012).

The integration of ICT in education through policy brings change into the learning environment. Research has shown that a connection exists between innovation and national policies that advance ICT use (Jones 2003). An impressive case of successful ICT policies and adoption can be seen in Jordan, which was recognized as a model in the Arab world and in international literature. Jordan's ICT initiative has served as a leader in ICT infrastructure and developed that can improve human capital, promote economic growth, and decrease poverty (UNESCO 2011a, 2013). Jordan's successful adoption of ICT has relied heavily on continuous development and updates to the policy documents that were initiated in 2004 and were updated to an overall policy framework for 2007–2011 and again for 2009–2013 (UNESCO 2011a).

In addition, the call for increasing ICT in education from developed countries has encouraged some countries in the MENA region to spend more on planning, buying, and implementing ICT in the education sector. Within the Arab world, KSA has

invested greatly in developing ICT in the public education sector. The Saudi government was interested in improving education reform and implementing modern technologies and invested over \$2,500,000 (almost £2 billion) in 2007 (Tatweer 2015). It also sought to improve the public education through revising the curriculum and by introducing technology to facilitate teaching. Furthermore, this improvement included development and training sessions for the educators to guarantee the success of the educators' ICT adoption. Over time, the Saudi government increased its budget for the education sector in 2015 to reach about \$47 billion (more than £36 billion). A considerable amount of the budget goes to funding the implementation of technology in schools' curricula and to enhancing the ICT facilities (Ministry of Finance 2015).

It is clear that countries in the MENA region are being influenced by the developed countries in the field of ICT in education. At the same time, the increased budget and planning in the MENA countries is evidence that they are willing to move forward in their adoption of ICT. However, we cannot conclude that all influences were successful and the spending and adoption were right on point. There are other issues surrounding the adoption process – whether it is before, during, or after adoption – that decision-makers should consider. From a global viewpoint, studies in developed countries have shown that neither the abundance of technology implementation nor the great investment in technology resources in the classroom directly contribute to academic achievement and improved learning outcomes (European Schoolnet 2006; Ungerleider and Burns 2002; Wozney et al. 2006).

Challenges and Relevance of Research for Education Policies on ICT

MENA countries are trying their best to have a successful ICT implementation by increasing their spending, but it has proven to be worthless without considering other factors that influence ICT success. Many factors need to be considered when planning to develop policies toward implementing ICT in education.

Financial Challenge

Some countries in the MENA region lack the financial support to add to or advance on the technologies needed to adopt ICT in education, while other countries can afford to do so. In the region, KSA is considered the biggest market for ICT, as the government has invested almost \$7 billion, and Qatar is considered the fastest growing, while Egypt is spending less than the amounts it used to spend in 2007 and 2008 (Hamid 2013). The countries that can afford the adoption and implementation must keep in mind that it is not a one-shot investment; it requires ongoing maintenance expenses, updating the system in use, and training and supporting the users.

Less Attention Given to Goals of ICT in Education

It is important for the governments in the MENA region to understand that installing ICT will not automatically improve learning standards. The “goals of using ICT” and the actual accompanying pedagogy must not be overlooked (Abuloum and Qablan 2008). Policy makers in the MENA region do not offer a pedagogical model or pedagogical vision toward the ICT implementation process. This lack of focus and interest has contributed to the absence of strategic directions on how to implement ICT policy and use ICT in the classrooms (Alkhezzi and Abdelmagid 2011; Alsharija et al. 2012). As Ghazal (2014) stated regarding ICT use in primary and secondary education in Jordan, the “absence of a focused strategy on the integration of ICT into schools is hampering the spread of the JEI, a public-private partnership that envisions accelerated education reform through technology integration, according to its CEO” (para. 1).

Resistance from Actors

The resistance of the actors in the educational system – principles, school managers, teachers, students, and parents and other stakeholders – can also hamper the use of ICT in schools. The lack of communication between the administrator and the user can cause a disconnect in vision, mission, and implementation. The disconnect in turn can lead the actors within the system to resist the ICT initiatives because they may not understand where the system is heading and why. They may thus question the sufficiency of their old skill sets and methods of assessment and whether it is needed or not.

Also, other countries have managed to counteract the resistance of integrating technology into education by partnering multi-stakeholders. The partnership initiative was promoted by the World Economic Forum and started by launching the JEI (UNESCO 2012a, b). The efforts toward having multiple partners involved in the learning process, including the stakeholders, teachers, and students, promote shared understanding and build a common vision that connects all players in the learning environment.

Lack of Cooperation

Teachers, students, and parents fail to cooperate and coordinate their efforts not only because they’re unaware of or do not understand the current reform efforts but also because they are unable to plan for ICT integration. They fail to contribute to the efforts because they are not equipped with the right skills and tools to enable them to enact the reform measures. Countries in the region still rely on the teacher-centered approach, a traditional teaching method that contradicts with the policy of ICT integration and decreases its benefits (UNESCO 2015). In other words, it is unreasonable to ask teachers to switch to a student-centered approach in teaching, while they

are not trained to do so; nor is it fair to ask students to answer critical thinking questions when their teachers themselves are not capable of teaching them how to think critically.

Contextual Challenge

An example of this challenge is lack of fluency in the English language. Poor English language, especially in K-12 education, among both students and teachers increases resistance to ICT use. The new ICT interface design uses English as the main navigation language; this causes confusion to the users since they are not fluent users of the English language. The absence of suitable and easy-to-use learning management system that fully or partly supports Arabic is still not an available option for Arabic-speaking users of ICT (Alfelaj [2016](#)).

Technical Challenges

Countries in the MENA region are faced with technical challenges when they implement a technology that does not enhance the users' technical or thinking skills. In Kuwait, K-12 ICT education curriculum books (e-books) can be found online; however, they do not add to the students' skills or knowledge, since they are no different than the printed books (Al-Hunaiyyan et al. [2008](#)). The K-12 e-books lack the interactive part, the extra activity related to the lesson learned, and the extra knowledge the student may benefit from.

Social and Political Challenges

Unstable governments in the MENA region lead to instability in the Ministries of Education of the affected countries due to frequent changes in education ministers. According to UNESCO ([2015](#)), the repeated change of administration alters the ICT educational policy status or the implementation process of the policy.

ICT Developments in the MENA

Infrastructure, Hardware, and Content

The enhancement of the Internet and networking technologies significantly impacts teaching and learning. Students and teachers use a variety of ICT tools in the technology-mediated learning environment to engage in learning opportunities anytime anywhere. They use these tools to communicate, collaborate, and share resources associated with the learning experiences. Table 2 below presents a selection (pertaining to the MENA countries) of the Networked Readiness Index (NRI)

Table 2 Networked readiness index 2015

Rank (out of 143 countries)	Country	NRI value	Income level
23	UAE	5.3	HI
27	Qatar	5.1	HI
30	Bahrain	4.9	HI
35	KSA	4.7	HI
42	Oman	4.5	HI
52	Jordan	4.3	UM
72	Kuwait	4	HI
78	Morocco	3.9	LM
81	Tunisia	3.9	UM
94	Egypt	3.6	LM
99	Lebanon	3.5	UM
120	Algeria	3.1	UM
131	Libya	2.9	UM
136	Yemen	2.5	LM

Income level: HI high-income economies, *UM* upper-middle-income economies, *LM* lower-middle-income according

2015 of 143 countries around the world (Schwab and Sala-i-Martin 2014). The NRI reveals that mostly rich countries benefit from the ICT revolution; that means ICTs have opened up a new digital divide. Although Internet access is expanding and schools increasingly have access to the Internet, the skills required to leverage ICTs remain inadequate in many countries.

The ICT divide within the MENA region is the largest among all regions. The UAE (23rd, moved up one) and Qatar (27th, moved down four) continue to lead, ahead of Bahrain (30th), KSA (35th), and Oman (42nd), which are all countries of the Arabian Peninsula. All owe their success to a very strong commitment to ICT development by their respective governments. On the other hand, Kuwait's performance (72nd) stands at odds with its peers, even though Kuwait has the financial resources to implement ICT in its schools. In the rest of the MENA region, only Jordan (52nd) features in the top half of the rankings. Morocco follows at a middling 78th, but it is the country that has improved the most (move 21 places up) over the past year. Yemen (136th) remains the region's worst-performing country, 115 places behind the UAE.

Pedagogical Practices and Conditions for Change

Just like countries with bigger budgets, some MENA countries have invested in computers in schools despite their limited educational budget. Their investment stemmed from the belief that the technology will change the "what and how teachers teach and learners learn" (Lightfoot 2012). Educational amendments associated with the advancement of the twenty-first century learning skills have become a trigger for investment in the ICT foundation in schools.

Table 3 shows that Kuwait and Jordan recommend the use of ICT in all subjects for every level, kindergarten through 12th grade. However, Egypt's policy recommendation for ICT integration does not cover all subject areas.

Conclusion and Recommendations

This chapter provides information concerning ICT and educational policies in primary and secondary education in the MENA region. The MENA region includes countries that vary in culture, language, religion, distribution, and resources. These factors contribute, directly or indirectly, to the adoption of ICT in any given country. In addition, the degree of political stability in the region contributes to the adoption process, the success of adoption, and the recent development of ICT. It influences ICT literacy in schools, the ICT infrastructure, the students and teachers' use of ICT, and teachers' ICT training.

Policies concerning ICT have been influenced differently according to each region's specific characteristics and educational goals. Six initiatives were developed based on the new policies. These initiatives included increased access to formal education, using media to improve teaching, preparing students for jobs, using data to align learning with the job market, analyzing performance to assess and personalize learning, and utilizing online learning for learning and developing skills.

Our research in the use of ICT in the MENA region highlighted the challenges facing ICT research on policy. Among the critical challenges that faced the researchers while reviewing the literature related to ICT educational policy in the MENA region is the lack of sufficient literature. It was difficult to locate studies, books, reports, or peer-reviewed articles discussing the efficiency and effectiveness of ICT policy and implementation. The majority of the literature available on ICT discusses the new ICT innovations in classrooms. However, the literature is missing the documentation of the ICT implementation process, from start to finish, and the follow-up part, including challenges, effectiveness, and analysis. It is an urgent matter in the field of education, development of ICT, and human development to have available information and documents dealing with the implementation process in the field of ICT.

Thus, we conclude our study with the following recommendations that may lead to a better understanding of the relationship between ICT educational policies in the MENA region and the real status of ICT integration within K-12 public schools. First, we recommend the cooperation of educators and education ministers from each of the countries in the MENA region. Second, we recommend to compile an information bank that contains studies and statistics and that can recommend new research topics in the area of ICT for those who are interested. Third, we recommend developing rules and regulations governing the adoption of ICT specific to each country. The involvement of stakeholders, especially educators, will help develop better rounded rules that fit each region specifically when formulating ICT policy in education. Fourth, a change in teaching approach is highly recommended in the MENA region to help teachers, educators, and policy makers move from traditional

Table 3 The status of ICT integration within the K-12 curriculum

Abstract

The chapter draws attention to ICT policies in primary and secondary education in Europe. The authors explore a selection of policy initiatives and policy developments at regional and local levels considered to be significant for primary and secondary education in the region. Policy trends and early history of different national and European policy initiatives are highlighted, with a particular focus on the role of the European Union on the matter. The chapter addresses an increased differentiation between policies that: a) promote pedagogical use of ICT for improving subject-specific learning, b) promote fostering of learners' digital competence, and c) express initiatives related to the field of computer science. Cross-national and national examples provide a rich base of examples that showcase the variety of policy initiatives in the European region as well as recent trends and challenges with regard to educational ICT policies. The authors call for a stronger evidence-base in the field, and underline the need to utilise evidence to greater extent when designing pedagogical approaches, methods and tools involving ICT. The most pertinent challenges found are related to teachers' professional digital competence, changes in the world of work such as automation and the importance of lifelong learning and finally the increased emphasis on digital citizenship and digital responsibility.

Introduction to ICT in Primary and Secondary Education in Europe

Europe is a diverse compilation of countries, regions, political unions, and partnerships. The region encompasses some of the world's most densely populated and some of the most desolated. Europe contains the world's largest trading bloc, the European Union (EU), and is also host to a wide range of bilateral and multilateral partnerships regulating economic, social, and political alliances between countries and regions.

The European region has been characterized by the term *variable geometry* (Delrio and Dondi 2008), which seeks to capture not only the area's diversity in culture, economy, politics, and demographics but also the somewhat fluid definitions through which countries or regions are included in the alliance. A United Nations list of European countries comprises 53 sovereign states, including Vatican City and the island of Sark. For the sake of consistency, this chapter will use the United Nations Statistic Division's list, as was used in a previous edition of this handbook. This list suggests that Europe is divided into four major regions based on environmental, cultural, and economic similarities. Eastern Europe consists of Belarus, Bulgaria, the Czech Republic, Hungary, Poland, Moldova, Romania, the Russian Federation,

Slovakia, and Ukraine. Western Europe consists of Austria, Belgium, France, Germany, Lichtenstein, Luxembourg, Monaco, the Netherlands, and Switzerland. Northern Europe includes the Åland Islands, the Channel Islands, Denmark, Estonia, the Faroe Islands, Finland, Guernsey, Iceland, Ireland, the Isle of Man, Jersey, Latvia, Lithuania, Norway, Northern Ireland, Sark, the Svalbard and Jan Mayen Islands, Sweden, and the United Kingdom. Finally, Southern Europe consists of Albania, Andorra, Bosnia and Herzegovina, Croatia, Gibraltar, Greece, Vatican City, Italy, Malta, Montenegro, Portugal, San Marino, Serbia, Slovenia, Spain, and Macedonia [Note 1].

Since each European country develops its education policies within a national context, content and structures vary widely. The aim of this chapter, *ICT Policy in Primary and Secondary Education in Europe*, is to provide an overview of ICT policies that illustrate some of the variety in the European region and the trends and challenges facing such policies as they relate to primary and secondary education. This chapter is not exhaustive and cannot cover the entire range and variety of policies in Europe. Instead, we will discuss a selection of policy initiatives and policy developments at the regional and local levels that we consider to be relevant and of interest to a wider audience both within and outside the region. In general, policies for economic, social, and political developments in European countries are increasingly geared toward recognizing the impact and importance of a digitized society, including for the educational sector. European countries were early to integrate information and communications technology (ICT) into primary and secondary education. Some countries developed policies for ICT in education throughout the 1990s, such as **Germany's** *Schulen ans Netz* [Note 2] and the **United Kingdom's** National Grid for Learning (BECTA 1998). Then, in the early 2000s, **Italy** released its Action Plan for the Information Technology Society (2001–2003), and **Finland** introduced its program for Education, Training, and Research in the Information Society, the National Strategy for 2000–2004 (Delrio and Dondi 2008).

The early phases of ICT integration in primary and secondary education often focused on teaching computing as a subject with limited additional curriculum integration. The early 1990s witnessed the advent of the multimedia computer as a possible learning resource within curricula (Plomp et al. 2009). With the introduction of the Internet, national governments began to develop policies for ICT as a tool for expanding learning in both content and topics (BECTA 1998). Then, in the mid- to late 1990s, several EU initiatives emerged for integrating ICT in primary and secondary education, representing an elevation of these priorities to the cross-national level. Lately, the use of ICT in primary and secondary education has been strongly connected to the general strengthening of knowledge, skills, and competences necessary for European citizens. Examples of this connection can be found, for instance, in the EU's definition of Key Competences for Lifelong Learning (European Parliament and Council 2006) and in the frameworks of the recent OECD PISA studies (OECD 2010a, 2013, 2016a).

In the following section, we will present some of the most recent and influential policy efforts at the EU level, look at current cross-national implementation strategies endorsed and implemented by European countries, and describe examples of extraordinary efforts at the country and local levels.

Recent Developments in ICT in the European Region

In this section, we will elaborate on recent developments and initiatives in different countries in the European region, focusing primarily on the topics of uptake of ICT in education, the concept of digitization in schools, and the use of ICT for student assessment.

Recent Findings on the Uptake of ICT in Education in European Countries

An important metric for the integration of computers into European schools has been the relationship between the number of students and availability of computers, aggregated at the national level. This metric is reported in, among other studies, the IEA studies SITES Module 1 (Pelgrum and Anderson 1999), SITES 2006 (Law et al. 2008), and ICILS 2013 (Fraillon et al. 2014), as well as in the OECD PISA studies from 2006 and onward (OECD 2006, 2010b, 2014a, 2016b). Though this metric is rough in the sense that it does not explore actual pedagogical usage in classrooms, it still provides an indicator of educational systems' capacities for investment and priorities concerning the integration of ICT in schools.

The latest PISA 2015 results (OECD 2016b) show that the median number of computers available per student aggregated at the country level is 0.66 for the 40 European educational systems participating in the study [Note 3], ranging from 0.14 in Kosovo to 1.49 in Iceland. Comparing countries, a median of 97.8% of computers are connected to the Internet, again with huge variations, ranging from 29.2% in Kosovo to 100% in Malta.

The results from IEA TIMSS 2015 [Note 4, 5] (Mullis et al. 2016) show that, of the 11 participating European countries [Note 6] that reported on the availability of computers for mathematics lessons in grade 8, the average coverage was 32% of students, ranging from 4% in Malta to 65% in Sweden. For grade 4, the average coverage among the 23 participating European countries [Note 7] was 40%, ranging from 13% in Serbia to 84% in Denmark.

Digitization of Schools and BYOD Initiatives

A wide range of parameters can be used to describe the uptake of ICT or, in a wider sense, the digitization of schools. According to a report from the European Schoolnet based on a survey of school IT administrators in Europe, countries vary widely with respect to their levels of digitization. The report states that six countries can be grouped together according to the extent of digitization:

- Highly digitized schools [Note 8] Denmark, Norway, and Sweden
- Digitally developing schools [Note 9] Poland, Romania, and Turkey

In addition, there are two Linux countries, Italy and Spain, with high levels of equipment and above-average Linux OS penetration (European Schoolnet 2015b, p. 24).

Educational authorities and school owners are increasingly supporting one-to-one learning environments for their students and teachers in primary and secondary schools. Due to considerable costs and maintenance demands, a growing interest in BYOD (bring your own device) or BYOT (bring your own technology) approaches rises. Such approaches to meet greater access needs also increase demands on teachers, who need to be ready to assist their students with a range of different digital tools (European Schoolnet 2015c). An example of BYOD implementation can be found in **Austria**, where two national initiatives are helping to drive eLearning, mobile learning, and BYOD (European Schoolnet 2015c).

The degree of digitization indicates an access divide, such that countries in Northern Europe seem to be better off in terms of equipment levels and policies supporting a diversity of technologies than Eastern and Southern European countries. However, this only indicates the potentials or opportunities teachers and students have to use ICT in school and does not reveal anything about the *extent* or *ways of use* of technology in schools.

Assessment and Digital Exams

Assessment practices influence and guide student learning in many ways. Efforts to digitalize matriculation exams are on the agenda in several European countries. Such interventions can have huge influences on digitalization and the overall implementation of ICT in schools. In **Finland**, the Finnish National Matriculation Examination Board is digitalizing the matriculation examination through the digitalization project DigiAbi (2016–2019) [Note 10]. This project will allow Finnish students to use the most common office applications, including multimodal text (including text, pictures, audio, and video), to respond to questions in the matriculation exam. Of all European countries, **Denmark** is likely the most advanced in terms of online exams in upper secondary schools. In 2013, Denmark adopted the Strategy for Digital Welfare, including an initiative for digital written tests in upper secondary education. The initiative also includes digital support for giving marks on academically relevant assignments and tests in primary and secondary schools (European Schoolnet 2015d).

Recent Developments on Policies on ICT in the European Region

Cross-national policies and, to a varying degree, national policies throughout Europe posit policy expectations that concern both the school and the education system as a whole. This is done in order to prepare students for further studies and their professional lives, which, to a great extent, will include the use of ICT (Balanskat and Gertsch 2010; Binkley et al. 2012).

A general observation on the development of policies for ICT in primary and secondary education in Europe is the move toward a more fine-grained understanding of different strands of applications of digital technologies. Initiatives concerning supporting ICT to improve subject-specific learning processes and general learning outcomes are increasingly being separated from initiatives supporting the fostering of digital competence. In this chapter, these two issues are treated under the heading “[National-Level Policies](#)” in the next section.

In addition, a separate strand of initiatives integrating “new” subjects or topics directly related to the field of computer science has also gained traction. These topics are labeled differently between countries but are commonly described in this chapter as the integration of ICT, technology, and coding within the curriculum. Recent developments see the use of the growing evidence base on ICT in schools, digital competence, and curricular operationalization as the foundation for evidence-informed policymaking at the national level (see section “[Integration of ICT, Technology and Coding in the Curriculum](#)”).

National-Level Policies

At the national level, we see a range of initiatives being implemented or emerging based on specific national educational contexts. Here, we introduce a few examples showcasing a variety of different policy approaches and related actions.

A concrete example of how research evidence is being utilized to shape national educational policies can be found in **Germany**, where the division of responsibilities between the federal and the regional (Länder) levels creates a complex context for policymaking. Based on, among other findings, results from the IEA ICILS 2013 study (Fraillon et al. 2014), in which German students performed lower than anticipated on measured ICT competences, German policy makers at the federal level took action by citing the study in an official 2014 decision (Bundesministerium für Bildung und Forschung 2016). Official exchanges between policy makers and experts in the field have been arranged, and the recent release of the national strategy for Education in a Digital World (Bildung in der digitalen Welt 2016) laid the foundation for systematic capacity-building for the inclusion of digital competences in Länder’s educational systems, including primary and secondary education, VET, and higher education. The Education in a Digital World strategy encompasses actions for digitalization within the fields of educational plans and curricular developments, CPD for educators and teachers, infrastructure, educational media and content, educational administration at all levels, and necessary actions within legal and functional frameworks. The strategy also promotes a strong focus on fostering digital competence as transversal competence for learning in all subjects.

Austria introduced a computer-based school-leaving exam in 2014/2015 and launched digital versions of schoolbooks in 2016. It has also initiated funding schemes for interactive whiteboards and mobile applications. Secondary school reforms aim to develop school policies that resonate with modern society, focusing on transversal key competences as their primary outcomes. Under the umbrella

agenda “eFit 21,” the Ministry of Education has collected strategic aims, measures, and concrete projects. The main strategic objectives are to use ICT in schools to enhance the quality and efficiency of teaching and learning and to foster digital competences and social inclusion. An example of tangible output is the LMS (Learning Management Systems) project, which provides teachers learning modules for competence-oriented teaching (European Schoolnet 2015e). The www.digikomp.at initiative in Austria is also worth noticing as it provides a digital competence framework for learners and teachers in grades 1–12. It emphasizes the importance of digital competence in subject teaching but has not been integrated as a part of teacher education.

The 21 German-speaking or multilingual Cantons in **Switzerland** have published the curriculum “Lehrplan 21.” It covers a new curriculum for all subjects including a new module called Media and Informatics “Medien und Informatik.” It derives from the existing ICT module and defines competence in the areas of media education and informatics and is obligatory for all students. Lehrplan 21 structures topics along seven fields of action [Note 11], and these provide schools with guidance on the implementation of the curriculum. All Cantons have to develop competence framework and websites for schools and teachers with examples for lessons and projects and provide new textbooks on the issue.

In 2012, **Flemish Belgium** implemented a new policy plan for ICT and media literacy, putting forward a comprehensive action plan and implementation policies. The main goals are to support the development of a competence-based curriculum and frameworks, to increase spending on ICT infrastructure in schools, to fund open digital educational resources (including serious games, in-service teacher training on digital competences, and media literacy), and to boost research and innovation in the field. A specific outcome is a personalized digital platform for students in primary and secondary education for integrating data, knowledge, and information across all relevant school actors. This system will be incrementally developed to support capabilities in learning analytics (European Schoolnet 2015f).

The **Czech Republic** has devised a strategy for educational policies for the period from 2014 to 2020. The strategy has three main priorities: to reduce inequality in education, to support quality teacher training, and to support the responsible and efficient management of the educational system. The strategy links to ICT in primary and secondary schools through a general recognition of the importance of the role of digital technologies in teaching and learning. The initiative also includes a separate strategy for digital education, with a strong focus on modernizing the Czech educational system and enabling students to become lifelong learners in a digital society and a digitized labor market. The digital education strategy has three priority objectives for interventions: new digital teaching and learning methods, students’ school-related digital competences, and the development of computational thinking. Concrete initiatives are operational programs focusing on the purchase of ICT equipment and teacher training in the field of ICT (European Schoolnet 2015g).

For the period 2011–2017, **Denmark** is pushing forward a comprehensive initiative for public schools addressing the structure of the school day, funding for teacher and headmaster training, and a nationwide system of learning consultants.

Boosting the use of ICT in public schools remains a high priority and is facilitated by a state initiative to develop a national market for digital learning resources by supporting 50% of school owners' purchases, providing funding to developers, and delivering an innovative quality framework. Capacity-building efforts involve building networks of digitally competent teachers, digital learning resource developers, and school principals involved in leading digital change. Beginning in 2013, the initiative has been followed-up with an extensive research program and a reform of teacher education (European Schoolnet 2015d).

An extensive strategy for lifelong learning between 2014 and 2020 guides efforts to modernize the educational system in **Estonia**. The strategy seeks to change the learning approach from teacher-led to student-driven and to accomplish personalization through the application of ICT. It also focuses on digitally competent school leadership and aligning lifelong learning opportunities with labor market needs. Estonia aims to foster digital skills and equal opportunities for learning in the long term. Responsibilities for fostering digital skills are shared between the state (e.g., through curricula, frameworks, and specific programs, such as digital learning resources) and school owners (e.g., through digital infrastructure, connectivity, and virtual learning environments) (Kerb 2015). A specific large-scale initiative at the school level is the 1:1 mobile learning initiative, which was organized according to a BYOD model. Together with university and business partners, Estonian authorities have also established the Information Technology Foundation for Education (HITSA) [Note 12], with a mission to "...ensure that the graduates at all levels of education have obtained digital skills necessary for the development of economy and society [and that] the possibilities offered by ICT are skilfully used in teaching and learning" (European Schoolnet 2015h, p. 6).

Integration of ICT, Technology, and Coding in the Curriculum

European education systems also take different approaches to relate to and integrate digital technology in their curricula and pedagogical use of ICT. This section explores countries that have introduced ICT as a separate subject taught either based on specific curriculum goals or as a general competence across disciplines. For instance, of the European countries participating in the ICILS 2013 study, ICT is a compulsory subject in secondary schools in the Czech Republic, Lithuania, Poland, Russia, and Slovenia and an optional subject in secondary schools in Germany and Slovenia (Fraillon et al. 2014). Based on a review of national instruction time, the Eurydice network monitors the national implementation of ICT and technology as separate subject domains in European countries (European Commission/EACEA/Eurydice 2016).

ICT is taught as an independent theme or subject in several EU member states. Some allocate a prescribed number of hours to the subject each year (Bosnia and Herzegovina, Bulgaria, Cyprus, Germany, Greece, Spain, Hungary, Lichtenstein, Latvia, Montenegro, FYROM/Macedonia, Malta, Portugal, Romania, Slovakia, and Turkey). Most countries in this group (except Greece, Slovakia, Spain, and Macedonia)

allocate time only at the secondary level. Overall, Greece dedicates the most hours to ICT at all grade levels, and Bulgaria dedicates the most hours to ICT in upper secondary classes. Denmark, the Netherlands, and the United Kingdom give schools and teachers the flexibility to allocate time across curriculum subjects as they see fit. A third group of countries incorporates ICT into instruction time for other subjects or as a flexible option (Switzerland, the Czech Republic, Denmark, Estonia, Ireland, Iceland, France, Lithuania, Austria, Poland, Serbia, Slovenia, and the United Kingdom), with varying degrees of implementation. Combinations of these three modes are also present in several countries (European Commission/EACEA/Eurydice 2016).

Technology is taught as an independent theme or subject in 19 member states (Bosnia and Herzegovina, Belgium [French-speaking and Flemish parts], Bulgaria, Cyprus, the Czech Republic, Germany, Estonia, Greece, Spain, France, Croatia, Hungary, Italy, Lithuania, Montenegro, the Netherlands, Poland, Portugal, Romania, Serbia, Slovenia, the United Kingdom, and Turkey). Of these, only three countries (Lithuania, the Netherlands, and the United Kingdom [Scotland and Northern Ireland]) offer technology education in upper secondary schools. Slovenia dedicates the most hours to technology, allocating a total of 319 h across grades 1–9. A variety of European countries also either integrate technology into other parts of the curriculum or offer a mix of the two modes of integration (European Commission/EACEA/Eurydice 2016).

Computer Programming, Computational Thinking, and Coding

As a part of the digital transformation in Europe and to strengthen students' competence, skills, and employability for the twenty-first-century job market, computer programming, computational thinking, and coding have been central to recent developments within European schools. Curriculum studies from European Schoolnet (2014, 2015a) show that among the European countries explored in the study, 15 (Austria, Bulgaria, the Czech Republic, Denmark, England, Estonia, France, Hungary, Ireland, Lithuania, Malta, Poland, Portugal, Slovakia, and Spain) include computer programming or coding as part of their national or local curricula, while Finland and the Flanders region of Belgium have plans to introduce these subjects. Countries offer multiple rationales for the integration of coding; however, the three most prominent involve this subject's ability to foster logical thinking skills, coding and programming skills, and problem-solving skills. Improving the ICT sector and increasing the number of students in computer science are also priorities for ten of the surveyed countries (European Schoolnet 2014, 2015a).

It is notable that the forthcoming IEA ICILS 2018 study includes a module for the direct assessment of computational thinking skills as an international option for participating countries [Note 13]. Though computational thinking is not directly analogous to programming or coding, the concepts are related. According to the IEA, computational thinking for working out how computers can help solve problems entails such processes as problem-solving, design, and relating basic concepts of computer science to human behavior. This signifies a breakthrough in terms of the objective assessment of this particular skill, and the results can also be used for national or cross-national educational policymaking.

Relevance of Cross-National and Worldwide Strategies and Plans for the European Region

For most European countries, the EU's systems for cooperation for educational development are the most important international frameworks for national policymaking. EU member states and other countries in Europe are included in both EU standardized statistical monitoring of educational systems (Eurostat 2016) and the EU-funded Erasmus + program for education, training, youth, and sport [Note 14]. The following section examines the common goals and frameworks put forward at the EU level.

Relevance of Cross-National Policies Under EU Frameworks

The EU has a long history in developing policies for including digital technologies in primary and secondary education. Current efforts in the field are closely tied to overarching cross-sectorial goals and strategic planning designed to tackle the combined ongoing effects of the financial crisis, youth unemployment, increased immigration, and the recent wave of terrorist attacks and threats. These efforts are also related to more proactive issues, such as the modernization of education, the fostering of skills in education that harmonize with labor market needs, and the wish for a civic intercultural dialogue across all layers of society (European Commission 2010, 2015a). In general, broad overarching policies for education at the EU level have usually been developed as cross-national intentional papers in the form of communications developed by the European Commission and debated and ratified by member states in the council. Given their abstract and intentional character, such overarching policy documents must be adapted and operationalized into more concrete measures, aims, and strategies that take local educational and political contexts into consideration.

Cross-national educational policies concerning ICT in education can be divided into (1) top-level cross-national policies targeting society at large, where education is one of many societal aspects addressed, and (2) operational policies specifically targeting the education and training sector. In the following sections, we will explore some specific examples of these two different modes of policymaking to better understand the dynamics in the discourse on educational developments and reform in Europe. The cases in question are the top-level cross-national policy goals of the EU 2020 strategy (European Commission 2010) and the Key Competences for Lifelong Learning framework (European Parliament and Council 2006). At the operational level, the ET 2020 cooperation framework (European Commission 2015a), the cross-ministerial European Schoolnet network, and the European Commission's newly developed framework for digital competence (Vuorikari et al. 2016), all geared toward improving the quality of national educational systems by increasing digitalization in education, will be used as examples.

Top-Level Cross-National Policies

Top-level cross-national policies tend to link rationales for educational developments to gains in other societal areas, mainly labor market outcomes. Such policies do not focus primarily on improving the educational system per se but rather seek to strengthen the output of education relevant to other sectors in society, including labor market outcomes, economic productivity gains through innovation and entrepreneurship, social cohesion through active citizenship and integration, and well-being perspectives.

The Europe 2020 Strategy (European Commission 2010) acknowledges that education and training play a strategic role in Europe's ability to remain competitive, overcome the current economic crisis, and grasp new opportunities. The digital transformation of education and training systems is, hence, a theme in several Europe 2020 flagship initiatives. Moreover, the European Commission's Opening Up Education initiative (European Commission 2015a) emphasizes the need for educational institutions to review their strategies in order to integrate digital technologies into teaching, learning, and organizational practices.

Recently, the New Skills Agenda for Europe (European Commission 2016) [Note 15] aims to align the skills available in the labor force with the actual skills demanded by the labor market. The Skills Agenda emphasizes that the digitization of society is an important backdrop for understanding the growing skills gap. As a consequence, digital transformation in society raises new demands for fostering skills inside the formal educational system, in adult learning and reskilling, and at the workplace. Thus, to increase the digital skills of European citizens, the Skills Agenda calls for specific actions mainstreaming and underlining the impact of digitization [Note 16]. To ensure that individuals are equipped with adequate digital skills, in this communication, the Commission stresses that digital skills and competences must be developed at all levels of education and training. Furthermore, it acknowledges that teachers and educators need to support best practices in bringing digital tools into the classroom. The Skills Agenda is also aligned with the educational sector through one of its main actions: the ongoing revision of the Key Competences for Lifelong Learning (European Parliament and Council 2006) [Note 17].

The Key Competences for Lifelong Learning were launched in 2006. They were originally devised as a framework for describing key competences across all sectors of society; however, evidence shows that the use of the framework in member states has been most pertinent in the educational sector (Gordon et al. 2009). The Key Competences framework originally defined the eight key competences as "... a combination of knowledge, skills and attitudes appropriate to the context. Key competences are those which all individuals need for personal fulfilment and development, social inclusion, active citizenship and employment" (European Parliament and Council 2006, p. 13). Furthermore, the framework defines digital competence as involving "the confident and critical use of information society technology (IST) and thus basic skills in information and communication technology (ICT)" (European Parliament and Council 2006, p. 15).

Operational Policies

An in-depth analysis based on PISA 2012 (OECD 2015) underlines that merely increasing access to digital technologies in schools does not yield higher learning outcomes, although specific and targeted use with clear pedagogical aims might do so. In pedagogical terms, digital technologies should ideally yield profound changes in learning contents and pedagogical practices and should lead to more immersive, connected, and natural learning processes. Digital technologies also hold the potential to increase institutional efficiency, data consistency, and interinstitutional connectedness (European Commission 2015b). At the cross-national level, there is limited mutual learning on best practices and/or failures in the process of integration and effective use of digital learning technologies, increasing the chances of cooperation opportunities being lost, work being duplicated, and mistakes or suboptimal implementations being repeated.

To address this situation, several cross-national mechanisms have been implemented. The current European Framework for Cooperation in Education and Training 2020 (European Commission 2015a) emphasizes the importance of developing transversal skills and key competences, particularly in the realm of digital competence. Specific actions include raising the skill levels of pupils and the workforce by improving the effectiveness of education and training systems. In line with this goal, the development of digital competence is a relevant priority area within the development of high-quality skills. Under the umbrella of the ET2020 cooperation framework, thematic working groups [Note 18] have been established, including a group on digital skills and competences, in which experts from national administrations in EU member states benefit from mutual discussion on the policy level and in situ peer learning activities on relevant issues.

The European Schoolnet (EUN) [Note 19] is, in itself, an example of and a mechanism for defining and implementing operational policies. The EUN is a network of 30 European Ministries of Education that aim to bring innovation to teaching and learning across schools, teachers, researchers, industry partners, and the ministries themselves.

Another good example of an operational policy developed in the EU is the Digital Competence Framework for Citizens (DigComp), first published in 2013 by the European Commission (Ferrari 2013) and updated in 2016 (Vuorikari et al. 2016). This framework is primarily a tool to develop policies that support digital competence building and to plan education and training initiatives to improve the digital competence of specific target groups.

Although the DigComp framework was designed to be of universal use for all sectors of society, the most prominent uptake has been within the educational sector. Successful examples of the use of DigComp as a backdrop for overarching school policies and a tool for revising instructional planning and designing self-assessment tools of digital competence for pupils can be found in several European countries. Examples of national and regional initiatives using DigComp for policy planning include the **Italian** National Plan for Digital School (Il Piano Nazionale Scuola Digitale) [Note 20] launched in late 2015; the **Maltese** “Green Paper: Digital

Literacy” [Note 21] launched in 2015; and the 2016/2017 work in **Navarra, Spain**, where DigComp is used for strategic planning in the regional Department of Education.

For instructional design purposes, prominent examples of the uptake of DigComp can be found in **Spain**, where a continuous professional development (CPD) program for teachers includes strong support for teachers’ digital competence building and the development of digital training material. Both **Portugal** and **Lithuania** have implemented similar CPD initiatives, while in **Norway**, DigComp is used as an inspiration for a new national digital competence framework for teachers targeting both initial and in-service teacher training. A more holistic approach is taken in **Croatia**, where the “e-schools project” uses the DigComp framework to build its understanding of teachers’ digital competence in digitally mature schools.

Another interesting use of the framework is as a background for designing assessment tools. In **Estonia**, starting in 2017, ninth graders will be assessed on their digital competence, an initiative that follows up on the inclusion of digital competence in the national curriculum in 2014. A similar project targeting teachers can be seen in **Croatia**, where an international research consortium has initiated a DigiComp [Note 22] project to facilitate hands-on understanding of the framework’s competence areas by designing an online course platform to train teachers in confidently and critically using ICT in teaching, including cooperation, communication, and content-making.

Other notable EU-level frameworks aimed to support the fostering of digital competences in schools are the forthcoming European Commission Digital Competence Framework for Teachers (DigCompTeach), which highlights the specific need to understand digital competences in the teaching profession, and the European Framework for Digitally Competent Educational Organizations [Note 23] (DigCompOrg) (Kampylis et al. 2015), which complements other frameworks, such as the DIGCOMP framework.

Challenges and Developments in the European Region

When considering further developments in the region, it is appropriate to explore some of the pertinent challenges. We have already touched upon some of the major struggles the region is currently facing, such as increased immigration and terrorist threats. Furthermore, at the school level, we see other types of challenges related to curriculum integration, the professional digital competence of teachers, digital divides, and a weak association between the use of ICT and pupils’ learning outcomes. The PISA 2012 results show that increased access to ICT is not synchronous with better learning outcomes in mathematics and reading (OECD 2015), and one reason may be that the potential of technology is not yet fully utilized.

The quantitative focus of (more) access to infrastructure, technological tools, and Internet connectivity supersedes the focus on a better pedagogical use of technology to optimize students’ learning outcomes. Technology does not transform education

by itself; rather, it facilitates innovative, multimodal, and flexible learning. Moreover, technology adaptation in schools needs to be viewed together with other aspects of school improvement and quality, such as school leadership, continuous professional development/lifelong learning of teachers, and assessment/evaluation systems.

Looking ahead, it is likely that the importance of lifelong learning and the continuous development of both learners and teachers over the course of their working lives will become the norm. Education systems will be informed by detailed and timely evidence through big data and developments in artificial intelligence. Pupils and teachers will be able to transport and combine education from various modes of formal and informal learning platforms. These shifts will lead to the development of formal qualifications, digital badges, ePortfolios, etc. (European Commission 2017).

However, though the European region is home to great disparities in access to technology and infrastructure, the user divide is even more prominent. We see great differences in teachers' competence when it comes to using technology within primary and secondary schools. Teachers claim that they need more training to gain the competence necessary to use technology in the classroom (OECD 2014b; European Commission 2013). Moreover, it is important to connect existing policies with actual practices and to understand that, despite good policy intentions, transferring them into practice is not an easy task. In addition to supporting good access and infrastructure, we also need school leaders and teachers to integrate policy intentions into local curricula. In accomplishing these objectives, we are dependent upon those school leaders and teachers who see the potential of ICT use for improving students' learning processes.

Professional Development of Teachers

In addition to primary and secondary education policies themselves, teachers' professional digital competence can also greatly influence the use and integration of policies at the school level. Therefore, we discuss this competence as an emerging theme in the region. Policy visions can be supported both by the provision of in-service training and by efforts to address the pedagogical use of ICT during the preservice training of primary and secondary school teachers.

The TALIS reports (OECD 2009, 2014b) reveals that teachers in primary and secondary education require more training in the use and integration of ICT into their practice. Teachers' professional digital competence is an important factor in ensuring the effective implementation of ICT education policies in primary and secondary education. Assisting teachers in developing their professional practice, knowledge, and skills in integrating ICT is an emerging theme in many European countries.

Professional digital competence refers to teachers' competence using ICT (i) as general basic tools, (ii) within the subject matter, and (iii) as a profession-oriented practice (e.g., to improve home-school communication, class leadership, relational competence, and teachers' own continuous professional development). Teachers

require both basic digital skills and critical skills to assess when it is (or is not) appropriate to use technology to teach their subject matter. Teachers, therefore, need to have knowledge and skills in technology, pedagogy, and content, as well as in the many possible combinations of these three, in order to embed ICT effectively into their teaching practice.

Competency frameworks focusing on the digital competence of teachers are being developed in several European countries in order to further assist teachers in integrating ICTs into their teaching and learning (see also section “[Operational Policies](#)” and the discussion on the DigComp framework). The UNESCO competence framework for teachers has been adapted and used to define teachers’ competence in **Ireland** (Department of Education and Skills 2015). Similarly, in **Norway**, researchers and policy makers have developed a competence framework that provides structure for ICT integration in the teaching and professional learning of primary and secondary teachers as well as in teacher education [Note 24].

Job Automation and Youth Unemployment

Demographic changes and ICT have influenced what kinds of work and career paths are needed in the future. Following the 2007 financial crisis, millions of people in Europe lost their jobs, and young people with limited work experience were often hit the hardest. Youth unemployment is still high in several European countries. In addition, ICT is changing the ways in which we work. Artificial intelligence, the Internet of things, and big data are all influencing how we work, when we work, and where we work. Against a backdrop of rising inequality and shrinking job security, demands for entrepreneurship and the innovative and effective use of ICT are growing.

There is, therefore, a need to better coordinate education with the needs of the labor market in order to enable youth to gain necessary skills, reduce mismatches between job requirements and competence, and cope with challenges of increased competence and economic and social demands. Curricula must bridge boundaries between subjects and “cross the borders between subjects, between ‘academic’ and ‘vocational’ learning, and between the worlds of adults and students” (Hampson et al. 2016, p. 15). Such steps will enable youth to personalize their career choices and gain the competences necessary for their future careers.

Digital Citizenship

Learners in primary and secondary education today are born into a digital world. Though many call this generation “digital natives,” it is important to remember that students who are familiar with technology do not necessarily know how to use educational resources and ICT for learning. For this reason, issues of digital citizenship are and will be of great importance both globally and within the European

region. The challenges teachers face concerning distracted students in technology-rich classrooms need to be addressed with strategies for class management (pedagogical, organizational, and technological). Challenges regarding online bullying and disrespectful communication and issues of privacy and copyrights are also of continuous concern within primary and secondary education in Europe. In this regard, efforts to incorporate policies promoting digital citizenship across the curriculum are critical. This message is underscored by research findings from the EU Kids Online project, which reported that children's chances of being exposed to hate messages and cyberbullying on the Internet rose significantly between 2010 and 2014 (EU Kids Online 2014).

Conclusion and the Way Forward

We have now discussed some of the policy initiatives targeting primary and secondary education in Europe. In so doing, we have identified several national and local initiatives and more holistic policy plans involving the EU and the European region as a whole. However, needless to say, the limitations of this chapter are abundant, and it is impossible to cover all the positive initiatives that are worth mentioning.

It is difficult to forecast developments and upcoming challenges within the field of ICT. One way to address future developments is to describe or predict some of the technological changes and developments that are likely to occur. Instead of taking this route, we chose instead to focus on some of the qualitative and pedagogical aspects influencing technology adoption. Therefore, we discussed three challenges that we are already facing: (i) teachers' professional digital competence, (ii) changes in the world of work and the importance of lifelong learning processes, and (iii) the increased focus on digital citizenship and digital responsibility.

The European region faces several challenges involving the integration of ICT in primary and secondary education. Some of these have been briefly mentioned in this chapter. However, supplementing teaching methods with ICT is only as effective as the teacher leading the teaching/learning process. In other words, ICT will never replace "traditional" teaching methods and/or teachers. The biggest challenge is, perhaps, how we assess empirical and research-based evidence to determine what works and when and to learn how the variety of pedagogical approaches and methods/tools in the classroom can lead to better learning for students. This challenge applies not only to ICTs but also to every method or means teachers use in the classroom. It can, in short, be defined as the challenge of leveraging evidence-based practices and policies to further develop education.

End Notes

1. See further <http://unstats.un.org/unsd/methods/m49/m49regin.htm#europe>
2. See, e.g., <http://www.dw.com/de/das-aus-f%C3%BCr-schulen-ans-netz/a-16481641>

3. These are Albania, Austria, Belgium, Bulgaria, Croatia, Cyprus, the Czech Republic, Denmark, Estonia, Finland, France, Georgia, Germany, Greece, Hungary, Iceland, Ireland, Italy, Kosovo, Latvia, Lithuania, Luxembourg, Macedonia, Malta, Moldova, Montenegro, the Netherlands, Norway, Poland, Portugal, Romania, Russia, the Slovak Republic, Slovenia, Spain, Sweden, Switzerland, Turkey, and the United Kingdom.
4. Calculations based on TIMSS 2015 exhibit 9.5 and 9.6 (<http://timssandpirls.bc.edu/timss2015/international-results/timss-2015/mathematics/classroom-instruction/computer-activities-during-mathematics-lessons/>)
5. PISA results are based on data on 15-year-old students, a population usually assigned to upper secondary schools in European countries. TIMSS covers the populations of both fourth graders (typically in primary schools) and eighth graders (typically in lower secondary schools). TIMSS 2015 was released at the same time as PISA 2015; thus, the studies are chronologically comparable.
6. These are England, Hungary, Ireland, Italy, Lithuania, Malta, Norway (grade 9), the Russian Federation, Sweden, Slovenia, and Turkey.
7. These are Denmark, Netherlands, Sweden, Norway (grade 5), England, Germany, Finland, Cyprus, Ireland, Belgium (Flemish), Italy, Spain, Poland, Lithuania, Turkey, the Czech Republic, Hungary, Bulgaria, the Slovak Republic, Portugal, France, Slovenia and Serbia.
8. With high equipment levels, large numbers of network access points, routers and switches, highly Wi-Fi connected classrooms, high use of cloud for hosting, BYOD policy and BYOD support.
9. With relatively low levels of equipment, low classroom Wi-Fi provision and services hosted in school.

Abstract

The chapter refers to policies towards ICT in primary and secondary education from the perspective of the Latin American and The Caribbean region. These policies show different levels of progress, maturity and consolidation which reflect the heterogeneity and social inequity that persist in the region. Analysis of these characteristics and differences are made by considering pedagogical models, teacher training issues, student access to technology for inside and out of school use and evaluation on the impact of technology within this context. A more detailed analysis is offered to some recent initiatives, such as the one-to-one model and the development of digital content for open educational practices. From the analysis of the global, regional and local ICT development policy for education, the short, medium and long term future challenges in training trends and technological innovations are pointed out. The main challenges still are related to decisions regarding technological infrastructure, conditions for pedagogical change, development of capacities in teachers and students, policies evaluation and research development.

Introduction to ICT in Primary and Secondary Education in Latin America and the Caribbean

The socio-educational reality of Latin America and the Caribbean is characterized by the coexistence of different realities resulting from social, ethnic, and/or geographical differences existing in the population. On the one hand, and coinciding with the last cycle of economic growth, the region as a whole shows important improvements regarding the fulfillment of the Education for All (EFA) goals set up in 2000, in Dakar; however, there are geographical areas and/or sociocultural groups which experience enormous educational inequalities keeping them far from meeting these goals (OREALC 2014a; UNESCO, IPE & OEI 2014). Therefore, in order to analyze ICT policies in education in the region, we need to consider different levels of progress, achievements, and urgencies.

The introduction of ICT in education in the region has been the product of national policies implemented by the Ministries of Education and financed by international organizations such as the World Bank or the Inter-American Development Bank. In a first stage, the main objectives of the policies were to institutionalize an ICT policy in the education area to expand the coverage and access to technological infrastructure in schools and reduce the differences caused by the “first” digital divide (Attewell 2001). At the end of the twentieth century, it is possible to see a few pioneers in addressing these challenges: Costa Rica and its National

Program for Educational Informatics (1988); Mexico and its Red Escolar (1990); Chile and the Red Enlaces (1992); Brazil with the National Programme for Educational Technology, ProInfo (1997); and Argentina with the Programa Educar (2000) (UNESCO, IPE & OEI 2014).

During the first and a half decade of the twenty-first century, governments in the region continued with the expansion and institutionalization of this policy. Since 2006, governments reinforced the expansion of infrastructure, including Internet connectivity and teacher training, thanks to the growing availability of resources, as well as the expansion of commodities with the consequent increment of the gross domestic product (GDP) and the implementation of social redistribution policies which was beneficial for the whole population (OREALC 2014b). During this period, two main challenges for ICT policies in education emerged: to use ICT to help develop the cognitive and social skills demanded by the information society (Ananiadou and Claro 2009) and to improve the results of teaching and home practices, including improving the ICT skills of socially and culturally disadvantaged students (Kuhlemeier and Hemker 2007).

Then, a second phase in ICT policies in education emerged which focused the attention on three main issues: renewed teaching and learning processes, the distribution of ICT equipment to students, and the implementation of more efficient school management procedures. Some initiatives of this period are Uruguay's Plan Ceibal (2007), Argentina's Conectar Igualdad Programme (2010), Colombia's National System for Innovation in Education with the Use of ICT, Peru's One Laptop per Child Project, and Mexico's Digital Skills for All Project (UNESCO, IPE & OEI 2014; OREALC 2014a).

In spite of the lack of evidence regarding the impact and results of these policies, the information available shows that the region has made great improvements; but these are uneven with profound differences, within and between countries, in the incorporation of ICT showing, thereby, the existence of multiple divides produced by a heterogeneous and unequal social reality (Hinostroza and Labbé 2011; Lugo and Kelly 2010; Lugo and Brito 2015; Sunkel and Trucco 2014).

Recent Developments on ICT in Latin America and the Caribbean

In order to understand recent developments on ICT in the region, one has to consider three levels of development based on how the countries have been able to solve different barriers involved in closing the digital divide.

In the *emergent* stage, which is characterized by scarce infrastructure, lack of financial resources, or policies that have not been able to institutionalize, are countries such as Guatemala, Paraguay, and Bolivia; then in the *application* stage, in which pilot projects become laboratories whose purpose is to demonstrate the effects of long-term innovations but implemented at a small scale within the limits of the school context, are countries such as El Salvador, Jamaica, Peru, the Dominican Republic, and Trinidad and Tobago. Lastly, in the *integration* stage, where policies have been institutionalized and show ample coverage in the school system with a

strong coordination to face the digital divide, are countries such as Chile, Uruguay, Argentina, Mexico, Brazil, Colombia, Cuba, and Costa Rica (Lugo and Kelly 2010; Sunkel 2006).

ICT Infrastructure and Models for Incorporating ICT in Schools

The region confronts four main divides in its efforts to overcome differences in access to equipment and connectivity: the *socioeconomic* gap, which impinges upon households and is reproduced in the school system, except in countries where integration tends to disappear; the *geographic* gap or the difference produced by the geographical place of residence, which is predominant in rural areas and has increased in Peru and Mexico, but declined in Uruguay; the *educational* gap, or difference in access to ICT depending on the type of school the students attend, with private schools being the most advantageous; and lastly, the *social* gap which affects disadvantaged social groups including indigenous students and groups with special educational needs (Sunkel et al. 2013; Sunkel and Trucco 2011; UNESCO 2013).

In this context, half or more than half of the students in the region does not have access to a computer or Internet connectivity in the home; however, variations by country show that 60% of students in Uruguay, Argentina, and Chile have access to equipment; in Peru, Colombia, Mexico, and Brazil, this amounts to 40% and, in the rest of the countries, less than 40%. Similarly, 40% of the students in the region have access to computers connected to the Internet with variations in Brazil, Uruguay, Argentina, and Chile where connectivity exceeds 50% and can reach 90%, falling to less than 40% in countries such as Mexico, Colombia, and Peru (Fraillon et al. 2014; Claro et al. 2011). These data indicate that the region is well below the Organisation for Economic Co-operation and Development (OECD) rate, where the average for both types of access reaches 80%.

The availability of computer equipment in schools has increased in the last decade, approaching the average values of OECD countries. In 2000, 62% of 15-year-old students had at least one computer available for academic use, a figure that increased to 93% in 2009 in countries such as Chile, Colombia, Trinidad and Tobago, and Uruguay (UNESCO 2013). Meanwhile, the student-computer ratio, which was 56 in the region in the year 2000, decreased to 21 in 2009 with great disparities ranging from 1/1 in Uruguay to 122/1 in the Dominican Republic. Thus, the availability of computers and/or Internet connection in schools reaches or exceeds 92% in Chile, Brazil, Cuba, and Uruguay; in Colombia, Mexico, Argentina, Ecuador, and Panama, the rate is above 75%, but in Guatemala and the Dominican Republic, it is well below 30%. Only Brazil and Chile reach or exceed the average 90% of the OECD countries; Mexico and Panama have an average of over 70%, and Paraguay, the Dominican Republic, Guatemala, and Cuba have rates below 30% (OECD 2015; Román and Murillo 2014). On the other hand, Caribbean countries (particularly Anglophone ones) have significantly higher levels of ICT access and use than most South American and Central American countries (UNESCO 2013). Regarding access to ICT by education level, regional data shows that secondary

schools have the largest proportion of ICT equipment (74%); Uruguay is the exception, as the Plan Ceibal has prioritized equipping all primary schools (Hinostrroza and Labbe 2011; UNESCO 2013).

In addition to this, since the end of the twentieth century, the region has seen the implementation of 15 types of projects and modalities for the integration of ICT into schools, out of which five have had greater development: (i) the computer laboratory model, (ii) the computers in the classroom model, (iii) the mobile lab or laptop model, (iv) the school networks model, and (v) the one-to-one model; this latter model has had the largest development in recent years (Lugo and Kelly 2010; Sunkel et al. 2013; Sunkel and Trucco 2011; UNESCO, IPE & OEI 2014).

In brief, since the middle of the first decade of the twenty-first century, the countries in the region have made substantial progress in terms of access to technological infrastructure and equipment in the home; however, this situation is heterogeneous with great variations among countries, with Uruguay taking the lead, thanks to its policy for universal access in primary schools including the provision of access to computers to about 50% of homes with school-age children in 2009. As regards connectivity to the Internet, the progress has been slower due to high costs in services that persist in the region; however, Internet connectivity is higher in homes with school-age children and mainly seen in countries such as Brazil, Uruguay, Chile, and Argentina (city of Buenos Aires); in the latter, access to the Internet in 13-year-old students' home reaches 98% (Fraillon et al. 2014). As of 2009, most of the school population in Bolivia and Honduras still did not take a leap forward in terms of home access to the Internet, while Caribbean countries (particularly English-speaking countries) have significantly higher levels of ICT access and use than most South American and Central American ones.

The Use of ICT by Teachers and Students

Information about the use of ICT by teachers and students in the region is scarce; however, it is possible to indicate that levels of ICT use by teachers tend to be low and uneven between and within countries. According to Sunkel and Trucco (2014), countries with a critical mass of teachers who already use computers have a basis for advancing in the incorporation of ICT in lessons; such is the case of Cuba, Chile, and Uruguay. Thus, teachers would be in an "adaptation" phase according to models of ICT adoption and integration, adapting traditional teaching strategies, incorporating new technologies, and organizing students to work independently in small groups.

With regard to ICT practices by students, the results of the PISA 2009 test with 15-year-old students from Chile, Panama, Trinidad and Tobago, and Uruguay do not reveal large differences in their patterns of ICT use compared to 2006's results; that is, students use technology at least once a week for different types of activities but commonly associated to recreation and communication uses, such as browsing the web for entertainment purposes, chatting, downloading music/movies, and sending e-mails. A higher percentage of students who declared to perform these activities with high frequency were from Uruguay and Chile. However, the activity most

frequently mentioned by the students in these countries was to use ICT in lessons for school work which set them quite above from the average OECD student (Claro et al. 2011).

Teacher Training in and About ICT

The ICT policy for education in the region has included teacher training which focuses on four main issues: (i) ICT literacy for the development of digital skills, (ii) pedagogical use of ICT, (iii) the creation of virtual communities for professional development, and (iv) school management. In recent years, students in initial teacher education and students from the school system have been included into this policy. Some countries, such as Panama or Paraguay, have defined guidelines to encourage an integral training system which blends professional development for graduated teachers with student teachers; other countries have proposed training actions aimed at teachers with the possibility of including student teachers, which is the case of Uruguay as part of the Plan Ceibal or Argentina as part of the National Teacher Training Plan. In other countries, differentiated actions for teachers and student teachers have been designed, as in the case of Chile with the definition of ICT standards and competencies led by the Red Enlaces, or Mexico with the Sectorial Education Program, or Brazil with its policy for continuous teacher training (Vaillant 2013).

In most countries, teacher training programs usually take the form of workshops, short courses, or postgraduate diplomas for the curricular integration of software applications or specific digital tools (e.g., digital whiteboards), for the appropriation of pedagogical methodologies based on ICT (e.g., project-based learning), or for developing specific skills required in the design of ICT-mediated learning environments (e.g., ICT and inclusion). One recent development in the region has been the promotion of teacher training in both blended and e-learning modalities, either in a collaborative, individual, or self-instructional mode.

Results and Quality Assurance on the Use of ICT

The education policy in the region focuses on quality, therefore assessing the impact and contribution of ICT to learning processes has been an ongoing concern over time. A first development on the subject has been the creation or use of conceptual frameworks for the definition of competencies or standards on what the use of ICT in the classrooms should be expected. In this regard, not only international frameworks elaborated outside the region have been used for this purpose but also conceptual models created within the region itself (Hinojosa and Labbé 2011; OREALC 2014b).

Among the main international models used, we find the ICT Competency Standards for Teachers Framework developed by UNESCO in 2008, the Standards for Teachers developed by the International Society for Technology in Education (ISTE), the framework for the integration of ICT in education based on the

Technological Pedagogical Content Knowledge (TPACK or TPCK) model proposed by the American Association of Colleges for Teacher Education (AACTE) and the Partnership for 21st Century Skills, and the Skills and Competency framework developed by the OECD and used in the PISA Program (Vaillant 2013). Among the models created in the region, we can find the following: the Competency Standards framework developed in 2008 by the National Council for Standardization and Certification of Labor Competencies in Mexico (<http://conocer.gob.mx/>) which seeks to enable teachers to manage information on the web, design learning materials, and facilitate school activities with the support of ICT; the updated Competencies and ICT Standards in the Teaching Profession framework, designed by the Red Enlaces in Chile (MINEDUC 2010); and the Adaptation of Teaching Guides in Costa Rica proposed by the National Program for Educational Informatics and the Omar Dengo Foundation in 2010 (Vaillant 2013).

A second development has been the implementation of assessment procedures to obtain data about educational impacts. In this regard, regional assessment initiatives have been carried out by the UNESCO Institute for Statistics (UIS), which, in the context of the Partnership on Measuring ICT for Development, seeks to gather information about the use of ICT in education. In 2009, the UIS constructed a set of indicators for the elaboration of databases and reports that are used as a benchmark for the fulfillment of the Millennium Development Goals and the goals of the Education for All movement. At the country level, the Chilean Education Quality Measurement System (SIMCE) elaborated a test which seeks to measure the development of digital skills in lower secondary school students. The results have allowed us to appreciate the impact of the use of ICT in schools for the development of higher-order thinking skills (MINEDUC, CEPPE & PAÍS DIGITAL 2013).

Recent Developments on Policies on ICT in Latin America and the Caribbean

Due to recent ICT policies that favor the incorporation of mobile devices into schools, the region has embarked on developing initiatives based on the one-to-one model and innovative educational practices that take advantage of open educational resources which are available on national education portals.

ICT Initiatives with One-to-One Models

In order to improve equal access to digital resources, economic productivity, and quality of learning, since 2006 ICT policies based on the one-to-one model have been implemented in the region. Digital devices such as laptops, usually with Internet access, are provided to individual students to facilitate their learning. By 2010, initiatives of this type had been implemented in 17 countries; Uruguay's Plan Ceibal is the most notable experience in the region; so far the program has covered all primary schools in the public school system.

The successful implementation of Plan Ceibal has been mainly due to a strong institutional support from the state as well as an efficient logistical implementation which has provided free Internet connectivity to all participating schools and homes (Severin and Capota 2011). However, one limitation of the project has been the high costs involved in the purchase of a laptop computer for each student, which has made other countries in the region decide to adopt different modalities such as the mobile lab model which consists of one or more trolleys carrying 20 or 30 netbooks into classrooms. Argentina and Chile have implemented experiences of this type (Lugo et al. 2012; UNESCO, IPE & OEI 2014).

A variant of the one-to-one model is the pedagogical use of varied mobile devices (e.g., tablets, cell phones, netbooks, pocket PCs) to carry out mobile learning experiences (m-learning). Projects of educational initiatives in this modality include marginalized populations and indigenous communities living in rural areas. However, regional and local national education policies that recognize this type of learning are still scarce due, mainly, to restrictions on the use of cellular phones in the classroom. Ecuador is the exception; the use of the cell phone in this country is allowed under the teacher's responsibility and for the implementation of pedagogical activities only (Chiappe 2016).

A few studies on mobile learning initiatives using cell phones in Latin American countries (no such initiatives were identified in the Caribbean) carried out by UNESCO show that more experiences of this type are implemented in secondary and postsecondary institutions than in primary schools. A few examples can be seen in Chile (e.g., PSU Mobile Program) where mobile phones are used to prepare students for university selection tests and also in Colombia and Chile (e.g., Global Bridge IT) where teachers use mobile phones to project videos or other digital content in the classroom. In Colombia, in rural areas, cell phones are used to improve illiteracy rates; in Argentina, school supervisors use cell phones to improve the management of the school system (Severin and Capota 2011; Lugo et al. 2012).

Despite the success achieved by mobile learning experiences in the region, there are criticisms regarding some shortcomings found in a few impact evaluations, as well as barriers that could restrict the expansion and sustainability of mobile learning initiatives in the region, such as the high costs of Internet connectivity, the limited access to terrestrial and mobile broadband, and the high costs of purchasing a smartphone or the lack of policies regarding the development of content for these devices (Lugo and Schurmann 2012; Lugo et al. 2012). All these factors have cast doubt on whether the choice of this model is the most appropriate for all countries in the region (Severin and Capota 2011).

Digital Educational Content and Open Educational Practices (OEP)

In the first decade of the twenty-first century, the countries in the region started to distribute digital educational resources through national education portals hosted on the web in Internet. The first countries to develop these resources were Argentina, Brazil, Chile, Mexico, and Peru. At present, 20 countries in the region have set up a network of

national portals called the Latin American Network of Educational Portals – RELPE (<http://www.relpe.org>) – whose main objectives have been to improve the quality and equity of education through the free exchange and use of digital educational resources located in member portals and to set up actions for the exchange of policies, experiences, and collaboration in the use of ICT in education (Ferreya 2015).

The content published in the Network is organized according to the level of education (primary, secondary, and tertiary) and has a curricular classification by learning domains. At present, some countries in the region, such as Chile, Peru, and Argentina, are restructuring their national portals and reorganizing the contents in terms of new forms of knowledge construction and how users interact with it (Ferreya 2015). Currently, there is a shortage of open educational resources (OER) policies in the region, as recommended by the Paris Declaration on OER in 2012; only 9 countries out of 38 have adopted a national policy in this regard (UNESCO 2013); in several countries, free-access licenses (e.g., Creative Commons) are used in order to protect a work's intellectual property rights (Chiappe 2016).

Among the barriers that could limit the generation and expansion of OERs in the region, we can find the lack of support to keep the “sustainability” of the projects due to difficulties in Internet connectivity in some countries, the lack of knowledge about this topic, or the lack of incentives on the part of educational institutions to favor the use of OERs (Hoosen 2012).

There is a great variety of experiences regarding the generation of learning objects and open educational resources in the region (see examples in Chiappe and Martínez 2016); however, the impact of their use has been low and not always the use of OER has evolved toward innovative pedagogical practices that could be promoted through ICT policies in education (Chiappe 2016; Andrade et al. 2011).

In recent years, there have emerged innovative educational initiatives known as open educational practices (OEP) that incorporate the use of open educational resources. These initiatives are practices of an educational nature (teaching, evaluation, didactic planning, or curricular design) to which some attributes of “open” are applied, such as free access, adaptation, collaboration, sharing, and remixing (Chiappe and Martínez 2016). Experiences of this type in the region are still scarce, with more initiatives at higher education levels than at school levels. One example is Uruguay, in the context of the Plan Ceibal, where teachers and teacher training students participate in a network of centers (Red REA) with the purpose of creating open educational digital resources and produce digital content in a distributed and open manner through micro-virtual workshops (Rivero and Rabajoli 2016).

Relevance of Cross-National and Worldwide Strategies and Plans for Latin America and the Caribbean

Policies and strategies for the incorporation of ICT in education in Latin America and the Caribbean have been influenced by the overall process of transition to the information society (Sunkel and Trucco 2014). From the political point of view, this influence has been exerted on three different levels: global, regional, and national.

At the *global* level, international agreements have been signed among the countries of the world within the context of forums and global summits. For instance, at the World Summit on the Information Society (WSIS) in Geneva 2003, governments from 175 countries committed themselves to “building an inclusive Information Society and putting the potential of knowledge and ICT at the service of development,” which meant eliminating the digital divide of access to ICT. Two goals relating to ICT in education were set up in the action plan: (i) “to use ICT to connect universities, colleges, secondary schools and primary schools” and (ii) “to adapt all curricula in primary and secondary education to fulfill the objectives of the Information Society, taking into account national circumstances” (UIT 2005, p. 28).

In this way, the Geneva summit calls on governments to “define national policies to ensure the full integration of ICT at all levels of education and training, including curriculum development, teacher training, institutional management, and support for the concept of lifelong learning” (UIT 2005, p. 36). In addition, the declaration recognizes the important role of universal primary education as a key factor in creating a fully integrated information society, thus highlighting the centrality of education in this global instance (Sunkel and Trucco 2014).

Lastly, another instance of global influence has been the World Forum on Education of 2015, which took place in the Republic of Korea, where 160 countries adopted the Incheon Education Declaration 2030 and made a commitment to “harness the technologies of (ICT) to strengthen education systems, dissemination of knowledge, access to information, effective and quality learning,” as a way to meet the goals of the Sustainable Development Objective 4, which seeks to “ensure inclusive and equitable quality education and promote lifelong learning opportunities for all” (Incheon Declaration, World Education Forum, UNESCO 2015).

At the *regional* level, a number of events have taken place, notably the Regional Ministerial Conference of Latin America and the Caribbean and the different versions of the Regional Action Plan on the Information Society in Latin America and the Caribbean (eLAC), all of them with the purpose of creating a regional approach to information society development and how to address its challenges. The Plan has given rise to four versions: eLAC2007, eLAC 2010, eLAC 2015, and eLAC 2018.

The eLAC 2007 Plan focused on developing three lines of action: (i) deepening knowledge and understanding of critical areas, (ii) formulating and strengthening concrete initiatives and projects at the regional level, and (iii) supporting the development and implementation of national initiatives through intra-regional exchange. In the education area, the goals of the Plan were twofold: increase the connectivity to the Internet in schools, particularly in educational centers located in rural areas, and improve the student-computer ratio in the region (CEPAL 2013a).

The eLAC 2010 Plan fostered the use of ICT for development and the achievement of economic growth with equity, reflecting thus a change in orientation, moving away from a technocentric tendency, to a more integral human and social development. The educational goals of this Plan were structured along four central themes: the environment (which refers to curriculum development), access (referring

to connectivity), capacities (students' ICT use and teacher training), and content (portals, applications, and services) (CEPAL 2013a).

On the other hand, the eLAC2015 Plan proposed the use of ICT as tools for development and social inclusion, aligning its goals with the Millennium Development Goals and the World Summit on the Information Society (WSIS). It recognized that education is one of eight priority themes among its educational goals and that ICT policy should be a state concern in the educational field. The goals of the Plan were (i) to connect all educational institutions to broadband Internet and promote public policies for the establishment of academic networks, (ii) to ensure ICT training for teachers and managers, (iii) to promote the production of multimedia content freely available on the Internet, and (iv) to promote support for the Latin American Network of Educational Portals (RELPE) (CEPAL 2013a).

Finally, in Mexico City, in 2015, the region set up the Digital Agenda for Latin America and the Caribbean eLAC2018, which was structured around five themes: access and infrastructure, digital economy, e-government, social inclusion and sustainable development, and governance. In the area of social inclusion and sustainable development, the agenda formulated an educational objective that seeks to "incorporate or strengthen the use of ICT in education and promote the development of programmes that include teacher training, new pedagogical models, the generation, adaptation and exchange of open educational resources, management of educational institutions and educational evaluations" (CEPAL 2013a), which implies a greater challenge for national ICT policy agendas in the education field.

One important factor for the region has been the uneven performance of countries in achieving the goals of the Education for All (EFA) movement (Dakar 2000, Geneva 2003) and the Millennium Development Goals (ONU 2000). In 2002, five strategic areas for the universalization of primary education were defined and the Regional Education Project for Latin America and the Caribbean (EPT/PRELAC) was created, which acted as a regional coordinating body for the global project (EFA). Although PRELAC gave little attention to technology issues, in 2008 a second version of the project, Educational Goals 2021, was presented which incorporated within the overall goal – to improve the quality of education and the school curriculum – two specific goals with regard to ICT: "to improve the computer-student ratio" and "to foster the regular use of ICT in the teaching and learning process" (OEI 2010, p. 118). This reinforces the sense of priority and dynamism of the present policies for the integration of ICT in education in the region which are formulated within a framework of new challenges for the education area in terms of coverage, continuity, quality, and equity (Severin 2014).

At the *national* level, the countries in Latin America and the Caribbean have developed national digital agendas which contain objectives and policies that each country must carry out in its transition to the Information Society. The first digital agenda emerged in Brazil in 2001; by 2012, most countries in the region have formulated national digital agendas. A recent study which included six countries shows that the most frequent objectives of the national digital agendas center around the following themes: infrastructure deployment, access to broadband Internet and connectivity, ICT industry including capacity building, content development,

e-government, and e-education; the study also identified some challenges that the countries in the region need to address, such as coordination among the actors involved in policy implementation, capacity building in local governments, support for the implementation of programs defined in the agendas, and evaluation and monitoring of policies (CEPAL 2013b).

In brief, although the plans and frameworks established at the global level have highlighted the importance of generating ICT policies in education, this influence has not been exerted in a direct fashion in the region due, mainly, to a lack of coordination between information society policies, designed at global or regional level and ICT policies for education set up at national level. According to Sunkel and Trucco (2014), the process of adoption of ICT policies in the region has not followed a “top-down” approach by which the guidelines established at the level of the World Summit would have a direct translation at the regional level and then at the national level. They illustrate this point by stating that the emergence of ICT projects and policies in education in the region dates back to the early 1990s (e.g., Educational Informatics Program in Costa Rica, Red Enlaces in Chile, ProInfo in Brazil, Red Escolar in Mexico), a while before the international agreements had been set out. In this regard, OREALC (2016) points out that this situation could be an important factor as to why the introduction of ICT in the education system in the region has not produced the desired impact, which could in turn affect the educational outcomes and goals that the policies seek to achieve.

The lack of coordination and alignment in the application of ICT strategies and policies in education, in addition to the complexity involved in the process of innovation and change, would appear to affect negatively the progress the region is making at closing the first digital divide, while securing that the second divide can be addressed effectively, in spite of new and challenging educational goals. Hence, the Economic Commission for Latin America and the Caribbean (CEPAL) and UNESCO/OREALC have proposed guiding frameworks for the integration, implementation, and monitoring of ICT policies for the education sector in the region, which jointly address issues of access, capacity building, applications, and policies (Sunkel et al. 2013; Sunkel and Trucco 2014) in accordance to national and international objectives and by taking a quality in education perspective (OREALC 2016).

Challenges and Relevance of Research for Policies on ICT in Education in Latin America and the Caribbean

In general, public ICT policies have been supported by a favorable climate of opinion about their contribution (promise) based on an aura of a priori success and effectiveness, rather than on evidence and results of empirical and contextual research (Sancho 2009). Thus, the synergy effect between research-decision and application-evaluation is not evident or long lasting. However, valuable studies have been carried out on aspects such as the implementation of the Internet in primary school systems in Argentina (Steinberg 2013) or the development of digital skills in

K-10 students after the application of the SIMCE-TIC Test in Chile (MINEDUC-CEPPE-PAÍS DIGITAL 2013).

Regional institutions regularly draw up reports and studies on the development of ICT policies. Among the most active, the following stand out: the Economic Commission for Latin America and the Caribbean (CEPAL), which has developed studies and frameworks for the analysis and evaluation of ICT policies in education (Sunkel et al. 2013); the UNESCO-OREALC Office in Santiago, Chile, which has developed analytical studies and proposals for the integration and evaluation of ICT strategies based on quality and inclusive education criteria (OREALC 2016; UNESCO 2013); the UNESCO Office in Quito, with contributions on the use of ICT in education on people with disabilities (Samaniego et al. 2012); and the International Institute for Educational Planning (IIEP) in Buenos Aires, which has focused the attention on the use of emerging digital environments, such as mobile learning (Lugo and Schurmann 2012), and the pedagogical introduction of ICT in schools. In addition, the United Nations Children's Fund – UNICEF – has contributed to a set of studies and research analyses on policies for incorporating ICT into the primary education level in Argentina, Chile, Uruguay, Peru, Colombia, and Mexico (Balarin 2013; Diaz-Barriga 2014; Galvis 2014; Jara 2013; Vacchieri 2013; Vaillant 2013). Finally, the Latin American Network of Educational Portals (RELPE) has also produced research reports on exemplary classrooms practices in one-to-one modalities (Marés 2012).

Extra regional institutions also provide very valuable comparative information; however, their analysis often includes a few countries in the region. One example is the report prepared by the OECD in 2015 to compare the development of digital skills for the learning of 15-year-old students, in which only Mexico, Chile, and Costa Rica participated, or the report prepared by the International Association for the Evaluation of Educational Achievement (IEA) (Fraillon et al. 2014), which evaluated the skills of eighth-grade students (13 years old) for collecting, managing, producing, and exchanging information; only Chile and the city of Buenos Aires (Argentina) were included in the analysis.

It is worth noting the design of instruments to support research on ICT in education that have been produced by some institutions in the region, such as the digital skills assessment matrix for the school population (e.g., HTPA Matrix), or the monitoring of the implementation of ICT in educational institutions (e.g., National Census of Educational Informatics) designed by the Red Enlaces in Chile. Also, the education portal created by Colombia Aprende which includes a section for researchers or the research studies on twenty-first-century skills and the effects of ICT use in the development of language and mathematics skills carried out by the Omar Dengo Foundation in Costa Rica.

As for future research developments, the latest Horizon Report (Adams Becker et al. 2016) identifies six challenges that the region needs to address: (i) narrow the achievement gap, (ii) foster personalized learning, (iii) promote digital equality, (iv) generalize innovations in teaching, (v) provide opportunities for authentic learning, and (vi) rethink teacher's role in the students' learning process. It also proposes the projection of short-, medium-, and long-term trends that should be

Table 1 Trends, challenges, and technologies for schools (K-12)

Trends		Technological innovations
Near-term	Coding as a literacy	Makerspaces
	Students as creators	Online learning
Mid-term	Collaborative learning	Robotics
	Deeper learning approaches	Virtual reality
Far-term	Redesigning learning spaces	Artificial intelligence
	Rethinking how schools work	Wearable technology

Source: Prepared by the authors based on Adams Becker et al. (2016, p. 2)

considered by educational systems, as well as the presence of particular innovations that are beginning to make their way into education (see Table 1).

Perspectives for Developments in Latin America and the Caribbean

The main challenges in the education sector in the region are contained in the regional Educational Goals 2021 project, which are very clear as to the need to improve the quality and equity in education so as to tackle poverty and inequality and thus foster social inclusion. In this context, the different countries seek to integrate ICT in educational projects as a way to address unresolved challenges such as illiteracy, early school dropout, child labor, students' poor performance, and poor quality of the public education offer (OEI 2010).

Despite the fact that the region has developed ICT policies for education in the last 20 years, the information presented in previous sections demonstrate the uneven progress made in this area. To this end, countries must continue to make sustained efforts for closing the digital divide relating to access, as well as tackle the challenges of the "second" digital divide so that young people are offered new opportunities for learning which can prepare them to deal with the challenges of the information society. In this sense, ICT policies in education should continue to focus their attention on outstanding issues but also on more current ones such as the following presented below.

Infrastructure, Technological Equipment, and Content

Although there has been a significant progress in the region in terms of access to technological equipment and infrastructure, yet half of households with 15-year-old students still do not have access to computers and Internet connection. Likewise, Internet connectivity has not had equal coverage in all countries, which is due to the high costs of its services. Therefore, it is necessary to continue with the improvement and expansion of the technological infrastructure, including Internet connectivity and connection to electric power networks, both in public school institutions and in

low-income homes, as well as in rural areas, ensuring that the costs of services are kept within the reach of low-income groups. Also, it is necessary to strengthen and include into this expansion effort schools from the primary level as well as students from ethnic minority groups, from different cultural backgrounds, and those with special educational needs. In addition to this, it is necessary to develop ICT policies for mobile learning, particularly the production of digital educational content and for the different types of devices that are being integrated in schools.

Pedagogical Practices and Conditions for Change

Teachers in the region are still in a stage of “adaptation” with regard to the adoption of ICT in education, which means that different barriers need to be solved in order for them to move to higher levels of ICT integration and use. As was seen in previous sections, there are different models of ICT integration in the schools in the region, meaning that teachers need to incorporate new pedagogical practices into their teaching repertoire and participate in permanent training to address the challenges posed by the new technological developments. According to Lugo and Brito (2015), change in educational practices is one of the most sensitive issues for the policies on ICT integration in the education system; therefore, it is necessary to constantly review both the pedagogical conditions in which the teachers work as well as teachers’ personal dispositions and skills toward change so that they can better deal with the barriers of the second digital divide.

Quality of Learning and Skills Development

Students in the region use ICT more frequently at home than in the school and for recreational and communication purposes. Although ICT use at school is less frequent, this is commonly oriented toward the development of skills and learning activities, meaning that ICT policies should continue their efforts in fostering the pedagogical use of ICT to improve the quality of learning, including the development of new information processing skills, problem-solving skills, and collaborative learning skills, among others, required for the full participation in the information society and digital age (Fraillon et al. 2014; Cobo 2010).

Evaluation of ICT Policies

At the national level, there has been a lack of coordination among the different actors involved in the design and implementation of ICT policies as well as in the alignment of goals of the ICT strategies or policies with those of the information society and the education in general, which can affect the expecting results or impacts. Therefore, an integral perspective to ICT policy design, implementation, and monitoring is needed, one which can consider the integration of digital

technologies in education within a more complex system of pedagogical innovations (Sunkel et al. 2013; OREALC 2016).

Educational Research on ICT

The great challenge of research in the region lies in the need to highlight the real contribution of ICT to solving the problems of inequality and inequity in education systems. Therefore, research on ICT in education should expand the focus of attention, which so far has been directed toward finding better means and better prescriptions to be included in the classroom (Sancho 2009), incorporating with determination, among other topics, the following:

- (I) Processes of resignification and naturalistic adaptation made by teachers and students based on their beliefs, dispositions, and experiences lived inside and outside the classroom
- (II) New ways of interacting with information and knowledge construction experienced by students
- (III) Relocation of the learning process and the conception of classroom
- (IV) The construction of diverse digital cultures that coexist within the educational system itself

It is necessary to promote research that analyses the contribution of ICT as part of a complex, non-predictable system, for which new research methods are required to allow for a more comprehensive, systemic, and longitudinal understanding and explanation. In an unequal and diverse region, research on ICT in education must contribute to equity and cognitive justice (González 2014).
