## Abstract

Self-assessment is a crucial skill that students need to develop during their educational years, especially at those educational levels where the curriculum leads to future jobs. By being able to assess their own performance, students can become self-regulated learners and continue their professional development throughout their careers. This chapter will explore what is known about self-assessment through an updated version of the state-of-the-art. Firstly, it will be defined what self-assessment is, the different

1359

forms it can take, and which of those forms are most conducive to enhancing students' learning. Secondly, it will be explored what is the relationship between self-assessment and academic achievement and between self-regulated learning strategies and self-efficacy. That section will also present an overview of the learning and psychological effects of self-assessment to conceptualize the internal cognitive, motivational, and emotional processes that are involved. Thirdly, extracted from the research literature, it will be explored what are the best instructional methods to train students to develop their self-assessment skills. In that section, both recommendations on how to help students develop the requisite skills and recommendations for teachers' training will be presented. Lastly, we will build from best-research examples on vocational education and training to consider how self-assessment can best be implemented and extract practical implications and recommendations.

## **Self-Assessment for Learning in Vocational Education and Training**

Most teachers will agree that one of the main skills students need to develop is their capacity to reflect, evaluate, and, if needed, improve their own work. This skill is known as self-assessment. Unfortunately, it is not so well known among teachers how self-assessment works or what to do to help students develop their expertise in such skills. This chapter will present the state-of-the-art knowledge on student self-assessment, answering those questions while providing examples of vocational education and training research and examples of practice on self-assessment.

---

### **Self-Assessment History**

Self-assessment in education has been studied for a long time. Topping (2003) mentioned George Jardine from the University of Glasgow (prof. 1774–1826) as probably one of the first to include self-assessment in his instructional plan. Throughout the twentieth century, there was an increasing interest in the topic, with some articles published as early as 1954 to the boom of the field by the 1990s (Sitzmann et al. 2010). In 1989 two crucial reviews gave a major push to the field: the meta-analysis by Falchikov and Boud (1989), which focused on scoring accuracy in self-assessment, and the more narrative review by Boud and Falchikov (1989), also revolving around matters of accuracy. Importantly, the seminal work by Black and Wiliam (1998), which launched the formative assessment movement, had self-assessment as one of the key pieces for students' learning. Consequently, self-assessment has been key for the formative assessment field.

The first two decades of this century have seen two main branches of educational research into self-assessment. Firstly, self-assessment accuracy has continued as an area of research with no major changes; hence no great developments in our understanding have been gained from an educational perspective (Panadero et al. 2016a). Secondly, increasing effort has been made to use self-assessment for formative purposes, with a relevant focus on self-assessment connections to self-regulated learning (Andrade 2010; Panadero and Alonso-Tapia 2013). Additionally, noteworthy research conducted in medicine (Eva and Regehr 2005) and social psychology (Dunning et al. 2004) has moved the field forward. If we consider all these approaches to self-assessment, we are in an interesting phase in the field, putting together new pieces of the puzzle.

---

## Purpose of Assessment

As mentioned earlier, in the last two decades, there has been a growing interest in how the use of self-assessment for formative purposes can enhance student learning, in contrast with summative self-assessment, which focuses mostly on the accuracy of the self-grading. Though there were some previous publications about formative self-assessment (e.g., Boud 1995; Goodrich 1996), the interest grew exponentially after the publication of the review by Black and Wiliam in 1998 (Wiliam 2011, 2014). What is this summative-formative comparison? Wiliam (2014) explains it as follows:

Where the inferences are related to the student's current level of achievement, or to their future performance, then the assessment is serving a summative function. Where the inferences are related to the kinds of instructional activities that are likely to maximize future learning, then the assessment is functioning formatively. (p. 6)

Therefore, when the assessment information serves the purpose of enhancing students' learning, then it is formative, and when the assessment includes elements of grading, selection, etc., it refers to summative purposes. As mentioned above, self-assessment is considered a key formative assessment processes (e.g., Andrade 2010; Black and Wiliam 1998). One of the arguments is that students need to be able to monitor and evaluate their work to be autonomous and self-regulated learners (Paris and Paris 2001). As those authors and many others claim, teachers need to provide the context and instructional scaffold for students to develop their self-assessment skills.

---

## What Is Self-Assessment?

A recent state-of-the-art review explored the different types of self-assessment that have been studied in research. Panadero et al. (2016a) found 5 taxonomies with 20 different categories of self-assessment. Importantly for our purposes, these

authors provided their own definition of self-assessment as involving “a wide variety of mechanisms and techniques through which students describe (i.e., assess) and possibly assign merit or worth to (i.e., evaluate) the qualities of their own learning processes and products” (p. 804). And this “wide variety” implies, as was expressed at the beginning of the paragraph, that there are different practices that are labeled as self-assessment. For example, out of the five taxonomies that were found in that review, the one by Panadero and Alonso-Tapia (2013) proposed three types of self-assessment practices based on the presence and form of the assessment criteria: (a) standard self-assessment, with no explicit criteria (i.e., just asking the students to self-assess); (b) rubric self-assessment, in which more clearly defined criteria are provided; and (c) script self-assessment, which includes criteria presented as questions that the students need to answer for themselves. Taken together, this demonstrates that self-assessment is a complex process that can take several forms and, therefore, can be implemented in different ways in the classroom.

Depending on its implementation features, self-assessment can serve summative or formative purposes (Andrade 2018; Panadero and Alonso-Tapia 2013). Picture a continuum with summative on one end and formative at the other. At the summative pole would be the type of self-assessment in which students are asked to estimate a grade for their performance with neither further instructions nor any request to generate more informative feedback. This is called self-grading and is probably the least optimal form of self-assessment implementation to enhance students’ learning (Boud 1995). The reason for the limited effects of this type of self-assessment is that it does not ensure a deeply engaged reflection on the performance or the learning processes. If students are only asked to provide a grade, unless they are given advanced tools to calculate it, they usually just make a guess with no further reflection (Andrade 2010). At the other end, the formative pole would be a type of self-assessment that asks the student to extract conclusions from his or her performance, provides opportunities for practice, and provides modeling and feedback on the self-assessment itself. In other words, self-assessment here is a crucial skill to be developed, one central to the curriculum, not a side activity (Brown and Harris 2014; Panadero et al. 2016a; Tan 2012). This formative approach also has important effects for students incorporation to the labor market where self-assessment is a crucial competence (Clayton et al. 2003).

As with many other things, we get what we aim for. If we implement more shallow approaches to self-assessment aiming at the grade level – e.g., merely asking students to guess their grade – that is what the students will perform. On the contrary, if we aim for a deeper type of self-assessment, then the students will use and follow our instructional scaffold and the effects of the self-assessment will have a greater impact on learning. Teachers can have several reasons for choosing one approach over the other, and of course there are plenty of types of self-assessment in between those two extreme poles. What is crucial is that the teachers make an informed decision on why they are using a particular type of self-assessment. Nevertheless, the general pedagogical recommendation is to aim for the highest level of formative self-assessment possible because that will provide more learning insights for the students.

## Self-Assessment Effects on Learning Variables

All that we have explained above would be pointless unless self-assessment had a positive effect on students' academic performance. There are two meta-analyses that have explored the effects of formative uses of self-assessment. Brown and Harris (2013) explored the effects of self-assessment on students' academic achievement. These authors found 24 effect sizes ranging from  $-0.04$  to  $1.62$  and reported that the median effects lay between  $0.40$  and  $0.45$ . They concluded, using Hattie's (2009)  $0.4$  effect size crosscut, that in light of the reviewed empirical evidence, it could be maintained that self-assessment can improve academic achievement across different grades and subjects. Though Brown and Harris also explored self-assessment effects on self-regulated learning, the more recent meta-analysis that will be presented next is more comprehensive.

Panadero et al. (2017) reviewed 19 studies that had explored effects of different self-assessment practices on self-regulated learning and self-efficacy. Though self-regulated learning theory contains self-efficacy within it (e.g., Zimmerman 2000), these authors decided to review the concepts separately because the included research had differentiated these effects. Importantly, the authors also separated self-regulated learning into three different types of measurement, according to how this construct had been explored in research. They found that self-assessment intervention's effects on self-regulated learning were  $0.23$  (learning SRL),  $-0.65$  (negative SRL), and  $0.43$  (SRL measured qualitatively), respectively, and for self-efficacy  $0.73$ . It was concluded that self-assessment interventions enhanced both students' use of learning strategies (i.e., self-regulated learning) and their levels of self-efficacy.

All in all, the conclusions of these two meta-analyses support the idea that self-assessment interventions do have a positive effect on students' learning, self-regulation, and self-efficacy. It is now important to explore what are the characteristics of VET and how these might affect the implementation of self-assessment.

---

## Vocational Education and Training Features and Their Implications for Self-Assessment

Vocational education and training presents some distinct features from other types of educational levels and systems. Probably the most relevant one is that in most countries, VET educational systems organize students' learning around two contexts with different requirements and conditions: the vocational school and the workplace (Schaap et al. 2014). In vocational schools, teachers are devoted to implementing and formally assess learning goals established in the VET curriculum and, therefore, they must generate a summative assessment (i.e. score students' performance). In contrast, in workplaces students during their internships engage in dialogue and many informal assessment situations with their instructors while performing daily activities related to their occupation (Sandal et al. 2014). This underlines the

importance of self-regulated learning for students' academic success in these two complex and evolving learning VET scenarios.

Three implications for students' self-regulation emerge from those contexts. First, in both vocational schools and workplaces, teachers and instructors should develop a strong learning environment that coaches and promotes students' self-regulated learning to support the acquisition of knowledge and skills (Bruijn et al. 2006, cited in Geurts and Meijers 2009). As in any other field, VET teachers and instructors need the ability, not only to intervene actively to deliver essential knowledge but also to take a back seat and allow learners to become more self-directed and learn through collaboration with their peers (Searle 2009). As Höpfner (2009) points out, "the teacher/instructor in technical and vocational education and training is no longer a master who gives all the information, demonstrates everything that has to be done and explains every detail" (p. 1702).

Second, summative assessment is still present in VET schools, influencing students' goal orientations. That means that students might be focused, not only on learning but also on their grades, which would generate types of goal orientation that are not conducive to learning outcomes (Montero and Tapia 1992). In order to alleviate this influence, it is recommended that schools implement authentic assessment scenarios which increase the likelihood of achieving learning goals and also promote higher-order thinking skills (Rojewski 2009). In these scenarios, with a focus on self-assessment activities, students have to demonstrate their comprehension of knowledge and skills within a real context (Boud and Soler 2015).

Third, integrating and building more meaningful relations between the knowledge and the skills developed in the VET school and those utilized in the workplace learning environment (Baartman and Bruijn 2011). Currently, the contradictions between vocational schools and workplace learning environments challenge students' adaptation to their future work. The school-based model sometimes demands assessment procedures that are disconnected the workplace activities, and the students may assume a dichotomy between "practical knowledge" and "school knowledge" (Sandal et al. 2014; Schaap et al. 2014). For this reason, VET teachers and workplace instructors should have a close collaboration to identify learning needs, mainly at the workplace, and thus optimize the teaching processes to solve students' educational needs. Through this collaboration, students will be better guided to take responsibility in their learning so they can develop, organize, and use professional knowledge more effectively (Placklé et al. 2014) and identify the possession of skills demanded in the labor market (Clayton et al. 2003). Therefore, it is essential that students be able to identify the workplace learning needs and fulfill them, that is, to self-regulate and to respond to their initial lack of knowledge when they arrive in their new workplace (Munby et al. 2009).

The use of self-assessment procedures covering general and specific competences is a way to develop VET students' self-regulation skills and to help them integrate their learning in workplace environments. The next section will explore what is known in the VET literature about self-assessment.

## Studies Using Self-Assessment in VET

Even though many authors and professional organizations defend the importance of self-assessment (e.g., Baartman et al. 2013; Clayton et al. 2003), within the VET literature, studies reporting the use of self-assessment tools to promote self-regulated learning are scarce. One of the few areas that has interesting studies within the VET literature in relation to self-assessment is the use of self-report instruments that measure general competences. Two of them will be presented in detail here.

First, Khaled et al. (2014) published a self-report tool that, according to the authors, is still in an exploratory phase. The instrument includes items regarding four competences – deciding and initiating actions, cooperating, applying perspective, planning, and organizing – with four to nine items per competence. Two examples of items for the competence of planning and organizing are “During the preparation of an assignment, I consider which results I want to achieve first” and “I put the tasks to be performed in a logical order.” The validity of the instrument was tested with 351 VET students from the field of health sciences, who had to rate their agreement with the items using values between 0 (“not at all applicable to me”) and 10 (“completely applicable to me”). The results of the study showed that it is possible to identify competences and indicators applicable to different educational settings. Nevertheless, some parts of the questionnaire were not entirely valid, and the authors recognized an important limitation: they noted that specific items could be too abstract because it was difficult to find particular indicators aligned with the variety and complexity of learning situations that VET students face in their daily activity. Nevertheless, this questionnaire represents a valuable effort in designing a standardized self-assessment tool with an emphasis on general competences that can be related to self-regulatory strategies.

Some of the difficulties identified by Khaled et al. (2014) were overcome in the study by Kyndt et al. (2014). Following a complete and complex mixed-method testing process, these authors developed an instrument for secondary vocational education to explore students’ perspectives on generic competences applicable to every occupation. The study included 826 students from many different VET fields (e.g., child care, auto mechanics, organizational assistance) to validate the instrument. The self-report includes eight general competences organized in two sections. The division of communication covers the competences of empathy, active listening, and assertiveness, whereas the section of professional conduct involves the competences of professional attitude, cooperation ability, problem-solving, diversity attitude, and planning and prioritizing. Students self-assessed these competences by answering 44 items on a 5-point Likert scale, from 1 (“completely disagree”) to 5 (“completely agree”).

This instrument shows that it is possible to generate reliable and valid self-reports to help students self-assess their levels in general competences. However, it is important to note, as Kyndt et al. (2014) argue, that competences are a complex learning outcome, so it is better to use this standardized self-report as a starting point to assess general competences and then work in more specific and content related interventions.

Indeed, as some authors have maintained, the assessment of competences must take into account that they are also context-dependent (Bartman et al. 2013). This means that, as well as assessing general competences with several instruments, VET teachers and instructors should assess and promote the self-assessment of specific competences that are appropriate to their VET field.

---

## How to Implement Self-Assessment to Help Our Students to Develop This Skill

Before presenting the list of actions that we can take as teachers, it is crucial to consider what Panadero et al. (2016a) called a “developmental approach to self-assessment.” There are three premises here. First, self-assessment in itself, like any other skill, needs practice. Teachers should not assume that their students will know how to self-assess if they have not been given opportunities for practice and instructional support. Second, self-assessment requires expertise in the task at hand. It is extremely difficult to self-assess a task in which we barely have experience. And third, we need to consider the developmental age phase of the student and ensure that the level of self-assessment asked for is realistic for their maturity. Importantly, though more empirical work remains to be done on this point, research on teachers’ assessment practices supports this developmental approach. Additionally, teachers also need their own opportunities for practices and training courses. One study found that, among the five identified predictors of teachers’ use of self-assessment in their classrooms, the highest one was previous experience in implementing self-assessment interventions, followed by knowledge about the benefits of self-assessment and participation in assessment training courses (Panadero et al. 2014).

Regarding what teachers can do to implement formative uses of self-assessment, a number of papers have explored this. Panadero et al. (2016b) reviewed and combined two previous lists of instructional recommendations as presented by Andrade and Valcheva (2009) and Ross (2006). The list combines six recommendations:

1. **Define the criteria by which students assess their work.** It is important that students know what the assessment criteria are so that they can establish goals aligned with those of their teachers and monitor and evaluate them more precisely (Andrade and Valcheva 2009; Panadero and Alonso-Tapia 2013). One approach that has become mainstream in recent years is the use of rubrics. These tools provide students with clear assessment criteria and also different achievement levels that can be used to structure the performance. The formative use of rubrics has been found to have positive learning effects (Brookhart and Chen 2015). Additionally, the negotiation of assessment criteria is also a productive way to help students internalize it by, for example, co-creating rubrics (Fraile et al. 2017).
2. **Teach students how to apply the criteria.** It is not enough to offer students the criteria; teachers also need to model how to use them. This might seem quite an

obvious recommendation, but, unfortunately, it is a much-needed one, and here we can also learn from research on rubrics. Just handing out a rubric does not have the same learning potential as teaching the students how to use it.

3. **Give students feedback on their self-assessments.** Teachers need to give information to the students about how well they are assessing their own performance. Importantly, teachers can provide feedback on the self-assessment *content accuracy* (Panadero et al. 2016a), in other words, how close the qualitative information created by the student is to what a teacher would give. Giving feedback about self-assessment turns the latter more into a reflective action.
4. **Give students help in using self-assessment data to improve performance.** Teachers also need to provide models and scaffold students on how to apply their self-assessment to enhance their learning.
5. **Provide sufficient time (and opportunity) for revision after self-assessment.** As clearly argued by Goodrich (1996), students need opportunities for improvement after having self-assessed. Otherwise, they do not fully internalize the application of self-assessment to improve their work, and their motivation to perform self-assessment might decrease.
6. **Do not turn self-assessment (only) into self-evaluation by counting it toward a grade.** This is a controversial issue. As mentioned earlier, teachers might have different reasons for wanting to implement summative self-assessment alone or in combination with formative uses – i.e., students would generate both qualitative self-generated feedback and a self-awarded grade. As discussed by Panadero et al. (Panadero et al. 2016a), there is still plenty of room for innovative research about self-grading. However, if self-evaluation is the only type of self-assessment implemented, then the teacher is not exploring the full potential of self-assessment as a learning activity.

---

## Conclusions

An initial conclusion is that there are a number of future lines of work directly related to VET literature. Firstly, there is a need for more research on self-assessment in VET environments. In comparison with other educational levels and systems, especially higher education, self-assessment publications in VET are scarce. Additionally, it would be interesting if that forthcoming research had a focus on the formative use of self-assessment, as the educational value of this approach is stronger, or explored different approaches to summative uses of self-assessment (for recommendations, see Panadero et al. 2016a). Secondly, future research needs to continue defining what are the specific characteristics and needs of VET contexts when it comes to self-assessment. The key is probably the one outlined in this chapter: VET schools have a number of educational goals and constraints that make them different from workplace settings. Importantly, self-assessment is crucial in both environments, but, for obvious reasons, the first place to teach how to self-assess is in the VET schools so that the students have developed this skill to a point when they reach their workplace. Logically, when those students start working, they

will have to adapt to that new environment and therefore will have to tailor their self-assessment knowledge and skills. But this is already something that can be taught in VET schools. Thirdly, in a similar fashion, it is important that those self-assessment interventions be linked to the development of self-regulated learning skills. This framework also has implications for the relationship pointed out just before: workers are supposed to be able to have regulatory strategies, and VET schools are the ideal place to start developing them.

In conclusion, self-assessment is a crucial skill to acquire over the educational years. It seems even more relevant in VET contexts where the connection to the workplace is constant. As one of the key skills for every worker is being able to conclude whether his or her performance has reached the needed goals, VET educators should have self-assessment as a key goal in their curriculum. Unfortunately, research seems to be lacking in this area, which might be a reflection of the lack of permeability of the formative assessment ideas in VET education. Therefore, this chapter has as a goal to issue a call to transfer over some of the relevant conclusions about the educational influence of self-assessment that have been found in other educational levels. Hopefully, this chapter will be a modest contribution in that direction.

## Abstract

Simulated conversations (SC) are an established method for teaching and assessing professional communication competences and other clinically relevant skills in medical education. In SC, participants lead a simulated professional conversation about a predefined authentic case scenario with actors trained to portray a standardized role. Recently, the use of SC has expanded to teacher education, and it is of general relevance to all vocational and professional domains that require conversations between professional and client. The present chapter outlines the applications of SC in medical and teacher education and

## Introduction

Conducting professional conversations is a major task in many vocational and professional domains (Hargie 2011). Typical demands in such conversations include counseling clients, delivering bad news, or resolving conflicts (Gartmeier et al. 2011, 2015). Because of its importance, training in conversation competence has received increasing attention in professional education study programs, particularly in medicine but also in other domains like teaching (Wiesbeck 2015). In this context, the formative and summative assessment of conversation competence is a major issue in providing feedback to learners and evaluating training success. This requires performance-oriented and valid assessment methods that measure participants' communicative behavior in authentic task situations (Braun et al. 2016; Blömeke et al. 2015).

Simulated conversation (SC) is a promising method for this purpose (Association of Standardized Patient Educators 2017; Barrows and Abrahamson 1964; Lane and Rollnick 2007). In SC, examinees lead a simulated professional conversation about a predefined authentic case scenario with actors trained to portray a standardized role. This assessment method has already started to expand from medical education to other fields, such as teacher education (Dotger et al. 2008; Gerich and Schmitz 2016; Wiesbeck 2015; Wiesbeck et al. 2017). It has a general potential for application across vocational and professional domains that require conversations between professional and client.

The present chapter aims to facilitate such a transfer by describing the construction and application of SC assessments for measuring conversation competence and provides a general blueprint for the design of such assessments. The section below provides a generic introduction to the existing research on the assessment of communicative competences using SC. Next, six key steps in the construction of a SC assessment are outlined:

1. Defining the competence based on theory
2. Developing assessment materials (cases, vignettes, and instructions)
3. Selecting or developing observable indicators
4. Recruiting and training SC partners
5. Recruiting and training raters for coding the data
6. Scaling the data to attain performance scores

These steps are illustrated by procedures and materials developed in the *ProfKom* project (for a general description of the project, see Bauer et al. 2018; Gartmeier et al. 2015). In *ProfKom*, parallel SC assessments of physician-patient and teacher-parent

conversations were designed and evaluated (Wiesbeck 2015; Wiesbeck et al. 2017). The chapter concludes with considerations on the strengths and weaknesses of SC assessments for specific purposes.

---

## **Simulated Conversations as a Method for Assessment and Teaching**

Due to its great potential in bridging the gap between theory and practice, learning through simulations has been implemented in a variety of domains, from the medical sector to, for example, the military, aviation, consulting, and social work. Simulations are generally well accepted as they allow for training and assessment within authentic contexts and situations, thus providing valid results (Rees et al. 2004). This section provides an overview of the application of SC for the purposes of assessment and teaching in professional education. Since SC is used most prominently in medical education (Association of Standardized Patient Educators 2017; Barrows and Abrahamson 1964; Lane and Rollnick 2007), the discussion begins by focusing on this domain. Subsequently, recent approaches to transferring the method to teacher education are sketched.

### **Simulated Conversations in Medicine**

Medical training has traditionally depended on immersing students in the everyday care of real patients (Cleland et al. 2009; Wiesbeck 2015). However, deploying real patients in the training and assessment of preservice physicians has a number of disadvantages. First, patients treated at the facilities in which medical education takes place – mostly university hospitals – cannot be considered representative of the full spectrum of relevant diseases that needs to be taught in medical education (Cleland et al. 2009). Second, there may be problems with the patients' consent as they are sometimes reluctant to cooperate with students, and this noncompliance can lead to bias (e.g., if patients with specific types or severity of diseases are more prone to decline). Third, the naturally occurring differences between patients with regard to the severity of diseases and personality can affect the reliability of assessments (Collins and Harden 1998). Encountering these different situations may be beneficial for learning the full range of patients' symptoms and behavior, but it is detrimental to reliable assessment, which requires a large degree of standardization across measurement situations. Lastly, the deployment of real patients into clinical teaching is sometimes inappropriate for ethical reasons (e.g., when practicing how to give a terminal diagnosis) because patients have to be protected from unnecessary harm (Gaba 2004).

The use of simulated patients to support clinical skills learning and assessment is a viable solution to counter the discussed problems (Barrows and Abrahamson 1964). According to Barrows (1987), “the Simulated/Standardized Patient (SP) is a person who has been carefully coached to simulate an actual patient so accurately

that the simulation cannot be detected by a skilled clinician. In performing the simulation, the SP presents the gestalt of the patient being simulated; not just the history, but the body language, the physical findings, and the emotional and personality characteristics as well” (p. 17). In the terminology, the term *simulated patient* encompasses *standardized patients* (Adamo 2003; Wiesbeck 2015). That is, conversations with standardized patients are always simulated ones, but SC can have varying degrees of standardization. This chapter follows Wiesbeck’s (2015) recommendation to use the term *simulated conversations* because it covers relevant aspects of the method comprehensively (e.g., conversation partners, situations, cases, coding criteria, and raters). The degree of standardization may vary from rough situation descriptions (similar to traditional role-play) to extensive training in specific reactions and responses (Cleland et al. 2009).

The SC method has several advantages (Cleland et al. 2009). First, regarding content, simulated patients can portray a broad range of cases that students may not encounter in real patients. Second, they are willing to perform scenarios many times with standardized, predictable behavior, and they are available as and when required. Third, simulated patients can be trained adaptively to reflect the student’s level of experience. Fourth, they can provide feedback to participants about their performance, which is important for both learning and formative assessment. Fifth, SC is well accepted by pre- and in-service physicians. Finally, there is strong evidence that SC can be highly objective, reliable, and valid if constructed and conducted thoroughly (Barman 2005; Cleland et al. 2009; Newble 2004).

For these reasons, the use of simulated patients increased quickly in medical education and was developed further, especially for assessment purposes (Cleland et al. 2009; May et al. 2009). Today, clinical skills are mostly assessed by *Objective Structured Clinical Examinations* (OSCEs) (Barman 2005; Harden et al. 1975) that encompass SC. These OSCEs are an examination format in which examinees rotate around a circuit of clinical task stations (Harden et al. 1975) that often require interaction with simulated patients (Iramaneerat et al. 2008). The *Association of Standardized Patient Educators* promoted best practices in the application of simulated patient methodology for education, assessment, and research (Association of Standardized Patient Educators 2017). Since 2004, encounters with simulated patients, including the examination of communication skills, have been a compulsory part of the US Medical Licensing Examinations (United States Medical Licensing Examination 2015), and communication skills are taught in nearly all medical schools (Lurie et al. 2008). In Europe, the employment of simulated patients was delayed (Ortwein et al. 2006) but spread quickly. In Germany, for example, communication competence has become a compulsory element of medical licensing, and almost all medical schools employ SC for assessment purposes (Görlitz et al. 2014).

In sum, simulated patients are today employed worldwide for teaching and assessing clinical and communication competences (May et al. 2009). Moreover, the use of simulated patients has expanded to other domains. Below, the transfer of SC to teacher education will be discussed as an exemplary case.

---

## Applications in Other Domains

Recently, attempts have been made to apply SC as a learning tool in teacher education (Dotger et al. 2008). Dotger et al. (2010a, b) constructed a learning cycle that included a variety of interactions between preservice teachers and parents, colleagues, school leaders, and students. According to these authors, SC in medicine and teaching differ mainly in the degree to which standardization can be achieved; it seems SC is more difficult to standardize in educational settings because anticipating participants' responses to verbal triggers is much more difficult (Dotger and Ashby 2010). Consequently, the training of the SC partners is especially critical in education to achieve a sufficient level of standardization.

SC as a method of assessing teachers' competences were first implemented and evaluated in the *ProfKom* project (Wiesbeck 2015; Wiesbeck et al. 2017). In *ProfKom*, a SC assessment was implemented to measure preservice teachers' competence in leading teacher-parent conversations. This was done in the context of a training study aimed at fostering such competences (Gartmeier et al. 2015). The results demonstrated that SC on educational topics can provide a similarly objective, reliable, and valid criteria measure of communication competence as it does in medical education (Wiesbeck 2015; Wiesbeck et al. 2017). Moreover the SC assessment format was well accepted by preservice teachers (Wiesbeck 2015), despite it being unfamiliar to them. In another application, Gerich and Schmitz (2016) used SC both for the training and the longitudinal assessment of preservice teachers' counseling competence. Their results corroborated the view that SC is a well-suited and motivating method to promote and assess preservice teachers' competences and a learning tool that helps link teacher education and practice.

---

## Constructing Simulated Conversation Assessments

This section provides a blueprint of the key steps required in the construction and implementation of any SC assessment. Naturally, these steps are consistent with general procedures in the development of assessment instruments (Furr and Bacharach 2013; Wilson 2005). Nevertheless, the features of SC give rise to a specific combination of challenges that must be addressed. Below, each respective step is elaborated conceptually and illustrated with examples from *ProfKom*. The discussion is mostly based on Wiesbeck (2015) work that can be consulted for a more in-depth treatment (see also Bauer et al. 2018; Gartmeier et al. 2015; Wiesbeck et al. 2017).

### Defining the Competence

A first and crucial step in designing any competence assessment is to define and operationalize the construct based on relevant theory (Furr and Bacharach 2013). Competences can be considered as the personal dispositions that allow a person to act successfully in specific task situations that are typical in the (professional)

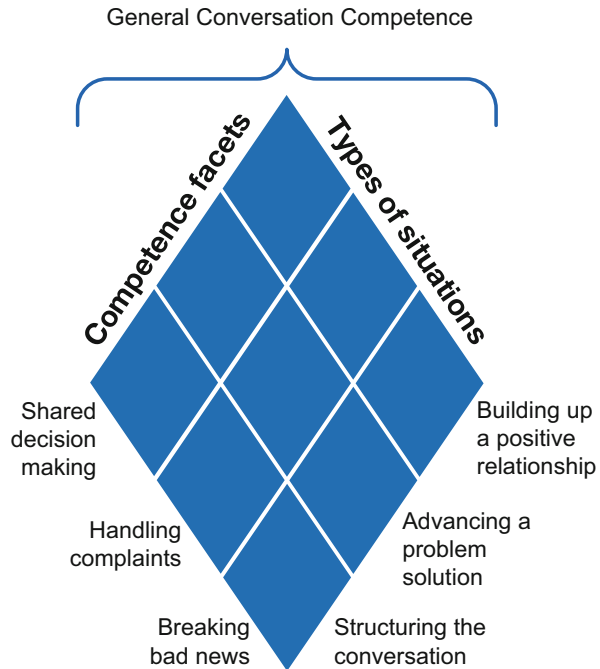

domain (Weinert 2001). Since the turn of the century, the approaches to modeling and measuring competences in educational contexts have been advanced substantially (Blömeke et al. 2015; Hartig et al. 2008; Shavelson 2013). Setting up a competence model requires deliberation about its dimensionality (i.e., whether there are different competence facets) and the relevant task situations in which the competence is required (Furr and Bacharach 2013; Wilson 2005).

Several competence models related to professional communication and consulting have been proposed recently (Aich 2011; Gartmeier et al. 2011; Gerich and Schmitz 2016; Hertel 2009). In *ProfKom*, professional communication competence was conceptualized as a hierarchical and multidimensional construct comprising the individual dispositions required to lead professional conversations effectively (Gartmeier et al. 2011, 2015). The *ProfKom* model proposed three generic facets of conversation competence that apply to the different types of conversations across a broad range of domains (Fig. 1). First, the ability to build a *positive interpersonal relationship* implies the establishment of a climate of mutual respect and trust as a prerequisite for working jointly on the problem that constitutes the topic of the conversation (cf. Rogers 1951). Second, *advancing a problem solution* refers to the professional's ability to foster a client's understanding of the problem and develop options for its solution. To do so, professionals should take charge of identifying the problem as a topic of communication and establishing a shared understanding (common ground; Clark and Brennan 1991; Horton and Keysar 1996). On this basis, potential causes of the problem can be elaborated, and possible solutions can be weighed jointly, with concrete agreements required on courses of action. Third, *structuring the conversation* means being aware of what are key steps and tasks in a specific conversation and managing their transitions smoothly and transparently. The goal is to cover all relevant aspects of, for example, a counseling conversation, and to be "on the same page" as the conversational partner.

Figure 1 also shows that the discussed competence facets relate to specific types of conversations. Thus, specific adjustments may be required to adapt one's behavior to particular types of conversations (e.g., regarding the conversational partner or the purpose of the conversation). Figure 1 lists three non-comprehensive, but typical, conversation formats: shared decision-making, handling complaints, and breaking bad news. The specific type of conversation and its goals determine the differential relevance of each competence facet and how it is applied to the situation (Gartmeier et al. 2011). For example, establishing and maintaining a positive relationship with the conversational partner may be more important and challenging in breaking bad news than in amicable shared decision-making conversations. Moreover, these two types of conversations follow different scripts (Baile et al. 2000; Charles et al. 1999). Thus, they impose different demands in terms of structuring the conversation.

The focus in *ProfKom* was on the shared decision-making conversations that frequently occur in medicine and teaching (Aich 2011; Makoul and Clayman 2006). In such conversations, the goal is to reach a mutual decision regarding a problem for which several viable solutions must be weighed up (Charles et al. 1999). This focus on a specific type of conversation helped with the standardization of the SC assessment.

**Fig. 1** Model of professional conversation competence. (Adapted/translated by permission from Springer Nature: Gartmeier et al. 2011)

## Developing Assessment Materials and Administrative Planning

A range of materials must be developed to use SC for assessing communication competence. The main purposes of these materials are to instruct actors and students about the conversation scenario, their roles, and tasks. Moreover, the organization of the assessment has to be clearly planned and scheduled to ensure the smooth flow of participants through the assessment process. These materials and routines will be elaborated below.

*Cases and role instructions for actors and students.* SC assessments require the development of authentic case scenarios in which the conversations are grounded. If such cases are not available, they can be developed based on expert interviews or similar techniques (Gartmeier et al. 2012). Designing the cases requires consideration of their prevalence and importance in the target domain and of the alignment of their difficulty with the participants' level of competence. Expert consultation and consensual validation are valuable tools in this regard. For example, in *ProfKom* case scenarios, the actor and participants' roles were created based on a Delphi study and expert interviews and were optimized through pretesting, expert consultation, and a consensual validation procedure (Wiesbeck 2015). As mentioned, all cases regarded shared decision-making conversations in the relevant domains (e.g., teacher and parent discussing different options for helping a student who recently received bad grades).

Actors need detailed instructions to be able to perform their role in a standardized way across several conversations. Hence, they should receive comprehensive and precise descriptions of their role covering, for example, the personal background

and life circumstances of the person they enact and given insights regarding the hopes, expectations, and ambitions the person brings to the conversation. Actor instruction materials also provide the basis for actor training (see “Actor Training”). For participants, role descriptions can be somewhat shorter. Unlike actors, participants only get to read about their role shortly before the SC. In order to avoid overburdening participants with overly detailed information, these instructions should cover only essential information on basic questions that the participants need to answer to be able to perform (e.g., “What is the scenario?”, “What has already happened so far?”, “What am I expected to achieve?”, etc.) (Khan et al. 2013). In most SC, participants are allowed to take their instruction sheet with them. However, they should not be able to scan these materials constantly during the SC because this decreases the authenticity of the situation.

*Organizational routines.* Since SC is a specific form of OSCEs, existing guidelines on administrative issues also apply (e.g., Harden 1990; Khan et al. 2013). Important issues regarding the organization of SC involve the following: How many SC should each participant complete? How can the timing of actors and participants be managed so that each participant has the same time for conducting the conversation and getting feedback? How can the total time for the assessment, and the individual assessment and waiting times for the participants and actors, be arranged efficiently? How many conference rooms are required, and how do they have to be equipped and set up (e.g., regarding cameras, assistants, and arrangement of furniture)?

In *ProfKom*, each participant conducted two shared decision-making conversations with different actors (one male, one female; randomly assigned to participants). The meetings were organized based on a rotation schedule that minimized waiting times (Wiesbeck 2015; Wiesbeck et al. 2017). Prior to the conversations, the participants received a standardized introduction and two case vignettes and had 20 min to prepare. After the preparation, each participant was assigned a conference room in which the two SC took place successively (i.e., the actors rotated between the conference rooms). Each of the SC lasted for around 10 min. In each room, a trained student assistant was present to conduct the video recording. The procedures also ensured that participants were kept separate from each other until all of them had completed the assessment.

## Selecting or Developing Observable Indicators

A fundamental issue in using SC for assessment involves the definition of specific observations of the participants’ behavior that provide indicators of their demonstrated competence. That is, the competence definition or model must be broken down to a behavioral observation coding rubric (Evertson and Green 1986; Seidel et al. 2005). In medicine, several coding rubrics for assessing conversation quality are available (e.g., EPSCALE; Edgumbe et al. 2012). However, in many cases, such instruments need to be adapted to the assessment’s specific purpose and circumstances (e.g., in terms of domain, competence definition, etc.). Regardless of whether an existing instrument is adapted or a new one is developed, the main challenge is that the coding rubric must define the relevant behaviors or events that are to be observed (including definitions

and anchoring examples). Moreover, the relation of these observations to specific aspects of conversation competence must be clarified, and relevant timeframes for the observations must be set. For example, specific actions may be relevant only at certain times during the conversation (e.g., in the opening phase), while others may need to be screened throughout the conversation for the frequency or duration of their occurrence (e.g., frequency of meta-communication, length of contributions).

Conceptually, two main types of scoring rubrics can be distinguished for this purpose: *checklist scales* and *global rating scales* (Khan et al. 2013). Checklists are behavior-oriented, low-inference instruments that typically feature actions that should (or should not) be performed during the communication task. Such checklist items are low-inference because they refer to directly observable behavior (e.g., gestures). Thus, they require only a minimum amount of judgment on behalf of the observer and are relatively straightforward to rate even for raters with little prior knowledge. Therefore, they tend to have high interrater reliability. In contrast, global rating scales ask observers for the overall judgments of the participants' conversations, which have to be inferred from the observations (e.g., "Shows interest in the perspective of the conversational partner"). Because such rating scales demand a higher level of qualitative judgments by the observers, they require more background knowledge and training (Langer and Schulz von Thun 2007; Seidel et al. 2005). It is also more challenging to attain a high level of interrater reliability with high-inference ratings (Seidel et al. 2005). However, it appears there are some advantages to high-inference rating items in terms of validity (Newble 2004; Regehr et al. 1998), as they often have a more direct relationship to the theoretical construct being measured and, thus, better content validity (Seidel and Prenzel 2010). Moreover, Regehr et al. (1998) hinted at the advantages for predictive validity. For a thorough assessment, it may be helpful to combine high- and low-inference ratings because they serve different and complementary purposes (Newble 2004); low-inference ratings can serve to identify specific elements of a competence that must be demonstrated, while high-inference ratings can provide a measure of process components and a more complex picture (Wiesbeck 2015). Bauer et al. (2018) found that the two types of ratings generally provided a consistent picture of differences in conversation competence but were differentially sensitive to treatment effects.

A related factor is who actually provides the observations. Typical approaches in SC are to use trained observers either in situ during the conversation or post hoc to code videotaped conversations. A third common option is to have the actors provide their observations after the SC. Video-based rating using trained external observers is probably most advantageous for assessment purposes (Chesser et al. 2009; see also "Recruiting and Training of Raters"). For summative assessment and high-stakes individual decision-making (e.g., pass/fail or grading judgments), consistent evaluation is crucial. Wiesbeck et al. (2017) found higher validity coefficients for such ratings compared to actors' ratings or participants' self-ratings. Moreover, unlike in situ observations, videos can be reevaluated if required, and thus their use is less likely to lead to errors. In contrast, the actors' observations may be a valuable source of feedback when the focus of the SC is on formative assessment for supporting students' reflection on their competence development and fostering the learning process

(Cleland et al. 2009). Though there is evidence that actors can provide reliable ratings (Barman 2005; Blake et al. 2006), it seems less advantageous to rely on these ratings as the only source for summative assessment because the dual tasks of acting and observing may interfere with the fidelity and standardization of the SC. This notwithstanding, a combination of observation sources probably provides the richest picture and allows for comparisons of different perspectives. As Schirmer et al. (2005) argue, a combination of ratings by external raters and conversational partners increases the validity of the assessment and adds an important dimension.

In *ProfKom*, a multimethod approach to operationalizing conversation competence was implemented, which combined different types of ratings and different observers (Wiesbeck 2015; Wiesbeck et al. 2017). Based on the model of conversation competence described above, high- and low-inference rating items were developed for the three aspects of conversation competence. These high- and low-inference items tapped into the same underlying constructs, but they did so at analytically different levels (i.e., global quality judgments vs. the assessment of concrete behavior). The choice of indicators was partly inspired by existing instruments from medicine (Edgcumbe et al. 2012), adapted to the cross-domain approach of the project and the specific competence aspects in focus, while the SC videos were coded by trained raters. These external codings provided the primary data source. Additional actor ratings and student self-ratings were gathered directly after each SC. High-inference ratings were used for this purpose because these had to be completed quickly and on the fly after each assessment. These additional data were used primarily for validation (Wiesbeck 2015; Wiesbeck et al. 2017) and feedback.

## Recruiting and Training Simulated Conversation Partners

Implementing a SC assessment requires recruiting a pool of actors and training them thoroughly to achieve the necessary level of standardization. The competence definition, the instructional materials, and the coding rubric provide the basis of this. Cleland et al. (2009) outline four key factors that should be considered when recruiting simulated patients: ability, suitability, conscientiousness, and credibility. These criteria can be applied easily to other domains. That is, the actors should have the *ability* to enact their roles consistently across repeated SC, maintain focus over time, and realize the importance of sticking to the script and guidance provided. *Suitability* refers to their attitudes toward doctors, as well as the reasons motivating them to participate as simulated patients. Actors with an adverse attitude toward doctors could negatively influence the experiences students gain when interacting with patients. *Conscientiousness* means that simulated patients should be dependable. Since the organization of SC is a logistically complex and costly endeavor, irresponsible actor behavior (e.g., not showing up on short notice, careless acting) could incur additional costs and decrease the reliability of the assessments. Finally, the *credibility* of the actors relates to how they match the case requirements. Characteristics that should be considered here are age, language, gender, race/ethnicity, body habitus, findings of physical examinations, and experience with the

illness (Adamo 2003). The decision to hire professional actors or to recruit lay-actors, such as students, relates to these selection criteria. Professional actors typically bring more expertise in acting, and, therefore, it can be assumed they provide a better standardization of performance. Recruiting lay-actors may be less cost-intensive but increases the amount of actor training required.

Though simulated patient training is considered crucial, there is no widely accepted standard for its extent and duration. One way of assessing the sufficiency of training is to test whether a SC partner can maintain a desired level of accuracy in multiple consecutive encounters (Adamo 2003). Since the portrayal of roles may change over time, it is strongly recommended to continually reassess the quality of simulated patients and, if applicable, retrain them. When simulated patients are well trained, they are hardly distinguishable from real patients (Rethans et al. 2007).

In *ProfKom*, six professional actors were hired and trained. The recruitment process took into account the four key characteristics discussed above. Overall, their experience suggested that all of them were able to serve as simulated parents (*ability*). During the recruitment process, they were asked about their motivations for participating (*suitability*) and had to offer assurances that they would be available for all dates on which conversations would take place (*conscientiousness*). Finally, applicants were screened and selected regarding case requirements such as gender, age, demographics, and personal background (*credibility*).

Actor training took place in two groups, each working on specific case vignettes. Training for each case lasted for approximately 2 h. Its first part consisted of a general introduction to the concept and purpose of SC and the responsibilities of being a SC partner. In the second part of the training, the case vignette and specific verbal triggers were discussed in detail and illustrated by video sequences from a pilot study. The divergent and consistent behavior of the simulated parents in the video examples was discussed in the group, and the actors agreed on guidelines for behavior in future conversations. The final part of the training consisted of trial runs. In order to provide a model for the simulated parents, the workshop leader acted out the first trial run; subsequently, each actor performed at least one trial run. The simulated parents were advised to watch each other closely and to adjust their portrayal of the role to match one another. Since the course of the conversations was not entirely predictable, the simulated parents acted out a variety of possible conversational directions and were advised to improvise if something unpredictable happened. It was stressed that the most important point was for them to always stay in character to ensure the authenticity of the situation (i.e., no meta-communication with the participants about the SC was allowed). Moreover, they were warned about the danger of cuing participants, and typical points in the conversation where this might occur were illustrated.

## Recruiting and Training Raters

A key aspect of achieving high-quality SC assessments is selecting appropriately skilled raters and training them thoroughly. Because SC is a form of rater-mediated assessment, particular challenges apply from a psychometric perspective (Engelhard

2002; Furr and Bacharach 2013; Shavelson and Webb 1991). Specifically, measurement errors introduced by the raters should be minimized by rater training and analyzed in the form of interrater reliability (Chesser et al. 2009; Gwet 2014; Lurie et al. 2008). Interrater reliability is a major concern because it is the very basis of building scores from the assessment (see also “Scaling the Data”). As mentioned above, possible raters for SC include external raters such as faculty staff, examiners or experts, the SC partners, or peer students (Each Assessment subgroup 2012). The purpose of the assessment (formative/summative) is essential in choosing whom to recruit. Regardless of the purpose, however, rater training is required to achieve sufficient psychometric quality. According to Wiesbeck (2015), there is no gold standard for rater training; instead, its type and duration depend primarily on the complexity of the coding manual the raters have to apply. As discussed earlier, low-inference coding rubrics (e.g., yes/no checklists or category classification systems) that focus on directly observable behavior are easier to use than high-inference rating scales. Thus, the latter generally require more intensive rater training to achieve reliable and valid results (Newble 2004). Below, we illustrate rater recruitment and training based on the procedures in *ProfKom*. Detailed guidelines for rater training can be found in Wiesbeck (2015) and in the general literature on behavioral observation methods (e.g., Seidel et al. 2005).

In *ProfKom*, a pool of five raters took part in communication training to provide a common prior knowledge base. Subsequently, they completed a 2-day rater training session based on video-recorded SC. The first part of the rater training consisted of six components, including training on core concepts, discrimination, and frequent rater errors (Langer and Schulz von Thun 2007; Seidel et al. 2005; Wirtz and Caspar 2002). In the concept training, the coding manual was introduced conceptually, and the raters had to assign the observed behavior to items and competence levels. Videos were rated jointly until the raters and the two experts had a common theoretical understanding of and between their ratings. During the group discussion, the coding manual was revised slightly. For example, coding rules were differentiated and examples added or modified. In a similar procedure, the discrimination training aimed at distinguishing different levels of performance on the indicators of the coding rubric. After this first part of the rater training, the five potential raters and the two experts coded ten videos in a trial run (approximately 10 h each), establishing good interrater reliability ( $ICC = 0.84$ ) across all seven raters (including the experts) and all items of the coding manual. The raters reached the a priori set cutoff point of  $ICC = 0.60$  for all but two individual items. Moreover, all possible rater pairs met this target. These results indicated that the rater training adequately prepared the raters for the application of the coding manual.

In the second part of the rater training, two selected raters and the two experts discussed the ratings in detail, based on empirical analyses, to fine-tune them. In a first step, the interrater reliability was targeted, with particular emphasis on and discussion of the two items that had insufficient interrater reliability in the trial run. Subsequently, the leniency/strictness of the raters was harmonized through discussion about the means of each rater for each item. Moreover, frequency analyses were employed to ensure that all raters used the entire scale. To calibrate raters further, ratings were again compared to sample solutions.

## Scaling the Data

Once the ratings are complete, a final step in SC assessments is to transform the raw scores into composite performance scores. This should be based on a psychometric model that accommodates the nature of the data (e.g., the indicators' level of measurement) and the assumed dimensional structure of the competence model (Furr and Bacharach 2013). For basic analyses, typical procedures based on classical test theory may be sufficient (given that the raw data have an appropriate level of measurement). For example, based on interrater reliability analyses, classical item analyses can be performed and composite scales can be built. Factor and reliability analyses are important tools for this purpose (Raykov and Marcoulides 2006).

It should be noted, however, that such basic analyses miss some of the complexities of SC assessments. For example, if more than one case scenario is used, the data have a hierarchical structure in which the observations are nested in cases. Hence, differences between the cases provide an additional source of variance that should be controlled. Moreover, such nesting increases the likelihood that independence assumptions inherent in many psychometric models are violated (Raykov and Marcoulides 2006). Indeed, there is evidence that case effects may result in more severe bias than rater inconsistency (Barman 2005; Guiton et al. 2004; Iramaneerat et al. 2008). A simple tool for gauging the size of potential case effects may be prior testing (e.g., using ANOVA) (Wiesbeck 2015). This does not control for the problem, however. More sophisticated options are available, such as generalizability theory analyses (Shavelson and Webb 1991) or specialized latent variable models that account for testlet effects (e.g., bifactor or testlet models; Cai et al. 2011). Item response theory models for rater data, such as many-facet Rasch models (Linacre 1989), additionally can account for rater effects and provide unbiased person estimates (Bond and Fox 2015; Eckes 2015). These more-sophisticated methods involve greater analytic complexity, however, and typically require large sample sizes.

The analyses in *ProfKom* relied on the basic tools mentioned above, partly due to the small sample size (overall  $N = 168$ ). After interrater reliability had been checked (see "Rater Training"), scores were built by averaging items over the two SC per participant. Confirmatory factor analysis indicated that the structure of conversation competence assumed in the *ProfKom* model fitted the data reasonably well (Gartmeier et al. 2015; Wiesbeck 2015). Moreover, reliabilities for the resulting composite scales were in an acceptable range (0.71–0.87) (see Wiesbeck (2015) for analyses of potential case effects).

---

## Conclusion

This chapter has outlined the development of SC assessments of professional conversation competence in medicine and teaching. As discussed, SC is probably the most adequate method for this purpose because it combines performance-based measurement in authentic case scenarios with adequate measures to achieve standardization. It is the authors' conviction that there is a broad range of potential applications of SC assessments to any vocational or professional tasks that involve

communication with clients. Since SC is also highly motivating for students and creates effective learning possibilities, educators may also want to establish SC as a standard method of instruction in their curricula. Doing so can contribute to establishing closer connections between professional learning environments and work life (Dotger 2013).

The chapter has also outlined the cornerstones of planning and implementing SC assessments in facilitating their transfer. For reasons of space, additional optional steps, such as providing feedback, were omitted (Cleland et al. 2009; Dotger 2010). Participants typically have a strong interest in receiving feedback on their performance. For this, video-based feedback probably offers the strongest learning benefits (Fukking et al. 2011), although other less demanding methods are certainly applicable.

Among the limitations of SC assessments of communication competence is clearly the fact that the measurement is bound to competence aspects that are either directly observable or that can be reasonably inferred by observation. Additional efforts or other methods are required to measure aspects that are arguably important in communication but less directly visible, such as empathy, experience, or reflection (Hertel 2009). Such characteristics might be elicited in, for example, stimulated recall interviews when watching videos of SC. Moreover, SC assessments are certainly more complex and time and resource intensive than traditional forms of assessment, meaning their benefit needs to be weighed against the costs. However, thorough planning can contribute to optimizing room requirements, actor salaries, and staff and participants' time. Moreover, the case made here is that other methods, such as self-report measures or paper-pencil tests of communication, are clearly inferior in terms of validity (Wiesbeck 2015).

## Abstract

People's self-monitoring of their learning has extensive impact on generating opportunities for professional development. Self-monitoring before, during, and after completing work-related tasks affects decision-making, learning behavior, strategy use, and learning motivation. When self-assessing, a person compares performance against some standard. When self-reflecting, a person makes in-depth judgments about the learning process, motivation, beliefs, plans, and outcomes. Engagement in self-monitoring is a prerequisite for professional development. However, in most work environments, there is only limited

facilitation of self-monitoring activities. Opportunities for self-assessment and self-reflection may be scarce, because it is complex to define individualized competency standards that match the workplace reality. This chapter describes reasons why it is often challenging for workplace learners to self-monitor their professional development. Then, recommendations to implement and improve self-monitoring activities are described. Development of competencies and learning goals that clarify the needed knowledge, skills, and attitudes can improve self-assessment accuracy. Further, to self-monitor professional development, people should be trained to focus on predictive cues that give indications about actual progress. Because persons remain largely unaware of their biased self-monitoring, they need continued opportunities and repeated feedback. Moreover, to reflect on affective and motivational aspects of workplace-based learning, employees could use learning journals and questionnaires as support tools to evaluate practice and identify areas for development and feedback seeking. Importantly, to stay motivated to self-monitor learning, people need to be informed about the usefulness of metacognitive activities and obtain autonomy to design individual learning trajectories.

## **Self-Assessment and Self-Reflection to Measure and Improve Self-Regulated Learning in the Workplace**

An extensive part of vocational training takes place in the actual workplace, where learners need to acquire the competencies to become an expert in their profession. Workplace learning is typically informal. It is directed through learners' individual needs and goals, rather than an outlined formal curriculum (Fontana et al. 2015). Professional development takes place through dealing with the demands, opportunities, and limitations of the work context. More often, learning occurs without the learner even being aware of it. Learning opportunities arise when interacting with colleagues and by practicing tasks (Gijbels et al. 2010). To effectively learn in the complex work context, learners have to be self-regulated, that is, taking an active approach to learning and adaptively adjust behavior and strategy use to achieve learning goals (Raemdonck et al. 2008). Learners themselves, rather than supervisors, are responsible for managing professional development. Learning needs to be organized through self-monitoring of the ongoing learning progress, successes, and possible challenges. Further, a learner should reflect on his or her learning attitudes, emotions, and learning motivation. Based on self-monitoring, a person adjusts learning behavior and strategy use to meet personal learning goals and external requirements (Zimmerman 2000).

In other words, in order to effectively learn from workplace opportunities, a person needs to engage in metacognition. The term “metacognition” was first used by Flavell (1976), who described it as “I am engaging in metacognition if I notice that I am having more trouble learning A than B; or if it strikes me that I should double check C before accepting it as a fact” (p. 232). Nelson and Narens (1990) proposed a model of metacognition, explaining that a person’s object-level (actual knowledge and skills) and meta-level (a person’s insight into the object level) are adapted through self-monitoring and self-regulation processes. That is, a person monitors the object level, and self-monitoring then influences a person’s development of knowledge and competencies through self-regulation.

Figure 1 shows the relation between self-monitoring and self-regulation. Zimmerman (2000) proposed a framework to further explain self-regulated learning and the influence of self-monitoring. This model explains self-regulation with processes that start, adjust, and maintain learning. Self-regulated learning consists of three phases: (1) before task completion (forethought phase), the learner sets goals, makes plans, and chooses strategies to reach goals; (2) during task completion (performance phase), a learner works on the learning tasks and self-monitors

**Fig. 1** The interplay between self-monitoring and self-regulation. Self-monitoring consists of self-assessment and self-reflection activities. Self-regulation is cyclical and takes place before, during, and after learning. Further, this figure shows examples of cognitive, metacognitive, and motivational factors affecting self-monitoring and self-regulation

performance by comparing the actual outcomes with the task goals; and (3) after task accomplishment (reflection phase), a learner evaluates whether and how the goals have been attained. It is important to note the cyclical nature of the model of self-regulated learning. During self-regulating learning, a person should continuously engage in self-monitoring, by observing and evaluating the learning process and the outcomes (Eva and Regehr 2007). The output of a learners' self-monitoring is used as a basis to evolve learning through allocation of time to specific tasks and adaptation of strategy use (Panadero and Romero 2014). For instance, a person's goal setting and planning (in the forethought phase) is affected by self-reflections about how the invested effort benefitted performance and whether the used strategies improved goal attainment. Self-monitoring of learning experiences influences the reflection phase after learning by affecting feelings of self-efficacy and motivation.

As shown in Fig. 1, self-regulated learning is affected by a variety of cognitive, metacognitive, and motivational factors (Boekaerts 1999). An effective self-regulated learner selects tasks with an appropriate level of difficulty; tasks should bring opportunities to learn, but at the same time, a person should try to avoid tasks that are too difficult (Metcalf and Kornell 2005). In particular, a students' personal agenda (plans and goals) plays an important role in task selection and the way time is allocated to tasks (Ariel et al. 2009). Moreover, beliefs about self-efficacy, interest in the learning tasks, and outcome expectations have influence on learning decisions and task persistence (Schmitz and Wiese 2006). Attributing learning progress and failures to controllable processes enables the learner to stay motivated when facing challenges and frustration (Cleary and Zimmerman 2004). However, when a learner attributes failures and poor performance to a lack of intellect and ability, this will be motivationally damaging, because it implies that learning efforts to improve performance will not be effective.

Most research addressed self-regulated learning in formal educational contexts. Although workplace learning may not always occur exactly as described by the framework on self-regulated learning, it involves the same phases and a similar need for self-monitoring and self-regulation (Margaryan et al. 2013; Van Eekelen et al. 2005). Because learners need to identify their own learning opportunities in the workplace, the ability to self-monitor and self-regulate learning may even have greater impact in comparison to formal learning contexts. An individual's self-monitoring may be the most important basis for identification of domains for feedback and creation of training opportunities (Freund and Kasten 2012; Zell and Krizan 2014). Active engagement in self-monitoring activities before, during, and after completing work-related tasks is therefore a prerequisite for adaptive adjustment of learning actions and learning motivation (Boud 1995; Panadero et al. 2017; Sadler 1989).

Unfortunately, many learners do not know how to self-monitor their learning, because they are only trained to acquire professional content knowledge and are dependent on their supervisors and colleagues for feedback on competence development and work-related knowledge. Learning cannot be sustainable when learners remain controlled by supervisors. Importantly, effective self-monitoring only improves self-regulation when persons accept responsibility for their long-term professional development (Beck et al. 2013).

The purpose of this chapter is to promote in-depth understanding of self-monitoring in the workplace context. Therefore, the remainder of the chapter is structured as follows: it first describes the measurement of self-monitoring and the match between monitoring judgments and actual learning. Then, after explaining factors hindering self-monitoring, guidelines are given to support trainees and educators improving self-monitoring activities. For consistency, the term self-monitoring is used as an overarching construct to describe one's self-evaluations of professional learning. The term self-assessment will be used when describing a person's quantitative self-monitoring of performance and the comparison of self-observed performance against some standard. The concept of self-reflection refers to either qualitative or quantitative in-depth self-monitoring of the learning process, learning outcomes, and the causes of one's errors or successes.

---

## Measuring Monitoring of Learning: Self-Assessment and Self-Reflection

### Measuring Self-Assessment

To self-assess, a learner has to judge the quality of performance before, during, or after executing a task ("Self-Assessment for Learning in Vocational Education and Training" by Panadero et al., this handbook). Self-assessments are made by giving a quantitative judgment about performance. For example, a person could make a judgment about the percentage of correct performance or could self-assess task outcomes with the use of a Likert scale ranging from very insufficient to highly sufficient. In a review, Panadero et al. (2016a) found 20 different categories of self-assessment formats, ranging from simple to complex. An example of a "simple" self-assessment is self-grading completed work. More specifically, in a study by Boud et al. (2013), students had to allocate grades to their completed work prior to receiving instructor grades. More complex forms of self-assessment are, for example, giving ratings for items per task sub-domain with the use of rubrics or completing checklists to assess whether and how sub-steps of the task are completed.

Because self-assessment measures are ratings of performance, the match between self-monitoring and performance can be calculated. Two measures are most commonly reported in literature to measure self-assessment accuracy: correlations between self-assessment and criterion performance and deviations between judgments and performance (Mengelkamp and Bannert 2010). The correlational measure, also referred to as relative accuracy, gives insight into an individual's ability to discriminate between higher and lower performance. Correlations close to +1 indicate a strong match between monitoring and performance, whereas correlations close to 0 indicate that judgments are not related to outcomes. To calculate correlations, the measures of performance and self-assessment do not necessarily need to be measured on the same scale. However, the correlational measure of self-assessment accuracy does not show whether a person over- or underestimated outcomes. To assess to what extent the magnitude of the judgments deviates from actual

performance, absolute accuracy measures are needed. These measures, also referred to as calibration or bias, show whether a person is accurately calibrated, overconfident, or underconfident. Relative and absolute accuracy measures do not necessarily correspond and seem to be based on different self-monitoring processes. For instance, even when an individual can discriminate between tasks for which she/he had high and low performance, this person may still be highly overconfident about the quality of performance (Dunning and Helzer 2014; Van Loon et al. 2013).

## Relating Self-Assessment to Performance

Studies investigating adults' self-assessment show that accuracy ranges from very inaccurate to highly accurate. Most of the studies using measures of absolute accuracy found evidence that self-assessments are biased in the direction of overconfidence (Davis et al. 2006). Several studies on relative accuracy in the field of health professions education found poor correlations between self-assessment and actual performance (Davis et al. 2006). Further, findings by Davis et al. (2006) indicated that physicians who were the least skilled were the most confident.

In an extensive meta-analysis in the domain of law, engineering, counseling, social sciences, and medicine by Falchikov and Boud (1989), correlations between self-assessments and external assessments of performance ranged from no accuracy at all to very high accuracy. In a similar vein, the meta-analysis in the health professions domain by Gordon (1991) showed that relative accuracy ranged from very inaccurate self-assessments to relatively high self-assessment accuracy. A more recent meta-analysis with medical students (Blanch-Hartigan 2011) showed moderate relations between self-assessment and performance. Mabe and West (1982) and Freund and Kasten (2012) conducted meta-analyses on the relation between self-estimated and psychometrically assessed cognitive ability. Both studies concluded that self-estimations were moderately accurate. The few studies showing high self-assessment accuracy may imply that people can have insight into their performance outcomes. However, most studies report low to moderate correlations. In sum, self-assessment accuracy is often poor but also varies as an effect of task conditions and domains.

## Explaining Poor Self-Assessment Accuracy

There are multiple explanations for people's limited self-assessment accuracy. Below, three explanations are further discussed as reasons for low self-assessment accuracy: (a) persons' lack of experiences with learning and self-assessment tasks, (b) a lack of metacognitive insight, and (c) poor design of self-assessment tasks and standards.

Experience with self-assessment affects its accuracy. For instance, medical students' self-assessments were more accurate later in medical school, as opposed to when starting with the education (Blanch-Hartigan 2011). The meta-analysis by Zell

and Krizan (2014) confirmed that the accuracy of self-perceptions improves as experience with the task grows. Moreover, they showed that self-assessments are more accurate for low-complexity than for medium-complexity and high-complexity tasks. A study by Macdonald et al. (2003) extended findings that practice improves self-assessment from the conceptual knowledge domain to the technical skill learning domain. Medical students were trained to perform simulation operation training; repeated task experience led to improvement in self-assessment accuracy and error recognition. Over time, learners' estimates of performance better mirrored their actual learning curves. Presumably, with experience, students become more familiar with the assessment types, and these both accelerate task performance and the ability to judge performance (Boud et al. 2013). Further, accuracy of self-assessment varies according to performance; Boud et al. (2015) showed that weaker students overestimated, whereas high ability students underestimated outcomes. Additionally, students in advanced courses were more likely to underestimate, whereas students in introductory courses overestimated their learning. This indicates that, in addition to experience, a person's knowledge and skills affect the accuracy of people's estimations of their performance. A lack of task skills and task experience makes it very challenging to self-assess.

A second explanation for poor self-assessment accuracy and people's inability to recognize their errors is a lack of metacognitive insight (Ehrlinger and Dunning 2003). The cue-utilization framework (Brunswik 1956; Koriat 1997) has been used to explain poor metacognition. People do not have direct access to the processes that influence their learning. Therefore, they cannot base monitoring judgments on direct insights into performance (Benjamin and Bjork 1996). Instead, metacognitive judgments are inferential, and self-assessment is based on a variety of cues that come to mind when judging performance (Koriat 1997). In order to self-assess, a person needs to rely on cues from a variety of sources, such as prior experience with similar tasks, familiarity with the domain, self-efficacy beliefs, the ease of information processing, and feedback (Freund and Kasten 2012; Rawson and Dunlosky 2002).

Cues have varying degrees of validity in predicting actual performance; accurate self-assessment is guaranteed when judgments are based on cues that have perfect validity (Benjamin and Bjork 1996). However, when self-assessment judgments are based on superficial, rather than valid cues, self-assessment may be poor. Then, subsequent self-regulation cannot be adaptive either. De Bruin et al. (2017) addressed cue utilization in the clinical reasoning domain. Medical experts were shown to use their own slowing down during clinical practice as a cue for processing difficulty. When they monitor difficulties with information processing, they interpret this as a sign to adjust their behavior and a need to search for additional information. However, adaptive utilization of valid cues seems especially difficult for novices, because the slowing down cues are not yet predictive of their performance. Particularly, self-assessments of inexperienced learners may be inaccurate because they have difficulties identifying valid cues.

Effective cue-utilization is especially challenging in the complex workplace, where people need to use and weigh multiple cues to arrive at accurate judgments. Individuals typically believe that they score higher than the average person in their

group, even though this is statistically unlikely, the so-called better than average effect (Guenther and Alicke 2010). Instead of using valid indices of performance, persons may base judgments on cues related to learning motivation and affect, such as one's desire to have flattering self-beliefs and to do better than other trainees (Freund and Kasten 2012; Sitzmann et al. 2010; Zell and Krizan 2014). A meta-analysis on self-assessment in the job-related training context (Sitzmann et al. 2010) showed that self-assessments were more strongly linked to affective evaluation outcomes indicating motivation and satisfaction, rather than cognitive learning outcomes. Even after repeated practice and feedback, self-assessments remained more closely related to motivational factors than to cognitive learning. Interestingly, people seem better able to identify other persons' judgmental biases and invalid cue use than their own biased thinking (Pronin 2008). They often do not realize that their own self-monitoring may be a result of motivational and contextual factors that are not predictive of actual learning (Zell and Krizan 2014).

Furthermore, poor self-assessment could be due to methodological reasons. Self-assessment accuracy may be constrained by the design of the self-assessment task and the measurement items. Self-assessment is typically inaccurate when global measures of perceived ability are used, which are made about a large grain size of the performance domain. For instance, a global judgment could be made by giving oneself a grade. However, when making global judgments, the learner cannot take differences in performance in sub-domains into account. Specific self-perceptions are more accurate than global judgments, because they are better matched to the performance domain and standards (Dunlosky et al. 2005; Zell and Krizan 2014). However, in some domains, matching self-assessment items to performance standards may be easier than in other domains, and this affects the accuracy of self-assessment. For instance, Blanch-Hartigan (2011) showed that medical students overestimated themselves more when self-assessing communication skills than when self-assessing knowledge-based performance. Further, self-assessment was more accurate for knowledge test than when practical skills were tested with clinical examination tests and simulation patient encounters. Moreover, the timing of the self-assessment activity influences accuracy. Self-assessment accuracy is typically lower when students judge performance before or during test completion than after completing tests (Blanch-Hartigan 2011). Additionally, information about the reference group affects self-assessment accuracy. Typically, people's judgments reflect how they think their own abilities compared with abilities of other people (Freund and Kasten 2012). When people are not informed about the reference group they should compare themselves to, validity of self-assessment will be limited.

In the workplace, learning standards and competency frameworks may not always match the reality (Embo et al. 2015). This results not only in unreliable self-assessment but also in unreliable performance measures. Although standardized knowledge tests have measurement errors and unreliability, test reliability is even lower in the workplace learning domain, where learning standards are individualized and learners have to develop competencies in ill-structured and unpredictable domains (Zell and Krizan 2014). When actual performance is measured with extensive measurement error and unreliability, self-assessment can never be highly accurate (Freund and Kasten 2012). In some workplace domains, matching self-

assessments of performance to actual professional development outcomes may not even be possible at all. To support learners in complex workplace domains to develop their self-monitoring skills, there may be a need to encourage reflection on professional development, rather than (only) focusing on self-assessment accuracy.

## Measuring Self-Reflection

Self-monitoring activities are considered most useful when these are used as a part of formative, rather than summative evaluation (Sitzmann et al. 2010). The formative assessment agenda had major influence on the change from a focus on self-assessment to a focus on reflection (Eva and Regehr 2005). Self-reflection refers to self-monitoring learning attitudes and competency development. Although measures of self-reflection may not be easily comparable to measures of performance, a person's judgments about the quality of the learning process may be very helpful to identify learning opportunities (Eva and Regehr 2005). Reflection tools can support students to direct their attention on the observation of their learning and the regulation of learning actions (Fabríz et al. 2014). Open reflection tools suggest persons reflect on their progress without giving strong directions. When using semi-structured tools, learners also give open-ended answers, but they respond to specific reflection questions, guidelines, or prompts. Several studies report the use of learning diaries, learning journals, and portfolios as open or semi-structured tools for self-monitoring (Fabríz et al. 2014; Driessen et al. 2005; Gamrat et al. 2014). These tools can focus the learner on the content (for instance, by prompting them to reflect on what they have learned) and on learning behavior (by asking them to reflect on how they learned). In a study using learning journals for teachers-in-training (Gamrat et al. 2014), the use of a learning journal supported decision-making in relation to professional development. Reflections on learning content and learning assessment supported teachers-in-training to identify and manage their learning goals and to select learning activities and assessment types that aligned with these goals. This way, reflection on learning supported acquisition of specific individual expertise that individuals considered necessary for their personal development plan.

When using structured reflection tools, people usually give quantitative responses on a Likert scale. For structured reflection, questionnaires have been designed that ask learners to reflect on the learning process, outcomes, and motivational factors such as self-efficacy. Examples of structured reflection tools that could be used in the workplace are, for instance, the questionnaire addressing goal orientations by Brett and Van de Walle (1999), engagement in reflection (Kember et al. 2000), and self-directedness in learning (Raemdonck et al. 2008).

## Connecting Self-Reflection to Professional Development

Although self-reflection measures support self-monitoring and self-regulation, these measures should not be used to calculate monitoring accuracy. In contrast to

self-assessment measures, reflection measures cannot be directly compared to learning outcomes. Further, a study by Van Loon and Van de Wiel (2015) showed that structured reflection outcomes did not correlate with item-specific self-assessment accuracy. However, reflective self-reports are extremely valuable, because they can give detailed insights into a learner's self-identified strengths and weaknesses, motivation, attributions, and learning plans. Even though self-reflection accuracy cannot be quantified, when reflections are used as a basis for a discussion between two (or more) persons about experiences, objective external feedback does not seem to be a necessity to acquire perceptions of progress (Frith 2012). Sharing subjective experiences about professional development with others may be sufficient to acquire reliable insights into the learning process. Therefore, work supervisors and colleagues should use a person's reflections to give guidance and formative feedback.

Panadero et al. (2016b) investigated effects of reflection activities on self-regulated learning; to reflect, learners used semi-structured diaries. They had to observe and document their thoughts, feelings, and actions regarding learning goal attainment. Self-reflections appeared to be related to the individual self-regulated learning cycle, and reflection activities improved learning behavior. The learning diaries supported reflection upon what went well and what could be improved. These reflections helped learners to set goals and plan actions in the forethought phase. Moreover, engaging in reflection with the use of diaries benefitted awareness of the components and the importance of effective self-regulated learning (Panadero et al. 2016b; Schmitz and Wiese 2006). Moreover, a study by Gijbels et al. (2010) shows that reflection on learning is related to actual self-regulated learning in the workplace. Students in vocational education filled out questionnaires with which they reflected on their self-directed learning orientations; specifically, they reflected on their active approach to learning, their intentions to take learning initiative, and the way they tried to overcome barriers. Personal reflections on self-directed learning appeared to predict actual work-related learning. This may imply that the content of personal reflections could be valuable to identify areas for supervision.

However, the study by Gijbels et al. (2010) also indicated that average students in the vocational education field do not have much autonomy and job control with regard to selection and execution of work task. They often have little opportunity to make decisions about the nature and the amount of work they complete within a certain period. For adaptive learning, persons need to have intrinsic motivation; without autonomy to define learning goals, plan learning steps, and try out strategies, people are most likely not motivated to reflect on professional development (Ryan and Deci 2017). That is, it makes no sense to ask learners to engage in self-reflection when there are no opportunities to use reflection output for self-regulated learning.

---

## **Fostering Self-Monitoring and Self-Regulation of Workplace Learning**

It is clear that workplace learners should self-monitor competency development, because it affects self-regulation and professional learning (Eva and Regehr 2005). When reflecting on learning attitudes, persons who indicated the willingness to

self-direct learning showed better performance in the workplace-learning context (Gijbels et al. 2010). People who are able to accurately self-assess learning improve over time, whereas learners who inaccurately self-assess may not improve at all (Boud et al. 2013). However, self-monitoring opportunities are often not embedded in workplace training. Therefore, people only have limited opportunity to compare their self-monitoring with actual outcomes and to use personal judgments to seek feedback. To support self-monitoring, monitoring activities need to be implemented as a fundamental part of learning. Supervisors will need to talk to learners about the effects of self-monitoring on self-regulation, and even more importantly, they also need to listen to trainees when they talk about their own metacognition. Studies on implementation of metacognition in the learning contexts show that students need prolonged training to practice self-monitoring. Further, learners need feedback to focus attention on valid cues that are indicative of actual competency development. Importantly, to stay motivated to reflect on learning, people need to be informed about the usefulness of metacognitive activities and obtain autonomy to design individual learning trajectories.

### **Training and Practice Benefits Self-Monitoring**

As with any form of expertise, when learning to self-monitor, a person needs continuing opportunities for development, practice, and feedback (Boud et al. 2015). Through practice, persons can learn to judge whether performance is sufficient or whether they need to take further actions to improve. Not only for self-assessment but also when using a more qualitative self-reflection approach, people should be trained on how they can self-monitor. Through experience and repeated support, learners can acquire insight into the learning standards and competencies they are expected to develop, compare these to their own progress, and learn how to take action to close the gap between the two (Sadler 1989; Sitzmann et al. 2010). Importantly, students need support from supervisors, to develop the ability to increasingly engage in more independent self-monitoring. For example, educators could ask people to practice elaborating on their thoughts and feelings before and after learning. Reflection assignments should not only address task performance; learners should also be taught to reflect on learning beliefs and self-efficacy. Rather than reflecting on overall aptitude, workplace learners should be instructed to reflect on their competency development and learning affect in relation to specific performance events (Zimmerman 2008). For instance, they could list challenging situations and reflect on how they dealt with these. To visualize progress, people could be instructed to plot and interpret changes in skill development and learning motivation over time. Although actual, objective change in learning may be hard to depict, plotting change over time may give some quantifiable indications about learners' feelings of progress and abilities.

When training self-assessment and self-reflection, it is important to embed these activities in the learning context, to provide authentic self-monitoring experiences (Sadler 1989). Schmitz and Wiese (2006) connected a reflection training with the learning context; engineering students received a 5-week training to improve

monitoring and self-regulation. They were instructed to use semi-structured diaries for reflection. In the forethought phase, they had to describe their learning goals and planning, motivation, interests, and feelings of self-efficacy. After learning, they reflected on how much time was spent effectively and to what extent they reached the learning standards and their own goals. During the training, they learned how to set learning goals, they practiced planning and time management, and they received training about how to motivate themselves to learn by searching for a supportive environment and by setting personal rewards. The training also focused on concentration and relaxation. After 5 weeks of reflection training, learners showed a higher level of self-efficacy, learning effort, attention, concentration, and motivation.

### **Feedback to Improve Monitoring**

Feedback is essential when learning how to self-monitor (Boud et al. 2015). People remain largely unaware of biases, and they need feedback to learn to recognize these. Feedback can help them to switch to valid cues for judgments, instead of using intuitively appealing non-predictive cues. Supervisors and colleagues are an important source of external feedback; they can support learners to base judgments on valid cues. Self-assessment accuracy improves when the tasks become more familiar, because people acquire more insight into which cues are diagnostic of performance. Self-assessment is particularly challenging when individuals lack task experience, and therefore, feedback is especially needed when completing unfamiliar tasks (Ehrlinger et al. 2008). When working on new tasks, co-workers and supervisors should give feedback on the match between learners' judgments and actual performance. Importantly, feedback should not only address limitations in task performance and self-assessment accuracy but also focus on improvements over time.

In the workplace, feedback on perceived discrepancies between self-monitoring judgments and actual competency development is probably even more important than feedback on performance itself. When persons hold misperceptions, they do not know that there is a need to adjust learning. Sitzmann et al. (2010) showed that self-assessment accuracy in the workplace was highest for learners who had chances to practice self-assessment and received feedback on their self-assessment accuracy. Self-assessments were less accurate for individuals who rated their performance multiple times without receiving feedback. Through repeated self-assessment and feedback, people learned about reasons for their failures and acquire familiarity with strategies they can use to improve learning.

Although the benefits of feedback are well-known (Hattie and Timperley 2007), in the complex workplace practice, feedback may be difficult to obtain (Zell and Krizan 2014). It may be especially challenging to self-monitor and receive feedback on interpersonal skills, communication skills, and professionalism (Davis et al. 2006). A part of a learner's responsibility in the workplace should be to adequately seek help and feedback. To support feedback seeking, learners could be instructed to take the initiative to regularly reflect on their progress in relation to competency

standards and to base their feedback seeking on their reflections. By combining daily reflections with feedback on competencies, learners become better able to evaluate performance and to diagnose their learning needs over time (Embo et al. 2015). However, feedback may not always be considered reliable and objective by the learner, because evaluation of learning standards and outcomes may be unclear. In order to implement feedback in learning, persons need to trust and believe in the feedback (Rich et al. 2017). To make feedback on competency development more objective and trustworthy, it may be beneficial to include multiple raters in the judgment process. In complex learning domains, multisource 360° feedback may be necessary (Davis et al. 2006). Individuals' exchange of authentic professional and personal experience can only be guaranteed when feedback is not expected to be humiliating (Van der Zwet et al. 2014). In some cases, it may be beneficial to engage in peer feedback sessions with co-workers or to exchange feedback with peers who work in different but comparable workplaces. This may ensure learners that feedback is given with the aim to support workplace learning, rather than to express authority and to judge learning. Moreover, learning from feedback may benefit from an intraindividual, as opposed to interindividual comparison process. That is, instead of comparing persons with others, self-monitoring and self-regulation may benefit from comparing one's own performances over time (Boud et al. 2013). For instance, curves could be used that show an individual's longitudinal competency development from the own and from other raters' perspectives.

Interestingly, in addition to using external feedback for improved self-monitoring, learners can also be trained to self-generate feedback (Griffin et al. 2008). Generating internal task feedback helps learners to activate valid cues. Learning happens most when a person is struggling with the material, as long as this is struggling while thinking about and dealing with task challenges, rather than struggling to think and to concentrate (Bjork and Bjork 2011). To improve this "struggling while thinking," learners can use explanatory questioning techniques, such as elaborative interrogation and self-explanation, to acquire insights into their task progress (Roediger and Pyc 2012). During elaborative interrogation, a person asks him-/herself "why" questions, and when engaging in self-explanation, a person tries to explain ideas to oneself when working on tasks. Further, Klein (2007) introduced the premortem technique with the aim to support accurate self-monitoring when dealing with complex decisions. The premortem technique is the counterpart of the postmortem, which refers to a session after a medical failure. During postmortem, the reasons for the failure are discussed with the aim to prevent this in future situations. The premortem is applied before decisions are made and potential errors occur; an individual or a team has to imagine reasons why a project could possibly fail. This way, people do not only need to consider how to plan their projects but also address reasons for potential failures. Hence, they become aware of potential errors and pitfalls, and this may improve planning and self-monitoring. Such elaborative generation strategies make self-monitoring more accurate and enhance self-regulation and performance. However, for most learners in the workplace, using these techniques may not seem attractive because it increases the learning effort and it slows them down. Therefore, supervisors need to inform them about the benefits of

these strategies and provide sufficient time and opportunities to implement exploratory questioning or premortem techniques when completing work assignments.

## **Benefitting Self-Monitoring with Structure and Standards**

The relation between self-monitoring and performance depends extensively on the design of the items that are used to measure monitoring and performance (Zell and Krizan 2014). Using clear self-assessment questions that ask learners to match their judgment to specific performance standards leads to highest accuracy (Dunlosky et al. 2005; Zell and Krizan 2014). When measures of self-assessment and performance are similar, correlations between self-assessment and actual learning are stronger than when measures are less similar (Sitzmann et al. 2010). To improve accuracy, Boud and Soler (2016) recommend to break down self-assessment activities and corresponding assessment tasks into different sub-tasks and sub-domains. To make outcome measures and outcome expectancies transparent, students should be involved in the identification of standards and criteria for success (Boud and Soler 2016). Besides using specific measures for self-assessment and performance, educators should also be aware of the self-assessment timing effects. Preferably, learners should have the opportunity to self-assess after completing the work-related tasks; engaging with the task informs learners about the specific task demands and their progress (Ackerman and Wolman 2007).

Tools such as checklists, questionnaires, and diaries could be used to give structure to reflection activities. Checklists can be designed according to individual learning goals. This way, learners can be supported to self-monitor which tasks have been completed and which tasks are yet open to complete and whether specific competencies have been reached (Gawande 2010). To support learners to self-evaluate the affective and motivational aspects of workplace-based learning, supervisors could provide students with validated questionnaires that assist them to reflect on their motivation and learning initiatives. Further, several studies showed that completing open or semi-structured learning diaries about motivation and learning strategies stimulates self-monitoring (Panadero et al. 2016b). Panadero et al. (2016b) endorse the use of reflection diaries before engaging in learning actions during the forethought phase and after completing learning tasks in the reflection phase. They recommend not to ask learners to complete these when working on actual learning tasks, because cognitive load may then be too high to solve problems and complete a diary simultaneously.

Moreover, to benefit from reflection, learners need to have insight into the learning goals and the competencies they are expected to develop (Harden 2007). Clear communication is necessary to clarify competencies and standards that mirror the knowledge, skills, and attitudes people need to acquire through training (Embo et al. 2015). Clarification of competencies helps learners and their supervisors to monitor progression; a list of competencies can contain both specific and more generic competencies. A first, important step in the supervision process is to design a framework of feasible, realistic competencies that match the workplace reality.

Learners should collaborate with their supervisors and co-workers to develop, fine-tune, and discuss the competency standards and the way these are interpreted. Embo et al. (2015) recommend that only a limited number of relevant competencies should be used for a reflection activity, in order to give sufficient clarity and opportunity for in-depth reflection. In the forethought phase, learners can formulate learning goals in relation to selected competencies. In the reflection phase, learners can address how and to what extent they progress in relation to competency standards. It is important that reflections are repeatedly discussed between learners and their supervisors and/or co-workers, because feedback helps to fine-tune reflections and to set goals for further learning.

### **Providing Autonomy for Self-Regulation**

Asking students to self-monitor can only make sense when students know about the benefits of monitoring and when they have the power to self-regulate their learning. Fabriz et al. (2014) showed that the use of learning diaries did not lead to any improvements in strategy use and self-efficacy when learners were not informed how their self-regulation could benefit from their monitoring activities. Without this information and training, keeping diaries even decreased learning motivation. However, when learners were informed about the benefits of self-monitoring, keeping learning diaries increased motivation. This implies that learners need to acquire insight why and how engaging in self-monitoring can support workplace learning. When individuals do not believe in the benefits, it is unlikely that they will voluntarily self-monitor learning progress. Through gaining understanding of how learning can be self-regulated, people can take greater responsibility for their professional learning and their competency development. Particularly in the workplace, people should learn that they are themselves responsible for their monitoring and regulation of learning, because after completing training, there will be no supervisors who instruct them to evaluate their progress and outcomes (Boud and Soler 2016; Fastré et al. 2013). When training people to become self-regulated learners, first of all, they need to trust that learning is under their own control. Cleary and Zimmerman (2004) refer to this as empowerment, a process by which learners gain autonomy over their learning. Persons need to acquire beliefs that their success is largely dependent on their ability to effectively use and adjust learning strategies. When learners acquire a sense of agency and control, work motivation and perceptions of self-efficacy increase.

However, although the urgency of empowerment and self-control is clear in theory, the fit between the psychological needs for and actual educational affordances may be limited in the workplace. Trainees may not be provided with sufficient opportunities for autonomy and may lack the support to grow in independence. People often feel evaluative pressure and control (through punishment but also through rewards) from their supervisors and co-workers. When people experience a lack of control, they may not be motivated to self-monitor their learning progress, and this then hinders flexible problem-solving, strategy use, and

performance (Ryan and Deci 2017). The degree to which workplace educators support a learner's autonomy is predictive of learning engagement and outcomes (Gagné and Deci 2005). Workplace learners acquire new skills best when they have the sense of control and when they can make their own decisions and have the opportunity to try out different ways of solving problems (Gijbels et al. 2010). Gamrat et al. (2014) provided teachers-in-training with the possibility to flexibly select their professional development activities and the way they were assessed. Through acquiring self-control over their learning journey, teachers-in-training felt supported and motivated to self-monitor their learning, to set individual learning goals, and to select learning activities to meet these goals. This indicates that reflection on learning is only beneficial when learners have sufficient autonomy to implement their self-insights into their self-regulated learning. Supervisors should therefore facilitate trainees to take control and to make choices.

---

## Conclusions

Self-monitoring is essential in all phases of self-regulated learning. In the forethought phase, self-monitoring affects planning and goal setting. During ongoing task completion, persons need to self-monitor to adjust their task performance. After engaging in work-related activities, people need to reflect on the behavioral and motivational aspects of learning to regulate their further learning activities.

Self-monitoring may often be challenging, and in most work environments, facilitation of self-monitoring activities is limited. Workplace learning is often complex, because learners have individual learning trajectories, because competencies and desired outcomes are often not clearly defined, and because learners have to self-organize their competency development and combine information from different sources for professional learning. However, considering the need for self-monitoring in order to self-regulate learning, workplace education should not only focus on teaching "what" to learn but also focus on teaching "how" to learn. Training self-regulated learning competence and lifelong learning should be a priority.

To benefit from both quantitative and qualitative self-monitoring activities, supervisors and educators should inform learners about the formats and tools they can use to self-assess and self-reflect. When training self-monitoring in the workplace, learners need repeated experience and practice with self-monitoring activities. Monitoring needs to be structured according to clear and specific learning standards, comparison groups, and competency frameworks. When aiming for accurate self-monitoring, people should be recommended to self-assess their past performance, rather than future performance. The importance of feedback should not be underestimated; ideally, feedback should give individuals a sense of their improvements in performance and in self-monitoring over time. Importantly, self-monitoring activities have to be integrated within the scope of self-regulated learning. People can only be motivated to self-monitor workplace-based learning when they believe in the benefits and when they accept the responsibility and acquire the autonomy to self-regulate their learning.

Although several studies investigated self-assessment accuracy when individuals completed tests for knowledge and conceptual understanding, not much research addressed self-monitoring in the workplace. An unknown area in research is how self-assessment and self-reflection tasks and tools can be most beneficial when learners need to develop competences in complex and unpredictable work domains. Self-monitoring clearly has strong implications for the learning process and the learning outcomes. Therefore, understanding how people use their self-monitoring of professional development to make and adapt strategies and decisions should be a major priority for future investigation.

**Acknowledgments** The author would like to thank Kevin Oehler and Niamh Oeri for their insightful comments and helpful discussions about the content of this chapter.

## Abstract

During workplace-based learning, e.g., clinical or during an internship, supervisors' quality of feedback and assessment is crucial for trainees' expertise development. Electronic portfolios (ePortfolios) are often used as tools for longitudinal assessment at the workplace. So far, ePortfolios have not realized their full potential, since they are often not well tailored to the workplace and trainees' needs. Potential data about trainees' behavior at the workplace is generally underused, and the management of the data is complex. It is expected that ePortfolios enhanced with learning analytics may serve as means to improve

S. McGrath et al. (eds.), *Handbook of Vocational Education and Training*,  
[https://doi.org/10.1007/978-3-319-94532-3\\_89](https://doi.org/10.1007/978-3-319-94532-3_89)

the quality of feedback and assessment regarding trainees' progress and development. This chapter addresses this by outlining an approach that is applied in a European 7th framework project ([www.project-WatchMe.eu](http://www.project-WatchMe.eu)).

This chapter shows the development of an ePortfolio environment enhanced with learning analytics, to be used at the workplace in medical, veterinary, and teacher education. Evaluation took place by means of a quasi-experimental design regarding the impact of this environment on trainees' motivation, their assessment experience, and their use. Data gathered in four institutes for medical, veterinary, and teacher education ( $n = 217$ ) showed that trainees were highly motivated for their internships and positively evaluated the perceived feedback. The use of learning analytics features varied. In general visual feedback by means of a timeline of trainees' progress was mostly used, while trainees barely used the features with written feedback. It is concluded that the promise of learning analytics connected to ePortfolios can only be fulfilled when developed and implemented through the eyes of the users.

## Introduction

Work in professions is increasingly driven by reflection, feedback, and collaboration with a decline in the number of desk workers and a rise in flexi-workers who tend to work at multiple locations. This urges the need for learning data, feedback, and visualizations to be made accessible anywhere at any time through mobile devices. Furthermore, there is an augmented need for accountability and certification in most professions, which has led to a compelling need for valid authentic assessments. Recent growth in the use of electronic portfolio environments (ePortfolios) and the increasing use of mobile devices (e.g., tablets and smartphones) at the workplace have further stimulated the demand for an advanced ePortfolio environment based on learning analytics. ePortfolios are purposeful digital collections of a learner's work, including their reflections, that provide evidence for their performance and progress (Butler 2006; Rezgui et al. 2014). They demand a learner's reflection on personal data and progress within the social cultural work context of the learner (Butler 2006; Dysth and Engelsen 2011). Learning analytics is defined as the measurement, collection, analysis, and reporting of data about learners and their contexts, for the purpose of understanding and optimizing learning (Elias 2011). Learning analytics can add to ePortfolios the modeling of learners' expertise development in order to provide automated feedback, intervene during learning processes (e.g., by sending alerts), recommend tutoring, and so on.

Meanwhile, learning in professions is shifting from an educational setting to a workplace setting, both within and outside schools (Billet 2004). Learning at the workplace is domain specific and includes an adaptation to constantly changing task demands (Feltovich et al. 2006). A concept that is important for understanding and

explaining the development of expertise in professions is deliberate practice. Core assumptions of deliberate practice are that expert performance is being acquired gradually and that effective improvement of performance requires the opportunity to find suitable training tasks that the performer can master sequentially (Ericsson et al. 2006). Key to deliberate practice is frequent feedback based on adequate analyses and evaluations of how tasks at the workplace are fulfilled. Although the concept of deliberate practice is less applicable to complex professional contexts without standardized tasks, such as teaching (Ericsson and Pool 2016), it emphasizes the importance of feedback and assessment on activities of (becoming) professionals as the most powerful sources for learning at the workplace.

Workplace-based feedback and assessment demands valid ways of dealing with unique (personal) multimodal data from a variety of sources gathered at unstandardized work contexts, over a longer timespan. Effective feedback provides learners with (1) insight into obtained performances compared to an expected norm, (2) the possibility to evaluate and monitor the own process, and (3) suggestions to bridge the gap between the expected norm and the actual performance (Sadler 2010). Feedback can support learners' development when it gives information about the goals the learners strive for, the progress that they made toward these goals, and the actions and practices to be undertaken for further improvement (Hattie and Timperley 2007). Essentially, this demands a process of drawing inferences about learners' performance and progress and feed this back, based on multisource datapoints in time (Toulmin 2003; Kane 1992).

To this end, since the 1990s ePortfolios are often used as tools to collect data and evidence about learners' development at the workplace. They include authentic products and performances, which are often seen as prerequisite for a valid assessment (Eynon et al. 2014; Peacock et al. 2011). ePortfolios can provide a supervisor with a timely overview, regardless of one's location, of learners' work over a larger timespan. They can serve as a reflective "log" of the learner including a repository of evidence demonstrating personal progress and performance (Van der Schaaf et al. 2008). ePortfolios can be used for formative goals, e.g., in terms of a developmental portfolio or reflective portfolio, or for summative purposes, e.g., a showcase portfolio. Formative assessment goals focus on providing input to a learner's further development. Summative purposes strive for high-stake consequences, such as graduation or merit pay. To fulfill ePortfolios' promises, a reflective pedagogy is needed to stimulate learners to compose a portfolio and to use it in conversations with peers and supervisors (Barbera 2009; Hamp-Lyons and Condon 2000; Van der Schaaf et al. 2012). The implementation of ePortfolios is often challenging, due to data management and implementation problems (Van Schaik et al. 2013). Consequently, potential data about learners' development in the workplace is often underused.

This chapter presents examples and experiences from a European project that aimed to improve the efficiency and quality of workplace-based feedback and assessment by means of learning analytics that is added to an existing ePortfolio environment. The project focused on the professions of medicine, veterinary medicine, and teaching, because in these domains, workplace-based learning has a central role.

## Background: ePortfolios and Learning Analytics

From a technical perspective, ePortfolios include (i) the storage of learners' artifacts or evidence (i.e., their asset repository), (ii) a presentation space where the learner can present him or herself in relation to the learning goals needed to be achieved and based on artifacts selected from the asset repository, and (iii) a feedback and reflection space where the learner and others can comment on the development or work delivered by the learner. Most ePortfolio environments include tools and services on top of this basic system, for instance, providing visualizations of a learners' progress, planning tools, or tools to include or add files as an input to other external systems (e.g., student information management systems). An ePortfolio's evidence can, for instance, include artifacts (regular products of a learner's work), reproductions (registrations of a learner's regular work, captured on behalf of the portfolio), attestations (records of a work made by others), or productions (documents prepared specially for the portfolio) (Barrett 1998; Van der Schaaf et al. 2008). An extensive amount of entrepreneurial ventures provides ePortfolio environments, stand alone or web-based. Besides, many organizations use existing digital systems that include tools with the potential for learners to capture and present evidence about their expertise development and to build an ePortfolio from that. Some examples are existing functionalities in learning management systems, web tools, tools in Blackboard, Wiki portal, PebblePad, OneNote, Microsoft Office, WordPress, and Webfolio.

Although the use of ePortfolios is widespread, the effects of ePortfolios on learners' performance are unclear and depend on how (well) the ePortfolio is used (Bryant and Chittum 2013; Eynon et al. 2014; Kennelly et al. 2016). In the last years, there has been an increase in efforts and evidence that support the promise of ePortfolios to impact on student learning and student success. Examples are shown in the *Handbook of Research on ePortfolios* (Jafari and Kaufman 2006) and the *International Journal of ePortfolio*, as well as the launch of ePortfolios as the 11th High-Impact Practice by the Association of American Colleges and Universities. Recently, several initiatives to improve ePortfolio assessment show promising results for feedback and assessment in terms of flexibility, interaction, and immediacy (e.g., Warren Lee Najmi 2014; Doyle Garrett and Currie 2014).

An upcoming approach in ePortfolio research is to connect ePortfolio environments to learning analytics to improve the efficiency and quality of workplace-based feedback and assessment. A main aim of learning analytics is to provide timely and relevant feedback to learners regarding their progress and learning (Siemens and Gašević 2012). Connecting learning analytics to ePortfolios parallels the so-called content analytics: "Automated methods for examining, evaluating, indexing, filtering, recommending, and visualizing different forms of digital learning content, regardless of its producer (e.g., instructor, student) with the goal of understanding learning activities and improving educational practice and research" (Kovanović et al. 2015, p. 78). Content analytics implies a human process of capturing a learner's performance and products to produce data that can be used

to make inferences linked to evidence that support claims about learners' expertise. An example of an inference is that data about the learners' performances need to be linked to assessment and feedback scores. This demands the alignment of a statistical model with a substantive theory regarding expertise development in the profession.

Today's leading approach of assessments based on multimodal data is Mislevy's evidence-centered design (Mislevy et al. 2012). Inspired by Toulmin's (2003) argument-based approach, Mislevy provides an architecture for the (re)design of assessments consisting of the components: (1) domain model, (2) task model, (3) evidence model, and (4) presentation. Between the components an assembly phase is centered that connects all components. The components are strongly linked. Validity evidence is needed for each component, the links between the components, as well as for the whole design (evaluation). The *domain model* determines the constructs to be measured (e.g., trainees' expertise) and describes how the constructs develop. The *task model* involves the choice of essential tasks (e.g., developing a lesson plan) and the exact key environment (e.g., classroom) needed to get information about the constructs (e.g., trainees' expertise). It also contains specifications of the type of ePortfolio environment and learning analytics required, for example, characteristics of the stimulus material (type of artifacts to be gathered), given instructions, affordances, etc. The *evidence model* focuses on the question: What counts as evidence of learners' expertise and how do we interpret this evidence? In this phase, learners' scores and interaction with the ePortfolio environment are analyzed for psychometric quality (e.g., validity and reliability) and usability (e.g., mouse clicks, time spent on certain features in the display). This data can be used to determine whether and to what extent the existing scoring rules and features of the ePortfolio environment should be adjusted. The ePortfolio environment including learning analytics will be finalized in its *presentation* form. During the whole design process, a close cooperation between educational specialists and computer scientists is key in order to obtain effective solutions. Next, evaluation of the implemented prototype needs to be carried out. Below are the components that were followed in the project that is central in this chapter. The components can be seen as an example of how to connect learning analytics to an ePortfolio environment.

---

### **Component 1: Domain Modeling – Entrustable Professional Activities as Units of Professional Practice**

The development cycle starts by gathering the necessary information from educational theories, research, and specialists into the development of learners' expertise at the workplace. Learning at the workplace is domain specific. In the past decades, competency-based frameworks were designed to restore the quality and structure of workplace-based education. The frameworks generally related to a competency-based approach, describing the knowledge, skills, and attitudes of professionals,

needed to carry out specific professional tasks. Examples of such frameworks are the Canadian CanMEDS framework in medicine (Frank 2005), the VetPro competency framework for the veterinarian domain (Royal College of Veterinary Surgeons 2014), and national teaching standards in many European countries.

So far, the concept of competencies has met with mixed success. This is partly due to unclarity of the concept and its operationalization of the concept in long (analytical) lists of subcompetencies. Essentially it is important to bring the concept of competencies back to the primary process of work of professionals (Mulder 2014). According to this idea, in 2005, the concept of Entrustable Professional Activities (EPAs), i.e., tasks or responsibilities to be entrusted to the unsupervised execution by a trainee once sufficient specific competency is obtained, was designed to link competencies to performances in the medical workplace (Ten Cate 2005). The focus of EPAs is not only about the evaluation of a learner's ability but implies an estimation of how much supervision a learner needs at the workplace, i.e., how autonomously the learner can carry out professional tasks. A crucial underlying question regarding EPAs is: would I entrust this trainee unsupervised with this task (e.g., with my sick mother) or, in teacher education, with teaching my daughter or son? Examples of EPAs are conducting patient handovers; anesthetic management of a patient; conducting a normal, low-risk delivery; and interviewing adolescents regarding high-risk health behavior. Levels of entrustment that go with EPAs are: acting is not allowed, more observation is needed (*low level*), and up to acting is allowed "unsupervised": under clinical oversight, distant/backstage supervision, or post hoc report (*high level*) (Ten Cate 2005). Originated in medical education, EPAs have now been applied also in allied health programs (e.g., nursing, physician assistant education, midwifery) and other programs. In teacher education the concept of EPAs comes close to the concept of Core Practices, i.e., the most crucial professional activities of a teacher's daily work (Grossman et al. 2009). In this chapter we use the word Core Activities instead, to describe teachers' work in practice.

The internationally emerging concept of EPAs is fundamental to define the criteria for workplace-based feedback and assessment. In the project underlying this chapter, a series of Delphi studies and focus groups was carried out to collect data among experts and trainees for health professions education and for teacher education to develop ready-to-use EPAs and Core Activities (Wisman-Zwarter et al. 2016; Duijn et al. 2017; Jonker et al. 2015; Leijen et al. 2017). These were described in rubrics to be useful for assessment purposes. A rubric is a description of aspects of work with associated performance level descriptions (Dekker-Groen et al. 2012). The development of rubrics showed clear differences in context and methodology between different professions. For instance, the healthcare context (medical and veterinary) is characterized by a large variety of short encounters between trainees and various supervisors and other healthcare staff. The teacher education context shows both a longer encounter with single supervisors (e.g., when a lesson is observed) and some professional activities that take place outside any observation (e.g., preparation for lessons, developing assignments, assessing students' work).

## Component 2: Task Model – Information Sources to Provide Evidence for Entrustability

The task model regarding relevant information sources at the workplace that provide evidence for a trainee’s EPAs and Core Activities was developed. Those aim to serve the purpose of feedback to trainees and support for entrustment or proficiency decisions. Based on literature reviews and research among experts and stakeholders (Ten Cate et al. 2015; Leijen et al. 2017), the project shows that the most relevant information sources for trainees’ progression in workplaces can be grouped into prior credentials, knowledge and skills tests in workplace settings, short practice observations, longitudinal practice observations, case-based discussion, product evaluation, self-report, and post hoc result checks. The EPA approach and the way of finding correct information sources are both described in a feasible guide (see Ten Cate et al. (2015)).

---

## Component 3: Evidence Model – Development of a Student Model-Driven Probabilistic Approach

Third, the developed EPAs and selected information sources, combined with technical considerations such as scalability, formed the input for the development of student models based on a probabilistic approach (Van der Schaaf et al. 2017). Decisions on entrustability or proficiency levels for activities were made on the basis of a set of workplace-based assessments, including written narrative information, e.g., written feedback by a supervisor. The underlying student model module advices on the following criteria:

1. Estimation of entrustability: What is currently the most likely level of entrustability or proficiency for this trainee, given the information in the portfolio? The answer to this question can be provided in terms of a probability distribution regarding the levels of that EPA or Core Activity given the current evidence:

$$P(\text{level } x \text{ for EPA} \mid \text{current evidence in portfolio})$$

2. Selection of improvement feedback: What feedback should be selected to give to the trainee, given his EPA or task level?
3. Selection of topic of interest: What EPA or Core Activity is at the moment the most of interest for a trainee and supervisor?

The UnBBayes library and the OpeNER Natural Language Processing toolkit were used for this purpose. A Multi-entity Bayesian Network approach (MEBN) (Laskey 2008) allowed building flexible student models that learn from incoming evidence. These models can be individualized but at the same time can be dealt with on a large scale with many concurrent trainees using the online environment. The MEBNs include five modules, namely, the:

- (a) Evidence collector: this interprets the individual pieces of (possible written) evidence or information about a trainee and translates it into more abstract and general terms.
- (b) Core student model: translates the portfolio and assessment data into the progress state of the trainee.
- (c) Context modeler: this describes the actual context for a given trainee, including models for the actual supervisors, assessors, and peers.
- (d) Feedback producer: this module must decide on whether feedback is required and, if yes, which feedback.
- (e) Aggregator: this part should be able to produce numerical data that can be visualized, together with data directly derived from the portfolio database.

These different parts of the student model have to work in close cooperation. They all consist of logical and probabilistic rules. The evidence collector consists of rules that decide, for instance, to translate written feedback that contains words like “excellent” and “well done” into the observation that “this feedback was positive with 80% of chance.” The context modeler uses the context information from the portfolio (e.g., information about the workplace, the supervisors, the tasks) and translates it into an observation such as “the assessment was done in a difficult setting with 60% of chance.” The core student model translates above statements and additional information from the portfolio into statements such as “this trainee is probably (>70%) at the highest entrustability level for this EPA.” The feedback producer takes output from the core model, the feedback, and input from the user to produce a statement like “it is probably wise (chance of 90%) to point the trainee at this moment to his lacking procedural skills in this EPA.” Such a statement would then result in a message to the user, for instance, visualized in a graph. The last part of the model, the aggregator, consists of the probabilistic knowledge in all other parts of the model, combined with aggregated data from the ePortfolio system. It might contain rules on how to select the best data to represent for a given situation.

Before a student model can be developed, different questions have to be answered among the users. Examples of questions are: When does a trainee require feedback? How do trainees perceive feedback? What kind of diagnoses are used by a supervisor to determine that a trainee requires feedback and what type of information sources are useful to make entrustment decision about critical responsibilities for trainees? Trainee’s motivation, self-regulation, and previous assessments are important in this regard. What timing of feedback is useful?

---

#### **Component 4: Presentation Model – Development of Written and Visual Feedback**

The presentation model addresses the written and visual feedback to be provided to trainees as well as their supervisors. Again, taking the requirements and specification as a starting point, this phase will develop the just-in-time feedback and visualization modules ready for integration into the ePortfolio system. In the project, Bayesian

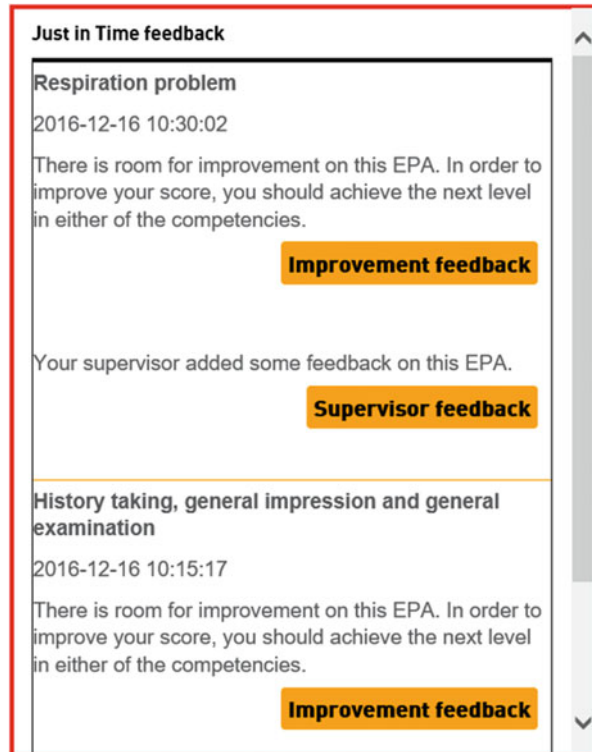

student models that are probabilistic in nature translate incoming ePortfolio data to represent progress states of the trainee in order to provide the most relevant feedback message to the trainee at any given moment. More specifically, the ePortfolio environment is enhanced with a Bayesian student model software module to monitor trainees' development on professional tasks, including a feedback module that delivers quantitative and written personalized feedback (denoted as "just-in-time" feedback, or JIT) and a visualization module that visualizes the feedback in terms of progress in the display (denoted as "visualization" or VIZ) (Van der Schaaf et al. 2017). The development of a feedback and visualization module demands input from the users on at least the following questions: What is feedback according to the users? What would trainees and supervisors like to see in the progress of learning of a trainee on the short and on the long term? What kind of feedback do they prefer, with what graphically display? With what frequency is feedback typically given and received? What are the time constraints for giving and receiving feedback? Where does the activity that must be assessed take place? Where is assessment performed? What kinds of devices are available when assessment is performed and received?

## Written Feedback

The developed system has a written feedback option that gives written personalized feedback to users. Besides the fact that supervisors or peers can write feedback in a trainee's portfolio, the project experimented with a natural language processor (NLP) that automatically identified and produced feedback messages to trainees or their supervisors based on incoming data. NLP tools aim to automatically interpret human language and their availability increased since the mid-1990s (Jarafsky and Martin 2008; McNamara et al. 2017). Based on the estimated performance scores in trainees' portfolios, *improvement feedback messages* are defined based on the rubrics that are underlying the system. For instance, when an estimated score of a trainee is near to entrustable level 2, the trainee will automatically get advice of actions that he or she can take to develop to level 3. This also counts for the other levels. The automatic feedback is defined beforehand by teams of domain experts that described many suggestions for what trainees can do to develop to a next level.

The student model module is used to decide which, if any, of the available improvement feedback messages should be selected from the underlying rubric for presentation to the trainee. The maximum probability is selected by the student model module for each EPA or Core Activity, and the trainee is given one improvement strategy for each plus supervisor feedback, if the supervisor gave any. See Fig. 1 for an example. The written feedback section on the dashboard in the ePortfolio environment is useful as it shows the available feedback of the most recent EPAs and Core Activities, aggregated in one overview. The trainee can quickly see what needs attention, and there is no need to scroll through the whole portfolio to get these insights.

**Fig. 1** Example of JIT feedback, regarding supervisor and improvement feedback displayed on the dashboard in a trainee's ePortfolio

Supervisors receive alerts, displayed as text messages. For each trainee who has at least one alert triggered, a button to navigate to his or her portfolio is available. Supervisors will see a list of trainees to whom they ought to pay special attention. From this, the supervisor can go to a trainee's portfolio to understand in detail the reasons behind the JIT message. Figure 2 shows an example.

## Visual Feedback

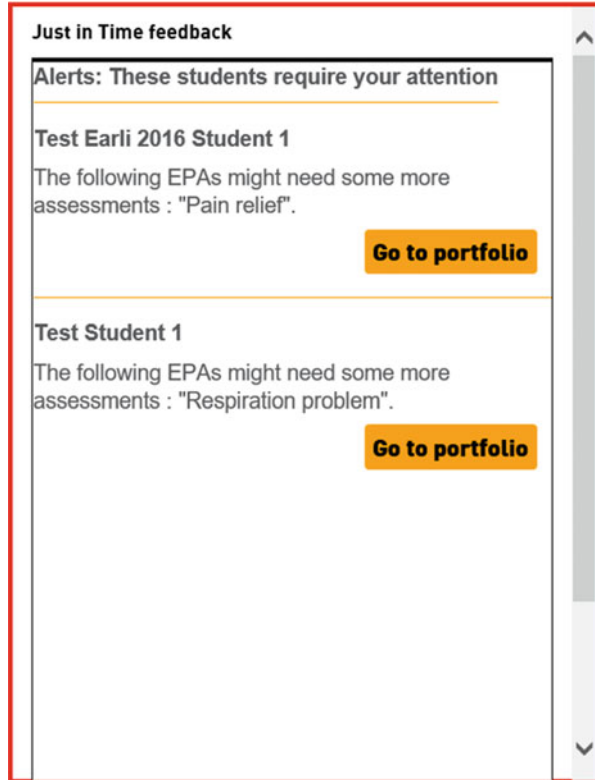

Trainees' progress is visualized in several ways, based on stakeholders' wishes in the project. Below some examples are shown.

*Timeline.* The timeline visualization provides an overview of a trainee's time-based development, using assessment forms as benchmarks (Fig. 3). It is interesting for users to track their development over time as they improve.

The dots in the timeline display the actual score for a trainee at a certain EPA or Core Activity. Inside the visualization, the user can:

- Hover on an assessment dot to see a summary of the assessment form in a pop-up box.
- Click on an assessment dot to see a written message from the assessment of that EPA or Core Activity in a pop-up box.

**Fig. 2** Example of written alerts to supervisors

- Go to a particular assessment form by clicking on the relevant button inside the pop-up box.
- Click on an EPA or Core Activity or on the legend explanation below to navigate to a timeline view of his or her development.
- Zoom in and out to see a longer or shorter period of time in the timeline, or use the dropdown list of preset time periods.
- A text analysis system that handles supervisor's written feedback, by recognition of positive, neutral, or negative elements and feedback this back "automatically" to trainees (see Fig. 4).

*Current performance.* The current performance visualization aimed to give the trainee an idea of where they are right now on their EPAs or Core Activities. It used the most recent scores for each EPA or Core Activity to show the user a contemporary picture of their performance. Current performance consists of two different visualizations presenting the same data: the spider diagram and the bar chart (see Fig. 5).

*Supervisor view.* Supervisors often supervise several trainees at a time. They will therefore benefit from an easy overview informing them, which trainees require attention. In order to fulfill this need, the project developed a specific

Fig. 3 Example of a timeline visualization

supervisor view in the shape of a timeline. The supervisor view comprises development curves for all the supervisor’s trainees in a single timeline visualization. In this visualization, a supervisor sees a timeline with graphs for each of their trainees. The graphs are generated by aggregating the trainees’ scores on different EPAs or Core Activities over time. This illustrates for the supervisor the approximated performance of each trainee (see Fig. 6).

### Component 5: Evaluation

The context of the evaluation concerned internships that trainees in the professions of medical, veterinary, and teacher education had to fulfill during a few weeks. It was assumed that ePortfolios enhanced with learning analytics functionalities contribute to motivation and feedback perception of trainees, because feedback can be provided more timely and personalized. A quasi-experimental study among 217 trainees of 4 institutes for professional education in 2 countries (the Netherlands and Estonia) was conducted to find out whether the ePortfolio with learning analytics impacted positively on trainees’ motivation for their internship, their assessment experience, and their use of the ePortfolio system. Data was collected at one institute for medical

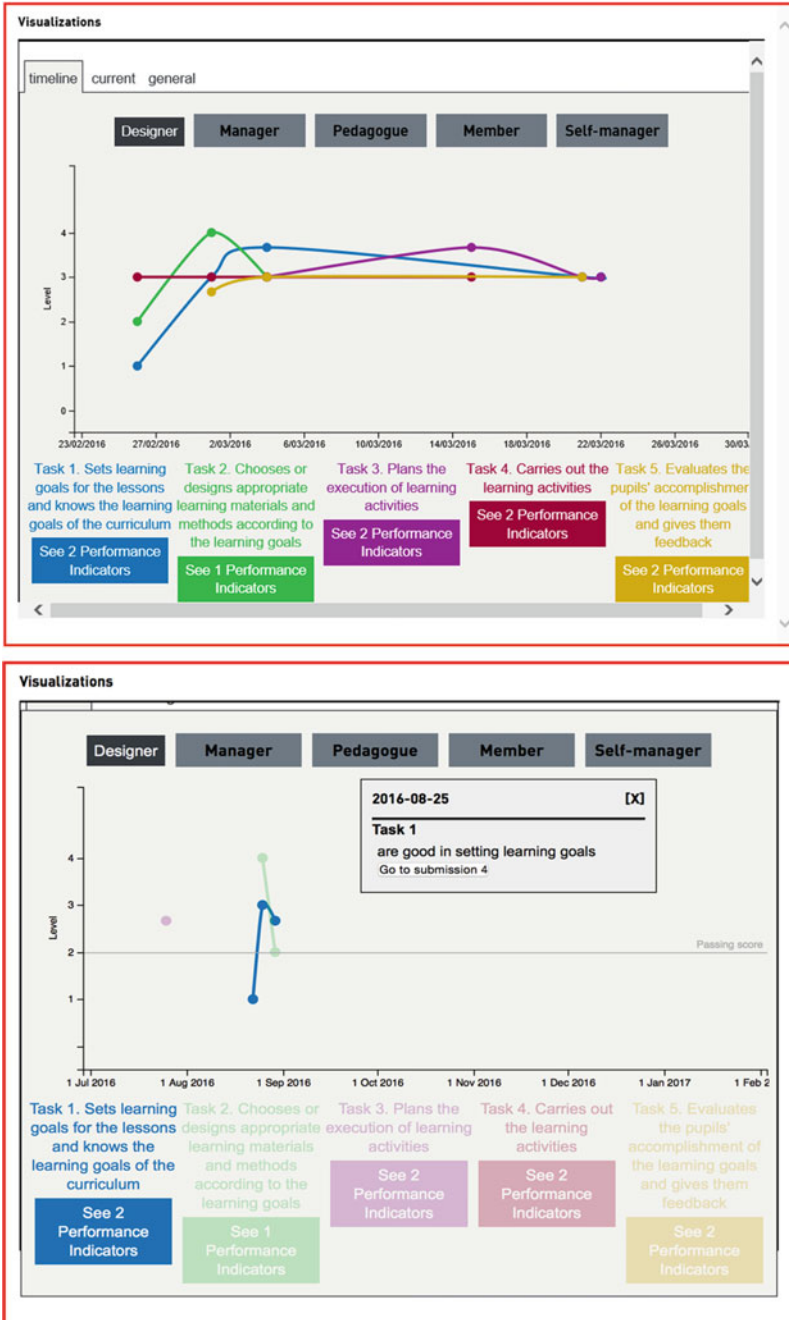

Fig. 4 Timeline with written feedback

Fig. 5 Interaction with the spider diagram (left panel) or bar chart (right panel) reveals written feedback

Fig. 6 Supervisor view

Table 1 Trainees’ use of written feedback (JIT) and visualizations (VIZ)

	n trainees that used the feature	Total n mouse clicks	Total time spent (minutes)
JIT, written feedback: improvement feedback, supervisor feedback	47	62	2037
VIZ, visualizations: timeline, performance, bar and spider chart	147	1949	8984

education (Utrecht, the Netherlands  $n = 56$ ), one institute from veterinary education (Utrecht, the Netherlands,  $n = 34$ ), and two institutes from teacher education (Utrecht, the Netherlands,  $n = 66$ ; Tartu, Estonia,  $n = 61$ ). Data was collected by questionnaires as well as by analyses of logs, i.e., amount of mouse clicks and time spent on written feedback (JIT) and visualization (VIZ) features in the ePortfolio environment. The questionnaires measured aspects of motivation (Ryan and Deci 2000) and assessment experience (Gibbs and Simpson 2003). Log files of trainees’ “mouse clicks” and time spent on the feedback features as presented in the former section were gathered to get insight into trainees’ use of the ePortfolio (Agudo-Peregrina Iglesias-Pradas conde-González and Hernández-García 2014).

Regarding trainees’ *motivation* for their internship, it turned out that trainees’ scores in the motivation questionnaire were rather high (at average around 3.5 on a 5-point scale) and that there were no differences between groups, indicating that their basic needs are mostly satisfied. This was also counted for trainees’ *assessment experience*.

In total mouse clicks and time spent on features were registered from 201 trainees (61 medical, 45 veterinary, 95 teacher education). Although the feature *timeline* had high numbers of visits and clicks, this did not count for the bar chart and spider chart. Almost none of the students clicked on this feature (Table 1).

In general, the students did not *use* the learning analytics modules as much as expected, or even if these features were used, students did not spend much time on looking at the represented content. Comparing the use of the two learning analytics

applications, i.e., the JIT with written feedback and the VIZ with visualizations, it can be concluded that the automated feedback module was used much less than the visualization module. The main benefit of the visualizations according to the respondents was that the VIZ module was easier to understand and it provided a simpler overview of the process the trainees made over time.

The results show that the learning analytics modules in the ePortfolio environment were not used as much as expected and that written feedback (JIT) was used less than the visualizations (VIZ).

---

## Conclusion

This chapter described a project that aimed to improve the quality of workplace-based feedback and assessment for trainees and supervisors through enhancing an existing ePortfolio environment with learning analytics. The ePortfolio collects and stores data about trainees' progress from diverse sources. Based on state-of-the-art probabilistic reasoning techniques, student models were created that allowed for aggregation and tailored just-in-time feedback. The learning analytics process as described in this chapter includes related processes (Elias 2011; Mislevy Behrens Dicerbo and Levy 2012; Toulmin 2003). First the domains with entrustable professional activities were defined. Then data were selected and captured. Next data were aggregated, and information was reported to make analyses, evaluations, and predictions based on the data. The human factor in learning analytics is represented by the trainees, content specialists, educational specialists, and technologists at workplaces throughout Europe.

The evaluation cycle, related to argumentation theory and evidence-centered design, provides useful insights into benefits and challenges of implementing ePortfolios enhanced with learning analytics in workplace-related contexts. Although the written feedback from the supervisors was highly valued, trainees did not or almost not use the automated feedback module. The visualization model, especially the feature "timeline," was used most by trainees. The main benefit of the visualization module according to the trainees was that it generated a simple overview of their development over time and was easy to understand.

There are, however, several scientific challenges that have to be dealt with. Firstly, the use of learning analytics for workplace-based feedback and assessments demands new solutions to make use of symbolic and numerical data and soft, written data and feedback as input to the models. This will require the use of text mining techniques and natural language processing to analyze written elements in order to resolve and encode them into probabilistic propositions to inform the student models. Examples of techniques that might be considered are the well-known latent semantic analysis but also more recent developments such as the application of ontologies or the application of sentiment analysis.

Foreseen practical challenges include the tailoring to trainees' and supervisors' feedback and assessment needs. Connecting learning analytics to ePortfolios demands multi-sorted learning and assessment tools at the work environment to be

used as an input into the system and a module for automated feedback provision. The overarching environment is assumed to improve the quality (validity and reliability) and efficiency of supervisors' and trainees' (self and peer) feedback and assessment at the workplace. However, this will only succeed when the environment is developed and implemented through the eyes of the users. This especially counts for the visualization dashboards for trainees and supervisors that will be developed to present the information at the workplace in a graphically easy to interpret way. First, this demands a strong integration of ePortfolios in the learners' curriculum as a tool for reflection, dialogues, and feedback on professional development. Second, training for trainees and supervisors to learn to work with the ePortfolio environment is fundamental.

Other practical challenges include the search for ways to easily integrate ePortfolios with other information systems. Since trainees alternately work in several organizations and bring their electronic portfolio with them, learning analytics-based electronic portfolios as used and improved in the described project in this chapter can enhance collaboration between trainees, supervisors, and organizations, for instance, by the exchange of information about trainees' development in organizations, and hence increase the learning opportunities for trainees. Here it is important to ensure that the use of data is aligned with the ethics of the institute or professional domain. Although it is common that the learner is the "owner" of the ePortfolio data and has to grant access to others (e.g., peers, supervisors) to enter the ePortfolios (e.g., in order to provide feedback), there is still the issue of datasets that are stored at servers and are limited in their transport (Greller and Drachler 2012; Selwyn 2015).

All in all it can be concluded that the use of learning analytics in ePortfolios is promising, but still in its infancy. Potentially it can contribute to more personalized, timely, and effective feedback at the workplace. In this end it contributes to the ultimate goal of learning at the workplace: entrusting professionals with, for instance, the critical care of patients, animals, and students.

**Acknowledgment** This study was conducted within the framework of the "Workplace-Based e-Assessment Technology for competency-Based Higher Multi-Professional Education" (WATCHME) project, supported by the European Commission 7th Framework Programme (grant agreement No. 619349). ## Abstract

Proficiency in spelling is a key influential factor in success with compositional writing, reading, and vocabulary knowledge. To facilitate student learning in spelling, educators should utilize spelling assessment systems that generate useful diagnostic feedback and that are informed by current theoretical underpinnings of learning and instruction in spelling. Nonetheless, within the vocational education and training (VET) sector, there is a notable lack of robust adult writing literacy measures, particularly in the domain of spelling. Assumptions about the nature of spelling development have important implications for the way spelling is assessed and taught. This chapter considers the importance of learning to spell and compares linear and nonlinear theoretical perspectives on spelling development. Assessment systems used for measuring spelling ability are then discussed in terms of their theoretical underpinnings and their suitability for VET contexts. Recommendations for spelling assessment and instruction in VET contexts are offered.

**Introduction**

Being a literate reader and writer increases one's capacity to successfully participate in education and training, in the labor market, and in social and civic life. Yet according to the United Nations Educational, Scientific and Cultural Organization (UNESCO) (2016), almost 10% of the global young adult population (aged 15–24 years) is illiterate. While it is widely recognized that there is an association between income and literacy levels, developed nations are not entirely immune to literacy problems. For example, the data from the Programme for the International Assessment of Adult Competencies (PIAAC) indicate that, in Australia, almost half of the adult population (aged 16–65 years) is deemed to have literacy skills below the minimum level required to adequately cope in modern societies (Organisation for Economic Co-operation & Development [OECD] 2013). The PIAAC data also indicate that literacy rates in the UK and in the USA are of even greater concern, as evidenced by their below international average literacy scores (OECD 2013). Furthermore, across the 24 countries and sub-national regions involved in this PIAAC study, between 4.9% and 27.7% of adults were deemed proficient at only the lowest levels in literacy. A combination of inadequate education and lack of opportunities to improve proficiency in literacy skills “has the potential to evolve into a vicious cycle in which poor proficiency leads to fewer opportunities to further develop proficiency” (OECD 2013, p. 23). For young adults with poor literacy skills, the vocational education and training (VET) sector can provide essential systematic literacy support and mentoring.

In order to address literacy issues among young adults, it seems logical to begin by considering how particular language-based subskills may predict later literacy. Among the predictors of literacy, proficiency in spelling is a key influential factor in success with compositional writing, reading, and vocabulary knowledge (Daffern et al. 2017a; Ehri 2014; Holmes and Ng 1993). As “spelling and reading build and rely on the same mental representation of a word,” knowledge of a word's spelling makes the representation of that word “sturdy and accessible for fluent reading” (Snow et al. 2005, p. 86). Equally, being able to spell with automaticity is a critical element of the writing process. Spelling “bridges idea generation and text generation” (Abbott et al. 2010, p. 296). Hence, a valuable way to help young adults improve their reading and writing literacy levels in the English language is to provide opportunities for them to develop deep understanding of the linguistic components that are particular to the Standard English spelling system.

As proficiency in spelling is a crucial aspect of literacy, VET educators may need to utilize spelling assessment tools that are informed by current theoretical underpinnings of learning and instruction in spelling in order to provide useful diagnostic feedback to students. Nonetheless, within the VET sector, there is a notable lack of adult writing literacy measures, particularly in the domain of spelling. Indeed, adult

literacy support programs are largely informed by data obtained from measures of reading literacy such as PIAAC. Furthermore, they are not informed by current theoretical perspectives on the nature of learning to spell.

---

## Becoming Proficient in Spelling

Spelling in Standard English is a key foundational literacy skill, but it is also a complex word-formation process that takes time to master. Multiple language sources need to be activated when spelling, and learning to do this efficiently may provide the intellectual engagement that is needed to become proficient at choosing and using words that precisely convey meaning through writing (Daffern et al. 2017a; Richards et al. 2009). In order to support student learning in spelling, educators should be mindful of the varied theoretical perspectives that exist regarding the nature of learning to spell, as the theoretical position that an educator chooses to adopt may influence the way spelling is taught and assessed (Daffern et al. 2015). Broadly, there are two schools of thought regarding the nature of spelling development. One perspective assumes that learning to spell proceeds in a linear manner, while several other perspectives broadly attest that learning to spell does not follow a linear trajectory. What follows is an overview of the diverse understandings of how proficiency in spelling is thought to unfold.

### Linear Models of Spelling Development

*Stage and phase theories* have offered one way of conceptualizing how children develop mastery in spelling (Ehri 1985; Frith 1980; Gentry 2000). These theories have been influential since the 1970s as they have helped educators and researchers to understand that learning to spell predominantly through rote memorization is limited and that the development of phonological knowledge in spelling is crucial. By analyzing spelling errors in written texts, stage theorists (Bear and Templeton 1998; Cataldo and Ellis 1988; Ehri 1985; Frith 1980; Gentry 2012; Read 2009) produced a linguistic index (a list of linguistic features, such as final consonants and short vowels) that they subsequently used to categorize spelling development into discreet and sequential stages (Daffern et al. 2015). While different terminology has been used among stage theorists to describe each stage of spelling development, stage theories share two common assumptions. First, they describe development in terms of five linear stages of development. For example, Gentry (2000, p. 324) explains that the first stage is “precommunicative”; the second is “semiphonetic”; the third is “phonetic”; the fourth is “transitional”; and the fifth is “correct” (or “conventional”). On the other hand, Bear et al. (2012, p. 9) label the five respective stages as “emergent,” “letter name,” “within word,” “syllables and affixes,” and “derivational.” Although proponents of stage theories use different terminology to conceptualize spelling development, they are broadly characterized by similar qualitatively descriptive categories. The second commonality

underpinning stage theories is their Piagetian assumption and the “notion that aspects of cognitive development proceed by way of qualitative stage-like change” (Gentry 2000, p. 319). According to this assumption, “spelling difficulties are viewed as an inability to move on to the next stage” (Kohnen et al. 2009, p. 116).

In avoiding the stringent assumption typically associated with developmental stage theories, Ehri (2005) proposed an alternative linear perspective by describing the progression of learning to spell according to sequential “phases,” rather than “stages.” In doing so, she acknowledges that progression through the phases of spelling development may slightly overlap. Further, Ehri’s (2005, p. 176) description accounts for only four “successive” phases of spelling development, namely, “prealphabetic,” “partial alphabetic,” “full alphabetic,” and, finally, “consolidated alphabetic.”

However, a weakness in stage and phase theories is their disregard for the coexistence of other emerging linguistic skills including orthographic knowledge (as demonstrated by an awareness of conventional letter sequences within written words) and morphological knowledge (as evidenced by an awareness of the meaning-based conventions within written words) (Treiman 2017a). Indeed, Devonshire et al. (2013) posit that models of spelling development should not be restricted to a fixed and “predetermined path of intellectual development” (p. 87). Rather, they should account for environmental impacts, including the opportunities afforded to a learner through instruction, or through their experiences with language through speaking, listening, reading, and writing, and through incidental exposure to written texts. It has been argued that stage and phase theories offer an overly simplistic account of learning to spell as they cannot capture the range of difficulties or experiential advantages students encounter throughout their journey toward proficient spelling (Berninger et al. 2010; Daffern et al. 2015). Paralleling such assertion, research has shown that children are capable of using all strategies that are available to them to spell and that these may develop continuously and in parallel (Daffern 2017; Lennox and Siegler 1994; Sharp et al. 2008). With explicit instruction, learners are capable of building morphological awareness during the early years of learning to read and write (Apel et al. 2013; Nunes et al. 2003). According to Bowers et al. (2010, p. 171), morphological instruction is “at least as effective for students in the early stages of formal literacy instruction” as it is for older students.

Nevertheless, for several decades, stage and phase theories have influenced the teaching and assessment of spelling. These theoretical perspectives have also been used to inform the construction of spelling assessments and teaching materials (Varnhagen et al. 1997) such as *Words Their Way* (Bear et al. 2012) and *Word Journeys* (Ganske 2000). Yet, there is no substantive evidence to support linear models of spelling development (Kohnen et al. 2009), despite their continued and prominent influence in educational contexts.

## **Nonlinear Models of Spelling Development**

A growing body of research provides unequivocal evidence that the trajectory toward proficiency in spelling does not proceed in linear stages or phases

(Devonshire et al. 2013; Garcia et al. 2010; Rittle-Johnson and Siegler 1999; Sharp et al. 2008). Alternative propositions are emerging and converging, collectively indicating that becoming proficient in spelling is a process of learning to abstract, apply, and interconnect multiple linguistic aspects of the written language in parallel rather than one after the other. What follows is an explanation of several nonlinear theoretical propositions of learning to spell.

*Dual-route theory* is fundamentally different to stage and phase theories as it assumes nonlinear pathways in spelling development. However, it offers a somewhat limited perspective of learning to spell as it theorizes that only two independent processes (“routes”) are involved in spelling (Barry 1994; Houghton and Zorzi 2003). These processes are labelled as the *lexical route* and the *non-lexical route*. The *lexical route* relies on long-term memory to retrieve the spelling of words that have been previously encountered and memorized through repeated exposures to print. This route functions like a mental dictionary, and the activation of this process has also been described as the “whole word procedure” (Kohnen et al. 2009, p. 117). The *non-lexical route* is activated when words cannot be spelled through the *lexical route*. Thus, the *non-lexical route* involves generating a spelling by mapping individual phonemes (sounds in speech) to alphabetic letters or groups of letters. Through this process, a word is segmented into individual phonemes and then matched to corresponding alphabetic letters. The letters are then stored in short-term memory, sometimes referred to as the “graphemic buffer” (Kohnen et al. 2009, p. 116), while they are being physically transcribed into their written form.

According to dual-route theory, learning to spell involves memorizing the spelling of whole words as well as learning to accurately apply phonological processes. Dual-route theory has been among the dominant nonlinear theoretical frameworks for several decades; however, in recent years, it has been regarded as overly simplistic as it does not fully capture the complexities of learning to spell in Standard English (Treiman 2017b). As Sheriston et al. (2016, p. 406) observe, dual-route theory does not “specify how other skills, such as the contribution of orthographic and morphological strategies, might fit neatly into this classification.”

The *integration of multiple patterns framework (IMP)*, proposed by Treiman and Kessler (2014), differs substantially to dual-route theory even though they are both grounded in nonlinearity. According to the IMP, the ability to map phonemes to spellings (*a non-lexical route*) is not the first skill to develop; rather, some knowledge of the “visual form of writing,” including knowledge of “how letters combine, . . . comes first” (Treiman 2017a, p. 4). The IMP also assumes that as learners gain experiences with written words they simultaneously refine their knowledge of the morphological structures of words. Although Treiman (2017a) supports the view that young children are capable of learning to correctly apply morphological structures in their spelling, she posits that morphological processing in spelling takes considerable time to master and that “even adults sometimes fail to adhere to certain morphologically based patterns” in their spelling (Treiman 2017b, p. 7). Considering English spelling is morphophonemic, that is, words are constructed through representations of both their phonemes (speech sound units) and morphemes (meaning units), the IMP offers a promising perspective. The IMP is based on the premise that

a variety of patterns need to converge in order to spell single words, including phonological (how sounds map to letters), graphotactic (the ordering and arrangement of letters within words), and morphological patterns (applications of morphemic, or meaning-based, properties in words).

*Constructivist theory* of learning was proposed by Ferreiro and Teberosky (1982) and has been somewhat influential in the teaching of spelling across South America and some parts of Europe (Treiman 2017a), despite absence of its efficacy from experimental research in the domain of spelling. According to a constructivist perspective, a learner constructs knowledge and meaning from their own experiences. Hence, becoming proficient in spelling is considered to involve the learner in constructing and testing their own hypotheses about the spelling of words. For instance, despite having received no formal instruction, some young learners have been thought to construct hypotheses, albeit incorrect, that each written alphabetic letter in a word represents a syllable in a spoken word and that visual features of printed words reflect the meaning of those words (Ferreiro and Teberosky 1982; Vernon 1993). For example, a learner may construct a misconceived assumption that the word *cat* is represented using larger-sized letters or with more letters than the word *kitten*. Although the constructivist perspective has helped to highlight that even young children may be capable of discovering a great deal about written communication even before formal instruction begins, it does not offer detailed and empirically informed insights into the complexities of learning to spell and the interplay between instruction and learning.

*Overlapping waves theory* acknowledges individual idiosyncrasies in strategy use when learning to spell, positing that, at any given time, a learner may rely on more than one type of strategy in order to spell a word (Rittle-Johnson and Siegler 1999). This theory is built upon three key cognitive features: “abundant variability, adaptive choice, and gradual change in strategy choice over time” (Farrington-Flint 2015, p. 134). For example, research investigating children’s spelling ability in Grade 1 to Grade 2 demonstrated substantial variability and adaptiveness in the strategies the children used, encompassing phonology, morphology, orthographic analogizing, and retrieval from memory (Rittle-Johnson and Siegler 1999). Other research has suggested that this theory may apply to adults learning to spell new words (Kwong and Varnhagen 2005). In their experimental studies, Kwong and Varnhagen (2005) demonstrate that children and adults have a range of “strategies in their repertoire at any given time, but they shift their reliance on different strategies over time” (Kwong and Varnhagen 2005, p. 149). They noted increased accuracy and efficiency in selecting and applying spelling strategies as a result of repeated experiences in spelling words, concluding that the “process involved in learning to spell new words does appear to be universal” (Kwong and Varnhagen 2005, p. 157).

*The lexical quality hypothesis* (LQH) is another nonlinear proposition (Perfetti and Hart 2002), and although stemming from research in the domain of reading development, it has helped to “enrich the understanding of vocabulary-spelling linkages” (Bahr et al. 2009, p. 123). According to the LQH, both spelling and reading development are dependent on the integration and interaction of three closely connected constituents: orthography, phonology, and semantics. When

applied to spelling, fusion of these linguistic constituents needs to occur in order to promote stability in rapid retrieval and accurate encoding (Bahr et al. 2009). Similarly, in the context of learning to read, accurate decoding and comprehension may be dependent on high-quality representations that include phonological, orthographic, and semantic knowledge. Although integration of these three key components is critical, in circumstances whereby orthography and phonology are of a low quality, semantic information becomes particularly vital to accurate word reading. While the LQH offers a promising perspective for examining learning in spelling and for the construction of spelling assessments, there is currently an absence of empirical evidence that explains how this hypothesis applies specifically to spelling.

*Triple word form theory* (TWFT) aligns closely with the LQH but offers a more robust nonlinear perspective of spelling development (Bahr 2015; Berninger and Abbott 2010; Daffern et al. 2015; Garcia et al. 2010). Grounded in neurocognitive and behavioral research, this theory assumes that learning to spell “depends on developing awareness of phonological, orthographic, and morphological word forms . . . and coordinating them” (Richards et al. 2009, p. 332). Consistent with the LQH, encoding involves analyzing and coding “phonemes in spoken words” (phonological word form), “letter patterns in written words” (orthographic word form), and “root words, prefixes, and inflectional and derivational suffixes” (morphological word form) (Bahr 2015, p. 74). TWFT proposes that spelling mastery is not entirely reliant on the alphabetic principle. Rather, spelling acquisition involves concurrent knowledge development in the phonological structures, orthographic regularities, and morphological properties of the English language (Apel 2014; Treiman and Kessler 2014). Critically, the view that young students “draw on phonology, orthography, and morphology from the beginning of spelling development” and gain increasing explicit control over these skills (Garcia et al. 2010, p. 88) differs from linear assumptions of spelling development, which assume that phonological skills develop first, followed by orthographic skills, and eventually morphological skills. Indeed, research has found that “orthographic awareness may not be dependent on first establishing competent phonological spelling skills” (Larkin et al. 2013, p. 409). According to TWFT, the process of developing accurate and automatic spelling is characterized by a growing awareness and integration of the phonological, orthographic, and morphological word forms (Bahr et al. 2009). TWFT has been supported by findings from several studies demonstrating that growth in spelling is not linear and that the development of robust written lexical knowledge, one that coordinates phonology, orthography, and morphology, follows a gradual but complex trajectory (Bahr et al. 2012; Daffern 2017; Garcia et al. 2010; Richards et al. 2006).

In contrast to linear, Piagetian, perspectives of spelling development, TWFT postulates that students who are beginning to develop their knowledge of Standard English spelling can learn to extract and coordinate phonological, orthographic, and morphological processes when encoding words (Berninger and Abbott 2010); however, efficiency and accuracy in the coordination of these linguistic processes may largely be an outcome of the kind of instruction they receive (Berninger et al. 2010; Daffern 2016; Graham and Santangelo 2014). As Treiman (2017a) notes, many orthographic patterns are not typically taught in schools, and even though most

students may be able to “pick up” conventional letter “patterns on their own, instruction could probably speed the process” (p. 7).

---

## Assessment of Spelling Ability

Individual student performance data obtained from a diagnostic assessment of spelling ability can inform instructional priorities. However, performance outcomes may be influenced by the particular theoretical position that underpins an instrument’s design. Therefore, in planning and implementing literacy instruction which targets spelling-related outcomes, educators should carefully consider the robustness of existing instruments which measure spelling performance, including the extent to which they align with particular theoretical perspectives. According to Kohnen et al. (2009), “a high-quality assessment” of spelling ability “depends on how far the assessment taps into the underlying theory of the spelling system and how that spelling system is acquired” (p. 114). Nonetheless, in VET contexts, there is a notable absence of assessment systems which adequately measure spelling ability. Additionally, the vast majority of existing spelling assessments currently being applied by educators in other contexts have largely failed to consider nonlinear perspectives of spelling development (Kohnen et al. 2009), despite unequivocal evidence in support of nonlinear models of spelling development.

By using reliable and sensitive assessments of spelling ability, it is possible to identify specific subskills that need to be taught (Al Otaiba and Hosp 2010). An established technique used to sensitively measure spelling subskills involves a systematic linguistic error analysis of words that a student spells in response to an oral dictation task (Daffern et al. 2015; Kohnen et al. 2009). While many popular standardized spelling tests employ dictation tasks, they are not necessarily adequately diagnostic as they do not allow for a systematic error analysis. Examples of these include the:

- (i) Woodcock-Johnson-III tests, forms A, B, and C (Woodcock et al. 2007)
- (ii) Wechsler Individual Achievement Test-II (Psychological Corporation 2001)
- (iii) Wide Range Achievement Test-4, forms Blue and Green (Wilkinson 2006)
- (iv) Kaufman Test of Educational Achievement (K-TEA)-Brief (Kaufman and Kaufman 1985)
- (v) K-TEA-Comprehensive (Kaufman and Kaufman 1998)

Calhoon et al. (2010) highlight several limitations of these five assessments in terms of their measurement design. First, even though they all employ a dictation method (whereby an examiner dictates a spelling word aloud, uses the word in a sentence, repeats the word, and then the student writes the word), they fail to identify the aspects of spelling that may be problematic for a student. In line with a constructivist perspective of spelling development, these tests merely identify production of whole words as either right or wrong, which may only serve to promote inefficient and ineffective rote learning of specific whole words. Second, the five

tests listed above tap into different orthographic skills, and their “alternative” (or parallel) test forms do not always significantly correlate with each other “in terms of specific orthographic skills covered” (Calhoun et al. 2010, p. 169). The lack of correlations is problematic, particularly if the tests are used to track longitudinal progress or to monitor the effectiveness of an intervention. Furthermore, spelling ability cannot be adequately measured using any of these instruments in isolation as each does not measure a broad coverage of linguistic components. As such, multiple tests may need to be administered to obtain sufficiently comprehensive feedback. More broadly, Kohnen et al. (2009, p. 113) acknowledge that, due to the complexity of Standard English spelling, educators may need to use “several tests in order to adequately assess spelling ability and to monitor spelling development” over time.

In order to tailor appropriate instruction, spelling assessments should enable systematic and comprehensive analysis of the kinds of errors a student makes when producing written words (Calhoun et al. 2010; Masterson and Apel 2000). Examples of normed assessment tools which involve an error analysis technique include the *British Spelling Test Series* (Vincent and Crumpler 1997) and the *Single Word Spelling Test* (Sacre and Masterson 2000), both of which are structured to broadly align with linear models of spelling development. Another example, though informed by dual-route theory, is the *Diagnostic Spelling Tests* of nonwords and irregular words (Kohnen et al. 2015).

While error analysis can yield useful diagnostic feedback, the results may be influenced by the theoretical framework that underpins the constructs of an assessment. For example, a spelling test that is informed by stage theory presumes that phonological spelling representations will be mastered first, followed by accurate orthographic representations, and eventually morphological representations. Under this presumption, spelling ability is assigned to a particular developmental “stage” of spelling by classifying spelling errors according to the descriptive stage that they most closely reflect in the constructs of an assessment (see, e.g., Table 1). An example of an assessment tool which adopts a stage-like framework is the *Words their Way Inventories* (Bear et al. 2012). In utilizing an assessment framework that is informed by a linear theoretical perspective, instruction is then focussed around helping the learners progress to the next assumed stage “by teaching the strategies defining the next stage” (Kohnen et al. 2009, p. 116).

As Kohnen et al. (2009) contest, “there is no evidence that children move from one stage to the next by shifting from the signature strategy of one stage to the strategy that is characteristic of the next stage” (p. 116). An assessment tool that adopts a stage-like classification of spelling ability is problematic as it does not acknowledge that a learner is indeed capable of concurrently developing skills across several “stages” (Daffern 2016; Devonshire et al. 2013; Sprenger-Charolles et al. 2003). The classification of ability into a single “stage” may result in an oversimplified and misconceived diagnosis, which may subsequently constrain a student’s opportunity to refine those strategies classified as more advanced according to linear theories of spelling development (Daffern et al. 2015; Varnhagen et al. 1997).

Using TWFT as a framework for spelling error analysis acknowledges prior phonological, orthographic, and morphological knowledge, which leads to better

**Table 1** An assessment structure informed by stage theory

Spelling stages	Subskills measured	Spelling examples	Characteristics	Instructional priorities
Stage 1 Emergent	Initial consonants in CVC words <sup>a</sup>	<i>t</i> (for “top”)	Spelling is largely pre-phonological. It may include some random marks, letters and numbers, or representational drawing	To progress to Stage 2, phonological skills are introduced, including concepts of print such as left to right directionality
Stage 2 Letter name	Final consonants and medial vowels in CVC words, initial digraphs, initial and final blends in monosyllabic words	<i>Hat, hit, hot, shop, place</i>	Phonological knowledge develops. Sound-to-letter knowledge is accurate. Correct left to right mapping of phonetic representation	To progress to Stage 3, phonological skills need to be mastered first
Stage 3 Within word patterns	Common long vowels, diphthongs, -r influenced vowels	<i>Drive, train, boil, serve</i>	Orthographic knowledge develops. Letter patterns are plausible and mostly correct	To progress to Stage 4, orthographic skills (e.g., knowledge of letter patterns for long vowel phonemes) need to be mastered first
Stage 4 Syllables and affixes	Inflected suffixes, syllable juncture consonant doublets	<i>Shopping, carries, bottle</i>	Morphemic knowledge develops. Some prefixes and suffixes are correctly affixed to base words	To progress to Stage 5, knowledge of how to accurately affix prefixes and suffixes to be base words must be demonstrated first
Stage 5 Derivational	Derivational suffixes, roots	<i>Pleasure, circumference</i>	Understanding of how words derive from base words and word roots expands	The study of word origins and their meanings is the focus of instruction during this final stage

<sup>a</sup>CVC words are consonant-vowel-consonant

understanding of how learners may combine this knowledge to translate spoken words into a conventional written form (Varnhagen et al. 1997). The *Components of Spelling Test* (CoST) (Daffern et al. 2015; Daffern et al. 2017b) directly aligns with TWFT, and this is evident in the three constructs included in this instrument: (i) phonological component, (ii) orthographic component, and (iii) morphological component. As can be seen in Table 2, the CoST involves a systematic error analysis of the phonological, orthographic, and morphological properties in written words. This spelling assessment is a standardized test consisting of 70 words which are dictated to the student/s in the context of a sentence. Internal reliability results for the CoST have been reported, ranging from 0.78 to 0.94 (Daffern et al. 2015), while robust predictive validity has been evidenced in a subsequent study (Daffern et al. 2017b). In administering the CoST to individual students or to a whole class of students at one time, an educator can use the results of the error analysis to determine instructional priorities across the three spelling components.

An analysis of spelling errors, as determined by using the specified CoST scoring sheets, reveals potential strengths and/or breakdowns in phonological, orthographic, and morphological processing, without confining overall spelling ability into a particular “stage.” This is starkly different to a stage-like approach to spelling error analysis and thus has important instructional implications. Specifically, in using the CoST, an educator should concurrently focus instruction on the weaker subskills identified in each of the three subscales, rather than sequencing instruction by prioritizing phonological skills first, followed by orthographic skills, and then eventually morphological skills. Although normed data are currently based on Australian children (Daffern 2017), the diagnostic capabilities of the CoST make this instrument a valuable tool for adults who are developing fundamental English language skills in VET contexts.

---

## Conclusion

In determining suitability of a spelling assessment tool for VET contexts, educators should begin by evaluating assessment tools in terms of their theoretical alignment and empirical reliability and validity. As the research evidence for linear spelling development is lacking, selecting a spelling assessment tool which confines spelling ability into a particular developmental stage of development is not recommended. Rather, VET educators are advised to utilize dictation assessment tools which measure spelling ability in a way that captures a learner’s capacity to successfully integrate the phonological, orthographic, and morphological components of the written language. Although the CoST may be a helpful tool to use in VET contexts, normative data for adult learners are yet to be obtained. There is also a need to design and validate supplementary assessments that systematically measure a learner’s ability to accurately represent the phonological, orthographic, and morphological components of the written language. Indeed, this work is currently underway, with promising results, yet to be published.

**Table 2** Structure of the Components of Spelling Test (CoST) and corresponding instructional examples

	Subskills measured	No. of items	Example of an instructional focus if the corresponding subskill is weak
Phonological subscale	Initial and final consonants in monosyllabic words	5	Manipulate initial and/or final consonants in consonant-vowel-consonant words (e.g., <i>tap, rap, map, lap, sap, nap</i> )
	Short vowel graphs in monosyllabic words	5	Compare medial vowel phonemes (e.g., <i>hop/hope</i> ), manipulate onset and rimes (e.g., <i>hot, hat, hit, hut</i> )
	Consonant digraphs	5	Identify digraphs, blend and segment phonemes in words containing digraphs (e.g., <i>sh-o-p, m-a-sh</i> )
	Polysyllabic-word medial blending	16	Syllabify, segment, and blend phonemes in polysyllabic words (e.g., <i>di-ag-no-sti-cian</i> )
Orthographic subscale	Common long vowels	7	Sort words with the same long vowel phoneme (e.g., <i>-igh-</i> as in <i>delight</i> , <i>-ie</i> as in <i>finite</i> , and <i>-eigh-</i> as in <i>height</i> )
	Ambiguous vowels	7	Sort words with diphthongs, on the basis of their positional constraints (e.g., <i>-oy</i> only occurs at the end of a word as in <i>toy</i> , but <i>-oi</i> occurs if followed by the letter <i>-n</i> as in <i>coin</i> or the letter <i>-l</i> as in <i>boil</i> )
	Complex consonant patterns	6	Sort words with complex letter clusters on the basis of their positional constraints (e.g., <i>-tch-</i> as in <i>batch</i> never occurs at the start of a base word but <i>ch-</i> as in <i>chip</i> does)
	Syllable juncture consonant doublets	5	Identify medial consonant doublets in disyllabic words (e.g., <i>throttle, ripple, paddle, nibble, pillow, dagger, manner</i> ). If the medial consonant letter is <i>t, p, d, b, l, g, m,</i> or <i>n</i> and if it appears after a short vowel in a two-syllable base word, double it
	Unaccented final syllables	5	Compare words ending with the letter patterns <i>-le, -el,</i> and <i>-il</i> (e.g., <i>ripple, label, tonsil</i> )  The letter patterns, <i>-le</i> and <i>-el</i> , in the final syllables of words are most common, while <i>-il</i> is least common
Morphological subscale	Inflected suffixes	7	Teach generalizations for suffixes marking tense and plurality (e.g., if a base word ends in a single vowel plus a consonant, the final consonant of the base word doubles when the “-ing” and “-ed” suffixes are added as in <i>hop/hopping, stop/stopped</i> )
	Derivational suffixes	8	Teach the generalization that <i>-ian</i> forms “people” nouns from “thing” or “place” nouns (e.g., <i>music/musician, India/Indian</i> )

(continued)

**Table 2** (continued)

	Subskills measured	No. of items	Example of an instructional focus if the corresponding subskill is weak
	Morpheme juncture schwa vowels	5	Teach the generalization that the long vowel phoneme in the 2nd syllable of a base verb (e.g., <i>propose</i> ) is reduced to a schwa when nominalized (e.g., <i>proposition</i> ); however, the spelling of that schwa does not change
	Homophones	7	Teach the meaning and spelling of words that have the same sound but different meaning and spelling (e.g., <i>sore/soar</i> )
	Greek and Latin roots	7	Teach word origins and meanings (e.g., <i>lumina</i> is a Latin root word meaning to <i>light</i> or <i>to shine</i> )
	Assimilated prefixes	7	Teach the generalization whereby the sound and spelling of the final consonant in a prefix is absorbed into the initial consonant of the base word (e.g., the prefix “in-” means <i>in</i> , <i>not</i> , <i>toward</i> , or <i>together</i> so <i>in</i> + <i>legal</i> = <i>illegal</i> , <i>in</i> + <i>mature</i> = <i>immature</i> )

**Abstract**

The international community of technical and vocational education and training (TVET) has basically reached a consensus that outcome-oriented quality control should be strengthened through external assessment. Professional competence assessment is generally accepted as an economical evaluation approach to acquire large amounts of in-depth and valid information. Two assessment programs are presented as case studies on the outcome-oriented quality assurance of TVET. The students' assessment program based on COMET was implemented by local government Chongqing as a quality assurance measure for secondary vocational education, while the teachers' professional competence assessment program aims at providing methodological reference for quality assurance in teacher further training programs. A fundamental research on the predictive validity of professional competence assessment is also presented to justify its availability as a quality assurance approach.

## **Introduction: From Input-Oriented to Outcome-Oriented Paradigm Shift in Quality Assurance of TVET**

Since the beginning of the new century, technical and vocational education and training (TVET) in China has been enjoying unprecedented growth. Nevertheless, numerous deep-seated problems have still not been effectively solved, the most prominent one of which is the training quality of vocational institutions (colleges and schools). If it is not good enough, graduates can't get employed directly after training; they have to get further qualifications through on-the-job or off-the-job training. Therefore, the training quality of vocational institutions influences the contents and forms of the training market. Besides, a comprehensive understanding of development levels and structural characteristics of the students' professional competence is of great significance for the systematic design of further training programs.

In the past, the quality evaluation of TVET students in China was mainly achieved through internal examinations. The assessment indicators could not meet the requirements of reliability and validity for quality monitoring in a large scale, making it impossible to carry out inter-institution and interregional comparison. Due to insufficient methodological support, evaluation results could not reflect the overall quality of training, and the interpretation model of the corresponding relations between evaluation results and the training mode has not been established. Even for National Skills Competitions that have a great influence in the Chinese society, there still exist organizational and methodological problems during the large-scale promotion, including the economic cost, the inter-rater reliability, and the validity of test tasks.

Large-scale education assessment projects like the Program for International Student Assessment (PISA) and Trends in International Mathematics and Science Study (TIMSS) have given a lot of inspirations to TVET in China. A consensus has

been reached: outcome-oriented quality assurance should be strengthened in order to achieve a paradigm shift in training quality control from an “input-oriented” one to an “output-oriented” or even “outcome-oriented” one. When it comes to outcome-oriented quality assurance, a tricky issue is how to acquire large amounts of in-depth and valid data without incurring too much cost. The professional competence assessment is in the process of becoming an important supplement to the traditional methods of TVET quality monitoring.

Outcome orientation is one of the most important perspectives of the competency-based education (CBE) (CBE is an instructional program that derives its content from verified tasks and bases assessment on student performance. Programs of this type are also sometimes called performance-based education (PBE) and performance-based training (Norton 1997, Appendix C, p. 1).) approach originated in North America. Since the beginning of the 1990s, CBE has been introduced in China through a number of international programs with Canada, the World Bank, and other donors. Practice has shown that the CBE approach, which takes learning outcomes of students as the goal and focuses on the requirements of the labor market, has almost a “revolutionary” significance in China, compared to the academic paradigm of the past, based on disciplinary knowledge, because the idea of “theory in service of practice” of the CBE is contradictory to the traditional precept of Confucian culture that “knowledge accumulation is superior to practice.” It has fundamentally changed the relationship between theory and practice and thereby determined the new position that “practice is more important than theory” in TVET. It has also, indirectly, given an impetus to the Chinese government while shifting its focus from the ideological conflict in the so-called culture revolution toward “economic development.”

The application of CBE has massively improved the relevance of the TVET to practice and its effectiveness in China. But since the last 15 years, CBE has been gradually criticized especially for ignoring pedagogical aspects in the discussion among education scientists (Jiang and Wu 2006; He 2016). The basic assumption of this concept is that practical knowledge as it appears in professional work is interpreted as being applied scientific knowledge, while the impacts of tacit knowledge are neglected (Rauner 2017). It regards learning as a simple process between input and output, and competence development as a top-down transfer from teacher to student, emphasizes the enhancement of qualification achieved through the accumulation of scientific knowledge, and focuses on observable changes in behavior. Insufficient attention was paid to professional cognitive competence (Hager 1995; Ertl and Sloane 2006). The notion of combining single skills into a competence also ignores the learning situation (Lave and Wenger 1991) and holistic qualities of work.

The development of information and communication technology (ICT) and the change of work organization bring higher requirements for the professional competence of skilled workers. Since the end of the last century, educationalists, TVET institutions, and entrepreneurs of advanced manufacturing industry have recognized that effective learning requires students’ cognition and reflection with respect to the tasks, processes, and contexts in real work situations. It is necessary to carry out an

integrated training approach designed to allow students not only to acquire knowledge and skills but also to gain holistic action competence and an occupational identity. At the political level, in 2003, the Ministry of Education (MoE) launched a pilot program to improve the education quality to deal with the shortage of skilled personnel by developing a new curriculum emphasizing the integration of knowledge learning, skills training, and experience acquisition in actual work situations (MoE 2004). From that time on, TVET institutions have done numerous experiments in curriculum development. These experiments can be categorized into two types. One simplified type is that project teaching has been promoted as a kind of curriculum model (Xu 2009) and has been implemented in Shanghai and the immediate vicinity of Shanghai; the other is the introduction of the “areas of learning” (Lernfeld) curriculum initiated in Germany (KMK 1996).

Chinese educationalists believe that qualified skilled workers should meet the requirements of professional competence, while the purpose of areas of learning is to promote the development of professional competence that is mentioned as individuals’ reflection in an occupation and in society and the willingness and capability responsible for the shaping of individuals and society. In the last years, TVET institutions have carried out a great number of pilot projects to develop Chinese “areas of learning” with the training objective of developing holistic professional (shaping) competence; the learning process is aligned with the work process, where students can conduct learning and thinking in comprehensive actions (Zhao 2009).

From the pedagogical-didactic point of view, the introduction of the areas of learning built a new curricular system according to the competence developmental logic after breaking the discipline-oriented curricular system. This curriculum can better help students to understand the work process and context awareness. It had also a policy impact. For example, in 2014 the MoE published the “Decision of the State Council on Accelerating the Development of Modern Vocational Education” (Guo Fa [2014], No.19), which promoted the spreading of “the work process-oriented teaching model” (MoE 2014). The Ministry of Human Resources and Social Security (MoHRSS) formulated a Guide for the Formulation of National Skilled Talent Training Standards (interim), which uses the professional task analysis method and defines a number of key elements for the evaluation of training programs (MoHRSS 2013).

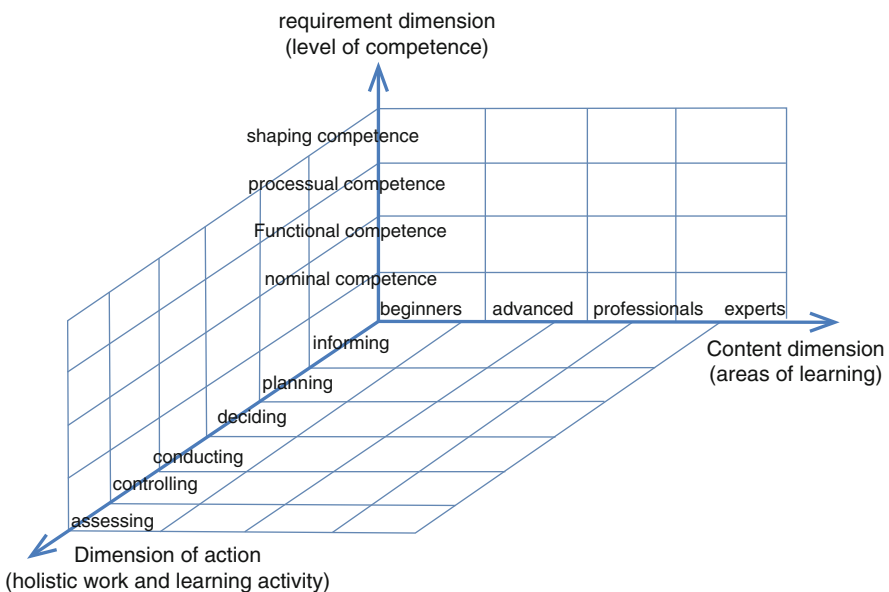

The implementation of the new curriculum requires corresponding quality monitoring methods. The project COMET – “Competence Development and Assessment in TVET” – is an ambitious effort to test a methodology for competence diagnostics in TVET. Under the leadership of Prof. Felix Rauner, University of Bremen, it has established a competence model and an assessment model which are across occupations (Rauner et al. 2009, 2013). These models take into account both the requirements of the world of work and the education goals of TVET. The test tasks are designed based on typical professional tasks (Reinhold et al. 2003; Howe 2008). The open-ended test form is adopted in order to guarantee the content validity of the test. Test questions are specially designed to reduce the length of the test and guarantee the test content’s coverage of occupational fields and the comparability of test results. The intrinsic linkages across professional tasks of the stages from

beginners to experts make the test task aligned with a continuous scale of professional competence, thus allowing for a vertical comparison of professional competence development at different stages. The training of raters and the test of their reliability have improved the accuracy and reliability of assessment results (Rauner 2017; Fischer et al. 2015).

Since 2009, Beijing Normal University (BNU) has introduced the COMET program to a number of innovative TVET projects, adapted them to the specific conditions in China, and conducted competence assessments among various occupations. This chapter introduces the COMET assessments on secondary vocational school students in Chongqing and the professional competence assessments on TVET teachers and verifies the validity of these assessments.

## COMET Professional Competence Assessment

COMET professional competence assessment uses a large-scale diagnostic method to evaluate the development of the professional competence, occupational commitment, and identity of students and teachers and compares the training quality in different TVET institutions and regions. The assessment is based on a three-dimensional competence model (Rauner et al. 2013). Three dimensions, respectively, are the requirement dimension, the content dimension, and the action dimension (Fig. 1).

**Fig. 1** Levels and criteria of professional competence. (Source: Rauner 2017, 64)

## The Levels of the Requirement Dimension

According to the COMET professional competence model, the four levels of professional competence are:

- Nominal competence: Students have superficial conceptual knowledge which is not enough to guide specialized activities.
- Functional competence: Students are required to master the basic knowledge and skills to do the work of specific positions, which doesn't need to understand of complex relationships and have little relevance with situations.
- Processual competence: The completion of professional tasks needs to have the quality awareness and work process knowledge as well as take various requirements into consideration, including economy, customer orientation, and work processes.
- Holistic shaping competence: The complexity of professional work tasks is fully realized, and tasks are solved with a view to diverging demands and in the form of intelligent compromises (Rauner et al. 2013, 47–49).

Students with nominal competence are at risk. They do not have enough professional skills and cannot fulfill their professional tasks independently in line with professional standards.

## The Learning Areas of the Content Dimension

According to the competence development theory, the career development could be divided into five stages: novices, advanced beginners, competent performers, proficient performers, and experts (Dreyfus and Dreyfus 1988; Rauner 1999). The research team of the University of Bremen identifies the corresponding forms of knowledge for each stage. Accordingly, the content of professional work is divided into four learning areas: orientation and overview knowledge, integrated professional knowledge, detail and functional knowledge, and experiential, systematic in-depth knowledge (Reinhold et al. 2003, 29–39).

## The Action Dimension

According to the paradigm of “complete professional action” in the labor studies (Ulich 1994, 198) and the action-oriented learning theory (Volpert 1983; Pätzold 1992), the process of completing a holistic task can be divided into stages of informing, planning, deciding, conducting, controlling, and assessing (Pampus 1987).

## The Levels and Criteria of Professional Competence

In order to develop test tasks and explain the test participants' task solutions, the COMET has established eight criteria to evaluate the task solutions given by the

participants. The eight criteria are clarity/presentation, functionality/operability, sustainability/utility, efficiency/effectiveness, business and work process orientation, social acceptability, environmental compatibility, and creativity (Rauner et al. 2013, 47–49).

As these basic theories of the COMET competence model and assessment model are widely accepted in the research and practice of Chinese TVET, including shaping-oriented vocational education concept (Rauner 1995; Heidegger 2001), action-oriented teaching and learning (Gudjons 1997; Pätzold 1992), developmental tasks (Havighurst 1972), the theory of work process knowledge (Kruse 1985; Fischer and Boreham 2004), and the COMET competence assessment concept was also accepted. A framework for interpreting the development of the professional competence has been established, which can be used not only to diagnose the quality of teaching and learning in TVET but also to provide direct support for teachers' instructional design with beneficial inter-occupational and cross-cultural characteristics.

---

## **COMET Professional Competence Assessments and the Related Practice of TVET Quality Assurance in Chongqing**

### **Overview**

In Chinese medical institutions, the concept of “holistic nursing” has been promoted for many years, but the curriculum development and instructional design of most nursing schools are still biomedical and function-oriented. The “innate” competence deficiency of the nurse has brought great pressure to on-the-job and off-the-job nurse training. In 2015, the city government of Chongqing decided to conduct a COMET professional competence assessment on students of nursing program in the secondary vocational schools and to analyze the factors influencing professional competence development.

### **Brief Report About the COMET Assessment on Students of the Nursing Program**

#### **Assessment Tools and Object**

There are 30 secondary vocational schools offering the nursing training program in the city of Chongqing. The assessment was conducted in 16 of the schools, with the participation of a total of 1,258 2nd year students. The assessment tools are mainly two open-ended comprehensive test tasks and a background questionnaire. These tests are designed on the basis of professional tasks, with the form similar to that of the actual work contract. The students are required to fill in a background questionnaire about the facts of vocational schools and employers providing internships (hospitals).

## Rating Process

To ensure the reliability of the raters, 17 teachers with rich nursing experience received a 1-day rater training.  $F_{\text{inn,just}}$  coefficients range from 0.71 to 0.80 in the rating exercises for 5 solutions, indicating a high degree of consistency (0.5 and above, pass; 0.7 and above, good).

## Assessment Results

### Students' Professional Competence Level

The overall distribution of the 1,258 students' professional competence level is shown in Fig. 2. Among them, 18.28% are at the nominal competence level, 53.82% reach the functional competence level, 26.95% reach the processual competence level, and only 12 (0.95%) reach the shaping competence level. The students' scores of professional competence are generally not high, and there are also big differences in all the schools. More than 30% of the students in four schools are still at the nominal competence level (Fig. 2).

The profile of the professional competence of all students participating in the assessment is shown in Fig. 3.

The students have higher functional competence than processual competence and have the lowest shaping competence. These students perform relatively well in terms of clarity and presentation, functionality/operability, persistence as well as service processes, and work process orientation, while their competence in the criteria like family, the social and cultural environment, as well as environmental and social acceptability needs improvement. This shows that although the concept of holistic nursing has been introduced to China's healthcare sector many years ago,

**Fig. 2** The distribution of the students' professional competence level. (Source: own compilation)

K1=presentation, K2=functionality, K3=sustainability, K4=efficiency, K5=business and work process orientation; K6 =environmental compatibility, K7=social acceptability, K8=creativity; KF=Functional competence, KP=Processual competence, KG=Shaping competence

**Fig. 3** The profile of the professional competence of all students. (Source: own compilation)

vocational schools have not yet responded to these requests from medical practice in time. On the whole, nursing training is still traditionally function-oriented (medical model); the development of processual competence and shaping competence is deficient.

As shown in Fig. 4, there is a large discrepancy in the distribution of professional competence levels among schools. In School 1 and School 7, for example, several students reach the shaping competence level. Both of these two secondary specialized schools (zhong zhuan) have a long training history, which shows that the nursing training program has high requirements for professionalization, and the improvement of its training quality requires long-term accumulation of experience.

### A Comparison of the Professional Competence of Students in All Kinds of Schools

Secondary vocational education in China consists of three types of schools: secondary specialized schools, vocational high schools (zhi ye gao zhong), and skilled worker schools/technician colleges (ji gong yuan xiao). Secondary specialized schools and vocational high schools are administered by the MoE, while skilled worker schools/technician colleges are administered by the MoHRSS. The results show that there are significant differences in the distribution of professional competence levels of students among the three types of schools ( $\chi^2 = 134.773$ ,  $P = 0.000 < 0.01$ ). Skilled worker school students score higher than those of the other two types of schools, and the

**Fig. 4** The distribution of the professional competence level of students in all the schools. (Source: own compilation)

distribution of scores is relatively concentrated (Fig. 5). That means, the professional competence of students in skilled worker schools has been developed better, which may be attributed to the teaching reforms led by the two authorities in recent years: the MoHRSS advocates the teaching with the “integration of theory and business practice” (yi ti hua jiao xue), while the MoE emphasizes the development of students’ comprehensive literacy. The results are similar to those of the COMET assessments for other training programs (Zhao and Zhuang 2013).

Other differences among different types of schools also deserve attention. For example, there is a significant difference in the distribution of professional competence levels between students in public and private schools ( $\chi^2 = 649.101, P = 0.000 < 0.01$ ). The professional competence development of the former is better than the latter. Different regions can also cause significant difference in the distribution of professional competence levels of students (e.g., urban cores and suburbs) ( $\chi^2 = 72.996, P = 0.000 < 0.01$ ).

The results show that most students have established a relatively high level of identity on their vocational training. 92.84% of the students say that they are more interested in their training programs than when they entered their schools. But the students lack confidence. In particular, their self-confidence in tests and in the learning

Competence levels	Criteria		
Shaping Competence	Acceptability	Socio-cultural background	Creativity
Processual Competence,	Organization of the teaching process	Training quality control	Efficiency and effectiveness
Functional Competence,	Functionality in a specialized domain	Teaching objectives and content	Teaching approaches / methods

**Fig. 5** The criteria of professional competence assessments on specialized course teachers in vocational schools (Rauner 2013, 6)

content taught in schools needs to be improved. As long as their self-confidence in tests increases, their professional competence will be improved accordingly.

### Other Findings

We make the one-way ANOVA analysis of the students' scores of Chinese, Math, and English in secondary school entrance examinations with their "professional competence level." The results show that the F values in the overall test of the three independent variables, i.e., Chinese, Math, and English, respectively, are 96.921 ( $P = 0.000 < 0.01$ ), 59.921 ( $P = 0.000 < 0.01$ ), and 50.687 ( $P = 0.000 < 0.01$ ), all reaching a significant level. This indicates that the students' academic learning performance and professional competence are related, which is different from the results of the assessment results of the training program of the automotive maintenance (Zhao et al. 2015). It shows that teaching and learning in literacy courses also follow the principle of "domain relativity."

In addition, the level of the students' professional competence development is significantly related to their satisfaction with training resources, teaching content, teachers' working attitude toward them, and hospitals' perception of their vocational schools. The students are satisfied with the attitude and teaching content of their teachers, but not satisfied with the cooperation between schools and hospitals. In particular, the organization and coordination of internship need to be improved. With the improvement of professional competence, the satisfaction of the students with the cooperation between schools and internship hospitals is increasing.

### Follow-Up Work

The above highly relevant data prove that the quality of TVET can be monitored through the diagnosis of the "outcome indicator" of professional competence. The results of COMET assessments can help the TVET institutions to understand the

curriculum and training quality as well as the cooperation between schools and enterprises so as to make a comparison among TVET institutions, regions, and even different countries. By collecting the test participants' background information, the students' occupational identity can be analyzed. This is beyond the scope of traditional knowledge examinations, resulting in a more profound and accurate understanding of the results of implementation of TVET measures.

On the basis of these results, the Chongqing Educational Evaluation Institute convenes a meeting on monitoring results each year, gives feedback to the city government and relevant institutions on the results of COMET assessments, and underlines the core requirements for TVET quality assurance. After the meeting, the Municipal Education Committee organizes relevant personnel to urge the schools with poor test results to rethink their performance and put in place corrective measures. Some vocational schools have reformed the existing examination methods with reference to the COMET concept and established a professional competence evaluation approach that highlights "holistic competence," which also provides inspirations for the reconstruction of enrollment methods of the further training institutions in the future. Competence assessments also offer advice to education authorities on strengthening school management.

---

## Professional Competence Assessments on TVET Teachers

In recent years, Chinese governments at national and regional levels have formulated many policies aiming at promoting teachers' professional development; a large number of further training programs have been carried out in public teacher training institutions and nongovernment further training institutions. Yet the effects of these policies and measures are far from satisfactory. Reasons why they are unsuccessful could be answered partly through professional competence assessments of TVET teachers.

### Research Foundations

Professional competence is cognitive psychological dispositions and development potential of a particular occupation. The professional competence of TVET teachers is their ability to holistically solve comprehensive education and teaching problems in a real educational work context (hereinafter referred to as "teachers' professional competence"). Figure 5 shows a three-dimensional model of teacher professional competence based on the COMET professional assessment concept (Rauner 2013; Zhang 2016; Zhao et al. 2017).

### Research Process

We implemented a psychometric test of the COMET teacher competence model and assessment model and analyzed the professional competence of TVET teachers

through formal tests based on that, including the verification of the professional competence model; pretest (pretest design and implementation, pretest rating, as well as the analysis and improvement of assessment criteria and test tasks); formal assessment, rating, and data processing; and diagnosis of occupational identity, organizational identity, and achievement motivation.

We conducted a criterion-related validity test on these tests and performed an independent samples t-test on the total scores of professional competence of two sample groups, i.e., teachers who have won awards in occupational skill competitions and teachers who have not. There were significant differences in the professional competence between the two sample groups ( $t(183.273) = -4.352, p \leq 0.001$ ). There were also significant differences in the scores of professional competence of teachers with different highest grades of occupational qualification certificates, showing that the professional competence test can effectively distinguish between excellent performers and average performers and has high validity (Zhang 2016; Zhao et al. 2017).

## Assessment Results and Data Interpretation

One hundred twenty-six mechanical manufacture teachers from five cities, i.e., Beijing, Guangzhou, Chongqing, Changchun, and Wuxi, participated in the test. The results show that 0.79% are at the nominal competence level, 3.17% reach the functional competence level, 39.68% reach the processual competence level, and 56.36% reach the shaping competence level (Fig. 6).

There is a significant difference in the distribution of the competence of teachers in different types of vocational institutions (Fig. 7). Teachers in higher vocational colleges are mostly at the processual competence level (accounting for 48.39%), and 46.24% reach the shaping competence level, indicating that the overall level of teachers in such colleges is high. Teachers in technician colleges in Guangzhou have the top professional competence. 84.85% of these teachers reach the shaping competence level, while 15.15% of them reach the processual competence level. None of them is at the nominal competence or functional competence level. These may contribute to the outstanding achievements of students from such colleges in the COMET professional competence assessment and in the last WorldSkills Competition in 2017.

The data show that there are differences in the level and characteristics of professional competence of teachers in different regions. The gap of the professional competence among teachers in Guangzhou is the smallest, indicating that the overall development of teachers in this city is relatively balanced. This gap in Chongqing is large, which reflects the regional differences and interschool differences between western regions and developed coastal cities.

The comparison of the competence profiles shows that teachers in vocational colleges have a high level of academic education, while teachers in technician colleges have rich work experience in enterprises. Compared with a high level of academic degree, work experience in enterprises can be more conducive to promoting teachers' professional competence development.

**Fig. 6** The distribution of the competence level of teachers. (Source: Zhang 2016, 119)

**Fig. 7** The distribution of the competence level of teachers in different types of schools. (Source: Zhang 2016, 119)

“Occupational identity” refers to the teacher’s recognition of the concept and meaning of the occupation in which he/she works, which gradually takes place in the process of professional work under the specific social context. The occupational identity of teachers in technician colleges in Guangzhou (13.03) is lower than the national average (13.40), which is in sharp contrast to the fact that their

competence level is higher than the national average. “Organizational identity” is the perceptions and feelings of members of an organization about the organization they work for. The average of the organizational identity of teachers in technician colleges in Guangzhou is 13.86, which is slightly lower than that of all types of schools participating in the test (14.11). The achievement motivation of the teachers was tested according to Gjesme and Nygard’s (1970) Achievement Motivation Scale (AMS). The average of the achievement motivation of teachers in technician colleges in Guangzhou is 10.99, higher than the national average of 10.38.

The level of professional competence and achievement motivation of teachers in technician colleges in Guangzhou is higher than the national average, but the level of their occupational and organizational identity is lower than the national average. Apart from the schools in Guangzhou, all other test participants come from institutions in the charge of education authorities. This shows that, compared to those institutions in the charge of the MoE, teachers in technician colleges in the charge of the MoHRSS (e.g., Chinese labor ministry) have a lower level of identity with their occupation and colleges, which may be related to their traditional low social status and poor well-being of these schools and of the workers.

The research shows that the similar structures of students’ and teachers’ competence profiles imply the transfer of professional competence from teachers to students (Rauner 2015, 432). It is reasonable to conclude that the competence deficiencies of teachers restrain the holistic competence development of students. So trainers in the private training market, with competence profiles complementary to that of vocational school teachers’ existing (knowledge-oriented) profiles, is required.

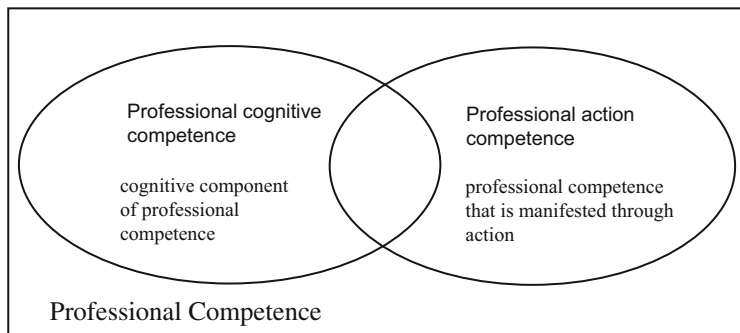

---

## The Predictive Validity of Professional Competence Assessments

COMET professional competence assessments have also raised some doubt and questions. There is a common concern: according to the COMET concept, pen-paper tests are organized to assess learners’ cognitive abilities. To what extent the results of such cognitive assessments can reflect test participants’ performance in real work process and contexts? This is the so-called predictive validity of competence assessments. Here we will discuss the accuracy of competence assessments in predicting the psychic traits or performance of test participant in the future working life.

## The Theoretical Framework

Professional competence refers to people’s ability to engage in a profession. It can be divided into the cognitive component, the component that is manifested through action, and the rest besides the two. As an operational definition, we understand the

**Fig. 8** Professional competence composition

cognitive component of professional competence as professional cognitive competence and the component that is manifested through action as professional action competence (Fig. 8).

### Professional Cognitive Competence

Professional cognitive competence refers to the cognitive competence that an individual needs to complete professional work. It is manifested as follows: to inform in work task, conditions, and context, to develop a reasonable action plan, to adjust the action plan based on the actual situation in the course of action, and to reflect on the course of action and results. Professional cognition is based on work experience and work process knowledge.

In professional working practice, theoretical knowledge can hardly guide and lead to a successful practice directly (Fischer and Boreham 2004). Work-related knowledge is not a mental state of an individual but a shared understanding built up through communication in the workplace. Work process knowledge is of great significance. It is the knowledge directly needed (as distinguished from theoretical knowledge) and self-acquired in the process of work. It is built up in the context of the successful establishment of work objectives, the development of plans, the implementation of plans, and the assessment on the results of the work (Fischer 2000, 121). Work process knowledge can be acquired through empirical learning, the application of theoretical knowledge, or reflection and integration of experience and theoretical knowledge acquired at work (Kruse 2002). Based on Benner's (1982) and others' empirical research, Rauner summarizes the characteristics of work process knowledge, i.e., sensitive, background, situational, paradigmatic, communicative, and forward-looking (Rauner 2017, 53). Work process knowledge exists in three levels, namely, occupation, organization, and individual (Lindberg 2003, 40–61). Occupational norms or practices belong to work process knowledge at the occupational level; business production and management processes belong to work process knowledge at the organizational level; in a specific work circumstance, an individual integrates knowledge at the occupational and organizational level to form work process knowledge at the individual level (Billet 1996). Cognition in

professional work has social and situational characteristics: The organization of labor which an individual works for is the basic unit that constitutes the society, and the cognition at work takes place in a particular social context (Lave 1988, 63).

### **Professional Action Competence**

Professional action competence is the professional competence manifested through action. It is the will and ability of individuals to think carefully and appropriately in specific occupational, social, and private situations and act responsibly for individuals and society (KMK 1996). During TVET learning process, action competence helps learners to design actions which are clear-headed, conscious, flexible, rational, and responsible with self-critical and reflective skills for complex and uncertain occupational contexts (Pätzold and Busian 2004, 504). The fundamental difference between professional action competence and skills is as follows: skills are manifested through the completion of a certain duty, while professional action competence can only be manifested through the completion of a complete professional task.

### **The Relations Between Professional Cognitive Competence and Professional Action Competence in Work Situation**

According to the action regulation theory, cognition is the starting point of action, which controls the action in the process and comes from the action. Cognition in professional work comes from professional action. Both are closely linked to solve problems at work. The individual cognitive process in work situation is a cycle of “identifying the problem – dialoguing with the situation – getting the response.” Work experience and work process knowledge help individuals identify problems and gain an understanding of the problem situation. The individual tests identified problems through “action” or “thinking operations” and then use work process knowledge to develop a solution. In doing so, they accumulate work experience focused on the current problem situation, which lays a foundation for solving similar problems in the future (Volpert 1982, 1987; Abeli 1980, 1981).

Professional action competence reflects the characteristics of professional action of individuals. Professional action is carried out in a specific society, organization, or community and subject to relevant norms. For specific problem situations, members of a community manifest similar professional actions; different problem situations trigger different actions. Complete actions include developing an action plan, implementing the action, and adjusting the action plan to the actual situation during the course of the action so as to ultimately achieve expected results. Professional tasks represent the typical work content and work style of the profession. The way of fulfilling the tasks and the results are usually open-ended (Howe 2008; Reinhold et al. 2003).

### **Research Methods**

The hypothesis that the research attempts to prove is that “the results of professional cognitive competence assessments can predict professional action competence.” Measurement indicators are chosen according to the following principles: “guided

by certain theoretical assumptions; can reflect the major dimensions of theoretical assumptions and research variables; and concise and feasible” (Dong 2008, 110). Two indicators, i.e., “informing” and “planning,” are used to measure professional cognitive competence, of which:

- Informing: refers to the search for information in complex and ambiguous situations and identifies key problems to define work objectives; after analyzing the gap between realities and the objectives, determine the subjective and objective conditions and tasks needed to achieve the objectives.
- Planning: devise a solution to the problem based on identified tasks, including the content, procedures, stages, and essential conditions of the work action. Consider the given equipment and organizational conditions, and determine the best solution from various options.

Two indicators, i.e., “implementation” and “assessment,” are used to measure professional action competence, of which:

- Implementation: refers to the process of work according to the best solution planned. There are often deviations between implementation and the plan. It is necessary to observe and record these deviations in time and make reasonable adjustments.
- Assessment: assess the work process and work achievements from various perspectives, including technology, economy, and the society.

Three training programs, i.e., automotive maintenance, CNC technology, and electrical automation, are chosen for the research of the predictive validity of professional cognitive competence tests. The professional work of these three programs has high requirements for professional cognitive competence and action competence and is representative for research questions.

We developed assessment tasks based on professional tasks and asked the test participants to complete the COMET competence assessment so as to assess their professional cognitive competence. After that, we asked the test participants to solve problems through practical actions so as to assess their professional action competence. Due to the complexity of the professional tasks and the length of time required to complete the tasks, the participants may experience fatigue and the accuracy of the tests may be reduced. In order to reduce the test time and ensure the representativeness of the test content, we developed two parallel assessment tasks, which were alternately distributed to the test participants during the assessment. Each participant only needed to complete one assessment task. This could ensure that the test content as a whole covers more than 50% of the professional work and learning content at corresponding stages. Here, “parallel” means that the assessment tasks have the same or very similar requirements on the participants’ competence. Whether the assessment task was “parallel” was judged by practice experts, and researchers made assessments by means of assessment techniques.

Based on the two main indicators to measure professional cognitive competence, i.e., “informing” and “planning,” and the two main indicators to measure professional action competence, i.e., “implementation” and “assessment,” we set out specific rating indicators and ensured the integration of the rating indicators of the professional cognitive competence assessment and those of the COMET program. Taking into account the high costs of professional action competence tests and the requirements of data analysis, we sampled by class at an affordable cost, taking two classes for each specialty.

According to the requirements of the assessment tasks, we requested relevant schools to provide qualified raters, test sites, equipment, materials, etc., before the tests. We rated based on the assessment criteria and on-site during the professional action competence assessment. For the specific content, the correlation analysis and the confirmatory factor analysis were conducted. Due to space limitations of this chapter, the research process and the specific data analysis are omitted.

### Findings Concerning the Predicative Validity of COMET

We found that the results of the COMET professional cognitive competence assessment can predict the professional action competence, and large-scale professional competence assessments can comprehensively and effectively assess professional competence.

- Training program of automobile maintenance: By using “informing” and “planning” to measure professional cognitive competence, and using “on-site analysis,” “preparation for maintenance and cleanup,” and “assessment” to measure professional action competence, we found that the standardized correlation coefficient between the results of the professional cognitive competence assessment and those of the professional action competence assessment was 0.32 ( $p < 0.01$ ).
- Training program of CNC technology: By using “informing” and “planning” to measure professional cognitive competence, and using “implementation” and “assessment” to measure professional action competence, we found that the standardized correlation coefficient between the results of the professional cognitive competence assessment and those of the professional action competence assessment was 0.60 ( $p < 0.01$ ).
- Training program of electrical automation specialty: By using “informing” and “planning” to measure professional cognitive competence, and using “installation,” “cleanup,” and “assessment” to measure professional action competence, we found that the standardized correlation coefficient between the results of the professional cognitive competence assessment and those of the professional action competence assessment was 0.55 ( $p < 0.01$ ).

According to the criterion of predictive validity, the correlation (or validity) coefficient between the test scores in practice and the real work performance rarely exceeds 0.5. In general, if the correlation (or validity) coefficient reaches 0.3 or

above, the test can be considered useful in predicting work performance (Biddle 2005, 79). The results show that the professional cognitive competence assessments for all the three training programs can predict professional action competence, which proves that large-scale professional competence assessments can not only directly assess professional cognitive competence but also effectively predict professional action competence.

The research also found that in different occupational fields or training programs, there are differences in the influences of mechanisms of professional cognitive competence on professional action. For the automotive maintenance sector, “planning” has a direct influence on “on-site analysis” and “maintenance,” with the standardized path coefficient of 0.10 and 0.15, respectively. For the CNC technology sector, “planning” has a direct influence on “implementation,” while “informing” has a direct and relatively large influence on “assessment,” with the standardized path coefficient of 0.29 and 0.18, respectively. Different influencing mechanisms led to the difference in the predictive validity of professional cognitive competence assessments on professional action competence in different sectors. For the CNC technology sector, the content of the existing assessment has high predictive validity. For the automotive maintenance sector, the standardized path coefficient of “on-site analysis (fault detection) → maintenance” reaches 0.55. If the assessment on the cognitive competence during the onsite analysis is included in addition to the existing assessment content, the predictive validity of the professional cognitive competence assessment will be further improved.

---

## Conclusion

COMET professional competence assessments can effectively evaluate professional competence. Such large-scale assessments can not only diagnose the level and characteristics of professional cognitive competence but also effectively predict professional action competence. In addition to assessing professional competence, COMET assessments can collect factors affecting professional competence development at the individual, school, enterprises, national, or regional levels through background questionnaires, so as to provide key parameters on the quality of TVET, to help education and labor authorities improve their ability of designing the TVET system and controlling training quality, and to provide an empirical basis for constructive dialogue and cooperation among all actors engaged in TVET.

However, it is difficult to track data in large-scale professional competence assessments, so it is hard to assess the process of students’ professional competence development. Longitudinal research and design is a key component of assessment research in the future.

Some international companies in China such as SAIC Motor and Apple have noticed the inspiration of the COMET assessment for human resource development, like the competence assessment for recruitment and the design of learning tasks for in-company training, who began to introduce its leading ideas and competence

model. The Japanese company FANUC even plans to develop its own trainer's competence profile and to train the trainers of its end-user organizations accordingly. Some training companies specializing in the development of educational technology are also trying to develop intelligent, scenario-based e-learning resources based on the COMET concept, so as to provide simulation training and capability evaluation services based on artificial intelligence technology for high-tech work. Whether this kind of effort will be successful depends on the effectiveness of COMET assessment model, especially the integration of scoring technology and artificial intelligence.

## Abstract

The Sainsbury (Report of the independent panel on technical education, Department for Education and Skills, London, 2016) draws attention to the importance of ensuring that proposed new standards for vocational and technical education in England are not reduced to the simplistic functional analysis of narrow job roles (an approach prevalent in England from the 1980s to the present), or limited to

include only the short-term, instrumental needs of individual employers. This lesson is either hard to hear or difficult to learn. Over 20 years ago, Wolf (Competence based assessment. Open University Press, London, 1995) and, more recently, Wolf (Review of vocational education. Department of Business Education and Skills, London, 2011) warned of dangers in the use of functional analysis in the development of vocational standards on the grounds that such approaches tend to lead to the production of “bewildering lists of atomised ‘skills’ and a rather ‘tick-box’ approach to vocational assessment.” Behind this stands the deeper point, that the search to find an absolutely perfect list of vocational standards of knowledge, skills, and attitudes is costly, time-consuming, and ultimately self-defeating because, at the end of the day, all that you have is a longer/different list. Sennett (*The Craftsman*. Penguin, London, 2008) reminds us that what we mean by good quality work and what we consider to be effective approaches to assessment are central to good educational practice in a wide variety of vocational contexts. Literature from the field of educational research supports the claim that when teaching, learning, and assessment are seen as integrated forms of good educational practice, high levels of achievement can be realized. However, meaningful and workable standards of quality and research-informed assessment practice are not yet well understood or widely evident in the English system of vocational education and training (and possibly elsewhere).

## Introduction

The history of education is marked by spirited and often contentious debates about its nature and purpose. It is interesting to note how the purposes and practices of education differ from time to time and place to place. These variations are partly due to the cultural, social, economic, and political priorities of the time and partly to do with different ideas about what constitutes knowledge and truth (Lawton and Gordon 2002).

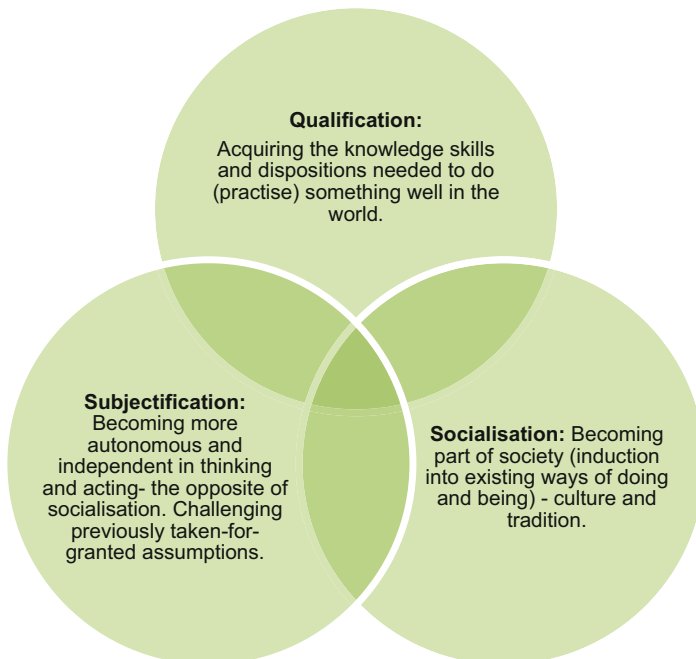

This chapter focuses upon the practices of vocational education and the development of craft. It traces the establishment standards of quality and approaches to assessment in vocational education, beginning with their origins in ancient Greece, through the early craft guilds of the middle-ages and beyond to policy initiatives which have impacted upon vocational educational in England from 1980s to the present. It aims to demonstrate how and why standards of quality and assessment practices in vocational education today might be better informed by returning to enduring understandings of what we mean by good quality work; questions of how to make vocational standards meaningful and workable in practice and by paying attention to how research evidence from the field of formative assessment might contribute to improvements in assessment practice in contemporary vocational education.

In England, the term vocational still carries second-rate connotations, in a culture where “academic” and “professional” education are prized above an education for the purpose of pursuing a craft or “trade.” Dewey (1916, 1933) is critical of such narrow thinking. He points to the importance of recognizing that the meaning of the word “vocation” (from the Latin *vocātiō*) involves a calling to do something well in the world for its own sake. This includes the intrinsic rewards that come from knowing that we have done something well, sometimes in the interests of others.

Dewey argues that it is necessary to define the meaning of a vocation with some fullness in order to avoid giving the impression that an education centered upon a vocation is narrowly practical or something that is done just for financial reward. Carr (1987) describes these returns as “delivering the internal moral goods of education” – the intrinsic rewards that come from doing a job well for its own sake. Most of us have experienced the personal fulfilment and other intrinsic rewards that accompany a sense of a job well done. On the other hand, the consequences of being on the receiving end of a badly designed/poor quality product or a shoddy service are all too familiar.

In relation to the question of “good” education, Biesta (2010) invites us to reconnect with considerations of the purposes of education. He identifies three fundamental dimensions of education, *subjectification*, *qualification*, and *socialization*. These are presented and described in the context of this chapter as follows:

The overlapping sections within Biesta’s (2010) Venn diagram underscore the argument advanced above by Dewey, regarding the importance of educating the whole person and not just “training” in a narrow skill or “teaching to the test.”

In the next section, the limitations of training solely for narrow job roles and the short-term instrumental needs of individual employers will be discussed more fully.

---

## Main Discussion

### Curriculum Design and Assessment in Vocational Education

Young (2008, p. 128) notes how in England the *Review of Vocational Qualifications* in 1987, signposted “a shift. . . from a qualification system based on *shared practices* and professional judgment, to one based on formally explicit *criteria*, capable of being defined independently of any specific experience or practice” (original emphasis).

Through the work of Raggatt and Williams (1999), Young points out that support for this type of vocational reform was initially tied to the government’s determination to break the power of trade unions, which they saw as using trade and craft qualifications to perpetuate restrictive practices. Young also notes that,

The attempt to ‘break with the past’ has been a familiar feature of qualification reform, and not only associated with the political Right. Similar frameworks have been introduced in Wales and Scotland strongly supported by the New Left of Centre coalitions leading the Assembly and Parliamentary Executives. (Young 2008, p. 129)

Young locates the roots of this shift to a political culture fuelled by the market-driven dogma of consecutive Conservative and New Labour governments. This he argues, marked the introduction of a more “user-led” vocational education and training system based upon competition and commercial values rather than upon more enduring educational concerns.

Drawing upon examples from England, New Zealand, and South Africa, Young supports Wolf (1995) where he identifies how the use of functional analysis in specifying vocational standards and developing outcomes-based qualifications has led to impenetrable jargon, endless over-specification, bureaucratic assessment procedures, and the trivializing of vocational learning. This move he argues has led to resistance rather than support from universities and other professional bodies, in part at least because it has tended to neglect the importance of curriculum content, context, and the role and nature of vocational pedagogy.

Elliott (2001) and Coffield (2008) draw attention to the ways in which outcomes-based qualifications and functional analysis, coupled with “top-down” approaches to the development, implementation, and evaluation of policy in vocational education and training in England, have led to an avalanche of policy initiatives and the specification of too many standards which, in turn, have become chronically over-prescribed. Functional analysis and outcomes-based qualifications have certainly not served the English system of vocational education well to date (Wolf 2011). There is clearly a big gap between specifying a set of standards and making them “good” in

practice. The amount of new learning involved in making vocational standards “good” in practice is often underestimated and even ignored in favor of political “quick fixes” and questionable claims regarding their success (Eraut 2004; Coffield 2008; Sennett 2008).

It is becoming increasingly obvious that long lists of vocational standards and outcomes-based qualifications cannot be put into practice effectively and that vocational standards arrived at via functional analysis and outcomes-based qualification appear to be ironically dysfunctional and unfit for purpose (Wolf 1995, 2011; Young 2008; Sainsbury 2016).

In the search to find the perfect list of knowledge, skills, and attitudes, functional analysis has generated lists of baffling complexity, which have proved to be difficult if not impossible to realize in practice.

Coffield (2008) notes wryly, that the English Emperor of Vocational Standards has “too many clothes!”

The shortcomings of current understandings of what counts as quality and what constitutes good assessment practice in vocational education and training in England are increasingly recognized and reported in the literature (Sainsbury 2016; Commission for Adult Vocational Teaching and Learning (CAVTL) 2013; Wolf 1995, 2011; Young 2008). If we accept that these curriculum, problems and their consequences in practice can occur at all levels of the education system, then we can see that a sound understanding of standards of quality and good assessment practice are as vital for teachers of vocational and technical education and training, as they are for teachers in any other sector of education.

The introduction of the Apprenticeship Levy in England in April 2017 offers employers opportunities to collaborate with providers of vocational and technical education to develop qualifications in which vocational standards and the assessment of learning can move beyond functional analysis, outcomes-based qualifications, and the ticking of lists. The success of the New Apprenticeship Standards in England will to a large extent depend upon how far curriculum design, pedagogy, and assessment practice in the field of vocational and technical education can loosen the grip of approaches to the specification and assessment of vocational standards which were introduced in England in the 1980s and are now ubiquitous across the sector.

This chapter argues that a sea change is needed in terms of perceptions of standards of quality, outcomes-based qualifications, and approaches to assessment in vocational education. It extends an invitation to the reader to engage in a discourse, which aims to enable vocational education to move beyond the use of long lists of occupational standards and assessment regimes based upon checklists. This will require, however, a return to considerations of what we take to be good quality work and how the craft of experience and the development of practice have been learned, modified, and extended into new crafts and practices in vocational education across centuries. As the actor Jake Gyllenhaal (2016) reminds us, “craft is in every job done well . . . and there is a public obligation and a duty upon each of us to practise our craft well.”

## Work and Standards of Quality in Vocational Education

For most people work is a necessity not an option. We work to make a living and in order to make a living we have to learn to do (or practice) something in the world, which is acceptable and of value to others and in which, ideally, we can find both intrinsic and extrinsic rewards. Dunne (2005) defines a “practice” as,

A coherent and invariably quite complex set of activities and tasks that has evolved co-operatively and cumulatively over time. It is alive in the community who are its insiders (i.e. its genuine practitioners) and it stays alive only so long as they sustain a commitment to creatively develop and extend it – sometimes by shifts which may at the time seem dramatic or even subversive. Central to any such practice are standards of excellence, themselves subject to development and redefinition, which demand responsiveness from those who are, or are trying to become practitioners. Dunne 2005, pp. 152–153

For Dunne, from this perspective, the range of “practice” includes examples as various as “cabinet-making, physics, farming, chess, computer-programming, metal-work, the study of history, rearing a family, music-making, drama-production, soccer and weaving” (p. 154). In acquiring a practice or a craft we learn how others think and have thought (Lipman 2003). How they have gone about making a living in this way before us. We also learn something of the history, traditions, skills, routines, and rituals of the craft we are pursuing and how we got to where we are in practice. Sennett (2012) observes that we make the way we live together through concrete practices and that these say a lot about the human condition. For Sennett, this includes our need and ability to co-operate with each other so that we can do together what we cannot do on our own. The concrete practices we use as we go about passing on craft knowledge and skills to future generations are perhaps the most important of all because they signal assumptions about what we think it means to learn a craft and to practice it well. They also mark our taken-for-granted understandings of: how skills should be passed from generation to generation; how we should arrive at assessments of progress; how we should recognize improvement and achievement in practice; and how we should make judgments about what we mean by and take to be good quality work.

Sennett (2008, p. 52) describes a “skill as a trained practice,” which begins with careful observation, imitation, and repetition and progresses in line with how repetition is organized. The first stage of skill acquisition he argues involves “ingraining the habit” through disciplined observation, obedience, imitation, and investigative repetition.

From the above points of view, a skill can be seen as a set of trained coherent and complex activities, which through practice (repetition/problem-finding and problem-solving) and critique can lead to the mastery, creative development, and extension of standards of excellence, which are themselves subject to active development and redefinition by practitioners in the light of practical experience.

The difference between brute imitation of procedure and the larger understanding of how to use what we know, Sennett contends is a mark of all skill development. Sennett notes that a person who cannot observe, cannot enter into an open dialogue

with someone more skilled about how to improve a practice. This is because the open relationship between problem-finding, problem-solving, and critique that builds and expands skills cannot be reduced or confined to a one-off demonstration or event. For Sennett, practice must develop through observation in conversation, in dialogic and open-ended ways which encourage the apprentice to think for themselves in action, as they interact with the tools, materials, objects, and human beings in the context of their practice and as they address often complex, unexpected, and unfolding problems at work (CAVTL 2013).

Sennett (2008, p. 80) points out that “there can be no skilled work without standards.”

He uses the term “embedding” to describe a process which he maintains is essential to all skills development, a process which involves the conversion of information and practices into tacit knowledge which has become so routinized that we don’t have to think about it.

In learning a skill we develop a complicated repertoire of such procedures. In the higher stages of skill there is a constant interplay between tacit knowledge and self-conscious awareness, the tacit knowledge serving as an anchor, the explicit awareness serving as critique and corrective. Craft quality emerges from this higher stage, in judgments made on tacit habits and suppositions. Sennett 2008, p. 50

In relation to the question of the role and nature of vocational standards, Sennett invites us to begin by considering what we mean by good quality work. One way to go about this, he suggests, is to specify how something should be done, a standard of absolute correctness (which he points out is rarely, if ever, reached). Another way to look at the issue of quality, he argues, is as a standard, which is good enough to get something to work (functionality - getting something finished to a standard where it can be used).

The deeper point, Sennett alludes to here, is that this dichotomy may be false.

He maintains that standards of practice (including tacit knowledge) are best passed on when they are embodied in a human being through shared practice and mutual engagement in the exercising of professional judgment in context, rather than in a lifeless, static code of practice. To do good work, he contends, means being curious about practice. This involves investigating and being able to learn from ambiguity in a “liminal” or “transactional” zone between problem-finding and problem-solving. Echoing Dewey’s (1933, 1934) pragmatic epistemology, Sennett calls for a more holistic form or standard of practice which involves, observation, investigative repetition, dialogue, and critique including learning to understand material/social resistances encountered in contexts where things do not always go as expected. Learning how to act in a “liminal” or “transactional” zone of practice, where it is difficult to know what to do next, takes us well beyond the ticking of checklists. Recognition of this liminal zone is important Sennett claims, because human experience and reality do not fit neatly into discrete or narrow systems of classifying practice. For Sennett, good practice has to be able to admit the unexpected, encourage experiment, and recognize the importance of contingency and context.

When a set of vocational standards begins to constantly churn out, reform in terms of ever more prescriptive lists of atomized standards and skills in the search for absolute perfection, the volume and pace of reform, “doesn’t allow the tacit anchor to develop, then the motor of judgement stalls” (Sennett 2008, p. 50). He goes on to draw attention to how, in such situations, “people have no experience to judge, only a set of abstract propositions about good quality work” (ibid.).

The experiential standard is treated with suspicion. In other words, people are expected to act as if experience is *not* real and as if abstract, absolute standards *are* real.

Young (2008) demonstrates how authors of vocational standards across the years who have attempted to eliminate embedded knowledge in the name of rational analysis have discovered to their cost that tacit knowledge does not easily translate into words or readily submit to being framed in terms of logical propositions.

On one hand, in relying upon standards of practice alone, people may simply muddle through settling for the “quick fix,” producing what is acceptable or even mediocre, neglecting the pursuit of higher standards. On the other, absolute standards of quality may prove to be too abstract and unworkable in practice. People need to learn how to put things into practice and that takes time, mutual engagement, and cooperation (Sennett 2008, 2012; Fielding et al. 2005). It also involves the opening up of dialogue and spaces at work where people can problem-solve, problem-find, imagine, invent, and share ways of working and being together as they learn about how to put good ideas into practice in new ways in complex and unfolding situations and contexts (Gregson and Hillier 2015; Sennett 2012; Eraut 2004).

Sennett asks us to consider three fundamental questions central to good vocational education. Firstly what we mean by good quality work including how to make standards of good quality work explicit, meaningful, and workable in practice? Secondly, how to encourage dynamic problem-finding, problem-solving, and curiosity in practice? Finally, how to create conditions where shared experience of resistance and ambiguity become the basis of a critical dialogue which enables and encourages people to work together in realizing the highest standards of practice?

When these principles of good vocational education are embedded in practice, Sennett claims, the lessons of experience can become the basis of a “dialogue between tacit knowledge and explicit critique” (2008, p. 51) in the pursuit of ever-higher standards of practice.

---

## Issues of Assessment in Vocational Education

In establishing the purpose of a system of education, a course of study or a single lesson, in other words what it is “for,” then it is wise to look carefully at its assessment practices and procedures (Rowntree 1977). Approaches to assessment adopted by political administrations, education, and training organizations and businesses can reveal (often despite rhetoric to the contrary) what is really valued and what is actually rewarded in practice.

In vocational education, assessment practices and procedures signal to learners and tutors what they need to do (or not do) in order to achieve success. It is important therefore that vocational tutors are aware of the messages that different approaches to assessment transmit to learners. As argued above, vocational education and training involves learning to do something in the world. It also includes encouraging and nurturing the disposition to do it well, including being able to stand back from the world and look critically at what is taken-for-granted so that we can begin to see what we could do better and how things might be done differently.

Hyland (2009) draws attention to the “undifferentiated rise of skills talk and an obsession with prescriptive learning outcomes” in vocational education in England. He argues that this discourse and, the practices that accompany it, reduce vocational education to a “predominantly utilitarian, one-sided, economic conception, which suggests that all that counts is providing bits of evidence to satisfy narrow, mechanistic performance criteria” (Hyland 2009, p. 122). If for example, all that is taught and all that is learned on a course or in a lesson is how to *conform* to existing practices and centrally prescribed standards, assessed through narrow and instrumental learning outcomes, then it is easy to see how vocational learning can become, at best, instrumental and superficial, at worst, mechanical, manipulative, out of date, or even useless.

Important contributing factors to “good” vocational education (as argued above) include providing opportunities for observation, participation, imitation, investigative repetition, problem-finding, problem-solving, critical dialogue, autonomy, mutual engagement and cooperation, as well as developing the disposition and capacity to take pride in a job well done.

According to the national Commission for Adult and Vocational Training in England (CAVTL 2013), approaches to assessment in vocational education for the twenty-first century should enable and encourage students to acquire well-developed capacities for careful thinking and systematic, situated, practical problem-solving. CAVTL also call for the development of assessment practices and procedures across the sector that enhance learning in ways which encourage people to develop the capacity to respond effectively to unexpected developments in life and in the workplace through individual and collective learning so that they can share and solve problems together in a wide range of immediate situations and in the future. This is a far cry from the discrete specification of narrow and prescriptive learning outcomes and the provision of fragmented bits of evidence to demonstrate that they have been met.

Empirical research and literature from the field of formative assessment support claims that the guiding principles of formative assessment, active learning, making learning explicit, questioning, critical dialogue, problem-finding, problem-solving, self-assessment – helping learners to assess their own progress as part of the learning process, formative feedback, “closing the gap” assessment and the identification of next “steps to success” can enable learners individually and collectively to realize high levels of learning and achievement. However it is also worth noting that to date, this research has largely been conducted in schools and some of the guiding principles and techniques advanced by (among others) Wiliam (2006) and Clarke

(2001, 2008) may not be appropriate to the many sites of practice of vocational education. That does not mean, however, that we should not explore the potential of contributions from this field of research to the development of approaches to assessment in contemporary vocational practice.

From the above, it is clear that the guiding principles and techniques of formative assessment resonate with many of the practices, which have resided at the core of learning a craft for a very long time. This is not to argue that formative assessment is currently completely absent from assessment practice in vocational education today. Indeed (as argued above), it could be claimed that the “mastery” of any craft has always involved observation, questioning, formative feedback, problem-finding, problem-solving, co-operation, the development of tacit knowledge, and explicit critique. A key point to note, however, is that while some formative assessment practice is evident in vocational education, it is currently being pushed to the margins, by the dominance of centrally prescribed, vocational standards based upon technocratic functional analysis, outcomes-based qualifications, and tick box approaches to assessment. Such highly instrumental assessment purposes and practices are in danger closing down the conversations and “spaces” in which formative assessment and the dynamic development of practice need to operate. Formative assessment is becoming disconnected from vocational practice to the extent that its guiding principles and techniques are not being used to their fullest capacity in vocational education contexts.

Drawing attention to how active learning is at the heart of formative assessment, Clarke (2001) illustrates that as with most things of any importance in education, formative assessment has been argued over, misinterpreted, and misused. She urges teachers and other educational professionals not to regard formative assessment as a series of techniques or “recipes” that can simply be mechanically “inserted” into educational practice, but rather seen as a kind of social practice which *integrates* assessment, learning, and teaching. She foregrounds how the techniques of formative assessment must always be put into practice in ways that promote active learning.

Clarke (1998, pp. 50–73) offers practical strategies illustrating how formative comments on written work can enable learners to see how they can begin to “close the gap” between their current and potential levels of achievement. Clarke (2008) demonstrates how the use of open questions and the identification and discussion of success criteria and process objectives can not only help learners to think more critically, carefully, and for themselves but also improve their learning and achievement. She argues that the use of open questions, the articulation and negotiation of “process success criteria,” and self and peer assessment are important in helping learners to “see” and share what success looks like and to learn from these shared understandings. These techniques, she maintains, are particularly helpful in enabling learners to recognize what is involved in the experiential and incremental process of moving towards success in their learning.

In order to maintain the principle of active learning in formative assessment, Clarke advises teachers to collaborate with the learners in planning; deciding contexts for learning; identifying success criteria; discussing “good work”/quality;

engaging in continual paired or whole group talk; critically analyzing learning as it is happening and through constantly reviewing what success and improvement means and looks like in practice. Guiding principles of formative assessment, first developed by Wiliam (2006) and later extended by Clarke (2008), are illustrated more fully in [Appendix 1](#).

---

## **Good Quality Work and Making Vocational Standards Explicit**

In considering the question of what we mean by good quality work and how to make standards of good quality work explicit, meaningful, and workable in practice, it may be helpful to look back before we look forward.

Lopez (1971) describes a time when the journey into a craft was literal and embodied in a wandering way of life in which craft workers moved from place to place plying their trade. The workshop, historically one of the oldest economic and social institutions, is significant because it signals settlement. In ancient Greece, through the use of more sophisticated if less portable tools, the workshop demonstrated how shared and settled workers could become more skilled than their itinerant counterparts. The growth of urban workshops in medieval times led to the establishment of craft guilds designed to manage conflict between competing workshops and to act as gatekeepers in assuring the authenticity and quality of the goods produced. Masters who owned the workshops contracted apprentices for 7 years. Apprenticeships came at a price, the costs usually paid by the parents of the young person in question. Journeymen who had completed their apprenticeships were contracted by masters for a further 3 years. The workshop doubled as the home for all three levels of craft worker and they lived and worked on the premises. At the end of their training, the apprentice presented a piece of work, which demonstrated to the rest of the workshop what they could achieve. The apprentice's presentation was largely focused on copying or imitating the journeyman or master with the master being the initial (and often final) judge of the quality of the work. This work was sometimes subsequently exhibited in the guildhall and could be commented upon by anyone in the city. Apprentices were not allowed to speak or explain their work during the assessment/exhibition nor were their journeymen or masters.

The work was expected to speak for itself.

Judges of the apprentice's final work engaged in shared critical thinking identifying the merits of each object and then decided if the work was good enough to pass. Apprentices whose work was not of a sufficiently good standard were given a second and sometimes a third chance to try again the following year. What is lost in this account are the moments of critical dialogue, shared practice, co-operation, mutual engagement in demanding tasks, problem-finding, problem-solving, and the exercise of professional judgment in context, which were threaded extensively and powerfully throughout the apprentice's everyday experience and deeply embedded in the formative and summative processes of assessment which contributed to the development of their practice prior to the final assessment of their work. In these relational circumstances, the spoken word, direct observation, repetition,

problem-finding, problem-solving, assessment criteria, explicit critique, feedback, and co-operation were and remain central pedagogical features in the development of practice.

Today in the workshop, studio, office, factory, or laboratory, the spoken word can often still prove to be more effective than written instructions. When a procedure becomes difficult, it is usually quite easy to ask someone else for advice. For this to happen you both often have to be in the same place at the same time. An advantage of this arrangement is that learning becomes local. A disadvantage, however, is that it also becomes less portable/accessible beyond the immediate context of the practice.

Modern journeys into practice have come to rely heavily upon the written word in the form of long lists of pre-specified, prescribed standards, framed in terms of discrete competences, which are in turn made up of knowledge skills and attitudes to be demonstrated and assessed through the completion of checklists. The language of instruction used to make the standards explicit is often expressed as verbs framed in terms of observable and measurable cognitive, psychomotor, and affective commands/outcomes. However, as Sennett (2008, p. 183) points out, “verbs name acts rather than explain the process of acting; this is why they tell rather than show . . . in their sheer number and density the verbs cast an illusory spell; in reality the verbs are at once specific and inoperative.” A problem here is that, while each verb used in contemporary vocational standards issues a command often framed in the terms of Cognitive, Psychomotor and Affective Domains set out in Bloom’s (1956) Taxonomy of Educational Objectives and although the list of commands may (arguably) be accurate, they are simply not enough to support vocational learning effectively. One reason for this is because they do not explain the process of acting. Another is that they do not attend to ways of thinking and acting in the cognitive, affective, and psychomotor domain, nor do they accommodate how learning in all three domains interacts in human thinking and in doing or making something in the world. They are also ominously silent on the subject of the internal rewards that come to human beings from doing a job well and together to the highest possible standard. Furthermore, written lists of standards do not help to convey what success looks, feels, sounds, smells, or taste like in the process of doing something well. Finally such lists rest upon the assumption that progress in the development of a skill is linear, thereby overlooking or underestimating the irregular developments, cul-de-sacs and detours which are the hallmark of the journeys towards skill development that most of us experience.

Put together by (often remote) experts, these lists of verbs are often only serviceable to someone who is already highly familiar with, and so experienced in, performing the task that they may well have forgotten what it was like to learn to do it in the first place. The paralyzing volume, density, tone of authority, and certainty in much of the language of contemporary standards of vocational education provide a clear indication of the writer’s inability to reimagine the insecurities and vulnerabilities involved in learning a practice in the first place (Sennett 2008) . . . including the *experience* and feelings of insecurity and lack of confidence involved of learning how to do something on our own for the first time.

Writers of new vocational standards, Sennett argues need to be able to share experiences of learning a practice by returning to the liminal point just before they themselves were competent and able to complete the task; just before they mastered the practice; before their routinized habits were formed. Reliving the threshold between knowing what to do and not knowing what to do is crucial in order to be able guide others in learning a practice. They need to be able to explain and make accessible, the process of acting. It is not enough just to name the act. Sennett (2008, p. 183) cautions, “familiarity risks producing only dead denotation. . . the challenge posed by dead denotation is precisely to take apart tacit knowledge which requires bringing to the surface of consciousness what has become so evident and habitual that it seems just natural.”

Anyone who has ever tried to assemble at home something bought on the internet or in a large department store, for example, a bean to cup coffee-maker, digital camera, sewing-machine, etc., only to find themselves faced with a confusing set of instructions, knows the problem. The need to turn to other human beings (sometimes literally, more often now via a web search engine) who have found the same problem and solved it becomes particularly pressing. Sometimes we are able to watch and listen as the “expert” shows and tells us what to do as in sites (for example when using YouTube) where we can watch the demonstration again and again, pausing at different points in the action, until we understand the instructions well enough to try to put them into practice. At other times, we are able to enter into a written dialogue with a remote “expert” on the web in order to ask a specific question to which we receive a written response (for example, when using a search engine such as Google) to which we can then, if necessary, ask another question.

The language and principles of instruction that we use to make standards of good work explicit, meaningful, and workable in practice matter because specific kinds of writing can confuse and bewilder or enable and empower us. Linguistic tools can help us to gain an overall sense of a practice as well as being able to imagine how others have thought, felt, and acted as they learned the practice before us. The challenge for writers of vocational standards is to present written instructions in ways which communicate a vivid sense of the practice overall, including a vicarious experience of what it means to learn the practice and to practice it well. This includes aiming specifically to inspire confidence by reminding vocational learners when a new task is similar to something they have done before.

Writers of new vocational standards will need to be able to retrace their steps to access the tacit knowledge that has become embedded into routine. The expert knows what comes next and where the danger lies. As such, they will need to be able to act as vicarious “masters” and “journeymen” in situations where face-to-face communication and co-operation in the same physical location are not always possible. Rather than getting rid of explicit written standards of vocational education, the challenge is to make them more manageable, intelligible, educational, and workable in practice. The first step as Wolf (2011) and Sainsbury (2016) suggest will be to ensure that there are less of them. New vocational standards will need to be based upon a coherent and grounded approach, articulated clearly enough to ensure national consistency but also broadly enough to be capable of accommodating a

locally negotiated proportion of practice and flexible enough to reflect context and employer need.

Such standards will need to take the importance and dynamics of face-to-face and remote observation and dialogue seriously. They will also need to provide supporting written materials framed in expressive language which not only instructs (tells) but also explains (shows) and supportively illustrates how practice is acquired and developed. This might best be achieved, Sennett (2008) argues, through representations of vivid accounts of experience (including liminal and affective experiences of learning), written and digital narratives, story, analogy, images, metaphors, and other linguistic tools which can bring to light the processes of practice fashioned from words, sounds, and images.

The same authors will need to remember and value what is ancient and enduring in the human condition, human capabilities of thinking and experiences of learning and thinking through making. The making of a craft and the experience of acquiring a practice include finding ways of being in the “presence” (one way or another) of those who have practiced the craft before us and those who continue to practice it with us.

---

## Vocational Pedagogy

In turning to the second question of problem-finding, problem-solving, and the development of tacit knowledge, it might at first appear that in order to learn a craft all we need to do is to simply observe, copy, and imitate the practices of skilled others until these skills become part of our own practice. However, the process of acquiring a craft is far less mindless, infinitely more interesting and much more complex. We watch to “develop an eye” for what is important to notice. We listen to “develop an ear” for sounds we should expect to hear. We touch, grasp, and hold to “develop a feel” for the tools, materials, and objects of practice. In some crafts we feel, smell, or taste to detect when something is going right or wrong. We co-operate with those who have already mastered the craft to develop a feeling for all of these senses in action in the rhythms, rituals, and social behaviors of practice – what it means to become and eventually be a member of this community of craft. We travel in the company of others on our journeys in practice.

From medieval apprenticeships onwards, programs of vocational education worthy of the name have encouraged apprentices to look at practice in the round to see its many sides. Historically this has been done in cooperation and dialogue with “masters” of craft and “journeymen.” The starting point has been, and arguably always will be, in developing an overall sense of the purpose, dignity, history, and currency of the craft and what it means to practice it well. Once this overall sense of the practice has been established, the values or “inner goods” of the practice (Dunne 2005) can begin to be realized. At this stage, Biesta’s *socialization* (2010) – induction into existing ways of doing and being culture and tradition can be introduced. At the same time, the apprentice can begin to focus upon particularly challenging/testing aspects of tasks, developing their skills through repetition and the forensic investigation of practice.

In order to develop a practice, Sennett argues, you have to repeat (practice) the skill until it becomes an ingrained routine and then by building up skills in sequence. He also notes that practicing although largely a solitary activity is not mindless repetition but often a forensic, investigative, experiential, and incremental process, which involves doing, judging, and improving at the same time. From this point onwards, Sennett contends skills open up through dialogue because the rhythm of solving and opening up needs to occur again and again in order for the apprentice to move beyond simple repetition of a practice towards ever higher mastery of a skill. For Sennett, the length of a practice session must be judged wisely to ensure that the number of times a practice is repeated is no more than an individual's attention span at a given stage and that as skill expands, the capacity to sustain repetition increases, so that the better your technique the more you can practice and improve it without becoming bored.

Sennett also points out that when a practice is simplistically organized as in a "one-off/checklist" means to a fixed end, the system becomes closed not open, so that the person being trained will meet a fixed target but will not progress (2008, pp. 37–38). In co-operating with a "master" who is more skilled than yourself, you enter into a dialogic open-ended conversation where each becomes more aware of the other's views/experiences and practices, expanding your understandings of one another. This is an exchange for mutual benefit, which involves questioning, re-phrasing, working together forensically to investigate concrete problems in order to understand "resistances" when things do not go as expected. In these "liminal" or "transactional" spaces the apprentice and the "master" can pay attention to the gap between the written page and the act (the gaps between the boxes in the checklist and experiences of practice). For each skill the apprentice learns, they need to develop, what Sennett describes as, a "quiver of techniques" to deal with differences in materials, tools, temperatures, machines, etc., as well as the range, context, and purpose of the practice. These might be developed for example by making, repairing (restoring, remediating, or reconfiguring) the object(s) of practice. Through the dynamics of observation, repetition, practice, and critical dialogue involved in working cooperatively with those who have already mastered the craft, the "unspoken and uncodified words and the thousand little everyday moves" (Sennett 2008, p. 77) that add up in sum to the tacit knowledge in a practice, start to become more explicit and a matter of habit for the apprentice.

Having explored issues in the development of vocational standards, including the role and nature of problem-solving, problem-finding, and tacit knowledge, we now turn to the third question of how to ensure that practice moves forward and that the pursuit of higher standards is not neglected in the name of the "quick-fix," marginalized as a luxury or caught in the vice of instrumental mediocrity.

The question then becomes how the lessons of experience (not only of the apprentice, but also the "journeyman" and the "master") can become the basis of a "dialogue between tacit knowledge and explicit critique" (2008, p. 51). For Sennett, this involves creating conditions where experience and ambiguity become the basis of a critical dialogue designed to enable people to work together in realizing the highest standards of practice.

Once again we return the issue of how to encourage problem-finding, problem-solving, curiosity in practice in a “liminal” or “transactional” space or threshold where apprentice (and possibly “master”) have left the tried and true, what they thought they knew and what they have not yet been able to replace, with anything else. This might involve beginning to question an already ingrained or existing habit in the interests of finding and re-ingraining a better habit. This can also include the modification of an existing habit or introducing a new way of thinking and acting which changes an aspect of practice or “transcends” existing practice to create a new practice or craft.

In circumstances when we are faced with a situation in which it is not clear what to do next, we enter into a dialogue between tacit knowledge and explicit critique where we can imagine or invent a new practice or simply improve an existing one. This might involve nothing more or less than an apprentice or “journeyman” finding their own way of making/saying/doing the practice – a practice which now has their own craft/skilled character stamped upon it – their unique style or way of doing. On the other hand, it might involve introducing an aspect of practice, which fundamentally changes the very way we go about the practice itself. In these “liminal” or “transactional” moments, the open-ended quality of the dialogue, coupled with the ability to critique and challenge what has until then been taken-for-granted, become powerful and integral drivers in the pursuit of the highest standards of practice.

---

## Engaging, Modifying, and Transcending Practice

Becoming good and being able to excel in a craft has always involved engaging in the characteristic tasks of a practice which embody standards which challenge us because at some point they are beyond us. When this goes well, Dunne (2005) argues it leads us not only to the mastery of the craft but also to the development of the moral qualities which enable us to transcend it. These qualities mark us out not just as a practitioner in that domain of craft but also as a person in life.

Dunne identifies “internal goods” as intrinsic rewards that come from doing something well. For Dunne, an internal good arises only in the context of the practice in which a person becomes engaged. To really engage with a practice in the sense of striving to realize the intrinsic goods and not just treat the practice as a means for attaining external good, he argues, is to acquire qualities such as honesty and humility (for example, in admitting the shortcomings of our attempts); patience and courage in sticking to a task even when it does not offer immediate gratification; a sense of justice and generosity in co-operating with others in projects that require a kind of partnership which overrides the rivalries of individuals as they work together to rise and respond to the demands of the practice itself. In such circumstances, if and when a person really “comes to excel, it need not be at the cost of other people’s chances to develop *their* talents. Every achievement of excellence enriches all who participate in or care about a practice” (original emphasis, Dunne 2005, p. 153).

It seems likely that many people have been greatly short-changed in their education because they were introduced to activities not as practices, but rather as sites where decomposed

drills, exercises and ‘micro-skills’ were rehearsed as means, while a taste for the whole activity as an end was continually deferred or displaced. (Dunne 2005, p. 154)

Responding to the difficulties involved in realizing standards of practice therefore requires discipline. However, it is important to note that this discipline is *not* a suppression of desire but an awakening of a person’s interest and a drawing in of the person by the goods that the practice has to offer so that the person comes to care about these goods because of the immense number of possibilities opened up by the practice. The attraction or “pull” of the internal goods of a practice leads us to the pursuit and realization of the possibilities offered by the practice. It is through engaging these embodied practices that we extend our powers. In doing so, we find or realize ourselves in practice. Engaging in a craft can release us from the tyranny of pre-occupations with ourselves, by focusing and concentrating our energies upon goods and practices that transcend ourselves through partnership, in a tradition that is richly alive in the present, stretches back into the past, and through our participation can be extended forward into the future. From this perspective, the density and variability of the concrete conditions in which a practice is brought to life provide no basis for discrimination between “cognitive” and “practical” (or manual) domains, let alone for privileging one above the other (Dunne 2005 p. 155). In both “academic” and ‘practical’ subjects, learners are introduced to activities that are specifically patterned to each practice including,

... its own way of conducting inquiry, asking fruitful questions imagining or empathising with characters or situations, devising plausible hypotheses or interpretations, sifting and weighing evidence, making creative connections or shifts in perspective, identifying and reflecting on basic assumptions, becoming sensitive to different contexts, making critical judgements. (Dunne 2005, p. 156)

Separated or isolated from these practices Dunne argues, facts, concepts or propositions make no sense. It is only through discussion and in co-operation with others that learners can be encouraged and empowered to think and begin to exercise and develop their own minds to the full. As we progress beyond the basic stages of learning a practice and begin to excel, the conversation becomes more open-ended. We start to think critically about what has been taken-for-granted in the past. We begin to parry conventional thinking here, build on it there, reject it in places, and modify it in parts until we have discovered our own way of making, saying or doing. The journey is the same for any craft, from would-be, physicians, pharmacists, engineers, lawyers, poets, musicians, philosophers and teachers and artists to carpenters, plumbers, hairdressers, and chefs (Lipman 2003, p. 259). To enter into the practices of a craft is therefore to enter into a conversation with, and be in the “presence” of those who have gone before us in realizing that practice and those who are with us in pursuing, modifying, and transcending it in the present.

In learning to practice a craft, we discover how to build up skills in sequence, how to learn from investigative practice and repetition, how to problem-find and problem-solve, and how to move knowledge (tacit or otherwise) forward through explicit critique. We acquire the discipline and habit of craft through experience, and in this way, we learn how to evolve and improve our craft.

Sennett argues that it is,

For this very reason it has proved easier to train a plumber to become a computer programmer than to train a salesperson. The plumber has craft habit and material focus which serve retraining. Employers don't often see this because they equate manual routine with mindless labour. For good craftsmen routines are not static they evolve. . . . But figuring out how to build on existing skills - to expand them or using them as a base for acquiring other skills - is a strategy that helps orient individuals in time. The well-crafted organisation will want to pursue this strategy in keeping itself together. (Sennett 2008, p. 266)

In the stages and sequences of the work process, from the basic learning of a craft to its modification and transcendence, we learn how to make judgments in action (judging while doing). Understanding the inner sequence of development in practicing a craft, the phases in becoming better at what we do, enables and empowers us to move practice forward. Sometimes that move forward is for the better, sometimes (as in the case of the use of technocratic functional analysis, outcomes-based qualifications, and tick box assessment in vocational education) it is not.

---

## Conclusion

Being fallible is part of the human condition (Dewey 1933). However making a mistake is often unhelpfully accompanied by a whiff of blame, and this can be a major barrier to recognizing and rectifying mistakes. The challenge for those with responsibility for vocational standards and assessment in England (and possibly elsewhere) is to admit that the deeply technocratic ambitions of functional analysis, outcomes-based qualifications, and tick box approaches to assessment have created more problems in vocational practice than they have solved. The beguiling and deeply influential prejudices underpinning such narrow technical-rational approaches to curriculum design, pedagogy, and assessment in England have served to diminish our understanding and practice of education in general, as well as relegating vocational education ever deeper into second, or even, third-class division status. The most problematic features of assessment practice in England have until recently been passed over in relative silence. The means, through which the external rewards of vocational education are distributed, in the form of outcomes-based qualifications and funding, rather than acting as helpful incentives to good practice, have subverted the intrinsic goods of vocational education by becoming its end purpose (Elliott 2001; Dunne 2005).

---

## Implications for Curriculum Design, Content, and Pedagogy in Vocational Education

Shared experience of practice, mutual engagement in endeavors, careful observation, forensic investigative repetition, problem-finding, problem-solving, critical dialogue, and the development and exercising of professional judgment are simultaneously old and new territory for practitioners of vocational education. The origins

of many of these practices can be traced back to the history and traditions of craft since the middle-ages and even before.

Re-connecting the shared practices of craft to systems of vocational education, which have been dominated for almost 40 years by “absolutist” over-specifications of standards of quality, and narrow functionalist approaches to curriculum design, development, and evaluation, will not be easy. The grip of technocratic functional analysis and outcomes-based qualifications and funding upon vocational education is strong and will be difficult to dislodge.

Dunne (2005), Sennett (2008), and Young (2008) find common ground where they argue that there can be no skilled work without standards; that we need to embed some form of standards in guiding the development of vocational education and that long lists of knowledge, skills and attitudes, and outcomes-based qualifications are in urgent need of review and replacement. For Young, the answer lies in “bringing knowledge back” into standards of vocational education. Young is critical of what he sees as anti-realist and relativist tendencies in pragmatist explanations of knowledge construction and development. Young argues that knowledge needs to be brought back into the curriculum through the identification of context-dependent knowledge (a blend of codifiable procedural and principled knowledge) and context-independent knowledge (uncodifiable, theory implicit and tacit knowledge). Biesta (2014, p. 29) agrees with Young, “that the question of knowledge may indeed have disappeared from parts of curriculum theory and curriculum practice,” a phenomenon which he attributes to the “learnification of education.” According to Biesta, this has led to the language of education being side-lined by the language of learning. He argues that this has shifted the discussion away from questions about the content of education to questions of learning outcomes, often framed in terms of skills and competences. However, Biesta (2014) challenges the work of Young and his colleagues not only on the grounds of their dichotomized and abstracted discussion of knowledge but also in terms of their failure to recognize how pragmatism (particularly the pragmatism developed by John Dewey) actually “operates beyond the age old oppositional views of objectivism and relativism” (p. 30).

Accepting Young’s version of knowledge construction in vocational and other educational contexts, ultimately returns us to a curriculum composed of abstracted lists of different kinds of knowledge and absolute standards drawn up by experts who “know better.” In contrast, Biesta argues, Dewey’s pragmatic epistemology allows us to frame the content and pedagogy of vocational curricula so that problem-finding, problem-solving, and critical dialogue drive knowledge forward through mutual engagement and shared experiences of practice. Such practices have been cornerstones of the development of craft for centuries. Functional analysis, on the other hand, is a relative newcomer, detached and technocratic with a rather disconcerting need for prescription, control, and micro-management.

Almost 40 years of technocratic functional analysis, outcomes-based qualifications and assessment regimes based on formally explicit criteria (which it is assumed are capable of being defined independently of any specific experience or practice) have undoubtedly operated to erode our capacity to reconnect with shared practices, which supported the development of craft across the ages. This is not to say,

however, that it has erased our capacity to recognize when mistakes have been made in framing curriculum content, pedagogy, and assessment in vocational education, nor our ability to rectify them.

The reduction of vocational curricula to what Wolf (2011) describes as “bewildering lists of atomised skills,” has served to repress and distort the development of practice and approaches to assessment in vocational education. Addressing these problems will require politicians, policy, and educational professionals to reconnect with issues at the core of vocational practice and pedagogy. As Sennett (2008) points out, this will require us to return to a number of questions. Firstly, what we mean by good quality work? Secondly, how to make vocational standards meaningful and workable in practice? Finally the pedagogical question of how to create conditions in the workplace, where shared experience, mutual engagement, problem-finding, and problem-solving can become the basis of a critical dialogue which encourages and enables the consistent realization of high standards of vocational practice?

Dunne reminds us that practices (including vocational practices) cannot be realized through a technicist logic which has attempted to prescribe “outcomes” from the top-down in ways designed to get teachers and tutors to maximize these outcomes by making them accountable for doing so.

However, functional analysis, tick box approaches to assessment, outcomes-based qualifications, and outcomes driven funding regimes are now deeply entrenched and pervasive in systems and practices of vocational education internationally. Given their deficits, broad and deepening cracks in the system raise important questions about the value and impact of these approaches to vocational education and the wider economy.

It has taken almost 40 years for the inappropriateness and ineffectiveness of applications of technicist logic and functional analysis in approaches to curriculum design, pedagogy, and assessment in vocational education to be brought to light. It is encouraging to see that these systemic shortcomings are now becoming more evident and are being publicly reported. This will make it increasingly difficult (but not impossible) for those with a political or financial stake in the continuation of such approaches in systems of vocational education, to block recognition of their shortcomings.

---

## **Appendix 1 Guiding Principles of Formative Assessment**

### **Making Learning Explicit**

This principle involves understanding the integrated nature of teaching, learning and assessment and the importance of being clear about what vocational tutors and learners want to achieve. The principle of ‘making learning explicit’ involves the use of key strategies such as, clarifying learning intentions and establishing learner generated and therefore learner owned criteria for success; identifying ‘steps to success’ (actions that will support achievement); helping the learner to ‘see’ what success might look like, feel like, sound like or taste like; and helping learners to identify how success will be known and how achievement will be recognized. This includes creating a culture in vocational

contexts in which all involved see ability as incremental rather than fixed; involving learners in planning both appropriately pitched content and meaningful contexts; enabling and planning for effective dialogic talk, where worthwhile questioning encourages learners to think ‘out loud and together’ (Mercer 1995); involving students in analysis and discussion not just about meeting the success criteria but how best to meet them and different ways to meet them (Clarke 2008).

## Autonomous Learning

The principle of autonomous learning involves learners taking responsibility for and exercising some measure of independence in their learning. It does not mean that they work on their own, although there might be occasions when they decide that this is the most appropriate thing to do. Promoting learning autonomy involves giving some level of choice to learners, and supporting them in developing the skills and confidence to make those decisions. A key feature of autonomous learning is that learners are able to become self and peer evaluators in order to decide on next steps in their learning without having to be reliant on someone else to tell them. Realistic self-assessment informed by knowledge of learning objectives/intentions and criteria for success and quality are crucial. From this perspective, self-regulating learning is not age or stage dependent, but is a learned process. Learners become more autonomous learners with guidance and through practice.

## Focusing on Learning

This principle asks teachers to pay attention to the nature of the learning that is promoted and valued. It foregrounds active learning with understanding at its core and encourages learning of intrinsic worth and long lasting value, rather than a mechanistic or narrow utilitarian approach to learning. This principle is closely linked to Dweck’s (2006) notion of a ‘growth’ mind-set rather than a ‘performance’ mind-set. Focusing on active learning involves an emphasis upon the process of learning, as well as what is to be learned. This means establishing systematic opportunities for timely review and feedback from tutors and learners, focusing on recognition of success and the identification of improvement and development needs. Clarke (2001) recommends that the processes of review and feedback should wherever possible include provision of time to *act* on feedback in the workplace/workshop/classroom/studio.

## Abstract

This chapter focuses on systems, policies, and processes for supporting vocational and technical learning in post-16 education in England. In England, this sector of education consists of a range of levels and types of provision in both public and private providers of further, adult, and continuing vocational and skills-based learning. The analysis considers expectations, challenges, and responses at the education system level, at institutional level and at practitioner level in the context of shifting government policies. At the system level, the analysis considers societal perceptions of academic and vocational learning and the provision and quality of training and continuing professional learning for VET teachers. At the institutional level, policies and support systems developed by VET providers to support students in colleges and workplaces in partnership with employers on different forms of college and work-based training, including apprenticeships, are considered. At practitioner level, the chapter examines teaching, learning, and assessment strategies used by VET teachers to enable vocational learning in different settings, from

classrooms, workshops, and laboratories in colleges and simulated learning environments to work placements in real working businesses. To support the highest standards of vocational and technical learning, colleges, VET teachers, and employers have to work in sustained partnerships to provide inspirational teaching in innovative learning environments, both college-based and in workplaces.

## Introduction

In England, the label currently being used to describe the diverse sector of education that encompasses vocational and technical learning and hence caters for VET learners is post-16 education. In 2016, the government carried out a wide-ranging national review of post-16 education (BIS 2015), which is discussed in more detail in the next section of this chapter. Previously post-16 education has been referred to as further, adult, and community education, and these differing terms are still used by policy makers and practitioners. Other terminology that characterizes this sector of education includes lifelong learning, work-based learning, vocational training (rather than education), apprenticeships, and skills. The latest announcement from the government are “plans to provide opportunity for all and ensure we have the skills needed for a modern, post-Brexit economy” (DfE 2017). The aspiration and intention is to develop a workforce with “world class skills,” a sentiment which continues previous government discourses around developing a highly skilled workforce to meet the demands of the knowledge economy. These expectations are, however, difficult to realize in practice as there are many challenges for supporting VET learners at system, institutional, and practitioner level, which are discussed in the following sections of this chapter. The challenges relate to the perception and status of vocational versus academic learning across national, and international, education systems as well as the practical training and development opportunities for VET teachers, learners, and employers. Societal attitudes and practical challenges which impact on the quality and level of support for vocational and technical learning manifest themselves at all levels of VET provision in England: at national education system level, at institutional/VET provider level, and at classroom practitioner/work-based placement level. The next section focuses on expectations, challenges, and responses at system level.

---

## Expectations, Challenges, and Responses at System Level

The range and variety of terms used to describe the sector that provides education and training for VET learners reflects both the attempt to find a label for a diverse sector and its status within the education system in England. The sector has been

described as the “Cinderella Service” (Randle and Brady 1997) which means “a person or thing that has been ignored or treated as less important than other people or things” (Longman Dictionary of Contemporary English 2017). This label reflects its inferior status in the English education system and the widely embedded perception that vocational and technical learning is not of equal status to academic learning. Also depicted as the academic/vocational divide and reflected in the words of a group of adult vocational learners as “Society’s view that academic learning is higher than practical learning” (quoted in Dhillon 2004b, p. 155). More recently, Bathmaker (2014) has suggested that vocational education can be portrayed as “education for other people’s children.” This portrayal captures the stigma associated with vocational pathways, as they are not options that parents or policy makers would choose for their own children. Despite reforms and policies espoused by successive governments over recent decades, the perception that vocational learning is second choice prevails, and this is a major challenge at system level.

Government rhetoric has espoused the vital role of vocational and technical learning as indicated in the introduction to this chapter (DfE 2017; BIS 2015), and previous governments of different political parties have endorsed this view. For example, in 2006 Education Secretary Alan Johnson described further education as the “engine for prosperity” (Johnson 2006) and the director of strategy and communications at the Learning and Skills Council, which at that time funded post-16 learning stated that “vocational learning is critical to the success of individuals, businesses and communities across the country” (Wye quoted in Johnson 2006). At the recent launch of the new T-level qualifications developed following an independent review of technical qualifications, Justine Greening, the current Education Secretary, declared “we are transforming technical education in this country. . . making sure that the technical education ladder reaches every bit as high as the academic one” (Greening 2017). It remains to be seen if this aspiration is realized over the coming years but the evidence from previous attempts is not encouraging.

The perception of VET as a second choice option in the English education system has profound negative effects, both on the self-esteem of learners on vocational pathways and the status of those who support vocational and technical learning in schools, colleges, and workplaces. Learners who study for vocational and technical qualifications are regarded as being less able than those who take academic qualifications. In a recent study of an educational partnership formed to deliver a generally vocational curriculum for 14–19 old learners in the northern part of the Midlands of England, Holmes (2017) found that “vocational skills possess less capital value than academic skills” (p. 150) and that government reforms over the course of his study contributed to the devaluation of vocational qualifications. In his research findings, he considers the impact of the devaluation of vocational qualifications on learners and quotes secondary school leaders who commented “we are saying one thing about vocational qualifications and practicing another” (Holmes 2017, p. 150). In an interview response, another member of the 14–19 educational partnership (the deputy head teacher of a secondary school), directly picked up the emotional impact of the perceived value of vocational qualifications on learners by stating:

I always feel quite saddened that they[vocational qualifications]appear, or perceive to be, devalued, because for the students that do them...it's often a route that they can be successful in, so to perceive them as being a second best...is very sad.... (Holmes 2017, pp. 153–154)

This evidence from a recent empirical study supports the view that despite government policies and reforms espousing support for vocational and technical qualifications parity of esteem for academic, vocational and technical education remains to be achieved. This is a major challenge for policymakers and practitioners who support vocational and technical learning in post-16 education. In addition to eroding the perception of VET as the poor relation in the education system, there is a need to provide high-quality training and continuing professional learning for VET teachers so that they can support learners to attain the “world class skills” advocated in policy documents.

There are two important facets to this issue. Firstly, the need to develop inspiring vocational pedagogies to engage and enthuse a diverse range of VET students in purposeful learning to achieve outstanding results. Secondly, the requirement to maintain (as a minimum), and ideally to continually extend, teachers' vocational and technical knowledge and skills at industry standards for the changing world of work. This challenge is being met at institutional level by some colleges, as the discussion in the later sections of this chapter will illustrate, but at national education system level it has suffered from neglect in the past.

Historically training for VET teachers has not been given the priority it has been accorded in the schools sector where teacher education/training leading to the award of qualified teacher status (QTS) has been a long-standing requirement for entry into the teaching profession. The award of QTS was regulated by the General Teaching Council for England (GTCE) until it was abolished in 2012 and is now the responsibility of the National College for Teaching and Leadership, whose “aims are to improve academic standards by recruiting and developing a workforce to meet the needs of our school system...” (NCTL 2017).

For VET teachers who may work in a varied range of post-16 education settings, such as further education colleges, private training providers, adult and community education centers, or in workplaces as trainers, instructors, mentors, coaches or assessors for apprentices, trainees, or other employees, the requirement to be qualified teachers is less clear. Although training and professional development courses for further education lecturers and tutors working in these settings have existed since the 1990s (see for example Dhillon and Moreland 1996), the award of Qualified Teacher Learning and Skills (QTLS) as a recognized teaching qualification equivalent to QTS did not take place until 2012 (SET 2017). This reflects the poor professional status of VET teachers in comparison to the status historically accorded to other teachers in the national education system. Thus, at a societal and education system level, it is not only VET learners who are perceived as second best but also the professionals who teach and support vocational and technical learning in a variety of post-16 education settings.

VET teachers like teachers working in academic schools, or universities, need to feel valued, respected, and empowered with the knowledge, skills, and opportunities

to develop creative pedagogies that most effectively meet the learning needs of their students. They also need to work in partnership with employers to provide learning experiences that reflect leading edge commercial and industrial practices in workplaces to equip their learners for the changing and demanding world of work. There is evidence that these challenges are being met by colleges, college leaders, and VET teachers at regional and local levels, despite cuts to funding (Boles 2015; AoC 2017) and recurring reviews and policy reforms at national level (Leitch 2006; Wolf 2011; Sainsbury 2016). At institutional level, there is evidence that the agency and passion of individuals and the collective and collaborative effort of VET organizations is transforming the life chances of learners on vocational and technical programs of learning despite the structural inequalities embedded in the national education system. The following section provides examples from empirical research that illustrate these responses.

---

### Expectations, Challenges, and Responses at Institutional Level

The expectation that vocational and technical programs of learning will deliver the “world class skills” needed for the economy is expected to be met by the providers of VET, working in the range of post-16 settings described in the previous section. Some VET providers have responded to this challenge by working in partnerships and by developing detailed policies and support systems in colleges and workplaces. There are some outstanding examples of practice as well as poor/inadequate provision of support services for learners. The examples of excellent and outstanding student support services reveal the passion, drive, and commitment of staff working at institutional level to enable successful outcomes for VET learners. This is also evident in the workings of local and regional partnerships, some of which have been motivated by educational rather than just business reasons for delivering the best possible vocational and technical education for VET learners in their region, for example:

Initially it [the partnership] was a stance of colleges and others in the region **standing together** and saying. . .we have common interests, we have common learners, and **there is much we can gain from each other**. . . (Gillian, a college principal, bold text indicates original emphasis by the speaker)

I think they [members of the partnership] are actually genuinely enthused by the notion of extending learning to people who are disadvantaged and when they come together [in the partnership] the enthusiasm grows and becomes more than the sum of its parts as it were . . .there’s something deeply political about it. (Margaret, a university senior leader and Chair of the partnership)

Both of the above quotes, taken from a study of partnership working in post-16 learning (Dhillon 2004a), reveal that some senior leaders of VET organizations are driven by their individual and shared values and commitment to social justice to extend learning opportunities for people who have been disadvantaged or “failed by schools.” In some cases, this is linked to their own trajectories as learners, for

example, Stephen, a member of the same partnership as Gillian and Margaret quoted above and a college principal in the same region reflects:

I was the first person in my family to go to university and now, as a college principal, I am in a position of power to help others achieve their ambitions. . . I'm a resource winner, a business conductor, and with a lot of good people [members of college management team] who actually do it. . . as a result of that I'm able to leverage more than if I had just remained as a teacher . . .

I can bring some of my value systems to bear and to have an effect on more people, . . . last year this institution touched 44,000 different lives during the course of the year . . . the opportunities we've created by harnessing resources enable all that to happen . . . we're pushing kids to the limit to achieve this sort of excellence . . . (Dhillon 2004a, p. 252)

These voices of a moral agency and commitment to supporting VET learners recorded some time ago (Dhillon 2004a) and during the implementation of VET policies and reforms introduced by a Labor government can still be heard in the context of more current VET reforms under a Conservative government. For example, Dhillon and Bentley's study of two colleges (2016) documents the passion and anger of senior leaders and college governors with the failure of support for VET in the English school system, as illustrated in the data extract below:

. . . because if **we** [the college] don't do it who will – the learners have been **failed** by the schools in the area so we have to provide the best chances for them to do well and get the skills they need to find work or carry on with further and higher education and training. . . (senior leader, College A, bold text indicates original emphasis by the speaker)

. . . I'm really pleased to hear that as we need people with engineering skills and **we must provide the best skills training in the region** (college governor and CEO of a major engineering company)

. . . I want to congratulate the senior leadership team on all the hard work they're doing. . . **our principal is excellent** and all the team work relentlessly to get the best for learners and we as governors should be proud of the achievements of our college. . . **I'm really proud to be associated with** [name of college]. . . (Chair of governing body, College A)

This depth of passion and commitment to VET engenders an organizational culture that supports all learners whether they are engaged in college-based courses or apprenticeships delivered in partnership with commercial businesses. In such organizations, staff are prepared to “go the extra mile” to support learners and senior leaders able to proclaim “it's in our DNA. . . I don't need to be here, the staff run the college and everyone goes the extra mile for the student” (member of senior leadership team, College A). This type of organizational culture is difficult to measure in metrics but it certainly can be felt and observed, as shown by the observational data below:

The vibrancy of the organisational culture in the college is clearly apparent; students are running a charity fund raising event in the atrium, wall displays showcase inspirational quotes from writers and poets, e.g. ‘If you can imagine it, you can achieve it; if you can

dream it, you can become it.’ Photographs of college events, awards and trophies won by staff and students adorn the main reception along with branding logos of partner organisations, who are market leaders in commercial businesses and providers of vocational and technical learning to the highest industry standards (observations of a college governor 2016)

In this college, staff from all levels of the organizational structure, from senior managers to lecturers, technicians, receptionists, and car parking attendants, welcome learners and visitors with enthusiasm and care and share a determination to provide an outstanding and supportive learning environment. The will to transform the life chances of VET learners and provide the highest standards of vocational and technical learning is explicitly stated and tacitly embedded in the teaching, learning, and student support services provided to learners. The college declares that it is “proudly vocational” and aspires to support learners into higher levels of study and jobs by providing outstanding learning experiences, education, and skills development. While anticipating transformational changes to the VET sector, arising from government cuts to funding and implementation of revised specifications to technical qualifications, the college confidently sets out a corporate strategy that centers on the ability of its staff to respond to challenges and deliver outstanding support for learners.

The support provided for learners includes a raft of student support services and institutional policy documents, which clearly set out the types and levels of support available to learners, whether they are students in college-based provision or in work-based training with employers, as in apprenticeships. These policies incorporate system-wide national statutory requirements (DfE 2016) and institutional principles and processes developed by dedicated staff who have collective responsibility for safeguarding the emotional, social, and mental well-being of VET learners. In addition to ensuring the physical safety of VET learners in different configurations of vocational and technical learning environments, such as training restaurants, beauty salons, engineering workshops, success in learning requires sensitivity to the wider personal needs of individual learners. Staff need to be able to recognize the signs of safeguarding issues and identify learners who may be at risk from harm so that they can refer them to appropriate institutional support services and where necessary to external counselling or support.

The range of risks in relation to safeguarding the welfare of VET learners (and staff) has increased in recent years as wider threats to safety and wellbeing surface in education and training organizations and in the neighborhoods and communities in which they are situated. These risks include abuse (physical, emotional, sexual), bullying and harassment (including cyber-bullying), radicalization and threats from extremism. There is increasing evidence of mental health conditions affecting the learning and achievement of students on vocational and technical courses in colleges, as well as in schools. For example, during 2016/2017, the student support services team at one vocational college saw a 22% increase in safeguarding services users. They dealt with 637 individuals over 1002 counselling sessions providing support for VET learners with mental health concerns. These mental health concerns included anxiety, depression, and low mood. During the same year, the college had

to manage a 62% increase in severe mental cases amongst its students, which required support from external multi-agency partnerships. These figures are indicative of the challenges and increasing demands on student support services at institutional level. VET learners with Special Educational Needs and Disability (SEND), also known as high needs, may experience further risks and need additional safeguarding support.

Institutional responses to these challenges center on a student support services team and a detailed set of policies, which clearly document the roles and responsibilities of staff and the procedures to be followed for safeguarding the welfare of VET learners. The institutional policy documents provide the names and contact details of staff and their responsibilities in relation to safeguarding, with flowcharts of the process to be followed in supporting issues brought to their attention by learners, teaching/other staff or employers in partnership organizations. The policy documents are regularly updated to reflect changes in statutory requirements and improvements to institutional practice, based on evaluation and feedback from learners, staff, and partner organizations about the quality and effectiveness of the support provided. The policy documents are scrutinized and approved by the governing body in its regular cycle of meetings and the senior leader with institutional responsibility for student support services provides verbal and written reports on the provision to the governing body at these meetings. These policies and procedures contribute towards providing accessible and effective support for VET learners and recognize that the emotional and psychological well-being of learners is as important as the quality of the vocational and technical teaching and learning activities in classrooms, workshops, and workplaces.

The variability of learning environments is another challenge for institutions as there may be differing levels of facilities and access to support services in multi-campus organizations (Dhillon et al. 2008). Colleges may consist of state of the art shiny new buildings with high quality teaching and learning environments and other facilities for learners, e.g., childcare provision in on-site nurseries for students with children, on the main campus, but struggle to provide adequate facilities on other campuses/in workplaces. This is often due to the legacy of VET institutions and providers, which have evolved over time but the responsiveness of staff to the needs for VET learners can compensate for less modern facilities. Personal tutor systems, work-based tutors, assessors, and mentors can help to ensure that all VET learners are aware of the support services available to them and can access them when needed. The importance of people and communication is key to providing high quality, equitable, and consistent support for learners. The following section considers how some of these people, at practitioner level, meet the challenges of supporting vocational and technical learning in the different settings in which they work.

Communication strategies used at institutional level to make learners, staff, and employers aware of the support available for VET learners include posters in classrooms, workshops, and social spaces; monthly newsletters on college websites; copies of safeguarding policy documents provided for all staff, including those in partner organizations and available on college websites and promoted through social

media. The effectiveness of these strategies is monitored through audits and random sampling using techniques such as mystery customers, learning walks, open meetings with students and staff, and online surveys. They are also assessed by external auditors when there is an inspection of provision.

---

## **Expectations, Challenges, and Responses at Practitioner Level**

The expectation that VET learners will gain “world class skills” from outstanding providers of vocational and technical qualifications presents significant challenges at practitioner level as it is here that teaching, learning, and assessment for VET qualifications takes place. VET teachers who undertake a range of roles, which are outlined below, are expected to develop vocational pedagogies that enthuse, engage, and most crucially lead to successful outcomes in terms of qualifications achieved by learners. The challenges they face at ground level arise from disparities in the resources and facilities available to them and the range and diversity of learner characteristics they need to support in their teaching and assessment for VET qualifications. The variability of learning environments and the different settings in which VET teaching, learning, and assessment takes place are significant, ranging from classrooms, workshops, and laboratories in colleges and simulated learning environments to work placements and supervised training in real working environments. The characteristics of learners also present substantial challenges as the previous educational experience of VET learners may continue to impact on their vocational and technical learning in post-16 education. Some learners may have been “failed by the schools,” as shown by empirical research data presented earlier in this chapter, and as the development of vocational pedagogies must center on the needs of learners, this is a key challenge for VET teachers. Furthermore, the identity and role(s) of VET teachers is not clearly demarked or widely understood as they need to be both teachers (experts in pedagogy) and experts in vocational/technical skills/occupational areas.

The term “VET teachers” encompasses a range of roles in relation to supporting and assessing vocational and technical learning in the different settings in which they work and a number of terms are used to describe these roles. These include “lecturers” and “tutors” (those on academic contracts in colleges), “instructors” (those paid at a lower rate than lecturers and may work in college-based provision, work-based training in companies, or in private training providers), “assessors” and “work-based assessors” (those who only assess trainees or students, usually in workplaces, but do not teach or support teaching/learning). In addition to these main distinctions in roles and responsibilities that are linked to different rates of pay for undertaking the role, other people such as mentors, coaches, critical friends support VET learners in a variety of formal and informal arrangements. This list of terms and roles and responsibilities is not exhaustive but seeks to convey the complexity and diversity of the work undertaken by VET teachers in post-16 education in England. The term “VET teachers” is merely a short way to refer to the range of roles and responsibilities

outlined here and is used in the following discussion of VET teachers' responses to the challenges they face in supporting VET learners.

Recent research data from a narrative study of VET teachers (Hooker 2016) has revealed the empathy they have with learners, which can be based on their own negative experiences of learning in school, for example:

I am quite aware of the fact that a lot of people have had horrendous experiences, particularly with maths . . . when I am teaching I try to always keep that in the forefront of my mind, that maybe this person may have had a bad experience of maths as I did, to be quite careful with them, the way I treat them and help them with maths (Hooker 2016, p. 99)

The data extract above illustrates personal qualities of VET teachers, some of whom may share bad experiences of learning at school making them even more sensitive to the needs of VET learners in post-16 education. It also indicates how they use this knowledge and experience to inform their pedagogic practice in a particularly troublesome area of learning: the teaching and learning of mathematics. Poor literacy and numeracy skills have been a long-standing challenge in VET and recent policy directives to colleges providing vocational and technical qualifications have required all learners to obtain "good passes" in English and Mathematics in addition to obtaining their vocational/technical qualification (AoC). In the English education system, "good passes" refers to passing GCSE (General Certificate of Secondary Education) examinations at grades A\*–C from the scale of A\*–G (Yorke 2017). These examinations are taken by all pupils in secondary school but VET learners do not all pass at grades A\*–C, many pass at grade D. Thus, they may be perceived as failures and this perception has been exacerbated by the government stipulation that colleges must ensure that VET learners with Grade D must retake those examinations and pass them with a grade C or above (AoC 2017). The implications of this policy play out in the classrooms and workshops of VET providers and have to be tackled by the responses and strategies of VET teachers and their managers and leaders.

Perceptions of failure can have long-lasting effects on the confidence and self-esteem of learners and pose additional challenges for VET teachers in supporting achievement of successful outcomes in examinations and other forms of assessment for qualifications. These negative perceptions can come from the views and attitudes of parents as well as experiences in schools as recalled by John, a retired RAF (Royal Air Force) officer:

My Mom [Mother] always used to say Brian's the brainy [intelligent] one . . . my brother was much more academic but I could pull an engine apart and put it back together (quoted in Dhillon 2004b, p. 154)

This memory of lack of approval from his mother had stayed with John throughout his life despite a highly successful career in the RAF and a portfolio of achievements in technical and vocational learning. However, on a more positive note this example also shows that learners can overcome such barriers to learning

with the support of inspirational VET teachers and others who are passionate about vocational and technical education. As the earlier discussion in this chapter has shown, this includes senior leaders, managers, and governors of VET organizations and the employers who work in partnerships with them to provide workplace learning. Another facet of post-16 education is that it gives second chance opportunities for learners to achieve their ambitions and gain qualifications which they have not managed to get from secondary schooling, e.g., a good pass in mathematics. VET teachers are the critical players in developing and implementing teaching, learning, and assessment strategies that enable this to happen.

In addition to their sensitivity to diverse learner needs, VET teachers respond to the challenges of developing inspiring teaching by working in cross-curricular teams to combine pedagogic expertise with vocational and technical expertise to develop methods and resources that will enthuse and engage VET learners. These methods include team teaching, learner-centered methods such as group work, research activities, problem-based learning, and carefully planned teacher-led presentations and demonstrations of practical skills using digital technologies. Team teaching, which consists of vocational/technical skills tutors planning and co-teaching with mathematics and/English tutors in classroom/workshop settings, is particularly effective in contextualizing numeracy and literacy skills for VET learners. This method of co-teaching supports both the achievement of successful outcomes in more academic examinations, such as GCSE, while also enabling learners to master the vocational and technical skills needed for employment in a changing world of work. It also supports the professional development of VET teachers in creating innovative vocational pedagogies for their areas of work.

In developing innovative vocational pedagogies, teachers also work in collaboration with employers and leading industry experts. These collaborative activities range from inviting guest speakers, such as CEOs (Chief Executive Officers) of leading companies, engineers, designers, awarding winning chefs, to come and give inspirational talks to VET learners on college-based courses to undertaking industry placements themselves to remain at the cutting edge of work-place practice. The knowledge and skills exchange through these activities is two-way, whether the arrangements are developed by a proactive individual teacher or part of more formalized partnership agreements, as is often the case in delivering apprenticeships. The importance of learning from others is fundamental to the continual process of finding effective teaching, learning, and assessment strategies for vocational and technical learning, just as it is for other education contexts and for the world of work.

Learning from activities such as learning walks, peer observations of other teachers and work-based assessors, reflections on practice with mentors, and engagement in professional organizations, such as the Society for Education and Training (SET 2017), can be empowering forms of professional learning for VET teachers. These activities can assist teachers in meeting the challenges of supporting vocational and technical learning and enabling VET learners to achieve their full potential. However, this can only be the case when innovations in teaching methods are driven by confident VET teachers who are recognized as professionals in pedagogy and experts in industry standard vocational and technical skills. This is not always

the case in post-16 education as performativity measures, such as graded classroom observations of teaching performance, can become a tool that instils fear and terror in VET teachers rather than being a process for enhancing teaching, learning, and assessment. To maximize the potential of these types of processes, VET organizations need to develop high levels of trust, a key characteristic of outstanding leadership (Dhillon et al. 2017) and of effective learning in VET providers (Thomsen et al. 2015). The discussion in the previous section of this chapter has illustrated how outstanding leadership in some VET organizations is engaging staff and partner organizations in supporting VET learners to achieve their ambitions.

---

## Conclusion

This chapter has explored systems, policies, and processes for supporting vocational and technical learning in England using empirical research data, relevant policy documents, and the author's extensive professional experience as a teacher, teacher educator, and researcher in the field of post-16 education. The voices of VET teachers, learners, teacher educators, and leaders and managers of VET organizations illustrate expectations, challenges, and responses at three levels: at education system level, at institutional level, and at practitioner level. In the voices represented in the empirical data, there is evidence of passion, commitment, and determination to provide high-quality, and in some cases outstanding, vocational and technical learning for VET learners. This passion and depth of feeling seems to be driven by a moral purpose and individual and collective agency and not just a business case, unlike what might be expected from people in VET organizations operating in a marketized system that is funded on a business model. The evidence discussed in this chapter suggests that despite the challenges at system level, at institutional and practitioner level some leaders of VET organizations and their staff are able to provide outstanding opportunities that can transform the life chances of VET learners.

At education system level, the legacy of VET as the Cinderella service (Randle and Brady 1997) and perceptions of VET as second choice continue to persist despite successive attempts to reform vocational and technical qualifications in the hope of achieving parity of esteem with academic qualifications (Johnson 2006; Wolf 2011; Sainsbury 2016; Greening 2017). The rhetoric of skills and "world class skills" needed for economic growth is a relatively enduring expectation that post-16 education is supposed to deliver, by colleges and other organizations working in partnership with employers and/or private training providers. However, in recent years, government funding for the sector has been cut (Boles 2015; AoC 2017), and the people who work and learn in the sector continue to be under-valued in English society. This, of course, is not restricted to the cultural or national context of England as these perceptions of VET also exist and persist in other countries.

The picture at institutional and practitioner level is less gloomy. There are instances of poor and inadequate VET provision with rogue providers of vocational and technical qualifications but also examples of excellent and outstanding practice, as illustrated by organizations such as College A, mentioned earlier in the chapter.

The leadership teams of such organizations manage to balance external accountability measures and financial pressures with the will and determination to create an organizational culture in which all staff and learners are motivated to exceed expectations and take pride in their work and learning. VET teachers and staff providing student support services “go the extra mile” to support VET learners both in and outside formally scheduled teaching and learning sessions to give individualized support where and when needed. This can mean VET teachers spending up to an extra hour with a learner/group of learners to explain an assessment task because the learner (s) were unable to get to the formally timetabled session/workshop. This type of dedication to the needs of VET learners is not without cost (usually unpaid), but it does demonstrate the commitment of VET professionals to supporting the learning and development of individuals who may have been failed by the schools system. It also means that senior leaders can confidently assert, “It’s in our DNA as a college. . . staff at the college are passionate and driven by their determination to do the best for the learners” (Dhillon, 2016, personal communication).

Finally, a key message in drawing this chapter to a close is that strategies for supporting vocational and technical learning should center on the holistic development of knowledge and skills, whether these be vocational, technical, social, or professional, so that they can be applied effectively in the changing world of work.

**Abstract**

With the PISA project, competence diagnostics has gained a significant international recognition. Although vocational training research initially assumed that it is not possible to develop an instrument for competence diagnostics applicable in the extremely heterogeneous international vocational training landscape, it finally succeeded with the COMET (Competence Diagnostics VET) method. The great challenge was to implement on the basis of complex tasks test instruments that correspond to the reality of the workplace. On the basis of a three-dimensional competence model and a measurement model derived from it, it was possible to depict the central idea of modern vocational education and training (enabling people to help shape the work place in a socially and ecologically responsible way) and to implement it in a test procedure. International test practice has shown that the application of the COMET methodology as an instrument of quality assurance also has an unexpectedly large didactic potential. This is due to the fact that the format of the test items is also suitable for learning tasks. In addition, the representation of the test results in the form of competence profiles representing its eight dimensions of the test instruments also allows for an expansion of the teachers' technical understanding on multiple professional competence. This is regularly shown by the reflection of the test results in the teaching staff, by the feedback events with the test participants, and finally by the higher quality of the competence development of the pupils/students.

**Introduction**

Since the advent of the apprenticeship, vocational education and training has had a lasting, timeless form of organization and organization of vocational education and training. It has not only surpassed the industrial revolution with its potential for mechanization of traditional technical work but also the introduction of scientific management into industrial production through principles laid down by Taylor and aimed at the control of work and its detailed governance through management (Taylor 1911). However, structural change in industrial development in the twentieth century as well as in the transition to the twenty-first century, reinforced by the “digital revolution,” has not succeeded in replacing skilled work and mastery in the working world. On the contrary, we can see a re-examination of the quality of professional work done by craftsmen where craft seems to hold fundamental significance in the interaction of man with nature. These conclusions are suggested by three current philosophical works in which this thesis is justified from diverse perspectives. Richard Sennett explains in his book *Handwerk* (Sennett 2008) that practical action and thinking of every good craftsman are in a constant dialogue. All

efforts to separate this connection, as Taylorism's especially radical approach has attempted, create social crises. Referring to climate change, Sennett says: "We will have to learn [...] how to build houses differently, to transform the traffic system and to develop rituals that accustom us to an economical approach to natural resources. We will have to be good environmentalists" (ibid., 24). Furthermore, Janisch (2015) shows that craftsmanship and science have an indissoluble connection, echoed by Crawford (2015) who founded a motorcycle workshop and published a famous volume based on his experiences in his craft. The latter's comments on the link between professional skills and professional ethics are of fundamental importance for competence diagnosis and the didactics of vocational learning.

---

## Realizing Professional Solutions to Modern Problems

The modernization of a heating system for a residential building installed in the 1980s is an everyday task for sanitary, heating, and climatic (SHC) engineering companies. A new challenge for the specialists are the local characteristics of buildings and the wishes of clients whose desires are not always realistic, as customers are rarely familiar with the latest heating technology. Consultation with customers and the translation of customer wishes, formulated after a detailed consultation into specification, realistic planning, and implementation of the plant, include – in addition to observing the functionality of the plant – the utilization value of costs and costs and work planning that considers safety, occupational safety, and health regulations. Creativity is of course required throughout.

A professional solution can only be expected if all aspects relevant to heating modernization are taken into account. Above all, the requirements for comfort, costs, and energy efficiency must be weighed up. A reduction in the complexity of professional tasks, as occasionally suggested by examining experts (see, e.g., Griffin 1990), is not *possible* – unless the specialists ignore the realities and risk inadequate or illicit solutions that endanger their employees or damage the reputation of their operation. The concept of *holistic* problem-solving illustrated in the example provided herein applies to specialists in all professional disciplines.

---

## The Characteristics of Vocational Training

The features of professional work mentioned above must be taken into account in the modeling of occupational competence and in the development of a procedure for competence diagnostics. The clarification of characteristics that distinguish professional from general education becomes important in the context of education policy initiatives that improve transitions from vocational education to higher education. Benchmarks for the measurement of professional competence development can be stated as follows:

## **Ability to Work**

Contrary to the thesis of “de-occupation,” the professional form of work has changed in its content, but not in its fundamental importance for employees and enterprises (Kurtz 2001; Lempert 2007). This implies that vocational education and training will be measured by the degree to which it delivers the competences defined in professional profiles, for example, whether the trainee can be entrusted with the title of professional. Regarding health- and safety-relevant competencies to be mastered in a profession are concerned, they have to be mastered unequivocally and have to be periodically reviewed for currency.

## **The Contents of Vocational Education**

The content of vocational education and training is purposive, as the working world, and beyond it the use-values established in society, arises from the objectification of purposes, interests, and needs. Professional work and vocational training therefore always imply dealing with purposes and interests and the need for compromises in evaluating divergent goals and criteria when undertaking professional tasks. An objective, value-free (“pure”) vocational education is therefore a contradiction in itself.

## **Shaping Competence**

Based on a historical process, society experiences the ongoing process of dealing with and balancing given creative alternatives and the values and purposes incorporated in them. There is no right or wrong world of work and life, but a process of development and change – a process of design – in which, in each case, given possibilities for social and ecological responsibility must be exhausted. Education therefore means the ability to contribute to the shaping of the working world and society with social and ecological responsibility by exploiting the given scope for design (Rauner 1988; KMK 1996). On the other hand, the notion of purpose-free education conveys an understanding of the world which is abstracted from participation: an educational concept which makes it easier for the “educated” to adapt to the given social structures.

## **Vocational Identity and Professional Ethics**

Motivation theory has found its way into educational research, since motivation is a significant intervening variable, with the aid of which learning effects can be explained. For vocational education and training, motivation is of particular importance in terms of occupational commitment. It originates from the link between professional identity and professional competence (Blankertz 1983) and establishes a sense of quality and responsibility – a fundamental prerequisite for the introduction

of flat corporate structures, with a shift of competencies and responsibility to value-adding work and business processes. In vocational education and training, the building of vocational identity and the professional commitment resulting from that is an equally relevant goal alongside the development of professional competence.

## The Education Paradox

Learning in the workplace is faced with the dilemma of how to acquire professional skills without first acquiring the appropriate theoretical knowledge. An answer to this is that professional beginners become skilled learners by learning what they need to, for example, trainers support learners by confronting them with work situations that challenge them. The reflected work experience is therefore the most important source of learning for professional competence development (Schoen 1983; Fischer 1995, 2000). If teachers, trainers, and vocational researchers are aware of the specificities of vocational training, there is no need for the many rules and regulations in designing, organizing, and researching vocational education and training.

---

## Modeling Vocational Competence: A Prerequisite for Competence Development

Competence models have a mediating function between the guiding ideals and objectives of learning areas (e.g., science education) and the development of test tasks for measuring competence. This results in further development of competence models as well as the measurement models derived from them, which have to:

- Include educational goals and guiding principles which can be justified by education theory, which are internationally accessible, and are therefore not linked to education and training systems or specific courses and forms (such as dual vocational training).
- Be in line with the basic findings of teaching, learning, development, and evaluation research.
- Be tailored to learning areas that allow the content dimensions of the competence models to be adequately represented.
- Provide a concrete guide for the development of test tasks.

Further critical requirements for vocational education and training are:

- The use of open test tasks, since only these are able to reproduce real professional tasks.
- Professional tasks that generally require the weighing of alternative solutions, which can be assigned to a solution area defined by specific requirements. It must therefore be “marked out,” since the solution areas must in principle be open to unpredictable solutions (see Euler 2011, 60).

In established competency research, competence is defined as a domain-specific cognitive performance disposition – a cognitive potential that enables tasks and problems to be solved in a specific domain (i.e., a profession or professional field). This pragmatic definition, based on a research perspective, does not, of course, preclude the continuation of theoretical theories and research on the abilities and educational concepts that elude large-scale competence analysis. What Jürgen Baumert et al. said about these questions in the first PISA report is still true: “One cannot stress emphatically enough that PISA does not intend to measure the horizon of modern general education” (Baumert et al. 2001, 21). In a transversal sense, this also applies to competency diagnostics in vocational education and training.

---

## Measuring Vocational Competence: The Three-Dimensional COMET Competence Model

The measurement of professional competence requires a theoretically and normatively justified competency model that can be designed according to psychometric criteria to form a measuring model (see Martens and Rost 2009, 95 ff.). Competence models have the function to operationalize the basic criteria that problem-solving in the workplace must meet, as well as the related guiding principles and objectives of vocational education and training, and to lead the construction of test tasks in a sufficiently specific form.

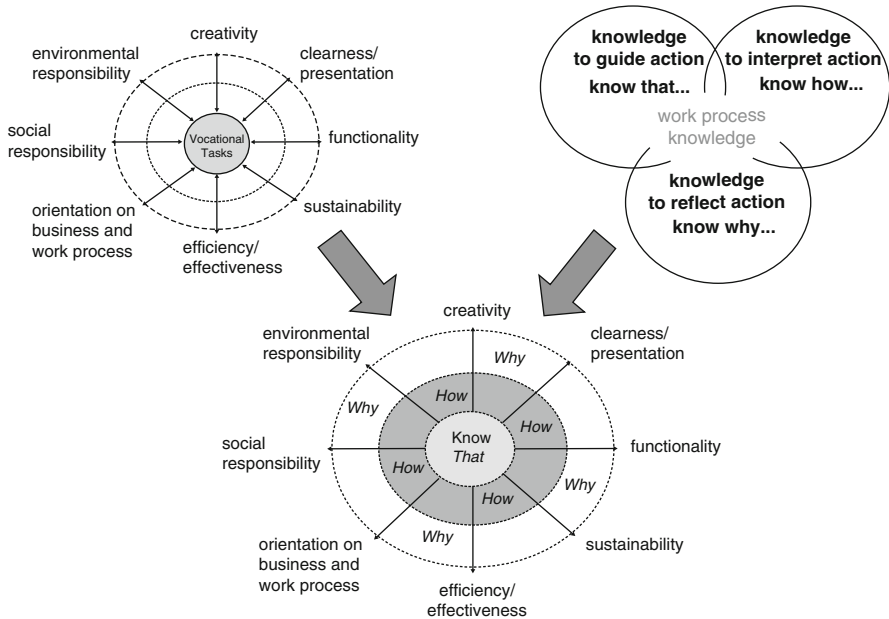

The criteria of holistic task solution in the COMET model can be interpreted as dimensions of multiple (professional) competence, where the degree depends on the level of work process knowledge (Fig. 1).

---

## Components of Professional Competence

1. *Functionality* refers to instrumental competency and thus to context-free specialist knowledge. The ability to solve a task is fundamental to all other requirements for solving professional tasks.
2. *Clearness/presentation*: The result of professional tasks is anticipated in the planning and preparation process, documented, and presented in such a way that the client (supervisor, customer) can communicate and evaluate the suggested solutions. It is therefore a basic form of professional work and professional learning.
3. *Sustainability*: Professional work processes and assignments always refer to “customers,” whose interest is a high usable value as well as the sustainability of the task solution. In highly separate work processes, employees’ awareness of the value of employment and the sustainability aspect of the solution of occupational tasks often disappear. With the guiding principle of sustainable problem-solving, vocational education and training counteracts this phenomenon.
4. *Efficiency/effectiveness*: In principle, professional work is subject to the aspect of profitability. The context-oriented consideration of economic aspects in the solution of professional tasks characterizes competent action of experts.

**Fig. 1** Shaping of multiple competences represented through the levels of action guiding, interpreting, and reflecting work process knowledge

5. *Orientation to business and work processes* includes solution aspects which take into account the hierarchical aspect of the business process, as well as the upstream and downstream workspaces in the process chain (the horizontal aspect of the business process).
6. *Social responsibility* particularly affects the aspect of human work organization and organization, health protection, and, where appropriate, the social aspects of professional work that extend beyond the professional context.
7. *Environmental responsibility* is a relevant criterion for almost all work processes. This is not a matter of general environmental awareness, but rather the occupational and specific environmental requirements for occupational work processes and their results.
8. *Creativity* is an indicator that plays an important role in solving professional tasks. This is also the result of very different scenarios in the solution of professional tasks.

### Competence Levels

For the modeling of competence levels, the COMET competence model is based on the four-level competence area model of Bybee (1997), which has also been included in the PISA project (basic science education) as follows:

*Nominal competence:* At this first level of competence, the trainees have a superficial, conceptual knowledge, without this already being guiding action in

terms of professional competence. The meaning of professional disciplines does not extend beyond the use of terminology.

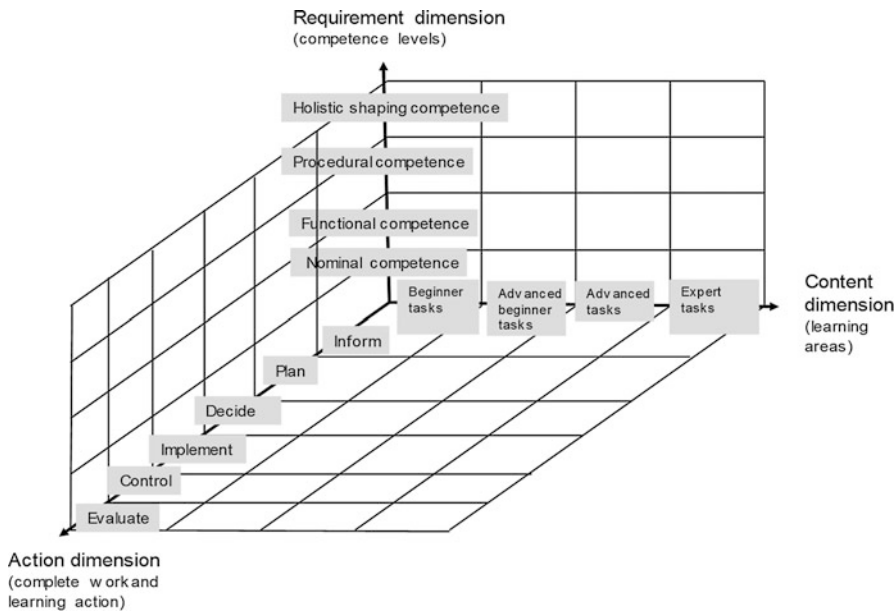

*Functional competence:* At this level of competence, the technical and instrumental abilities are based on the basic skills required for this, without their being interwoven or interrelated with their importance for professional work. “Professionalism” expresses itself as context-free, expert knowledge and corresponding skills.

*Processual competence:* Vocational tasks are interpreted and dealt with in their references to company work processes and situations. Aspects such as profitability, customer, and processor orientation are taken into account.

*Holistic shaping competence:* At this level of competence, professional tasks are perceived in their respective complexity and solved taking into account the diverse operating and social conditions as well as the divergent demands on the work process and the work results.

### Three Dimensions of the COMET Model

During the identification of the basic criteria of work-related problem-solving, an abstraction level was chosen in the COMET project, which ensures that these criteria are applied across all occupations (Rauner 2017). The three-dimensional COMET competence model differentiates between the *requirement dimension* (level of competence), the *content dimension*, and the *action dimension* (see Fig. 2 below).

**Fig. 2** The three-dimensional competence model. (see Rauner et al. 2009b, Band I: chapters 1 and 2, b; Band II: chapter 1, 2011; Band III: chapters 1 and 2)

---

## The Requirement Dimension

The modeling of the *requirement dimension* is based on the theory of complete (holistic) solution of professional tasks as well as three successive levels of knowledge to guide, interpret, and reflect action.

The competence levels are allocated to eight competency components, which are of fundamental importance when it comes to the solution of professional tasks.

## The Content Dimension

Describing the content dimension in the form of a systematic systematization model, which can claim general validity for vocational education, the novice to expert paradigm is appropriate. According to this, the professional fields of action and the test assignments assigned to them can be differentiated by levels for beginners, advanced beginners, advanced, and experts.

## The Action Dimension

This illustrates the concept of the complete learning and work action. In the vocational-pedagogical discussion, a distinction is made between the purposively rational and the creative-dialogical type of action (Brater 1984).

Both types of action are of fundamental importance in all professions, with varying significance. The concept of complete work action has a clear affinity with the purposively rational action. This type of action is particularly pronounced in specific work projects and processes in which the scope for action and design is rather small. For the creative-dialogical type of action, an open objective and a course of action which can only be planned within limits are characteristic. The sequence of the steps of action arises from the work process itself. As the subjects of the learning process, the learners determine the course of the educational process very decisively. For the design of test tasks, the differentiation according to types of action is particularly important since the dialogical form of the task solution limits the scope of the conceptual-planning solution of tasks.

---

## Open and Realistic Test Tasks

The basic premise that technical and economic (professional) tasks are not solved “correctly,” but rather more or less appropriate to the situation, and that solutions always represent a compromise between criteria to be weighed against one another, presents a very specific problem for competence diagnostics in the field of vocational education and training.

The format of the test assignments is consistently based on the practice of professional work as well as the guiding principle of a training focused on process

and shaping competence. This results in three basic requirements for the design of test tasks:

1. The degree of complexity must be chosen in such a way that the contextual understanding – and not just a sum of individual skills – can be measured.
2. Open test tasks are necessary, since the solution of professional tasks of specialists must be balanced among alternative solutions.
3. The test tasks must be characteristic and representative of the particular profession. It is not necessary to represent the respective occupational profile in its technical scope – completely – through test tasks.

The scaling of the test results is performance-based (Martens and Rost 2009, 97 ff.). If a candidate only offers the presentation and justification of a working solution, their competence differs from another candidate, who succeeds in developing a solution in which criteria defining the second and third levels of competence are also taken into account. Based on a rating scale consisting of 40 items (five per competence criterion), the raters assess the task solutions.

When using open, complex test tasks, it is crucial to ensure that the evaluators (raters) independently of each other have a high level of agreement when evaluating the task solutions. If this is the case, one speaks of a high degree of interrater reliability. A psychometric test of the rater behavior is performed following the rater training as well as after each test run. The so-called Finn coefficient is used as a measure of the interrater reliability. It has been shown that “the Finn coefficients in the COMET projects are invariably in the range of high reliability as the target criterion of 0.7, defined for this study, was usually reached or exceeded. Overall, interrater reliability can be described as satisfactory” (Haasler and Erdwien 2009, 154 f.; Martens et al. 2011, 105). “Reliability for the competence levels of both vocational education and training theory as well as for the whole construct of professional competence are very high” (Erdwien and Martens 2009, 72, Table 1).

**Table 1** Implementation of reliability tests for the three declared levels of competence (based on the results of the first test date 2008)

Competence level	Competence dimension	Alpha value
Functional competence	Clearness/presentation	0.93
	Functionality	
Procedural competence	Sustainability	0.92
	Efficiency/effectiveness	
	Orientation on business and work process	
Holistic shaping competence	Social responsibility	0.93
	Environmental responsibility	
	Creativity	
Professional competence	All 40 rating criteria	0.97

## Representation of the Test Results

The representation of the COMET test results aims to:

1. Illustrate the professional competence development of the test groups at the level of, e.g., classes, federal states, or national states according to various aspects, in the form of:
  - (a) The competence shape – differentiated according to an overall point value as well as the attained competence levels (in a competence model)
  - (b) The competence level as competence profile (net diagrams)
  - (c) The percentile bands to illustrate the spreading of the results within and between test groups
  - (d) The heterogeneity or variance of the shaping of the competence aspects
2. Represent the professional identity as well as the three dimensions of professional commitment.
3. Graphically illustrate the many connections that result from the interrelations between the test results and the results of the context survey.

The representation of the test results through percentile bands makes it possible to cluster different information about different groups (school locations, sectors, years of training, etc.) vividly. The mean mark (MW) shows the mean value of the groups. By comparing the various mean values, differences in the average performance become visible.

Whether these differences are significant is shown by the gray-colored areas around the mean values on the bands, the confidence intervals. In these areas, the “true” average is 95%. A further important illustration of the percentile bands relates to the spreading of the results. The white areas (including the confidence interval) represent the values for 25–50% and 50–75% of a group, respectively. In this range, the values for half of the test participants are grouped around the mean value. The outer gray areas finally include those cases that form the lower (10–25%) and upper (75–90%) regions, respectively. The best and worst 10% of the results are not covered by the bands, in order not to distort their width by individual outliers (See Fig. 3). For comparing several test groups, bar graphs are used as in the examples in Fig. 4 below.

Net diagrams are used to illustrate the competence profiles of the test group.

This form of representation of the test results is also chosen for feedback to the test participants and their teachers (Fig. 5).

Net diagrams illustrate two further test values:

1. The overall point value (GPW) and the shaping of the eight competence aspects (K1–K8).
2. The variation factor V. It indicates the extent to which the competence profile is homogeneous (uniform) or one-sided.

**Fig. 3** Example for percentile bands showing professional competence (according to test groups, results of 2009)

**Fig. 4** Percentual spreading of the test participants according to competence levels for eight test groups (results of 2009)

**Fig. 5** Representation of a competence profile (extract of a feedback chart for a trainee)

---

### Conclusion: What Is Important for Competence Diagnostics?

First, it is important to understand that professional competence should be able to utilize all the scope for creativity (solution scopes) in the working world, taking into account all the relevant criteria and the values incorporated therein. Does a task solution fulfill its purpose? Which side effects intensify or reduce the solution variants? These and similar questions show that the proposals for the complexity reduction of test tasks involve risks: safety, health, environmental responsibility, and the existence of companies are at stake (e.g., if their offers are highly functional but cost-prohibitive for customers). The competence diagnostics of vocational education and training is challenged to depict this reality of the professional world of work.

An extension of competence diagnostics for the examination of employability at the end of a vocational training is possible. A modernization of the examination system on the basis of the COMET competence model increases the quality of the test results (MHB, Chap. 6.1).

---

### Implications of the COMET Competence Model for the Design of Professional Education Programs

#### What Distinguishes Learning Situations of Work Tasks in COMET?

Learning tasks are aimed at professional competence development. They are similar to project-oriented forms of learning, since the tasks are realistic and are based on the concept of the complete task solution. If learning tasks

**Table 2** Examples of professional fields of action/activity

Logistics manager	Automotive mechatronics engineer	Caring professions
1. Import-export orders	1. Service/maintenance	1. Care during the care process
2. Procurement	2. Repair	2. Carrying out initiated steps
3. Marketing/tendering	4. Retrofitting	3. Training, guidance, and counseling of patients and relatives
4. Forwarding and logistics	4. Diagnostics	4. Administrative tasks/management
5. Business process/controlling		

are also able to be solved practically, it is useful to speak of “work and learning tasks.”

Learning tasks include a situation that:

- Is typical of a professional field of action
- Is formulated from a customer perspective
- Is open to alternative solutions, as is the case with professional practice.

Learning tasks have a practical advantage. Project-based learning is preserved, especially when the didactic concept of the complete task solution is taken into account. However, the organizational and temporal conditions are uncomplicated for the execution of learning tasks.

This also means that these tasks can be edited to varying depth and breadth.

The first reference point for identifying learning-supporting work and learning tasks are the training professions. In addition to the professional qualification profiles (professional skills), they describe the professional fields of action as follows (see Table 2).

---

### **The Learning Objective: Dealing with Heterogeneity Is Aimed at the Individual Promotion of Professional Competence**

Formulating and substantiating learning objectives without prescribing the learning process but rather through exploiting the potential of a learning situation in a subject-oriented manner is based on the educational skill of the teachers. What is common in the design of educational processes is the idea of a learning-oriented instruction. Accordingly, the didactic action of the teacher has to be structured according to the learning objective as there is a direct relationship between the learning objectives and the didactic planning of the lesson. However, this concept of planning,

designing, and evaluating teaching is often problematic because it ignores the reality of vocational education and training, which is geared toward the occupation or workplace. The following schematic representation illustrates how learning objectives can be achieved through developing competencies in vocational education (Fig. 6).

## Developing Learner Competences

The COMET competence model offers a solution that is oriented to the guiding principle of mediating professional competence by processing and solving professional tasks that achieve the quality of development tasks. The overarching educational objective, the ability to completely solve occupational tasks, cannot be called into question, since incompletely solved professional tasks often involve large risks. The empirical competence research shows that the great degree of heterogeneity within and between test groups (e.g., classes) persists even if the teacher succeeds in raising the competence level of his/her class (see Fig. 7).

If the professional competence (development) of trainees or students of technical colleges is represented in the form of competence profiles (see Fig. 8, p. 15), learners and teachers can answer important questions such as:

- Did the trainee/student solve the problem completely?
- If not, which solution aspects were not or inadequately taken into account?
- Is the competence shaping similar for all students?
- If this is the case, the teacher is challenged to promote the underdeveloped sub-competences, e.g., by means of appropriate learning situations.
- On which level of knowledge was the task solution justified?

The competence profiles of the students are a good basis for the design of differentiated teaching (individual support).

This form of diagnostics (evaluation) also depicts the level of knowledge at which the trainees/students are able to solve professional tasks: on the level of action guiding, interpreting, or reflecting work process knowledge.

The strengths and weaknesses of task solutions or of project results can be discussed so that each learner/student recognizes how their solution or the project result of their work group can be classified. The standards are always the same and seek to answer the following questions:

- Has the task been solved completely in the sense of the situation description?
- Were the solution aspects weighed against each other in relation to the situation?
- At which level of differentiation was the task solution justified with reference to the result and the procedure?

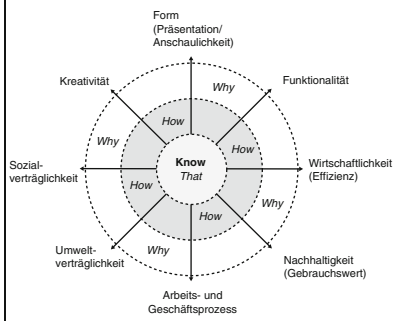

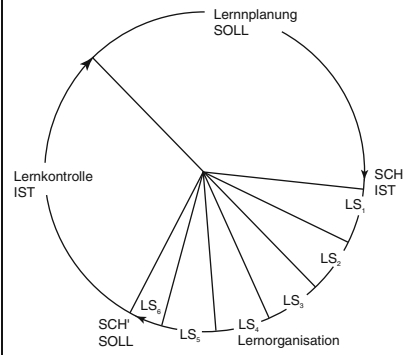

<p>Trainees grow into a profession by learning to solve increasingly complex professional tasks in a complete and responsible manner: the professional abilities as well as the understanding of and the responsibility for one's actions form an indissoluble connection.</p> <p>Therefore, the potential of the learning situation of triggering competence development is particularly important. Professional competence arises from the reflected work experience.</p>  <p><i>Schematic presentation of work process knowledge</i></p>	<p>The teacher defines the learning objectives for his/her lessons: desired learning behavior of the students = planning of learning/classes.</p> <p>He/she organizes learning by arranging the learning steps in an optimal manner:</p> <p>Attempting to achieve the desired learning behavior of the students = organization of learning;</p> <p>the teacher checks whether the student Sch has become student Sch' as a result of learning: control of learning</p>  <p><i>Schematic presentation of classes oriented at learning objectives according to Möller 1969, p. 20</i></p>
<p>The degree to which skilled trainees (apprentices/students) can make use of the scope for solutions and/or scope for their work in the area of professional tasks is the indicator for the extent of professional competence</p>	<p>The didactic action of the teacher is based on the type of the purposeful action and corresponding didactics, e.g. in the concept of programmed learning.</p>
<p>Teacher as “development worker“ and “learning consultant“</p>	<p>Teacher as “teaching system“</p>

Fig. 6 Develop competences to achieve learning objectives

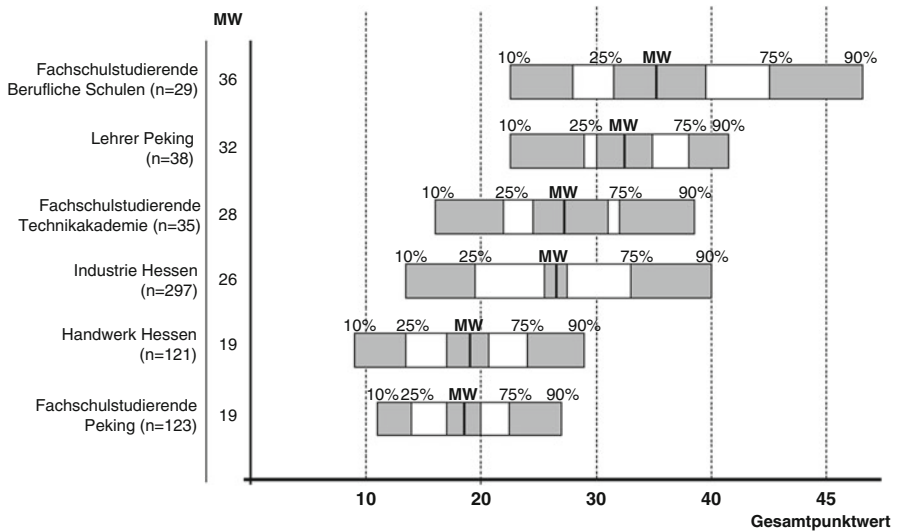

## Design and Organization of Vocational Education and Training Processes: Opening Up Action Scopes and Learning Opportunities

Planning and preparation of project-based learning are confronted with a dilemma. Detailed planning largely defines the objectives, contents, and course of didactic action. However, a good teaching plan is only possible if it opens up problem-solving scopes for the students. A first reference to dealing with the described dilemma can be found in the already discussed educational paradox: Vocational beginners become skilled learners by doing what they desire to or are required to learn. The instructor is not allowed to simply present the students with what she/he wants them to learn. This is where the new role of teachers comes into play, namely, the opening up of shaping and decision-making scope for the trainees/students, thus moving from knowledge mediator to process facilitator.

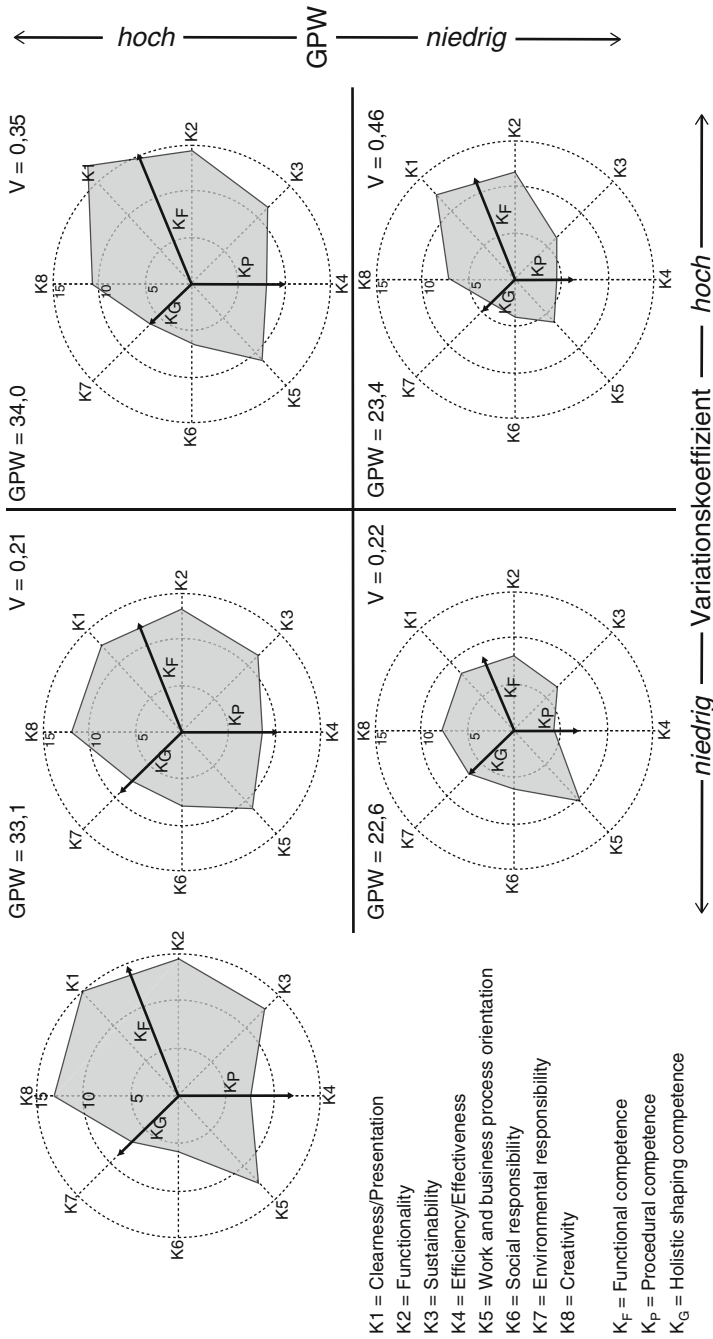

Steps in the design of a professional education process can be outlined as follows:

*Step 1: Selection of a customer assignment with “appropriate” learning potential and formulation of a learning task*

A central role in the design and organization of professional education processes is the selection of suitable customer assignments and their formulation as learning tasks. Based on the selected assignments, the teacher can create learning situations with appropriate situation descriptions. The question from the point of view of the learner is thus: Where do I see the challenges that the job provides for me? When asked what he can actually learn by dealing with the new situation, he will not find an

**Fig. 7** Percentile bands for the professional competence between test groups on class level for trainees (results 2009)

**Fig. 8** Average competence profile of a test group of students of technical colleges (type “vocational training”),  $n = 27$  and (Fig. 2) differentiation of the competence profiles according to the overall point value (GWP) and the variation factor: **(a)** E\_B, class Nr. 7,  $n = 26$ ; **(b)** E-B, class Nr. 5,  $n = 18$ ; **(c)** E-B, class Nr. 24,  $n = 19$ ; **(d)** E-B, class Nr. 23,  $n = 17$  (Rauner et al. 2011)

answer until the task has been solved. At this point, the teacher is particularly responsible for the fact that the learners can learn something while working on the learning task. In order to fulfill this responsibility, he/she has to clarify very clearly the experiences that (individual) learners have already made and the knowledge they have acquired. Only then can the challenge through which they can gain new work experience be described. The work and learning process structure is represented in the diagram below (Fig. 9).

Learning tasks and their possible solutions leave open the level at which they are solved and have an individual development potential for the trainees/students. Issues that teachers should consider in this first step are:

- The learning task has to be selected in such a way that it has a corresponding learning potential for the learning group and all trainees/students on the way to reaching employability (see the professional profiles and the vocational curricula).
- The learning task should pose a challenge for the low-performing as well as the high-performing learners and offer correspondingly challenging possibilities for solutions.
- The learning task must be described from the customer perspective. In the case of extensive tasks, the question arises of a work-division procedure in groups. This form of learning organization is very challenging as the coordination of the work-based learning includes the cooperation between the groups and all participants should benefit from the learning processes and results.
- The combination of the partial solutions and the new knowledge must be planned carefully.
- How should the group inform each other about what has been learned?

### *Step 2: Analysis of the situation description of the customer and professional specification*

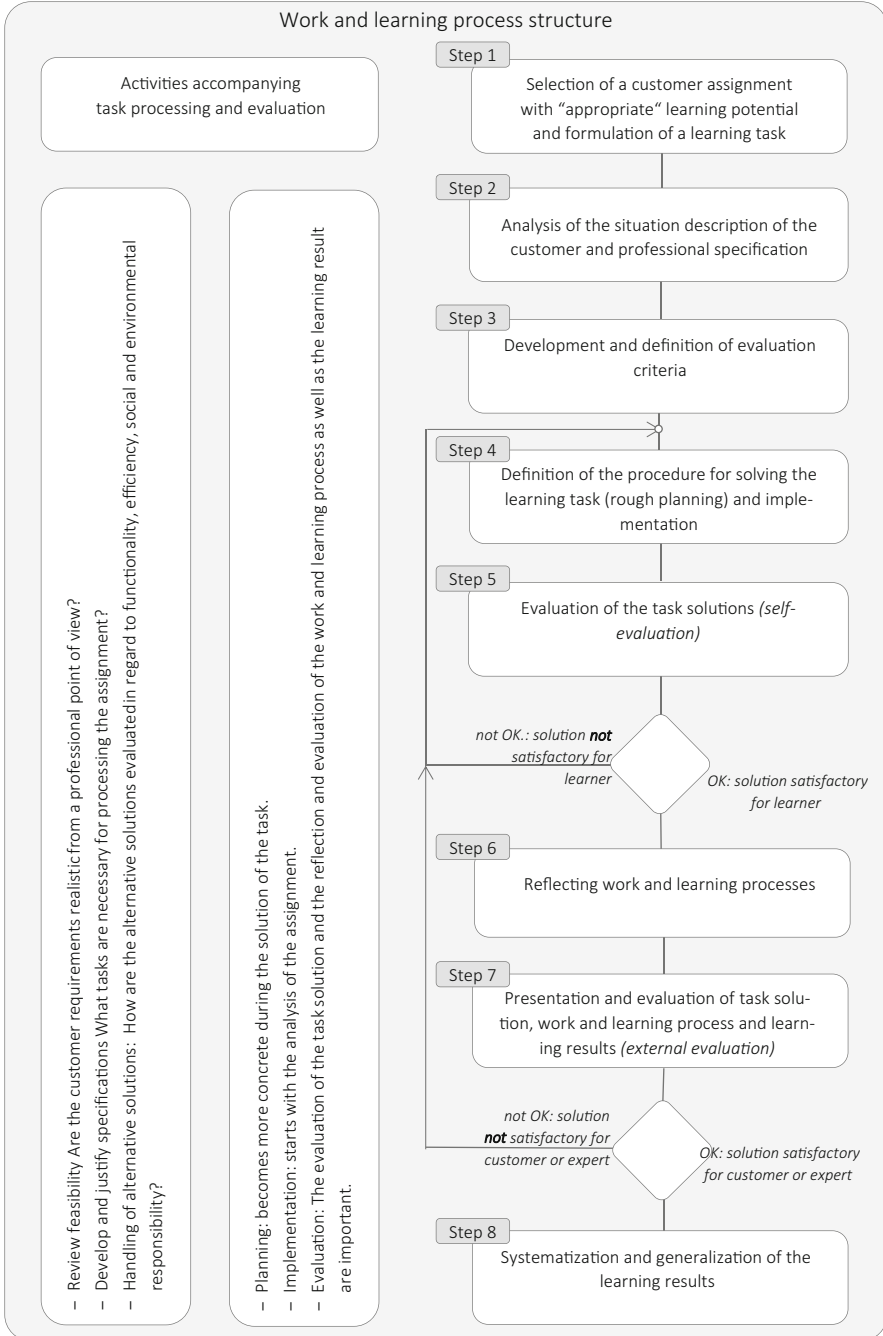

All learning tasks are described from the customer perspective. The task of the learner as skilled expert then becomes:

- To check the requirements of the customer for their feasibility
- To check whether individual requirements contradict each other and how to resolve these contradictions by weighing all requirements against each other
- To check whether the customer has overlooked requirements that are technically possible

### *Step 3: Development and definition of evaluation criteria*

The results of empirical teaching research show that the development of evaluation criteria (and their application in the self-evaluation of work and learning outcomes) increase learning success with regard to:

- The scope and evaluation of alternative solutions
- The possibilities for design and organization of the task solution (work process)
- The reflection of the learned content and the learning process

**Fig. 9** Work and learning process structure

**Table 3** Evaluation criteria for task solution, approach, and competence

Task solution	Approach	Acquirement of new skills
Does the task solution have an appropriate sustainability value for the customer (contractor)?	Has the planned procedure proven itself?	What prior working experiences and knowledge could be used?
Was the task solved completely?	Has the description of the situation been translated into professional requirements?	What knowledge and skills had to be acquired to solve the task?
	Were there deviations from the requirements of the customer and if so, why?	Where and how was the teacher's knowledge and know-how used?
Were alternative solutions weighed against each other and justified?	In which steps did prior knowledge not suffice for the task solution?	What resources have been used solving the task (technical books, Internet, etc.)?
Was the presentation of the results (for whom) successful?	What help has been used for problem-solving?	Was the know-how of individual students (students learning from students) helpful?
How is the quality of the task solution assessed based on the evaluation criteria?	What mistakes and deadlocks arose and how were they corrected?	What role did experimenting play in the acquisition of new competences?

Since the evaluation criteria describe not only the expectations of the result but also the process of the task solution, they form a good basis for reflecting what was learned and the quality of the task solution.

The evaluation criteria for solving open tasks allow learners to make their competence development transparent (Table 3).

#### *Step 4: Procedure for solving the learning task*

In the course of designing a learning situation or a project, planning is provisional because, as a task progresses, experience is gained and unpredictable difficulties arise which must be solved. Frequently the newly acquired knowledge suggests a modified approach.

The practical experience thus provides the basis for decision-making for further planning. This possibility of decision-making is particularly important in the case of challenges to which a competence-promoting potential is attributed (Fig. 10).

On the way to finding a solution, planning, executing, and evaluating are therefore alternating steps in the process of learning situations and in the execution of projects. This “cautious approach” is an explanation for the dissolution of the described training paradox in the context of action learning.

Teacher's help should be process- and not product-related. References to information sources, methods of learning, experimental possibilities, software tools, or

**Fig. 10** Steps to solve challenging situations

even mathematical methods are part of the process-related aids, which give the trainee the chance to solve the task him-/herself.

*Step 5: Evaluate the solution (self-evaluation)*

When the solution for the task is found, the process of learning is not yet complete. Now it is important to evaluate the quality of the task solution. As a rule, it turns out that different solutions have been developed by different trainees/students or working groups. The competence profiles (Fig. 11) show the differences. The COMET rating method is useful in this process (Table 4).

*Step 6: Reflecting work and learning processes*

The following questions are designed to help with taking into account different perspectives in the reflection process.

Questions for the reflection process:

- How did I proceed during task processing (what was my first, second, etc. step)?
- What could I solve without difficulty due to prior knowledge?
- What did I consider especially for solving this task?
- How exactly did I proceed within the respective steps?
- Why did I proceed this way and what are the reasons for my choices?
- Which methods did I use?
- Which “cliffs” were contained in the task and what did I have to learn anew?
- What new learning methods did I have to acquire in order to completely solve the task?

(continued)

**Fig. 11** Varying solutions (Final report 2010, Hessen)

- How do the estimated challenge and the actual learning growth converge?
- How did I organize my work and what will I do differently next time?
- At which “cliffs” did I use the teacher’s support?
- What were the most important tools for solving the task?

Note: Depending on the organization of the task processing, the questions must be answered individually and/or in the group.

*Step 7: Present and evaluate task solution, work and learning process, as well as learning results (external evaluation)*

The presentation and assessment of the task solution, work and learning process, and learning results are of high didactic value:

- The satisfaction/dissatisfaction of the “customer” with the presented task solution is clarified.
- The sustainability of the task solution is assessed by professionals (learners, teachers, trainers, etc.).
- Questions concerning the success of the procedure (including the use of methods) and its optimization for further use for learning situations/projects are clarified.
- Explanations, justifications, and considerations are assessed for their appropriateness and conclusiveness, taking into account alternative solutions and procedures.

**Table 4** Evaluation chart for use in the classroom, example electrician (Katzenmeyer et al. 2009, 202)

	Criteria/indicators	Notes	Fully met	Rather met	Rather not met	Not met at all
Clearness/presentation						
1	Presentation appropriate for client? For example, description, operating instructions, cost plan, construction plan					
2	Presentation appropriate for professionals? For example, wiring diagrams, installation plans, terminal plan, cable plan, program printout commented					
3	Solution illustrated? For example, technology scheme, map, sketches					
4	Structured and clear? For example, cover page, table of contents, page numbering, company contact information, customer contact information					
Functionality						
5	Functionality given? For example, dimensioning/calculation OK, protection, necessary interlocks, end switch					
6	Practical realization taken into account? For example, electrical and mechanical construction possible?					
7	Presentation and explanation correct and technical state of the art taken into account?					
8	Solution complete? For example, are all requested and necessary functions given?					
Sustainability						
9	Use value for clients? Are useful and helpful functions taken into account? Automatic fault detection, changes possible					
10	User friendliness for users? For example, operability, operator guidance, clarity, alarm and operating displays					
11	Low susceptibility taken into account? For example, preventive error information, redundancy, partial solubility, are the material properties optimal for the application?					
12	Long-term availability and expansion taken into account?					

*(continued)*

**Table 4** (continued)

	Criteria/indicators	Notes	Fully met	Rather met	Rather not met	Not met at all
Efficiency/effectiveness						
13	Cost effective? For example, time and human resources, material use					
14	Follow-up costs taken into account? For example, electricity costs, maintenance costs, standstill costs in the event of loss of control					
15	Economic aspects taken into account? For example, standstill costs in case of component failure weighed against production costs?					
Work and business process						
16	Process organization in own company and at customer's premises, e.g., time and assignment planning, basic conditions for installation work clarified?					
17	Work process knowledge (work experience), e.g., does the solution have a structure that shows the workflow? Are upstream and downstream processes taken into account?					
18	Limits of own professional work? For example, structural changes, orders for other trades, foundation for control cabinet, scaffolding for sensor assembly taken into account					
Social responsibility						
19	Humane work and organizational design, e.g., ergonomics, serviceability					
20	Health protection taken into account? For example, toxic fumes, radiation, noise, risk of injury prevented					
	Actions in an emergency possible and explained?					
	Hazard analysis for assembly, operation, service, disruption and disassembly carried out?					
21	Occupational safety and accident prevention?					
	Work on ladders and scaffolding, PSA, instruction of third parties, hazard notes, labeling of dangerous substances					

(continued)

**Table 4** (continued)

	Criteria/indicators	Notes	Fully met	Rather met	Rather not met	Not met at all
	Environmental responsibility					
22	Recycling, recyclability, sustainability, e.g., ROHS material, PVC-free material, prevention, reduction, and recycling of waste					
23	Energy saving and energy efficiency, e.g., energy-saving lamps, EFF class for motors, minimize standby losses, displays with LEDs instead of lamps					
	Creativity					
24	Does the solution show problem sensitivity? For example, customer wish fully captured and implemented?					
25	Design scope exhausted? For example, useful additional functions planned?					
26	Economic aspects taken into account? For example, standstill costs in case of component failure weighed against production costs?					

- Experiences with different learning methods and structures of work organization are exchanged.
- Knowledge development, new experiences, and new abilities are described and evaluated, and the question “What else was learned?” is answered.

Of critical importance are reflections on:

- The methodological approach
- The ability to work together
- How conflicts were handled

#### *Step 8: Systematize and generalize the learning results*

The gradual generalization of professional experience in the process of dual vocational education and training leads to concepts and theories available to the individual as generalized “tools of thought” as well as tools of communication and reflection, which point to the real context from which they originated.

Generalization is about decoupling the work experience from the concrete learning situation and the task solution in order to make it available for the following customer orders. Teachers are now encouraging their students to become aware of their extended specialist understanding and to use this in their thinking, action, and skills in a professional way.

## Conclusion

In this chapter COMET as a competence diagnostic framework has been theorized and explained with reference to empirical examples taken from studies in various contexts. As a multidimensional tool for competence analysis, COMET adopts a step-by-step approach to understanding students' strengths and weaknesses and is able to assist teachers to plan the appropriate didactic interventions in a systematic manner. The goal of holistic shaping competence is key to realizing the ultimate purpose of professional vocational education.

## Abstract

The needs of learners in technical and vocational education and training (TVET) have been widely researched and documented. The same is true of ways to support such learning needs. This chapter addresses one specific question: what support do TVET learners need to enable them to acquire behaviors, knowledge, and attitudes to succeed in TVET, employment, and life? Success appears in many guises. It can mean achieving officially desired outcomes such as retention, completion, and employment. It can also mean achieving less measurable outcomes such as deep learning, well-being, and active citizenship. The chapter first introduces an overarching *success framework* before exploring how the widely used student engagement pedagogy can support learners to achieve both official and personal success outcomes. It then develops two specific constructs applicable to TVET and found in *success frameworks* and student engagement: facilitated peer learning and active citizenship. Peer learning is here connected to teacher-facilitated but peer-run mentoring; active citizenship to educational experiences in classrooms, institutions, and workplaces that support flexibility,

## Introduction

This chapter addresses one overarching focusing question – what support do learners in technical and vocational education and training (TVET) need to succeed in their study? A paragraph in the summary of UNESCO's (2015) General Conference on TVET offers a summary:

In addition to knowledge, skills and competencies relating to occupational fields, learning processes should build on foundation skills and further deepen understandings of the scientific, technological, social, cultural, environmental, economic and other aspects of societies. TVET should be holistic and develop transversal and entrepreneurial skills, skills for health and work safety, cultural development, responsible citizenship and sustainable development, as well as knowledge of labour rights. (Paragraph 29, General Conference, UNESCO)

Researchers into TVET echo this view that vocational knowledge, skills, and attitudes, while necessary, are not sufficient for TVET learners to achieve all learning outcomes (e.g., Billett 2009; Tyson 2016; Webster and Sausner 2017). They posit two distinct meanings of vocation. One focuses on occupation – the ability to practice a vocation competently. The other is more about preparing learners for a journey or trajectory, “a calling” that prepares learners for life, including life beyond employment. Tyson (2016) speculates that this second type of learning is akin to vocational *Bildung* – a German word that suggests that TVET is also a lifelong process of personal vocational development and maturation that includes ethical and aesthetic knowledge/capability as active citizens, capacity for wise reflection and judgment, relationship building, and the development of personal autonomy.

The chapter explores how vocational competence and *Bildung* support TVET learner success. It responds to the focusing question in four sections. The first explores a possible overarching success framework for TVET students to frame the chapter. This focuses on generic institutional and teaching program policies and practices that support learner success. The second section summarizes key findings from student engagement research. These sketch a pedagogy for TVET that shows how success frameworks might be implemented in practice. It explores three propositions from student engagement: successful students invest in their own learning; instructors and institutions enable engagement; and success requires supportive environments. While these are general principles of engagement, particular interest has emerged in how learner voice, learning partnerships, and practicing citizenship while learning can affect TVET. Hence the third section discusses the use

of facilitated peer learning to develop the active citizenship of TVET learners. The chapter concludes with some examples of how facilitated peer learning and active citizenship might work in practice.

---

## Toward an Overarching Success Framework in TVET

Supporting learner success belongs in the first place to educational policy and the TVET providers that implement it. Since the late 1990s many governments have adopted policies that expect learners to succeed in education and the workplace and as socially integrated citizens. Success in TVET is often judged by whether “hard” quantifiable outcomes such as retention, persistence, achievement, completion, and employment are achieved. To support learners attain such hard outcomes, policies must set measurable standards and goals toward which institutions, teachers, and learners strive. However, meeting hard outcomes does not give a complete picture of learner/learning success. Learner’s own goals and experiences independent of hard outcomes are equally important. One approach that reaches beyond hard outcomes like retention and completion focuses on soft outcomes (Butcher et al. 2006). Such outcomes are derived from students’ cognitive investment in, active participation in, and emotional commitment to their learning (Reschly and Christenson 2012). Numerous governments and international agencies have developed frameworks of soft outcomes also labelled “key” or “twenty-first-century competencies.” Voogt and Pareja Roblin (2012), for example, analyzed eight such frameworks from around the world. They found they shared a number of similar competencies: collaboration, communication, ICT literacy, and social and/or cultural competencies, and most also included creativity, critical thinking, productivity, and problem-solving. Such soft outcomes are not easily quantified but offer important learning outcomes that require support from institutions and inclusion in teaching programs.

Researchers in California Community Colleges constructed a *success framework* for TVET using both hard and soft outcomes (Booth et al. 2013). They asked nearly 900 students from 13 California community colleges what they thought supported their learning successes. They found that learner support must be integrated into students’ daily experiences with administration, teachers, peers, and members of the community. They concluded that learners are more likely to succeed when they are directed, focused, nurtured, engaged, connected, and valued by institutional and program practices. Learners are *directed* if they have a goal and know how to achieve it, *focused* when they stay on task by keeping their eyes on the goal, *nurtured* if they feel they are supported to succeed, *engaged* when they actively participate in learning activities, and *connected* if they feel part of the institutional and wider community. While all success factors contain hard and soft outcomes, hard outcomes dominate the *directed* and *focused* factors. Where everyone knows what outcomes must be achieved and understands that the curriculum is directed to and focused on such outcomes, the road to success is set out. *Engaged* and *connected* success factors include both hard and soft outcomes. Hard outcomes such as retention and completion can be met where learners engage and connect with the curriculum. Soft

outcomes such as positive energy and commitment are also embedded in engagement and connection. The *nurtured* and *valued* success factors are personal and subjective and align more with soft outcomes than the others.

Other researchers too have generated practical suggestions about supporting successful hard and soft learning outcomes in TVET programs. To abstract a reasonably systematic overview of this literature, the chapter investigates support in terms of what TVET providers and teaching programs can do to enable learners achieve success. For example, Kuh et al. (2005) investigated the practices of 20 successful higher education institutions in the USA. They found that these organizations focus on supporting student success, foreground learning, establish high expectations, aim for continuous improvement, invest money in support services, support diversity, and prepare students for learning at work and in the wider community. Only a small sample of what this might entail can be noted here. But there is consensus that a learning- and success-centered provider and program culture are part of the learning experience; that enrolment processes, course advice, and monitoring of progress are evident, user-friendly, and efficient; and that communication channels between learners and providers are clearly established, well publicized, and open (c.f. Tinto and Pusser 2006; Ramsden and Callender 2014; Tinto 2015). Researchers also agree that providers that support student success offer a wide range of student services. Examples include child care, pastoral care, financial advice, counselling, health services, library support, resource centers for minorities, employment services, study skills assistance, and active learning and support networks. In short, providers and teaching programs that build and maintain *success frameworks* support learners' total well-being (Field 2009; Gill 2009).

Another key aspect of a *success framework* is what providers and program leaders do in TVET programs to direct, focus, nurture, engage, connect, and value learners. Again, relevant research literature is rich and varied and can only be selectively summarized here. But Chickering and Gamson's (1987) time-honored seven principles of good practice synthesized what teachers and programs can do to support learners in higher education including TVET. The principles are encouraging teacher-learner contact, developing cooperation among learners, using active learning techniques, giving prompt feedback, emphasizing time on task, communicating high expectations, and respecting diversity. Together, these principles help learners meet both hard and soft outcomes in a *success framework*. More speculative but equally serving both hard and soft outcomes is the work of Arvanitakis and Hornsby (2016). They contribute to a TVET *success framework* with four future proficiency clusters. The first is creativity and innovation. Programs placing critical thinking, problem-solving, and reflection at the heart of learning support learner success in times of rapid technological and social change. The second proficiency cluster centers on resilience. Learners encouraged to adapt to change are nimble and flexible, learn from mistakes, and persevere. The third proficiency cluster is teamwork. Programs in which individual and collective success are considered equal help prepare learners for success in life. The final proficiency cluster is design thinking. Here providers and their programs place learners' success first with the entire system designed to meet this outcome.

## A Pedagogy for Success

Yet, designing an overarching *success framework* is only a first step in supporting TVET learners' success. *Success frameworks* offer a variety of high-level principles designed to help learners and instructors visualize meeting both hard and soft outcomes. However, such high-level principles can neglect the day-to-day pedagogy required to support learner success. Student engagement is mentioned as a key ingredient in most *success frameworks*. It is a well-researched pedagogy, a meta-construct and template for action-based teaching and learning that implements the strategies in *success frameworks*. Student engagement offers a heuristic shortcut for understanding the complex behaviors, thinking, and emotions that lead to successful learning (Reschly and Christenson 2012). The overriding purpose of TVET is to engage learners to develop their vocation and life skills by achieving outcomes expected in program design, industry, and wider society and by learners themselves. But like all learning and teaching, student engagement is complex. Its complexity lies, first, in its generic and applied nature. It offers a pedagogy that must be adapted to many different contexts (Reschly and Christenson 2012). Second, it blends learning and teaching without separating them. Barr and Tagg (1995) introduced the term "learning paradigm" in which students are not just receptacles for instructors' knowledge, but co-producers of knowledge with shared responsibility for their learning. Third, it applies at all levels of TVET – at secondary schools, at higher and further education, and in the workplace.

Student engagement research provides the TVET community with evidence-based and practical approaches to teaching for learner success. Kuh (2009) and Pascarella et al. (2010), for example, show that student engagement is an important predictor for retention and improved grades in higher education. It is also positively correlated with a range of softer outcomes such as critical thinking, cognitive development, self-esteem, satisfaction with life, and the building of positive relationships with others. With such evidence governments, providers, and instructors can implement engagement as a pedagogy for TVET that supports learner success in training programs and subsequently in productive employment. Kuh et al. (2008) found that right behaviors by learners and teachers support engagement and success. Fredricks et al. (2004) suggested that engagement is not only about right behaviors but also involves students' cognitive investment in and emotional commitment to their learning. Cognitive engagement points to investment in deep learning of concepts and skills, of individual construction of meaning, and of transforming meanings (Marton and Säljö 1976). Emotional engagement results from feelings of psychological well-being such as a sense of belonging and security in relationships both inside and outside the learning context (Wimpenny and Savin-Baden 2013). Together these modes of engagement are critical for achieving success in vocation and life more generally.

Carey (2013) goes even further. He views engagement as an expansive idea that in addition to fostering active behavioral, cognitive, and emotional student participation in learning involves building a sense of identity with, belonging to, and involvement in the work of their teachers, providers, and occupations. Lawson and

Lawson (2013) go wider still with a multidimensional view of engagement. They synthesize student engagement using a sociocultural ecological lens tracing student, teacher, provider, and external environment perspectives. Kahu (2013) suggested that while engagement occurs within a specific learning context, it has positive proximal and distal consequences, such as satisfaction and well-being, citizenship, and personal growth, thus highlighting a connection between well-being, citizenship, education, and engagement both inside and outside the learning context. Leach (2015) endorses Kahu's holistic model of engagement with the following definition:

Student engagement is understood as the time and effort students invest in educational activities. The consequences of their engagement – their success in their study, their personal growth and the contribution they make to society through active citizenship – are affected by personal and contextual antecedents as well as the actions taken by teachers, institutions, families and friends to facilitate their engagement in an active partnership.

In TVET student engagement supports learner success by offering a learning culture that helps achieve hard and soft outcomes both in vocational and personal development.

## **Proposals for a Student Engagement Pedagogy**

Many different behavioral, cognitive, and affective characteristics of student engagement have been proposed as models for quality teaching since the 1980s (e.g., Entwistle and Ramsden 1983; Kuh 2009; Zepke and Leach 2010). These models have had a major impact on educational practice. The National Survey of Student Engagement (NSSE) has been particularly influential with its survey of behaviors assessing mainly the achievement of hard outcomes. While this offers a powerful data set about behaviors that engage students, Zepke (2017) used a “meta-synthesis” (Erwin et al. 2011) of over 500 research publications to make 10 proposals that engage learners to achieve both hard and soft outcomes. This section now summarizes Zepke's proposals for a supportive student engagement pedagogy under three general headings: (i) learners invest in their own success; (ii) instructors and providers are vital enablers of engagement; and (iii) engagement requires enabling external environments.

### **Learners Invest in Their Own Success**

Four proposals under this heading were arranged into two pairs around self-belief and diversity. The first proposal stated that learners' self-belief is vital for success. All learners have individual and collective strengths. A strengths-based approach assumes that learners can achieve hard and soft outcomes if they have self-belief and are supported to develop it. Self-belief requires pedagogy that builds strengths and is not fixated on problems. Strengths-based learning is rooted in *appreciative inquiry* (Bushe 2013). This de-emphasizes the negatives people bring to learning. *Appreciative inquiry* requires learners and instructors to demonstrate in word and deed that learner strengths are appreciated, that learning activities and assessment methods

vary so that different strengths come into play, and that affirming feedback focuses on strengths while recognizing weaknesses. The second proposal suggests that learner motivation grows from self-belief. Learners invest in their own success when able to learn autonomously, enjoy learning relationships, and feel they are competent to achieve their own and others' objectives (Ryan and Deci 2000). Of the three motivational factors – autonomy, belonging, and competence – feeling competent is the most important. Examples of this proposal in action include learning tasks and activities that enable students to feel competent to develop strengths without hiding weaknesses; feedback on completed tasks that is timely and specific, reinforces strengths, and provides guidance on how to address weaknesses; and group activities that encourage interdependence, a sense of belonging, and the opportunity for individuals to work autonomously with others.

The second pair of proposals under this heading focuses more on student engagement as a pedagogy that recognizes and values individual and group differences. The first proposal in this pair is that TVET learners' different social and cultural learning capital is recognized, valued, and built to increase feelings of self-worth and competence. This suggests that whether due to social class, culture, ethnicity, age, gender, geographic location, or sexual orientation differences influence how students engage and whether they succeed. For learners from minority “nontraditional” groups to feel like fish in water (Thomas 2002), learners must have the social and cultural capital needed to succeed in TVET. But they often lack support and do not bring the “right” social, cultural, and vocational competence to engage and succeed in TVET. A curriculum that builds social and cultural capital supports, for example, specific learning needs of minorities in a learning group, adopts strategies based on *appreciative inquiry* to acknowledge practices of minority groups, and offers feedback that is aware of social and cultural differences. The second proposal in this pair is that engaged learners are deep learners. The Higher Education Academy in the United Kingdom (n.d.) brought together numerous characteristics of deep learning from the research literature. Examples include examining facts, ideas, and practices analytically by matching them to learners' existing knowledge structures, linking ideas and practices to different social and cultural settings, looking for meaning, solving problems, distinguishing between argument and evidence, and developing curiosity and personal interest in the subject.

### **Instructors and Providers Are Vital Enablers of Engagement**

The previous proposals highlight the importance of teachers supporting TVET learners' confidence in self. This next cluster of three proposals comprises the following: (i) quality teaching and institutional support enhance engagement; (ii) vocational knowledge engages students; and (iii) quality teaching adapts to changing student expectations. According to Trowler (2010), questions of how quality teaching can support student success dominate engagement research. Engagement-enhancing practices are many. As observed above, Chickering and Gamson's (1987) seven principles for good practice still serve well as a guide for engaging teaching in TVET. But instructors must remain aware that to engage their learners often requires specific applications of generic ideas. This is particularly true

for teaching in TVET where specific vocational knowledge, skills, and attitude are taught and general teaching approaches must be adapted to meet TVET requirements. For example, conceptual understandings and practices must meet the changing requirements of an occupation. Such understandings involve key terms, concepts, and principles and how they can be applied in the “real world.” Teachers must also respond to changes in technology and keep abreast of changes in evaluating and interpreting knowledge and practices. This last point is critical in times of ever-changing learner expectations. Examples of instructors meeting learner expectations include being on top of changes happening in the world of work and employment, particularly in technology. Providers and instructors also need to keep up with changes in the way learning support like library services, pastoral care, and support networks are delivered to keep up with changing learner demands.

### **Engagement Requires Enabling External Environments**

The three proposals in this section suggest that learning generally, and TVET particularly, does not just occur in formal instructional settings. The first proposal captures the idea that learning is lifelong and lifewide. It adds an extra dimension to student engagement in TVET. It suggests that learners inhabit multiple learning spaces simultaneously and can draw inspiration from them. Barnett (2010) lists a number of potential learning spaces. Formal learning in credit-bearing courses is one space. Learning at home, work, and even the pub and on the train can provide unaccredited but personally stretching spaces that can transfer knowledge, skills, and attitudes to TVET learning programs. The second proposal in this cluster focuses on soft outcomes of TVET. It proposes that learners are citizens and should become active citizens in TVET. Learners want to feel they have a voice in what and how they learn and “student voice” has become a powerful metaphor for active citizenship. Where educators give students voice and opportunities for collaboration, engagement rises. Klemenčič (2011) suggests that participation serves as an indicator of democracy and results in a culture of dialogue. The third proposal is that student engagement is linked to well-being. Personal and social well-being is achieved in TVET in supportive relationships and sense of trust and engagement with others. Personal well-being requires autonomy, competence, engagement, and self-esteem; social well-being involves social engagement, sound interpersonal relationships, and social competence.

---

### **Facilitated Peer Learning and Active Citizenship in Practice**

Peer-facilitated learning and active citizenship offer two practical learning approaches supportive of TVET learner success. Both approaches draw on *success frameworks* and student engagement pedagogy. Voogt and Pareja Roblin (2012), for example, found that *success frameworks* share similar curriculum goals such as collaboration, communication, creativity, critical thinking, citizenship, productivity, and problem-solving. Student engagement invests heavily in the notion of *partnership* as a way to transform the learner from *consumer of teaching* into a *producer of learning* (e.g., Neary et al. 2014; Nygaard et al. 2013). According to Arvanitakis and

Hornsby (2016), a combination of peer-facilitated learning and active citizenship helps “future-proof” learning by enabling learners achieve success now and in the future. They propose that “future proofing” requires TVET learners to apply ever-changing knowledge, skills, and values in their own context for the betterment of their occupation and society. But the idea of future-proofing TVET challenges current curriculum thinking and practices. From a philosophical standpoint, Biesta (2013) argues that curriculum is currently far more concerned with accountability and performativity than the needs of learners in a changing world. He suggests a switch in curriculum focus from the individual to the collective, the democratic, and the political. Tagg (2003) agrees from a practical standpoint. He advises instructors to focus on collaborative activities and real-world applications so that learners engage with each other to achieve hard and soft outcomes.

Future proofing involves learners pursuing occupational training objectives and vocational “Bildung” by drawing on the experiences of peers as well as the knowledge and skills of their instructors and experienced practitioners. Modelled on Wenger’s (1998) version of learning communities, such learning partnerships result in mutual engagement and joint enterprise, working together to achieve common goals and sharing responsibilities and resources (McIntosh and Cross 2016). There are many slightly different versions of peer-facilitated learning: peer-assisted study sessions (PASS), peer-facilitated study, peer-assisted learning (PAL), learning communities, supplemental instruction, and transition mentoring are some examples. Research has found that whatever the form, all versions contribute demonstrably to learner success. For example, there is a strong correlation between students regularly attending PASS and an approximately 10% increase in learning success, a lowering of the failure rate, and an increase in high achievement (Fostier and Carey 2007); a meta-study of published research on peer-facilitated learning shows an average improvement of 15% obtaining A, B, or C grades (Gosser 2015); and in another meta-analysis, Hattie (2012) shows that every facet of a robust peer tutoring model has a high effect size. All forms of peer-facilitated learning are designed to enable learners to grow as vocational practitioners and as citizens who learn actively, thrive on such learning, and feel connected to vocation and society. Some versions are developmental, others remedial.

Peer-assisted study sessions (PASS) provide a prominent example of peer-facilitated learning. I discuss PASS now in greater detail as a representative example of peer-facilitated learning. The purpose of PASS is developmental, not remedial. It supports and supplements learning by employing the combined agency and power of instructors, student facilitators, and learners working together in voluntary but usually timetabled sessions. It contributes to student engagement, retention, and learner well-being, supports active and collegial learning, improves learner-instructor and peer relationships, and opens channels of communication between learners and their vocation giving learners agency and voice (Zacharopoulou et al. 2015). By working in learning communities, learners become “stakeholders” or partners in their own learning, active citizens. According to Carey (2013), student voice is already a vital part of learning processes through quality assurance and student feedback, for example. But he suggests that such uses of student voice allow learners to speak while not necessarily being heard. Fielding (2004) argues that

restrictive uses of learner voice must be expanded by learning that is active and democratic and contributes to decision-making about curriculum, learning activities, and assessment processes. According to Trowler (2010), confident and proficient learners exercising their voice become co-producers of learning, active co-workers in organizational structures, and identity builders in the wider community. Having exercised their voices in their own learning contexts, learners gain the potential to influence their occupation in the future.

Like other forms of peer-facilitated learning, PASS integrates and nurtures the use of learner voice and agency. It contributes to future proofing TVET by supporting learners to become co-producers of learning and active citizens. Agency works on two levels. On one it shows appreciation of learners' strengths in achieving their own learning goals and those of peers. As mentioned previously, strengths-based teaching, rooted in *appreciative inquiry*, recognizes that students bring cultural, age-related, educational, character-related strengths, among many others. According to Bushe (2013), recognizing these strengths develops more agentic individuals who engage in independent and interdependent learning and feel competent to achieve their own and contribute to their peers' success. On a deeper level, agency is about students having power to shape their own learning. Examples of agentic students sharing power in democratic classrooms have been published over the years (e.g., Shor 1996; Ody and Carey 2013). Ody and Carey report on a transition program into higher education using senior student facilitators to prepare learners for university life. The program enabled learners to work with peers how to learn necessary content, attitudes, and skills but also how to take part in discussion groups focused on cultural, economic, and political issues. Shor writes about a radical experiment in power sharing that led to autonomous peer learning. One former student reports that: "we decided what the class talked about. We asked the questions. . . . We shaped the class. We co-developed the curriculum" (Shor 1996, p. 223).

PASS programs are widely offered internationally in secondary schools, in further and higher education, as well as in six international PASS national centers (Keenan 2014). While PASS programs are offered to a wide range of TVET learners, most information about how they work is available from the higher education sector (e.g., Keenan 2014; Ody and Carey 2013; van der Meer and Scott 2009). Most frequently they aim to transition learners to the next level of TVET learning. Multiple case studies suggest that programs are typically organized in small groups and tailored to meet the needs of diverse learners and subjects. But they also share a remarkable consistency in approach. They often involve hour-long structured group sessions. Each session is facilitated by trained PASS leaders, often advanced learners from within the community of practice. Leaders are advised by an instructor who is familiar with PASS facilitation skills and the content underpinning the sessions. PASS sessions are voluntary and integrate how-to-learn with what-to-learn. Participating learners review course content through active learning exercises and activities and work together to develop sound study techniques and strategies. They compare experiences and understandings; clarify readings; discuss, analyze, critique, question, and solve problems; and propose changes to programs and assessment protocols. Abilities in problem-solving, understanding what is expected, key concepts, and proficiency in the language of the vocation

are all key competencies facilitating success. Also embedded in PASS programs are growth in self-confidence, critical reflection, planning skills, effective communication, and relationship building.

---

## Conclusion

This chapter addressed the question “what supports do learners in TVET need to succeed in their study?” The answer offers a complex array of factors. They are complex because while TVET offers a coherent concept of purposes and processes, it is also incredibly diverse. It occurs in schools, in further and higher education, as well as in workplaces. It seeks to develop knowledge, skills, and attitudes that prepare diverse learners to work in a wide variety of vocations in multiple contexts as competent practitioners/employees but also active citizens able to contribute constructively to the future of their vocation and to society. It is argued that to lay the foundation for their success in this complexity, they must achieve hard and soft outcomes set by vocations and themselves. Hard outcomes are measurable, officially set outcomes such as retention, completion, and vocational competence. Soft outcomes are less measurable and include deep learning, well-being, and active citizenship. These success indicators require three levels of support: a general policy orientation resulting in overarching *success frameworks*, student engagement pedagogy that engages both learners and instructors, and a work program that applies two specific practices applicable to TVET and found in *success frameworks* and student engagement: facilitated peer learning and active citizenship.

## Abstract

University Technical Colleges (UTCs), introduced in 2010, represent a new form of vocational education for young people in England. They contribute to an increasingly complex landscape of education and training, promoted as a creative means of meeting the diverse educational needs of young people (Fuller and Unwin, *Lond Rev Educ* 9(2):191–204, 2011). UTCs respond in particular to national and international policy agendas that seek to promote participation in STEM subjects (science, technology, engineering, and maths). They have been

championed by the UK's Edge Foundation as providing a "highly regarded" course of study "with clear progression routes into higher education or further learning in work," especially careers in technician and degree level engineering.

However, there is very limited research evidence to show whether young people and their parents understand the different options available, how decisions to attend a UTC are made, nor whether the education offered in these new institutions enhances or conversely limits the opportunities of students who attend them.

This chapter draws on data from a project that carried out detailed case studies in two UTCs in England during 2014. The project addressed the following core question:

What impact does vocational diversification in the form of UTCs have on the decision-making and experience of boys and girls from different class backgrounds?

The research used a holistic approach focusing on the whole institution in relation to the introduction and development of new educational policies. This encompassed analysis of "the situated, material, professional and external dimensions" (Braun et al., *Discourse* 32(4):585) of the schools, recognizing the schools' origins (and that of their communities), their ethos and culture, their physical environment and resources, and their staff, students, and families as well as external influences. The chapter offers an analysis of policy enactments (Ball et al., *How schools do policy: policy enactments in secondary schools*. Routledge, 2012) in the two case study institutions and considers how these enactments may reinforce or challenge historical patterns of gender and class divisions in vocational education in England.

**Introduction****UTCs**

University Technical Colleges (UTCs) were introduced in England in 2010. They are government-funded schools for 14–18-year-olds, which focus on one or two technical specialisms. They are the brainchild of Lord Baker, former Conservative Minister for Education under Margaret Thatcher, and are backed by an Educational Trust established by Lord Baker and the late Lord Dearing. Each UTC works with employers and a local university to develop and deliver their curriculum. They are expected to commit at least 40% of time to the technical specialism, which can also include working in teams and problem-solving. They are smaller than traditional secondary schools, catering for approximately 600 students in total. They are subregional and have a catchment area that may extend across a number of local authorities, and they are not academically selective. In 2014, when the data for this project were gathered, there were 17 UTCs. By 2018 a total of 50 were in operation.

The rationale for UTCs is linked to arguments about labor market need for high level technical skills. At the time of this research, the UTC website stated:

The UK needs advanced technical skills at all levels if we are to prosper in the 21st century. Whether in manufacturing, wind farms, rail links or hi-tech hospitals we need a workforce that can develop new products, stretch and reuse existing resources, and meet all the challenges of the future.

UTCs are meeting the needs of the skills gap and by 2016 more than 30,000 students will be able to follow this new technical education pathway.

<http://www.utcolleges.org/about/overview/> (Accessed 30 Aug 2014).

The website promoted UTCs in two ways. Firstly, there was an aspirational vision of what they do that distinguished them from other schools:

University technical colleges (UTCs) are government-funded schools that *offer* 14–18 year olds *a great deal more* than traditional schools. They *teach* students technical and scientific subjects in *a whole new way* and are *educating the inventors, engineers, scientists and technicians of tomorrow*. [author's emphasis]

<http://www.utcolleges.org/about/overview/> (Accessed 30 Aug 2014).

Secondly, there was a rather more pragmatic claim about the progression achieved by UTC students:

Amongst the first UTCs no student has joined the ranks of the unemployed. Every student continued in education, or went into employment or training. There were no “NEETs” [Not in Education, Employment or Training] and this is our aim for all UTCs.

Lord Baker, Chairman, Baker Dearing Educational Trust

<http://www.utcolleges.org/about/baker-dearing-educational-trust/> (Accessed 30 Aug 2014).

## UTCs as a Policy Ensemble

The notion of policy ensembles (Ball et al. 2012) provides a way of conceptualizing the clustering of a number of key policy imperatives shaping the work of the two UTCs in this study. The UTC initiative in itself represents a clustering of policy ideas. The headline focus is on the teaching of technical and scientific subjects, which fits with a UK government policy emphasis on the importance of STEM subjects:

The government believes that if we want the UK to remain a world leader in research and technology we will need a future generation that is passionate about, and skilled in, science, technology, engineering and maths (STEM).

<https://www.gov.uk/government/policies/engaging-the-public-in-science-and-engineering%2D%2D3/supporting-pages/inspiring-students-to-study-science-technology-engineering-and-mathematics> (Accessed 20 Aug 2014).

But UTCs also bring together other significant policy “ideas,” one of which is particularly relevant to the focus of this chapter. This concerns the promotion of school choice through the provision of an array of different types of school,

particularly those independent of local authority control, as outlined in the UK Department for Education's *School Choice Framework* (2013: 3):

There are now more types of state school to choose from, including more Academy schools which are run independently from the local authority. The government has a school reform programme that allows interested parties – such as education providers, charities, community groups, teachers and/or parents – to establish new education facilities such as Free Schools, Technical Academies, University Technical Colleges and Studio Schools.

These schools are established in response to parental, student and/or community demand for a specific type of provision.

UTCs (along with Studio Schools) add a further dimension to school choice in England, as they recruit young people from the age of 14, the beginning of key stage 4, rather than 11, which is the regular transition point from primary to secondary education in England. While 14 has become a transition point in recent years for some students who follow an alternative, vocationally oriented curriculum for part of the week, usually in colleges of further education, such provision has tended to be taken up by young people deemed to be disengaged from education.

#### **Floor standards: secondary schools**

The UK government currently sets and assesses state-funded secondary schools' performance against minimum requirements referred to as 'floor standards'.

A school will be below the floor standard if:

- Fewer than 40% of pupils achieve five or more GCSEs at grade A\*-C or equivalent, including GCSEs (or iGCSEs) in both English and mathematics
- The school has a below median score for the percentage of pupils making expected progress between Key Stage 2 and Key Stage 4 in English
- The school has a below median score for the percentage of pupils making expected progress between Key Stage 2 and Key Stage 4 in mathematics

The median school score for pupils making expected progress in English and in mathematics is 73 per cent for each in 2013.

The recommendations of the Wolf Review will be implemented for performance measures based on 2014 results. This means that, for example, no vocational qualification can count for more than 1 GCSE and a maximum of two vocational qualifications per pupil can count in performance tables measures. These changes will make the floor standard more demanding.

**Fig. 1** Floor standards for secondary schools 2013 and 2014. [http://www.education.gov.uk/schools/performance/fs\\_13/index.html](http://www.education.gov.uk/schools/performance/fs_13/index.html). Accessed 29 Aug 2014

While the above might suggest difference and innovation, it is set within a context where GCSE performance policy – an “A-C economy” (Gillborn and Youdell 2000) – dominates the work of all secondary schools. Interviews with staff indicated how the pressure to meet GCSE “floor standards” (see Fig. 1) was ever-present in constituting teaching and learning practices in the two UTCs.

The A-C economy had a further significant effect in shaping how the UTCs in this study were constituted in practice. As discussed below, a considerable number of students chose to move to a UTC as a reaction against the effects of the A-C economy, whereby “Students are objectified as talented, borderline, underachieving, irredeemable, etc.” (Ball et al. 2012: 78). At both UTCs, there were students who believed they had been objectified negatively in this way and had moved to escape how they were positioned in their previous schools.

---

## Who Wants to Be an Engineer? Students’ Enactments of Policy in Two UTCs in England

The analysis of the data below draws on Ball, Maguire, and Braun’s work on policy enactments (Ball et al. 2012; Braun et al. 2011). However, their work focuses specifically on staff rather than students, whereas this chapter turns its attention to students. The exploration of how young people choose to study at a UTC suggests that students play a highly important role in how policy becomes enacted – in shaping what constitutes a UTC – and how its mission and practices evolve on the ground. Of course staff also contribute to the enactment of UTC policy, but in what follows, the focus is on who the students are and how this shapes and redefines the enactment of UTC policy. The data on which the analysis is based were gathered in 2014 and involved a questionnaire distributed to all Y10 students at each UTC and interviews with 16 Y10 students at each UTC.

### The Two UTCs in Context

*New UTC* specialized in new technologies and was located in a medium-sized town in England. The area had a predominantly white British population, with 93% of residents from a white British background and only 3.4% from a minority ethnic background (Town area profile 2013).

There was engineering and manufacturing industry in the area, including some larger companies, and a considerable number of small- and medium-sized enterprises. The biggest areas of employment were wholesale and retail trade (including motor vehicle repair) (18% of the population) and manufacturing (12%). 32% of the population had no qualifications or only a level 1 qualification.

The history of secondary school education in the town was not strong. The two local schools achieved lower than national average results at GCSE and had been in and out of special measures. Young people regularly went out of the area for post-16 education. The creation of a UTC in the area was part of a bigger regeneration plan. The UTC was in a brand new purpose built building, which was funded through

sponsorship from two councils, the partner university and the regional development corporation, and match-funded by central government. While the UTC served the local area, like all UTCs it had a remit to serve the wider region, and students came from up to 25 miles away each day.

*Established UTC* specialized in engineering and science and was located on the edge of another medium-sized town in England, which was part of a much larger urban conurbation. The specific area surrounding the UTC had a predominantly white British population (c. 90%). However, the town as a whole had a significant and growing minority ethnic population, with just over 21% of the population from a minority ethnic background, 15% of whom were Asian.

The biggest areas of employment in this area were skilled trades, elementary occupations, and manufacturing. 25% of the town's population worked in skilled trades (including motor vehicle repair) or elementary occupations, while nearly 15% were employed in manufacturing.

In the immediate area of the UTC, around 50% of the population had no qualification above level 1, and low qualification levels were a particular concern in the town as a whole (Town Council 2011a, b).

## Who Attended the Two UTCs?

### Schools for the Boys

Very few girls attended either of the UTCs in the study, as shown in Table 1.

Anecdotally, this pattern appeared to be typical of participation across UTCs in England, but there were no data to confirm this at the time of the study, neither on the UK's Department for Education nor the UTC website. However, a 2014 document produced by WISE, a UK organization that aims to increase the gender balance in the UK's STEM workforce and which aimed to support UTCs in recruiting more girls, offered the following comment:

despite offering direct pathways to rewarding and successful careers in STEM, UTCs are struggling to attract girls in significant numbers and are at risk of being seen as 'schools for boys' by many parents unless they are pro-active in challenging stereotypical perceptions. (WISE 2014: 3)

### Schools for "Ordinary" Kids

In this study, students were categorized by social class based on what they said about their parents' occupations, their parents' participation in higher education, and whether they stated that they were eligible for free school meals. Not all students chose to respond to these questions, so that 17 out of a total of 103 responses were not

**Table 1** Breakdown by gender of all Y10 students who completed questionnaires at the two UTCs

	New UTC	Established UTC
Female	12	6
Male	66	19
Total students	78	25

**Table 2** Breakdown by social class of all Y10 students who completed questionnaire at the two UTCs

	Both UTCs	New UTC			Established UTC		
	TOTAL	Female	Male	Total	Female	Male	Total
Working class	59	8	37	45	2	12	14
Middle class	27	3	16	19	4	4	8
Insufficient information	17	1	13	14	0	3	3
<b>TOTAL</b>	<b>103</b>	12	66	78	6	19	25

**Table 3** New UTC: social class, gender, and ethnic background of all Y10 students who completed questionnaires

	Middle class	Working class	Insufficient information	Total
White male	16	32	13	61
White female	3	8	1	12
Asian male	0	2	0	2
Mixed race male	0	1	0	1
Other male	0	2	0	2
<b>TOTAL</b>	<b>19</b>	<b>45</b>	<b>14</b>	<b>78</b>

categorized by social class. Based on the information students gave, the majority were from working-class backgrounds. Interviews with both working-class and middle-class students suggested that the students categorized as middle-class came mainly from aspiring middle-class backgrounds, rather than secure middle-class positions (Table 2).

### Schools that Reflected the Ethnic Background of the Immediate Local Population

Both UTCs in the study were located in areas with predominantly white British populations. This was reflected in the ethnicity of students attending the two UTCs, with only 10 from backgrounds other than white British out of a total of 103 students. The questionnaire offered the students the following categories to define their ethnicity: white, Asian, black, mixed ethnic group, and other.

At New UTC, out of 78 students, a total of 5 came from backgrounds other than white, all of whom were male (see Table 3). There were no students (girls or boys) who identified as black, and no girls who identified as Asian, mixed race, or other.

At Established UTC (see Table 4), out of 25 students, a total of 5 identified as black, Asian, or other, none identified as mixed race, and no girls identified as black or Asian.

While the lack of diversity among the student population can be explained in relation to the immediate local populations surrounding the two schools, it should be noted that UTCs have complex transport policies that are intended to enable students from a wide, regional catchment area to attend the school. This picture of who attended the UTCs therefore raises questions about which types of school might encourage students to decide to travel out of their locality and how this impacts on participation by students from black and minority ethnic backgrounds.

**Table 4** Established UTC: social class, gender, and ethnic background of all Y10 students who completed questionnaires

	Middle class	Working class	Insufficient information	Total
White male	4	9	2	15
White female	3	2	0	5
Black male	0	2	1	3
Asian Male	0	1	0	1
Other female	1	0	0	1
<b>TOTAL</b>	<b>8</b>	<b>14</b>	<b>3</b>	<b>25</b>

## Why Were They There? Deciding to Study at a UTC

Tables 5 and 6 show the reasons that students gave for deciding to move to each of the UTCs.

### Enacting the UTC Vision: Actively Choosing Technology and Engineering Subjects

The Edge Foundation, which actively campaigns for UTCs, expresses the belief that young people from the age of 14 will choose a pathway “based on their motivation, talents and career aspirations” (Edge Foundation 2012: 8) and that UTCs provide a route for those who are particularly interested in science, engineering, and technology. However, the student responses in Tables 5 and 6 show that only some students actively chose to attend the UTC for these reasons.

While at Established UTC the specialism was the highest named reason for choosing the UTC, named by 14 or nearly three fifths of all the students and by 5 out of the 8 girls, this nevertheless means that 11 students did not choose the UTC for its subject focus.

At New UTC, the proportion of students who chose to study at the UTC because of its specialism was smaller. 22 students gave this reason, including only 4 out of 12 girls, which means that 56 students were attending the UTC for other reasons.

### Reacting to the A-C Economy

There were two main alternative reasons for attending either of the UTCs; firstly to have a fresh start, and secondly, the UTC was deemed better than their previous school. Interviews with students at both UTCs suggested that these reasons were associated with students’ experience of the impact of the A-C economy at their previous school. Ball et al. (2012) observe that focusing attention on certain students means the relative but systematic neglect of others. Once it came to working toward their GCSEs, students in both UTCs appeared to be well aware of being neglected in

**Table 5** Why study at the UTC? Breakdown of New UTC questionnaire responses by gender, class, and ethnicity

Reason	Total	m/c white boys	w/c white boys	No s/c white boys	BME boys (all w/c)	m/c white girls	w/c white girls	No s/c white girls
Fresh start	35	7	15	5	1	2	5	0
UTC deemed better; previous school deemed poor	25	4	11	6	1	0	3	0
UTC specialism	22	5	9	1	3	3	1	0
Bullying at previous school	2	0	2	0	0	0	0	0
Miscellaneous other reasons (proximity)	1	0	1	0	0	0	0	0
Had to move	1	0	0	1	0	0	0	0
Does not know why	1	0	0	0	0	0	0	1
<b>Total responses</b>	<b>88</b>	<b>17</b>	<b>38</b>	<b>13</b>	<b>5</b>	<b>5</b>	<b>9</b>	<b>1</b>
Total students in category	78	16	32	13	5	3	8	1

comparison with their peers. Their decision to move to the UTC was in reaction to this experience, rather than a strong desire to study engineering, technology, or science subjects.

Particularly at New UTC, a fresh start was the reason given most often in student questionnaires for deciding to move to the UTC. Nearly two fifths of students gave this reason ( $n = 35$ ). A further 25 responses stated that students expected the UTC to be a better school than their previous institution. This could at least in part be related to the specific location of the UTC, as the two other local schools were reputed to have a checkered history. At Established UTC, only 1 student said they were looking for a fresh start, but 7 out of 25 students said that they did not like their previous school and thought the UTC would be better.

## Where Were They Going? Students' Career Goals

Tables 7 and 8 show a categorization of the career goals named by students at each UTC.

Viewed positively, careers associated with the specialisms of the UTCs received the highest number of responses at both institutions. At New UTC, 28 students named jobs associated with the UTC's specialisms (including 1 in the armed forces) and a further 11 named trade jobs such as mechanic or welder. But 33 responses named jobs that were not obviously connected to STEM, such as chef, physiotherapist, and PE teacher. At Established UTC 12 responses named jobs associated with

**Table 6** Why study at the UTC? Breakdown of Established UTC questionnaire responses by gender, class, and ethnicity

Reason	Total	m/c white boys	w/c white boys	No s/c white boys	w/c BME boys	No s/c BME boys	m/c white girls	w/c white girls	No s/c white girls	m/c other girls
UTC specialism	14	3	5	0	1	0	4	1	0	0
UTC deemed better than previous school; previous school deemed poor	7	2	3	1	1	0	0	0	0	0
Fresh start	1	0	0	0	0	0	1	0	0	0
Vague idea that UTC was what they wanted	1	0	0	0	0	0	0	0	0	1
Miscellaneous other reasons (proximity; moved to area; mother chose the school; liked the look of the school)	5	1	0	0	2	1	0	1	0	0
Does not want to say	1	0	0	1	0	0	0	0	0	0
<b>Total responses</b>	<b>29</b>	<b>6</b>	<b>8</b>	<b>2</b>	<b>4</b>	<b>1</b>	<b>5</b>	<b>2</b>	<b>0</b>	<b>1</b>
Total students in category	25	4	9	2	3	1	4	2	0	1

the UTC's specialism (including 3 in the armed forces) and 1 named a trade job (mechanic). Seven responses referred to destinations quite unrelated to STEM (such as journalist, English teacher). These responses came from questionnaires, and the interview data suggested that a considerable number of students had no clear idea about the future or an ideal and idealized imagined future that might prove unrealizable.

### Constructing the UTC Narrative: Students as Policy Narrators

Given the picture above, which suggests that neither of the schools was filled with students who were passionate about STEM subjects, and heading for careers as inventors, engineers, scientists, and technicians, how did students enact and construct a meaning for the UTC?

**Table 7** Students' career goals: New UTC (Y10 questionnaire responses)

Career goal	Total	m/c white boys	w/c white boys	No s/c white boys	w/c BME + other boys	m/c white girls	w/c white girls	No s/c white girls
Career associated with UTC specialism	27	6	10	3	3	(3)	(1)	0
Various trade jobs	11	3	5	2	0	0	1	0
Armed forces for career with UTC specialism	1	0	0	0	0	0	1	0
Armed forces	10	5	2	3	0	0	0	0
Graduate jobs, not UTC specialism	11	4	4	1	2	0	4	0
Misc. unrelated to UTC specialisms	12	1	5	2	3	0	1	0
No response	9	2	2	3	0	0	1	1
Don't know	1	0	0	1	0	0	0	0
<b>Total responses</b>	<b>81</b>	<b>21</b>	<b>28</b>	<b>15</b>	<b>8</b>	<b>3</b>	<b>9</b>	<b>1</b>
Total students in category	78	16	32	13	5	3	8	1

Ball et al. (2012) identify a number of roles that different actors take on in the enactment of policy. One of these is the role of “narrator.” Narrators are involved in the interpretation, selection, and enforcement of meanings (Ball et al. 2012: 49). In Ball et al.’s study of policy enactments in “ordinary” secondary schools, staff acting as narrators are involved in “explaining” policy to colleagues, deciding, and then announcing what must be done, what can be done and what cannot (Ball et al. 2012: 50). They join up disparate policies into an institutional narrative, “a story about how the school works and what it does” (ibid.: 51).

In the present study, it was not just teachers who acted as narrators. Students “narrated” the UTC too, sometimes offering back a version of the narrative that they had heard from the principal and other teachers and sometimes constructing their own narrative about how the UTC worked and what it did. The following extracts offer three of the aspirational narratives constructed by students about how the UTC worked and what it did.

### **Narrative 1: An Opportunity to Get an Apprenticeship**

Narrative 1 perhaps best reflects the intended goals of UTC policy. Students at both UTCs described the UTC as a stepping stone to getting an apprenticeship with one of the sponsor companies or with other companies that might be involved in the school. In both institutions, representatives from companies got actively involved in the

**Table 8** Students' career goals: Established UTC (Y10 questionnaire responses)

Career goal	Total	m/c white boys	w/c white boys	No s/c white boys	w/c BME boys	No s/c BME boys	m/c white girls	w/c white girls	m/c other girls
Career associated with UTC specialism	9	0	5	1	0	1	1	1	0
Various trade jobs	1	1	0	0	0	0	0	0	0
Armed forces for career with UTC specialism	3	1	2	0	0	0	0	0	0
Armed forces	2	0	2	0	0	0	0	0	0
Graduate jobs, not UTC specialism	1	0	0	0	0	0	1	0	0
Misc. unrelated to UTC specialisms	3	1	0	0	0	0	1	1	0
No response	8	1	2	1	3	0	0	0	1
<b>Total responses</b>	<b>27</b>	<b>4</b>	<b>11</b>	<b>2</b>	<b>3</b>	<b>1</b>	<b>4</b>	<b>2</b>	<b>1</b>
Total students in category	25	4	9	2	3	1	3	2	1

teaching that took place in workshop sessions, and this was an opportunity to be noticed, as well as an opportunity to work on what were seen as industry-standard projects.

A white boy from a lower middle-class background at New UTC offered one example of this narrative.

They [staff from a sponsor company] come in Thursday, they're our sponsors. They come in Thursday all day, teaching us on the machines.

[...] if I'm on the computers doing the 3D CAD it's like what all the professionals use in industry and that.

[...] My dad said, here's a better opportunity, cos you can get an apprenticeship but at [previous school] you wouldn't get an apprenticeship as good as this or you wouldn't be able to get as far.

*What do you plan to do at the end of year 11?*

Hopefully I'll get an apprenticeship with [sponsor company]. If not I want to go to college and study either engineering or motor mechanics.

[...] *In what ways does here help you prepare for your future career like work experience...*

They give you 200 days, I think it's 200 days work experience.

[...] *What would you say to a friend who was thinking of coming here?*

Um. Great opportunity, but you need to use it wisely, you have to work.

## Narrative 2: A Route to an Idealized Future

Narrative 2 involved the construction of a wishful, idealized future, which was at some distance from the programs of study that the students were following. It was unexpected in the research to hear that five girls at New UTC said that they wanted to become architects. As told by a working-class girl at New UTC, this narrative seemed to involve a fairy tale imagined future. She had found a university in Texas that she wanted to attend:

It's one of the best universities for architecture and engineering in the United States so I want to try and go there.

*Ok and how did you hear about that and have that as an idea in your mind?*

Cos in student development we had to like research where places we wanted to go to and study afterwards. So I came across that university and it looks really good cos I could get, as an international student, scholarship and that.

[...] I don't wanna design like normal houses, I wanna kind of recreate Alice in Wonderland into a housing estate.

*Ok and what ways here are helping you prepare for that?*

Because I'm doing construction, so I'll have the upper hand of doing three years of construction so I'll be more likely to be accepted into a university.

*Ok, and this university that you've looked at, are the qualifications that you're doing here the right kind of thing to get you into there?*

Yeah, I need C and above to get into there.

A more probable narrative of a route into the architectural field was told by a middle-class white girl, who explained that a number of them would have a good chance of being offered an apprenticeship locally:

There's about three, four of us in construction who actually do try and it's more likely that all of us will get apprenticeships cos we're just like doing the work, improving all the time, so obviously they'll see how we work and they'll want those sort of people on their team.

*And is that something you've been told will be in your favour by careers people here?*

Yeah, they said. ..., when we first, before we chose construction or engineering, they told us about the apprenticeships and then they was telling us about how at the end of the year they'll be, the people who sponsor here will want to take on apprentices. And then so, they said the way to get that is to have all your work completed, when they come and visit, like always do the work, don't be sitting back talking, and just getting on with it really and just showing how you work in the place. If you work confidently, like you improve all the time, they're gonna want you on there. So they let us know how we're gonna get there.

Yet this narrative was also problematic, in conflating the intermediate skilled work of architectural technician with that of professional graduate skilled work of architect and for implying that the apprenticeship opportunities with partner companies would include apprenticeships for architectural technicians.

The data suggested that the notion of “architect” had been offered to the girls at the UTC as a means of reconciling them to having to learn construction or engineering. But this narrative seemed to be “very inventive, even fantastical” (Ball et al. 2012: 51) as part of the enactment of UTC policy. In reviewing this hoped-for career goal as part of the research, there was a sense of considerable unease with these narratives of aspirational imagined futures, which appeared to be not just idealized, but unrealizable given on the one hand the work of the UTC and on the other the rate of educational progress and achievement of the students that were interviewed.

### **Narrative 3: A Chance to Reposition Yourself as a Worthwhile Student**

Narrative 3 was not associated with the policy goals of promoting vocationally oriented study through UTCs. For a considerable number of students, moving to the UTC provided an opportunity to reposition yourself. In interviews, numerous students described how they were unhappy that they were deemed less important because their anticipated achievement at GCSE was not sufficiently high at their previous school. A number of them explained that they did not want to be denied the opportunity of taking GCSEs and were not happy that they were put in sets taking what they saw as less highly regarded BTEC or ASDAN qualifications.

One working-class girl at New UTC said that at her previous school “The teachers did not care about you if you weren’t in the top set.” The teachers only gave attention to the best students so “I didn’t really get much of an education.” Another working-class white girl presented a narrative of how different things were at New UTC – in her words “practically too good to be true”:

My parents wanted to look into it because they knew how, how bad I was at [previous school] and how I felt about my old school. So they met up with the deputy head and the principal, and spoke about all the options that they would be providing. And I was also sat with them and I thought that this school was practically too good to be true. It was all the options that they were giving you, not just GCSEs, of course they’re going to focus on GCSEs but they also focus on past that. They help you understand **all** your options and help you understand different pathways you can achieve and they’ll help you with that. And I also found it very useful for the fact that they also said to us that they will treat us like an adult if we respect them. If we act like an adult, they will treat us like an adult.

Which I found was very good for the fact that they understood that we are our own person and that we can go our own path.

The data suggested that this story of a new opportunity to make good either through a chance to take GCSEs or to follow an alternative route that was deemed worthwhile was an important narrative in both UTCs but that it might be vulnerable to drift, since the UTCs, like the schools that the students had moved from, were subject to the same GCSE floor targets and inspection requirements.

## Conclusions

Ball and colleagues suggest that “policies can be clustered together to form new policy ensembles” and that these new policy ensembles “can have unintended or unexpected consequences in schools” (Ball et al. 2012: 5). This chapter has sought to show how UTCs are shaped and constituted both by the official UTC policy ensemble of STEM subject specialisms and school choice but also by the overwhelming presence of an A-C regime. This regime directs schools’ attention toward getting students to meet performance targets, over and above any other considerations, which affects students’ positions and dispositions, and can have a considerable influence on how they view the opportunities available to them at the age of 14. For a considerable number of students in this study, the UTC represented a fresh start, rather than a pathway to a STEM-oriented employment future. Indeed, quite a number of students named science and engineering subjects as those they least enjoyed. The enactment of policy in this way might help to explain why the two UTCs could be described as schools for “ordinary,” mainly working-class students, schools for the boys, and schools whose ethnicity reflected the ethnic background of the local population, rather than including students from a range of backgrounds from across the wider subregion. The UTCs provided the sort of opportunity for which vocational education has historically been used in England: a second chance for young people who struggle with academic subjects and who are therefore deemed inferior (Fuller and Unwin 2011; Richardson and Wiborg 2010).

Yet the Edge Foundation, which plays a key role in promoting the UTC concept, made the following claims and demands in their 2014 manifesto:

University Technical Colleges combine rigorous academic study with stretching technical qualifications to boost the achievement and prospects of students in science, engineering and technology. They open up pathways to apprenticeships, higher education and long-term careers. We need a UTC in every major town. [...]

The next government should create more high-quality specialist 14-18 schools and colleges of these kinds.

[http://www.edge.co.uk/media/138357/edge\\_manifesto\\_290614\\_final.pdf](http://www.edge.co.uk/media/138357/edge_manifesto_290614_final.pdf) (Accessed 10 Aug 2014).

This study suggests that we should treat such demands with caution. We need to look carefully at how policy is constituted and enacted in practice, how this shapes what it means to study at a vocationally oriented school such as a UTC, and in what ways these sorts of specialist institutions enhance or conversely limit the opportunities of the range of students who attend them.

## Abstract

There is a general agreement that assessment feedback does not result in the automatic improvement of learning. Deliberate strategies for learning support aimed at student efficacy are therefore essential. While there are numerous studies on assessment feedback, it is not in the context of occupational competence needed for the twenty-first-century TVET student. This chapter offers a conceptual and empirical investigation of the interrelatedness of a competence assessment model and the impact thereof on the provision of meaningful assessment feedback. The competence assessment and development model (COMET) encompasses occupational competence diagnostics and equally so, the elements of teaching, learning, and training according to the COMET didactic approach for TVET (Rauner et al., *Competence development and assessment in TVET (COMET)*, Springer, 2013; Hauschildt, *COMET South Africa: final report and documentation of test results*, Bremen University, 2016) and served as a

## Introduction and Background

This chapter highlights the importance of structured occupational competence assessment and development model to enhance assessment feedback for learning in TVET. It is of particular relevance to examine a feedback model that exceeds the traditional feedback processes by providing empirical data that informs intervention processes and policy strategies in a systematic manner.

Feedback is regarded as part of assessment in numerous scholarly studies but is predominantly narrow and curriculum-based of nature. Feedback that serves as a “method for further action” (William 2011, pp. 121–122) is inherent in the origin of the term “feedback” first used by Norbert Wiener in 1946 and borrowed from an engineering “feedback loop” idea in which four key elements steer the process: first, a means to determine the desired state; second, to establish the current state; third, to compare the current state with the desired state; and finally, to attune the current and the desired state (Wiener 1948, pp. 96–97). This sequence of events illustrates the complexity of feedback and the need for a reliable model to support students to develop from a novice to an expert within domain specific occupational competence.

Pettifor and Saklofske (2012) reflect on the relationship between the quality of assessment and its potential for effective feedback by describing assessment as the process of obtaining the type and amount of good information needed to make informed decisions that will guide subsequent actions. Assessment in TVET generally encompasses formative (on course) and summative (end of learning) assessment according to specific assessment standards which are qualification driven, an approach, which limits the transformative potential of assessment for learning as assessment should serve the purpose of advancing and facilitating student learning. Research has found that assessment can positively inform learning when feedback by educators and students engaged in self-assessment, assist in modifying teaching and learning activities accordingly. This feedback should focus on what needs to be done, not on the ability as projected in “feedback by grades” (Black et al. 2003, p. 2). Pedder and James (2012) argue that when teachers and students use assessment information for supporting improvements in learning, the educational purpose of assessment is achieved. They refer to this as Assessment for Learning (AfL), where autonomous learning is a fundamental principle (Pedder and James 2012, pp. 33–48). Assessment for Learning moves the focus of assessment from being solely a process of grading, or endpoint testing, to assessment as a learning process (Webb and Willis 2010, p. 2).

TVET is closely linked to work as a social construct but equally so to an innovation agenda. The DHET *White Paper for Post-School Education and Training* identified the ability of a post-school system to prepare workers for the labor market or to enable individuals to earn sustainable livelihoods through self-employment or establishing a company or cooperative as a key imperative. “Everyone should be able to make a living for themselves and contribute skills to a developing economy” (DHET 2013, p. 8). Giving more feedback on the social learning environment where learners learn with and from each other is critical for active learning, but too often disregarded by educators, resulting in the inability to construct active learning environments that genuinely demand the student’s individual planning, elaboration, and evaluation (Keuvelaar-van den Bergh 2013, p. 13; Van den Berg et al. 2014, pp. 772–809). Research has shown that meta-cognition that leads to self-regulation and social learning enhances reflective thinking, knowing and doing, which is required for innovation in the competitive world of work (Pink 2005; Du Toit 2012; Jacobs 2015; Schön 1983).

Feedback, together with concepts like “feed up” and “feed forward” are essential for successful learning and development but are often overlooked. Feed up refers to – *where am I going*; Feed forward asks *where to next* and feedback reports on *how am I doing* (Chan 2015, pp. 113–117). Effective Feedback focuses on goals, progress made, and actions needed to improve the progress. The levels at which a task is being accomplished, process understanding and reflective competence, are critical for closing the gap between existing and preferred performance (Hattie and Timperley 2007, pp. 81–112).

Competence Measurement in Vocational Education and Training (COMET) was initiated and developed in 2006 in the domain of electrotechnology and later on adapted to other fields (crafts, administration, health care) by a team of researchers at Bremen University, Germany (Hauschildt 2016). COMET was designed to measure occupational competence by using open-ended test tasks that correspond to the processing of instructions and training objectives in the world of work (Heinemann and Rauner 2011). Responses are based on eight competence criteria, namely, presentation, functionality, sustainability, cost-effectiveness, business orientation, social acceptability, environmental compatibility, and creativity. These criteria are situated in the COMET pedagogy and structure of the test tasks where students are asked to solve complex, occupation-specific problems within the context of real work. This comprehensive competence model with its corresponding assessment methods offers improved insight into the strengths and weaknesses of TVET teaching, learning, and training (Rauner et al. 2013). Occupational competence as defined in the COMET model entails the readiness of students to solve complex, real work problems that are characterized by applications that are contemporary as well as future focused. Learning tasks are a fundamental component of occupational competence assessment and development where the levels of competence, skills, and knowledge for the target group range from being detailed help and specifications for beginners, to minimal assistance for advanced learners (Scholz and Heinemann 2013, pp. 107–110).

## Rationale for the Study

The vital role and potential of TVET to transform societies is emphasized in various literature and policy documents (Anane 2013; Dewey 1997; Mourshed et al. 2013; McClelland 1973; OECD 2014; DHET 2013; Rauner et al. 2013; UNESCO 2017).

In South Africa, policy and strategy documents such as the National Development Plan (NDP 2030), National Skills Development Strategy 3 (NSDS III 2011–2016), and Sustainable Development Goals (SDG's) (UNESCO 2017) outline high expectations of TVET as a “system that is responsive to sector, regional and national skills needs and priorities” (NSDS III 2011–2016, p. 16). TVET Colleges are reportedly failing to produce the appropriate skills, hence government's drive to upskill the labor market and alleviate unemployment. The implementation of “lean production” strategies in companies poses a risk to the employment prospects of these students. Lean production involves simplified process that eliminates costly and burdensome wastage throughout the system. Recently, the focus has shifted to linking lean-oriented improvements to the operational management of the production process in a holistic organizational approach deemed necessary to remain competitive in dynamic global businesses today (Armstrong and Diehl 2015, pp. 26–30).

The increase in youth unemployment in South Africa, in spite of numerous policies and strategies, from 32.7% in 2008 to 38.6% in 2015 is cause for concern (Statistics South Africa's Youth Labour Market Survey 2008–2015). Unemployment for males in 2008 was 28.4% and in 2015, 33.8%, while female unemployment rates pitched at 38% in 2008 and 40.75% in 2015. In South Africa, the youth of working age population numbers 19.7 million, which is 55% of the total working age population (Statistics South Africa 2015). This trend of increasing youth unemployed is further illustrated by the not in employment, education or training (NEET) statistics reported in the Quarterly Labour Force Survey (QLFS) of quarter 2: 2018, at a high of 39.3% (Statistics South Africa 2018). Clearly, an effective and efficient workforce is needed to counteract the poor state of youth employment, to improve social equity and livelihoods and enhance occupational competence required for the twenty-first-century workplace. Such twenty-first-century skills enable students to use technology, be efficient problem solvers, embrace participatory management of tasks, and adopt a global perspective (Greenstein 2012, pp. 187–188). The COMET diagnostic model encompasses the development of professional competence beyond technical training desired to activate such global developmental priorities.

The expectations of TVET in global debates and government priorities for national development are immense as illustrated in Strategic forums such as the African Union (AU), the European Union (EU), as well as multinational groups such as the G20, the OECD, and the International Labour Organization (ILO) and UNESCO. TVET is seen as a source of skills, knowledge, and technology needed to enhance productivity for knowledge-based and transitional societies of the twenty-first century (Marope et al. 2015, p. 11). In addition to knowledge, there is a significant focus on conceptualization, for what is described as a “conceptual age,” characterized by a move from the typical *Knowledge-worker* to an economy built on inventive, empathic and big-picture capabilities (Pink 2005, pp. 1–2).

## What Is Competence?

Jessup (1991) describes being competent as the ability to perform according to professional or occupational standards that extend beyond technical job requirements and include skills such as communication, to meet the requirements of a work role. Occupational competence within the COMET model is based on the assumption that the assessment and development of *readiness to act* in a specific domain is necessary for the accomplishment of occupational competence. McClelland already in 1973 launched the modern competence movement (McClelland 1973, pp. 1–14).

Rauner et al. (2013) conceptualizes the differences between competence and intelligence in the Table 1 below:

Vocational education as a fundamental element in development allows for individuals and societies to be responsive to local and global demands in terms of unlocking potential, expanding horizons and adapting to changes in global dynamics (Anane 2013, pp. 117–127). There is an increasing demand for adaptability to new demands, responsibilities and technologies in the workplace that requires more than intelligence but also a focus on competence. The didactic principle of transforming students throughout their course from a novice worker, working in an abstract manner according to rules, to an expert worker who responds to complex problems and change in a reflective, intuitive, and practical manner, necessitates teaching, learning, assessment, and feedback tools capable of influencing TVET systems beyond an examination focus.

---

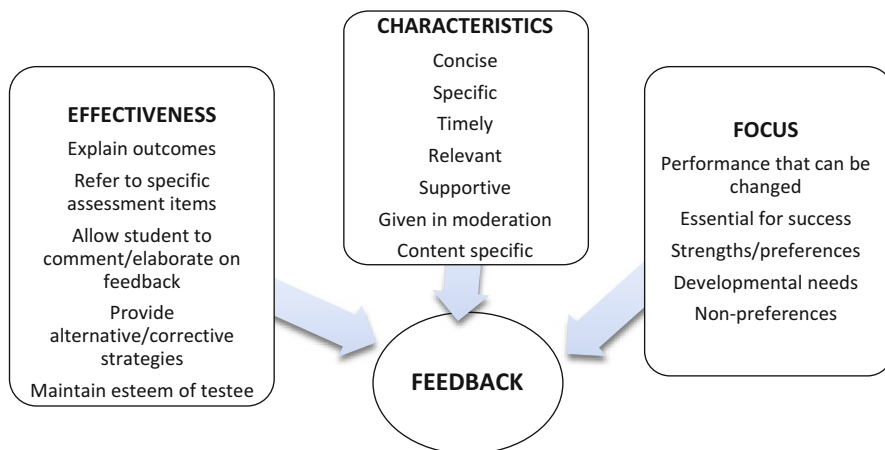

## About Feedback and the Need for a Competence Diagnostic and Development Model

Assessment for learning and development requires quality feedback developmental action as an integral part of the assessment practice (McShane and Von Gilnow 2009, pp. 50–54; Pedder and James 2012, pp. 33–48). It is imperative that corrective strategies be communicated as soon as possible after the assessment. Williams (2002) suggests feedback should focus on criteria such as the effectiveness, characteristics, and focus of the feedback process as outlined in the following diagram (Fig. 1).

**Table 1** Competence versus Intelligence

Criteria	Competence	Intelligence
Ability	Contextualized ability to adequately respond to specific situations and demands.	General ability to solve new problems.
Acquisition	Can be learned and is acquired through experience with specific situations and demands.	Stable over time and determined by biological factors to a significant extent.
Internal structure	Determined by situations and demands.	Determined by fundamental cognitive processes.

**Fig. 1** Feedback criteria

These criteria were assessed as part of the research study reported herein, to determine their value for diagnostic feedback to the extent where the impact on TVET learning could be identified and elaborated on. Diagnostic findings are fundamental to further occupational competence development and curriculum planning responsive to sector skills need and priorities (Botha et al. 2013, pp. 46–50; DHET; NSDS III, 2011–2016, p. 15). The imperative to transform policy into practice is an opportunity for diagnostic assessment towards occupational competence in TVET.

In support of research that can reform TVET, Owens refers to the concept of a new era in manufacturing that requires an *elite* worker who is equipped with reading, writing, and mathematics skills, as well as advanced problem solving capabilities. The need for elite workers necessitates creative, resourceful and tangible solutions as a precondition for addressing the skills gap characterized by mismatched workers attempting to do “today’s work with yesterday’s tools” (Owens 2015, pp. 37–39).

Feedback should not only focus on immediate improvement of student performance and education outcomes but more so, on capacity building for being effective practitioners in the world of work that requires more than structured thinking (Boud and Molly 2013, pp. 1–10). It is of particular relevance to examine a feedback model that exceeds the traditional feedback processes to provide the opportunity for comparative studies among, for example, holistic problem solving competence levels in occupations and tangible data to inform intervention processes and policy.

Harlen (2012) identified the purpose of summative assessment as being to ensure that what is assessed and how it is assessed, have positive impacts on learning. Feedback assists in regulating teaching and positioning it as a mechanism for the implementation of effective operational actions that will lead to new experiences pitched at a level that is not too difficult nor too easy for the student. Harlen further argued that feedback is most effective in promoting learning if it involves students in

the process of deciding what the next steps should be. Feedback therefore allows students to play a role in the collection, interpretation, and use of the evidence of their learning (Harlen 2012, pp. 87–102).

Finding a healthy balance between positive feedback that is optimistic, encouraging, and affirming and negative feedback that is critical and corrective can be challenging. Feedback without any critical content can be unrealistic, untruthful, and detrimental to student development, while oppressive, relentless and critical comments may discourage and de-motivate the student (Webb and Willis 2010, p. 6).

Several South African policy and strategy documents raise concerns regarding TVET educator competence, as echoed in the *White Paper for Post-School Education and Training* (2013), which states that “The most important indicator for the success of a (TVET) college is the quality of education offered by a well-educated, capable and professional teaching staff.” An assessment model that is innovative imposes profound challenges on educators’ structured, curriculum-based assessment conceptions, hence comprehending the conceptual change needed for assessment practice is imperative (Gulikers et al. 2013).

---

## The Underpinnings of the COMET Approach

Rauner et al. (2013) identified the following components as key elements of a framework for vocational education:

- The concept of professional/occupational knowledge
- The learning objective “action and shaping competence”
- The objective of professional/occupational aptitude as defined in the professional profiles and curricula
- The theories of professional/occupational competence development

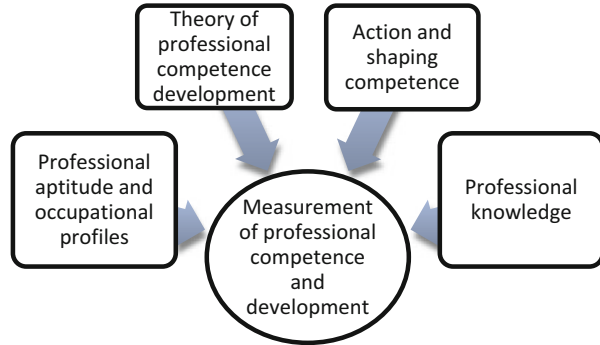

The conceptual framework for the measurement of professional/occupational competence is illustrated in Fig. 2:

The conceptual framework of the COMET occupational competence model includes a normative component based on the virtue of social agreement embedded in vocational training processes. A thorough and precise understanding of the anticipated results of programs and institutions of vocational education constitute the basis for the development of a competence model, as illustrated in the training objectives below.

The training objectives of a vocational institution are to develop the following:

- Professional Aptitude – Trainees are capable of performing the vocation according to rules and criteria of the selected occupation.
- Acting Competence – Activities inclusive of preparations followed by the evaluation of the results according to set criteria derived from work tasks to be solved.
- Shaping Competence – Professionally and socially contextualized work tasks completely accomplished and reinforced by reflective meta-cognitive evaluation.

**Fig. 2** Professional/ Occupational competence framework. (Rauner et al. 2013, pp. 19–20)

Taken together, the common objective for the above is “to learn an occupation” (Rauner et al. 2013, pp. 23–27).

Furthermore, holistic problem solving competence as a fundamental element of the COMET framework is embedded in eight competence criteria:

- **Functionality/operability:** The ability and evidence to perform a task that demonstrates technical competence, skills, and subject knowledge is an essential criterion for a proposed solution and serves as a prerequisite for further requirements related to COMET competence criteria for work tasks.
- **Clarity/Presentation:** The proposed solution is planned, presented, captured, and communicated meticulously to all stakeholders inclusive of customers to an extent where the outcome can be anticipated. The presentation must be factually correct and indicative of clear and organized thinking required for effective communication in the work context.
- **Efficiency/Effectiveness:** Taking the economic aspects of a solution in terms of expenses and benefits in the context of occupational duties into consideration is evident of professional work. Long-term costs and societal aspects such as the impact on the national economy should also be considered.
- **Sustainability/Utility:** A strong focus on sustainable and high utility value solutions related to customer care in terms of usefulness, durability, liability factors, maintenance, and repair in occupational work processes and context.
- **Business and work process orientation:** Preceding and following workflow processes are considered in finding a solution cooperative of aspects beyond the individual’s professional work. Relations in the business process chain regarding higher and lower tiers of the company hierarchy are considered.
- **Social acceptability:** The solution focuses on the impact thereof on social aspects beyond the work context such as a humane organization of work, health, and safety matters and the possible impact thereof on the social environment
- **Environmental compatibility:** Professional and technical ecologically friendly work processes and outcomes, which are relevant to the solution of the work task, are applicable to almost all work processes.
- **Creativity:** Finding creative and unique solutions for occupation-specific problems to be solved as a distinct aspect of professional competence. Creativity in a

specific solution demonstrates sensitivity and respect for the problem to be solved and is a relatively independent concept of professional work and leaning (Rauner et al. 2013).

The development of occupational competence in vocational education is further regulated and underpinned within the COMET didactic dimensions of content, action, and requirement wherein the content dimension is a critical part of the data analyses and refers particularly to subject domains. This impacts on the development of a solution space, where typical aspects of a solution are generated to cover the eight competence criteria, to assist in the analysis of test solutions. The Action dimension is applied to advance holistic problem-solving as opposed to fragmentation of solutions and is fundamental in the development of test tasks as well as the rating of solutions.

Finally, the Requirement dimension that is cumulative in nature is presented as Nominal competence, Functional competence, Processual competence, and Holistic shaping competence. Quantitative scores obtained serve as performance indicators for a criteria-oriented interpretation of test results (Rauner et al. 2013, pp. 41–47). Nominal competence implies that the cognitive domain specific performance is at a superficial conceptual knowledge level that does not adequately guide the solving of vocational tasks. Functional competence is based on basic technical, pedagogical, and subject knowledge to guide actions. Processual competence is achieved when domain specific, complex professional tasks can be adequately interpreted, solved, applied, and reflected on in the context of company work processes and situations. Holistic shaping competence is accomplished when vocational tasks can be solved completely, responding to divergent demands of the vocation and shows evidence of intelligent compromises (Rauner 2012; Hauschildt 2016).

## **A South African Case Study**

The research reported on herein is based on data obtained from a 2014 COMET large-scale assessment conducted in South African TVET institutions. The sample for the study was obtained from six public TVET colleges (seven campuses), two private TVET institutions, and three industry training academies offering specific study programs, namely, mechatronics, millwright, welding, and electrical engineering.

Respondents were selected after being exposed to the COMET model and on the basis of the respective academic staff accepting the validity of the test tasks. A pre-test, comprising a set of test tasks to expose students to the nature of the assessment, was conducted. Test tasks were validated and adapted where necessary to ensure content validity.

715 students of which 69.1% were male, 26.1% female, and 4.8% who did not indicate gender, took the test. Participants ranged from 17 to 39 years. We found 34.4% were in the 21–24-age bracket, followed by 20.3% aged 25–29 years, and 18.3% aged 17–20 years. Only 6.5% of students were 30–39 years.

The focus in this study was predominantly on the quantitative data, which was measured first and was followed up by a small-scale qualitative data collection to refine the results from the quantitative data.

Subject experts developed the COMET open-ended test tasks which were followed by a rater training seminar. Four test tasks per occupation (electrical, millwright, mechatronics, and welding) were selected. Occupational competence was measured on the three-dimensional COMET occupational competence and commitment model. A high degree of consistency, also referred to as inter-rater reliability, in the rating of solutions was a prerequisite for open-ended test tasks. The 40-item rater responses were validated by means of an exploratory factoring analysis based on the correlations among the 40 items. A typical test task comprises a realistic narrative of a problem that is typical and representative of the occupation at stake, to be solved by means of problem solving, using the eight COMET criteria. The degree of complexity must allow for the assessment of contextual understanding. The grading of the test outcomes is ability based, making it possible to differentiate test takers according to levels of solutions presented as being “functional,” “procedural,” or “holistic” of nature (Rauner 2010).

A feedback questionnaire measured the impact of assessment feedback on learning and the development of occupational competence. Eighteen TVET staff members involved in the COMET assessment development and rater-training exercise completed the questionnaire. Raters reported on assessment feedback criteria applying a 4-point Likert scale ranging from Strongly Disagree to Strongly Agree.

Focus group semi-structured interviews yielded valuable information to improve sense making of behavior and performance measured in the quantitative research. Data was collected at the sites where students were being trained and interviews were supported by direct observation of group dynamics where complex reasoning and thinking were facilitated to explore students’ underlying understanding of the problem. The interviews were adapted where necessary, according to emerging themes outside the initial questions.

Three focus group interviews of approximately 60 min each were conducted with 62 students at three test sites after receiving the COMET feedback reports. The purpose of the semi-structured interviews was to ascertain the students’ reasons for the levels of occupational competence achieved in the COMET large-scale assessment, their understanding of and experience of COMET assessment versus the curriculum assessment and their values with regard to TVET.

---

## Findings

The results of the 2014 COMET large-scale assessment in the South African study, in Fig. 3 illustrate the need for transformational Assessment for Learning.

One of the key findings was that 60.4% of the students functioned at a Nominal competence level. 14.9% of students achieved functional competence, which indicates that they significantly lacked proficiency in terms of occupational problem solving competence. Processual competence was recorded for 13.1% of respondents. Only a small percentage of respondents (11.4%) achieved Holistic Shaping

**Fig. 3** Occupational competence achieved per level

competence, indicating they are capable of solving complex occupational problems holistically.

The small percentage of students (11.4%) who achieved holistic problem solving competence limits TVET to respond to a demand for skilled labor that is responsive to global competitiveness and innovation. It was evident that the current TVET curriculum resulted in a “teach to test” paradigm that did not equip students sufficiently for the world of work. The OECD meeting in Paris in 2014 on youth unemployment identified the role of TVET to provide programs that are responsive to labor market needs, inclusive of work-based learning as one of the key imperatives. The poor capacity to solve complex problems within the framework of their occupational domain as measured during the COMET large-scale assessment is of massive concern.

### How COMET Assessment Feedback Influences Learning

For feedback to have a significant impact on learning, the learning context must be considered and assessment tasks designed to enable the establishment of information and interpretations about the difference between the current and desired performance (Hattie and Timperley 2007, pp. 81–112). The feedback regarding the efficiency of assessment models is therefore a critical element of feedback for learning. The possibility of COMET for positive Feedback in the TVET context was illustrated by the high convergence of responses of the Raters, on the following aspects inter alia:

The impact of the COMET open-ended test tasks to allow for specific feedback action is valued at 66% *Agree* and 22% *Strongly Agree* level which signals that assessment should be based on diverse, holistic problem solving skills.

The eight COMET competence criteria assisted staff with the self-evaluation of their work, hence strengthening their professional development to provide

feedback that is more accurate to students. The COMET “solution space” describing possible solutions and variants associated with the open-ended test tasks improved staff confidence and competence for the feedback process. Decisions on how to improve teaching and learning rely heavily on previous assessment outcomes and feedback.

COMET feedback reports provide a clear, graphic illustration to students on their performance, assisting in self-evaluation and reflection. COMET feedback can assist the students to be actively involved in shaping their progress from being a novice (beginner) to an expert (skilled) in their respective occupations.

Focus group interviews with the students showed the importance of assessment feedback from all stakeholders as engaged participants, capable of agency and not merely passive receivers of feedback.

There was a general consensus amongst students interviewed that their current TVET studies has the potential to improve their quality of life, but they raised concerns about the curriculum being effective to equip them sufficiently for the world of work.

Students valued the COMET assessment tasks that focused extensively on their levels of thinking, research requirements, creativity, and applied knowledge when compared with their current TVET curriculum, as a student reflected:

Curriculum Tasks at college are not scenarios. You just do theory. With COMET, you must think more, do a lot of research. You must do a lot of stuff such as being creative while at normal college work you study the text book and you give it back. We are not used to this type of (COMET) thinking. With COMET, you also need to understand how the outside world works.

All the respondents agreed that COMET occupational competence assessment and development had the potential to offer a TVET delivery model that is responsive to workplace readiness demands and opportunities. Another student opined:

Yes. You will be able to solve problems. Using creativity will help you solve tasks that you are not familiar with in the workplace. You can contribute to problem solving. Before you solve a problem, you must analyse it. If you do COMET tasks all the time you will be able to analyse any problem in record time.

Students expressed the need for more experience in the real-world workplace to improve the quality of TVET:

When you get to the workplace you feel that you know nothing. You know the name of objects but if you actually see it, you won't know what it is.

Students reported that feedback processes differed at various institutions and amongst staff at a particular institution. According to them, there was no evidence of a clear process and minimum standards of quality assurance:

We definitely receive good feedback with COMET tasks. We know where we went wrong vs. No, we do not receive good feedback. Lecturers must explain topics that most students fail.

The feedback from the focus group interviews highlighted the students' negative perceptions related to learning at a TVET institution. A possible reason for this is the gap between institutional learning and the reality of real work. In a company, students receive direct feedback on whether a solution is working or not when they perform a practical task. The difficulty students experienced in transferring knowledge from theory to practice in a fragmented learning system is a contributing factor as well. At higher levels of work process knowledge, requiring reflective thinking, it is even harder to understand the relevance of value-free knowledge in the workplace. The ability to transfer conceptual knowledge to practical competence is needed for personal development, but educator occupational competence is a further contributing factor. If the teacher has a rigid approach towards the curriculum, this transfer of conceptual knowledge to practical learning may leave poor prospects for students and employers. A prescriptive curriculum and assessment policy may impact on the potential of colleges to properly prepare students for the workplace, thus hampering TVET reform and student experiential learning processes.

---

## Discussion and Conclusions

This chapter presented an overview of the COMET diagnostic model as a theoretical framework for teaching, assessment, feedback, and learning towards the development of occupational competence in TVET.

Empirical data obtained in a study of TVET students showed that poor occupational competence levels achieved could attribute to the lack of a focus on critical, creative thinking skills, the disjuncture between theory and real work tasks, as well as the neglect of the holistic solving of real work problems. A TVET didactic approach that focuses on applied knowledge appears to be insufficient in preparing students for the world of work.

The findings in this study endorsed the potential of an open-ended test task structure and the provision of a solution space to capacitate students and staff to solve domain specific, real work tasks, holistically. The rater-feedback questionnaire and the focus group interviews with students provided evidence of the relevance, effectiveness, and potential of the COMET occupational competence model to advance assessment for learning that results in feedback capable of improved teaching, practice, and learning in TVET.

Empirical findings from this investigation revealed that COMET allowed specific feedback actions to support the development of diverse, holistic problem solving skills. Rater-feedback substantiated the possibility of feedback beyond only grades for student performance, as well as better assessment methods and tools. Feedback amongst all participants in this study exemplified the potential of COMET feedback and feedforward reports to direct interventions and innovations in TVET.

Semi-structured focus group interviews generated valuable data for clarification of student performance as shown by the quantitative data in Fig. 3. Data from the interviews illustrated the limitations of the current assessment system to develop

professional competence. Students at all test sites indicated that holistic problem-solving of complex occupation specific problems was not part of their current assessment experience.

In conclusion, these research findings have implications for TVET curriculum design and theory capable of transformative change. The necessity for a comprehensive theoretical and empirical assessment feedback model to be developed in order to enhance occupational competence in TVET was abundantly evident.

## Abstract

The divide between vocational colleges and universities in South Africa, in spite of government attempts to institute articulation and progression policy, is still too great for many students to make the transition. A 5-year research and development project that brought colleges and a university together to collaborate around enabling TVET college students to progress from a professional financial planning program into a university qualification in finance revealed rather dismal outcomes if judged by throughput rates alone. Analysis of the reasons for the poor performance of these college students at university revealed significant disparities between the kinds of support offered at TVET colleges and that offered at university. Notwithstanding contextual differences, scholarship on student transitions to university and learner retention resonate with the findings of the qualitative research conducted into the project and its outcomes. This chapter focuses on students' experiences of transitioning from a vocational college to a

## Introduction

Successful student transitions from Technical Vocational Education and Training (TVET) colleges to universities in South Africa are minimal and poorly recorded. While official policy states that the primary goal of South Africa's public TVET college sector is to train towards employment, there is also an increasing policy focus on producing high-level skills and on an integrated post-school education and training system in South Africa (DHET 2013). A joined up system that enables effective student transitions is one of the aims of this policy focus.

An innovative research and development project which is the subject of this chapter brought public TVET colleges and a university into a partnership to create a pathway for adult college learners in a professional program, into a university qualification. As part of evaluating the project and its outcomes, students' experiences of their transition to university were probed, particularly to understand why the throughput rate of these students at university was so low. Scholarship on student transitions and student support was used to place this study into a larger international context, and findings from both the literature review and the qualitative enquiry revealed that student transitions into higher learning or work are fraught. Student data showed inter alia that support services in colleges and in university are currently not aligned or consistent, and illuminated differences in approaches to student support, a misalignment that was found to be a contributory factor in the poor success rates of students in the project. An overview of the South African education and training system follows in order to situate the research and development project that is described later herein.

---

## South Africa's Post-School Environment

One of the first education and training policies in South Africa introduced after the end of apartheid was an outcomes based National Qualifications Framework (NQF) in 1995 for all education and training provision, under the oversight of the South African Qualifications Authority (SAQA). An overarching objective of the NQF legislation was to "facilitate access to, and mobility and progression within, education, training and career paths" for all South Africans and to "accelerate the redress of past unfair discrimination in education, training and employment opportunities" (SAQA Act 57, March 1995). The introduction of the South African

qualifications framework drew on the experiences of Australia, New Zealand, and Scotland (Allais 2007) and was initially composed of 8 levels which later increased to 10 levels in 2008. University qualifications were pegged at NQF Levels 5–10, which accommodated all undergraduate and postgraduate qualifications. In 1998, legislation for TVET colleges was passed that situated their offerings at NQF Levels 2–4, corresponding with Grades 10–12 in the formal schooling system, although an allowance of 10% allocation of programs at first year university level was made. Prior to 1998, many colleges had offered the majority of their programs at Levels 5 or first year university level (Akoojee and McGrath 2007) even though these programs were not formally recognized by universities to be equivalent.

From 2008, the South African NQF was revised into three sub-frameworks with a quality assurance body for each sub-framework governing compulsory school offerings, vocational/occupational programs, and university qualifications, respectively (NQF Act 67, 2008). Coherence and progression of professional qualification pathways remains a systemic challenge, with the National Committee on Articulation Policy (2013) noting that:

The South African Post-School Education and Training (PSET) system is riddled with conceptual and systematic challenges and incongruities. Users of the PSET system experience a lack of coherence and articulation between and within the sub-frameworks that constitute the NQF. (RSA Government Gazette 2014, No 37775, p. 7).

Despite the unifying aims of the South African NQF, learner transitions between TVET colleges and universities are significantly complicated by unaligned education and training legislation. At a regulatory level, post-secondary institutions in South Africa have different authorities that determine student and academic policies. Universities have had a long history as autonomous institutions similar to many Anglophone countries such as the UK and Australia (Polesel and Freeman 2015), and every public university in South Africa has its own juristic act (Higher Education act 1997).

In addition to structural changes since democracy, universities have experienced changes in their student cohorts and have put in place comprehensive measures to assist students' transition from school to university (CHE 2013). For instance, public universities have extensive support measures that include infrastructural accommodations for access, student wellness schemes, and professional staff available for academic and other support. Universities have considerably better financial resources to support interventions due to the funding formula that allows universities discretion in their allocation of resources. TVET colleges on the other hand, enjoy less autonomy and are centrally regulated by the Department of Higher Education and Training (DHET). Although each of the 50 public colleges are juristic bodies, they are bound by centrally driven policies and funding norms of the national government, such as uniform student support policies and guidelines for implementation by all colleges.

A national Student Support Services Framework was first introduced to public TVET colleges in 2008 (Department of Education 2008). This framework document

identified a number of barriers facing college implementation of student support services, such as fragmented student development services at colleges; minimal consultation between colleges and provincial departments; no state funding for student support services within TVET colleges; minimal staff allocations for student support services; a lack of understanding of the need for student support services; and a lack of financial and infrastructural resources to facilitate student support services (P. 3–4). A critical emphasis of the 2008 framework document was placed on academic support (DHET SSS, p. 6) in view of poor pass rates in TVET programs. The document acknowledged the lack of foundational knowledge (mathematics and literacy) and weak general subject knowledge of students and exhorted TVET colleges to focus on language, maths, and literacy as initial support interventions.

The stark contextual differences between universities and TVET colleges with regard to decision-making, funding, and student support provided the backdrop for a funded intervention that aimed to offer students a progression route from their financial planning program at college, into a university qualification, an innovative project that, it was envisaged, would boost the sparse local knowledge on post-school student transitions.

---

## College to University Transitions in the South

Research into student transitions from TVET colleges to universities has in the main consisted of large-scale studies commissioned by the World Bank and UNESCO. In the early 2000s, a UNESCO study of TVET in Sub-Saharan Africa noted that for most of the countries, TVET was offered at secondary schooling level and that for the majority of students entering vocational schools, access to higher education was not an option (UNESCO 2002). Francophone countries generally had stronger articulation linkages between secondary and higher education TVET institutions. A 2008 World Bank study of higher education articulation and differentiation conducted in 12 African countries largely corroborated the UNESCO 2002 report findings. The World Bank Report (N'gethe et al 2008) found that most universities require school-leaving qualifications as a minimum for entrance. Exceptions were found in Francophone countries, where education followed the French model and nonacademic vocational institutions enjoyed high esteem. Generally in Africa, very weak linkages exist between technical vocational education and training (TVET) institutions and polytechnics and universities, and student transitions between these sectors is minimal. The report notes the introduction of qualifications frameworks but shows very little evidence that qualifications frameworks have impacted on student transitions and progression.

A 2013 UNESCO study of 13 Southern African Development Community (SADC) countries, similarly states that student transitions from TVET institutions to universities “remains uncommon and fraught with difficulties” (Chakroun 2013, p. 15). The report notes that:

TVET qualifications are not primarily designed with a view to progression to higher levels but with a view to the competencies required for a specific occupation or set of occupations. This typically means that TVET graduates have much less prior formal learning and are less prepared for higher education programmes than academic school graduates. Given the low esteem for TVET in many cases, it is not surprising that universities are concerned about offering places to TVET graduates, and there are particular, and rational, worries about levels of formal mathematics and scientific knowledge. (p. 42).

Further afield, UNESCO commissioned a study of student transitions from secondary school to universities in Asian and Pacific countries. A case study of Australian higher education systems revealed similar tensions between “the vocational curriculum” and its relationship to general or academic secondary programs. Indeed, Polesel and Freeman (2015) state that:

While the academic curriculum has been subject to remarkable stability and treated as canonical, often due to the power of universities and examination boards over its content and delivery vocational studies have been controversial, their establishment contested and their form subject to the interests of competing stakeholders. . . . Vocational programmes play a minimal role and sit uneasily within a senior secondary curriculum still largely used to teach, select and rank students for university. (pp. 10–11).

This brief review of African students’ transitions from TVET colleges to universities in the South reveals the range of tensions and difficulties in enabling student progression from vocational studies to university, since universities still prioritize general and academic school knowledge over and above vocational programs. Furthermore, poor retention and throughput continue to be features of a lack of progression from TVET college to university, for which the following section provides some theoretical framing.

---

## Theorizing Student Retention and Throughput

A dominant theoretical framework which has implications for student support is Tinto’s work on student retention in higher education (2005, 2010). Tinto acknowledges that student retention and graduation can be attributed to students’ own social, aspirational, and academic attributes, but that there are factors within the control of institutions which affect retention and throughput. His 2010 research identifies four broad “institutional conditions” that affect student retention, namely, student expectations, student support, student feedback, and student involvement (p. 56). However, he argues that the most important factor affecting student retention is academic support offered in the classroom. On the other hand, Astin (1999) foregrounds student development through “student involvement,” which he defines as the “quantity and quality of the physical and psychological energy that students invest in the college experience.” (p. 528).

Longitudinal surveys of student retention in the USA have shown conclusively that student throughput rates differ significantly between high-income and

low-income students and that the rate of low-income students not completing higher education qualifications is widening (Tinto 2010, p. 53). Similar studies of South African higher education data have shown that student retention and completion rates are significantly affected by low income backgrounds rather than racial identity, and that support offered to students from low-income backgrounds is insufficient (HSRC LMIP Seminar, November 2017). Despite the dominance of Tinto's theoretical approach, there has been significant critique of "institutional" approaches to student retention and development, for instance, Rovai (2003) notes that Tinto's Student Integration Model has limited applicability for students who are not studying full time within a university, and McCubbin (2003) shows that non-traditional students, such as those with disabilities, are far less socially integrated within universities.

In South Africa, there has been minimal research on the TVET colleges sector and particularly on student experiences in vocational education. Jeffery (2015) traces student support approaches within South African higher education student development and notes post-apartheid transitions from targeted minority black student support to a more inclusive institutional approach for the majority of students. However, all of these approaches have tended towards a deficit model of support. In comparison with universities though, student support policy and implementation in vocational education are still in their infancy.

---

## A Test Case of College to University Progression

In 2007, at the request of a professional body in the insurance industry, a traditional public university undertook to assist in developing a pathway for TVET college students in a financial planning program that enabled them to progress into an appropriate university finance qualification (Needham 2014). The qualification offered by vocational colleges was located at Level 5 (a first year university level), and the first year university level on South Africa's qualifications framework is described as follows:

This is an entry-level higher education qualification. The qualification is primarily vocational, or industry oriented. The qualification also serves to provide students with the basic introductory knowledge, cognitive and conceptual tools and practical techniques for further higher education studies in their chosen field of study. The knowledge emphasises general principles and application. This qualification signifies that the student has attained a basic level of higher education knowledge and competence in a particular field or occupation and is capable of applying such knowledge and competence in an occupation or role in the workplace. (p. 19).

The university agreed to collaborate with five public TVET colleges to ensure that the financial planning program offered at the college would enable students to access the university at a later stage. Consultations were held with the relevant university faculty as well as with the quality assurance body responsible for the industry accredited program being offered by the colleges.

The university agreed to amend its admission policy so that employed students who completed the part-time financial planning program at TVET colleges would be able to enter the second year of the university level Diploma. This was a significant concession for the sake of progression. On completion of the university qualification, students would furthermore be able to access a postgraduate certificate which would allow them to write an internationally recognized board exam set by the insurance industry, a process that would effectively take part-time students 5 years to achieve professional status. In order to lessen the financial burden on students undertaking this route, funding was obtained for the 5-year period.

In 2009, 100 part-time students, all employed adults in the insurance sector, were enrolled in five public TVET colleges for the Level 5 financial planning program. Students were required to have a school-leaving certificate in order to satisfy minimum university entry requirements and had to have worked in the insurance industry for at least a period of 1 year to qualify for the funding. Twelve of the enrolled students were people with disabilities that included visual impairment, deafness, and two quadriplegics. Of the 100 students admitted to TVET colleges in the Level 5 program, 77 students passed, of which 23 students enrolled for the part-time 2-year Diploma qualification offered at the university. Of these 23 students, 18 students managed to complete their first year and continued into the second year. However only 12 students completed the second year and were awarded the diploma, of which none were students with disabilities. Finally, at the end of an arduous journey, six diplomates entered the postgraduate certificate and were successful, making them eligible to write the professional board exam for financial planners.

An evaluation of the project outcomes clearly pointed to the low throughput rate which was of huge concern. How was this poor transition performance to be explained? In an attempt to find answers additional to the comparative literature, students were asked to respond to questions about their experiences at college and university, and to expand on issues that they felt had impacted on their progress, the results of which are reported below.

---

## **Student Experiences of Transition and Progression**

Most of the students interviewed reported that they had found learning at TVET colleges physically difficult as the training facilities were much poorer than the corporate offices in which they worked. Students with disabilities struggled with physical access, and as a result of this, two of the five TVET colleges relocated to training rooms within large insurance companies which had better access facilities. Students did acknowledge though, the strong support from the college for their learning needs, as one college had dedicated an occupational therapist within their Student Support Services division to work with the students with disabilities. However, a few students noted that student support had waned at colleges towards the end of their program. Another student noted specific difficulties experienced by students with disabilities at the university:

...unfortunately, we do not have the necessary assistive devices to complete the course ...speech calculator, notes, tutorial memo's ...and it just lacked any accommodation for the visually impaired to make a success of it.

Concerns were also raised with the quality of the learning materials. Because university lecturers were unfamiliar with the format and requirements of vocational college-based qualifications, the learning materials were drawn from varying sources and updated during the delivery of the qualification, which was not ideal. No funding was allocated for additional curriculum development.

While students felt the college and facilitators provided insights into their industry, a few students raised difficulties in their teaching and learning experiences, especially with regard to assessment, as, in the words of a student, "the college assessment is not close to that of the university, therefore it (college assessment) does not prepare you for the work load." Students struggled with being exposed to widely differing assessment approaches between the college and the university. Within the Level 5 program provided by colleges, students were able repeat formative and summative assessments up to three times in order to prove their competency of the outcomes based qualification. At university, however, students were provided with only one opportunity to pass assignments. A further difference in assessment was that the program at TVET colleges involved recording workplace learning experiences in a log book. College staff were not involved in the workplace assessment and insurance companies appointed workplace mentors to supervise students. The workplace mentors, however, were not remunerated for their additional work, and in many cases, students did not get sufficient exposure to workplace learning areas necessary to complete their log books. At the university, students simply received no workplace exposure as the qualification they transitioned into was entirely theoretical.

A critical challenge identified at the outset of the project was that students would need subject knowledge assistance in mathematics, economics, and literacy skills to ensure their successful transition to university.

In this regard therefore, students felt that colleges did not adequately prepare them for university. One student noted the diversity of performances at university in their combined classes, and the high expectations of academic performance:

It is very intense... it is assumed by the lecturer that we all on par and will be able to work at the same pace. No extra classes are provided for those students struggling as well. In my experience I had to attend 5 extra classes, at a cost of R 100 per class.

Despite overwhelming support for the development of an innovative transition route, a few students expressed a note of caution, as in the following:

Yes, I have recommended this route to others as it is very informative and provides broader understanding of the insurance industry. But I would caution them when it comes to the university program as the levels between the two programs is very different. It would be great if some of the modules in the TVET College program could be swapped for more in-depth modules about economics and finance.

The project definitely showed the possibility of student transitions from vocational colleges to university, but serious questions remained about the role of student support offered by institutions involved and revealed the stark differences between them. The following section highlights these contextual differences in the light of the literature drawn on.

---

## **Broader Institutional Issues and Their Impact**

The introduction of a Level 5 professional qualification within South African TVET colleges provides an example of the influence of privatization aspirations (Ball and Youdell 2007). Vocational colleges provided this qualification as it afforded additional third-stream income for the colleges. Colleges had to appoint external industry recognized facilitators to teach this qualification as this was an accreditation requirement of the industry accreditation body. Facilitators were hired on a contract basis for the duration of the qualification, which did not build the internal capacity of the college to develop their own staff expertise in this area. In addition, industry facilitators did not hold teaching qualifications and were poorly equipped to provide academic foundational support. Student support services were drawn on but these resources were stretched as the funding did not extend to colleges for support services. Despite this, most students felt well supported by the colleges they were enrolled in. However, no provision was made for additional learning needs that could enable successful progression to university studies. From an industry perspective, the sole purpose of this qualification was to address the professional needs of the long-term insurance industry, and broader public provider commitments to holistic development and progression of learners were largely ignored.

Critiques of Tinto (2005) and Astin's (1999) institutional approaches to student retention and development provided by Rovai (2003), McCubbin (2003), and Rutschow et al. (2012) were validated in the public university's approach to student development. As students in the project were studying part-time and after hours, they were unable to draw on the range of the university's student support services as in the case of full time students. Despite a much larger and better resourced student support services division, students at the university were more poorly served than they had been at TVET colleges. In particular, students with disabilities struggled to complete their qualifications at the university. This was not due to a lack of commitment by student support personnel, but rather that public universities remain ill-equipped and under-resourced to serve a range of people with disabilities when they are not full-time students attending class during day time hours. From an academic perspective, students had little recourse to additional academic support and were required to pay for additional support. Most of the students in the progression route had been out of school for years and their completion of the industry-based qualification within TVET colleges did not prepare them sufficiently for academic disciplinary study.

While the academic and inclusive support people with disabilities received from TVET colleges enabled most of these students to complete the requirements of the industry-based qualification, this support did not assist them to adjust to the rigors of

a traditional research university where options to repeat assignments were not available. Most students struggled to cope with the academic requirements of the university qualification, and they were not able to access additional foundational knowledge in disciplinary areas such as mathematics, economics and English. Students also struggled with literacy skills for the completion of assignments at the university, as the industry-based qualification at vocational colleges did not prepare them for academic essay writing.

Student support services in the vocational colleges and the university were fully supportive of this progression project. However, the support services provided at the college and at the university differed substantially in their approaches to student development. At the colleges, student support services were deployed to ensure that students achieved an industry-recognized qualification that enabled them to practice as insurance brokers. This involved working closely with all students to prepare portfolios of evidence that demonstrated competence in the outcomes-based qualification. But this support did not prepare students for disciplinary-based learning and academic study at a traditional academic university. The university's student support services proved too limited for part-time students, and they were unable to provide the academic and foundational support needed by most students to complete the transition to university successfully. While this intervention was able to prove that progression from a professional industry recognized qualification to a disciplinary-based qualification at university is possible, such innovative projects are likely to achieve only limited success if approaches to student support, for instance, are so divergent. Bridging the gap between college and university will need more creative alignment and appreciation of the needs of students as they transition between traditionally separate learning contexts.

---

## Conclusion

Research into student transitions in Southern and Sub-Saharan Africa has shown that there is minimal student progression from vocational institutions to universities. The student transition and progression project in South Africa revealed important learnings that ought to be taken into account for successful student transitions between these educational sectors. The student transition project attempted to enable employed students within the South African insurance industry to undertake a professional qualification route through college and university. In examining why such a low throughput rate was achieved, some theorization of student transitions as well as the experiences of students were examined to try and determine the issues that impacted their success. Most of the student support literature places a strong emphasis on the integration of students into institutional support systems and adequate academic support, noting though that part-time students are considerably less integrated and supported at institutions than mainstream full-time students. The dangers of privatization imperatives were also discerned.

While there was considerable evidence of institutional student support offered to the cohort of students in the project, the support stemmed from fundamentally

different approaches. Support provided by public TVET colleges was to ensure that employed learners completed a workplace qualification. Support within the workplace for these employed students was generally weak as workplace mentors were unfunded, yet were expected to mentor students as an additional part of their workload. A more flexible assessment approach allowed learners to repeat formative and summative assessments and this in part contributed to high throughput rates at TVET colleges. Students found that no additional funding was provided for the academic support required by them in their transition to academic university programs. While TVET colleges provided strong student support, they were unable to build their internal capacity to continue offering the industry Level 5 program as their accreditation body would only approve instructors from the insurance industry to teach the course.

A range of challenges confronted students upon their arrival at university, as student support there did not enable them to address subject knowledge deficits and they struggled to comply with the academic requirements of economics, mathematics, and literacy. Support offered to part-time students was substantially limited as most student support structures were only available during daily working hours. Additional academic student support offered by the university had to be paid for by students as the funding provided did not include student support. Students with disabilities struggled with infrastructural access to venues and with limited accommodation for their range of disabilities.

In sum, the project showed that competing approaches to student support did not serve the students within the professional qualification route. Despite significant frustrations, nearly a quarter of the student cohort persevered and obtained a university diploma. Very few students were, however, able to sustain the necessary level of academic involvement and only six students completed a postgraduate qualification. Future interventions of this nature would need to incorporate student support structures into the academic planning, conceptualization, and resourcing of these from inception, if such initiatives between post-school institutions are to succeed. This would necessitate a coordinated approach from institutions that to date have operated largely in siloes, and the recognition that resourcing student support adequately is critical for student progression, more especially in South Africa's post-school education and training sector.

## Abstract

The expansion of Technical and Vocational Education and Training (TVET) in order to address goals of economic participation and poverty alleviation through skills development, particularly for youth, is currently on the agenda of many developing countries. In South Africa TVET has only recently emerged from decades of neglect and marginalization, and national policies are attempting to rebuild the profile of vocational training institutions through targeted advocacy and funding. In light of employment imperatives however, narrow human capital and productivist perspectives have tended to dominate, at the expense of broader human development outcomes which have been under-theorized in the literature. This chapter focuses on students who typically enrol at public TVET colleges and the significant barriers to success that they confront, not least of which is the

negative stereotyping which is still part of the TVET experience. While policy initiatives have recognized the wide-ranging support services that may be needed, many colleges are still a long way off from adopting a holistic and systemic approach to student support, for which funding is only gradually coming on-stream. To date there have been some sponsored intervention programs, one of which is highlighted herein for the potential it has shown in the psycho-social support of students as they build skills for both life and work.

## Introduction

Technical and Vocational Education and Training (TVET) has in most developing countries been tasked with economic upliftment through skills development and with social inclusion of under-represented and/or disaffected youth. Widening participation of the eligible youth cohort is a goal in that agenda, as is improving academic success of academically under-achieving students who enter vocational colleges largely as a second choice or second chance. A policy strategy to increase participation and student success has been to enhance student support services at TVET colleges, inter alia to promote learner-centeredness and the removal of barriers to learning. Scholarship around these concerns has, however, problematized student disengagement and one-dimensional approaches to student success, in addition arguing that TVET should be focused on human development rather than crude human capital development imperatives (Lopez-Fogues 2016; Ngcwangu 2015; Powell 2012; Strathdee 2013; Winch 2000). Drawing on South African initiatives in this regard, this chapter posits that student support services are critical to achieving both access and success, and to attaining the goal of widened participation. Policies on student support services and institutional interventions are described in light of the contextual realities of TVET reform in South Africa and the typical backgrounds of students who enter college vocational programs, and the chapter highlights an initiative that has been showing some success in providing psychosocial support to college students. Initiatives such as the latter, though have to date been unfunded systemically, and have relied on private or donor funding.

---

## TVET Reform in South Africa

TVET goals of skills development and inclusion (Karmel 2010; Leney and Green 2005) have been articulated in various UNESCO and multinational documents such as the Bologna and Lisbon declarations in established TVET contexts, and the Bandung Declaration in developing TVET contexts. In particular, the inclusion

agenda has been tied to enhancing employability and to widening the tertiary education sector so that it extends beyond university studies (Grubb 2003). By broadening the scope of post-school studies, it was envisioned that more opportunities could be made available to those historically under-represented in education and training.

The South African government is committed to the expansion and improvement of the TVET sector. For instance, its White Paper on Post School Education and Training (PSET) (DHET 2013) proposed that the TVET sector headcount enrolment be expanded from 350,000 in 2010 to 650,000 by 2013 and to one million by 2015, where headcount enrolment refers to the number of students who register in a year. The NATED programmes are offered on a semester or trimester basis which means that the same student could enrol 2 or 3 times during the same year, potentially resulting in misleading participation figures. With the introduction of bursary funding for vocational students in 2008/2009, by 2014 there were over 700,000 students enrolled in public TVET colleges, and a further 80,000 students in private TVET colleges (DHET 2016, p. 25).

Since the advent of democracy in 1994, TVET in South Africa has undergone extensive reforms to address its discriminatory past. By 2003, the approximately 150 racially separated, unequally resourced colleges were merged into 50 multi-campus colleges so as to redistribute resources across campuses in each of the nine provinces (DoE 2001). Since 2006 the college sector has been recapitalized through significant injections of state funding in an attempt to address its “Cinderella” status (Wedekind 2016). In 2009, there was a government department restructuring which resulted in the establishment of the Department of Higher Education and Training (DHET) which now regulates all education and training outside of formal general schooling, including adult learning centers, public and private skills development, vocational colleges, and universities. This broad remit of the DHET is referred to in policy as the “post-school” sector.

In addition to institutional and governance reform, colleges have also undergone curriculum reform since 2006, introducing in 2007 a new qualification, the National Certificate Vocational (NCV) (DoE 2006). The NCV had the initial intention of replacing the traditional National Accredited Technical Education Diploma (NATED or N courses) programs which were theoretical modules undertaken in college settings, to be complemented by work-based training thereafter. Modernized learnership programs leading to occupations were meant to replace the traditional apprenticeship system but this met with resistance from various quarters (largely from industry familiar with the historical programs), and the new NCV programs were allowed to continue in parallel with the NATED programs, (Wedekind 2016, p.17) Colleges also have the option of offering training which attracts public funding from national industry sector authorities or private funding from companies.

The new NCV programs were designed to be more cognitively demanding with a modernized content, in addition to having a practical component. The NCV program has three certificate levels, the final level being an exit level with a certificate equivalent to a school leaving certificate and has a stringent assessment regime and pass criteria. Given the “typical” TVET student described herein, annual pass and completion rates in the NCV have been low, albeit that these have improved somewhat since the rollout of the NCV in 2007 (DHET 2016).

## Widening Participation in Post-Schooling

The post-school system has been described as a low participation, high attrition sector (Fisher and Scott 2011) with chronic failure rates. In South Africa in 2011, a national census found that about 60% of adults had not graduated from high school, and only 12% of adults had higher education. While this had improved considerably since the 2003 census in which 70% of adults had not graduated from high school (Statistics South Africa 2012) it still indicates that the majority experience in South Africa is that of not completing school. Considering youths at a post-school age (20–24-year-olds), only 12% entered post-school education while 16% remained in general academic schooling, 21% were in employment, and 51% were not in employment, education, or training (NEET) (Branson et al. 2015). An earlier study had reported that 2.8 million youths between the ages of 18–24 were NEET (Cloete 2009). These statistics point to a crisis of participation among youth and raise questions about the potential for inclusion and social justice goals of TVET systems.

Moreover, while there have been significant increases in student numbers, TVET college attrition and pass rates have been low. In 2014, there were over 702,000 headcount students enrolled in TVET colleges, compared with under 360,000 students in 2010 (DHET 2016, p.25). However, of the 151,000 TVET students who wrote the exit level NCV4, N3, and N6 programs (which are matric and post-matric equivalent levels), there were reported pass rates of 35%, 48%, and 42%, respectively (DHET 2016, p. 26). This is despite indications that a substantive number of TVET students already possessed a school leaving certificate upon entering TVET colleges (Branson et al. 2015; Cosser 2011a). It would appear that even high school graduates are not coping with TVET studies.

The reasons for the low pass rates are debatable. Explanations proffered have been the onerous pass requirements of the qualifications themselves, the level of difficulty of some subjects, low levels of academic preparedness of students, poor resourcing of student support, inadequate teacher preparation, inappropriate pedagogies for vocational learning, and so on. However, there have been few empirical studies into the causes of TVET students' poor performance (see FET Institute 2013a; Papier 2009), thus evidence is still largely anecdotal.

Despite the low pass rates, many students attending TVET colleges did not display a negative attitude to the college itself. In a study conducted among vocational students, interviews revealed that they were “studying their passion” and “preferred learning things practically” (Needham and Papier 2012). However, TVET and high school students were concerned about the economic prospects of a TVET education, confirming earlier survey findings in this regard which suggest that factors informing student perceptions of vocational learning are related to the status of college in relation to university, and to employment prospects (Cosser 2003). It is clear from the limited research that TVET college students face significant hurdles societally and personally along the road to achieving positive outcomes pursuant to their obtaining access to vocational studies, and they require significant on-course support at colleges once enrolled.

Therefore policy imperatives for widening participation in post-schooling necessitate an understanding of the dynamic patterns underpinning student participation and the attendant student profiles. Letseka et al. (2009) suggest that participation in TVET is an “interweaving of choice and constraint, of aspiration and actualisation” (Letseka et al. 2009, p. 11). While the TVET student population is diverse, TVET colleges by and large are the recipients of students who have not gained access to high status education institutions, are from low socioeconomic and education attainment backgrounds, and/or are often early school leavers (Cosser et al. 2004; Cosser and Sehlola 2009). Studies suggest that TVET has not always been a first choice for students, including for those at TVET colleges (ibid.). A review of the literature on student choice and transition into higher education, as well as a follow up study of actual destinations taken by students, confirmed that student choices are constrained by personal and social economic circumstances as well as institutional factors (Cosser 2009; Cosser et al. 2004; Cosser and du Toit 2002; Cosser and Sehlola 2009). While nearly 90% of those surveyed said they intended studying further, only 47% found themselves in TVET colleges or universities. The reasons Grade 12s gave for entering TVET were as follows: 40% of those in TVET wanted to improve their marks to enter university, 28% could not afford university, and only 22% entered TVET to improve their prospects of employment. The findings suggest that while there were students who were interested in studying at TVET; the majority of students at TVET colleges were not there by first choice but were constrained by funding and/or previous academic achievement from attending university as a first choice institution.

In South Africa, public colleges especially bear the brunt of this social stigmatization and consequent low self-esteem of vocational students. As demonstrated in other countries, the task of lecturers in this context is thus more burdensome, as they engage “in emotional labour unrecognised by their normal workload” (Avis and Bathmaker 2004; Brockmann 2013; Robson and Bailey 2009).

---

## Theorizing TVET Goals and Student Profiles

### Human Capital Perspectives

Human capital theorizations of TVET students provide insufficient understanding of the complexity of students’ lives. However, this perspective which draws on the conception of the “21st century learner” remains dominant and can be traced through “networks of documents, events and bodies that transcend borders and hemispheres” (Williams et al. 2013, p. 792) to a particular notion involving the increased economization of the learner and corporatization of TVET colleges (ibid.).

Thus, TVET policy documents mostly invoke narratives of economic upliftment, individualization of structural problems, globalization, and the pedagogy of self (Papier et al. 2012; Powell and McGrath 2015; Wedekind 2008). In the South African context, human capital narratives, in promoting employment,

inclusion, or even student achievement, have not focused on the challenges facing young people or the broader society.

Research evidence points to implementation conundrums emerging within the dominant framework with respect to widening policy agendas. For example, a study in Canada found that policy directions and youth trajectories are not always congruent (Molgat et al. 2011). In South Africa similarly, quantitative and qualitative accounts have found that students “zig-zag” through the system, using TVET as “stepping stones” through repeat enrolments in various courses of the same type and at the same level (FET Institute 2013a; Wildschut et al. 2012); students were enrolling in courses at lower levels to their previous exit levels (Cosser 2011b), and were either dropping out or stopping out (DHET 2016). Gale and Parker (2014) argue that the dominant conceptions of students are potentially “largely system-driven and self-serving” (p. 747). Adams (2011) for instance, reported a widely held lecturer belief that South African TVET college managers were recruiting students to fulfil funding norms rather than for educational reasons. In this scenario, inappropriate placement of learners into programs not of their own choosing had resulted, disadvantaging the learners but meeting institutional targets. Human capital perspectives appear to have contributed to a disconnect between individual and institutional imperatives.

## Human Development and Capability Perspectives

An alternative, emerging literature on human development takes issue with productivist conceptions of students (Lopez-Fogues 2016; Ngcwangu 2015; Powell 2012; Strathdee 2013; Winch 2000), and critiques ideological underpinnings that individualize exclusion and mask structural failures (Fergusson 2013; Simmons and Thompson 2013) rather than emphasizing more holistic development of students in the spaces that vocational colleges provide. In light of more holistic student development concerns, increasing access through widened participation alone, it is argued, cannot be the end goal. Student success would entail that the learning institution is responsive to students’ needs, and that students are able to meaningfully participate within the spaces that have been created.

A human development perspective is especially relevant in cases where TVET students are characterized as having low socioeconomic status, have poor previous academic achievement, and/or are early school leavers. These student profiles are often accompanied by narratives of hurt, alienation (Jonker 2006), and/or exclusion and unequal social outcomes (Lewis 2007; Polesel 2010; Smyth et al. 2013).

But contrary to some critical theory perspectives, human development perspectives do not depict TVET students as victims. Literature is emerging which show illustrations of agency, resilience, or fortitude (FET Institute 2013a, 2014b; Needham and Papier 2012; Powell and McGrath 2015). Recent developments in South African scholarship have posited the capabilities approach as a counterbalance to human capital conceptions of TVET students. A capabilities approach sees the capacity to work as only one aspect of human development, and hence of education and training (Lopez-Fogues 2016; Powell 2012).

However, there has been little attempt to build capability or to conceptualize the construct in the TVET sector. The task of developing better human beings has yet to be defined, and there has been limited discussion around the difficult question of what constitutes a curriculum that takes TVET students beyond academic and economic outcomes to becoming “more fully human” (Freire 1970). It is not yet clear what would constitute a healing, affirming and humanizing pedagogy for students who often have entered TVET from histories of hurt, alienation, and exclusion – a topic currently under discussion in South African universities.

How students develop agency, resilience, or fortitude under trying circumstances is poorly researched within TVET. It is unclear whether demonstrated fortitude is innate, or whether it can be taught and learned, but there is a reservoir of research in positive psychology that can be productively accessed (Seligman and Csikszentmihalyi 2000; Snyder and Lopez 2002). Notions of resilience and fortitude recognize that some people are better able to adapt to adverse circumstances, but this acknowledgement could be used to individualize responses and mask structural conditions (Ecclestone and Lewis 2013; Joseph 2013). While definition and operationalization of the concepts of fortitude and resilience are still unclear (Luthar et al. 2000), the fact remains that society often produces adverse circumstances and students will need to be able to cope irrespective of outside agendas. How people, particularly youth at transition points, engage with their own subjectivity has implications for social reproduction (Cooper 2017). Moreover, it is possible that alienated individuals bring with them cultural resources which are often untapped – for instance, Powell (2012) provides some evidence of TVET students’ contribution to their communities – narratives that are often silent in TVET discourses.

In higher education, there have been some studies around the concepts of fortitude and resilience at universities in South Africa (Barends 2004; Rahim 2007) which have found that fortitude is positively correlated with mediating demographic factors that impact on academic outcomes. However, it was also found that there were significant differences in the distribution of fortitude constructs among different demographic groups (Barends 2004; Rahim 2007). Research on resilience and outcomes within the TVET sector is far more limited though, and the impact of resilience on academic achievement or on employment outcomes has not been investigated.

Thus there is an emerging literature pointing to the salience of capabilities, fortitude, and resilience but more limited discourse around *how* TVET systems can assist to develop student capabilities and the support services that are necessary to aid these capabilities development.

Life Course theory (Elder 1998; Elder et al. 2003) provides a potential theoretical orientation for TVET to develop the capacity to assist in human development. Life Course theory conceives of human beings as “becoming” (Gale and Parker 2014), holding that students can encounter “turning points” in their lives (either positive or negative), and that understanding (and intervening) in students’ life courses may impact on the ways in which they transition from these turning points. Turning points are not fixed phases of human development but occur within their life courses. Conceiving of being better human beings can serve as “turning points” for students

in their process of “becoming” (Gale and Parker 2014), not only in enhancing their academic and economic prospects but also in its own right.

More complex and nuanced understandings of student participation are becoming available. Gale and Parker (2014) identify three approaches to student transitions: induction, development, and becoming, and argue that transition as “becoming” presents the most sophisticated, but most under-utilized, approach. Understandings of student transitions are important, since different understandings could result in different approaches to practice. Currently, dominant development narratives impose normative and/or universal identities on students that fail to understand the diversity of life courses and identities. In the alternative conception,

Becoming explodes the ideas about what we are and what we can be beyond the categories that seem to contain us . . . [It] offers a radical conception of what a life does. (Sortorin cited in Gale and Parker 2014, p. 745)

There is still much to be done in South African TVET colleges with regard to instituting support services that mitigate the personal trajectories of vocational learners, hence the following section sets out the lengthy pathway that policy has been on towards more comprehensive student support provision.

---

## Systematizing Student Support Services

Within the South African policy and institutional landscape, provision has been made for student support services (SSS) that are more holistically intentioned, are based on principles of inclusion, and offer a range of services that extend from college recruitment and access, through on-course support to exit from the college.

Some 20 years ago, South Africa’s Education White Paper 4 of 1998 had the intention to “*ensure that all learners, including previously excluded or disadvantaged groups are given every opportunity to succeed*” (DoE 2008, p. 4), and to this end, the Department of Education had recommended a wide range of services, including Student Support Services (SSS). This commitment to SSS was extended by the Department of Education’s successor, the Department of Higher Education and Training (DHET) through its White Paper on Post School Education and Training (DHET 2013). Earlier, Education White Paper 4 (1998) had noted that the provision of student support services in TVET colleges was uneven and ad hoc. Not all colleges had support services, while some colleges had centralized support and did not offer support services at each of their campuses. The range of support services varied from college to college, and there was a lack of a proper infrastructure for staffing and referral systems. Education White Paper 4 had therefore proposed a dedicated funding grant for student support services so as to enable services to be extended to all colleges that would encompass “academic development, guidance, counselling, health, welfare and other learner support services” (DoE 2008). The intention of the White Paper stated that:

Learner counselling and support services will be established to help new entrants to FET to make meaningful choices about their direction of study and to ensure that all learners, including previously excluded and disadvantaged groups, are given every opportunity to succeed. Career guidance and support services will provide information on learning programmes, education and training providers, qualifications and job opportunities. FET providers will be required to ensure that learners have access to up-to-date labour market information, indicating skill shortages, career opportunities and trends in the job market.

This intention was supported by the FET Colleges Act (2006) which provided for academic support services and student support services as different categories of support staff and required college councils to consult with students on a college student support policy. A Student Support Services Framework document emerged in 2008 (DoE 2008) which conceptualized holistic student support services integrated into the colleges' functioning but led by a Student Support Services unit. Student support services were to be supported by Student Support Officers (SSOs) and a system of referrals.

The domain of student support services is potentially wide, including student financial support, psychosocial support, and academic support *inter alia*. Government policy has also categorized student support services according to the various stages at which students might require support at college, for instance, student support services ought to cover services at "pre-entry" (including career guidance and orientation); "on-course" (for instance academic support, tutorials, job readiness skills); and "exit level" support such as preparing students to find employment or continue their studies, as well as developing skills for finding employment such as compiling CVs and assisting with obtaining work placement (DoE 2008, p. 5).

Research around the poor performance of students in TVET colleges (for instance Papier 2009) pointed to the nature of student support services that should be considered with a view to improving performance. In a multi-stakeholder study of TVET students' performance across six colleges (*ibid.*), it was reported that students struggled with the cognitive demands of particular subjects (e.g., Mathematics) which they possibly had insufficient prior grounding in, hence the need for academic support; there were significant socioeconomic challenges that students experienced, for example, financial difficulties, poor nutrition, poor living conditions including gangsterism and substance abuse, thus indicating a need for economic and psychosocial support, as well as safe spaces and transport for after-hours study.

The DHET has been cognizant of the historical disparities among colleges that have resulted in the prevailing uneven conditions, and which require varying levels of intervention and support relevant to the current realities of colleges (DHET 2013). Specifically rural institutions have weaker infrastructure, fewer teaching facilities and staff, and are less able to present a range of program options to students than urban institutions. Furthermore, national socioeconomic surveys have found that most students at TVET colleges are from poor family backgrounds (DHET 2013) and that there are more opportunities for urban than for rural students.

The challenge, however, is to systematize these student support policies within institutional practices. Various student support services have been provided at TVET

colleges, but the range of services is not standardized or generally available across colleges (DHET 2017). Support services offered include academic support (particularly in the language of instruction, Mathematics and ICT); student financial aid; and locating workplaces for practical experience or employment on completion of studies. Even though colleges have, in spite of funding constraints, managed to offer such support services, these are reported to be inadequate for the support needs of colleges, a reason being that support services have in many cases depended on individual colleges using resources generated by themselves rather than services being included in state funded budgets. Sustainability of service provision at particular colleges has therefore been uncertain.

Many students experience a lack of proficiency in the language of instruction in TVET colleges which is inevitably English or Afrikaans as a result of the South African apartheid legacy which privileged these two languages at the expense of indigenous African languages. This lack of proficiency in the language of instruction has had the effect of hampering the progress of students for whom neither English nor Afrikaans is a first language, and necessitating learning strategies that improve academic reading and writing (Jeffery 2015, p. 27).

Furthermore, colleges have reported students being generally uninformed about the courses on offer, and being guided rather by the availability of student bursaries in their choice of program. Since 2013 though, significant progress has been made with development of a national, multimedia advisory service, and it is envisioned that this facility will ensure that young people, including those who are poor and disadvantaged as well as those in rural areas, can make informed choices about their studies and their careers. In a study highlighting student perspectives on the provision of support services or lack thereof, a possible correlation between incorrect career choices and student attrition was presented. More than a third of the students who were interviewed reported that they were not studying their first choice because the courses they wanted to study were already full, and as they did not want to wait for the following year to register, they chose another available program (Jeffery 2015, p. 25).

The student support services framework document (DoE 2008, p. 7) recommends that “academic support be prioritised for students from educationally disadvantaged backgrounds for the enhancement of academic success.” Although pass and through-put rates have improved since 2012, they are still relatively poor, indicating that academic support for the foreseeable future is sorely needed.

Since the introduction of state student funding for TVET college students in 2007 with the advent of new national vocational programs, students have been relatively well supported to undertake college studies through the National Student Financial Aid Scheme (NSFAS). The National Student Financial Aid Scheme (NSFAS) has assisted poor students with tuition fees, accommodation and transport costs (DHET 2013) to some extent. The national bursary allocation for TVET colleges increased from R300 million in 2010 to R1.988 billion in 2013 (p. 13) and has led to the substantial expansion of college student numbers. More recent figures (2014 and 2015) provided by the National Student Financial Aid Scheme (NSFAS) indicate an increase in the number of students funded and the value of the funds. In 2014 NSFAS

supported 228 642 TVET students in the amount of R1991 487 809 (close to R2 billion). In 2015, 235 988 students were funded in the amount of R2 095 129942 (over R2 billion). Funding for college students is in the form of bursaries and there is no repayment required. TVET colleges have to monitor bursary recipients' attendance as subsequent grants are dependent on attendance being maintained. Travel and accommodation allowances are subject to availability of funds on a pro-rata basis (DHET 2016, p. 11), and it is these allowances that have been the reason for student unrest from time to time, when there has been insufficient funding of travel or accommodation costs.

However, the impact of managing a large scale bursary scheme has been felt by colleges in their administration of it, with college staff having to undertake student means-testing, advice on applications, disburse grants, monitor and report on expenditure, and the like. Colleges are required to keep careful records of payments made to students. Nonetheless, in spite of these rigorous policy checks and balances, there are anecdotal reports of students in a "revolving door" syndrome, who manage to secure successive bursaries while not completing prior programs. Travel and accommodation allowances have been the reason for student protests from time to time on the belief that these were insufficiently funded. The net result is that, according to the DHET, student support services have tended to focus on the administration of bursaries (DHET 2017).

Factors generally accepted as contributing to poor performance of college students have been cited as poor living conditions, poor nutrition, a lack of self-management skills and self-discipline. In a study (Fryer 2014) found that "college adolescents are inclined to be emotionally immature; experience peer pressure; and have difficulty in assuming responsibility for their own studies" (p. 64). The official policy framework holds that students in need of psycho-social support should be referred to relevant institutions and to persons trained and capacitated deal with such challenges (DoE 2008 p. 7). In colleges where such referrals were either not possible or not done, student support staff reported that they felt emotionally overburdened, lacked counselling experience, were unsure about the manner in which they should deal with student issues; and would prefer to be supervised by someone experienced in a counselling or psychology field (Fryer 2014, p. 90).

In colleges where support services were available, it was found that students did not always utilize these services as they often lacked the confidence to ask for help or to use a language which was not their home language to do so (Jeffery 2015).

Colleges in some instances have had to rely on the voluntary services of individuals or donor funded organizations to offer psychosocial support through funded programs that work with students to build self-esteem and emotional maturity. One such program which has been operating in TVET colleges in South African for a number of years to date is based on an international youth rehabilitation program with the motto "show courage." The donor funded organization offering the program on a voluntary basis to youth at TVET colleges, has a structured schedule of workshops that include role play, simulation, self-reflection, discussion, and group tasks. Annually the program asks students to participate in feedback research in order to gauge the impact of the program and to make improvements where

necessary. Consistent evaluation reports have revealed students' pathways to self-discovery, better choices, lifestyle changes, and better interactions with peers (FET Institute 2012, 2013b, 2014a, 2015, 2016). However, programs such as these are not mainstreamed and rely on "soft funding" in spite of demonstrated successes and remain "add on" or supplementary to the academic programs offered.

---

## Conclusion

The widening participation agenda, particularly in development contexts, necessitates that students are supported towards successful outcomes. South African policy indications are that government is committed to doing so, but implementation at grassroots level is still emergent. Student support service provisioning across TVET colleges suggests that current attempts by individual colleges to provide various support services are not capable of yielding substantive positive results that impact on the system as a whole. With large numbers of students from low socioeconomic and/or poor academic backgrounds that are characterized by alienation and exclusion, student support services require systemic mainstreaming and dedicated funding.

Student support programs that build skills for life and work have shown distinct personal growth benefits for TVET student and should be integrated into the TVET academic mainstream in order to maximize their potential. In a mixed methods study, that explored the impact of student support services on student achievement it was found that coordinated student support was a contributory factor to students' academic achievement and that the majority of the participants believed that support services had contributed to their academic success (Maimane 2016). Additionally, students indicated that their support services had provided them with guidance about college life, taught them how to access information, and had afforded them opportunities to meet students from different socioeconomic backgrounds (ibid). These and similar offerings ought to be further interrogated and their longer-term impacts on the lives of young students investigated, in the interest of finding strategies that work in supporting youth to be resilient in the face of adverse circumstances.

In spite of the preoccupation of TVET systems with labor market and human capital outcomes, the available evidence suggests that holistic approaches to student development may yield more rewards for individual students to achieve academically and in the workplace, and may harness their potential to create a more caring society ultimately.

## Abstract

This chapter aims to address the two issues of teacher knowledge and pedagogy of VET in the English FE sector. Drawing from a larger research project, it uses the empirical findings from the questionnaire survey and semi-structured interviews of seven FE participants, who teach on VET provisions.

In addressing the issue of teacher knowledge, a delineation of teaching knowledge, relevant disciplinary knowledge (Becher. *Studies in Higher Education* 19:151–161, 1994), and theories of learning (Bernstein. *Pedagogy, symbolic control and identity: theory, research, critique*. Taylor and Francis Limited, London, 1996) is included. Typologies of teacher knowledge (e.g., Clandinin. *Curriculum Inquiry* 15(4):361–385, 1985; Shulman. *Harvard Educational Review* 57(1):1–22, 1987; Loo, *International Journal of Lifelong Education* 31 (6):705–723, 2012) are employed to offer a wider perspective of teacher knowledge. From an occupational perspective, conceptions of theoretical knowledge, knowledge of procedures, skill sets, dispositions, and past work know-how are drawn from researchers such as Bernstein (*Pedagogy, symbolic control and identity: theory, research, critique*. Taylor and Francis Limited, London, 1996),

Eraut (Workplace learning in context, Routledge, London, pp. 201–221, 2004), and Winch (Knowledge, expertise and the professions, Routledge, London, pp. 47–60, 2014). The teacher know-how is used to conceptualize a VET pedagogy framework. Using a Bernsteinian conceptualization of knowledge types, the processes of recontextualization are used. These processes offer insights into how teacher knowledge may be modified through selection, relocation, and refocus for application in a VET pedagogic setting.

Using examples of the empirical data, the types, sources, and application of VET teachers' know-how are delineated. In this delineation, the theoretical framework draws on concepts such as knowledgeable practice (Evans. Vocationism in further and higher education: policy, programs and pedagogy, Routledge, Abingdon, pp. 117–130, 2016), practice architectures (Kemmis, Green. International Journal of Training Research 11(2):101–121, 2013), and systems 1 and 2 (Kahneman. Thinking, fast and slow, Penguin Books, London, 2012). The concepts offer additional insights into how VET deliverers use their know-how toward the final choice of the relevant teaching strategies in their specific pedagogic settings. This chapter finally offers contributions and implications resulting from this study.

## Introduction

This chapter contributes to the “VET Teacher/Trainer Education” section and the two themes of teacher knowledge and experiences and vocational pedagogy. It starts with Brian Simon's premise that there has been a lack of a rigorous pedagogical approach in England. He suggested that this was due to the views of a then homogeneous sociocultural elite such as the independent fee-paying schools (“public schools”) and the well-established higher education institutions of Oxford and Cambridge. They viewed the character development of males as more important than a professional approach to teaching and learning (Simon 1981). This amateurish and pragmatic approach continued in the further education (FE) or post-compulsory education sector in England. Coffield (1998) critiqued the amateurish manner concerning the lack of conceptual definitions such as pedagogy and vocational education and training. The unprofessional approach coupled with undefined concepts remained in spite of the continual emphasis on the importance of teaching and learning in the UK (e.g., Department for Education (DfE) 2010, 2016) and internationally (Tatto 2013).

Against the above backdrops, this chapter aims to address the issues of teachers' knowledge and their experiences and the pedagogy of vocational education and training or technical vocational education and training (TVET). TVET is an internationally recognized term to denote work-related provisions (United Nations

Educational, Scientific and Cultural Organization 2012). This term is preferable as it dissociates the English context of work-related studies where issues of the academic-vocational divide and sociocultural aspects have impeded robust research in the sector (Loo 2018). The post-compulsory sector in England offers a wide range of teaching settings. It includes FE colleges, adult and community learning providers, armed and uniformed services, commercial organizations and independent training providers, industry, specialist colleges, prisons and offender learning institutions, public-sector organizations, and voluntary and community sector organizations (Education and Training Foundation 2014). The students include 16 plus, adult, and lifelong learners who may have varied learning abilities. This sector is known for offering additional learning opportunities for those leaving compulsory education. The provisions are diverse with over three-quarters of the provisions in work-related areas. The popular programs (regarding the estimated number of teachers) are in the visual and performing arts and media, health, social care and public services, foundation programs, business administration, management and professional, and hospitality, sports, leisure, and travel (Frontier Economics Limited 2014, Table 15). By implication, these lecturers of vocational-related courses will have the requisite TVET or occupational experiences in addition to their pedagogic experiences. The access to occupational programs and additional learning opportunities are some of the characteristics of the FE sector in England.

This chapter examines the TVET teachers' knowledge (including their occupational experiences) and its relevance on the pedagogy concerning teaching strategies. Even though the focus is on TVET delivery in England, the findings may have implications for the equivalent work-related programs in other countries. In elucidating this focus, the chapter has five sections following this introduction. The second section investigates the conceptual framework of TVET teachers' knowledge and pedagogic activities and the following section on details of the supporting research project. The fourth section delineates the findings and discussion using empirical data. The final section ends with contributions and implications resulting from this investigation.

---

## **Conceptual Framework of Vocational Teachers' Pedagogy**

This chapter begins with a dual professional approach (Handal 1999; Robson et al. 2004; Peel 2005) to understanding teachers' pedagogic activities where they refer to their teaching and professional/vocational know-how including knowledge and experiences. These two practices – teaching and vocational – offer a starting basis to theorizing a framework. This ontological approach of starting from knowledge acquisition and application is derived from researchers such as Bernstein (1996), Eraut (2004), and Winch (2014). For this chapter, knowledge is defined eclectically to capture the varied forms of know-how in delineating a vocational teacher's pedagogic knowledge. The delineation of the acquisition and application of know-how also offers the theorization of a conceptual framework, and this separation of knowledge, for this chapter, merely offers a logical discussion structure. In reality,

the separation of the two aspects of knowledge may not be simple and is often complex. In arriving at a conceptual framework, only the circumscribed accounts of the relevant theories are employed and not exhaustive accounts to satisfy the aims of the chapter.

From the teaching practice dimension, Becher (1994), Bernstein (1996), and Smeby (1996) suggested that knowledge of the relevant disciplines, such as psychology and sociology for the education field, is required as a starting basis. Included in the relevant disciplines may be theories of learning where teachers are needed to acquire and understand how learning may occur and that the eventual pedagogic strategies/approaches may result (Becher 1994; Bernstein 1996; Smeby 1996). Bernstein classifies knowledge into two forms: vertical and horizontal discourses. The former type represents theoretical knowledge that is “explicit, coherent, systematically principled and hierarchical organization of knowledge” and “a series of specialized languages, each with its own specialized modes of interrogation and specialized criteria as in the humanities and social sciences” (Bernstein 1996, p. 172). These two vertical knowledge structures – hierarchical and horizontal – offer ways of classifying subject areas where hierarchical knowledge may include areas such as biology, chemistry, and physics. These areas are similar to Becher’s (1994) classification of hard-pure disciplines. These areas have significance in vocational learning such as equine studies (biology) and gas fitting (chemistry and physics). From the “horizontal knowledge structure” variety of vertical knowledge, social science areas such as sociology (e.g., learning theories) may be used in education. Bernstein offers a link between vocational training and compulsory education where he viewed horizontal knowledge structures as strong and weak grammars. His link with vocational learning such as in the area of crafts (especially pottery) is indicated below:

‘Crafts’ are often acquired through apprenticeships where mastery is more a tacit achievement than a consequence of an explicit pedagogy. This suggests from the point of view of this paper that ‘crafts’ could be regarded as *tacit* [Bernstein’s use of italics] horizontal knowledge structures. (Bernstein 1996, p. 181)

This passage is relevant to this investigation as Bernstein acknowledges that the learning of crafts can be a form of vertical discourse despite the fact that his primary concern is in compulsory education. This link with vocational learning offers conceptual space to explore theoretical knowledge and pedagogy.

Turning to teaching knowledge, Shulman (1987) offered a typology. It consists of general pedagogical knowledge (comprising principles and teaching strategies for classroom management and organization), pedagogical content knowledge (which is a combination of content and pedagogy), knowledge of learners, knowledge of the educational contexts (such as team members and teaching institutions), and knowledge of educational values. Some researchers have developed from this typology by focusing on the tacit aspects as opposed to Shulman’s more explicit nature of teaching knowledge. Loughran, Mitchell, and Mitchell’s (2003, p. 870) tacit investigation was a listing of the “rich array of information, ideas and

understandings that inform teachers' practice." Verloop et al. (2001) used the above two studies to focus on teachers' practical knowledge and beliefs, and they offered six categories related to subject matter, students, learning, and intuitive aspects of teacher's know-how, subject specificity, and teachers' know-how. Verloop et al.'s cognitive foci provide another perspective to Shulman's explicit teaching know-how, and Verloop et al.'s tacit approach (Clandinin 1985) uses the concept of "personal practical knowledge" to denote a teacher's experiential history, both professional and personal. This form of know-how is further developed by Loo (2012) where teachers' occupational practices are explicitly included in teaching know-how. Finally, Banks, Leach, and Moon's (1999, p. 95) teachers' professional knowledge model incorporates the "complex amalgam of past knowledge, experiences of learning, a personal view of what constitutes 'good' teaching and belief" that draws on the earlier literature sources. In short, teaching know-how may have the following characteristics: explicit, tacit, cognitive, practical, pedagogy-occupation-life-related experiences that are relevant to teachers.

Similarly, knowledge concerning occupational practices requires a base of disciplinary or theoretical know-how that may be explicit. The base may include knowledge of procedures, skills (e.g., interpersonal and intrapersonal ones which are tacit), techniques, transversal abilities, project management abilities, personal capabilities, and occupational awareness (Eraut 2004; Winch 2014). This occupational knowledge base constitutes a wider spectrum than a pedagogical one. It includes a worker's past know-how (including theoretical and procedural knowledge and experiences), understanding of work and specific job contexts, skills (such as technical and nontechnical ones), workers' dispositions, and perceptions of the work environment, which they operate.

The occupational know-how has elements of explicit and tacit forms. The individual aspect of tacit know-how may be scientific (as suggested by Polanyi [1966]). Collins (2010) offers three types of tacit know-how: relational tacit knowledge that individuals view as either secret or that which is not known to others; somatic tacit knowledge, which people can perform such as riding a bicycle; and collective tacit knowledge, where people use knowledge (e.g., linguistic rules) as part of society. Nonaka and Takeuchi (1995) offer the final variation of tacit knowledge. It is tacit knowledge that resides in people and is used in commercial activities. Collins' collective tacit knowledge is posited in the Western tradition and Nonaka and Takeuchi's in the Japanese one. Also, Collins' CTK resides in society whereas Nonaka and Takeuchi's in business organizations (Loo 2017). These tacit knowledge types offer useful insights into understanding the tacit aspects of teachers' know-how and how they may be applied.

The applications of teaching and vocational/occupational knowledge may be understood through the processes of recontextualization (Bernstein 1996; van Oers 1998; Barnett 2006; Evans et al. 2010; Loo 2012, 2014a). Knowledge may be modified through selection, relocation, and refocus in another setting (Bernstein 1996). From a teaching perspective, a learning theory such as cognitive constructivism (from psychology discipline) as advocated by Bruner (1996) is used in an educational setting. This setting includes contexts that relate to the academic level of

the program (e.g., in health and social care), the types of learners, and the specific aspect of the curriculum in which this know-how is applied. From an occupational/vocational angle, physics as a discipline may be used in the area of gas fitting. From a recontextualization process, the nature of the disciplinary knowledge is changed and similarly from the users such as teachers and learners concerning the specific vocational area (Loo 2012, 2014a). This modification of knowledge and users' perspectives is contrary to Bernstein where even after recontextualization, the vertical knowledge remains the same.

The recontextualization process is situated in dynamic environments, and it involves people in sociocultural dimensions. The process is also context related and can be innovative (van Oers 1998). It occurs in teaching and work-related activities at the TVET academic level (Loo 2016). There are different types of this process. Barnett (2006) suggests two types: reclassificatory recontextualization, which is viewed as a toolbox of applicable knowledge, and pedagogic recontextualization for teaching. These identifications of recontextualization processes offer insights into how theoretical or disciplinary knowledge may be used for teaching vocational programs where disciplinary knowledge is made relevant to the specific vocational area. Evans et al. (2010) use four types of recontextualization to provide a greater understanding of teaching and learning. They are content recontextualization (relating to the specifications of a program), pedagogic recontextualization (relating to teaching), learner recontextualization (relating to the strategies that a learner employs to acquire and understand the relevant know-how), and workplace recontextualization (relating to the procedures and protocols of the workplace). Loo (2012, 2014a) provides explicit insights into how the recontextualization processes may be used in vocational teaching from the teachers' perspectives.

In addition to the possible types of recontextualization processes, there are relevant concepts that add to the understanding of practitioners in vocational work settings to carry out their roles. The next three frameworks focus on learners, and they acknowledge a sociocultural dimension. Kemmis and Green (2013) use "practice architecture" to indicate the sayings, doings, and relatings of these users in the respective work organizations. Evans (2016) identifies "knowledgeable practice" as a means to understanding how formal and informal learning can occur in workplace settings and beyond. Learning occurs when mentoring, coaching, and peer learning happen where these activities impact both learners/workers, either individually or collaboratively, and the specific work institutions. Kahneman (2012) uses his systems 1 and 2 to explain how decisions are made in areas of work. System 1 is reliant on a worker's intuition that is based on experience and is irrational. It offers a quick decision. System 2 relies on rational and cognitive interactions, which is a slower form of decision-making process.

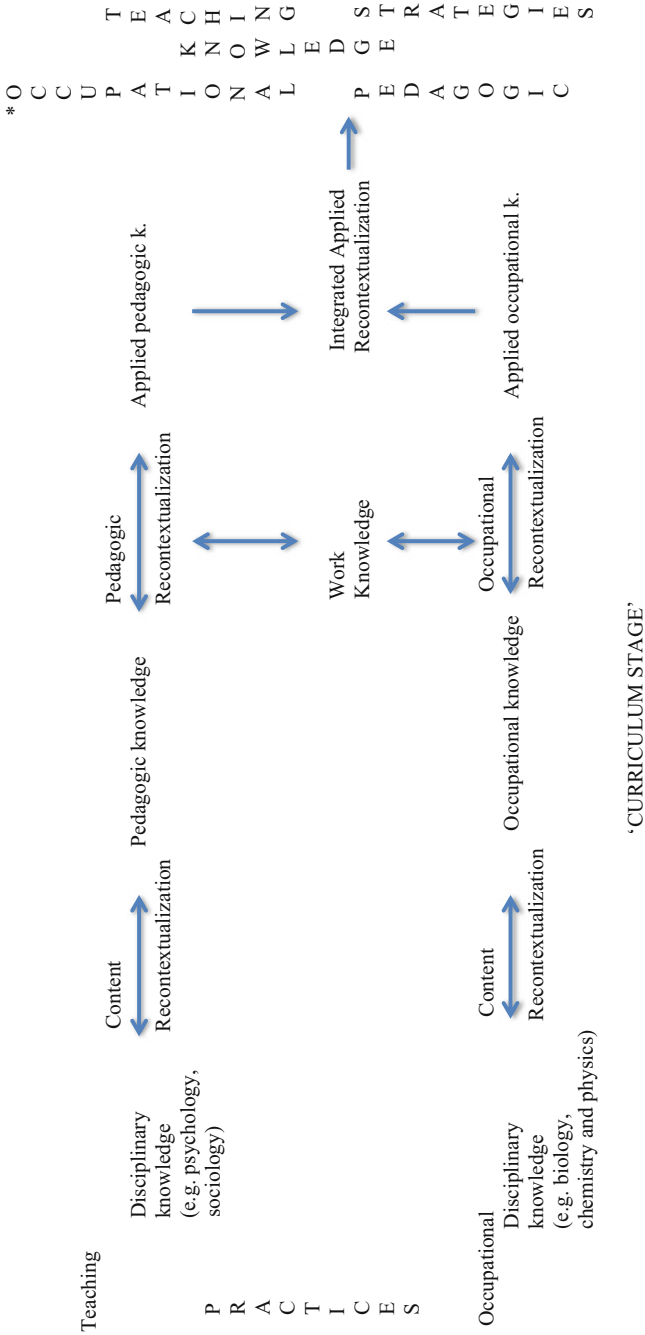

The above eclectic and relational approach of defining teaching and occupational knowledge offers insights into the types and sources of know-how that are needed for teaching and vocational working. These forms of know-how are applied in pedagogic and work settings through the various recontextualization processes and three identified practices. The next part maps out a conceptual framework to illustrate how these types of know-how may be used in facilitating a teacher with vocational experience to carry out the pedagogic activities on a TVET program.

The theoretical framework (Fig. 1) draws from the above literature reviews and is structured initially with the dual professionalism dimensions of teaching and TVET/occupational practices (starting from the left-hand side). Starting with the teaching practice, disciplinary knowledge is referred to for teaching purposes. Examples of learning theories such as behaviorism and social constructivism are derived from the subjects such as psychology, sociology, and business management (Loo 2014b). This knowledge needs to be applied to the content or specifications of the specific TVET program to ascertain how this can be made relevant to use for teaching. The process of relocating and refocusing of knowledge is termed content recontextualization. The modified type of know-how is known as pedagogic knowledge, which can be used for teaching. This stage also includes another aspect of curriculum development where other types of disciplinary knowledge such as from the subjects of physics and biology may also be made relevant to the specific TVET area. An example of gas flow theory in physics will be required for learning and teaching in the gas fitting specifications. How this is made relevant to the learners will be the task of the curriculum developers and deliverers via content recontextualization.

The pedagogic knowledge is then applied for teaching purposes, and the process related to this is pedagogic recontextualization. This is where the pedagogic knowledge is selected and refocused for teaching. Examples include a series of lessons or a 1-day long session, depending on the structure of the provision and the identification of the particular aspects of the specifications that need to be delivered at the appropriate academic level. The typologies of teaching knowledge mentioned earlier would be relevant to this process. Also related to this recontextualization process is the “work knowledge.” This know-how refers to the nature of the teaching institutions that the teacher works in and knowledge of its aims (e.g., visions of the institution), systems (e.g., IT and mentoring), and protocols (e.g., regulations governing extracurricular activities). It can have both individual and collective dimensions. The know-how may be tacit or explicit, and it can consist of skill sets (e.g., interpersonal), knowledge resources (from colleagues and the Internet), and understanding (of situations, contexts, and stakeholders) and involves decision-making and professional judgment. Notions of “knowledgeable practice” and “practice architectures” regarding the organization’s practices such as the mentoring system and the articulations with peer teachers and stakeholders are useful in understanding this complex activity.

Both types of work and pedagogic know-how are included in this complex application in the teaching process and are called pedagogic recontextualization. The modified form of know-how is applied pedagogic knowledge. Included in this complex amalgam of know-how is the teacher’s belief or vision along with other pedagogic dimensions such as subject area, learner types, academic level, etc. to influence the eventual choice of an appropriate teaching strategy in a specific teaching session in the final recontextualization process – integrated applied recontextualization (IAR). Before this process is discussed, we now turn to the other dimension: TVET/occupational practice.

This dimension refers to the working and learning processes of a TVET worker. It is relevant for those teaching in the work-related provisions as they need to rely on

\* Occupational Pedagogic Knowledge (OPK) may also be termed Occupational Teachers' Capacities (OTC)

Fig. 1 A theoretical framework of the TVET/occupational pedagogy of teachers

their occupational know-how to inform their learners. It adheres to a similar structure as in the teaching dimension. Through the content recontextualization process, the disciplinary knowledge such as physics can be relocated and refocused to suit the needs of the specific TVET area such as gas fitting. Aspects of this occupational knowledge such as gas flow knowledge can be used by the learners/workers for gas fitting. This know-how is changed from its initial disciplinary/theoretical know-how since it is contextualized to the specific TVET area requirements. This occupational knowledge is then used to frame a curriculum as part of the acquisition phase. Aspects of the curriculum are then selected, relocated, and refocused for work purposes through a process of occupational recontextualization. This process involves another type of knowledge source – work knowledge. This work knowledge relates to the work institution such as its systems, protocols, and other aspects relating to the work settings. Work knowledge, like in the other dimension, offers individual and collective forms and can be tacit or explicit; includes skills (e.g., interpersonal), knowledge resources (e.g., colleagues), and understanding (of contexts and stakeholders); and involves decision-making and judgment.

One may argue that the occupational and work know-how may be specific to the user or worker, as a teacher, as each has specific practices and experiences even though the training may be similar. Concepts such as “knowledgeable practice,” “practice architectures,” and “systems 1 and 2” provide rich understandings of this complex work activity. This activity, together with the pedagogic activity after the pedagogic recontextualization process, offers insight into the final process: IAR. Thus, IAR is a result of two knowledge types – applied pedagogic knowledge and applied occupational knowledge – to produce occupational pedagogic knowledge (OPK) or occupational teachers’ capacities (OTC). From this final know-how, a teacher may ascertain the relevant teaching strategies/approaches. These approaches are dependent on contextual factors such as the TVET area, academic level of the provision, learners, accreditation of professional bodies, types of TVET artifacts, and teachers’ beliefs (to name a few). Some of these teaching strategies include demonstration, simulated environments, field trips, and problem-based scenarios. Publications by Huddleston and Unwin (2013) and Lucas et al. (2012) offer a wide selection of these pedagogic approaches. Lucas et al.’s report (2012, p. 115) acknowledges that “vocational pedagogy and practical knowledge is an under-theorized area of education” and that the report offers a “proof of concept” and not a comprehensive theory of vocational pedagogy. It appears that the report focuses on teachers and learners and that the role of knowledge (Sect. 8.2.1) merely plays a part without a comprehensive discussion or a conceptual framework of vocational pedagogy. It, however, offers a broad survey of the teaching strategies in the FE sector rather than specifically of vocational education.

This framework (Fig. 1) exhibits dynamism and fluidity in differing directions along its structure. A teacher may revisit any of the stages of the framework (and not necessarily at the start of the two practice dimensions) resulting from either teaching or occupational triggers/incidents. This ongoing reflective process offers different perspectives, which the deliverer can utilize in future teaching activities such as a different choice of teaching strategy or a different ordering of teaching sequence from a specific part of a curriculum specification over a period.

---

## Project Details

The findings of the chapter are based on a larger project (Loo 2018). The main research questions include the following: What is occupational pedagogy? And how is its related knowledge acquired and applied by those teaching on the programs? “Occupational pedagogy” refers to the type of teaching and learning across the academic levels of vocational/TVET, higher vocational/first-degree, and professional education. Occupational pedagogy is used to denote work-related teaching and learning activities across the academic levels as well as varied occupational/professional disciplines. For this chapter, the focus is on the TVET provisions, and the disciplines that are featured in the project are airline studies, art (painting and printmaking), equine studies, fashion and textiles, gas services, and health and social care. A purposive sample of seven teachers (P1–7) in the TVET level is included from a total of 21 participants from the larger project. The research methods employed included a questionnaire survey and semi-structured one-to-one interviews. Salient details such as gender; age; pedagogic, occupational, and relevant life experiences; and academic and professional qualifications were captured from the quantitative survey, following a pilot study in which the survey questions were fine-tuned. This process was carried out on the topic questions for the interviews. The interviews captured data related to the participants’ perspectives of the types and sources of know-how that were applied in their teaching of work-related programs. Documentary evidence such as program specifications was also gathered to triangulate data from the other two research sources. The types of data were analyzed using generated codes, identified phrases, patterns, and themes and the identified scenarios were further triangulated to form a typology. This typology was then linked to the theoretical frameworks (Robson 2002). The analyzed empirical data from the project was then used in the next section to discuss the types, sources, and applications of the teachers’ know-how.

---

## Discussion

This section has two parts consisting of the acquisition and application of knowledge for vocational teaching and learning. This structure is used to parallel the conceptual framework (Fig. 1), which has been derived from the relevant literature reviews.

From the perspective of the acquisition of teaching knowledge, P1 is a full-time FE college lecturer of travel and tourism with 7 years’ teaching experience and has worked in the airline industry as part of a cabin crew for 8 years. She uses her disciplinary knowledge (Becher 1994; Bernstein 1996; Smeby 1996) from her first degree in geography, teacher training qualification (PGCE), and occupational experiences in the airline industry to teach on the Edexcel BTEC Level 3 Certificate in Aviation Operations (NO25388-L3-AOps [page 1 of 66]). This provision consists of mandatory and optional units, and they include the UK aviation industry, health and safety in the aviation industry, aviation geography and terminology, customer service in the aviation industry, human resources in the aviation industry, handling air passengers, and onboard passenger operations. She relied on her first-degree

theoretical knowledge to assist her in teaching the BTEC units such as aviation geography and terminology (Unit code: T/504/2281). The aims of this unit include developing “knowledge of the location of major destinations and airports of the world.” The unit also enables “learners to expand their knowledge in relation to countries, capitals, hubs, gateways and air travel destinations and to recognise air travel routes through different hemispheres, International Air Transport Association (IATA) areas and sub-areas via different global indicators” (p. 1). The theoretical/disciplinary knowledge from P1’s first degree is used to make it relevant to the aviation industry provision via the content recontextualization process.

Similarly, P2, who teaches gas servicing at an FE college with 15 years’ teaching experience, has worked in the gas service industry as an engineer (6 years’ experience) and as a trainer and assessor (13 years). He uses his occupational know-how (knowledge and vocational experiences) (Clandinin 1985; Banks et al. 1999; Loo 2012, 2014a) as he has “the relevant theoretical and practical skills to pass onto our students. I can also use anecdotes to put into context the theory.” He views his sources of knowledge from NICEIC textbooks, industry update bulletins, and trade magazines in addition to his initial acquisition of industry-related knowledge.

For P1 and P2, from a curriculum development perspective, the disciplinary knowledge of aviation and gas service sectors, respectively, needs to be selected and refocused in appropriate bit size for each lesson. Lesson planning over the duration of the 1-year program is required. Also required is the establishment of the appropriate academic level for the learners (Shulman 1987; Verloop et al. 2001; Loughran et al. 2003). Winch (2015) suggested an arbitrary rule of equivalences, which is a level below the “academic equivalent” provision concerning the vocational one. P2 suggested the depth of knowledge that his students needed was not the same as the advanced level equivalent (Level 3) in the related subjects but necessary for their occupational practices. The unspecified knowledge level places the onus on the deliverer to ascertain the appropriate academic level of disciplinary knowledge for the learners, the amount for a given lesson, and ultimately the teaching strategy to disseminate it (Bernstein 1996).

Also, participants such as P2 espoused the related pedagogic theory for their subject area where he mentioned his charges were more likely to be kinesthetic learners. He also indicated that he would use a social constructivist learning theory to engage with his learners to aim for “at the end of the first year of the BTEC programme, the learners would have developed synthesis, analytical and critical skills and discussion abilities.” For P3, a health-care and social care lecturer at an FE college with 8 years’ full-time teaching experience, utilized behavioral management strategies, and P1 used Bloom’s taxonomy (Anderson et al. 2001) to enhance her travel and tourism students’ learning. These education theories may be drawn from disciplines of psychology, sociology, and business management (Loo 2014b). To date, knowledge from disciplines such as geography (by P1), physics and chemistry (by P2), and psychology (P3) is used to engage with their learners in their respective vocational areas. Similarly, they drew from disciplines of psychology, sociology, and business management to enable them to use their learning theories to make relevant their vocational areas via the content recontextualization process.

The next part of this section focuses on the applications of know-how of these teachers. Having selected and refocused the related aspects of the disciplines, the teachers would then need to apply the know-how to their specific teaching contexts. Some of these contexts relate to the appropriate academic level (Level 3) and the manner in which the specifications are delivered (such as front loading of theory before vocational practice as suggested by Clarke and Winch [2004] and learning while in work settings [Hager 1999]). Also, the contexts include the pacing of the content over the duration of the program (Bernstein 1996) and the specificities of the teaching institution (Shulman 1987; Banks et al. 1999). Finally, contexts may refer to the types of learners and the individuals' and group's requirements (Shulman 1987; Verloop et al. 2001). The relevant process – pedagogic recontextualization – utilizes the previous recontextualized know-how of pedagogic knowledge (from teaching) to modify the specifications in readiness for teaching.

This revised knowledge is known as applied pedagogic knowledge. Equivalent to this teaching dimension is the occupational/vocational strand. It is where the disciplinary know-how is made relevant for the particular vocational area via content recontextualization to become occupational knowledge, and this is then used in the vocational practices such as P1 in the aviation industry, P2 in gas fitting services, and P3 in health and social care.

Related to the pedagogic and occupation recontextualization processes is another type of knowledge – work knowledge. For teaching, this refers to knowledge of the educational institution. It can be the modus operandi of the particular FE college of P4, a female lecturer of fashion and textiles in an FE college where innovative pedagogic practices were encouraged. They included field trips to the Alexander McQueen exhibition at the Victoria and Albert Museum, London, and holding of thematic fashion shows on *Queen Elizabeth 1* and *Petrushka*. P2 uses IT software such as Socrative of crossword games and questions to encourage his students' learning of the related physics and chemistry theoretical knowledge as gas fitters. In addition to an institution's pedagogic vision, other work knowledge includes the availability of a mentoring system for teaching staff, IT systems, and institutional protocols. Examples include field trip guidelines that can frame and structure pedagogic activities (Kahneman 2012; Kemmis and Green 2013; Evans 2016), which may affect the pedagogic recontextualization process. Similarly, from a vocational dimension, the work knowledge includes the structures and protocols that are in place for occupational practices. They, in turn, affect the occupational practices along with the practitioners' occupational knowledge. These recontextualization activities produce modified forms of know-how. From the teaching dimension, it becomes applied pedagogic knowledge and, from the vocational strand, applied occupational knowledge.

The combinations of the modified know-how from the two dimensions – teaching and vocational/occupational – finally undergo another recontextualization process known as integrated applied recontextualization (IAR) where the related know-how is fashioned to ascertain the choice(s) of teaching strategies/approaches for application in the classroom/teaching setting. This final modified know-how is occupational pedagogic knowledge (OPK) or occupational teachers' capacities (OTC). The participants use metaphors and descriptive narratives to identify their teaching

approaches (Lucas et al. 2012). P2 uses terms like “teaching in conference style,” “building up layer by layer to help my learners,” “workshop-based teaching,” and “the use of analogies of tractor and bicycle types” to illustrate the impact of gas flows of varying sizes of gas tubing. P3 has a strong notion of “differentiation” to engage with her health-care and social care students and identifies with “Maslow’s hierarchy of needs” in ensuring a safe environment in her health-care and social care work with vulnerable families. Participants (such as P1 and P4) mentioned the symbiotic relationships between their teaching and occupational practices. P1 and P4 encapsulated the IAR process where “both teaching and occupational know-how are reflected in the specifications.”

---

## Summary

This study focused on how vocational deliverers used their teaching know-how to teach on work-related provisions in the TVET sector. In delineating this investigation and using circumscribed accounts of the relevant literature sources on knowledge and recontextualization processes, this chapter offers some contributions. Firstly, teaching know-how is defined broadly to include experiences, vocational practices, abilities, capacities, skill sets, and judgment. Secondly, a conceptual framework of TVET/occupational pedagogy of teachers is offered using five types of recontextualization processes, and thirdly, a definition of occupational pedagogic knowledge or occupational teachers’ capacities is offered. Lastly, a deeper understanding of how TVET teachers acquire, make relevant, and apply their know-how from the curriculum development stage to the choice and use of pedagogic strategies in particular teaching contexts is explained. These contributions have implications for users such as teachers, managers and teacher educators of TVET provisions, and policymakers. For educators, a clear understanding of the sources and types of teaching know-how legitimizes and supports them in their complex pedagogic activities with clear implications for their continuous professional development. Managers and teacher educators need to include the eclectic definition of teaching know-how into their managerial and teacher training planning and implementation processes to support the teachers and, ultimately, to enhance the learners’ learning. Policymakers need to offer financial and pedagogic structures to facilitate the teachers’ pedagogic roles in the teaching institutions, provisions, and the relevant work settings with the aim to provide credible TVET provisions.

## Abstract

The effectiveness of vocational education and training (VET) systems depends upon their teachers. The teachers are regarded as “dual professionals,” requiring expertise in both their background industry areas and in VET pedagogy itself. This chapter uses Australia as a case study of what happens when the accepted regime of qualifications for VET teachers alters. In Australia full-time VET teachers were, until recently, required to undertake degree level qualifications in VET pedagogy, taught at universities, either before or, more usually, after entering the occupation. The required level has now reduced to the regulatory minimum of a Certificate IV level qualification, taught by training providers not

universities, and often provided to their own teachers. The qualification contains only 300 nominal hours of training. It has been recognized as a particularly poorly taught qualification, requiring the introduction of a high degree of regulation and most recently a special compliance framework for training providers wishing to deliver it.

In this chapter, the historical path of the decline in VET teacher professionalism in Australia is charted, including research evidence from a national project managed by the author, about the effects of higher-level qualifications on VET teacher practices and quality and teachers' propensity to engage in professional development. A conceptual model of the attributes of professional VET teachers with regard to qualifications and professional development is presented. The chapter concludes with some recommendations for change and implications for other countries.

**Introduction**

In the introduction, the VET system in Australia is briefly described, together with a discussion of the qualification regime for VET teachers. This chapter confines itself to the formal VET system, i.e., the teaching and assessment of formal qualifications, whether delivered in training institutions or within workplaces. It does not include company trainers working in companies which are not involved with the award of formal qualifications, nor with those working on VET programs within secondary schools even if formal VET qualifications are awarded. The reason for the exclusion of the latter so-called "VET in school" teachers is that they are required to adhere to the qualifications regime for school teachers, which always demands a pedagogy degree or above.

In 2016, the most recent year for which precise figures are available, there were around 1.3 million government-funded learners in the VET system (National Centre for Vocational Education Research 2017), with a large number of additional non-funded participants paying full fees. (The system for counting non-funded students is not reliable.) The public VET provider in Australia is known as TAFE (Technical and Further Education). TAFE colleges are managed by the eight States and Territories. Until the end of the last century, most formal qualification-based VET was delivered by TAFE, with private providers only having access to specific government funding programs. Indeed, prior to the 1980s, all private provider courses were fee-paying. Regulation of the VET system at this time was minimal. The system has now moved to a position where private providers of training, through progressive access to all types of government funding and to VET student loans (known initially as VET FEE-HELP), have much greater market share, although this is beginning to reverse due to the deregistration of some large private providers because of

poor business practices (Yu and Oliver 2015). There are over 4500 private providers (PwC's Skills for Australia 2017) and 40 TAFE institutes, each with multiple campuses. In some States, one TAFE institute covers the whole state. The recent de-registration of some for-profit providers, and also cuts to funding rates by states and territories, has led to the current relatively low figure of students which is below the 2003 figure (NCVER 2017) although Australia's population increased considerably, from 20 million to 24 million.

In 2008, it was estimated that there were 57,800 full-time TAFE teachers in Australia, but it is thought up to 300,000 or even 400,00 people were involved in VET teaching or workplace training as part or all of their jobs (Guthrie 2010c). The exact number of VET teachers is unknown as there are many part-time and casual teachers who are not recorded centrally by most training providers. In Australia, it is the norm for VET teachers to enter the occupation after a career in industry, often a lengthy career. For this reason, the majority of VET teachers are middle-aged or older (Smith et al. 2009)

From around 1975, full-time TAFE teachers starting work were required by their employing state or territory to gain, while working, a university diploma in VET teaching (which became a degree around 1990) or a graduate diploma if they already had a degree in another discipline area (Guthrie 2010a). In each State, at least one university provided such qualifications (Harris 2015). In 1998, a Certificate level qualification (now called the Certificate IV in Training and Assessment) was approved, containing only 300 nominal hours of training. The qualification was introduced to provide a mandated "floor" for qualifications for VET teachers; this however rapidly became a "ceiling" (Smith and Keating 2003; Wheelahan and Moodie 2011). Over the first decade of the twenty-first century, progressively in each State-based TAFE system, the requirement for pedagogical qualification for full-time TAFE teachers was reduced to this regulatory minimum. According to the Australian Qualifications Framework (<https://www.aqf.edu.au/aqf-levels>), level 4 qualifications "will have theoretical and practical knowledge and skills for specialised and/or skilled work and/or further learning." To set this in context, a trade apprenticeship is at level 3; the VET sector delivers mainly to level 6, and a degree is at level 7. The minimum qualification for the lower level of nurses (known as "enrolled nurses"), for example, is a diploma, at level 5. In recent years, Australian government-sponsored reports have shown, on many occasions (e.g., Skills Australia 2011), deficiencies which could to some extent be attributed to a low level of qualification among VET teachers. For example, an ongoing concern has been the quality of assessment of learners.

After a background section, this chapter maps changes in qualifications and professional development provision for the VET workforce and suggests contextual reasons why this was allowed to occur. Findings from a national research project concluding in 2017 and led by the author are provided to show the difference that higher-level qualifications make both to teaching and to engagement in professional development. The chapter concludes with a model of VET teacher professionalism and some recommendations for change and implications for other countries.

## Background and Literature

In this section, more detail is provided about the complexity and importance of VET teachers' work in Australia. The qualification regime for teachers is explained further, the nature of professional development is described, and the concept of professionalism is introduced.

### The Nature of Teaching and Assessment in VET

Since the late 1980s, the VET system has moved entirely to a competency-based system. In Australia this means that the competencies to be attained (which contain skills as well as knowledge) are clearly defined on a national basis, but the training delivery method is not so prescriptively laid out. Since around 2000 (beginning in 1997), the competencies have been laid out in national Training Packages (Smith and Keating 2003). A few courses fall outside these, but the vast majority are within this system. Prior to 1997, competency-based training (CBT) was delivered in some industry areas using “national modules” or industry-developed standards (Smith 2010).

A Training Package contains qualification and units of competency, each with an accompanying assessment guideline. The Package provides rules about how the units of competency are combined into qualifications, at different levels. Qualifications have cores and electives. In some qualifications the core forms most of the qualification, while in others, there is a small core and a large range of electives from which a specified number are then chosen by the RTO to deliver. The Certificate IV in Training and Assessment itself is included in the Training and Education Training Package (hence, it is shown as the “Cert IV TAE” rather than Cert IV TAA). Training Packages contain no guidance about delivery, as this has not been permitted by the Training Package Development Handbook (Department of Education & Training 2015) except that proxies for delivery may be found in the assessment guidelines. These may include, for example, the need for assessment to be carried as part of a work placement. Thus, teachers have the task of creating a “curriculum” from the units of competency and assessing the learners, although in practice many training providers have developed prescriptive methods for delivery and also for assessment, for quality assurance purposes, and because they find teachers are not capable of development of curriculum (Smith 2016).

There have been well-documented cases of unethical – indeed sometimes criminal – activity by some private providers, using government funds inappropriately or recruiting students unwittingly to VET sector student loans (e.g., Yu and Oliver 2015). These instances, and reports by the regulatory body, have included widespread evidence of inadequate course length (Australian Skills Quality Authority 2017) and other delivery issues. TAFE institutes and reputable private providers report being forced to “cut corners” in order to compete (Guthrie et al. 2014). As the VET system in Australia, being competency-based, focused on outcomes rather than inputs, with assessment being of overriding concern, it has been difficult for the regulatory system to move against inadequate training provision.

## Expertise Required of VET Teachers Compared with Their Qualification Levels

There have been expressed concerns by most stakeholders in the Australian VET system that quality in the system is declining, evidenced partly through poor business practice as explained above but also because teachers appear to be lacking in the necessary skills and knowledge to work with the national VET curriculum regime and to assess students (National Skills Standards Council 2013). It has been recognized since the early days of competency-based training that teachers needed high-level skills and knowledge to work in a competency-based system (e.g., Smith 2010). In recent years, other matters have necessitated higher-level activities by VET teachers, such as the requirement to liaise closely with industry and the increasing diversity of student groups. In this context, a Certificate IV seems an inadequate level of qualification, as has been shown in several ways. Robertson (2008), for example, mapped the qualification against accepted knowledge bases of teachers, and a comparison was made between the documented requirements of the job against Australian Qualification Framework levels (Australian Council of Deans of Education 2011) in a submission to a Productivity Commission inquiry into the VET workforce (Productivity Commission 2011). The latter report showed clearly the complexity of the tasks involved in VET teaching but did not recommend an increase in qualification levels, primarily because there was a fear that people might not be attracted to the occupation if they had to gain higher-level qualifications. Finally, while teachers cannot be expected to compensate for poor business practices by management in private training providers and indeed TAFE colleges, ethical issues posed by such practices have become a major concern to teachers (e.g., Nakar 2017; Smith 2016). The Certificate IV qualification does not contain any component about such matters, to equip teachers to forestall or address events such as being required to enroll students who are clearly not capable of completing a particular qualification (Nakar 2017).

As well as the inadequate *level* of the qualification, problems with the *delivery* of Certificate IV in Training and Assessment have been well-recognized; such problems in this qualification exceed the sector norm. To some extent, the problems are shared with some other VET sector qualifications where relatively new regulation is involved. The Certificate III qualifications in the security and aged care industries, for example, exhibit similar patterns of poor delivery practices to the Cert IV TAE but are, likewise, popular qualifications for students, as they are necessary to undertake work in the respective industries (Halliday-Wynes and Misko 2013). While these industries are regulated to some extent, there is no industry body providing licensing or regulation of practitioners or qualifications as there is in other industries such as engineering, electrotechnology, or financial services; hence the pressure for learners to gain qualifications has led to demand for courses that provide the qualification quickly and at low cost but are unlikely to develop significant learning. The Certificate IV qualification has always had notoriety as being delivered in an unduly short manner, often partly or even wholly by Recognition of Prior Learning, or in weekend courses (Smith and Keating 2003).

In response, a degree of regulation and a special compliance framework specifically for this qualification have been implemented via changes to the “provider standards”

(Commonwealth of Australia 2014) used for audits by the regulatory agency for the VET sector (the Australian Skills Quality Authority). Revised regulatory standards for training providers were introduced in 2016 for training providers, requiring inter alia evidence of VET teachers' professional development in VET pedagogy as well as in teachers' industry areas (the latter have always been part of training provider standards), in an attempt to boost teachers' capabilities. Also in this update, higher-level qualifications in what was termed "adult education" were deemed to be equivalent to the until-then mandatory Certificate IV level qualification; and higher-level VET pedagogy qualifications (i.e., diploma or above) were from 2016 required to teach the Certificate IV qualification. In 2016 the large number of training providers allowed to deliver the qualification was reduced through an expedient of making changes to the qualifications that allowed it to be declared "not equivalent," requiring every training provider to re-register for the updated qualification and for the Diploma of VET as well (PwC's Skills for Australia 2017).

Since the advent of the Certificate IV as the mandated qualification, it has been left to individual TAFE institutes or private training providers to encourage teachers to undertake higher-level pedagogical qualifications. The VET sector's Diploma of VET' qualification is popular in some states where there is a TAFE teacher pay rise associated with completion (Guthrie 2010a) and TAFE colleges tend to deliver the diploma to their own teachers during working hours, reducing perceived burden on teachers. There are also a much reduced number of teachers undertaking degree or graduate diploma qualifications in VET teaching while they are working. Numbers are low partly because there is an expectation based on previous practice in the public system that such study would be funded by the employing TAFE institute and time off for study provided; and training providers are not always in a position to provide this level of support, in a reduced funding environment in the public system. The VET teacher trade union has, for this reason, not aided or been involved in any moves for higher qualification requirements, although in public pronouncements the union has provided generalized support for the principle (Australian Education Union 2010).

The universities offering VET teacher training have reduced in number and capacity, and all programs are now offered only by distance (online and/or printed learning materials), sometimes with occasional face-to-face workshops. Nevertheless VET teachers report a high level of satisfaction with their experiences studying such courses (Smith et al. 2015). These universities have formed an official group within the Australian Council of Deans of Education (faculty heads of the Education discipline in universities) known as ACDEVEG, the Australian Council of Deans of Education Vocational Education Group (<https://www.acde.edu.au/networks-and-partnerships/acde-vocational-group/>). This group lobbies for higher qualifications for VET teachers as well as working with VET sector stakeholders to improve the Certificate IV qualification and generally lift the standard of VET teaching.

It should not be forgotten that, in Australia, teachers in the VET system are also required to have industry qualifications, as well as experience in the industry for which they are preparing or upskilling students. Generally, teachers' qualifications in the industry area need only be at the same level as the qualification being taught by that teacher, but some training packages have additional requirements. By contrast,

in the higher-education regulatory framework in Australia, there is a general “one level higher” rule (Commonwealth of Australia 2015). However it should be noted that in some discipline areas, VET teachers routinely have degree level industry qualifications; these are often apparent in, but are not confined to, “professional” areas such as nursing, marketing, and social welfare. All VET teachers (except those in specialist roles such as literacy support) are required to maintain their industry currency and engagement (Smith et al. 2009), and most identify with their previous industry areas as well as with their role as teachers.

## Professional Development for VET Teachers

Professional development (PD) for VET teachers is important and is needed in both “educational and industry-specific expertise” (UK Commission for Employment and Skills 2010). However, with recent funding cuts to the VET sector, fewer resources are available for PD, with teachers increasingly needing to take responsibility for their own PD. It has been established that engagement in PD by VET teachers is affected by many factors, with the nature of “initial teacher qualification” being one among many (Smith 2000; Guthrie 2010b). Professional development is also pointed to as part of a potential solution to the quality of VET teachers especially given the decline in qualification levels (e.g., Wheelahan and Moodie 2011; Smith et al. 2009; Harris et al. 2001).

But teacher engagement in professional development is often patchy and influenced by many factors (Smith 2000). One complication is that many VET teachers and trainers work part time or undertake the role as part of other jobs (Guthrie 2010b), although as Guthrie and Every (2014) argue, there is a substantial core who sees their main role as teaching/training. Substantial barriers to undertaking PD have been identified, including time, access, lack of funding, lack of information, and cost (Harris et al. 2001). In the VET sector, there is a perennial issue of “who pays” for PD and the need for more information “about the relative contributions being made by VET staff and their employers to relevant training” (Guthrie 2010b:19). It has been noted that the approaches of public and private VET providers to PD differ (Harris et al. 2001). Harris et al. (2001) noted that TAFE institutes were more likely to have specialist staff development structures and the internal capacity to deliver a wide range of PD activities, including formal qualifications, than private providers.

## Professionalism

While this chapter focuses on VET teacher qualifications and to a lesser extent professional development, as these issues are being discussed in terms of their contribution to the professionalism of the VET teaching workforce, it is necessary to provide a brief overview of the concept of professionalism. It is recognized that professionalism is a large topic which is contested in the literature, and all of the debates cannot be covered. Many occupations describe themselves as professions. Long-established occupations such as school teaching, medicine, the law, the church,

and the military have traditionally been seen as professions (Tobias 2003). Tobias claims that new professions or *quasi-professions*, such as accounting, architecture, nursing, engineering, pharmacy, and surveying, display only some of the traditional characteristics of a profession, but by no means all (Tobias 2003). Saks (2012) sees a profession as a body of people engaged in significant and cognitively complex service for society that requires specific education and adherence to ethical regulation (Saks 2012). The Australian Council of Professions defines a profession as:

A disciplined group of individuals who adhere to high ethical standards and uphold themselves to, and are accepted by, the public as possessing special knowledge and skills in a widely recognised, organised body of learning derived from education and training at a high level, and who are prepared to exercise this knowledge and these skills in the interest of others. <http://www.professions.com.au/about-us/what-is-a-professional>

It is clear that the possession of a high level of “education and training” is seen as an integral part of professionalism in these definitions. This is usually understood to be, and operationalized via, requirements for initial qualifications and for ongoing professional development. A profession is seen as policing such a body of knowledge, regulating learning practices, admission, and subsequent practice (Professions Australia 2006). It is recognized that professions and the concept of professions evolve over time and involve matters of power and influence (Crues and Crues 2004; workfare Abbott 1988), but the concepts of expert knowledge and of attention to the public benefit seem to remain constant.

VET teachers in Australia do not tend to regard themselves as professionals; in fact “practitioner” is the term preferred by the sector (e.g., Innovation and Business Skills Australia 2013), with even the word “teacher” being unpopular in some quarters, with some people preferring to use “trainer.” The latter term is used by the national regulatory body, ASQA, for example. Yet there has been discussion in recent years by researchers (e.g., Wheelahan and Moodie 2011; Guthrie and Clayton 2012) and in government reports (e.g., Department of Education & Training 2016) about the possibility of establishing a professional body and/or a registration body. These align with debates over the years in the UK where plans were actually carried to fruition, with a professional membership body, the “Society for Education and Training,” now managed by the Education and Training Foundation (<http://www.et-foundation.co.uk/about-us/>). However currently there is no appropriate body in Australia to manage such functions and a reluctance to establish an additional body.

---

## **Developments in VET Teacher Qualifications and Professional Development in the Decade to 2018**

The previous section has established the complexity of VET teachers’ work, the changing and sometimes chaotic environment in which they operate. and, paradoxically, the low level of qualifications existing in the workforce and the barriers that exist for participation in professional development.

A chapter on the Australian VET teaching workforce published in a previous Handbook (Smith 2009) recorded the variety of teaching and training roles, classifying teachers by their site of practice, their role focus, and the formality of training which they delivered. Some challenges to practice were analyzed; and it was noted that the Certificate IV qualification was flawed and that professionalism of the VET workforce was essential in order to ensure continued development of skills and knowledge. This list of challenges seem relatively minor with those faced today.

The 2009 chapter (Smith 2009) provided an account of qualifications and professional development for VET teachers at that time, under a series of headings. Table 1 below uses these headings to provide a comparison of the account presented in that chapter with the situation a decade previously, as set out in Smith and Keating (1997), and a decade later, in 2018.

This table documents a number of events which have occurred. The main features can be summarized as:

- A reduction in the qualification levels required of full-time VET teachers.
- The introduction of a minimum qualification for all VET teachers which has been a consistent failure through various iterations.
- The withdrawal of national and State governments from responsibility for professional development.
- A change to professional development within training providers from being provider-led and even, in some instances, teacher-led to a focus in compliance with an audit regime requiring evidence of PD.
- A consistent failure to conceptualize how workplace trainers delivering non-qualification-based training should be accommodated within the qualification regime for VET teachers.

For example, there have been constant but minor changes to the Certificate IV qualification. These changes have been undertaken to meet perceived inadequacies in the VET system or in the economy. For example, a unit on “Developing assessment tools” was included as core in the qualification in 2016 to meet accusations of poor-quality assessment, and a unit of competency on addressing language, literacy, and numeracy in VET students was the result of peak industry bodies arguing that the general workforce’s skills in these areas were too low (PwC’s Skills for Australia 2017).

But there have been some positive developments, which are indicated by the word *However* in a small number of places in the table. These include, for example, a probable major review of the Training and Education (TAE) Training Package led by the Education Industry Reference Committee which now manages this Training Package, subject to approval from the national government committee which approves development work on Training Packages.

**Table 1** Changes to VET teacher qualifications and the provision of professional development over the two decades 1997–2018 in Australia

	1997 and 2008	2018
“Initial teacher training” via universities – almost always undertaken after commencement as a VET teacher and while working in the role	In 1997, this training was undertaken by all new TAFE teachers	Fewer universities offering VET teacher training, with fewer students. Some universities now combine their degrees with preparation for teaching “VET in schools.” All students are now studying part time and at a distance, and all programs offer credit for the Certificate IV and occasionally Diploma of VET. Two states offer pay incentives on completion of university such as qualifications in VET teaching
	In 2008, “initial teacher training” via universities was beginning to be less common as it was no longer a requirement in any state. Programs generally embedded or offered pathways from the Certificate IV	<i>However</i> , a “higher-level qualification in adult education (either the Diploma of VET or university degree) is now recognized as an alternative to the Certificate IV TAE
Certificate IV qualification in Training and Assessment	In 1997, there was no national qualification. There were “Category 1 and 2” workplace trainer standards. TAFE systems offered introductory courses for part-time teachers	This qualification has had many small changes since 2009, some of which required, variously, either all teachers or only new teachers to gain additional units of competency. It is still the main VET pedagogy qualification. However, there is the “higher-level” proviso. A higher-level qualification is now needed to teach the Certificate IV qualification. There is a Diploma of VET within the TAE Training Package. Because of poor quality, the 2016 update was made “nonequivalent” which meant that all providers had to re-register to deliver either the certificate or diploma qualification. Approval of re-registrations was deliberately slow to try to improve quality

*(continued)*

**Table 1** (continued)

	1997 and 2008	2018
	By 2008, there had been two iterations of a Certificate IV qualification which was the only VET pedagogy qualification recognized by the regulatory system in VET. It was not well respected	<i>However</i> , the qualification will be reviewed comprehensively during 2018–2019
National-level and state-level professional development	In 1997, a National Staff Development Committee, which had provided national leadership for some years, had just been disbanded. Among other programs, it had run a “CBT in Action” program and programs on disadvantaged groups	The national government ceased to have direct role in staff development in 2011; the “Reframing the future” web site with details of previous programs was decommissioned. State governments do not provide professional development, except that the Victorian government alone provides substantial funding to a semiprivate entity known as the VET Development Centre. (However as some States have state-wide TAFE systems, it may be argued that their PD systems are State-funded and supported). The national regulatory body (ASQA), which replaced State regulatory bodies in 2011, does not have the remit of offering professional development and will not offer advice
	In 2008 the national government still encouraged professional development, but not directly, via a program known first as “Framing the future” and then as “Reframing the future.” It provided funding which was provided to ideas put forward by training providers or groups of providers. State governments provided programs in-house sometimes offered via the regulatory authorities which were State-based	<i>However</i> , changes to the Provider Standards (against which audits take place) since 2016 require training providers to show that their staff regularly update their knowledge and skills in both their discipline areas <i>and</i> in VET pedagogy. <i>But</i> large private PD providers have grown rapidly as a result in order that providers can show compliance with this standard A national body of state managers of VET workforce development, which also incorporated a representative

(continued)

**Table 1** (continued)

	1997 and 2008	2018
		of university providers of VET teacher education, ceased to meet in 2015 as state bodies were gradually closed down
Provider-level staff development	In 1997, professional development was carried out in different ways by different training providers, although there were commonalities in topics such as a focus on working with CBT and recognition of prior learning	With the frequent changes to the Certificate IV, a large part of in-house effort has gone into updating teachers so that they are compliant with the requirements. A requirement for 2018 is for all teachers to gain units of competency on developing assessment tasks and on incorporating language, literacy, and numeracy into their teaching. This is reported to be taking all available PD effort in some TAFE institutes. In-house units in larger providers deliver the Cert IV and sometimes Diploma to their own staff, often separately from the departments that deliver these qualifications to other students. Otherwise PD units spend most of their time ensuring that teachers meet the requirements in the 2016 Provider Standards to undertake regular PD in both industry and pedagogy
	In 2008, providers were required to document how they developed their staff. Some providers, public and private, had staff development units. Industry currency was seen as being the most important type of teacher development	<i>However</i> , some larger TAFE institutes or statewide TAFE systems (e.g., TAFE Queensland) have developed capability frameworks for their teaching workforces
Industry trainers	In 1997, workplace trainers were very much part of the national training picture. The “Category 1 and 2” standards were ostensibly for workplace trainers	Dissatisfaction remains with the relevance of the Certificate IV for industry trainers. The Enterprise RTO Association (companies who are registered as training providers – registered training organizations – for their own

(continued)

**Table 1** (continued)

	1997 and 2008	2018
		workers) is vociferous in its opposition to the Certificate IV even for trainers who deliver and assess VET qualifications as opposed to other training for workers. There is no other qualification suitable for industry trainers outside the VET system
	In 2008, it was recognized that the Certificate IV qualification had never applied well to trainers in industry. But where (occasionally) a company awarded VET qualifications, trainers were required to hold the qualification	<i>However</i> , the planned 2018–2019 review of the TAE Training Package proposes to address this matter

Sources: Smith and Keating (1997: 194–203) and Smith (2009)

## Reasons for the Low Levels of Qualification and of Professional Development in VET

In this section an attempt is made to explain how this deteriorating situation has occurred. At first glance, it seems surprising that a country should deliberately reduce the qualifications required for its VET teachers and that the national government should remove itself from responsibility for professional development. Over the same period of time, and particularly in the last decade, there has been considerable focus on school-teacher qualifications (which have been at degree level and above for decades), with considerable intervention by governments at both national and state level in the content of university school teaching-training programs and in the entry levels for these programs (e.g., Department of Education 2015). Also, in early childhood teaching and care, while the basic qualification for childcare workers is only at Certificate III level, there is now a requirement for a proportion of workers to be diploma-qualified and degree-qualified (Margetts 2014). University teachers are not required to hold a university teaching qualification, but most universities in Australia mount a graduate certificate program which they either require or encourage their own academics to undertake (Hardy and Smith 2006)

A tentative model is presented in Fig. 1, which may explain the low levels of qualification required of, and also undertaken by, the VET teaching workforce. In this Figure, which may also be applicable in other countries, the qualification regime is seen to be affected by the low status of VET in Australia and hence the low status

**Fig. 1** Contextual factors affecting the VET pedagogy qualifications required of VET teachers, and undertaken by the teachers

of VET teaching. One effect of this is that it is reportedly difficult to attract good applicants for VET teaching positions (Productivity Commission 2011). But another is that it makes it difficult to argue that VET teachers should be well qualified. The low status of VET and of VET teaching is compounded by the fact that those who make decisions in this area are unlikely to have had any direct experience of the VET system, as government officials are university-educated. It is therefore easy for them to underestimate both the importance of VET and the expertise required to teach in VET, as they know little about it. In the Australian system, the voices of industry dominate over those of educationalists (Smith 2010). Little attention is therefore paid to pedagogical issues; an assumption is that a good industry practitioner will be able to “transmit” knowledge and skills to learners without any teaching expertise.

None of these factors, of course, prevent individual teachers from gaining higher-level qualifications, nor do they prevent training providers from demanding that their teachers undertake higher-level qualifications. With encouragement from their employer and a supportive stance from their trade union, teachers can choose to study further. Hence the box on the right-hand side of Fig. 1 assumes extra importance when examining the *actual* take-up of higher-level qualifications.

Engagement with professional development is affected by the same issues as contextual factors, and there are also other, more direct influences on engagement. Figure 2, adapted from a model by Smith (2000), indicates a range of factors – some personal and some related to the teaching context – and is updated to the current

**Fig. 2** Contextual factors affecting engagement in professional development by VET teachers. (Adapted from Smith (2000))

VET professional development context in Australia. In this Figure, the level and nature of teachers’ prior qualifications is one factor that affects engagement in professional development.

### **Research Evidence on Whether Teacher Qualifications Affect the Quality of VET Teaching and VET Teachers’ Engagement with Professional Development**

Evidence is now presented from a national research project undertaken between 2015 and 2017, led by the author. The project was funded by the Australian Research Council (LP1401000440) and a number of partnering organizations from the VET sector. It was entitled “Would more highly-qualified teachers and trainers help to address quality problems in the Australian vocational education and training system?” and set out to answer the following questions.

1. What differences do VET teachers’ levels of qualification (both pedagogical and discipline-based) make to their teaching concepts, approaches, and practice?

2. How do levels of qualification affect VET teachers' engagement in further professional development activities?
3. In what ways do more highly qualified VET teachers contribute to improved quality in VET?

The project involved participating training providers and individual VET teachers from every State and Territory in Australia. The method involved initial interviews and focus groups of stakeholders, teachers, and students, two major teacher surveys, and two sets of case studies in public and private training providers, as well as a three-stage validation process with two sets of respondents. The phases and the numbers of participants are shown in Table 2.

As higher-level qualifications in VET pedagogy are still available, and as there is a legacy population of previously well-qualified teachers, a comparison between teachers of different qualification levels was possible. The key findings of the project were based on the qualitative and quantitative data and were as follows:

1. Higher-level qualifications in VET pedagogy improve teaching approaches, confidence, and ability to address diversity in contexts, learners, and AQF level of teaching.
2. VET teachers often have high-level qualifications in their industry area or other disciplines, and these too improve teaching approaches, confidence, and ability to address diversity in contexts, learners, and qualification level of teaching.
3. Higher-level qualifications in VET pedagogy make a significant difference to VET teachers' confidence in teaching a diversity of learners.
4. The key qualification level that makes a difference is a degree.

**Table 2** Research method for national project on VET teacher qualifications and quality 2015–2017

Phase	Activity	Number of research participants
1.	Stakeholder interviews	11
2.	11 focus groups of teacher/trainers and students	Teachers: 29 Students: 40
3.	National Teacher/Trainer Survey administered through 8 TAFE and 48 non-TAFE RTOs	574
4.	Case studies about the effects of teacher qualifications on teaching quality, at four TAFE and four non-TAFE RTOs. Interviews with managers, teachers, and students	128
5.	Professional Development Survey of teachers administered through three external professional development providers	368
6.	Professional development case studies at three TAFE and three non-TAFE RTOs. Interviews with managers and teachers	50
7.	Delphi process – three stage on-line survey	55
Total		1255

*RTO* registered training organization (public or private training provider)

5. Participation in both formal and informal PD, in both industry/discipline and VET teaching/training, increases with higher qualifications, irrespective of the type of qualification.
6. VET teaching/training PD needs to be tailored for teachers with higher levels of VET pedagogy qualifications.

In the final three-stage Delphi process (Phase 7), the findings were validated by the respondents who were (in Stream 1) policy-makers or other influencers in the VET sector or (Stream 2) chief executive officers or senior managers of TAFE colleges or major non-TAFE providers representing all categories of private providers.

The findings about the effects of higher-level qualifications on teaching approaches, addressing student diversity, and overall contribution to the employing training provider were very clear in qualitative and quantitative phases alike. While any type of higher-level qualification was helpful, VET pedagogy qualifications had specific utility in matters such as dealing with diverse teaching contexts and student groups. The Diploma of VET qualification made a difference; but the significant difference was at degree level.

Husband (Husband 2015), in the UK, found that teachers with shorter pedagogical qualifications report more need for professional development. Yet the Australian project showed that engagement in professional development was more common among more highly qualified teachers. They reported some dissatisfaction with the type of PD available from specialist commercial VET PD providers. It was disappointing to see all respondents report that the PD they undertook at external providers was most likely to be based around compliance with the VET sector audit regime rather than on pedagogical development. Teachers reported that in-house PD was also focused on compliance with the audit regime; and staff development personnel within training providers reported that the addition of PD requirements to the provider standards merely added another layer of compliance focus to the PD they could provide.

The Delphi phase respondents reported, with a very few exceptions, that the findings of the project rang true and advocated the mandating of the Diploma of VET as a minimum pedagogical qualification for all full-time VET teachers. Although all major stakeholder groups were involved either in the conduct of this research project or on the project reference group, it remains to be seen whether there is the will to translate the findings into a new qualification regime or into more strategic and rigorous professional development provision.

---

## Implications for the Nature of VET Professionalism

A model of professionalism in VET teachers in Australia is now proposed (Table 3). It is based on consideration of the changes in the qualification regime and professional development provision since the turn of the twenty-first century and on the findings of the research project reported in the previous section.

**Table 3** Characteristics of different levels of professionalism in full-time VET teachers, based on research evidence

	Qualifications in VET teaching	Qualifications in discipline area	Professional development
Highly professional	The highest available VET teacher-training qualification (Degree or Graduate Diploma)	The highest available qualification of relevance to the discipline area	Engages in frequent professional development (PD), whether funded or not, and often in own time. Identifies and seeks out PD. Provides PD to others
Moderately professional	Diploma of VET	One level higher qualification than that taught to students	Engages in PD as often as possible when brought to attention; makes occasional own-expense and own-time contributions
Not professional	Certificate IV in Training and Assessment	The qualification level that is taught to students	Only attends PD where it is funded and in working time; may even avoid PD unless necessary

(i) The Australian context is used for this table, with regard to qualification level

(ii) Research evidence is taken from the research project discussed above, which is available at <http://federation.edu.au/research-vet-quality>

The research evidence is crucial in the development of this model. In the research, groups of teachers were interviewed who displayed markedly different approaches to qualifications and to professional development. This enabled clear distinctions to be made among different groups of teachers which in some instances were related to differing discipline areas and in some instances were not. The role of managers in colleges, and also of department heads in larger providers, was also very important, but in the end, the key differentiator appeared to be the attitude of the individual teacher. For instance, some undertook a Diploma of VET only because it entailed a rise (and were “surprised that [they] actually learned something,” in the words of one carpentry teacher). Some attended professional development only because of the new regulatory requirements in VET or because of the regulatory requirements of their industry area; some reported learning from professional development, and others were negative in their evaluation of events. Some sought out professional development; others only attended when they were urged to do so. Yet as Husband (2014) points out, more professional development is actually needed for teachers with less rigorous pedagogical qualifications.

## Conclusion and Implications

The discussion in this chapter leads to a conclusion that the VET teaching workforce in Australia has become increasingly de-professionalized. In terms of the literature on professionalism, the occupation lacks a “high level” of education and training; there is no acknowledged body of knowledge (Professions Australia 2006) for the

occupation; and, except for content in some university-level VET teaching qualifications, there is no discussion of ethical practice or the interests of others in the occupational qualifications. Professional development is mandated, but not by a professional body; it is now primarily a compliance requirement. In this context, while individual professionalism is possible, it is unlikely; Table 3 might be expected to show a heavy weighting toward the bottom right-hand corner.

It seems likely that the documented deterioration of quality in the VET system is at least partly due to the decline in the proportion of degree-qualified staff. In interviews undertaken in the case studies in TAFE institutes in the 2015–2017 research project, some managers reported that, on average, teachers were becoming less and less capable of developing assessment tasks for their students or of developing teaching programs. The managers needed to hire consultants to perform these tasks. Some also said that teachers could not understand basic principles of quality teaching; they saw quality as merely a compliance issue. Some private providers felt the need to provide all teaching and assessment materials to their teachers, even prescribing particular PowerPoint presentations which could not be changed. Managers were also finding it increasingly difficult to find candidates for promotion positions. In TAFE institutes, some managers said that many teachers were unable to contribute to working parties or to debates about appropriate teaching and assessment practices. While the project did not investigate how teachers approached the ethical dilemmas of, for example, inappropriate enrollment of students into qualifications, it is not unreasonable to imagine that without a high level of education, teachers would not be equipped to recognize or address such matters either.

The logical recommendation that can be drawn from the arguments in this chapter is that in Australia the teaching qualification, at least for full-time VET teachers, should be raised from a Certificate IV level to a VET Diploma level or preferably returned to the pre-1998 level of a university degree or graduate diploma. However, when this possibility is mooted, arguments about the cost to training providers (since it is assumed that teachers would refuse to pay for their own studies) or a perceived barrier to entry to the occupation (Productivity Commission 2011) are raised, regardless of the fact that these barriers did not seem insuperable before 1998. However, the cost of *not* qualifying the VET workforce, both to training providers and to the system as a whole, has been shown in this chapter to be great. In early childhood education, it was argued that the need for higher qualifications for teachers would make childcare unaffordable (Margetts 2014), yet the government proceeded to mandate them. Similarly, qualifications for school teachers have become longer and more rigorous; there would be no thought of reducing them below degree level. It would perhaps not be unreasonable to think that national and state governments think that VET does not matter very much compared with other sectors of education.

The matrix of professionalism in the VET workforce developed in this chapter may help VET teachers to locate their attitude toward their expertise as teachers, compared with others. It may also assist training providers in encouraging reluctant members of their workforce to take more responsibility for professional development. However, in the absence of a professional body, leadership is required at national and State levels.

Concern with the quality and qualifications of VET teachers is by no means confined to Australia; for example, recent initiatives have taken place in countries and regions as diverse as the UK (UK Commission for Employment and Skills 2010), Finland (Volmari Helakorpi and Frimodt 2009), and Southeast Asia (Paryono 2015). In England, for example, there are VET teacher training programs offered at different levels by the VET sector and by universities (Simmons and Walker 2013), as in Australia. For other countries there are clear lessons to be learned. If VET teachers are already qualified to a high level, there should be no countenancing any attempt to reduce the levels of qualification, no matter how powerful the lobbies that argue for such a reduction. If VET teachers are not already well qualified, the findings from the research project provided here make a powerful argument for considering increases to qualification levels. Since vocational education and training underpins nations' economies and provides the only available means of education for many people, particularly those from disadvantaged backgrounds, it needs to be delivered by highly expert teachers.

## Abstract

The chapter traces the historical evolution of professional development of vocational teachers from colonial to postindependence Zimbabwe. Professional development of VET teachers has a long history in Zimbabwe and is officially recognized as an important component for improving the quality of teaching and learning. While there was a strong indigenous form of vocational education,

since the colonial period, vocational education has been viewed as of lesser status. During the period of settler-colonial rule, vocational education was racially stratified and viewed as inferior, and this has continued into the postindependence years. While the periods of expansion, adjustment, and crisis all had a different impact on the way professional development was viewed, it continued to be a lesser priority when compared to general education. Currently professional development of VET teachers remains fragmented and in a state of neglect. It is argued that until VET generally is valued, that professional development of VET teachers will continue on the same historical trajectory.

## Introduction

In developing countries there is a renewed emphasis on the potential of Technical and Vocational Education and Training (TVET) to play a catalytic role in addressing social and economic challenges and to actively create the conditions for development. Logically this requires skilled and competent educators, who are able to adapt to changes in the society, in the labor market, and in the processes of production. To what extent are the professional development needs of vocational teachers catered for? This chapter seeks to address this question by looking at the case of Zimbabwe, a country that has gone through a series of extreme social and economic changes. We trace the history of the professional development of Vocational Education and Training (VET) teachers from the pre-colonial to post-independence periods in order to understand what role teacher professional development played at each of these stages. We suggest that regardless of the state of economic development or economic crisis, vocational education and the preparation of vocational teachers have been relatively poorly supported despite policy that sought to promote it. By tracing the historical developments, we attempt to answer why that is the case.

Zimbabwe reflects many of the broader trends that have been identified throughout Africa. VET in Africa is provided in the context of weak national economies characterized by high population growth and fewer job opportunities (Union Africa 2007). It has a highly developed pre-colonial economy, a period of colonization and colonial settlement leading to a settler state, and a postcolonial period that initially saw positive growth and development followed by structural adjustment and economic and political crisis. Thus, while not all African countries have followed these trajectories, aspects of Zimbabwean history are reflected in most of them. The TVET system in Zimbabwe reflects patterns not dissimilar to those noted in studies of other countries (see European Commission 2015).

We start by defining key terms in the context of Zimbabwe. The first section discusses VET professional development policies in Zimbabwe. The later sections

of the chapter discuss the colonial and postcolonial as well as the current state of professional development of VET teachers in Zimbabwe.

## Vocational Education and Training

In the Zimbabwean context, VET is a comprehensive term used to describe technical education and vocational education, inclusive of training done in the workplace as well as in training institutions. The institutions range from primary and secondary schools to colleges and universities as well as industrial training centers. In primary and secondary schools, vocational courses are called practical subjects or vocational subjects. In Zimbabwe, terms such as Technical Vocational Education (TVE) and Technical and Vocational Education and Training (TVET) are sometimes used in place of VET. Generally, VET consists of technical education and training, which, in addition to its vocational aim, cannot neglect the general objectives of education (Ministry of Higher and Tertiary Education 2005). The dominant model in Zimbabwe VET is the competence-based education and training approach. Official policy on VET applies Bloom's taxonomy of learning, focusing on the three domains, namely, the cognitive (knowledge), the affective (moral aspects and values), and the psychomotor (skill area). In terms of weighting, the psychomotor domain accounts for 60%, cognitive 30%, and affective domain 10% (Ministry of Higher and Tertiary Education 2005).

## Professional Development

Professional development can be broadly defined as a capacity-building mechanism that seeks to develop an individual's skills, knowledge, expertise, and other characteristics (Corcoran 1995). Professional development helps VET teachers to keep pace with the constant changes in the world of work such as the introduction of new skills, migration and redundancy (UNEVOC 1997). It can take place in various ways. It is not limited to formal structured learning but can also occur in everyday activities at the work place (Broad 2016). Professional development for VET in Zimbabwe is not limited to formal courses such as diplomas, undergraduate, and postgraduate degrees but also includes nonformal programs. Professional development is used for the development of both pedagogical knowledge as well as occupation related knowledge. Bound (2011, 107) points out that planning and implementation of professional development need to be highly contextualized.

## VET Teacher Profiles in Zimbabwe

VET teachers are those teachers primarily responsible for teaching vocational skills. VET teachers have a dual professionalism; that is the expectation of quality in their technical subject area as well as vocational pedagogy (Andersson and Köpsén 2015).

This means VET teachers should be “Janus-faced” in terms of focusing on both the educational domain and the world of work, simultaneously.

VET teachers work in various educational settings (Billett 2011; Grollman and Rauner 2007). This is also the case in Zimbabwe where VET teachers are found in primary schools, secondary schools, colleges, universities, and workplaces. The titles given to VET teachers differ depending on the level of the VET system in which the teachers operate as well as the institutions they belong to. In both primary and secondary schools, VET is provided in the form of practical subjects by teachers who are trained in the particular vocational subject. Practical subject teachers teach both theory and practice. Practitioners who offer their services in industries are referred to as “trainers” or “instructors.” Those who serve at the postsecondary school level in vocational training centers, polytechnical colleges, as well as universities are called “lecturers.” In colleges and universities, there is a distinction between lecturers and instructors. Lecturers are mainly responsible for theoretical skill instruction. They were traditionally assisted by “instructors” or “laboratory assistants” responsible for demonstrations in laboratories and workshops. In colleges the distinction between lecturers and “laboratory assistants” or “instructors” has been eroded of late due to the shortage of funds to employ assistants. This has resulted in understaffing of many VET colleges.

Trained VET teachers work in a variety of settings depending on their expertise. The deployment of VET teachers into these various institutions is mainly based on qualifications they possess. UNESCO estimates that there are just over one thousand VET teachers in Zimbabwe; this number is insignificant compared to general education teachers who are estimated to be over one hundred thousand (UNESCO 2013). However, the distribution of VET teachers in Zimbabwe in terms of their qualifications is unknown.

---

## **Importance of Professional Development of VET Teachers**

Internationally, professional development of VET teachers has become a central focus of economic and social policy in recent years (UNESCO 2011). This is because of the realization that quality VET teachers are a precondition for improving the capacity of the sector to supply skilled workers (Grollman and Rauner 2007; Axmann et al. 2015). Another development that necessitates professional development is the ever-changing roles of VET teachers due to changes in labor market structure as well as curricular and technology. By extension the quality of VET teacher training programs forms the basis for producing highly skilled teachers, which in turn acts as a base for organizing effective professional development programs (Yonemura 2011).

VET globally has been long regarded as an important attempt to make education more relevant to the world of work. The effectiveness of VET is to a greater degree influenced by the availability of qualified VET teachers who have skills that are continuously updated and responsive to the changes in the local and global landscape, hence the need for professional development. VET teachers therefore play

a significant role in the vocationalization of education in primary and secondary schools to help in the transition of students from school to work. It is, however, surprising that VET teacher training programs in most countries have not received attention which is consistent with the renewed interest in its contribution to economic development (Lloyd and Payne 2012). Grollman and Rauner (2007, 1) refer to the astounding paradox between the significance of vocational teachers and the status accorded to them. This is revealed by the few organized programs available for professional development as compared to those for teachers in academic disciplines.

The majority of policy makers in both developed and developing countries agree that VET contributes to economic prosperity of nations (UNESCO-UNEVOC 2016). However, this has not been complemented with efforts to improve VET teacher training and professional development. This is despite the recognition of the central role played by teachers in maintaining quality of learning at all levels from primary up to tertiary levels inclusive of VET. There is increasing concern over the limited opportunities for the professional development of VET teachers at the global level (Parsons et al. 2009; Lloyd and Payne 2012, 2).

Studies done on VET teacher training in the European Union and Africa reveal that there is a shortage of vocational teachers (European Centre for the Development of Vocational Training 2004; Grollman and Rauner 2007; European Commission 2015). Meanwhile, the few available teachers do not possess the required qualifications to teach in vocational settings. The quality of VET offered on the African continent is generally low, overemphasizing theory and certification rather than skills acquisition and proficiency (Union Africa 2007). Hence there is a need for constant updating of their skills through professional development (European Centre for the Development of Vocational Training 2004). For VET programs to be effective, the professional development of VET teachers needs to take center stage in response to changes in the world of work and self-employment (European Commission 2015). In order to understand teacher development in Zimbabwe, we need to understand how it has been viewed historically. It is to this that we now turn.

---

## Professional Development of VET Teachers in Colonial Zimbabwe

Vocational education in Zimbabwe has a long history stretching to pre-colonial times. Before colonization, Africans had an established system of industrial education that flourished in the *Rozvi* and *Munhumutapa* empires (Ministry of Higher and Tertiary Education 2005). This training was in fields that included forge work, sculpture, painting, iron mongering, and architecture (Ministry of Higher and Tertiary Education 2005, 1). It is, therefore, possible that technical education in Zimbabwe has links with the craft education of pre-colonial times. Its provision was in the form of apprenticeship in the classical sense. The apprentices of the time were mainly young men and women trained by their skilled senior kinsmen and kinswomen. The latter were the “trainers,” experienced in various trades (Busia 1968). Evidence of these skills still exist in modern-day Zimbabwe, for example, the Great Zimbabwe Monuments, the rock paintings in Matopos, and artifacts across the

length and breadth of the country that testify to the presence of such artisans. The traditional apprenticeship system benefited the economy in that it provided tools for use in agriculture, mining, and building.

Britain colonized Zimbabwe as part of the general partition of Africa following the 1884–1885 Berlin Conference (Dube 2017). Colonization meant the introduction of colonial education that was informed by British education policies. The nature of colonial education was summarized by Zvobgo (1981, 13) who notes that, historically, two salient features characterized the educational system. It was racially segregated, and education for the African majority was largely for exploitation. Siyakwazi (2014, 33) notes that colonial education policies in Zimbabwe were inadequate and deficient in fulfilling the aspirations of African learners, for it promoted inequality, repression, and discrimination.

The earliest attempts at establishing a VET policy in colonial Zimbabwe was the Master and Servant Act of 1891 followed by the Education Ordinance of 1899 (Zengeya 2007). While the Master and Servant Act stipulated conditions for apprenticeship training, the Education Ordinance specified the need for industrial training and laid the foundation for teaching low-level skills along racial lines. The Education Ordinance of 1891 set up two separate systems for the education of whites and blacks just 9 years after the occupation of Rhodesia. Education for Africans was offered exclusively by missionary churches with minimum government support through grants. The curriculum for Africans was purely vocational with half the time allocated to industrial training (Siyakwazi 2014; Zvobgo 1981). The purpose of this curriculum was to make Africans manual workers in the fields of building, carpentry, bricklaying, and agriculture and thus prevent them from competing for “white jobs” (McGrath 1993; Zvobgo 2007). The Native Education Commissioner made it clear that education for African students was meant to enable him to take his place in life, a life which is and will continue to be predominantly rural (Zvobgo 1981). This was supposed to be the focus of missionary schools. These schools were underfunded and could not enroll large numbers of students. That distinction negatively affected Africans’ perception of the education they were offered.

It is worth noting that European schools, on the other hand, were subsidized through government grants that covered salaries of teachers and equipment. Such assistance was nonexistent in African schools (Zvobgo 1981). Disproportionate funding of education along racial lines meant fewer professional development opportunities for African VET teachers. The colonial government took overall responsibility in the running of European schools which had a mainly academic outlook though it embraced a vocational element aimed at producing managers and supervisors. The education system for whites had clear dual pathways for academic as well as vocational education (Madondo and Phiri 2014). European children were given incentives to encourage them to attend school. They also had access to secondary education. This was also strengthened by the promulgation of the Compulsory Education Act of 1930 which made education free and compulsory for European children. The colonial government only assumed full responsibility for African primary education in 1945. Consequently, missionaries dominated the provision of teacher education for Africans (Zvobgo 1996).

The vocationalization agenda, however, dominated debates on curriculum in colonial and postcolonial Zimbabwe. This is evidenced by the commissions of inquiry set up to investigate ways of vocationalizing the school curriculum in the country (Mandiudza et al. 2013). The pre-independence commissions included the Phelps Stokes Commission, the Frank Tate Commission of 1929, the Fox Commission of 1935, the Kerr Commission of 1952, and the Judges Commission of 1962 (Mandiudza et al. 2013; Zengeya 2007). The above commissions contributed immensely to the growth of VET, especially the Phelps Stokes and the Judges Commissions. The Phelps Stokes Commission led to the setting up of Jeanes schools in Africa in 1924. Jeanes schools were “industrial” schools set up in Kenya, Nyasaland, and Northern and Southern Rhodesia (King 1971; Davis 2013; McGrath 2011). In Southern Rhodesia the first two Jeanes schools were opened at Domboshawa near Harare and Hope Fountain near Bulawayo providing training in agriculture (both crop production and animal husbandry), building, and wood work. The trainings had both theoretical and practical components needed by agricultural and home demonstrators (Davis 2013). This was the first attempt at establishing training centers for vocational teachers in colonial Africa.

Just like general education, VET curriculum in colonial Zimbabwe was racialized. The Judges Commission in 1962 made recommendations that led to the introduction of different technical and vocational education curriculum for blacks and whites. This signaled the formalization of a practical/vocational curriculum for blacks, known as the F2 system, which ran parallel to the prestigious F1 “academic” and higher technical system for whites, Asians, and coloreds. The F2 schools for Africans were introduced in 1970 (Mupinga, Burnett and Redmann 2005; Gudyanga 2014); however, not much progress was made in this sector because of serious under funding (Zvobgo 1994, 21).

In colonial Zimbabwe, teacher education in VET and the professional development of VET teachers did not receive adequate attention. The colonial government focused more on general education. This was a reflection of the long history of preference given to academic education (Siyakwazi 2014). Teachers, both for general and vocational education in African schools, were inadequately trained. In terms of qualifications, they were mostly underqualified.

In 1965, the colonial government of Rhodesia under Ian Douglas Smith pronounced the Universal Declaration of Independence (UDI). The proclamation of UDI meant that the settler-colonial government had severed ties with the British government (Hawkins 1967). In response to UDI, the British government imposed sanctions on the settler-colonial government. The sanctions by the British government were later complemented by those imposed by the United Nations. All the realms of life, including education, were affected by the imposition of sanctions (Machingura 2006). Though the imposition of sanctions over UDI did not have the desired results in terms of crippling the economy, teacher training and professional development were affected because expatriate teachers were no longer coming to support teacher education programs (Machingura 2006). Funding for African education was reduced to about 2% of gross domestic product (GDP) (Robinson 2016).

From 1964 to 1979, the Zimbabwean war of liberation, known as the *Second Chimurenga*, was waged between Africans and the Rhodesian forces (Mlambo 2014). The war presented challenges to the professional development of VET teachers in the mid- and late 1970s because some students who were being trained as apprentices were simultaneously fighting in the war under the National Service Programme.

In 1968 the Apprenticeship Training Act was passed, which enabled the setting up of the Apprenticeship Training and Skills Development Authority (ATSDA). Among its responsibilities, the ATSDA was to assess future skilled manpower and training needs and to encourage the training of technicians (Zengeya 2007, 165). The ATSDA introduced trade testing thereby contributing to increased quality of personnel. This served to enhance the professional development of VET teachers as well.

The passing of the Vocational Education and Training Act in 1978 was a huge milestone in the promotion of vocational training, including bringing order to the training of personnel. This led to the establishment of the Manpower Development Training Authority (MANDATA) which took over role of the Apprenticeship Training and Skills Development Authority established after UDI. Among MANDATA's responsibilities was to supervise the training of apprentices both in industries and training colleges. The Vocational Education and Training Act also provided for the establishment and maintenance of technical colleges, the imposition of a levy to fund manpower development, as well as the regulation of private providers of VET (Zengeya 2007). VET teacher training and professional development activities were enhanced by the establishment of MANDATA.

---

## Professional Development in Postindependence Zimbabwe

Zimbabwe formally attained independence from Britain in 1980. Postindependence Zimbabwe cannot be treated as a uniform period. Rather, it can be analyzed based on the sociopolitical and economic experiences of the country, subdivided into the decade of growth 1980 to 1990, economic liberalization 1991 to 1998, and the crisis period of 1999 to 2013. Thereafter, the current state of professional development of VET teachers is presented.

### Professional Development of VET Teachers in the Decade of Growth, 1980–1990

The newly independent government of Zimbabwe inherited a highly developed and diversified, yet racially stratified, economy (Mlambo 2014; Saungweme 2013; Kanyenze et al. 2011). Zimbabwe had a stronger industrial base than most countries in the SADC region. Agriculture was the mainstay of the economy, though the manufacturing sector also fared well because of the self-reliance approach necessitated by the period of sanctions. Race-based inequalities still existed in social services including education, health, and housing. Top on the agenda of the new

government was to reduce inequalities through massive expansion of the social services sector, especially to the marginalized African population.

During the first decade of independence, Zimbabwe massively expanded education provision as a clear departure from the colonial past (McGrath 1993; Zvobgo 1986). This expansion was not limited to primary and secondary education but extended to vocational and tertiary education. There was also significant expansion of teacher training institutions and universities.

At independence, there was a serious effort to reform teacher education, including VET teacher education, to meet the demands of the new social and economic order (Dzvimbo 1989, 17). The inherited teacher education program was not able to produce the numbers of qualified teachers needed by the expansion. In view of this, a novel approach, the Zimbabwe Integrated National Teacher Education Course (ZINTEC), was started in 1981 that sought to fast track teacher training and get teachers into class (Dzvimbo 1989). Focusing on primary teachers, it started as a 4-year course in which student teachers spent the first 16 weeks of the first term of their first year in college, 10 terms on teaching practice internship, and the final 16 weeks of the final term of their fourth year in college. It has subsequently been reduced to a 3-year course (Maguraushe 2015).

The National Manpower Survey of 1981 revealed that Zimbabwe had a critical shortage of skilled vocational personnel including lecturers for technical colleges. The survey also showed that Zimbabwe's VET workforce was composed of 8% professionals, 12% skilled, 20% semiskilled, and 60% unskilled (Government of Zimbabwe 1981). This was a result of the emigration of skilled whites mainly to the United Kingdom, Australia, and South Africa (Kanyenze et al. 2011). The few lecturers who remained were underqualified; hence there was an urgent need to address the skills vacuum created. The new government had a drive toward expansion of provision of VET as well as an expansion in vocational teacher education programs (Dorsey 1989).

In light of the realization of the importance of skills development, the government introduced the Zimbabwe Foundation for Education with Production (ZIMFEP), drawing on the ideas developed by Van Rensburg in Botswana McLaughlin et al. (2002). This was after a realization of the shortcomings of the colonial education it inherited (Chinyamunzore 1995; Dorsey 1989; Gustafsson 1985; Kasambira 1987). The ZIMFEP programme also sought to deal with the challenges of structure, content, and methods used in the delivery of practical subjects under the F2 system that was used during the colonial times. Education with Production, with its emphasis on the need for people to be skilled in several vocational trades, led the government to establish technical colleges to train vocational teachers especially in trades not offered at the only university – the University of Zimbabwe (Ministry of Higher and Tertiary Education 2005).

From 1982 onward, Gweru Technical College was mandated to train VET “teachers” for schools as well as lecturers for other technical colleges in Zimbabwe. The majority of those trained included vocational teachers for secondary schools in the following disciplines: Electrical Engineering, Metal Work, Technical Graphics, Building, Computer Science, Accounting, and Secretarial Studies. After initial

training at Gweru Technical College, they would move into vocational occupations, while others furthered their studies in the newly formed degree awarding universities such as Harare Institute of Technology (HIT), Chinhoyi University of Technology (CUT), and the National University of Technology (NUST) (UNESCO 2013).

The Manpower Planning Development Act of 1984 which was later revised in 1996 and 2002 is the overarching policy document which empowered the Ministry of Higher and Tertiary Education to superintend over “all human capital development” issues in Zimbabwe. The philosophy behind the Manpower Planning Development Act was that, for any country to develop, it must have sufficient numbers of skilled people to meet the needs of its industries. The Act, among other things, was responsible for the provision of a comprehensive and constantly developing service for teacher education, for technical or vocational institutions, and for technical or vocational education (Government of Zimbabwe 2002). By extension this included professional development of VET teachers.

For instance, Section 4 of the Act specifically focuses on the promotion of VET, including the establishment of providers of VET as well as the coordination and standardization of all professional qualifications. The Act also has provisions for the promotion of teacher training by capacitating the training institutions with relevant facilities. The Manpower Planning and Development Act also led to the establishment of the National Manpower Advisory Council (NAMACO) and the Zimbabwe Manpower Development Fund (ZIMDEF). NAMACO was responsible for ensuring the supply of well-trained personnel in all occupations.

NAMACO contributed significantly to the professional development of VET teachers. The composition of NAMACO included government trainers and industry level trainers who worked together in identifying areas in need of training and professional development. NAMACO’s needs assessment was coordinated by industry players who were in touch with the recent developments in technology and suggested revised proficiency standards, working together with trainers from the Ministry of Higher Education. A growing and robust industry provided a good environment for an effective NAMACO. Multinational companies operating in Zimbabwe played a significant role in the professional development of VET teachers by providing their training centers and expatriate trainers to facilitate workshops. The ZIMDEF was used in training and professional development of VET teachers as well as in supporting the training of apprentices in various trades. The funds from ZIMDEF were also used in infrastructure development projects at many VET colleges and universities in the country.

In 1990, the government of Zimbabwe introduced the Rationalization of Technical and Vocational Education and Training policy document in order to structure VET into levels for easier progression in professional development (Kanyenze et al. 2011). The lowest level was the prevocational level (PVC), followed by the National Foundation Certificate (NC), the National Diploma (ND), and highest level the Higher National Diploma (HND) which was equivalent to an undergraduate degree (Kanyenze 2011). VET teachers were expected to have a minimum qualification of the National Certificate for those teaching at national foundation and prevocational levels. Those with the National Diploma could teach at National Certificate level,

whereas those with Higher National Diploma could teach at Diploma level. VET teachers with the NC and above had mostly technical skills and no pedagogical skills. In order to fill the pedagogical gap, technical colleges introduced the Further Education Training Certificate (FETC) and the Further Education Training Diploma (FETD). The FETC and FETD are examples of in-service programs that VET teachers in Zimbabwe would undertake. These two qualifications became mandatory for VET lecturers to possess as part of their professional development.

The first decade of Zimbabwe's independence was generally quite progressive in terms of expansion of the provision of education including VET. Significant progress was realized in teacher training and initiatives as well as the professional development of VET teachers. During this decade, participation in professional development activities by VET teachers at all levels was high. It also included staff exchange programs with European countries such as Germany and the United Kingdom, countries with well-developed VET systems. Nevertheless, VET teacher education training institutions remained few in comparison to those for general teachers during this decade. Most VET teachers were trained together with primary and secondary school teachers, and their status remained lower than those of teachers in academic fields.

### **Professional Development of VET Teachers During the Economic Liberalization Era, 1991 to 1996**

Zimbabwe adopted the policy of economic liberalization from 1990 onward at the instigation of the World Bank and the International Monetary Fund (Chinyamunzore 1995). These institutions encouraged governments of developing countries to adjust their economies by eliminating trade barriers and reducing the amount of public expenditure in order to reduce their debt (Kanyenze et al. 2011). In the Zimbabwean case, the program was named the Economic Structural Adjustment Programme (ESAP). The program encouraged the privatization of most government enterprises and reduced government participation in social services. ESAP, however, had a number of negative consequences. Most notable were massive job losses through retrenchments. The impact of ESAP was particularly felt on the education fraternity. Its effect on industrial growth and the education sector specifically had ripple effects on professional development of VET teachers. Firstly ESAP led to deindustrialization as local firms failed to compete with international conglomerates after the removal of import tariffs (Kanyenze et al. 2011). Instead of achieving industrial growth, ESAP led to the opposite. Some of the companies which closed down had made long-standing investments in professional development of VET teachers.

ESAP resulted in serious underfunding of the education sector, which in turn contributed to a shortage of VET teachers. The available teachers were often underqualified as revealed in the Presidential Commission on Education and Training (popularly known as the Nziramasanga Commission Report of 1999) (Kanyenze et al. 2011; Nziramasanga 1999), but the lack of funding meant that this issue could not be addressed.

ESAP also coincided with the ravaging impact of HIV and AIDS in Zimbabwe. HIV and AIDS led to the deaths of a significant number of qualified VET practitioners. Brain drain and HIV and AIDS impacted negatively the professional development of teachers during the ESAP period (Shizha and Kariwo 2011). The influence of ESAP on the reduction of budget allocation for social services including education cannot be ignored. It had obvious implications of compromising delivery of vocational education including teacher education and professional development. Many companies, apart from downscaling their operations, could no longer sustain professional development activities.

### **Professional Development of VET Teachers and the Crisis Period in Zimbabwe, 1997 to 2008**

The years 1997 to 2008 are considered as the crisis years in Zimbabwe. The crisis in Zimbabwe was political, social, and economic, in some respects associated with ESAP, though that had officially ended in 1996. Other emergent causes of the crisis included the payment of gratuities to War Veterans by an already overstretched fiscus and the Fast Track Land Reform Programme (FTLRP). The FTLRP programme resulted in the displacement of former white commercial farmers from their farms without compensation, which were then redistributed to the black majority (Meredith 2002).

The FTLRP seriously affected relations between Zimbabwe and Britain, its former colonial master. Farm seizures through the FTLRP led to the condemnation and isolation of Zimbabwe from the international community. Britain cut diplomatic relations with Zimbabwe, as did other countries in Europe, Australia, and America, and economic sanctions were imposed on Zimbabwe. The sanctions meant that most companies of European and American origin had to relocate from Zimbabwe to the neighboring countries such as Zambia, South Africa, and Mozambique. This led to investor flight and company closures ultimately leading to the shrinking of the Zimbabwean economy (Duri 2016). Massive job losses ensued. The companies that continued operating reduced their spending on industrial training. The FTLRP also affected agricultural production as well as manufacturing sector output because there were close links between the two sectors (Moyo 2000).

The economic crisis in Zimbabwe negatively affected the provision of social services in the country including education and health (Nyazema 2010). In spite of the crisis, the government remained the biggest provider of teacher education in Zimbabwe, both for general education and vocational education. UNESCO TVET Report for 2005 noted the government providers of VET constitute 55%, followed by the private sector which accounts for 28%, while parastatals contribute the remaining 17%. However, state provision of VET teachers' professional development during the crisis period was seriously compromised. Challenges faced by government providers of VET teacher education and professional development included funding, low student enrollment, and dilapidated infrastructure. Data from Zimbabwe revealed that the massive drop in enrolment was a result of

declining holding capacity of these institutions in terms of infrastructure, equipment, and qualified trainers (Nziramasa 1999). VET teacher education providers were no longer supported financially by the treasury for operating expenses. The government, however, continued to pay for salaries of staff.

In spite of the above, the government of Zimbabwe from 2004 introduced a VET lecturer professional development program at the B-Tech, M-Tech, and eventually D-Tech levels. Though this was a good direction for professional development, the B-Tech program offered in technical colleges faced some challenges. The major challenge was that of low salaries compared to lecturers teaching similar degree programs in universities. This negatively affected staff motivation to enroll for professional development.

At the peak of the crisis, hyperinflation reached 231 million percent by May 2008 (Gono 2008). The social services sector including education was severely affected and came to a standstill in 2008 (Gono 2008; Gukurume 2015; Mazani 2015). The situation was worse for professional development of VET teachers because most institutions were operating without requisite resources. Most institutions did not have budgets for professional development. VET institutions were again affected by brain-drain leaving very few VET teachers in post, with the majority having moved to other countries in Africa and abroad. The number of lecturers in polytechnical colleges declined significantly. The brain-drain mostly attracted the most qualified and experienced teachers. This left skeletal staff comprising of inexperienced and underqualified personnel manning the depleted programs.

## **The Current State of Professional Development Programs for VET Teachers in Zimbabwe**

The current situation in Zimbabwe shows that professional development of VET teachers is in a state of neglect. This is not entirely unique to Zimbabwe, but reflects the general trend on the African continent (Yonemura 2011). Though VET providers in the country acknowledge the importance of professional development in increasing the professionalism of teachers, evidence on the ground suggests that they do not have deliberately planned professional development programs in their institutions.

Professional development should normally follow a training needs assessment exercise. In the case of VET teachers in Zimbabwe, these assessments have never been done properly, apart from the annual performance appraisal, which is, in most cases, associated with bonus payments rather than in identifying performance gaps which can be filled by professional development. This important aspect is missing from VET providers. Hence, professional development needs of VET teachers are either unknown or speculative.

Due to the absence of systematically organized professional development programs in institutions, VET teachers who engage in professional development often do so through their own initiative. Even in cases where VET teachers need financial support for professional development, they are not assisted by their institutions in monetary terms. Oftentimes such teachers are not given Manpower Development

Leave (MDL) to pursue professional development programs such as undergraduate or postgraduate degrees. Ultimately, engaging in professional development for the few who do so is at a huge cost to them personally. The employer often cuts salaries by half. In extreme cases, upgrading teachers go on leave without pay. As such, VET teachers have to choose between their salaries and professional development. In the majority of cases, however, the latter loses. Lack of financial incentives hinders VET teachers' participation in professional development. Moreover, there is no salary increase for lecturers who have undergone professional development and attained higher degrees. They still earn equally with those with minimum qualifications for the job (Mazani 2015). The absence of incentives hinders the participation in professional development by some VET lecturers.

The apparent neglect is often attributed to the economic crisis over the past two decades in the country. This affects investment in VET, be it materially or in human resources development. Most principals in VET institutions are more worried about the daily survival of their institutions at the expense of their teachers and lecturers. Oftentimes, there are no budgets set aside for professional development in institutions offering VET.

The Zimbabwean government remains the biggest employer of VET teachers in Zimbabwe through the Public Service Commission (PSC). The PSC sets minimum qualifications for VET teachers. Currently, the minimum qualification for lecturers in polytechnical colleges is a diploma in the relevant specialist area. No reference is made for the need of any other qualifications (Mazani 2015, 4). This creates the mistaken belief that professional development is optional. This might explain the reluctance of some lecturers to engage in professional development. Human resources departments in VET institutions lack a professional development focus in their work and prioritize compliance with regulations.

The government, through the two ministries of education, is focused on curriculum reforms emphasizing Science Technology Engineering and Mathematics (STEM) and vocational subjects. The challenge, however, is that there are no deliberate efforts to professionally develop the teachers and prepare them to meet the demands of this initiative. Teacher training institutions are hardly prepared to respond to the STEM initiative. At the end of 2016, the Ministry of Primary and Secondary Education introduced a new education curriculum known as the Curriculum Framework for Primary and Secondary Education CFPSE 2016–2022, which is vocational in nature. In the new curriculum, vocational education is now introduced much earlier in grade three, which has additional implications for teacher preparedness through initial teacher training as well as professional development.

---

## Conclusion and Future Directions

This chapter has offered a historical overview of professional development of VET teachers in Zimbabwe in the context of wider social and economic forces. The pre-colonial traditions of apprenticeship were largely replaced by a more formal, race-based, and socially stigmatized model during the settler-colonial period. The

optimistic early years of postindependence witnessed an expansion of the education system, but the professional development of vocational teachers was largely an afterthought. The crisis years up to the current period have seen massive pressures on the system due to structural adjustment and economic crisis, resulting in the both the economy and the educational system facing serious pressures. The chapter has shown that professional development of VET teachers has suffered different levels of neglect throughout these different time periods. It remains fragmented and lacks coordination in most institutions in Zimbabwe despite the fact that it is central to the success of educational and economic reform agendas. VET teachers are currently operating below their capacity due to the absence of deliberately organized and systematic professional development programs.

The precarious nature of the Zimbabwean economy makes finding solutions to the issue of professional development of VET teachers difficult. While rhetorical commitments to VET are common, underlying social prejudices that are rooted in the colonial tradition mean that the rhetoric is seldom matched by resource commitments. It is unlikely that professional development will be prioritized until economic demands require teachers with higher level skills. Without major changes in the status of VET, the development of VET and the professional development of VET teachers in Zimbabwe will continue to follow the patterns of Zimbabwean economic and social development rather than actively shaping them.

## Abstract

Teachers' well-being is a crucial prerequisite of high-quality education and training. More specifically, research on teachers' resilience – the ability to stay engaged and satisfied with the profession despite the highly demanding nature of teaching – is very informative to identify difficulties and resources that mostly impact teachers' well-being. Based on empirical evidence, this contribution provides an overview of the main risks and protective factors related to teachers' resilience by specifically focusing on the vocational education and training (VET) teacher population.

In this respect, the findings of a Swiss national study on VET teachers' resilience are illustrated and then integrated with the most recent literature on teachers' resilience and well-being. The empirical evidence reported here is

consistent with a socio-ecological interpretation of teachers' resilience as the result of a dynamic interplay between individual and contextual factors. On the one hand, difficulties related to teaching and classroom management and difficulties in work-life balance and critical job conditions were found to have the most direct impact on teachers' well-being. On the other hand, sense of vocation, teaching and classroom management abilities, and school-related resources played a crucial role in supporting teachers to be resilient in times of adversity. Peculiarities of VET are described both in relation to risk and protective factors. Differences across the professional career phases are additionally discussed. Moreover, implications for VET education policy and practice are reported. Finally, recommendations for future research on teachers' resilience are outlined.

## Introduction

There is a strong consensus among scholars that teaching is a potentially stressful job (see Beltman et al. 2011). Studies by Schaarschmidt (2009) and Schaarschmidt and Kieschke (2007) compared teachers with many other groups of employees (e.g., policemen, firefighters, caregivers) and found teachers to be much more prone to excessive work and a reduced buoyancy, much less satisfied with their lives, as well as less able to resist stressors and to relax and distance themselves from job-related problems.

International surveys report that 20–40% of teachers are at risk of burn-out, which implies emotional exhaustion, depersonalization, and perceived reduced personal accomplishment (Maslach and Jackson 1981). In addition, the attrition rate in the first 5 years of teaching reaches 35–50% in various countries (Darling-Hammond 2003; Howard and Johnson 2004; Kardos and Johnson 2007; OECD 2011).

A different way for teachers to cope with chronic stressors consists of reducing their effort and occupational engagement. In such a case, teachers do not consider to quit the profession, but the quality of their teaching is strongly compromised by their disengagement with the job. The term “worn-out” was coined to describe that condition by Stephenson (1990) who showed that three times as many teachers were worn out than burned out.

On the contrary, schools not only need to reduce teachers' attrition, but high-quality schools also need teachers who are able to stay satisfied, motivated, engaged, and confident in their teaching despite everyday challenges they encounter. In other words, they need teachers to be resilient.

Teachers' resilience has been positively associated with students' achievement and teaching quality (Gu and Li 2013; Day and Gu 2014). Moreover, motivated and healthy teachers help to develop in students a positive and enthusiastic relationship to learning, which is crucial for a lifelong learning perspective (Brophy and Good

1986; Feldman 2007; Kunter et al. 2008; Keller et al. 2014). This is particularly important nowadays, as boundaries between work and education are increasingly overlapping and employees are asked to be able and motivated to continuously learn.

From this perspective, determining how to keep teachers satisfied, engaged, committed, and self-confident despite the difficulties they encounter throughout their career is a key issue for education and society in general. Literature on teachers' resilience deals specifically with this question.

This chapter aims at illustrating the more recent theoretical and empirical evidence on teachers' resilience with a particular focus on vocational school teachers.

In this respect, the findings of a mixed methods Swiss study on vocational school teachers' resilience and well-being are reported (for more details, see Sappa, and Boldrini 2018; Sappa et al. 2018). The study was launched in the Italian-speaking part of Switzerland and then extended to the other linguistic regions (German- and French-speaking regions) with the main intent to identify challenges and resources that most impact vocational school teachers' well-being as well as to empirically understand what supports teachers to be resilient.

Moreover, findings from the Swiss study will be compared and integrated with the wider literature in the field.

The first section provides contextual information about VET teachers in Switzerland. Based on empirical data and theoretical insight, the second section presents an overview of the main difficulties impacting teachers' well-being. Then, a definition of teachers' resilience is given together with an argumentation about its main components. The third section illustrates individual and contextual resources that contribute to making teachers resilient. Subsequently, the chapter discusses how difficulties, resources, and resilience differ across the phases of professional life. In conclusion, implications for practice in VET and teacher education as well as recommendations for further lines of research are outlined.

---

## Background

Switzerland is acknowledged for its long-standing and widely encompassing VET system (Wettstein et al. 2017). Around two thirds of its students coming out of compulsory education at age of 15 (lower secondary level) enroll in vocational upper secondary level programs. Many of them continue with higher VET at the tertiary level (SERI 2017). Most of the curricula are provided in a dual mode, that is, by combining learning at school and at the workplace where students are employed as apprentices. The VET curricula, including both vocational and general education subjects, are developed in close collaboration between educational institutions (at the federal and cantonal level) and professional associations. An integrated teaching between school and workplace is highly required particularly to vocational subject teachers, who, as a consequence, are very pressed to combine pedagogical skills with competences in the specific professional domain and to keep up to date with professional developments. In order to facilitate this integration, teacher candidates need to have the highest possible qualification in a particular professional

domain in addition to a minimum of 6 months of occupational experience, with several years being the norm (Hof and Leiser 2014). Therefore many vocational subject teachers in Switzerland are career changers. Also, around 42% of all teachers employed in VET schools work in a quota of less than 50% as a teacher. Most of them combine teaching with another job. The multiple job holder condition is a specificity of Swiss VET teachers in comparison to other types of secondary school teachers (see Sappa et al. 2015).

Furthermore, consistently with the international educational mainstream, recent reforms were launched in the Swiss Education system – including VET – where teachers are asked to provide a more standardized, multidisciplinary, and competence-oriented education. In addition, a closer collaboration between vocational schools and training companies is requested. Although Swiss VET curricula are basically centralized, a certain room for maneuver is left to cantons and individual schools to implement and adapt such reform to their needs. School leaders play a key role in such an adaptation.

Differently to other types of teachers, VET teachers in Switzerland are trained while already in service. Usually, teachers are asked to attend a compulsory training course after 1–5 years of teaching. Teachers' training provides teachers for general pedagogical and subject-specific didactical skills.

Finally, although very popular, VET paths are not always attractive for higher-achieving students. Particularly in the Italian-speaking cantons – and partially in the French-speaking ones – academic pathways enjoy a higher social status. This condition is probably due to the influence of the academic-oriented educational culture in Italy and France. As a consequence some students and their family perceive VET pathways as a “second choice” (Boldrini and Bausch 2009) to be accepted when it is not possible to attend the more selective and desirable lyceum school path. Therefore some students are less motivated to learn a chosen profession, and teachers are challenged to support them in developing a professional identity.

In the next section of this chapter, we illustrate main reasons why teaching can be considered as a potentially stressful job, particularly in VET.

---

## What Makes Teaching a Potentially Stressful Job

Scientific evidence suggests that multiple challenges contribute to putting teachers at risk of negative stress (Brunetti 2006; Day and Gu 2009; Gu 2014; Mansfield et al. 2014). However, few studies have investigated vocational school teachers. Among those, Kärner et al. (2016) found that German VET teachers suffer from less work-life balance, less resilience, and higher perceived stress than employees in other professions. Also, Meristo and Eisenschmidt (2014) showed vocational school teachers in Estonia as having lower self-efficacy beliefs in classroom management and student engagement and having low scores relating to aspects of the school climate in comparison with teachers in comprehensive schools. To contribute to a better understanding about main difficulties and resources related to VET teachers, a local study in the canton of Ticino was conducted as a pilot. In this framework,

37 vocational school teachers were selected by means of maximum variation sampling procedures and then interviewed. Participants were first asked to indicate – while narrating professional experiences related to critical situations – those challenges that most affect their well-being. The findings showed 24 categories of difficulties that are perceived by teachers as particularly threatening (Boldrini, Sappa and Aprea 2018). They were clustered into six factors (i.e., difficulties related to teaching and classroom management, difficult relationship with the school leader and colleagues, work-life balance difficulties, critical job conditions, a low level of social recognition, and identity challenges) whose impact on teachers' well-being was then quantitatively investigated by means of a questionnaire-based survey involving 2,163 Swiss vocational school teachers (Sappa and Boldrini 2018; Sappa and Boldrini, submitted) from six selected cantons, including German-, French-, and Italian-speaking areas.

By means of various statistical analyses (factor analysis, regression analysis, structural equation modeling technique), four factors were identified as directly contributing to threatening vocational school teachers' professional well-being: *difficulties related to teaching and classroom management*, *difficult relationship with the school leader and colleagues*, *work-life balance difficulties* and *critical job conditions*, including contractual issues, workload, organizational difficulties (e.g., those related to teaching timetables), and pressure from curricula reforms.

*Difficulties related to teaching and classroom management* were shown to have the highest negative impact on teachers' professional well-being. In particular, the relationship with students both as individuals and as a group was described by teachers as very demanding and sometimes emotionally exhausting. The increasing classroom size and the internal diversity in terms of cultures, ethnicities, levels of achievement, and learning styles contribute to making classroom management more complicated. In addition, relationships with students, especially during adolescence, can be very challenging and complex. Moreover, as reported in the background section of this chapter, in some Swiss regions, vocational paths are more likely to be chosen by those students who have lower levels of achievement and motivation to learn. To this respect, teachers interviewed in the Swiss study reported feelings of anger, frustration, a sense of inadequacy, and demotivation caused by the low professional motivation and weak vocational identity of some of their students. Teachers feel they are not prepared to face the students' professional identity issues, and they are required to make considerable efforts to activate a remotivation process among the students. On the other hand, peculiar didactic challenges were found in relation to vocational teachers. One of the more demanding reported challenge dealt with the need to adapt disciplinary or technical knowledge to the practical experiences that students have on the job.

*Difficult relationship with the school leader and colleagues* was shown in the Swiss study as significantly affecting teachers' well-being. In particular, negative feelings were associated with an unsupportive school climate, the perception of being alone in facing challenging classrooms, as well as a lack of a shared pedagogical culture in the teachers' team. This latter issue seemed to be particularly prominent and tricky when teachers are asked to decide how to manage students'

failures and misbehaviors. Building a shared pedagogical culture can be particularly difficult in vocational schools due to the heterogeneous learning cultures that usually coexist in those settings: on the one hand, the disciplinary view rooted in the educational tradition and, on the other hand, the practical understanding of learning that is typical within the world of work.

Moreover, school leadership was described as very relevant for teachers' well-being. Specifically, teachers reported feelings of frustration, anger, and high dissatisfaction when the school principal was perceived as unsupportive, unable to value his/her employees, and incoherent in school management. The risky impact of a lack of collegiality and dissatisfaction with school leadership on teachers' well-being is widely confirmed by the scientific literature (Day 2014; Howard and Johnson 2004; Le Cornu 2009).

Similar to the findings by Kärner et al. (2016) in their German study, we found *work-life balance difficulties* to significantly impact vocational teachers' well-being, particularly among women. The in-service training model adopted for VET teachers in Switzerland partially contributes to make work-life balance more demanding.

Furthermore, *critical job conditions* significantly affect teachers' well-being. First, scientific evidence has been found showing the negative impact of job insecurity and a low salary on professional well-being and satisfaction (e.g., Liu and Onwuegbuzie 2012). In Switzerland, teachers' salary and job stability are largely unproblematic. However, those teachers who reported low levels of satisfaction with their job contract also indicated a lower level of professional well-being. Second, an excessive workload and a stressful exposure to reforms are additional sources of job dissatisfaction and frustration. Swiss teachers reported feeling stressed and pressured by a standardization process that threatened their freedom of teaching, causing a sense of demotivation, frustration, and disengagement. More specifically, VET reforms in Switzerland have led vocational schools to develop more standardized teaching plans. As a consequence, teachers have been asked to negotiate and in some cases to design common didactic materials and training objectives. However, this process was not always easy to implement, as it competes with a traditional and common interpretation of teaching as the personal product of the expertise of single teachers. In other words, many teachers were frustrated by the feeling of losing their "freedom of teaching" in favor of a more standardized – and then impersonalized – culture of teaching. Similarly, Gu and Day (2013) argued that results-driven, performativity, and new public management cultures of school environments are contributing to increasing the workload for teachers by threatening their sense of autonomy, control, and freedom and, in turn, their sense of agency and commitment.

The four threatening factors described thus far are also reciprocally correlated. For example, a difficult relationship with school leaders and colleagues contributes significantly to reducing teachers' ability to successfully face challenging classrooms and students. In addition, critical job conditions make everyday relationships with students and colleagues more challenging. Moreover, work-life balance difficulties increase when curricular and extracurricular activities at school become too demanding.

Finally, two additional factors were found to indirectly contribute to threatening teachers' well-being. On the one hand, although the social reputation of VET is basically positive in most of the Swiss cantons, some teachers – particularly from Italian- and French-speaking areas – reported that social status of school education, and VET in particular, is perceived as declining. Also they feel not to be sufficiently valued as a teacher by the current society. Quantitative analysis on the large sample demonstrated that those feelings contribute to increase teachers' difficulties at the level of both classroom management and relationships in school as well as with respect to work-life balance. On the other hand, an *identity challenge* emerged from teachers who reported the perception of being engaged in multiple overlapping roles, such as educator, social worker, instructor, and counselor. For teachers, the boundaries of their professional identity seem increasingly difficult to define, which can cause stress and fatigue. Such a feeling was found to contribute to increase teachers' difficulties in facing challenging classrooms and to make it more difficult for them to achieve a healthy work-life balance.

In sum, a multitude of factors contribute to make teaching a potentially stressful job; these are reciprocally interrelated, and all may contribute to a progressive deterioration of teachers' well-being. Very few participants in the Swiss study reported a single disruptive event as the main cause of a serious distress. In addition, the quantitative data did not show any prominent effect of single disruptive events on teachers' well-being. On the contrary, both qualitative and quantitative data converged in describing teachers' loss of engagement, satisfaction, and sense of competence as the cumulative effect of overlapping daily stressors.

The following sections will outline the details of what this kind of resilience means and which individual and contextual resources contribute to making teachers resilient.

---

## Teachers' Resilience: Definition and Main Constituents

Although teachers' resilience has been approached from multiple perspectives and disciplines, a common understanding can be traced with respect to the definition of resilient teachers. Resilient teachers can maintain enthusiasm and engagement in the profession despite professional adversities they encounter. In addition, resilient teachers can manage ongoing and multiple challenges over time while continuing to grow and thrive professionally (Mansfield et al. 2016b). However, there is still debate on the main constituents and processes of teachers' resilience. Related to the clinical understanding of resilience, teachers' resilience was initially defined as primarily an individual trait, quality, or capacity that makes teachers able to adapt and thrive in times of adversity (Brunetti 2006). More recently, a multidimensional and context-sensitive view of resilience has progressively emerged, including in the field of teachers' resilience (Mansfield et al. 2016a; LeCornu 2009). In particular, scholars tend to agree in describing resilience as a dynamic *process* or *outcome* that is “the result of the interaction over time between a person and the environment and [that] is evidenced by how individuals respond to challenging or adverse situations”

(Mansfield et al. 2012, p. 358). From this perspective, although resilience can be mainly observed as an individual ability, such an ability should be considered the result of a complex and dynamic interaction between contextual and individual risk and protective factors.

In addition, resilience is closely related to adversities, as it might be demonstrated only while facing an adverse situation (Doney 2013; Fletcher and Sarkar 2013), be it a single disruptive event or, as more likely in the case of teachers, the result of multiple ongoing daily challenges (Gu and Day 2013).

Furthermore, dynamic and reciprocal tensions among the difficulties and resources generate differential states and outcomes in terms of professional well-being and positive, negative, or dysfunctional adaptation, where resilience refers to positive and functional adaptation. Various interpretations of positive adaptation have been reported in the literature. For example, Mansfield et al. (2016a) found ten main resilient outcomes: well-being, commitment, job satisfaction, agency enthusiasm, work engagement, a sense of belonging, responsibility, passion, enjoyment, and engagement. A sense of effectiveness was also mentioned by Day and Gu (2014) as a key component of teachers' resilience. Finally, a sense of balancing between professional and personal identities was emphasized by Antonovsky (1997) as the core aspect of teachers' resilience. Day and colleagues (Day et al. 2005) also argued for the importance of considering the reciprocal coherence between professional and personal life as a key aspect of teachers' resilience. In the Swiss study mentioned in this chapter, positive adaptation was interpreted in terms of professional well-being as a combination of job satisfaction, a sense of positive engagement with the profession, and a sense of perceived effectiveness.

Finally, teachers' resilience is an ongoing process rather than a stable condition. The processual nature of teachers' resilience is particularly evident in relation to the different professional and life phases. Individual developmental needs and priorities usually change across the professional life phases as well as teachers' identity, values, beliefs, and expertise that progressively evolve. Overall, these transformations contribute to modify teachers and the ways in which they experience and face professional difficulties.

---

## Resources that Most Support Teachers' Resilience

Then, the question is, what differentiates teachers who stay resilient and their colleagues who feel highly stressed or even in a burn-out condition?

The Swiss study contributed to answering this question by empirically comparing teachers at risk and resilient teachers. Specifically, by means of a two-stage cluster analysis, the Swiss researchers first identified different profiles of teachers on the basis of their *perceived exposure to difficulties* (i.e., how often they perceived themselves to be exposed to threatening situations) and their *professional well-being* (here investigated in terms of job satisfaction, work engagement, a sense of effectiveness as a teachers, and a sense of confidence in facing professional challenges).

Five profiles of teachers were identified (Sappa and Boldrini 2018; Sappa et al. 2018):

- The *enthusiastic teachers* (36% of the sample), i.e., those who reported a high level of professional well-being and a low level of perceived difficulties.
- The *fairly at ease teachers* (19% of the sample), i.e., those who reported medium-high levels of professional well-being, without perceiving themselves to be particularly exposed to critical difficulties.
- The *weak teachers* (19% of the sample), i.e., those who showed a medium-low levels of professional well-being combined with high level of perceived difficulties.
- The *teachers at risk* (8% of the sample), i.e., those who indicated a very low level of professional well-being and a high level of exposure to professional difficulties.
- The *resilient teachers* (18% of the sample), i.e., those who showed a high value of positive well-being despite a high level of perceived exposure to professional difficulties.

By analyzing the interview data collected in the pilot phase of the Swiss study, 24 resources were identified and then grouped into six factors: (a) *sense of vocation*, (b) *resiliency attitude*, (c) *teaching and classroom management abilities*, (d) *school-related supports*, (e) *training activities*, and (f) *extra school supports*. Perceived resources and their impact on teachers' professional well-being were subsequently investigated by means of the questionnaire-based survey conducted in the second phase of the research project. Multiple analyses were performed to better understand what factors most contribute to making teachers resilient. In particular, the impact of each resource on teachers' well-being was tested. In addition, it was investigated how resources differ across the different teachers' profiles.

Unsurprisingly, all factors were found to contribute somehow to impacting teachers' well-being and to explain differences across the teachers' profiles. The theoretical interpretation of teachers' resilience and well-being as the product of the interplay between multiple individual and contextual resources was then confirmed.

At the individual level, *sense of vocation* and *teaching and classroom management abilities* were found to play a key role in supporting teachers' well-being and their resilience. First, *sense of vocation*, including passion for teaching, passion for working with young students, and the feeling of being able to make the difference in their lives, has a considerable impact on teachers' professional well-being. In addition, such a motivational attitude is typical of the resilient group of teachers, particularly in comparison to the colleagues at risk.

Another significant finding concerns *teaching and classroom management abilities* that directly affect teachers' professional well-being. In this respect, the ability to be didactically flexible and use a multitude of methods and pedagogical techniques to successfully face heterogeneous classrooms plays a key role for teachers. Such flexibility was described as particularly supportive for VET teachers who need to adapt their technical and disciplinary knowledge to real students' experience in

heterogeneous workplace settings (e.g., small vs. large enterprises, traditional vs. very innovative companies, different professional sectors). Teaching-related personal resources had a positive effect on teachers' professional well-being and contributed significantly to explaining the differences between resilient teachers and teachers at risk.

The literature on teachers' resilience provided additional confirmation of the role of intrinsic motivation for the profession and of effective teaching skills development in building teachers' resilience (Mansfield et al. 2016a). In addition, various studies have emphasized how resilience is enhanced by personal traits, such as optimism, reflectivity, and persistence. In the Swiss study, those factors were clustered in a single category, *resiliency attitudes*, found to significantly affect teachers' professional well-being. However, no differences were shown with respect to resiliency attitudes between resilient teachers and teachers who are at risk. Resiliency attitudes were instead related to enthusiastic teachers. As a consequence, our data suggest that resiliency attitudes contribute primarily to reinforcing professional well-being in the absence of critical adversities. When threatening situations occur, teaching-related personal skills and motivational resources play a more relevant role in maintaining professional well-being.

At the contextual level, *school-related resources* were very important, both in terms of professional well-being and in terms of a source for teachers' resilience.

A positive school principal's leadership was reported as being essential to supporting teachers while facing adversities. The key role of supportive, constructive, and inspiring school leaders has been demonstrated and argued by various scholars (Day 2014; Steward 2014).

Teachers' narratives collected in the Swiss study were informative about the various constituents of a positive leadership style. First, constructive feedback and encouragement from school principals were mentioned as very supportive for teachers. Especially when they are coping with difficult situations in the classroom or with other colleagues, teachers find it very helpful if school leaders can provide constructive feedback. Moreover, daily challenges are perceived by teachers as less stressful if they feel encouraged by school leaders. In addition, school leaders have a key role in moderating curricula and educational reforms' impact on teachers. Specifically, the findings suggested one factor that can make the difference between a positive and a negative implementation of such changes: the ability of the school board to negotiate the processes of standardization with the teachers and to give them an active role in defining how to manage the reform implementation and its implications. On the contrary, when those changes were perceived by teachers as strictly imposed in a top-down perspective, it had a negative and frustrating impact on their professional well-being. The importance of supporting agency among teachers, particularly in the stream of curricula reforms, has been well demonstrated in a Finnish study by Vähäsantanen (2015). The study emphasized the extent to which educational reforms can impact teachers' identity and how important it is to guide teachers to approach structural transformations in an agentic way. Any reform implies, in fact, a revision of the professional identity and activities, and it needs to be negotiated at both the individual and community levels. This process also

needs to be mediated at the school level. As reported by Vähäsantanen (2015), “leadership of educational organizations should do more to promote teachers’ professional agency, in preference to merely disempowering teachers or regulating their work” (p. 10; see also Ravitch 2013; Billett 2014).

Collegiality and a sense of belonging to the school community have an important effect on Swiss teachers’ well-being, as they prevent them from feeling alone in front of adverse situations. In this respect, training initiatives were particularly appreciated by teachers when they turned into opportunities for sharing and exchanging experiences with other colleagues.

*External supports* (from parents, friends, etc.) also contribute to reinforcing teachers’ well-being. Being supported and encouraged in the social and family environment outside the school is relevant to achieve a positive and coherent balance between professional and personal life. However, the Swiss study showed that, similar to what was reported with respect to resiliency attitudes, external supports (e.g., being supported and encouraged by family and friends) play a greater role when teachers are perceived not to be very exposed to difficulties. On the contrary, when adverse situations occur, external supports reduce their positive impact, and other variables play a major role, including motivational, teaching-related, and school-related resources.

Finally, additional analysis revealed the protective role of being involved in multiple jobs for teachers. Particularly, the interviewees described the supportive role of combining teaching with another profession at three levels.

First, at the emotional level, combining teaching with another job seemed to support teachers in “stepping back” from situations encountered at school, modulating the perceived seriousness of such situations and keeping problems in perspective. In addition, being engaged in different professional activities was described as a source of strength and a way to remain continuously stimulated by different inputs. The following quote is an example of such a feeling:

The fact of exerting my professional identity not just in the teaching domain, but also as a professional . . . that fact gives me the strength . . . and it gives me a different stimulus . . . (VET teacher, male)

Second, at the cognitive level, combining teaching with another job seems to support teachers in using different perspectives to analyze problems by improving their flexibility and their capacity to use alternative strategies to cope with problems. In addition, as reported in the following quote, interviewees declared that being engaged in different jobs empowers their organizational skills, making them even more capable of combining and balancing different activities:

In my experience, colleagues burned out mainly because they were not able to manage work and extra-work activities. . . And the surprising thought is that people who are more stressed are mainly those who were not involved in other jobs beyond teaching . . . Differently, people like me, who combine teaching with other jobs . . . see the problem [of managing a multitude of activities] in a different perspective. . . it is probably a sort of “forma mentis” . . . you need to get used to organising your time . . . (VET teacher, female)

Third, at the instructional level, various advantages were associated with the opportunity to combine teaching with another job, especially if that job was in the same field. Interviewees declared that extracurricular experiences in their field gave them stronger credibility in front of students. They were able to offer students more opportunities to connect the subject matter with the real world of work, thus reducing the risk of the students' losing sight of applicability in the world "outside the school walls." The following quote well describe those aspects:

[when combining teaching with other jobs] you are much more credible in front of your students . . . because you do not talk about things you had just studied at school, but you teach stuff you do every day . . . and that gets students even more interested and motivated (VET teacher, male)

Quantitative data confirmed a positive contribution of combining teaching with another job on teachers' professional well-being. In particular, multiple job-holding helps moderate the negative effects of school-related challenges as well as the difficulties in balancing work and other activities (Sappa et al. 2015).

In sum, teachers' well-being is the product of a combination of multiple individual and contextual factors that are reciprocally related. However, some factors are particularly important in times of adversity, when teachers are asked to be resilient. In this respect, the Swiss study suggests a prominent role for a sense of vocation, teaching and classroom management abilities, and support from school leaders and colleagues. In addition, the opportunity of being involved in multiple jobs acts positively by reducing the negative effects of threatening factors.

In the next section, teaching difficulties and resources are examined in relation to the different professional life phases.

---

## Teachers' Resilience and Well-Being Across the Professional Life Phases

Michael Huberman (1993) in his seminal work on teachers' professional life reported, "Teachers have different aims and different dilemmas at various moments in their professional cycles" (p. 193). More recently, Gu and Day (Day 2008; Day and Gu 2014) have highlighted that different teachers' professional life phases are characterized by different challenges as well as by different resources. As we have illustrated in the background section of this chapter, many vocational teachers are career changers. Data reported in the following paragraphs refers to professional life stages as a teacher. Certainly we have to consider possible effects of being involved in multiple careers. However, moving to a new job implies necessarily new paths of professional development in terms of both identity and expertise.

The first 7 years of teachers' professional life can be considered an *early career stage*. Although some differences can be found between the first and the second halves of this period (see Day 2008), the main challenging task in those years consists of testing and reinforcing teaching skills. Early teachers are often very

motivated and engaged and are very likely to be driven by a highly idealized view of the teaching profession. However, various studies report at this stage the highest rate of teachers' drop out (see Mansfield et al. 2014). The main risk in this phase is to lose self-confidence and one's sense of efficacy while experimenting in authentic challenging classrooms. Individual support through tutoring and mentoring programs is very important in this phase, as well as the opportunity for early teachers to constructively reflect on their practice and identity as a teacher (see also Mansfield et al. 2014). Similar findings were reported in the Swiss study on VET teachers. In the early career phase, Swiss vocational teachers reported a lower level of a sense of competence. Moreover, early teachers reported lower values of teaching-related personal resources. These resources are perceived to progressively increase through further professional life phases. The Swiss findings additionally showed that the highest values of identity-related challenges are reported in the early career phase. Early teachers seem to be particularly engaged in identity work to position themselves as teacher as well as to define the boundaries of their actions. Thus, teachers' resilience in this phase depends on how individual and contextual resources are particularly able to support teachers in building a sense of competence and a strong, realistic, and coherent sense of identity.

The phase between 8 and 15 years of teaching experience can be defined as the *middle phase*. Day described this phase as characterized by a growth in tensions and transitions. Skills and expertise become more consolidated, and responsibilities grow. Relationships with colleagues become progressively more important as well as recognition from school leaders. The quality of the school climate has an increasing effect on teachers' professional well-being. Findings from the Swiss study also showed that teachers in the middle phase of their career report the highest values of perceived difficulties. Teaching-related challenges are still high, and difficulties with colleagues and school leaders increase. At this stage, the focus on individual skills and competences is declining, and a sense of belonging to the school community as well as a feeling of collegiality can play a crucial role in supporting teachers' resilience.

In the *middle-late phases*, i.e., between 16 and 24 years and between 25 and 30 years, motivation is further questioned, and support and recognition from school leaders and colleagues become even more important. As reported by Day (2008), "the risk at this stage was a feeling of career stagnation linked to a lack of support in school and negative perceptions of student behaviour" (p. 248). Work-life balance becomes more demanding as teachers are likely to go through the middle adulthood life phase (approximately between 40 and 50 years old) when very often individuals – especially women – are involved in multiple caring tasks (including children and parents). Consistent with this consideration, the Swiss study reported the highest levels of difficulties in work-life balance among teachers in the middle-late phase. Moreover, generativity is described by Erikson as a core issue in middle adulthood (Erikson 1968). Generativity is closely related to the teaching profession, as both refer to the relationship with young people. While analyzing the interview data, the Swiss researchers realized that teachers in the middle of their career, who very often were between 45 and 50 years old, are those who more frequently reported a feeling

of frustration in front of demotivated students. Their authentic and profound need to make a difference in youth's lives as well as to be a role model for their students was mainly unmet due to students' lack of interest in their teachers' expertise and knowledge. Although this interpretation needs further confirmation, it seems that reaching a positive balance between personal and professional identities is a particularly prominent and delicate process in this phase.

Finally, the last phase of teachers' professional lives – over 30 years of teaching experience – has been found to be generally characterized by a high level of motivation and commitment and a strong sense of “active” engagement in the profession (Day 2008). However, a portion of teachers in this phase report demotivation, particularly because of a lack of support from school leadership and a low level of recognition of their expertise. In this respect, the opportunity to be valued for the high level of expertise within the school community is particularly important to maintain high motivation and engagement. Moreover, exposure to reforms and changes in cultural pedagogical standards is particularly frustrating for the “veteran generation.” The Swiss study also showed high levels of motivation and job satisfaction at this stage. However, perceived difficulties emerged, particularly with respect to the social recognition. Interview data also informed us about intergenerational conflicts that can emerge because of different pedagogical views or ways to approach teaching reported by younger and older teachers. Teachers' resilience at the last professional stages seems to also depend on the teachers' opportunities and capabilities to be actively involved in an intergenerational dialogue with colleagues. The main risk for veteran teachers is to develop a feeling of alienation and distance with respect to the school as it has changed over time. On the contrary, a sense of continuity in spite of changes is needed for individuals to maintain their engagement with the profession, as well as a coherent identity as teachers. Furthermore, the feeling that their expertise and knowledge will not be lost after their retirement is essential to make sense of their last years at school.

---

## Conclusion and Implications

This chapter aimed at providing an update and evidence-based overview of the difficulties and resources that most affect VET teachers' professional well-being and their ability to remain satisfied and engaged with the profession despite adversities they encounter during their career, i.e., to be resilient. The findings from a Swiss study on VET teachers' resilience and well-being were reported to explain some peculiarities of this population in addition to aspects that are emphasized by the general scientific literature on teachers' resilience.

A multitude of contextual and individual factors were described as contributing to differentiating between resilient and at-risk professional paths. Variations across professional stages were also illustrated. The result is an intricate and multifaceted description of teachers' resilience. As such, complexity, systemic, and multilevel interventions are required to support teachers' resilience.

At the *macro policy level*, teachers need to be valued and socially recognized to anchor their professional identity on a shared feeling of pride and awareness that teachers and schools can actually make a difference in students' lives. In this respect, salaries and contractual conditions represent the first evidence of social recognition and contribute significantly to supporting or hindering teachers' commitment and engagement over time. Additionally, the interpretation of vocational schools as "second-chance schools" needs to be overcome to empower teachers – as well as students – who attend those schools. In Switzerland that interpretation is limited to the Italian- and partially to the French-speaking cantons, while in the majority of the Swiss regions, VET schools enjoy a high social reputation. However, a low social recognition of VET is an important challenge for many European countries to be faced with. Furthermore, educational reforms also have to be questioned, as they have contributed to threatening teachers' well-being and enthusiasm in many countries, including Switzerland. Teachers' voices need to be more strongly considered in times of reforms to drive an authentic and participatory process of change instead of treating teachers as passive executors. An active positioning of teachers in front of a reform process is essential to prevent teachers from experiencing feelings of frustration, disengagement, and disempowerment.

The findings also showed the possibility of being involved in multiple jobs as a protective factor. In this respect, policy makers in the vocational education field should consider the potentialities of creating institutional conditions that encourage teachers to have exchanges with professional fields other than teaching, by promoting opportunities for additional job experiences (even for a short period) or by reinforcing interprofessional teams between teachers and experts in other professional fields. Some initiatives have been carried out in Switzerland.

At the *level of the school environment*, literature has widely demonstrated the key role of school leaders. Referring to the studies reported in this chapter, school leaders are crucial to build a positive climate and to spread a collaborating culture as well as to reinforce individual teachers' identity and commitment. In addition, the school board plays a key role when educational reforms are implemented at the single-school level. School leaders also contribute to determining the impact of such reforms on teachers' feelings and well-being. As a consequence, school leaders need to be adequately trained to manage not only financial and administrative tasks but also human resources and work teams. Mentoring and tutoring approaches are also recommended to provide personalized support. Teachers' resilience is, in fact, a delicate process involving personal sense-making and identity development. Contextual supportive conditions therefore need to be reinforced by the opportunity to be individually sustained. Moreover, different dilemmas, challenges, and resources are represented in different professional life phases. Thus, individual supervision or counseling should be provided throughout one's teaching career and considering variations across the professional life-span.

Finally, at the level of *teachers' education*, two implications can be outlined. First, adequate didactical and classroom management skills need to be provided, particularly in terms of flexibility. Many studies have demonstrated the strict relationship between professional well-being and self-efficacy. A sense of competence

or efficacy is also described as an essential part of the resilience concept. In this respect, VET teachers need to be supported in adapting conceptual and practical knowledge to take advantage of the full potential of integrated learning, that is, to learn by combining theory and practice in a meaningful way.

Second, students' low motivation toward their occupation was found to be a source of frustration and anger for vocational school teachers. However, professional identity development is a part of the vocational learning process, and teachers need to guide students in this process. VET teacher education should support teachers in accomplishing this task, and new pedagogical and didactic frameworks are needed to include the students' identity development as an integrated part of the vocational learning process.

To conclude, several considerations can be pointed out with respect to VET research. Although there is a growing interest in investigating resilience among specific types of teachers, e.g., primary school teachers, special education teachers, and inner-city school teachers, few studies have focused on vocational school teachers. The Swiss study reported in this chapter aimed to fill this gap. However, other studies are needed to reach a more comprehensive and generalizable view of this population. In addition, the dynamic and multifaceted nature of teachers' well-being and resilience is difficult to capture empirically. Longitudinal research should be encouraged to explore resilient trajectories instead of depicting the resilient status of teachers in a "one moment in time picture." Finally, a further investment in multi-method approaches is needed to make research more consistent with the multi-dimensional nature of teachers' resilience.

## Abstract

The first federal legislative and financial involvement in the development of formal vocational education programs in the United States, the Smith-Hughes Act of 1917, required teacher preparation in vocational education. Historically, there have been two pathways to vocational teacher certification/licensure. The first is focused on a traditional teacher preparation model, using colleges and universities with degree programs consisting of general education, technical content, and teacher pedagogy, including student teaching. An alternative pathway has relied on work experience in the discipline in which certification/licensure is sought, supplemented by a teacher education program at a university. These differing pathways have existed for over 100 years. Vocational education in the United States has suffered from negative perceptions of quality and effectiveness, and vocational teachers have also been subject to concerns regarding their teaching abilities. The alternative preparation route has had widely diverse requirements and pedagogical preparation from state to state, due to the decentralized US educational system. As a result, vocational teacher preparation

is not standardized across the United States. In addition, vocational schools using the alternative route to employ teachers have faced challenges in recruiting and retaining teachers from private industry. Another current challenge facing vocational teacher preparation in the United States is the reduction in financial support for vocational education programs, despite the need for skilled labor throughout the country. This has led to a corresponding reduced number of colleges and universities providing vocational teacher preparation programs. At a time when high-quality vocational teachers are needed, these and other concerns and challenges face the field.

## Introduction

Secondary vocational education courses and programs of study have been formally recognized by the US government for over 100 years. The first federal legislation to address vocational education, the Smith-Hughes Act, was signed into law in 1917. Since that time vocational education has struggled to find a foothold in the US educational system, battling perceptions of it as “second-class” education and as a dumping ground for less capable students. One of the primary contributors to these struggles has been public perceptions of the preparation of vocational education teachers, the resulting quality of teachers, and thus the abilities of these individuals to prepare students for the workplace or further education and training (Adams 2010; Dykman 1993; Lynch 1991, 1997; Rojewski 2002; Ruhland and Bremer 2002, 2003, Silverberg et al. 2004; Zirkle and Martin 2012). In addition, in recent years, as the United States has faced a teacher shortage in many academic disciplines, vocational education has faced its own shortages of qualified teachers, continually hampering the field’s efforts to improve both the quality of vocational education courses and programs and public perceptions of their quality. This chapter will provide a brief historical context and will examine the methods and requirements of present-day vocational teacher preparation, with a comprehensive discussion of the challenges and opportunities facing the field of vocational education as it relates to teachers in the field.

In some US states, an official credential to teach is known as a teaching license, while in other states, the required credential is referred to as a teaching certificate. The wording difference is due to the preference of individual states and is a result of the decentralized nature of the US educational system, which requires responsibility for educational policy and implementation to be held by each state. For the purposes of clarity, the teaching credential will be referred to as a teaching license in this chapter.

At the present time, vocational education is known as “career and technical education.” The name was changed in 1998 as part of a national effort to address

the negative perceptions surrounding vocational education. For the purposes of this chapter, the term vocational education will be used throughout.

---

## Historical Perspectives

In the United States, the concept of teacher preparation and licensure has been in existence for almost 200 years. In 1825 in Maryland and Massachusetts, local counties set up rules and guidelines for the licensure of teachers for area schools (Kinney 1964). However, the initial preparatory requirements for teachers were generally modest, as prospective teachers only needed to persuade a local county school board of their moral character and, in some cases, pass a test of their general academic knowledge (Ravitch 2003). In the late 1830s, noted educational reformer Horace Mann of Massachusetts proposed a system of free, universal, and nonsectarian schooling (Public Broadcasting Service 2001). These schools, called Common Schools, would provide educational opportunities for all children, regardless of religion or social class. As a result, Mann and others realized that quality schools would require quality teachers, and the Normal School was developed to train teachers for the Common Schools. Normal Schools provided training in instructional methods and subject matter. Normal Schools began to emerge in the mid-1840s; during this time some states developed and required a summer institute as a way for prospective teachers to develop skills and knowledge in both pedagogy and subject matter (Mattingly 1975). These institutes were offered as a quick way to cope with the growing number of Common Schools being opened and the resulting need for teachers.

As the country grew and developed, school systems and educational policies grew in complexity, also including requirements for the preparation and licensing of teachers. By 1927, 33 states had specialized requirements, such as 4 years of college and professional education coursework, for secondary school teaching (Kinney 1964). It was also during this time that efforts emerged to professionalize teaching and education courses and teacher preparation programs began to gravitate into regular colleges and universities. By 1960, 44 states required a bachelor's degree to teach in elementary schools (Armstrong and Stinnett 1962).

By the early 1900s, many of the Normal Schools which began as teacher training institutions had progressed into regional state universities, and their mission grew from teacher training to educational programming across the arts and sciences, business, and engineering. Universities, such as Central Michigan University, Eastern Washington University, the University of Northern Iowa, and Illinois State University, all began as Normal Schools focused on teacher training and evolved into much larger educational institutions.

An important milestone for the credentialing and preparation of teachers in the United States occurred in 1954 with the founding of the National Council for Accreditation of Teacher Education (NCATE) (2017). The organization developed initial national standards for the preparation of teachers. The organization operated independently with no government assistance and worked with a majority of states to

accredit teacher licensure programs at various educational institutions. In 1997, a competing accrediting body, the Teacher Education Accreditation Council (TEAC), was founded, and in 2016, TEAC and NCATE completed a merger into the Council for the Accreditation of Educator Preparation (CAEP), which is now the de facto accrediting body for teacher preparation in the United States.

Although organizations such as NCATE and CAEP have a role to play in assuring the quality of teacher preparation programs, teacher preparation and requirements for licensure are largely a responsibility of individual states. As a result, while there are significant similarities among the states in what is required to become a teacher, there are also notable differences. Nowhere are these differences more pronounced than in vocational education, as we will see with the forthcoming sections of this chapter.

Vocational education was one of the first content areas to require a teaching credential of its teachers, and the Smith-Hughes Act expressly required vocational teacher education programming of the states receiving federal funding (this requirement also exists in the Carl D. Perkins Act of 2006, the present-day version of the Smith-Hughes Act). However, the initial group which advocated for vocational education programming in schools, the Federal Board for Vocational Education, also pushed for different teacher preparation methods for vocational teachers. The group, led by Charles Prosser, believed that traditional college and university teacher preparation programs were not capable of meeting the needs of vocational teachers. Prosser's group also believed that vocational teachers needed practical work experience in their occupation before they could teach students (Prosser and Quigley 1949). As a result, the requirement for occupational work experience has been a consistent component of vocational teacher qualifications through the decades.

This occupational work experience requirement espoused by Prosser and others was grounded in the belief that occupational work experience would result in better student outcomes (Lynch 1997) and that these benefits would increase as more experience was held by the teacher. It was also believed that vocational teachers needed specialized preparation that university-level teacher training could not provide. The Smith-Hughes Act of 1917 specified states must have sufficient programs of vocational teacher education and provided funds to do so. Most of these initial programs were provided by the states themselves in the form of specialized workshops, not college or university preparation programs. Thus, alternative pathways for both the preparation and licensing of vocational teachers were put into place.

As noted by Lynch (1997), an interesting contradiction existed in the thinking of the individuals charged with defining the training needs of vocational teachers. While teachers from the technical trades, such as drafting, machining, or construction, needed work experience and specialized teacher training, other areas of vocational education, namely, agriculture and home economics, could prepare teachers in a traditional college or university teacher training program, provided the students had agricultural experiences on a family farm or had "homemaking projects under the cooperative tutorage of her mother and her high school homemaking teacher" (Prosser and Quigley 1949, p. 310). This approach mirrors the educational

philosophy of John Dewey, who believed that education should prepare students for a lifetime of learning and “teachers must be prepared in general education and in professional education courses dealing with the context and understandings related to students’ activities” (McCaslin and Parks 2002, p. 13). The preparation of vocational teachers in broad vocational areas, such as agriculture and business, represents a more traditional approach to licensure, requiring baccalaureate degrees in a related subject area with professional education coursework (Ruhland and Bremer 2002), and more closely resembles the traditional requirements of academic teacher licensure in areas such as mathematics, language arts, and the sciences (Zirkle et al. 2010).

This dichotomy of parallel methods for the preparation of vocational teachers continues today. As vocational education programming has expanded into other subject areas, such as marketing education and health occupations, meeting the pedagogical training needs of such a variety of individuals has presented other challenges. In response, numerous vocational teacher preparation approaches among the 50 states have emerged. Most states have developed alternative teacher preparation programs for vocational teachers from industry using the resources of colleges and universities, moving away from Prosser’s earlier assertions that the needs of these individuals cannot be served by higher education institutions. Today, many alternative programs “blend” their curriculum into programs that prepare traditional vocational teachers of agriculture, business, and home economics (now known as family and consumer sciences).

Over the years, these dissimilar approaches have sparked discussion and criticism, mostly of the alternative pathways that have been developed, some of which require very little in the way of pedagogical training (Zirkle 2016). In 1994, the National Assessment of Vocational Education, conducted by the US Department of Education (Boesel et al. 1994), concluded that the decades-long belief that extensive occupational experience was key to positive student outcomes conferred no particular benefit, although some occupational experience was beneficial. The report noted that vocational teachers “would be better off with more formal education and less occupational experience” (Boesel et al. 1994, p. 75).

A companion study by Cramer (1994) cited these alternatively licensed vocational teachers for their lack of academic preparation, while still others have noted other concerns, including exemption from teacher proficiency testing (Bonsu et al. 2013; Gray and Wang 1989; Ohio Department of Education 2017a) and widely varying requirements as well as the shrinking number of preparation programs at colleges and universities nationwide (Fletcher and Gordon 2017; Fletcher et al. 2015; Zirkle et al. 2007).

In recent years, various state departments of education have responded to these criticisms in a variety of ways. Some have sought to increase alternative vocational teacher requirements, while others have reduced them. Other states have implemented vocational teacher testing, only to remove it (Ohio Department of Education 2017b). With respect to what is needed to enter vocational teaching, these events have led to a wide and diverse set of requirements, depending upon method of entry into teaching and the state in which licensure is sought.

## Teacher Licensure Requirements

Vocational education teachers in the United States currently number approximately 231,800 (United States Department of Labor 2017). Most teach in middle and junior high schools, comprehensive high schools, and area vocational centers, although 2-year community and technical colleges and correctional institutions also employ vocational education teachers (however, most states have no licensing requirements for vocational teachers at the postsecondary level). Each teacher must meet the requirements for licensure set forth by the respective state. As previously mentioned, vocational education, with its many subject disciplines, has historically had two pathways to certification/licensure: a traditional degree-based program and several different types of alternative pathways based on occupational work experience and some form of pedagogical training. Over the past three decades, a small number of studies have attempted to define more specifically the various requirements to become a vocational education teacher in the United States.

*Traditional pathway.* In the United States, the overwhelming majority of teachers in grades kindergarten through high school are licensed through a state-approved degree program of courses leading to either a baccalaureate or master's degree in education. A typical baccalaureate degree in education generally contains three broad course categories: general education courses in English, mathematics, the arts and humanities, natural sciences, and social sciences, usually to meet a given university's degree requirement; a specific number of courses in the content area to be taught, such as a vocational business teacher taking courses in accounting, finance, business law, economics, business writing, management, and information technology; and education/pedagogy courses, including field experiences and culminating in a student teaching experience. Individuals pursuing vocational teacher licensure through a master's degree program typically have a baccalaureate degree in a vocationally related subject area, such as agriculture, business, or consumer sciences. The master's degree would consist of the education/pedagogy requirements, including the field experiences and culminating in a student teaching experience.

The education/pedagogy requirements are fairly similar across all teaching disciplines, including vocational education, although some vocational preparation programs may have work experience requirements and testing variances (Zirkle et al. 2007). Sample pedagogical preparation that is required for vocational education teachers includes such courses as:

- Foundations of education/vocational education
- Educational psychology and learning theories
- Teaching methods
- Curriculum development
- Classroom and laboratory management
- Assessment/grading of student performance
- Using educational technology in instruction (Zirkle 2015)

To obtain a traditional vocational teacher license, additional requirements may need to be completed, such as exit tests. This requirement is prevalent in traditional vocational teacher preparation. As mentioned previously, each state is responsible for setting its own educational policies, and with regard to testing of these teacher candidates, there is wide variation. Some states require a test of basic academic skills such as the PRAXIS core academic skills tests, developed by the Educational Testing Service (ETS). These tests measure academic skills in reading, writing, and mathematics. Content area tests are very common, and many states require vocational teachers to pass tests of their knowledge of agriculture, business, family and consumer sciences, or marketing. Tests of pedagogical knowledge are also very common. Some states use the PRAXIS series of teaching assessments, while still other states develop their own tests. A few states partner with testing agencies to develop state-specific tests. An example of this approach is Ohio, which uses the Ohio Assessments for Educators (Ohio Department of Education 2017c), developed by Person VUE, a major producer of educational tests in the United States.

*Alternative pathway.* It must be noted and clarified at this point that the primary requirement for licensure in an alternative pathway to vocational teacher licensure is occupational work experience. This dates back to the early days of formalized vocational programming, when the Smith-Hughes Act stated that only personnel with practical work experience were permitted to teach in programs that were federally funded (Miller 1982). From a definitional standpoint, Humphrey and Wechsler (2007) defined alternative programs as “licensing routes that allow persons to enter the teaching profession by earning a standard license or teaching certificate without completing a traditional 4- or 5-year university-based program” (p. 485).

Alternative pathways for vocational teacher preparation are quite different than the traditional pathway. While the traditional pathway has many similar structural requirements across the states, the alternative pathway does not. Zirkle et al. (2007), in their comprehensive review of vocational teacher education, found more than 100 different sets of requirements for the initial licensing of vocational teachers through an alternative pathway. Variability exists in several areas, including the number of years of occupational work experience required, the requirement for specific occupational credentials, educational background, and the length, type, and methods of vocational teacher preparation.

As noted previously, occupational work experience has been a hallmark of vocational teacher licensure dating back to the early 1900s and has been specified through a variety of policies and state requirements through the years (Lewis 1926; Barlow 1967; Pinchak 2007). In a 1996a study, Lynch found the requirement for occupational work experience to be a range between 2 and 9 years. Zirkle et al. (2007) found this range to be 2–7 years, although they found some alternative routes which did not require work experience, but required passage of an occupational knowledge test. A study by Bonsu et al. (2013) found the occupational work experience requirement to be prevalent but also listed more flexible options to the work experience requirement, such as appropriate content area coursework professional development or passage of an occupational knowledge test.

The requirement for a specified level of education for vocational teachers entering through an alternative pathway is also varied. While traditional academic teaching disciplines have parallel content area degrees (e.g., baccalaureate degrees in mathematics, English, or chemistry), many vocational areas, such as automotive mechanics, electrical trades, or welding, may have no postsecondary degree. Instead, individuals in these areas get their training through various methods, such as apprenticeships, military training, on-the-job with a private company, or perhaps an associate degree from a community or technical college. The licensure requirements for vocational education teachers generally recognize these circumstances and set the minimum educational standard at a high school diploma. In some cases, there are a set of requirements that specify a minimum level of both occupational work experience and education and there can be some “give and take” between these requirements. For example, a state may require a high school diploma and 5 years of work experience, or if the individual holds a 2-year associate degree in a related occupational field, the work experience requirement may be reduced to 3 years.

Certain states may also require that industry-recognized certifications be held by vocational teachers. For example, industry certifications such as Automotive Service Excellence (ASE) and the American Welding Society (AWS) may be required to teach automotive technology or welding programs, and a separate professional license to practice as a registered nurse may be required to teach some health occupations programs.

Testing of these alternative pathway vocational teachers has been varied and has occasionally resulted in unforeseen outcomes. In addition to requiring occupational work experience, some states require a test of occupational knowledge. An example of this assessment is the National Occupational Competency Testing Institute (2017) set of teacher tests. These tests assess the technical knowledge of vocational teachers, and states can set requirements for an appropriate passing score in order to be licensed. Other states have developed their own technical knowledge assessments, while others do not require a technical knowledge assessment. To add to the variability of testing requirements, some states require passage of a test of pedagogical knowledge, using the PRAXIS tests or some other similar assessment. In some cases, these requirements have had mixed results. Many of these pedagogy tests have been standardized or “normed” on graduates of 4-year university teacher education programs. An overwhelming majority of individuals entering teaching through an alternative pathway do not have degrees in education; instead they may have degrees in nursing, agriculture, or business or perhaps no college education at all. In 2005, the state of Ohio implemented the use of the PRAXIS teaching assessment, only to remove it soon after when many vocational teachers could not pass the test.

Actual pedagogical preparation of vocational teachers has also been extremely varied with respect to the amount of training provided and required. Zirkle et al. (2007) found a few states that required as few as 90 clock-hours (equivalent to 6 semester credit hours) of teacher training as part of initial licensure, to states requiring between 45 and 60 semester hours, depending on the alternative pathway taken. This variability in the preparation of vocational teachers may be in part

responsible for the negative public perceptions of vocational teachers and vocational education in general in the United States.

Most states have limits on the duration of a teaching license and require periodic renewal of the credential. Again, there is much variability in this area due to individual state requirements. However, in general, teaching licenses generally are in effect for 4–5 years and then expire. Teachers must complete professional development activities to renew the license. These activities can include college/university coursework in a vocational content area, or teaching pedagogy; professional development activities, such as workshops and seminars; or, in the case of some vocational teachers, industry updates in the form of manufacturer-sponsored technical update training. With respect to the renewal of their teaching licenses, vocational teachers can be challenged to keep up with innovations in teaching methods while, at the same time, be required to stay current with technological changes within their occupational area.

---

## Providers of Vocational Teacher Preparation

As referenced earlier, based on the beliefs of Prosser and others, the early years of vocational teacher preparation saw special workshops and other activities delivered by the states to those individuals entering teaching through business and industry. These efforts did not initially include colleges and universities. However, as time passed, many of the land-grant universities, which initially prepared agricultural education and home economics teachers, also began to offer alternative programs for vocational teachers entering the profession from business and industry. The Pennsylvania State University, the Ohio State University, and the Virginia Agricultural and Mechanical College (now known as Virginia Tech), which are all public, land-grant research universities, developed programs to prepare individuals for the teaching profession in a variety of traditional, degree-based programs as well as alternative pathways.

Vocational teacher preparation has historically had the support of the federal government, both in legislation and with monetary funding. Beginning with the Smith-Hughes Act of 1917, federal monies have been earmarked for various vocational teacher preparation programs. These funds, directed to the states, eventually found their way to college and university programs, which provided the needed pedagogical training. It should be noted that while much of the training in recent decades has been provided by colleges and universities, states have held the ability to provide the training themselves or to use third-party providers, dependent upon the individual state requirements for vocational teacher licensure. Lynch (1996b) found that pedagogical training provided to vocational teachers outside the confines of a college or university consisted of an average of only 120 clock-hours of training through either state programming or third parties.

In 1991, Lynch sought to define a national database examining, among other data, a listing of the providers of vocational teacher preparation at colleges and universities. In this study, Lynch found 90 teacher education programs in agricultural

education, 236 in business education, 32 in health occupations education, 268 in home economics education, 89 in marketing education, 176 in industrial arts or technology education, 122 in trade and industrial education, and 98 in vocational special needs (Lynch 1991, p. 191). A total of 432 educational institutions were listed as providers of vocational teacher preparation programs (some institutions offered preparation in more than one program area). At the time of Lynch's work in 1991, traditional degree-based programs were found within agricultural education, business education, home economics education, marketing education, and industrial arts or technology education and in vocational special needs, while alternative programs made up most of the preparation health occupations and trade and industrial education teachers, as these individuals were more likely to be entering teaching through business and industry. This structure is largely still in place today.

By 1996, many vocational teacher education programs were beginning to consolidate (Gray and Walter 2001) and had merged the preparation of their teachers into one common program of study. Thus, programs that previously may have prepared business teachers were folded together with home economics programs or agriculture education programs as a way to survive. In 2001, Bruening et al. sought to replicate parts of Lynch's earlier work and found some of the effects of this consolidation. Their study found 385 institutions across the United States offering some type of vocational teacher preparation program, an 11% decrease from Lynch's study just 10 years prior.

Numerous other studies in the late 1980s to early 2000s also documented the decline of various forms of vocational teacher preparation (Anderson 1986; Camp 1998; Hartley et al. 1996; Lynch 1996a, 1997; Miller 1982; Pratzner and Ryan 1990; Ruhland and Bremer 2002). Some of this decline can be attributed to declining enrollments in secondary vocational courses and programs in the late 1980s and early 1990s. These events also helped serve as a catalyst for many of the curricular changes occurring within the discipline of vocational education, starting in the late 1990s with the name change to career and technical education.

In 2015, Fletcher et al. replicated in large part the work of Bruening et al. (2001). Their study found 263 higher education institutions providing some form of vocational teacher preparation, either traditional, degree-based programs or some type of alternative preparation. This study documented the continued decline in vocational teacher preparation programs. In the past decade, a number of large universities with notable legacies of vocational teacher preparation have dropped some or all of their programs, including the University of Kentucky, Purdue University, and the University of Minnesota. A follow-up study by Fletcher and Gordon (2017) elaborated upon the 2015 study and noted the need for colleges and universities to consider online instruction in teacher preparation, the need for the recruitment of a talented and diverse vocational education teaching force, and that declining enrollments in vocational preparation programs were an ongoing concern.

As colleges and universities have reduced their involvement with vocational teacher preparation, states have offered workshops and seminars themselves or have contracted with third-party providers to provide teacher training. One of the more well-known providers is the Southern Regional Education Board (SREB), which offers a

program entitled *Teaching to Lead*, a 200 clock-hour program designed for new vocational teachers pursuing an alternative route to licensure. Many southern states, such as Mississippi, Tennessee, and Western Virginia, use the SREB-developed program to prepare at least some of their vocational education teachers.

---

## Present-Day Issues and Challenges

At present, vocational education is experiencing a renaissance of sorts. Decades-long negative perceptions of vocational education programming are slowly changing (Zirkle 2016). Several initiatives have contributed to increased interest in vocational education. Project-based learning has become a common instructional method in vocational education courses and programs. These projects are often multidisciplinary, integrating multiple core academic areas. This approach incorporates rigorous academic content and focuses on skills needed by the workplace such as collaboration, communication, and critical thinking. As such, the academic preparation of vocational education students has vastly improved, which better prepares them for the workplace of the twenty-first century. This focus on academics has also helped develop initiatives such as postsecondary articulation between secondary and postsecondary vocational education courses and programs, which have led to “dual-credit” courses, in which students can earn college/university credit while enrolled in a secondary program. In addition, vocational education curricula have moved away from preparation for one specific occupation. The curriculum has been organized into career clusters, a curricular framework of broad career areas, designed to prepare students to transition successfully from high school to postsecondary education and employment in a career area. Imbedded in many of these courses and programs is an emphasis on work-based learning, featuring internships, pre-apprenticeship programs, and other efforts to get students “real-world” experiences outside the classroom.

As vocational education becomes more a part of the educational mainstream in the United States, other events are affecting the discipline in less positive ways. The United States is experiencing a nationwide shortage of skilled labor, particularly in several areas specific to vocational education (Applebaum 2017; Donnelly 2017; Mayersohn 2017). Occupations such as the construction trades (carpenters, electricians, plumbers, etc.), the manufacturing industry (machinists, welders), and the transportation sector (automotive technicians and mechanics) are facing an aging workforce with significant uncertainty as to where replacements will come from.

In addition, the American culture still prizes a 4-year college/university degree above all other forms of education. Many students, school officials, parents, and policymakers still believe the only path to success is through a baccalaureate degree. This perception exists despite the data documenting wages for technically skilled workers in the construction, healthcare, manufacturing, and transportation industries ranging anywhere from \$48,000 to \$65,000 for occupations requiring less than a bachelor’s degree (United States Department of Labor 2017).

The teaching profession in the United States does not hold high social status. In a recent study of the social status of teachers, the United States came in the ninth,

behind such countries as China, South Korea, and New Zealand (Klein 2013). In addition, the attrition rate for teachers in the United States is high, with as many as 8% of the teaching force leaving the profession each year (Westervelt 2016). This statistic, coupled with dwindling numbers of college and university students entering teacher education programs, has led to significant teacher shortages, especially in the areas of math, science, and special education.

The variability of the requirements for vocational education teachers, particularly those prepared through some type of alternative pathway, has led, in part, to a long history of challenges and concerns related to vocational education teacher quality and the expertise and abilities of these individuals. Numerous studies and analyses in the last quarter-century (Adams 2010; Cramer 1994; Dykman 1993; Lynch 1991, 1997; Rojewski 2002; Ruhland and Bremer 2002; Silverberg et al. 2004; Walter and Gray 2002; Zirkle and Martin 2012) have discussed this issue, with various recommendations made, largely on the basis of anecdotal evidence and observations. To date, scant research has been conducted to examine the associations between specific characteristics of CTE teachers and student performance in CTE courses and on standardized assessments. The lack of a national research agenda for vocational education has exacerbated this issue.

Finally, despite the recent resurgence of vocational education, the federal funding for courses and programs through the Perkins Act (the present-day version of the Smith-Hughes Act) has actually decreased by \$188 million in the period from 2004 to 2017 (Advance CTE 2017). This has led states in many cases to cut or discontinue funding for vocational teacher preparation, whether to colleges and universities, state programs, or third-party providers.

All of these issues have had significant impacts on vocational teacher preparation and the licensing of vocational teachers. As vocational education becomes more of a “first choice” in the minds of students, the need for quality teachers has never been more apparent. The ability for vocational education courses and programs to offer college/university credit and prepare students for both college and a career has put more of an emphasis on teacher quality and, in turn, high-quality teacher preparation.

This focus on quality comes at a time when skilled labor is in high need, and enticing talented workers to enter teaching is a challenge. This has led vocational education to experience many of the same teacher shortages documented in academic areas. This situation is not helped by the present social status of teaching in the United States nor the fact that recent studies have shown teacher salaries have fallen when compared to other professional occupations requiring a similar level of education (Baker 2017; Mulhere 2017; Partelow 2016). On average, beginning teachers make about 20% less than college graduates in other fields (Podolsky et al. 2016). While business and industry is increasing salary and benefits to recruit and retain skilled individuals, schools simply cannot compete on these key aspects of employment.

Part of the teacher shortage is driven by the low retention rates of new, beginning teachers. With respect to alternatively prepared teachers, research has shown (Carver-Thomas and Darling-Hammond 2017; Schaffhauser 2014; Strauss 2017) that the longer a teacher receives mentoring and stays engaged in pedagogical preparation, the longer they are likely to remain in teaching. Unfortunately, one of the current trends in

vocational teacher preparation has been to lower the requirements for entry into teaching as a way to address the teacher shortage, either through lowering the number of college/university credit hours needed or by creating more alternative-type paths, using third-party providers or state-developed online “modules” designed to get a vocational teacher into the classroom quickly. These efforts would seem to be in opposition to the research that demonstrates the need for ongoing, structured mentoring and training of vocational teachers entering from business and industry. This situation has also been magnified by the lack of increased funding for vocational education through the Perkins Act. As less funds are available overall, monies for teacher training of any type are compromised.

It would seem there exists a “perfect storm” of events affecting vocational teacher preparation at the present time. The labor market needs skilled labor, which reduces the pool of potential teacher candidates. The social status of teachers in the United States, along with low salaries, is discouraging individuals from entering the profession from either traditional or alternative pathways. Vocational teacher preparation programs at colleges and universities are struggling to keep operational, in part to lower requirements and standards for vocational teachers, and because of a lack of federal funding to support their efforts. The reduced requirements, while intended to reduce a teacher shortage, may actually be compounding the situation by producing poorly trained teachers, unprepared for the demands of teaching. The resulting revolving door of teachers entering and leaving the profession as a result will only harm efforts to improve the status and quality of vocational courses and programs.

---

## Conclusion

It would seem prudent for the United States to invest in their vocational teachers, rather than “watering down” both the requirements for entry into the profession and the resulting preparation. Doing so will require effort and allocated resources on the part of legislators, policymakers, educators, and the public at large. To stem the skilled labor shortage, the country must have a cadre of teachers to prepare both present and future workers. These individuals must be prepared to address the challenges inherent in a vocational classroom and laboratory. Shortcuts and abbreviated preparation will not achieve the needed results, nor will it improve the public perceptions of vocational education and its teachers. More than 100 years ago, Prosser and his colleagues, and the resulting Smith-Hughes Act, recognized the importance of teacher training in the vocational education equation. It is equally important today.

## Abstract

This chapter addresses different perspectives on the development and current state of play of TVET teacher training in Russia against a historical context of TVET evolution in the country. In the Introduction, basic facts and figures about the TVET system are presented followed by a brief historical overview of the evolution of TVET teacher training in Russia. This is presented against the transformations of the training of workers in the twentieth century when training teachers for TVET acquired a systemic character and respective research and programs began to be developed. The next section looks into the impact of societal and developmental factors, such as challenges of sustainable development, green economy, and green skills fostering, on the competences of teachers. Key weaknesses of the system of TVET teacher training are identified, and a set of measures to enhance its quality are reviewed. Challenges for TVET teacher training as well as solutions adopted are addressed, including the search for ways to effectively foster new competences of TVET teachers relating to changes in the graduates' skills required by the labor market in the framework of the sustainable development agenda and of the greening of the economy (green jobs, fostering

## Introduction

In this chapter, a brief analytic overview of the evolution and current state of play of the TVET teacher landscape in Russia is presented against the background and evolution of the TVET system that in Russia is called secondary vocational education (SVET). However to avoid confusion, in this chapter, it will be referred to as TVET. Under the Law “On Education in the Russian Federation” adopted on December 29, 2012, the TVET system in the Russian Federation embraces both initial VET programs training qualified workers and secondary vocational education programs training mid-level specialists (Zakon 2012).

Before the adoption of the Law, the vocational education system was explicitly divided into two strands, namely, initial and secondary vocational education.

In terms of qualification levels (the European Qualifications Framework), programs training qualified workers can be compared to EQF level 3, while those training mid-level specialists can be compared to EQF level 4 and 5 (the latter advanced programs with a stronger practical focus) (The European Qualifications Framework 2011).

Initial and secondary vocational education programs can be accessed after completion of general secondary education (9 grades) or complete secondary education (11 grades). For those after the general secondary school, the programs integrate general education subjects, so that upon graduation students have an occupational qualification and a certificate of complete secondary general education. Naturally, the duration of training under these programs will be longer. The vocational education component of the curricula is identical for both categories of programs.

The overall TVET teacher cohort in Russia amounts to about 220,000 (2016 data) people, including 50,000 instructors of practical training. Over 87% of TVET teachers and 36% of instructors of practical training have a higher education; in addition, over 200 and 4,500 teachers have a doctoral and a postdoctoral degree (in Russian terminology, they are candidates and doctors of science), respectively. TVET programs are offered by technicums and colleges, and they are also implemented at 400 higher education institutions (Zolotaryeva 2016).

Like in many countries across the world, TVET in Russia originated in the fourteenth century within the crafts shops where apprentices learnt on the job from

the master craftsman. At this period, the knowledge, skills, and know-how for a specific trade were vested in craftsmen.

In the first half of the eighteenth century, first signs of the state's regulation of education appeared, with the opening of vocational schools, accompanied by the adoption of regulations for the content of study programs and of procedures for organizing instruction.

Starting from the early nineteenth century, in the context of the country's industrial growth, crafts schools emerged that were very well equipped and employed the best teachers and instructors available. During this period commercial schools (training students for the sector of commerce) and popular/people's schools (training teachers for primary schools) appeared. These were followed by engineering schools (also called industrial-technical schools) that marked the birth of the system of higher engineering education. The network of industrial-technical schools was later transformed into sector-affiliated higher education institutions, with profiles ranging from pedagogy to architecture to technology to civil engineering to agriculture and later on to railroad building and to veterinary science.

By the second half of the nineteenth century, the TVET system as such was formed, and the "General normal plan for industrial education in Russia" was adopted. (The titles of documents and publications are reproduced in the word-for-word translation.) Toward the end of the nineteenth century, the TVET system comprised crafts schools and lower and secondary technical schools for boys of 11–14 years of age. The content of 3-year programs was largely practical work-based training under the guidance of specialists from industry. No specific preservice TVET teacher training was in place, which negatively impacted the quality of training.

At this time the never-ending debate about the content of TVET programs started, triggered off by a publication "Vocational schools and teaching crafts to the youth" produced by Nicolay Vessel who advocated against teaching general subjects at TVET schools, claiming that TVET should admit only the youth with a sound general school education. This debate recurs every once in a while up to the present day (Saprikin 2009).

At the turn of the past century, the first theoretic approaches to TVET were developed that later impacted the content of TVET teacher training. For example, it was proposed to organize the TVET training around operations and techniques appropriate for an occupation, but without regard to the final products (Kairov and Petrov 1968). At that time, this methodology was widely acclaimed internationally. Namely, the Russian TVET system got international recognition at the Polytechnic Exhibition in Moscow in 1872, at the International Fair in Vienna, and at the International Industrial Fair in Philadelphia in 1876.

The above approach persisted for decades in the Soviet and post-Soviet TVET system in Russia, and it still widely – even if subconsciously – impacts the mentality and practices of TVET teachers and methodologists, slowing down the implementation of outcome-based approaches.

However, at the time of its origin, it had an indisputable advantage, allowing one teacher to train a big group of apprentices.

Due to the development of the TVET system, in 1910 there were 1,423 TVET schools in Russia, with over 80,000 students. And to regulate the system in 1916, the Council for Affairs of Vocational Education was established chaired by Minister of People's Education Ignatyev.

After the 1917 revolution, the TVET system lived through various stages. During the first years of the Soviet State, all achievements of the earlier TVET system were disowned, and the continuity with the past was severed for ideological reasons (Shaïdenko 2002). As a first step, all TVET schools (private, public, sector affiliated) were integrated despite the differences in the content and methods of training, and about 20 policy decrees were issued about TVET. In July 1920 a Decree on the compulsory participation in TVET (the so-called TVET "conscription") was issued making it mandatory for all workers from 14/18 to 40 years of age to undertake some sort of vocational training. Then the so-called factory-plant apprenticeship schools were established that were the first TVET schools in the Soviet Union. The keynote idea underpinning these developments (advocated by Alexei Gastev [1882–1939, a revolutionary, trade unionist, poet and writer, theorist of the scientific labor organization, director of the Central Institute of Labour]) in terms of the content of training was to separate TVET and general education content.

On October 2, 1940, a centralized system of vocational and technical education was established by the Decree of the Presidium of the Supreme Soviet "On the state labour reserves of the USSR," and a Regulation "On conscription of urban and rural population to crafts schools, railroad-building schools and schools of factory and plant training" was adopted. The Decree stipulated the establishment of two types of TVET schools – schools with a 6-month duration of training to train workers of mass occupations and 2-year crafts and railroad schools to train qualified workers.

During the Great Patriotic War of 1941–1945, TVET schools were transformed into the so-called "school plants" that produced ammunition for the front. In 1959–1963 the above schools were transformed into TVET schools with differing duration of training. And then a whole package of reforms followed. In 1987 all TVET schools were transferred under the jurisdiction of the Ministry of General Education.

---

## **TVET Teacher Training**

The above processes of TVET evolution could not but impact training of the teaching staff for the system. Some issues relating to this evolution bear a systemic character and were common to many countries, conditioned by a gradual crystallization of TVET as a system in its own right, and some are country specific, as the dramatic turns in the development of Russia exacerbated TVET's quest for its identity, which naturally reflected on the training of teachers.

TVET teacher training was shaped within the overall social institute of teacher training and will be examined against this broader context.

As indicated above, originally occupational knowledge and skills were transferred from craftsmen to apprentices in the process of what we now call work-based

learning. The first mention of the training of vocational teachers in Russia goes back to the end of eleventh century. However at that time the teachers did not receive any pedagogic education, they taught the skills they themselves had been taught.

In the nineteenth century, teacher education (or, as it is commonly called in Russia today, pedagogic education or professional-pedagogic education) was meant to train teachers who could teach literacy and numeracy or a broader range of general education subjects to children. Teacher training programs offered at universities aimed largely at training teachers for the same universities. On top of that, 3-year pedagogic institutes (preservice teacher training institutions) were opened at universities to train primary and secondary school teachers. However, they did not last long.

After 1864, specialized preservice teacher training institutes were established. In 1892 “Rules for future specific subjects teachers and for supervisors of practical classes at secondary and lower technical schools” were adopted, stipulating the requirements to hiring teachers. According to these requirements, people from industry, who were graduates from sector institutes and secondary technical schools, were eligible to work as TVET teachers.

Later, 1-year teacher training courses were launched for holders of a university or higher technical school diploma. However, the curricula did not have a practical training (work place) component, and the courses of pedagogy and history of pedagogy were very generic. The above model was not perfect and often relied on a trial and error method that could hardly prove effective for a beginning teacher, or instructor of practical training.

By 1917, there were 58 preservice teacher training institutes, and their graduates were offered a sound grounding in pedagogy and methodology.

Within the above system of teacher preservice and in-service education, the system of TVET teacher training (also often referred to as professional-pedagogic education and engineering professional education) shaped. The history of professional—/engineering-pedagogic education can be said to have passed through a number of stages.

Stage 1 started in the 1920s. During this period, the “Head Committee for Vocational Education” was established. Also, research in this area began to emerge, on issues of the organization and methodology of preservice TVET teacher training and of curricula content, using the experience of Germany and the United States. At this stage the term “engineer-teacher” emerged, and its evolution started. The term “engineer-teacher” suggests a combination of functions of the instructor of practical training and of a teacher of specific and generic occupational subjects. The term “engineering-pedagogic education” is often used in Russia as a synonym of a broader term “professional-pedagogic education.”

The need for TVET to have its own teacher training system was first voiced in Russia by Rubinstein who claimed that a TVET teacher must be an engineer competent in his or her occupational field, with competences in the field of psychology and pedagogy. According to him, the curricula for training TVET teachers must embrace philosophy and methodology of technical sciences, pedagogy, and history of pedagogy, psychology, anatomy of a human being, hygiene, and others (Rubinstein 1927).

In Petrograd (now St. Petersburg), the first professional-pedagogic education institution was opened in 1920 – a Technical Pedagogic Institute – which offered part-time programs for holders of a higher education diploma. The 6-month program comprised 30 general technical, specialization, and psychological-pedagogic subjects. However, the latter were very modest in volume and comprised experiential psychology, experiential pedagogy, history of schools and methods of teaching, and four methodological disciplines. Unfortunately, this experiment was short-lived for lack of equipment, manuals, and teaching and learning materials.

Other forms and formats of engineering-pedagogic education also existed, like the higher scientific-pedagogic courses, to retrain holders of higher education diplomas or graduate students. These courses trained TVET teachers of polytechnic and specialization (occupation specific) disciplines. However, their organizational and pedagogic aspects lacked an in-depth perspective. With time, three strands of training (or profiles) crystallized, namely, two for teachers of technical subjects (1 or 3 years of study) and one for instructors of practical training (9 months).

The training of instructors of practical training began after the establishment of Moscow industrial-pedagogic technicum where future instructors not only obtained a secondary TVET diploma (equivalent of level 4 EQF) but also acquired a sound occupational training.

A prototype of higher education institutions and faculties making up the contemporary system of professional–/engineering-pedagogic education can be observed in the Losinoostrovsky Agro-Pedagogic Institute (1922/1923) that offered fully fledged higher education programs integrating pedagogic and occupation-specific subjects.

As a rule, the engineering-pedagogic curricula covered engineering and technical subjects, psychology, pedagogy, and occupational skills development, as well as subjects relating to the management of TVET institutions or of training units at enterprises. As a result all curricula had sector-specific elements.

In the beginning of the 1930s, there were three professional–engineering-pedagogic institutes and over ten teacher training institutes offering training to TVET teachers. However, in 1937 all of them were closed down, and the preparation of staff for TVET went back to the short-term courses (lasting from several days to 6 months). This can be explained by a number of reasons, the central one being a lack of research to support the development of professional-pedagogic education.

The second stage goes back to the early 1940s. By 1942–1943 in the context of the Great Patriotic War (Second World War), industrial-pedagogic technicums (technical colleges) and teacher training departments at sector-affiliated colleges were established to train TVET teachers and instructors of practical training (the latter would have a secondary technical qualification, pedagogic knowledge, and a high occupational qualification).

The attention to instructors of practical training was conditioned by their dramatic shortage. In 1945 instructors were trained at 16 technicums and in 22 occupations of training. These technicums offered programs to workers who had an incomplete secondary education (seven classes at that period) and an occupational qualification of workers and who opted for a qualification of an instructor of practical training.

The content of training embraced general education subjects (39.9%), generic technical subjects (20.0%), specialization subjects (26.2%), pedagogic subjects (8.6%), work placements at the enterprises, a practical teaching period, and a practical training period prior to the presentation of the diploma project, as well as military training and preparation of the diploma project. There was a mandatory requirement for graduates to work as instructors of practical training for no less than 5 years after graduation.

After the war, the mass character of TVET resulted in the establishment of professional-pedagogic departments at universities. However the programs implemented at these departments focused on specialized occupation-related content, which undermined the quality of training TVET teachers.

The third stage began with the reform of the system of education stipulated in the Law “On the strengthening of links between school and life and on the further development of the system of people’s education in the USSR” that was promulgated at the end of 1958. To implement the reform, more TVET teachers were needed. To this end new departments/faculties were opened at the teacher training and sector institutes. By 1959 such education institutions amounted to 123 (On the reform of general and vocational school. Collection of documents and materials 1984).

In 1966, the All-Union Institute for Upgrading Qualifications of Engineering-Teaching Personnel opened with branches in many regions. Later on, upskilling faculties for this target group were established at sector HEIs.

Despite the above, the quality of training was not high for lack of a systemic approach, as the content of the implemented curricula represented a sum total of subjects from engineering and teacher training programs without a due focus on the specifics of the environment the graduates were supposed to work in.

At this stage the number of industrial-pedagogic technicums and occupations of engineers-teachers grew. In 1970 they were also trained at 13 higher education institutions.

It was during this period that in-depth theoretical and methodological research into issues of professional-pedagogic education began (Ternovskaya et al. 2014).

Until the late 1960s to early 1970s, TVET teacher training was still seeking its identity within the teacher training education. As a result, a network of higher education institutions training TVET teachers emerged that grew rapidly in the 1970s to early 1980s. By 1970 there were 52 universities in Russia, one third of graduates from which got jobs at schools and TVET schools. For example, in 1975 TVET teachers for the agricultural sector were trained at five HEIs (Batyshev 1976).

The fourth stage began in 1979 with the establishment of the Professional-Pedagogic Institute in Yekaterinburg (transformed in December 1993 into Urals State Professional-Pedagogical University), followed by two more – in Kharkov (now Ukraine) and in Nizhny Novgorod. These institutes pursued a twofold aim of providing a sound pedagogic/psychological education and occupation-relevant skills to its students – future teachers for secondary and higher education institutions (Romantsev and Fedorov 2010).

Currently, the Yekaterinburg University is the leader in professional-pedagogic education (that is also called engineering-pedagogic education). It has initiated a

methodological network of universities and colleges involved in training TVET teachers and instructors that comprises 222 education institutions (134 HEIs and 88 colleges where a qualification of instructor of practical training can be obtained). The university delivers both bachelor- and master-level programs.

In the 1980s much attention was given to enhancing quality of teachers for general and TVET schools, as was stipulated in the policy documents “Key areas of reforming general and TVET schools”; “Key areas of re-structuring higher and secondary specialized (TVET) education” (Key areas of reforming higher and secondary specialized education in the country. Collection of documents and materials).

By the mid-1980s, the content of university TVET teacher training curricula integrated provision of sound knowledge related to the sector occupation and to academic subjects, and fostering psychological and pedagogic skills.

The fourth stage lasted from late 1980s to early 1990s and carried further the developments of the previous stage. At this stage the quality of skills of graduates from TVET teacher training institutions enhanced. However, the taken measures failed to fully meet the demand for teachers and instructors of practical training.

The fifth stage started in the early 1990s of the past century, with a tectonic and often dramatic change in Russia’s political, social, and economic developmental paradigm and is currently on (Bolotov et al. 1992).

In the early 1990s, many HEIs stopped training TVET teachers for about 5–7 years. By the early 1990s, there were 2 engineering-pedagogic universities, 38 faculties at HEIs, 68 industrial-pedagogic technicums, and a network of institutes for upgrading teacher qualifications (Fedorov 2001).

---

## Current State of Play

In the overall number of TVET teachers of generic occupational and specialization subjects, the majority have a higher professional-/engineering-pedagogic education, 5% have a secondary professional-/engineering-pedagogic education, and 1% have initial vocational education. About three quarters of the administrative and teaching staff are specialists with an industrial background without a teacher training qualification.

Quality of training teachers for the TVET system is a key target of the national policy in education, including TVET. This objective is explicitly stated in the Strategy for the Development of the System of Training Workforce and Fostering Applied Qualifications up to 2020 (Zeer et al. 1994). This issue is also in the sights of the Union of TVET Principals (a professional association of principals of TVET institutions established as a forum for fostering mutual learning, disseminating best practices, and initiating relevant change on the policy level).

The adequate supply of qualified teachers and instructors of practical training for the TVET system remains an issue and continues to top the education system agenda both on the policy and practical level, despite abundant research and publications on these issues. It would not be wrong to assume that the traditional model of training

TVET teachers lacks a student-centered orientation and a focus on practical aspects of organizing the learning of the students. This may be due to the gap between the research findings and their implementation.

Despite the above, positive developments are obvious. Namely, after the period of the early 1990s marked by political and economic changes due to a dramatic change in the political and economic development paradigm, and despite the never-ending chain of financial crises, enterprises in Russia have developed an awareness of their own role in enhancing quality of TVET and that of training teachers for the system. To this end, they are increasingly cooperating with TVET schools, which results in fostering new skills in TVET teachers relating to the cooperation with the world of work. Teachers and instructors of practical training now have access to internships at enterprises and to a first-hand exposure to industrial developments.

On the whole, the awareness of a need for new TVET teacher skills is growing, and opportunities for their acquisition are formally integrated in the content of preservice curricula and in-service teacher training programs, all of which are competence-based and address fostering subject-specific and generic competences.

However, the new developments have not yet fully transformed the TVET teacher training system, and the current situation remains characterized by a dual bottleneck, that of skills shortages and skills gaps. The first issue relates to a persistent shortage of TVET teachers and instructors (around 30%, by the RF Ministry of Education and Science estimates). The second relates to a lack of up-to-date competences in teachers.

This may be due to the fact that TVET teacher training curricula fail to offer a balance of psychological, pedagogic, and occupational content. Also, university teachers training TVET teachers remain themselves largely within the knowledge-based teacher-centered paradigm and fail to implement in practice the synergy of up-to-date methodologies adequate to the present-day requirements.

The content of curricula in higher education remains discipline-based, even though formally competences underpin the structure of the curricula. The comprehensive student-centered paradigm is missing and is often replaced by active methods of teaching.

Another problem the training of teachers for TVET is facing is low prestige of the teaching profession (cf. in 1913 this profession was very popular, namely, every third student wanted to be a teacher; by 1925, every tenth student) due to its social status and low pay.

The RF Government has approved a number of policy documents concerning the development of the system of education, in which issues relating to enhanced quality of training TVET teachers are mentioned (Federal Programme for Education Development 2016–2020; Kairov and Petrov 1968; Shaidenko 2002). For example, in the Package of measures to develop the TVET system for the period 2015–2020, it is envisaged to put in place a comprehensive system of continuing training for TVET teachers and administrators (Package of measures aimed at enhancement of SVET for 2015–2020). The objective of TVET teacher upskilling is explicitly set down in the Strategy for the Development of the System of Training Workforce and Fostering Applied Qualifications up to 2020.

Under the draft Concept of Staff Provision for the TVET System currently under development, by 2020 about 70% of SVET teachers and instructors will have undertaken an upskilling course. The draft concept is supplemented by draft Methodological Recommendations aimed at updating and piloting new models of training teachers and instructors of practical training for the TVET system. These Recommendations stipulate a merger of academic- and occupation-specific subjects and – as a consequence – of the jobs of teachers and instructors of practical training, a shift to teamwork, as well as enhanced methodological, psychological, and pedagogic skills of teachers (Methodological recommendations for upgrading and piloting model of training teaching staff for the system of secondary vocational education, Package of measures aimed at enhancement of SVET for 2015–2020).

Preservice TVET teacher training curricula are to provide opportunities for students to acquire multiple qualifications that would enhance their mobility on the labor market and employability. For example, under the master-level program “Pedagogic Education,” three qualifications can be obtained, that of a:

- Methodologist specializing in the program development
- Methodologist for an education institution
- Teacher of generic occupational modules (multidisciplinary courses) or instructor of practical training

The Methodological Recommendations outline different trajectories for the entry in the profession and stress a need to estimate and anticipate the labor market needs for TVET teaching staff. It is indicated that all teachers at professional–/engineering-pedagogic higher education institutions must have a bachelor degree in pedagogic education of a specific profile matching the subject area they will teach.

Hence the curricula should emphasize methodological and psychological grounding as well as an up-to-date knowledge in a specific subject/occupational area.

Specific competences of future TVET teachers envisage abilities to:

- Identify learning outcomes based on the labor market requirements
- Construct and implement outcome-based curricula integrating theory and practice
- Organize and manage students’ individualized learning plans
- Perform assessment of learning outcomes in the format of a skills demonstration
- Interact with different categories of customers including employers
- Create the learning environment and organize work-based learning opportunities for their students at enterprises
- Manage individualized learning of students, for which aim teachers must be knowledgeable of the concept of the learning styles and have good negotiation and conflict resolution skills
- Manage one’s own learning and professional development

To this end it is recommended to allocate more time in the curricula for independent student work, including projects and individual learning plans. The content of

the curricula must build around the competences to be fostered and not use the traditional discipline-based approach (ibid).

To meet the above ambitious goals, the TVET teacher training curricula are gradually undergoing a transformation. In this context, teachers are living through a very painful period of transition from the role of the “talking heads” and “holders of the truth in the last instance” to advisors, mentors, and managers of the teaching and learning process, who are responsible for the final product – graduates’ skills – and not for the students’ marks for a specific subject.

Hence, the methodologies and didactics of TVET teacher training are becoming more oriented toward new constructivist and behaviorist approaches underpinning the competence-based approach, as well as those of social learning, even if the teachers themselves are not aware of the theoretical foundations of these transformations. The constructivist approach involves letting the students create own new meanings in the context of a more and more complicated and sophisticated knowledge-based economy and society and in the context of the fourth industrial revolution. The behaviorist component includes social learning and enhancing own behavior to adequately address the challenges of the rapidly changing environment.

It was expected that the TVET teacher training curricula’s content would improve under the impact of the occupational standards “Teacher in vocational training, vocational education and continuing education” (Approved by Ministry of Labour on September 8, 2015, № 608Н), as currently all education curricula must reflect the requirements set down in the occupational standards. (Development of occupational standards covering all qualifications levels was institutionalized by the Presidential Decree of May 2012.) However, the expectations have not been justified, as the given occupational standards are not based on learning outcomes and contain a list of functional duties that lack a qualitative element and can hardly serve to improve the TVET teacher training.

---

## Sample Curricula

To illustrate the current state of play in TVET teacher training/engineering-pedagogic education, two examples are given below of bachelor- and master-level curricula in “Engineering Pedagogy,” based on the Federal TVET Teacher Training Standard for Higher Education. The Federal HE Standards stipulate requirements to the content of education and to the quality of the education content (curricula and syllabi), to the teaching and support staff, and to information support of the teaching and learning and of the research.

The Federal Standards carry descriptions of universal (generic) competences, generic occupational competences, and specialization occupational competences. All HE curricula in Russia are described in credits, adapted from the ECTS system. One credit is 36 h.

The new generation of standards (currently under finalization) will carry only descriptions of the universal (generic) competences and generic occupational competences for a broad occupational area of training. However, to form a picture of

SVET teachers as they are and have been for the decade, an overview of the acting curricula may prove illustrative.

The examples are taken from Yekaterinburg Professional-Pedagogical University. Overall, master-level programs comprise profiles such as organizational psychology, professional-pedagogic technologies, research and methodological support for VET students with special needs, engineering pedagogy, economics and entrepreneurship, economics and governance of TVET schools, vocational education, etc.

Structurally the master-level curriculum in engineering pedagogy – taken as an example – may be represented as shown in (Table 1).

The program comprises over 30 mandatory disciplines relating to the engineering sector-specific occupational areas (e.g., transport, welding, machine building, automotive industry, metallurgy), including: management; organization of operation of work units at enterprises; quality management at enterprises; pedagogy, andragogy, teaching methodology of engineering education, innovative technologies in science and education, ICT in education, history and methodology of engineering education, history and methodology of pedagogical science, mathematical modeling in engineering education, expert assessment in education, pedagogic measurements, pedagogic projects development, development of the learning environment, development of curricula, psychology of engineering occupations, and current problems in TVET.

On top of that, the curriculum also incorporates such general/academic subjects as history and methodology of science (with courses in social ecology and in methodology of scientific creativity), mathematical and IT aspects of engineering education (courses in IT and mathematical modeling), as well as modules in the theory and methodology of engineering education (history and methodology of engineering-pedagogic education and psychology of engineering occupations), and psychology and pedagogy of engineering-pedagogic education (psychology of labor; pedagogy of higher and vocational education).

To add to the mandatory core subjects, there are electives (e.g., “Curricula development,” “Assessment of quality of education,” “Pedagogic measurement of learning outcomes”).

To that list, the university has added more subjects, namely, psychology and pedagogy of higher education and projects in education and methodology of teaching engineering disciplines; pedagogic technologies in engineering education; systems analysis, modeling, and design in engineering occupations; and quality management at machine-building enterprises.

**Table 1** The structure of the master program

Structural elements		Credits
Element 1	Disciplines (modules)	57–66
	Core part	9–18
	Electives	
Element 2	Practical training periods (work placements and research project)	45–57
Element 3	Final assessment	6–9
Total credits		120 credits

Also, the curriculum envisages two compulsory work-based training periods and a research graduation project.

The syllabus envisages the following formats of the program's delivery: lectures, practical classes/seminars, laboratory assignments, and students' independent work.

As is, the curriculum is mosaic looking and lacks a holistic character, which can be accounted for by the domineering disciplinary approach that has yet not given way to a multidisciplinary perspective.

The overview of the above curricula reveals a number of bottlenecks in the description of competences that inevitably tell on the ultimate quality of training. Namely, there are many overlapping competences, certain competences are formulated in a way that precludes their transparent assessment, and differing "scales" are used to describe competences – some are very broad, while others are too narrow, to mention but a few.

On top of that, there is a lack of competences relating to green skills, green economy, etc. Hence the overview also reveals that the TVET teacher training curriculum is not addressing in full measure the concept of green economy and green skills in the context of the sustainable development agenda. These issues are only mentioned in the course of economics, and some aspects of lean management are sometimes addressed in generic occupational subjects.

It has to be mentioned that in the multitude of in-service teacher training courses, there are practically none relating to sustainable development and green skills.

---

## **Internationalization as a Tool to Enhance TVET Teachers' Skills**

In the age of globalization and ICT, internationalization of TVET is imminent, including the teacher training curricula. In the recent years in Russia, the key internationalization factors impacting quality enhancement of training TVET teachers can be identified as the Tempus and Erasmus+ program, the WorldSkills movement, and the Russian-German project on dual education.

Under the earlier Tempus and the current Erasmus+ program, the overall philosophy of student-centered, project-based, and work-based learning is promoted irrespective of the subject area of the project. Due to dissemination, the "ripple effect" reaches out to the university community at large.

Enhancement of TVET teacher skills has been performed via the dual education project with GIZ (Germany) – "Training of workers for high-tech sectors by means of the dual education model" – which has offered TVET teacher internships at enterprises during which they could come to grips with the latest developments in the occupational area, acquire new occupational skills, familiarize with lean management practices, as well as enhance their soft skills (communication, business etiquette, etc.). This project started in 2013 and involved over 100 TVET schools from 15 RF regions.

A third venue to upskill and professionally develop TVET teachers is the involvement of teachers and instructors of practical training in the WorldSkills movement that Russia joined on May 17, 2012. Currently, practically all RF regions

participate in WorldSkills. The high standards of the WorldSkills competences, the competitive spirit of the movement, as well as the involvement in the WS Russia of over 250 industrial companies/enterprises are a benchmark both for TVET teachers and for students to improve performance and to enhance quality of teaching and learning.

---

## Conclusion

As a result of the overview, it can be concluded that training teachers for TVET in Russia has its own history that abounds in dramatic turns, upheavals, and problems. The dramatic turns in the TVET development including the training of teachers for the system were conditioned apart from the natural search by the TVET system for its own identity, by the multiple changes in the country's development paradigm.

Despite the wealth of theoretical research in diverse areas of pedagogy, including the professional–/engineering-pedagogic education, its impact on the actual quality of TVET teacher training curricula has not been strong, and the gap between science and research and the implementation of the results generated there persists.

Currently the quality and efficiency of TVET teacher training is topping the policy agenda, and ways are being sought and piloted to introduce up-to-date methods in the preservice curricula and in-service upskilling programs.

## Abstract

Mexico enjoys dynamic industrial growth and is seen as one of the world's largest economic centers. Its demographic profile is favorable to this growth, with nearly one fifth of the population aged 15 to 24. Against this backdrop, vocational education and training (VET) is particularly relevant, yet it enjoys only low status in Mexico. Vocational training is considered an option only for those young people who cannot afford high university fees or who fail the university entrance examinations. Their peers prefer to enter the labor market immediately after finishing school, without “wasting time” on technical education of any kind. Meanwhile, companies complain of the inadequate quality of formal vocational schools, including the low level of qualifications held by teachers.

This study focuses on these issues and aims to shed light on the Mexican educational and VET system. Particular attention is paid to training for vocational

school teachers. The study also explores the work of in-company trainers in production companies, their educational background, and how their activities fit into the wider context of the educational system.

The findings show that vocational school teachers are inadequately prepared for their role, since there is no formal training for VET teachers. They also address the demand for well-trained trainers and train-the-trainer provision at company level. Most companies rely for their supply of trainers on workers who, while technically experienced, have not been trained to teach and therefore have little, if any, pedagogical and methodological knowledge. This creates challenges, especially in the manufacturing sector. As production processes become increasingly complex, companies – both national and multinational – are in growing need of skilled workers for their production operations. For specialist positions in particular, task-specific on-the-job-training (OJT) by experienced colleagues is of only limited value. As a consequence, there is a huge demand for methodologically and technically well-qualified trainers to improve in-company training.

**Introduction: Vocational Education and Training in Mexico**

Mexico is an emerging economy with an excellent demographic profile: 66.2% of its population of 127.5 million are of working age (15 to 64), with almost one in five aged between 15 and 24. Many in this age group are making the transition between school and employment (World Bank [n.d.](#)). However, the potential represented by this favorable demographic starting point needs to be exploited if it is to give Mexico a competitive advantage over the steadily ageing populations of the advanced economies and offer real scope for economic and social development. The labor market has a particular need for well-trained technical specialists with excellent practical skills rather than formal academic qualifications. However, the training provided in vocational schools is not very practice-oriented, so those completing courses in vocational schools often find the transition from training to employment problematic, while companies report difficulties in meeting their needs for skilled labor (Horna and Santana [2012](#)).

The Mexican vocational education and training system seems only partly to reflect companies' needs. While education generally enjoys a high status in Mexico and is often linked with the concept of social and economic advancement, these expectations are in practice confined largely to academic education and training. Vocational training has long been seen as peripheral: specifically, it has been viewed as the alternative for young people who cannot afford to spend years in formal education at school and university or who fail university entrance examinations. Many young people in these situations seek out other academic education or training pathways, but where these are not an option, the alternative is

often low-skilled work. Vocational training generally enjoys a poor reputation, with both companies and young people and their families associating it with poor quality and inadequate preparation for employment. Meanwhile, the plethora of private and public sector provision is frequently difficult to navigate (Arteaga García et al. 2010).

The Mexican government has recognized these weaknesses and has embarked on far-reaching reforms to the country's education and training system. Since 2008, upper secondary-level education has undergone a root and branch transformation. In 2013, meanwhile, a pilot project jointly run by Mexico and Germany got under way. One of its aims is to tailor vocational training better to the needs of companies. The project is known by its Spanish initials as MMFD – the Mexican Model of Dual Vocational Education and Training.

As many studies have shown, vocational educators – vocational school teachers and in-company trainers – are crucial to improving the quality of training systems (see, for example, Hattie 2009; Terhart 2013 in relation to vocational schools and, for example, Rose and Wignanek 1990 in relation to companies). There are many existing professional profiles of vocational educators (Grollmann 2008, 2009), but our focus here is on teachers in vocational schools and in-company trainers. Against the background of the growing importance of lifelong learning, these groups can be regarded as “core professions in the knowledge society” (Grollmann 2008, p. 536). However, they are also crucial stakeholders in the process of adapting and reforming training policy: reforms will be successful only where they support and implement such change (Wernstedt and John-Ohnesorg 2010). In other words, change can be successfully implemented only where it is integrated into day-to-day teaching and learning processes.

The lack of skills development activities for vocational educators has in the past been a major contributor to the poor quality of the VET system, and such activities now underpin reform initiatives introduced by the Mexican government. Two initiatives in particular can be singled out: the 2013 professionalization of teachers across upper secondary-level education and the wide-ranging expansion and formalization of skills development provision for in-company trainers as part of the MMFD.

Research findings on vocational educators in Mexico are limited. One reason for this is that vocational education and training enjoys only low status among young people and their families and among employers. Another factor is the profile of educational research in Mexico, which frequently focuses on general education or regards VET as merely a non-differentiated area of upper secondary-level education.

The aim of this chapter is to provide an overview of the Mexican VET landscape with a particular focus on vocational educators. In line with the title of this edited volume – *International Handbook of Vocational Education and Training for the Changing World of Work* – this chapter focuses particularly on the changes currently under way in the areas of skills development and professionalization for vocational school teachers and in-company trainers.

The chapter begins by providing an overview of Mexico's vocational education and training system with a view to contextualizing the specific aspects of the work

of vocational educators before moving on to outline the issues represented by the current situation, focusing both on teachers in vocational schools and on in-company trainers. In the case of the latter, the focus is on companies in the production sector, since their demand for skilled personnel is particularly high. This is followed by a presentation of the current reforms and change processes initiated by the government in response to weaknesses in the system. Here, too, the chapter considers vocational school teachers and in-company trainers separately. It concludes with an overview of the reforms currently under way, centering on the extent to which these approaches by the Mexican government promise success and represent effective ways of tackling the challenges outlined.

The design and methodology of this study are based on a comprehensive search of both the national and the international literature. As noted above, there is very little robust academic research on this issue, so use was made primarily of reports and other documents published by the institutions involved and of their constitutions. The Ministry of Education is a vital source of information, supplying a range of information to enable (future) teachers to come to terms with the changes introduced by the reform. However, our research into in-company trainers proved more difficult: this area is (or, as will become evident below, has traditionally been) largely nonformalized, so little theoretical attention has been paid to it. The findings of earlier research funded partly by the German Research Foundation (known by its German initials as DFG) were an addition to the information available. (The project described here was partly funded by the DFG as “TITLE” (REFERENCE). We would like to thank our project partners NAME and NAME for their many valuable insights and suggestions from an economic geography perspective.) This qualitative study explored in-company learning in Mexican and German companies and used 21 semistandardized interviews with eight experts in Mexican manufacturing companies, a further eight in German manufacturing companies and five vocational training experts in Mexico (Wiemann and Pilz 2017). The focus in this study was on Mexican companies. The German government has been very influential in introducing the dual model of vocational training in Mexico, so the views of Mexican multinationals are also an important addition to the literature, giving the reader a comprehensive insight into a range of options for vocational learning and the requirements different options make of teachers and trainers. Our description of the reform process and its current impact is, however, a snapshot, and rapid changes can be expected in this area.

---

## Overview of Vocational Education and Training in Mexico

Compulsory education in Mexico comprises preschool education (*preescolar*) (normally for children aged between 3 and 5), primary education (*primaria*) (children aged between 6 and 11), and lower secondary-level education (*secundaria*) (children aged between 12 and 14). These three elements together make up basic education (*educación básica*). Since 2012, upper secondary-level education (*educación media*

*superior*) has also been compulsory in Mexico. Higher education (*educación superior*) follows upper secondary education.

Vocational education begins at secondary level. School students who have completed primary education but not secondary education have the option to move on to courses that prepare them specifically for employment (*capacitación para el trabajo*). On average, these courses last for between 3 and 6 months and provide theoretical and practical knowledge of the core activities involved in a particular vocational profile, enabling those completing the course to enter directly on to the labor market. They do not, however, enable students to move directly into postsecondary academic training. Students at technical secondary schools (*secundarias técnicas*) are able to opt for a technical focus at the lower secondary level.

Traditional vocational education and training in Mexico is provided by vocational schools, which offer three options. First, students can complete a vocationally-oriented higher school-leaving qualification (*bachillerato tecnológico*), which is more or less equivalent to a vocational baccalaureate, but focuses more on general than on vocational subjects. Students acquiring this qualification can either move on to higher education or directly access the labor market in their chosen specialist area (for more detailed information, see Kis et al. 2009, Sánchez-Castañeda 2007, Villar et al. 2013). The qualification is offered by a range of schools under the centralized supervision of the Ministry of Education and includes a number of vocational focus areas, including manufacturing, agriculture, and marine studies.

One of the most important institutions providing vocational education and training is the National College of Technical Professional Education (*Colegio Nacional de Educación Profesional Técnica* or CONALEP). This decentralized provider, which forms part of the Mexican government, runs more than 300 training locations across the country. CONALEP offers the second option, a special form of the vocationally oriented upper secondary-level qualification, the *profesional técnico bachiller*. This qualification has a clear vocational focus, although around 40% of course content is general in nature. Particular emphasis is placed on self-competencies and social skills (including modules in independent learning, problem-solving, and communicative skills). The remaining 60% of course content focuses on the student's chosen vocational specialism. Students can specialize by choosing a focus that is more or less practical or academic. Students who complete this course have the option of either entering the labor market directly or going on to higher education.

Third, students who have completed secondary education can complete a 2- or 3-year course of specialist vocational training (*educación profesional técnica*). This is geared to direct entry to the labor market and therefore comprises practical training units (CONALEP 2016a). CONALEP has traditionally been the major provider of this "pure" form of vocational training, but the year 2013/2014, this qualification has been replaced by the *profesional técnico bachiller* and is now offered only as an exception. In the year 2015–2016, 36.5% of students acquired the *bachillerato tecnológico* (or completed the course of CONALEP training that led on to the

*profesional técnico*). Only 1.4% of all students enrolled in upper secondary-level education completed the traditional *educación profesional técnica* (SEP 2016).

Formal vocational education and training in Mexico is not particularly geared to the needs of companies, so companies rely on their own training activities to fill in the gaps. In-company on-the-job training (OJT) is therefore highly relevant and may be regarded as the most common form of initial and continuing training provided by companies (Arteaga García et al. 2010, p. 209). Many companies use this form of training to develop their employees' skills, with most setting only very low conditions in terms of prior vocational knowledge. Completion of lower secondary-level education is often sufficient, while for some occupations – especially in technical fields – trainees need only to have completed primary education. Employers place greater emphasis on the right personal attitude and aptitude as reflected in such characteristics as punctuality, reliability, and honesty.

There is very little standardization of in-company training, which tends to be shaped directly by the requirements of the individual company, although there are, of course, exceptions. Frequently, no specific induction program is offered, with new employees being inducted on the job. They usually begin with simple tasks and work their way up the company hierarchy on the basis of long service and good performance within the company. Training therefore varies in content, but there is substantial similarity between companies in terms of their basic pattern of vocational induction (Wiemann and Pilz 2017). Labor legislation is largely irrelevant here: it stipulates that every company must offer its workforce continuing training and that employees should take advantage of these activities. However, the law does not specify how much training should be provided, and half-days or single days of training are often considered adequate provision for a whole year. Companies can determine the content of their own courses, and training provision often focuses on aspects of health and safety (Cámara de Diputados del H. Congreso de la Unión, 04-01-1970).

---

## **Overview of the Situation of Vocational Teachers and In-Company Trainers**

This section considers the current situation of vocational educators, distinguishing between vocational school teachers and in-company trainers. The picture is currently undergoing reform, so future changes are likely. However, the challenges described are not new – some have existed for decades – and nothing will change overnight. Moreover, it is not yet possible to predict the outcome of the change processes currently under way.

### **Training for Teachers in Vocational Schools**

Mexico has institutions that train primary and lower secondary-level teachers, including teacher training institutes and pedagogical universities, but there are few

options for training specifically to teach at upper secondary level. Some universities offer a degree in upper secondary-level teaching, but teacher training for this level of education has long been largely unregulated, especially for teachers in vocational schools. Our experts noted that the formal requirement – that trainee teachers must have a university level qualification, although not necessarily in the area in which they wish to teach – is not always enforced where schools face a shortage of teachers in certain subjects. Teachers do not require specific training in pedagogical skills, either, and the selection and recruitment criteria for teachers tend to be arbitrary. Vacancies are often reallocated or even exchanged for payment, with clear interference from the teaching union. Promotions are based on seniority, and many teachers opt for teaching solely because of the social security covering their affords. Many supplement their low teachers' wages with freelance work, often in the informal sector.

### **Training for In-Company Trainers**

Similarly, low-quality standards also apply to in-company trainers in production companies. Training trainers enjoys only low status in Mexico, and theoretical courses and the induction of new employees is left either to representatives of the HR department or to technical experts at supervisor level or above, depending on the subject area. Expert interviews in companies show that supervisors or experienced colleagues are responsible for OJT as initial and continuing training. In small and medium-sized companies in particular, there is often nobody in overall charge of coordinating induction. OJT is an add-on to the role of those who undertake it and one that they have to fulfil along with their main duties, so it tends to be perceived as a burden. In the companies interviewed, the selection of these *instructors* was made primarily on the basis of their technical expertise. Vocational and person-based criteria (such as “excellent communication skills” or “positive presentation”) are also important. It is rare to find continuing training provision (e.g., provided by the Ministry of Labour, private providers, or vocational schools) or preparatory courses organized by companies themselves. Moreover, even where such provision does exist, it focuses less on pedagogical content and primarily on enhancing trainees' presentational skills. A supervisor or line leader, with support from the HR department, usually coordinates individual activities.

Registered “training agents” are used to provide compulsory in-service and continuing training measures. Their registration is overseen by the Ministry of Labour and is a very straightforward process, requiring only minimal formal conditions to be met. In theory, authorization to conduct continuing training is subject to certification of some kind; in practice; however, it can also be based on personal experience where an appropriate case is made (STPS 2016).

It became clear from our expert interviews that both national and international companies are sometimes dissatisfied with this situation. Role-specific induction by colleagues has limitations, in particular where future specialists in production are being trained (e.g., in repairs and maintenance (Wiemann and Pilz 2017)), because trainers can only pass on what they themselves have learned. Practitioners who have

learned and developed the skills for individual processes within their role will find it difficult to support new employees in acquiring complex skills; so will graduates with a broad theoretical basis but only limited insight into practice. This applies particularly where the trainer also lacks experience in actually teaching content.

---

## **Changes in Vocational Education and Training in Mexico: Two Reforms**

As described, then, training activities for vocational training staff fell short of their major potential to improve training for many years. There is a clear need for skilled labor, both to facilitate transitions from school to work and to provide companies with skilled workers. The government has therefore introduced two reforms intended to improve the situation. The first is the current reform of training courses for all upper secondary-level teachers, including those in vocational schools. Second, the introduction of dual vocational training is changing the profile of in-company trainers and giving them an entirely new role. Both these approaches will be described in the following sections.

### **Teachers in Vocational Schools: Greater Structure**

Poor quality across the Mexican school system – to which the low standard of teacher training is regarded as a major contributing factor – led in 2013 to a far-reaching reform instigated by President Peña Nieto. The enactment of two new pieces of legislation has had an impact on initial and continuing training for teachers. A law on the Institute for National Educational Evaluation (*Ley del Instituto Nacional para la Evaluación de la Educación*) and another on services in the education sector (*Ley General del Servicio Profesional Docente*) represent a new framework for the recruitment, induction, regular appraisal, and permanent employment of teachers in both basic and upper secondary-level education. It should be pointed out again here that these changes apply not only to general schools but also to vocational schools, which are regulated by the Ministry of Education. In terms of the provisions of the legislation, there are only minor differences between general and vocational school teachers, however, so we shall not explore these differences in detail but focus solely on teachers in vocational schools.

With regard to recruitment, a competency profile has been developed with the intention of making recruitment decisions transparent. Recruitment is now based on selection procedures carried out regularly once or twice a year in each federal state. For teachers at vocational schools, selection takes the form of a nationwide aptitude test comprising a standardized multiple-choice assessment of candidates' knowledge of the skills required for the teaching profession and compilation of a lesson plan. These two elements together give the candidate a total points score, and those scoring above a minimum number of points are allocated to vacant teaching posts on the basis of their points score (SEP 2017a).

Contracts of employment are initially based on a 6-month probationary period. During their first 2 years in post, new teachers are supported by an experienced tutor and have access to training provision to enhance their teaching skills. Once they have completed their first year in post, they then undergo a diagnostic assessment intended to identify their needs for further targeted support. Assessment involves a report on the teacher's current performance on the basis of a standardized questionnaire completed independently by the teacher and the school principal. Teachers also describe their wishes and needs for further support (SEP 2017b).

Once a teacher has completed 2 years' service, he or she begins regular appraisals. Appraisals explore whether the new teacher is able to teach in line with formal requirements and form the basis for subsequent appraisals, as the next section explains. If a teacher reaches a satisfactory standard, he or she is employed permanently in the school system. The introduction of the new legislation on teacher training also provides for teachers in this position to be reconfirmed in post at least every 4 years in a three-stage procedure. The first stage involves two standardized online questionnaires designed to identify the teacher's strengths and weaknesses; one is completed by the teacher and the other by his or her direct superior (usually the school principal). The second stage involves compilation of a lesson plan and a written piece of reflection, which are both submitted online. The third stage involves a standardized online test in which the teacher has 4 hours to answer questions both on his or her subject and on pedagogical issues (SEP 2017c, 2017d).

There are four possible outcomes to an appraisal: teachers can be graded "unsatisfactory," "satisfactory," "good," or "outstanding." If they are graded "unsatisfactory," then participation in further training courses is compulsory, and they are reassessed a year later. Any teacher graded "unsatisfactory" at his or her third attempt is barred from continuing to work as a teacher and is offered employment in school administration or voluntary early retirement. Teachers graded "satisfactory" are confirmed in their post for a further 4 years and, by agreement with their principal, can voluntarily take courses to further develop their teaching skills. Those graded "good" or "outstanding" receive a salary increase and are eligible for promotion to more demanding posts. If they wish, they can participate in courses to deepen their skills, which count toward a possible academic specialization (Cordero Arroyo and González Barbera 2016). The first appraisals to be held under this system, in academic year 2015–2016, involved more than 29,000 teachers, with around 78% being graded at least "satisfactory" (SEP n.d.).

The provisions of the legislation on teacher training apply to all teachers within upper secondary-level education and also explicitly include decentralized institutions. However, there is a gray area here. Only few of the teachers at CONALEP are employed by the Ministry of Education; the rest are employed directly by CONALEP and are therefore exempt from Ministry of Education regulations with regard to appraisal and in-service training. They are also covered by the collective agreements negotiated by other trade unions. CONALEP has adopted the closer competency orientation of the education reform and is guided by the upper secondary-level teacher profiles laid down by the Ministry of Education but has formulated its own recruitment rules. These rules are derived from CONALEP's own

academic model, which is based on the findings of constructivist theories of learning and is geared to general, academic, and vocational competencies. This is intended to establish a clear connection between aspects of education and training and the demands of everyday life and of the world of work. A key component in this model is the trainee's ability to deal with diverse groups in terms of their cultural and social characteristics and of their educational background.

Against this background, CONALEP has its own program for boosting teachers' skills (*programa de fortalecimiento de las competencias de los docentes*). The program comprises eight basic modules and ten specialist modules, each with a differing focus. The modules are delivered either face to face or online, and some have been developed as collaborative ventures with national and international institutions and companies (CONALEP 2016b). In addition to CONALEP's own program, there are also further smaller courses, but these will not be further described here.

### **In-Company Trainers – Key Figures in Dual Vocational Training**

In 2013, dual vocational training was introduced in Mexico, initially as a pilot project in 6 vocational skill areas and across 11 federal states. At the time the research for this chapter was being completed, the reform had been implemented in 24 of Mexico's 32 federal states (BIBB 2017). The overarching goal of this initiative, which was financed and supported by the German government, has been to make vocational training in Mexico more needs-oriented and practical in its focus. It takes two main forms. The first is based closely on the German model of dual vocational training, while the second is geared more to the Mexican context. Changes planned include strengthening the strategic and regulatory framework for this latter model and further developing standards for in-company training. The intention is that companies in particular should be more closely integrated into the formal education system, given that vocational training currently focuses more strongly on vocational schools (BIBB 2015; Cáceres-Reebs and Schneider 2013). On completion of the pilot project in 2015, the dual vocational training model was officially acknowledged by the Ministry of Education as part of upper secondary-level education with a formal announcement in the Mexican Federal Law Gazette. The legal framework was at this stage very vaguely drafted and stipulated that dual training provision must last for at least 3 years and follow a curriculum built around general, technical, and vocational competencies. As part of the final examination, students are required to demonstrate their acquisition of the relevant competencies (SEGOB 2015). The aim is to put these provisions in place nationwide and to roll them out to other training occupations. Mexico's dual vocational training model is still bedding in and may yet take a number of different directions, but the concept of the dual model of vocational training is increasingly popular and attracts substantial interest from companies, training providers and political stakeholders alike.

Train-the-trainer measures are crucial to implementing dual vocational training in Mexico. The German-Mexican Chamber of Commerce (known by its Spanish acronym as CAMEXA) is a key provider of such measures and offers two

internationally oriented courses geared closely to the training standards laid down in the German Ordinance on Trainer Aptitude (AEVO) regulations. The AEVO stipulates legally binding conditions for training providers operating in Germany. In over 80 hours (or 40 hours in a shortened variant), participants acquire the basic skills required to deliver high-quality vocational training. The second variant addresses those participating in the Mexican model. CAMEXA cooperates with the employers' association COPARMEX to offer 40-hour courses for trainers, some of which are delivered online. These cover similar content to the AEVO training but are geared more closely to the Mexican employment market (CAMEXA n.d.).

Planning and preparation of training processes, recruitment of trainers, and implementation and award of certification underpin train-the-trainer courses. Formulation of rotation plans for trainees, communications and coordination with vocational schools, employers' association and CAMEXA coordinators, and other stakeholders, and handling the learning platform used by trainees to access academic content are key components. However, of course, the core remains supervision of apprentices and the design of practice-based opportunities for workplace learning.

---

## Conclusion

The reforms we have outlined demonstrate that the Mexican vocational training landscape – and in particular, the skills development and professionalization of vocational teachers and trainers – is currently in a state of flux. Changes are currently bedding in, making it difficult to draw any conclusions about their prospects for success. Nevertheless, this chapter concludes with an exploration of some of the potential represented by the reforms and the challenges they face.

The introduction of reforms to the teacher training system is intended to boost transparency and consistency of quality. The formulation of skills development standards, with a focus on changes to the recruitment criteria for teachers, and of regular appraisals are the means by which these goals will be achieved. However, these changes have triggered mass protests in some regions in Mexico, which reached their peak in 2016. With clear evidence of interference by the teaching union, teachers and union officials protested for several weeks, blocking main roads, and there were violent scuffles with the police and strike breakers. According to the interviewed experts, opponents of the reform are critical of the fact that it does not tackle the core issue of quality shortcomings in the education system. In the view of these critics, the core issues are the lack of resources in schools, particularly in disadvantaged regions, along with poor infrastructure and poverty, which prevent children from attending school. Implementation of national standards is, they argue, unhelpful, as it simply exacerbates existing inequalities. Critics also argue that the appraisal criteria for teachers are insufficiently transparent and actually make it easier for schools to dismiss teachers, thereby saving costs. Finally, the rigid requirements resulting from the profiles of “good” teachers are, in the view of the critics, too academically focused and hamper teachers excessively in their work (Wiemann 2018; for a more detailed discussion of the National

Teacher Qualification Standards, see Gerds 2009). The Organisation for Economic Co-Operation and Development (OECD 2015) considers consensus between teaching unions and reformers a crucial factor in effective implementation in the classroom and, hence, in the eventual success of the reforms. It is therefore likely that existing political differences will make successful implementation more difficult.

Moreover, only time will tell whether these changes really do boost teachers' professionalism. Learning in the workplace is a crucial element and a key factor in professionalizing vocational school teachers. Grollmann (2009, p. 1198) makes it clear that "[...] the professionalization strategy of TVET teachers has to balance policies that improve the individual learning of teachers, their education and preparation [for] their job, but needs to take into account at the same time the continuous reform of their institutions. The institutions are the environment that needs to allow for the teachers' knowledge and skills to be enacted quite autonomously in the reality of everyday practice." Against this background, the impact of teacher training reforms offers scope for directly embedding induction in actual teaching, though much will depend on exactly how it is implemented. In their expansive and restrictive framework for teachers, Evans et al. identify the key factors underpinning successful workplace learning in the context of a school (2006, pp. 52). These include "close collaborative working with colleagues," "[o]ut-of-school educational opportunities, including opportunities to reflect and think differently" and "[a]n explicit focus on teacher learning, as a dimension of normal working practices." "Isolated, individualist working," "only narrow, short training programmes" and "[t]eacher learning dominated by government and school agendas," by contrast, inhibit such learning processes, they argue. Mexico's current reforms could go either way and here, too, much will depend on how measures are designed and implemented. The focus is not only on teachers themselves but also on the school principal, who has the capacity to promote or restrict such learning processes for his or her staff. Where there is little time for learning activities and reflection, colleagues are unable to share views and experiences and deterred from focusing on issues outside their own narrow area of teaching. Under such circumstances, the changes now under way cannot realistically be expected to achieve major success.

Change is also currently under way in Mexico in terms of improving company-based training processes. Despite initial success by the MMFD, a number of challenges remain. Here, too, it is important to note that the MMFD is currently bedding in. Many of the arrangements described represent the current favored forms of implementation, but there are a number of other options. For example, increasing standardization is an important step both for vocational schools and for companies if they are to guarantee an adequate level of quality. Training the trainers is an important aspect here. In terms of prospects for success, it is currently difficult to make an assessment because provision in this area is still at an initial stage. In general terms, however, the introduction of established and experienced trainers into a company enhances the status of

training activities within that company. And when the status of the trainer is enhanced, training itself takes a more prominent role in a company. The introduction of “train-the-trainer” programs means that teachers are not limited to the experience acquired as part of their own training and do not, therefore, pass on outdated training models to apprentices. In particular, more complex teaching and learning activities, such as promotion of problem-solving abilities and transferable skills, require background knowledge of teaching methods if teachers are genuinely to encourage such processes rather than merely to teach (OECD 2005). Nevertheless, it is logical that trainers do not bear sole responsibility for the day-to-day delivery of training: underpinning any dual vocational training scheme is the involvement of apprentices in everyday working processes and their ability to cooperate with a wide range of colleagues, learning from them even where those colleagues have not themselves had any specific training in teaching or training others (Ostendorf 2012). Nonetheless, there is an argument that better skilled trainers enhance the status of training and make it easier to manage in a more structured way. Here, too, the impact will, though, depend on the practical implementation on the ground.

There are already many examples of good practice. For example, national and international companies are implementing complex training arrangements for people working on the shopfloor, especially for highly skilled specialists. Some of these are their own programs and have been strongly influenced by the home base of the parent company, while others are directly integrated into Mexico’s dual training model (Wiemann 2017; Wiemann and Pilz 2017). Well-trained trainers, whether from within the company or from an external or international skills development program, are now carrying out complex training activities.

The question of the extent to which the change processes set in train by the Mexican government can solve the problems described above is impossible to answer at this early stage. What is clear, however, is that the challenges have been acknowledged and are being tackled. Whether the “right” measures have been taken, and whether these measures are being introduced in day-to-day teaching practice in the “right” way, are questions that cannot be addressed here and now.

A further step toward improving vocational training provision, facilitating transitions from school to work and avoiding a shortage of skilled labor is better coordination between the training provided in vocational schools and the actual needs of companies. Sustainable success requires companies to express their willingness to make a greater investment in training than merely providing skilled trainers and representatives of vocational schools to be willing to design their teaching to be practically oriented and based on actual needs.

**Acknowledgements** I gratefully acknowledge financial support for this study as part of the research project “Global strategies and local forms of technical vocational education and training in German multinational companies: A comparison across Emerging Economies” (Grant No. PI 418/5-1). I would like to thank the project partners Matthias Pilz, Martina Fuchs and Judith Wiemann for their constant help and inspiration for this research.

## Abstract

Training teachers to impart quality Vocational Education and Training (VET) to learners is a worldwide concern. Technology keeps upgrading and changing in a rapid phase. Teachers have a responsibility to upgrade their knowledge, and the same must be imparted to learners. Simultaneously, there have been debates in the field of education regarding whether the profession of teaching is a “vocation” or “calling.” Considering these two sides of a model, we need to analyze how prospective teachers identify teaching as a vocation and how vocation operates in one’s own life. If teaching itself is a vocation, teachers themselves gain knowledge and know the existing social practices to choose the vocation. One needs to cultivate real interest in teaching to keep the students attentive, if he/she chooses teaching as a profession. More than that, preparing students to become

learned professionals and showing the path to discover their own vocation are a challenging task. In this context, this chapter discusses how Indian teachers in VET choose teaching as a profession in VET and how they constantly upgrade their knowledge in the changing situation.

On the one hand, the chapter gives an overview of the Indian VET system and teacher training in VET in India. On the other hand, it discusses the aspects mentioned above by focusing on the existing literature in the field and empirical findings of teaching quality in the different regions of India.

## Introduction

India is of interest for researchers in VET from all over the world (Pilz 2016a). The country is one of the fastest growing economies in the world, which faces dual challenge in the current scenario. One is the paucity of the trained workforce, and another is the lack of opportunity for the large sections of the educated youth who possess little or no employability skills (Basu 2008; Pilz et al. 2015; Ministry of Skill Development and Entrepreneurship 2015; Mehrotra 2014). Along with the growing economy, more than 62% of its population are in the working age group of 15–59 years as well as more than 54% of its total population is below 25 years of age (Ministry of Skill Development and Entrepreneurship 2015; Mehrotra 2014). India is considered as one of the youngest nations in the world. It is estimated that the labor force in industrialized nation will decline by 4% in the next 20 years. At the same time, the labor force in India may go up by 32% (Ministry of Skill Development and Entrepreneurship 2015). The Government of India has taken a number of initiatives to reap the benefits of demographic dividend. It has set up a separate Ministry of Skill Development and Entrepreneurship and notified the same in the year 2014. It has also devised a National Policy for Skill Development and Entrepreneurship 2015 by superseding the existing policy of 2009 with the objectives of skilling youth with quality in a sustainable manner. There are various schemes/programs to upgrade the existing Industrial Training Institutes (ITIs) and setting up of new ITIs (Mehrotra 2014; Wessels and Pilz 2018). In the process of achieving set targets, it is necessary to train and appoint the teachers in the vocational training institutes. It is also significant to improve the infrastructure. Infrastructure not only means physical infrastructure, necessary human resources for the training is the prime concern. Trained teachers need to be appointed in the ITIs and polytechnics to train the youths. The Ministry of Labour and Employment in the Government of India takes the efforts to train the youths to appoint as instructor/teachers in the ITIs. It is required to look at the existing research on the perception of teaching as profession before discussing teacher training in VET in India.

## Teaching as Vocation

There have been debates in the field of education regarding whether teaching is a “vocation” or “calling” (Booth 1988; Hansen 1995, 2001; Huebner 1987). Considering this contradiction, this chapter discusses how prospective teachers identify teaching as a vocation and how vocation operates in one’s life. Hansen (1995) provided two approaches to vocation. Both refer vocation as the activity or work that provides personal satisfaction and service to others. In this context, Buechner (1973), a theologian, defines vocation as “the place where your deep gladness and world’s deep hunger meets” (Buechner 1973, p. 119), which plays an important role. According to Hansen (1995, p. 3), “Vocation is a work that results in service to others and personal satisfaction in the rendering of that service.” Bearing in mind the above definitions, we can conclude that vocation is not just about financial security, but more about individuals calling for self-satisfaction in helping others. Teachers are the backbones of education. They facilitate learners to acquire knowledge and skill. Education serves a number of social purposes. The core activity of education is knowledge acquisition, acquiring capability of generating knowledge, applying the same for initiating qualitative changes in one’s own attitude and behavior, and skills for human resource development. Along with knowledge creation, it has to impart skills and values. Human development is to ensure the overall well-being of the person. Education plays a significant role in human development. Educational indicators are part of measuring the phenomena of continuity and change in both qualitative and quantitative indicators in education. Teachers are core persons in these activities. Teaching is a diverse and complex activity. It is multidimensional. Boys/girls learn and acquire knowledge culminating in overall personality development with skills of self-reliance. There are various stages in these processes. Various teaching methods need to be adopted in each stage of humans to impart knowledge and skill. The methods and content may vary depending upon the age of the learners. Teachers can draw and construct teaching methods and transmit knowledge by identifying significant points from these elements. Unlike other professions, education not only creates knowledge base but is also a practicing profession. Teachers need to draw theories of learning and bodies of knowledge to generate student learning, understanding, and later on helping them to apply it in their lives for addressing different challenges. Teachers are not only generating learning in others, they also learn while teaching. There are three forms of teacher knowledge as suggested by Shulman (1986). These are propositional knowledge, case knowledge, and strategic knowledge (Shulman 1986).

---

## An Overview of the Indian Education System and VET System

The Indian education system consists of primary education (1st standard to 5th standard), upper primary (6th standard to 8th standard), secondary education (9th and 10th standard), higher secondary (11th and 12th standard), and collegiate education (3 years for science and arts stream and 4 years for engineering). Students

need to learn in schools till secondary education, whereas higher secondary education is imparted “either in schools or junior colleges” (Gupta et al. 2016, p. 43). After completion of higher secondary education, students have access to higher education. School education at the level of secondary and higher secondary education is considered to be significant as students must decide if they want to continue in regular stream or vocational training (Gupta et al. 2016, p. 42 f.).

The Indian VET system includes two levels: the school level and the higher educational level (Wessels and Pilz 2018). At the school level, VET starts at the higher secondary level (11th–12th standard) and offered as separate group, which lasts for 2 years. The Department of School Education in the Ministry of Human Resource Development is responsible for the vocational education at schools (Venkatram 2012, p. 172; Agrawal and Indrakumar 2014, p. 484ff.). One hundred sixty vocational courses in agriculture, business and commerce, engineering and technology, health and paramedical [care], home science, and science and technology are taught at around 10,000 schools in India (Agrawal and Indrakumar 2014, p. 487; Gupta et al. 2016, p. 45).

At the higher educational level, VET is mostly provided by the government ITIs and private ITIs (Agrawal 2012, p. 456; Venkatram 2012, p. 172). Directorate General of Training (DGT) in the Ministry of Skill Development and Entrepreneurship is responsible for the vocational training and education at the higher education. Training at the higher educational level is imparted under two schemes, namely, the Craftsmen Training Scheme (CTS) and the Apprenticeship Training Scheme (ATS) (Agrawal and Indrakumar 2014, p. 484 f.; Gupta et al. 2016, p. 46).

ITIs were set up with the goal to fulfill the requirements of the labor market under the CTS in the year 1950 (Sodhi 2014, p. 458). The structural reform in the macro economy in the year 1991 has increased the economic activities. It has also created the demand for skilled labor. The government and private players rapidly have expanded the number of ITIs in the 1990s. The number of ITIs has doubled, from 2,137 to 4,274 between 1990 and 2000. The number of ITIs has grown even faster since 2000. Most of the newly established institutions were private ITIs whose number has grown from 2,772 in 2001 to 6,498 in 2010 (Joshi et al. 2014, p. 87). The growth of government ITIs was not so strong. It has increased from 1,727 in 2001 to 2,189 in 2010 (Joshi et al. 2014, p. 87). In 2015, there were 11,964 ITIs (2,284 government ITIs and 9,680 private ITIs) in India that offer training courses in 126 trades (DGT 2015).

The period of training ranges from 1 to 2 years depending upon the course in the ITIs (DGT 2015). Those who completed 8 or 10 years of schooling may get admission in ITIs (Gupta et al. 2016, p. 46). The courses at the ITIs have been designed in such a way that the percentage of practical component occupy the major portion of the syllabus. But, teaching or instructions of theory dominate over practical instruction in reality (Tara et al. 2016, p. 3). Students receive National Trade Certificates after the completion of the training program (DGT 2015).

ITIs also train “semiskilled workers” (Venkatram 2012, p. 174). ITI graduates should undergo and complete apprenticeship training in order to be considered as a skilled worker (Venkatram 2012, p. 174). On-the-job training is imparted in different

government-run and privately owned companies under the ATS. The duration of the training ranges from 6 months to 4 years (DGT 2017d). There are five categories of apprenticeship training: trade, graduate, technician, technician (vocational), and optional trade apprenticeship training (DGT 2017d).

Furthermore, there are polytechnics that offer diploma programs in the engineering and technology streams. They offer programs for 3 years and are open to students who have completed 10th standard and above (Wessels and Pilz 2018). The level of the polytechnic studies is considered as higher than the certificate courses offered in the ITIs (Majumdar 2008, p. 20). Thus, we are not dealing with the polytechnic programs in this chapter.

---

## Problems in VET

As we have mentioned earlier in this chapter, India needs skilled manpower for the growing needs of the economy, but “the progress in establishing vocational schools and the subsequent enrolment are rather slow” (Venkatram 2012, p. 173). It is estimated that 12 million people will enter the labor market annually. However, the training capacity of the technical institutes is about 4.3 million, which means that including all forms of training in different institutions, 64% of the labor force will not be able to undergo any formal training (Saini 2015, p. 4).

Moreover, the participation in vocational courses is very low. According to the National Sample Survey Office (NSSO) data collected in 2011–2012, only about 3% of the Indian population aged between 15 and 59 years have completed or are completing vocational training (Ahmed 2016, p. 333). In 2014, less than 3% of students have opted for vocational education at the school level (Agrawal and Indrakumar 2014, p. 487).

This is partially due to the fact that the manual jobs are associated with poor educational achievement and low income in India (Venkatram 2012, p. 173 f.). People show huge reluctance to undertake vocational training due to the absence of a qualification framework. Vocationally trained workers remain in blue-collar jobs throughout their lives (Sodhi 2014, p. 459). As general and vocational education in India is separated from each other from higher secondary schooling onward, it is not possible for learners to switch over from general to vocational or vice versa. There is a stigma attached to vocational education also. Many learners may feel reluctant to undergo vocational training since it has an inferior status in society as compared to other streams of education (Ajithkumar 2016, p. 190; Agrawal and Indrakumar 2014, p. 488).

Furthermore, the quality of education at VET institutes is very low, and many skills imparted to the students are out of date (Saini 2015, p. 4; Pilz 2016b). Learning in the vocational education establishments resembles academic learning, and the training curriculum has little relevant to the requirements of the labor market (Agrawal 2012, p. 456; Sodhi 2014, p. 459).

As many vocational graduates do not possess the required skills, companies often choose to employ candidates with higher qualifications in engineering or people with

secondary education and provide in-house training (Agrawal 2012, p. 458). As a result, vocationally trained workers have difficulties in finding jobs. The World Bank report (World Bank 2008) showed the employment situation of the vocationally trained graduates and their difficulties in finding jobs. The situation of the large percentage of vocationally trained graduates has not improved much after the completion of the course. Only 16.2% of the trained workers in the State Orissa managed to find paid employment or became self-employed or joined family business according to the study conducted by the International Labour Organization (ILO) in 2003 (Agrawal 2012, p. 455).

In response to the abovementioned problems, the Indian Government devised a policy with the support of the World Bank and its own scheme to upgrade 500 ITIs during 2005–2006 with the goal to train labor force to world class standards (DGT 2017e; Tara et al. 2016, p. 7). In 2016, there were 1,896 government ITIs in India that had been upgraded into the Centers of Excellence (COE) (Tara et al. 2016, p. 7). However, despite the great significance of VET for the development of Indian economy and many efforts of the government to improve it, its capacity has still not been utilized effectively because of many problems; one such problem is the shortage of competent instructors (Ajithkumar 2016, p. 183). For this reason, it is important to analyze teacher training in VET in India and its current challenges, which is studied and discussed in the forthcoming section.

---

## VET Teacher Training Programs

The DGT in the **Ministry of Skill Development and Entrepreneurship** is responsible for the training of VET teachers in India. The schemes related to the training of instructors include the Craft Instructor Training Scheme (CITS) and the Hi-Tech Training Scheme (HTS) (Ajithkumar 2016, p. 193 f.).

Teachers or trainers are trained by the CITS at various DGT training centers. There are 1 national level Craftsmen Training Institute (CTI), 5 regional Advanced Training Institutes (ATIs), 1 National Vocational Training Institute (NVTI), and 12 Regional Vocational Training Institutes (RVTI) in India. They cover 29 out of 121 disciplines of teacher training (DGT 2014). The total training capacity of the institutions for engineering trade is around 1,600 teachers per year, including the NVTI and RVTI for women's training, which alone train around 500 female participants per year (DGT 2017a).

The applicants must possess either an academic or a technical qualification to get admitted into Craft Instructor Training course (Central Training Institute for Instructors 2016). Moreover, all candidates must clear the All India Common Entrance Test, which consists of multiple-choice questions (75%) on a specific trade and open-ended questions (25%) measuring “logical, numerical, and reasoning” ability (ATI Chennai 2017).

In 2009, 1-year craft instructor training was converted into modular training program to allow more flexibility in the choice of the training institutions. Single modules could be completed in 3 months (Ajithkumar 2016, p. 194; DGT 2017a). In

August 2014, a revised version of the teacher training program was introduced, which lasts for 1 year (Central Training Institute for Instructors 2016).

Courses consist of four modules. All students undergoing instructor training must complete a module on Training Methodology (TM) that covers the topics such as “principles of teaching, learning psychology, workshop administration, motivation, use of computers and audio-visual aids in teaching, preparation of lesson plan,” etc. (Central Training Institute for Instructors 2016). Moreover, trainees in engineering trades must successfully complete a module on Engineering Technology (ET) and two modules on Trade Technology depending on their trade. Trainees in non engineering trades are required to complete a module on Vocational Calculation and Science and two Trade Skill modules (DGT 2017a).

Trainees must complete the two-semester training course “within 3 years of their admission” as an eligibility criterion to take the final exam (Central Training Institute for Instructors 2016). After completing their training, they undergo All India Final Trade Test and receive a National Craft Instructor (ITI Instructor) Certificate (Ajithkumar 2016, p. 194; DGT 2017a).

The Central Training Institute for Instructors was founded in 1962 under the auspices of the NCVT, the DGT, the MoLE, and the Government of India with the support of the ILO. The aim of the institute is to provide training to the trainers for ITIs and ITCs. The only national facility is located in Chennai with all modes of good connectivity like flight, train, and road network. The 1-year program is divided into four modules, each with a duration of 3 months, in the subjects of Trade Technology I (TT-I) and II (TT-II), ET, and TM. In order to complete the TT-II module, the trainers need to complete the TT-I module and should pass.

The cost of the training varies depending upon the individual and the form of enrolment. The cost of a module for already posted officials is 1.50 euros. It costs 8 euros for regular participants, and it costs only 2.50 euros if the participants belong to the Scheduled Castes (SCs) or Scheduled Tribes (STs) community. Since the CTI is local, accommodations are made available to the teaching staff. The cost of accommodation is 4 euros per module (Central Training Institute for Instructor 2014).

The ATS program employs a total of 15,000 teachers, which shows a positive growth with respect to number of participants. For this reason, the DGT calculates with an increase of 2,000 teachers per year. In addition, approximately 3,000 teachers are required each year to counter natural processes such as retirement (ATI Chennai 2017). With the ATS and CTS training programs, an additional 10,000 teachers may get recruited every year (ATI Chennai 2017).

The ATIs were founded by the DGT with the support of the United Nations Development Program (UNDP) and the ILO. A total of five ATIs are located in Howrah, Hyderabad, Mumbai, Kanpur, and Ludhiana. The programs (like the central CTI teaching facility) are addressed to the incoming teachers at ITIs/ITCs or other training facilities. The courses last for a year and teach the “Principle of Teaching (PoT).” There are also refresher courses for teachers who want to expand their knowledge and skills or incorporate the latest technologies into the classroom (see National Skill Development Corporation Mart 2011, p. 82). This flagship program can train up to 1,200 per year.

Under the HTS, high-technology training is provided for 2- or 3-week courses in the ATIs/Advanced Training Institute for Electronics and Process Instrumentation (ATI-EPI) for the industries/public sector undertakings/government organizations/trainers from the institutes/industries, etc. (Ajithkumar 2016, p. 195).

The HTS was envisioned as a scheme of the World Bank-financed Vocational Training Project. It is currently funded by the Government of India. The aim of the HTS is to impart skills in the application of electronics, computer, and the modern production system required by the industry, commerce, and domestic consumers (Ajithkumar 2016, p. 195; DGT 2015). A total of ten ITIs and central institutes (ATIs/ATI-EPI and Apex Hitech Institute at Bangalore) teach courses in CAD/CAM, CNC, Control Technology, and other programs (DGT 2017b).

A number of vocational training institutes for women have been established by the national and state governments to improve employment prospects of women from different age groups and social backgrounds (Ajithkumar 2016, p. 194). The NVTI in Noida and the RVTIs in Mumbai, Bangalore, Thiruvananthapuram, Jaipur, Allahabad, Indore, and Vadodara offer instructor training programs only for women “in non-engineering trades like Secretarial Practice (English), Secretarial Practice (Hindi), Electronic Mechanic, Dress Making, Computer Aided Embroidery & Needle Work, Fashion Technology, Architectural Assistantship, and Beauty Culture & Hair Dressing” (DGT 2017a).

In response to the rapidly changing technological development, Mentor Councils were established, which make recommendations for curriculum development, necessary equipment, pedagogy, and assessment of different courses provided by the Ministry of Labour and Employment (Ajithkumar 2016, p. 195). The Ministry has recognized the necessity to impart training to the existing VET teachers with the newly developed curricula and has even thought about the employment of technology-powered distance learning for this purpose. After a large-scale study of different technologies, DGT opted for a nationwide Internet solution (Ajithkumar 2016, p. 195).

For the CTS program, 60,000 teachers are currently employed (20:1 pupil-teacher ratio), whereby the ITCs require about 5,000 new teachers per year (see DGT 2014).

---

## Problems in VET Teacher Training

Despite the abovementioned VET teacher training programs, India faces a huge shortage of qualified instructors. We look at the problems of VET teacher training in India based on our study. One of the major problems is the low availability of seats in the teacher training institutes. Currently, few seats are available for teacher training in VET institutes. Under the CTS, there are 8800 ITIs (2,217 government ITIs and 6,583 private ITIs) as per 2011 date offering 1,220,000 seats, which need approximately 60,000 instructors. The number of training seats in the ITIs is growing by about 100,000 annually. This means that the need for instructors in ITIs is rising by 5,000 yearly (DGT 2017b).

Under the ATS, training is provided by 25,472 establishments in 235 designated trades (DGT 2017b). The number of seats offered by these establishments was 310,000 in 2011, which means that 15,000 instructors were required. The demand for instructors is also growing in these establishments by 2,000 instructors per annum (DGT 2017b).

Moreover, about 3,000 additional instructors are needed in case of retirement and job change of instructors. Therefore, the total demand for instructors for the CTS and ATS schemes was about 75,000 in 2011, and the additional demand was 10,000 instructors per year (DGT 2017b). Especially in rural and less attractive areas, the vacancy of teaching positions is high (Pilz and Wilmshöfer 2015).

However, despite a huge need for qualified trainers, the maximum seating capacity of Craft Instructor Training institutes is only 1,600 instructors per year (DGT 2017a, b). Of those 1,600 seats, approximately 500 seats are reserved for women undergoing instructor training in NVTI and RVTIs (DGT 2017b). Also, the ATI in Chennai and ATI-EPIs in Hyderabad and Dehradun began to train instructors, and the maximum seating capacity has risen to 3338 (DGT 2017a). Moreover, in 2010, the national government granted permission to the state governments and different types of organizations (such as “companies like sole propriety, private/public limited registered under Companies Act, Societies and Trusts registered as per Act and promoters of SEZs” [special economic zones]) to undertake instructor training (DGT 2017a). Such establishments are called Institutes for Training of Trainers (IToT), and they must fulfill specific requirements to be approved by the government (see DGT 2014).

Another problem in VET teacher training is the availability of limited financial resources. The investments from the governments for the vocational education are not sufficient (Venkatram 2012, p. 173 f.). The jobs at ITIs are not attractive to the qualified trainers because of the low payment (Pathak 2017). Moreover, vocational education is seen as low status and, thus, does not attract qualified teachers (Sharma 2014, p. 411).

As a result, most ITIs suffer due to the lack of instructors. As half of the posts remain vacant, ITIs are forced to employ “ad hoc instructors” and instructors on short-term contracts (Joshi et al. 2014, p. 108 f.; Pathak 2017). According to a survey conducted in 2010, contractual and ad hoc instructors consist of 55.3% of the faculty (Joshi et al. 2014, p. 108 f.).

In 2014, Tara et al. (2016, p. 5ff.) interviewed principals at government ITIs in the states of Karnataka, Orissa, Tamil Nadu, and New Delhi and found that about 50% of respondents had difficulty in finding qualified trainers and were forced to employ temporary instructors without required skills. Consequently, ITIs are often criticized for their poor teaching quality, which is looked closely at the next section.

---

## Empirical Findings: Teacher Quality at VET Institutions

Joshi et al. point out (2014, p. 106) that the qualification of instructors is “[o]ne of the indicators to measure quality of training.” The Federation of Indian Chambers of Commerce and Industry (FICCI) Skill Development forum stresses

pedagogical competence of the instructor to bring better student learning outcomes (FICCI n.d., p. 15). Thus, it is important to examine the teacher quality at VET institutions in India (Jambo and Pilz 2018).

As has already been mentioned, teaching at ITIs in India has often been subject to criticism. The National Policy on Skill Development emphasizes the importance of improving the quality of instructors by “innovative ways of recruiting” them, “award and incentive mechanisms,” “innovative skill development schemes” (students acquiring theoretical knowledge “at the institution [. . .] [and] practical skills in the workplace”), etc. (DGT 2009, p. 19).

In their study, Joshi et al. (2014, p. 89ff.) analyze the qualifications of instructors at government ITIs and private ITIs on the basis of the IAMR survey conducted in 2010. The results (see Table 1) have shown that the majority of instructors (37.1%) only possess the ITI certificate. Only 18.5% of instructors have completed 1-year Principles of Instructor Training (PoIT). Only 6.8% of the instructors working at ITIs (both government and private) possess degrees. While the percentage of instructors possessing a diploma or a degree is slightly higher at private ITIs than at government ITIs, the proportion of graduates with Instructor Training Certificate is significantly higher at government ITIs.

Even at the Centers of Excellence, which are supposed to train “multi skilled workforce matching world standards,” the majority of instructors are only ITI certificate holders (292 out of 421 instructors) (DGT 2017c; Joshi et al. 2014, p. 114). Only 42 instructors possess academic degrees and 87 are diploma graduates (Joshi et al. 2014, p. 114). Joshi et al. (2014, p. 111) describe this situation as “distressing” as, although the need for skilled workers is rising, there is a serious lack of qualified instructors, which has a negative effect on the training quality. Joshi et al. (2014: 108 f.) also examine other factors that could lead to poor training quality such as instructors’ salaries, involvement of instructors in “activities other than training students,” and their “employment status.”

Mathur et al. (2014, p. 179ff.) look at the quality of training at ITIs from the learner’s perspective. For this purpose, they interviewed 2,507 ITI graduates (out of them 508 did not plan to undergo an apprenticeship training), 905 ATS graduates, and 1,518 trainees. The results of the survey have shown that most students are primarily disturbed by the low quality of training, which they mainly attribute to poorly qualified teachers. Students reported that in order to reduce personnel costs, ITIs employ instructors only for a short period of time. Frequent change of staff

**Table 1** Technical qualification of instructors in government ITIs and private ITIs. (Modified from Joshi et al. 2014, p. 107)

Technical qualification	Government ITIs (%)	Private ITIs (%)	Total (%)
ITI graduate	37.8	34.5	37.1
ITI graduate with PoIT	20.1	13.1	18.5
Diploma	30.4	38.1	32.1
Degree	6.7	7.1	6.8
Data not reported	5.0	7.1	5.5

hampers the continuity of learning. Moreover, courses are occasionally taught by instructors specialized in other trades since no suitable instructors are available.

In her study, Ajithkumar (2016, p. 198ff.) interviewed 47 instructors in private ITIs (six of which are principals) in the State of Maharashtra. The data has shown that only 27% of instructors completed “preservice training in ATI.” The principals revealed that there is lack of instructors with National Craft Instructor Certificates due to the insufficient number and geographical “inaccessibility of ATIs.” Moreover, it is practically impossible to grant 1 year off to teachers for their professional development. Ninety percent of instructors reported that they are not motivated to improve their qualifications since they do not get any rewards, for example, in the form of a pay increase, “paid leave [. . .] [or] promotions” (Ajithkumar 2016, p. 200).

Although 100% of trainers recognized the significance of information and communications technology, all of them indicated that it was not included in their preservice training. Fifty-seven percent of instructors reported that they kept themselves up to date with the technological developments with the help of the Internet, 41% attended “workshops and seminars,” and 2% did research (Ajithkumar 2016, p. 202 f.).

After they had undergone their preservice training, none of the trainers were sent to “any refresher course at the ATIs” (Ajithkumar 2016, p. 203). Nevertheless, all instructors participated in different kinds of “professional development programs” which they consider to be “inadequate” (Ajithkumar 2016, p. 204).

Although all instructors recognized the significance of “industrial work experience,” 68% of them possessed not more than 6 months of work experience, and only 6% of the instructors had work experience of over 2 years. As a result, the majority of instructors reported it was easier for them to teach theory than practical skills (Ajithkumar 2016, p. 204).

In a study conducted by MART engaged by National Skill Development Corporation Mart (2011, p. 11ff.), 360 instructors at 71 training institutions (government and private ITIs, NGOs) in 8 regions of India were interviewed. The study covered 18 trades (plumbing, dressmaking, housekeeping, accounting, etc.) across 6 sectors. The results of the study have shown that most teachers at government and private ITIs possess technical skills (96% and 90%, respectively). However, they lack teaching skills as only 38% of trainers at government ITIs and 30% at private ITIs have acquired teaching skills.

Only 29% of trainers at government ITIs possessed skill certificates (technical, teaching, soft, and entrepreneurship development certificates) (26% government certificates and 3% private certificates). At private ITIs, the number was even lower as only 25% had certificates (13% government and 12% private certificates). A great proportion of instructors were in the age group below 30 years and had experience of less than 3 years.

In the abovementioned study of Tara et al. (2016, p. 5ff.), the interviewed principals at government ITIs emphasized the importance of upgrading the skills and technical and pedagogical knowledge of the teaching staff. The majority of the teachers interviewed at six CoEs in the state of Karnataka stressed that it was imperative that training programs were offered regularly to keep up to date with the industrial developments (see also Jambo and Pilz 2018).

Joshi et al. (2014, p. 115) emphasize that qualifications of instructors play a crucial role in vocational training, and it is crucial that more instructors are trained and that the quality of their training improves. According to Mathur et al. (2014, p. 192), it is essential that instructors undergo high-quality training along with regular “refresher courses.” One of the main recommendations of the FICCI Skill Development forum for the 12th Five-Year Plan was to improve the quality of instructor training (FICCI n.d., p. 15).

---

## Conclusion

The Indian Government has realized the importance of skill development and has initiated many schemes intended to impart skills to its young population. However, there are still many problems that impede skill development in India. Student enrolment in vocational training programs is still very low due to the prejudice attached to vocational training as being of low status and only for people who fail to pursue higher education.

Furthermore, the Indian Government has failed to provide high-quality training and sufficient number of seats at VET institutes. As training has little connection to the needs of the labor market, it does not improve employment prospects of VET graduates. To a large extent, this is due to the lack of qualified instructors at vocational training institutes.

The results of the studies revealed that the majority of instructors possess an ITI certificate but lack teaching qualifications. Even in upgraded ITIs (CoEs), most trainers do not have teaching qualifications. Moreover, most instructors lack relevant industrial work experience and do not attend any refresher courses after their preservice training. Despite the great importance of being up to date with technological advances, it was not included in the instructors’ preservice training.

Low investments in teacher training, few job performance incentives, and social stigma attached to vocational training lead to frequent staff turnover and employment of instructors with short-term contracts and no relevant skills.

The overview on VET teacher education in India has shown very clearly the demand for future developments not only in quantitative ways but also in relation to quality. The upgrading of VET teacher education by offering academic programs combined with practical experience in the world of work on the one hand and a proper VET research at universities and other high-ranked research institutions on the other hand are highly important in the future.

## Abstract

In Switzerland two-thirds of all young people completing compulsory education enroll in upper-secondary vocational education and training (VET) and subsequently choose one of around 230 occupations. Most VET programs consist of part-time classroom instruction (1–2 days a week) at vocational schools combined with part-time apprenticeship at a host company (3–4 days a week). There is also a large availability of professional education (PET) which can be

attended after initial upper-secondary level VET training. Since VET and PET are highly connected, this chapter refers to vocational *and* professional education and training (VPET). Within this system specific teacher and trainer profiles are required. Providing training to apprentices at a host company, for example, requires work expertise as well as a pedagogical qualification, teaching vocational subjects at vocational schools or colleges of higher education requires work related as well as theoretical and pedagogical knowledge, whereas teaching general education subjects requires a teaching diploma but no work expertise. Because of the challenge of combining practical and theoretical training in VET and because young people can choose from a large variety of further studies and career options within the framework of professional education and training, various roles and different functions have to be assumed. The entire personnel educated for this purpose in Switzerland is called “professionals responsible for vocational and professional education and training.” This chapter focuses on their responsibilities, their training, and on the training and certification structures.

**Introduction**

The academic performance of children and young adults is inter alia influenced by school-related factors of which teacher ability is generally seen to have the biggest impact on student learning (Hattie 2009). This is also assumed for the sector of vocational and professional education and training (VPET). Teachers and trainers and their professional qualities are a key factor for successful vocational and professional learning (e.g., OECD 2010; Hensen-Reifgens and Hippach-Schneider 2015, p. 17).

The quality of the work of VPET teachers is essential, because with their work at the interface between the education system and labor market they contribute to the efficacy and quality of the future workforce (Hensen-Reifgens and Hippach-Schneider 2015). The demands on the work of vocational and professional teachers and trainers are high and constantly changing, for example, due to innovations in products and processes within trades and the usage of new media and technologies, but also due to changing expectations of young people and societies (Hensen-Reifgens and Hippach-Schneider 2015, p. 17). Even though the work of VPET teachers and trainers is important and challenging, not much is known about their work and training (Kirpal and Wittig 2009, p. 2). One difficulty of the research in the field of VPET teachers can be seen in the fact that “VET is nationally focused like no other form of education” (Shaw et al. 2016, p. 94). Vocational and professional education and training respond to national economies, are “delivering to national employment needs,” and have to be able to adapt to local changes (Shaw et al. 2016, p. 94). Accordingly, it is difficult to make generalizable statements about VPET teacher education, and it is not easy for VPET institutions to

collaborate in research on a global scale. Also, practitioners have difficulties “to understand what equivalence there is in other countries to their job, or their courses, or the qualification level they teach” (Shaw et al. 2016, p. 99).

This chapter focuses on VPET teacher education in Switzerland and is based on research as much as policy papers, guidelines, and expert interviews. Switzerland has one of the lowest youth unemployment rates of OECD countries (OECD Data 2017). The dual structure of training, which can be found in Germany and Austria as well, enables early labor market experience of young adults as well as socialization into the world of work and employment opportunities after graduation. It can be assumed that “traditional apprenticeships, strongly supported by the firm, where the apprentices are trained for a large amount of time, are still an attractive alternative to firmly school-based VET-models, which produce in some cases overqualified, in other cases low qualified or simply wrongly qualified students and alumni, who face transition problems from school to the world of work” (Gonon 2007, p. 7). VPET in Switzerland facilitates the inclusion of almost all adolescents in the education system and leads to a high percentage of young adults with a professional qualification (Gonon 2007, p. 8). Apprenticeship teachers and trainers, who significantly contribute to the functioning of the VPET system, are rarely a research topic. Therefore, this chapter is a first attempt to summarize how training and certification of professionals responsible for vocational and professional education in Switzerland is conducted.

---

## The Swiss VPET System

In this section an overview of the Swiss system of vocational and professional education and training (VPET) is provided, the framework in which the different roles and functions of professionals responsible for vocational and professional education have to be carried out.

After compulsory school, young people enroll either in upper-secondary vocational education and training (VET) or in upper-secondary schooling to get admission to universities. Two-thirds of all young people in Switzerland take part in VET programs. Although the number of students enrolling in VET is slowly decreasing, while upper-secondary schooling becomes more popular, with about 70% of each cohort, Switzerland currently has the highest percentage of students enrolling in VET in Europe. VET students work at a host company in a chosen occupation, and from the beginning of their apprenticeship, they earn a salary that increases over time. Besides the training at the host company, they attend a vocational school for 1–2 days per week where vocational subjects and general education subjects are taught. Some VET programs take place entirely at schools, where vocational and general education subjects are taught and practical skills are trained, but the majority of VET programs consist of schooling at a vocational school and “on-the-job training” at a host company. One particularity of the Swiss VET system is that there is a “third learning site” provided by labor market organizations. Labor market organizations carry out special training sessions (courses from 1 day to 1 week) “off the job” once or several times per year for learners from different companies. These

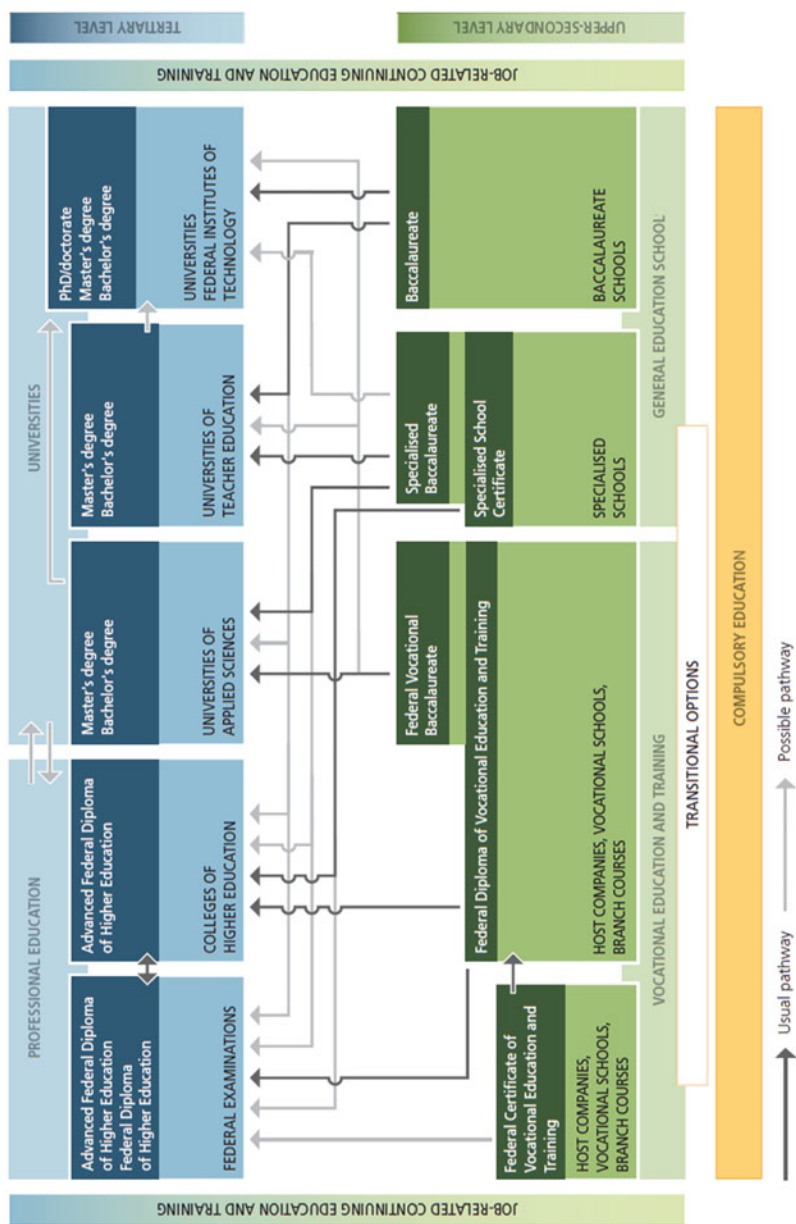

training sessions (branch courses) aim at connecting the knowledge of workplace and school-based learning (Wettstein and Gonon 2009, p. 175).

Regular VET programs take 3 or 4 years and lead to the Federal VET Diploma (Federal Diploma of Vocational Education and Training). It is also possible to attend a less demanding 2-year program (leading to the Federal Certificate of Vocational Education and Training) that consists of training at a host company and schooling at a vocational school as well (Stalder and Nägele 2011).

Tertiary-level professional education and training (PET) offers a variety of career options that build on upper-secondary vocational education and training (VET) and are aligned to labor market needs. After obtaining the Federal VET Diploma, young people can take federal examinations on two levels. Federal examination on level 1 can be attended to specialize in a particular field. It leads to the Federal Diploma of Higher Education. Federal examination on level 2 requires expertise in practice (working in the corresponding occupation for several years) and is intended for people that want to hold managerial positions. It leads to the Advanced Federal Diploma of Higher Education (State Secretariat for Education, Research and Innovation SERI 2017, p. 7). Since both examinations are competency-based, they provide the possibility to credit prior learning such as informal learning from working in the field. After obtaining the Federal VET Diploma, young people also can study at colleges of higher education. The study programs of colleges of higher education build on work-related knowledge and enable learners to develop specific skills as well as leadership and managerial competences. Besides the abovementioned VPET programs, there are lots of non-formal, job-related courses and seminars at all levels which support transition processes into the different programs and provide the possibility of lifelong learning.

Although the Swiss VPET system is aligned to the demands of the labor market, it is also an integral part of the education system (Gonon 2007, p. 9). The Swiss education system has no dead-end pathway. Instead it is highly “permeable.” Learners can switch between different levels and between VPET pathways and general education/university pathways (see Table 1). In the Swiss education system, “the academic-vocational divide” in the past last 25 years has diminished (Gonon 2007, p. 10). A popular career, for example, with both vocational and general education qualifications, can be realized through the Federal Vocational Baccalaureate (FVB) which exists since the early 1990s (Wettstein and Gonon 2009, p. 165). After upper-secondary vocational education and training, learners can attend a 1-year preparatory course in general education subjects and then take the FVB examination. The preparatory course is often also attended already during the 3- or 4-year VET program. Candidates that pass the FVB examination are entitled to enroll at universities of applied sciences. Holders of the FVB have the option to take the University Aptitude Test. This “pathway” exists since in the year 2003. Successful candidates are entitled to enroll in the cantonal universities or in one of the two federal institutes of technology (For further information about the Swiss VPET system, see Wettstein and Gonon (2009) or Dubs (2006).).

**Table 1** The Swiss education system (Source: State Secretariat for Education, Research and Innovation SERI 2017)

## Roles and Responsibilities at the Different Learning Sites

The Swiss VPET system is governed by three partners, the government, the cantons (communal authorities), and the labor market organizations. The government leads the VPET sector strategically, the cantons are responsible for implementing the strategic guidelines, and together with the government they finance the VPET sector. In all other sections of the Swiss education system, the cantons are fairly autonomous, while the VPET sector is centrally (nationally) managed since it is interlinked with the world of work and its regulations. The collaboration with labor market organizations of different trades facilitates a good coordination of VPET with the labor market.

The government provides ordinances (*Verordnungen*) for the VET program of every occupation based on the Federal Act on Vocational and Professional Education and Training (portal of the Swiss government 2017a). In the ordinances it is determined which part of the VET program is covered by vocational schools, host companies, or branch course training centers. Comprehensive curricula build on the ordinances and provide didactical guidelines for the specific occupations. They contain a detailed description of the aims and the structure of the program as well as of the organization of the branch courses and the qualification process. Curricula are also provided for PET programs. For each occupation there are committees, consisting of representatives from labor market organizations, cantons, and government that keep the ordinances and curricula up to date in respect to labor market requirements. For the professionals responsible for VPET, ordinances and curricula are relevant for their work at the following learning sites:

### Vocational schools

- Teachers of vocational subjects
- Teachers of general education subjects, including sport teachers
- Teachers of subjects of the Federal Vocational Baccalaureate

### Host companies

- Workplace trainers

### Branch course training centers

- Branch course instructors

### Colleges of higher education

- Teachers at colleges of higher education

The training and certification of the abovementioned professionals responsible for VPET is officially regulated and will be focused on in this chapter. Besides these professionals, other groups of people are working in the framework of VPET. An example are the trainers in the facultative preparatory courses for the federal examinations on levels 1 and 2 that are widely not regulated (Fazekas and Field 2013, p. 15),

people involved in job-related education and training such as seminars or workshops (also called continuing education and training (CET)), people working in examination processes within VPET, or managerial staff leading VPET institutions.

## Vocational Schools

Learners are taught in classes from 10 to 24 learners in the closest VET school to their host company. Vocational schools often are specialized in one occupation or a group of occupations. All learners of one class learn the same occupation or very similar occupations. The vocational schools are organized by the cantons. To cover locally required schooling, inter-cantonal collaborations are possible. In most cases the students are taught by a teacher of vocational subjects, a teacher of general education subjects, and a sport teacher. Often preparation courses for the Federal Vocational Baccalaureate are held at vocational schools as well (Wettstein and Gonon 2009, p. 163).

**Teachers of vocational subjects.** Teachers of vocational subjects are responsible to teach the theoretical foundations and background knowledge of an occupation. In most cases they are holders of the highest professional qualification of the corresponding occupation (e.g., hold an Advanced Federal Diploma of Higher Education), have elaborated subject-related knowledge, and often have a great deal of working experience (Hof et al. 2011, p. 2).

**Teachers of general education subjects.** According to Gonon (2007), “preparing for the world of work does not only include the acquisition of solid professional skills but also of knowledge management skills and the ability to ask the relevant questions in order to prepare for uncertainties” (Gonon 2007, p. 10). Teachers of general education subjects are responsible to ensure that VET programs lead to an adequate level of general knowledge. Although teaching general education subjects like mathematics, languages, and communication, in their teaching teachers always refer to professional situations as a point of reference. Teachers of general education subjects are usually not experts in practice but have a high level of general knowledge. Typically they might, for example, have a regular teaching diploma for primary or secondary schools or they have studied at a university.

**Teachers of subjects of the Federal Vocational Baccalaureate.** Teachers of subjects of the Federal Vocational Baccalaureate (FVB) are responsible to prepare learners for the FVB examination and support them to develop the skill sets for studying. They are responsible to pass on extended general knowledge to VET learners. Students that prepare for the FVB examination are taught basically the same subjects as students in high schools, such as a first (regional) national language, a second national language, English, mathematics, and natural and social sciences (Erziehungsdirektion des Kantons Bern 2017a). Teachers of subjects of the FVB in most cases have an academic background and sometimes also are holders of a high school teacher diploma.

## Host Companies

Dual VET requires low public expenses. Only around 25% of the costs of VET programs in Switzerland are paid out of public budget (of government and cantons); approximately 35% are paid by the host companies (who, in average, get these expenses back from the productive work outcomes of the apprentices). Around 40% of the costs are covered by VET learners, who, because they are receiving only a small salary, are financing a part of their training themselves (Maurer and Gonon 2013, p. 62). Cantons give companies the authority to train apprentices if they can provide adequate structures for it. The maximum number of apprentices simultaneously trained in a host company depends on the number of skilled workers that a company employs (Wettstein and Gonon 2009). To hire VET learners can be an advantage for enterprises because in most cases the productive outcome of the work of apprentices exceeds the training costs (Wettstein and Gonon 2009), and companies and labor market organizations profit from providing career prospects for young people because this secures the supply of skilled workers needed in a branch (Staatssekretariat für Bildung, Forschung und Innovation SBFI 2017a). Around 20% of all companies in Switzerland train apprentices (Mühlemann et al. 2007, p. 144). The engagement of firms in training is relatively stable over the years and a sufficient amount of posts for VET learners is provided. In the year 2017, firms in Switzerland offered 97,000 new posts for VET learners, of which in August 2017, 90,000 were taken. The supply exceeded the need of posts, 7000 posts for VET learners remained open (SBFI 2017b). Jobs for VET learners in general are opened in branches where the demands for skilled workers are high, which also means in branches, in which future skilled workers probably will find an employment.

In countries with dual VET systems, it is important that the “involvement and commitment of industry and firms” is continuously strengthened (Gonon 2007, p. 11). In Switzerland the engagement of enterprises in training apprentices is supported by the development of new forms of vocational training at workplaces such as intercompany alliances in which enterprises work together in training apprentices, which facilitates the development of the branch-specific skills (Wettstein and Gonon 2009, p. 122). Though, in general it can be assumed that “as long as training regulations and the market situation permit a cost effective training of apprentices, companies do not need specific labor market regulations or institutions to offer training posts” (Wolter et al. 2003, abstract). Cost-effective training can, for example, be ensured, if the major part of the VET training takes place at workplaces and not at vocational schools, so that apprentices are able to contribute effectively to the productive outcome of their host company and if workplace training is not hampered by “too restrictive curricular guidelines” (Wolter 2008; Maurer and Gonon 2013, p. 69). Also workplace trainer education should not be too cost- and time-consuming for that reason. In Switzerland the trainer education, that skilled workers who want to train have to attend, is relatively short, only taking 100 learning hours, which corresponds to 3 ECTS (The European Credit Transfer and Accumulation System (ECTS) was

**Table 2** Training duration for teacher/trainer profiles “as a second job” and “on a full-time basis”

Profile	Specification	Learning hours	ECTS
Teachers of vocational subjects	As a second job	300	10
	On a full-time basis	1800	60
Teachers of general education subjects		1800	60
Sport teachers		1800	60
	With high school teacher diploma	300	10
Teachers of subjects of the FVB		1800	60
	With high school teacher diploma	300	10
Workplace trainers		100	3
Branch course instructors	As a second job	300	10
	On a full-time basis	600	20
Teachers at colleges of higher education	As a second job	300	10
	On a full-time basis	1800	60

established to make students’ workload comparable and transferable from one university in Europe to another. 1 ECTS point is equivalent to an average student workload of 30 h.) (see Table 2).

**Workplace trainers.** Workplace trainers in host companies generally have work expertise related to the business of the host company. They are responsible for supporting the practical skills development among apprentices, plan and evaluate their training, and “have a very important role to play by helping the apprentices to socialize in the world of work and to develop a professional identity as well as commitment to the enterprise” (Hensen-Reifgens and Hippach-Schneider 2015, p. 5). In small companies, the work of apprentices is closely coordinated with the work of the workplace trainer who is often also the head of the company. This allows the apprentices to acquire the skills by working together with a more experienced colleague, whereas “the trainer is a crucial role model for the following generation of employees” (Hensen-Reifgens and Hippach-Schneider 2015, p. 5). Apprentices working in larger companies are often trained by several skilled workers responsible for sections of the training curricula.

Typically, “on-the-job” training takes place while productive work is carried out for an internal or external client. During this process, instruction is secondary to production and training should not hamper productive work (Wettstein and Gonon 2009). VET learners also work without supervision and are responsible for a part of the productive work, which can include highly demanding and complex work steps, and some VET learners carry a lot of responsibility (Hoffman and Schwartz 2015). Workplace training provides the opportunity for “authentic learning processes.” The fact that what is learned at a workplace can directly be used with the workplace setting is considerably motivating for young learners (SBFI 2015, p. 5). A study that compared school-based VET programs to VET programs at workplaces showed that 89% of young people in VET preferred

workplace to school-based learning. Typical statements of young learners displayed in the study were “I am fed up with school,” “I want to do something real,” and “I want to work practically and not struggle with theories” (Mjelde 1993 cited by Gonon 2007, p. 7).

## Branch Course Training Centers

Branch course training centers are organized by labor market organizations. The cantons support their development and have to ensure that all necessary courses are provided. Some of the costs for the branch courses are paid by the cantons which include corresponding contributions of the government; the other part is paid by the companies or by labor market organizations or, where they exist, out of vocational training funds (Wettstein and Gonon 2009, p. 176). Large labor market organizations hold regional training centers or even national training centers, like, for example, the “Center for Young Professionals in Banking (CYP).” Smaller labor market organizations that have to provide only some courses during the year therefore rent rooms in a vocational school or in a company.

Branch course training centers provide the kind of practical training that cannot easily be acquired at the workplaces because the resources needed are not available there (SBFI 2015). Because practical training “off the job” does not have the same relevance for every occupation, the duration of the branch courses varies largely between occupations, and for some occupations these courses have to be attended by learners at the beginning of a VET program, while for others it occurs later on (Wettstein and Gonon 2009, p. 175).

**Branch course instructors.** Branch course instructors are responsible for the practical training “off the job.” Instructors and apprentices are not bound in an employment relationship. In branch course training centers, apprentices are learners rather than workers. In contrast to the situation of workplace trainers in a host company, branch course instructors are exclusively responsible for good instruction and not to guarantee productivity. Branch course instructors provide learning environments that simulate the reality of the most relevant and representative problems and work processes. The aim is to teach very closely to practice but also to include, where necessary, theoretical concepts and to connect the skills from workplace training to what is learned in vocational schools (Wettstein and Gonon 2009). The skills that VET learners acquire in their everyday work at the host company can be more or less specific, and there can be differences in the training quality. According to Reto Catani, from SVIFET, branch course instructors teach VET learners what the “standards in practice” of a certain occupation are (personal communication, November 6, 2017).

## Colleges of Higher Education

Colleges of higher education are run by cantons or private providers. For former VET students, they provide (nonacademic) tertiary schooling. Study costs are paid

**Table 3** Subject areas of colleges of higher education (Erziehungsdirektion des Kantons Bern 2017b)

Subject areas of colleges of higher education
Technology
Hospitality industry, restaurant, and tourism
Economics
Agriculture and forestry
Health
Social affairs and adult education
Art and design
Traffic and transport

by students as well as by cantonal contributions that cover around 50%. For some study programs that are currently of high public value (e.g., the health sector), cantonal contributions can be up to 90% (SBFI 2017c). Approximately 8500 persons annually get qualified by colleges of higher education and often work in leading positions later on (SBFI 2017c). When they start their studies, students at colleges of higher education usually are under 25 years old which means that they often start to study only some years after they have obtained their Federal VET Diploma. In general students at colleges of higher education are employed and study part time (Schmid and Gonon 2013, p. 152). Colleges of higher education in Switzerland offer 52 different study programs in 8 subject areas (Table 3).

**Teachers at colleges of higher education.** Teachers at colleges of higher education in general are experienced skilled workers. They are holders of a Federal VET Diploma and have studied at a corresponding college of higher education. Teachers at colleges of higher education are responsible for supporting their students in developing methodological competences, in analyzing occupation-related problems, and in applying theoretical knowledge in practical contexts (Erziehungsdirektion des Kantons Bern 2017b).

---

## Training of Professionals Responsible for VPET

### Standardization and Quality

Even if in Switzerland VPET teacher/trainer education can have local specifics (e.g., in the different linguistic regions), in general VPET teacher/trainer education follows national standards. SERI publishes a list of all recognized providers for teacher/trainer education programs that lead to a nationally recognized teacher/trainer diploma (Table 4). Federal, cantonal, or private institutions provide a diverse selection of programs which are evaluated by SERI (yearly reporting and visits every 6 years). Workplace trainer courses are only provided by private institutions and corresponding certificates are valid in the canton that issued it. Workplace trainer courses are supervised by the cantons, with the exception of courses

**Table 4** Prerequisites of VPET teacher/trainer education programs, summary of training contents, and training institutions

Prerequisites of VPET teacher/trainer education programs, summary of training contents, and training institutions
<b>Teachers of vocational subjects</b>
<b>Prerequisites</b>
PET diploma (Federal Diploma of Higher Education or Advanced Federal Diploma of Higher Education) or university degree (bachelor/master) in the corresponding teaching field
Six-month practical work experience in the corresponding teaching field
Employment at a vocational school and sometimes also teaching experience
<b>Summary of training contents</b>
Development of methodical competences such as how to initiate, support, and evaluate learning processes
<b>Training institutions</b>
SFIVET, University of Applied Science HAFL, Universities of Teacher Education (St. Gallen, Zurich, Lucerne), Federal Institute of Technology Zurich ETH
<b>Teachers of general education subjects</b>
<b>Prerequisites</b>
Teaching diploma for obligatory school or university degree (bachelor/master) preferably in a field related to general education subjects
Six-month practical work experience in the corresponding teaching field
Employment at a vocational school
<b>Summary of training contents</b>
Building up methodological competences of teaching general education subjects
<b>Training institutions</b>
SFIVET, Universities of Teacher Education (St. Gallen, Zurich)
For sport teachers with high school teacher diploma: SFIVET in collaboration with Universities of Teacher Education (Berne/Jura/Neuchâtel, Vaud, Thurgau, PHFHNW, Zurich, Lucerne), SFIVET in collaboration with the University of Fribourg
<b>Teachers of subjects of the Federal Vocational Baccalaureate</b>
<b>Prerequisites</b>
Tertiary education in the corresponding teaching field. For teaching subjects that require a university degree: high school teacher diploma or university degree bachelor/master in the corresponding teaching field
Six-month practical work experience in the corresponding teaching field
Employment at a vocational school
<b>Summary of training contents</b>
Knowledge of the dual VET system, understanding the working situation of learners
<b>Training institutions</b>
Universities of Teacher Education (FHNW, Zurich, Lucerne), University of Zurich, University of St. Gallen, SFIVET in collaboration with Teacher Universities (Berne/Jura/Neuchâtel, Vaud, Thurgau, Lucerne), SFIVET in collaboration with the University of Fribourg
<b>Workplace trainers</b>
<b>Prerequisites</b>
Federal VET Diploma in the corresponding teaching field
Two years practical work experience in the corresponding teaching field

*(continued)*

**Table 4** (continued)

Prerequisites of VPET teacher/trainer education programs, summary of training contents, and training institutions
<b>Training contents</b>
Vocational pedagogy, how to support the “theory-practice transfer”
<b>Training institutions</b>
Private providers
<b>Branch course instructors</b>
<b>Prerequisites</b>
PET diploma (Federal Diploma of Higher Education or Advanced Federal Diploma of Higher Education) or university degree (bachelor/master) in the corresponding teaching field
Two years practical work experience in the corresponding teaching field
Employment at a branch course training center
<b>Summary of training contents</b>
Planning of the branch courses according to the teaching plans
<b>Provider</b>
SVIFET, private providers, Universities of Teacher Education (St. Gallen, Zurich, Lucerne)
<b>Teachers at colleges of higher education</b>
<b>Prerequisites</b>
Diploma of a college of higher education or university degree (bachelor/ master) in the corresponding teaching field
Employment at a vocational school and sometimes also teaching experience
<b>Summary of training contents</b>
Andragogic methods, support of the “theory-practice transfer”
<b>Training institutions</b>
SFIVET, Universities of Teacher education (St. Gallen, Zurich, Lucerne), Federal Institute of Technology Zürich ETH

For foreigners it is possible to apply for the recognition of their diploma by SERI that recognizes diplomas if they are equivalent to corresponding Swiss diplomas (VPETO Art. 69, portal of the Swiss government 2017b).

provided by large labor market organizations such as “Swissmem” or VSSM, which are supervised by SERI because they operate at a national level (SERI 2017d). Research in Switzerland supports the development of VPET teacher/trainer education. Changing conditions in the framework of VPET that are aligned to changes in the labor market require constant adjustment and updating. According to Barbara Grob of SFIVET, for example, some structures of the teacher education for VET sport teachers are being changed (personal communication November 2, 2017).

## **Institutions of Teacher/Trainer Education**

The implementation of a new act on vocational and professional education in 2004 set off several processes. Former institutions for teacher education in Switzerland

were restructured to be “universities of teacher education,” and some of them started to offer VPET teacher/trainer education programs. As can be seen in Table 4, regular universities are also involved in VPET teacher education. The former institution for VPET teacher/trainer education, called Swiss Pedagogical Institute for Vocational Education (SPIVE), was restructured in 2006 and today is called the Swiss Federal Institute for Vocational Education and Training (SFIVET). SFIVET, under contract to the government, provides teacher/trainer education programs for all professionals responsible for VPET (with the exception of workplace trainers), a variety of courses for further training (*Weiterbildung*) in the VPET sector (such as courses for examination experts and leading staff), a research/development center for VPET, and a master’s program (MSc) in VET. Many collaborations have been established between SFIVET and several Swiss universities of teacher education as well as with cantonal universities and international partners.

### **Structural Characteristics that Support the Linkage of Theory and Practice**

The linkage of theory and practice of VPET in Switzerland is facilitated by a particularity of the teacher/trainer education. Professionals responsible for VPET can study toward a “teacher/trainer as a second job” designation (*Lehrperson im Nebenamt*). After studying in this pathway, they can teach/train “as a second job” (work quota 1–50%). This is different from regular part-time employment. Whereas, for example, a regular teacher can work part time or full time as a teacher, teachers/trainers that have completed the “teacher as a second job” profile are only allowed to work 50% or less as a teacher/trainer. They continue working as regular workers in industry, which allows them to include their up-to-date knowledge of the developments in the world of work in their teaching, which helps them to support VPET learners in linking theory and contemporary practice. For teachers and trainers who teach full time, it can be difficult to hold their professional knowledge up to date, a problem that can lead to legitimacy issues.

Because in Switzerland the linkage of theory and (contemporary) practice is considered to be of utmost importance, to study in these profiles is attractive: compared to the profiles that lead to “teacher/trainer on a full-time basis” (*Lehrperson im Hauptberuf*, possible work quota 1–100%), they require less time (see Table 3). The study profile “teacher/trainer as a second job” is only available for a part of the professionals responsible for VPET: teachers of vocational subjects, branch course instructors, and teachers at colleges of higher education (see Table 3). For teachers of general education subjects and for teachers of subjects of the FVB, up-to-date skills and knowledge of developments in industry are less important. They can only study in the profile “teacher on a full-time basis” (see Table 3). Most recent statistics show that around 42% of all teachers employed at VET schools work less than 50% as a teacher (Bundesamt für Statistik 2014).

## Dimensions of VPET Teacher/Trainer Education

**Theory and practice.** According to Reto Catani, SVIFET, to be well trained after a VPET program and to be “professionally competent” means that a person does know what to do and also knows why he or she does it this way (personal communication, November 6, 2017). Professionals responsible for VPET support the development of VET learners’ professional competences, which requires comprehensive learning beyond separately taught subjects (SBFI 2015, p. 5). Professionals responsible for VPET have to be educated so that they are able to refer to the context of practical work, e.g., by including learners’ work-related experiences in class, and simultaneously are able to familiarize young learners with the essential theories that help them to better understand, plan, and carry out their work (SBFI 2015, p. 5). Theory and practice can be integrated in teaching/training through the concept of “situated learning” or “problem-based learning.” Applying these concepts, a teacher organizes teaching and learning processes from the perspective of relevant work situations or work-related problems. “Real-life work situations” or problems are addressed with knowledge and theories to encourage a linkage of theory and practice.

**Collaboration of colleagues at the different learning venues.** Of main importance for the quality of VET in Switzerland is the coordination of the learning at the three different learning venues: vocational school, host company, and branch course training center. If it functions well, students can profit from learning in different environments and from the accumulated knowledge of the teachers/trainers involved. VET teacher/trainer education therefore aims at developing the teachers’ and trainers’ ability to cooperate with colleagues at the different learning venues (SBFI 2015, p. 5). It is, for example, vital that all teachers/trainers involved know and understand the different learning environments their students are confronted with. Only if they understand the learning situation of learners and their level of education can they address them accordingly and effectively support their learning process. How to build bridges for the learning among the three learning sites (e.g., through media usage such as iVideo or REALTO) is also a particular concern of research (e.g., Cattaneo and Sauli 2017; Aprea et al. 2012).

**Pedagogy and andragogy.** VPET teacher education in Switzerland aims to pass on pedagogical approaches as well as andragogic approaches to future teachers and trainers. Since at the start of their VET programs, young learners on average are around 16 years old, VET teachers/trainers have to act as general educators and need pedagogical knowledge (Hensen-Reifgens and Hippach-Schneider 2015). During the 3 or 4 years that regular VET programs take, young learners get more independent and start to manage their own lives as adults. For the professionals responsible for VET, this means that in this time, they have to start to address young learners more as adults and apply andragogic approaches. How this transition toward adulthood, the first steps toward financial and social independence of VET learners, has to be reflected in the teaching is a core theme of VET teacher/trainer education (SBFI 2015, p. 5). It can be summarized, that, within the progress of a VET program, young learners have to be supported to take over the responsibility for their learning progress. Teachers therefore, for example, can provide the opportunity of self-regulated studying.

## Prerequisites to Be a Professional Responsible for VPET

VPET teacher/trainer education programs in Switzerland are short, but they all build on specific prior experience and qualifications and are addressed to existing specialists. Specialists (some in technical occupation specific subjects, some in vocational subjects, some in general education subjects) are trained in relatively short programs on how to use their knowledge or skills to teach/train learners in VPET.

Table 4 shows which prerequisites for the different education programs are requested (which specialists the programs are addressed to). What is common for all profiles is that students have to have at least some experience in the industry, i.e., work (not teaching) experience for at least 6 months (see Table 4), which is supposed to facilitate the connection of theory and practice in their teaching. Table 4 also gives a summary of the basic contents of each program to show what the different “specialists” additionally are trained in to become a professional responsible for VPET. As can be seen in Table 4, the backgrounds required for the different profiles are diverse and (future) professionals responsible for VPET are a heterogeneous group. The diversity of backgrounds of teachers and trainers leads to a vocational and professional education and training that is strong in developing practical skills as well as strong in developing general subject knowledge.

---

## Recruiting Professionals Responsible for VPET

Several factors contribute to successful recruitment of professionals responsible for VPET.

1. As can be seen in Table 4, enrolling in training programs for professionals responsible for VET (with the exception of workplace trainers) is only possible if a candidate is already hired by a vocational school or a branch course training center. The recruitment of the professionals responsible for VPET is carried out by vocational schools and branch course training centers where the “best candidates” (most suited regarding subject knowledge, practical experience, personality, and social skills) are selected before they attend teacher/trainer education (Hof et al. 2011, p. 2). This increases the number of people who are eligible to apply for open positions. For example, all skilled workers with 6-month practical work experience that have an (Advanced) Federal Diploma of Higher Education can apply for a job as a teacher of vocational subjects. If they have 2 years of practical work experience, they can also apply for a job at a branch course training center. All teachers for obligatory school or high school and persons with a university degree in the corresponding teaching field can apply for vacancies at vocational schools.
2. The work of professionals responsible for VPET can be considered to be attractive. Pay is at least equal to industry for teachers/trainers that work at branch course training centers or vocational schools (Hof et al. 2011). The wage of teachers at vocational schools is equal to regular teacher wages (D-EDK

Deutscheschweizer Erziehungsdirektoren- Konferenz 2017). At vocational schools such as at every public school in Switzerland, in general, teachers (in one canton) have the same wage, regardless of their previous career or background (Hof et al. 2011, p. 3).

3. Teacher/trainer education is based on previous education and work experience of candidates. The additional training of professionals responsible for VPET can be completed with relatively low expenditures, for example, 600 learning hours (20 ECTS) for the certificate to be a trainer at a branch course training center on a full-time basis or 1800 learning hours (60 ECTS) for the certificate to be a teacher of vocational subjects on a full-time basis (see Table 4), which leads to regular teacher status and a high wage. Teacher/trainer education programs only have to be completed in the first 5 years of working as a teacher/trainer, which means that for the completion of teacher/trainer education programs, an ideal time can freely be chosen (Vocational and Professional Education and Training Ordinance VPETO Art. 40, portal of the Swiss government 2017b). If professionals responsible for VPET work less than 4 h per week on average (around 160 h in a year) as a teacher/trainer, they legally even are not required to complete a teacher/training education program at all (VPETO Art. 47, portal of the Swiss government 2017b).

---

## Challenges and Criticalities Within the Approaches to Teacher/Trainer Qualification

Workplace training builds the major part of most VET programs, and therefore the quality of training on the job is of utmost importance. However, workplace trainer education is very short (100 learning hours, 3 ECTS), and their certification is not nationally regulated. Higher requests on the training of workplace trainers could hamper company engagement in VET training. As a result of these minimal regulations, the quality of workplace training can differ widely between companies. For learners in VET, this means that quality training is not always assured. This is also discussed against the background of relatively frequent cancellations of VET contracts (10–40%, depending on the occupation), which is related to high individual and collective expenses (Schumann et al. 2015, p. 2) (After a cancellation of a VET contract, most of the young learners do not drop out of the VET system completely, but start a new program or start/continue in a new company (Schumann et al. 2015, p. 2).).

In comparison with the neighboring country Germany, VPET teacher education is quite a bit shorter. (Ongoing) practical work experience is higher valued than academic credentials and academic learning in the teacher education program. VPET teachers often start working without a specific pedagogic qualification and acquire pedagogic skills later on while working. This can have implications on their teaching quality and raises questions in respect to the readiness of teachers to develop their own teaching material, adjust to new curricula, respond adequately to the large variety of classroom management situations, etc. However, the persisting

argument in defense of the design of VET teacher education programs is that work experience is largely relevant and provides credibility in the classroom. “Learning by doing” is a persisting Swiss narrative which permeates VET teacher education and teaching practice as well.

In Switzerland teachers for around 230 occupations have to be educated. The challenge is that teachers of vocational subjects need general pedagogical knowledge and knowledge how to teach aspects of a particular occupation. Today the teaching methodology of all of these occupations is not systematically elaborated. To find an adequate teaching methodology for a specific occupation, teachers of vocational subjects often refer to their own experiences as a learner and worker in the field; they sometimes refer to related academic subjects and teaching methodologies, or they simply rely on general methods and approaches and apply them to the occupation they teach. It is an ongoing exercise for teachers of vocational subjects to find adequate solutions to balance the situation.

---

## Conclusion and International Perspectives

Successful and well-considered recruitment of professionals working within VPET is essential for high-quality VPET, especially to maintain a high connectedness of VET to the labor market. It can be assumed that it is only possible to find good practitioners to teach the future skilled workers if working as a professional responsible for VPET is attractive and if getting there is not too demanding. In the Swiss context, equal conditions of work as a teacher/trainer to industry and to regular teaching and the low training expenditures contribute to the fact that it is possible to recruit talented, experienced, and successful practitioners for teaching and training in VPET. Programs of VPET teacher/trainer education are short. The programs build on prior knowledge, experiences, and corresponding certificates and only cover the contents that the different “specialists” additionally need to use their prior knowledge and skills to successfully teach in VPET. Because the VPET teacher education programs are short, research to increase the quality and quality assurance are of utmost importance as well as the possibility to develop and adjust structures where needed.

Various publications have addressed the possibility of policy transfer between countries in respect to teacher education (e.g., Barabasch and Watt-Malcolm 2013; Dehmel 2011; Grollmann 2005; Steiner-Khamsi 2015). Particularly relevant is the topic for the European Union, signified by a large number of publications released by Cedefop (2014, 2015). The Swiss education for teachers and trainers takes a unique approach that could be a model for various countries with an interest in applying an affordable and pragmatic approach to quality training for VPET teachers and trainers. In contrast to its neighboring country Germany, Switzerland’s VPET teacher education is mostly not based at regular universities but instead provided by various universities of teacher education. Although academic in nature, it largely builds on practical expertise, which is highly valued. VET teachers often come with a wealth of acquired work experience and are skeptical of theoretical content brought across within higher education. They enforce quality training with their critical

questions and expectations toward the “usefulness” of the knowledge delivered in teacher/trainer education programs. In this way universities of teacher education are constantly challenged to provide an education that serves the particular needs to this target group and strongly builds on applied research and practical content and on building strong bridges between the world of work, the world of VPET education, and prior knowledge and experiences of the VPET teacher. Additionally, there is the possibility for VPET teachers to choose between part-time or full-time teaching for which different conditions apply. This flexibility is attractive to many practitioners, who either have a strong intrinsic interest or need to compensate their existing income. With this possibility a strong ongoing relation to practice is ensured while at the same time making the profession of VET teacher or trainer much more attractive to a large group of workers.

For all the reasons mentioned above, the Swiss approach to VPET teacher and trainer education has much to offer and can be considered as a potential model for policy transfer or policy borrowing. More systemic comparisons between countries’ approaches to it would be needed, especially within Europe, where making the profession more attractive has been a policy concern over many years. An open question that remains for the system, however, is to what extent the relative small amount of academic education within teacher education programs in comparison with their German counterparts, for example, will be sufficient in the future.

## Abstract

This chapter explores pedagogical approaches used by vocational teachers to capture new techniques, technology, and knowledge developed through shared practice in workplaces. It argues that this is both a challenging and a problematic endeavor as teachers are situated in contexts removed from where vocational knowledge is developed. In addition, the nature of vocational knowledge which is complex, complicated, and in constant motion and flux compounds the practical

e-mail: [j.broad@ucl.ac.uk](mailto:j.broad@ucl.ac.uk)

problems of collection and recontextualization of new techniques and innovations from workplaces to teaching environments. Examples are given from research findings of how vocational teachers overcome these challenges by utilizing professional development activities to capture new techniques, technologies, and knowledge. These are discussed in order to shed light on the agentic action of vocational teachers and how they self-determine and self-select the activities they engage with. It is also shown why some activities are perceived by teachers to be valuable and why some hold little value. It is further shown that this is largely determined by the relational value of the activities engaged with and how relevant they are to the day-to-day practices of the individual teacher. The hidden nature of the pedagogy that teachers use is also illuminated. This exploration reveals the main characteristics of effective teacher pedagogy that are (a) teacher agency, (b) relational networks, and (c) hidden pedagogical practices. The chapter concludes by arguing for new ways to both organize and conceptualize pedagogical approaches to the development of vocational teachers' occupational expertise.

**Introduction**

In everyday workplaces, new approaches, techniques, and technologies are developed; new ways of doing are adopted. It is therefore reasonable to say that vocational knowledge as it is applied and used in context is in a constant state of flux; it is temporal and has high levels of currency. This raises particular pedagogical issues for vocational teachers in how to keep abreast of new knowledge, skills, and work processes. Once vocational practitioners have moved away from their occupation on a day-to-day basis to become vocational teachers, they are removed from where vocational knowledge is developed and so find it deeply problematic to ensure that their vocational expertise is maintained and refreshed. Regardless of these practical problems, the expertise and therefore the continuing professional development (CPD) of vocational teachers is central to high-quality vocational education and training (VET) pedagogy. Within many of the debates concerned with high-quality provision are calls for highly experienced vocational teachers with a broad knowledge base and extensive expertise (see, *inter alia* Gamble 2013; Billett 2011). For Gamble (2013), vocational teachers require formal subject or technical knowledge, pedagogic expertise, and practical workplace experience. Wheelahan and Moodie (2011) in their report on Australian VET teachers also focus on the skills held by vocational teachers. Their view is that this rests on both initial training, mainly focusing on pedagogy and on continuing professional development to ensure currency in the occupational area is maintained. Congruent with these views, the focus of this chapter is the pedagogical approaches used in CPD activities by teachers to ensure that vocational expertise is maintained. The chapter argues that high-quality

vocational pedagogy offered by these teachers to vocational students, in the main, rests firmly on the vocational skills and expertise they hold.

Through exploring the interplay between teachers' professional development activities and subsequent enhanced student learning, a further and central argument of this chapter is that teachers are able, through CPD activities, to link occupational contexts to learning contexts so as to transport updated and fresh vocational expertise to share with their students. This central role of vocational teachers is described as

They reformulate vocational knowledge from work where it has mainly a productive function to a teaching-learning function, and they make this recontextualized vocational knowledge comprehensible to others – to students and novice practitioners or workers. (Moodie and Wheelahan 2012: 17)

This also suggests that an important aspect of high-quality VET provision is how a teacher's newly acquired vocational knowledge and skills is recontextualized from occupational sites to learning sites so as to provide rich and meaningful learning experiences for their students. It suggests that transportation of vocational knowledge across contexts is not a straightforward process.

Following this introduction, the chapter first examines currently accepted approaches to the CPD of teachers. From here, the theoretical positions on the nature of vocational knowledge, the development of expertise, models of professional learning, and how vocational teachers know are discussed. Within these discussions, the importance of context is also explored. The following section briefly explains the research methodologies adopted in a study of the professional development activities of vocational teachers, followed by a presentation of findings. These findings begin to shed light on how vocational teachers are able, through their development activities, to enrich the learning experience of their students. To further illuminate the approaches taken, the discussion exemplifies how, due to the very nature of vocational knowledge and practice, it is problematic and difficult for vocational teachers to maintain and enhance their vocational expertise once removed from vocational settings where it is developed and practiced. The particular pedagogy of the professional development activities that vocational teachers engage with to manage these difficulties is explored and examined. It is argued that their CPD activities enable them to cross boundaries and to link the geographical and contextual sites where vocational knowledge is produced, to learning sites where it is shared with vocational students. Within this process, they recontextualize this new and refreshed knowledge and so enhance the curriculum offered to their students through richer learning experiences.

---

## **The Continuing Professional Development of Teachers: A Brief Exploration of Models**

Effective pedagogy within accepted approaches to vocational teachers' CPD is problematic to identify as while there is a relatively wide and mature body of literature on school teachers' professional development, post qualification, relatively, there is

paucity on that of vocational teachers. However, while the literature focused on school teachers is not directly transferable in all instances, it can shed light on what works generally for teachers in their developmental activities. Suggested within this literature is a duality of approach which tends toward conceptualizing professional learning as knowledge transmission or, alternatively, as collaborative and more social approaches. The literature suggests that collaborative approaches have long been recognized as being effective by providing the richest opportunities (see, e.g., Goodson and Hargreaves 1996; Hargreaves 1994). In their study, Hodkinson and Hodkinson (2005) found that high levels of collaboration bring an additional dimension to learning. It is richer and not bounded by notions of formal learning. Learning is informal and ongoing whenever teachers are together through discussions, consultations, and sharing of materials and ideas.

In contrast, Day (2002) has argued for a more individualistic model of reflective practice and suggests that the normal CPD offer to teachers was through narrowly conceived “training” models, implemented for external compliance requirements. More recently, Day (2017) suggests that the application of competency-based approaches, in the form of professional standards for teachers, atomizes knowledge and skills. He argues that any professional development activities for teachers must provide opportunities for deep learning and take account of the individual motivations of teachers.

Turning to the CPD of vocational teachers, Andersson and Köpsén (2015), drawing on the concept of dual professional identity (for an example of this within the English vocational education system, see Orr and Simmons 2010), argue that to be knowledgeable about their subject (occupation) requires them to have a distinct vocational identity that must be current and thus maintained. In order to do this, vocational teachers need to continue to have contact with their original occupational field and be active participants within it. This appears to suggest that vocational teachers are best served in their professional development by returning in some way to their original occupation. This further suggests that they will meet and work in collaborative and informal ways with those still working within the original occupation. However, the actual activities and thus the pedagogical approach that vocational teachers engage with through collaborative learning to maintain their vocational identity are problematic to easily identify. A comparative study by Lloyd and Payne (2012) sheds some light on this, and they identified three ways in which hairdressing teachers maintain and develop their occupational expertise. These were through working occasionally in a friend’s salon, by suppliers of hairdressing products running workshops in the college salons, and through collaborative learning within the college by sharing ideas and reflecting on practice.

This short review of pedagogy within approaches to teachers’ CPD suggests a duality of approach, either through knowledge transmission and individualist or through collaborative and more social approaches. It begins to suggest that the more collaborative approaches are the more effective. The following section offers a theoretical exploration.

## **Understanding Vocational Knowledge: The Interplay with Teacher Expertise and Context**

This section explores three key conceptual frameworks for understanding pedagogical issues in vocational teachers' development. It begins by addressing concepts of vocational knowledge to identify what it is that vocational teachers need to refresh and learn to maintain their expertise. To enable the exploration of key elements of effective pedagogy for vocational teachers, the discussion then moves to explore the concept of expertise and, within this, models of professional learning. Finally there is a brief discussion on how vocational teachers know, and the debates as to where knowledge is said to reside are explored. Discussed within these sections is the importance of context for professional learning.

## **Understanding Vocational Knowledge: What Teachers Need to Acquire**

The ways and mores of a vocation or occupation and thus the knowledge, skills, and attributes that vocational teachers pass on to their students in learning settings are complex, complicated, and multiplicitous. In starting to explore this further, this section focuses on the often-contrasted concepts of codified and tacit knowledge. Guile (2011) distinguishes these two types of knowledge as "know-how" which is situated, tacit knowledge and "know that" which consists of decontextualized, codified knowledge.

Codified knowledge is also deemed by Lave and Wenger (1991) as being decontextualized, and Eraut (2000) describes it as public and propositional knowledge. Within these conceptions, it is understood to be separated from practical activity and to be abstract in nature. The style that codified knowledge takes is that it is embedded in written form and as such can be presented to others in transparent and more easily understood ways. Codifying knowledge enables it to be transported across contexts. For vocational teachers and their students, codified knowledge is separated into disciplines and occupational areas and is found in course materials, assessment tools and accompanying textbooks, and other teaching and learning materials (Guile 2011). However, this form of knowledge has inherent limitations. Gamble (2006) draws attention to this and suggests that codified knowledge enables a separation of thinking from execution. It divorces the "know that" from the "know-how." However, even given its limitations, within the realm of the teaching and learning of vocational knowledge and skills, it forms a distinct and influential aspect of what vocational teachers use and deploy in their teaching of students. A further limitation, however, is that once codified, knowledge becomes static and thus loses its currency fairly rapidly.

Distinct from this, tacit or uncoded knowledge makes up the significant majority of knowledge shared, used, and applied in vocational settings. It is developed through practice; Hordern (2014) and Kotzee (2012) describe it as being what

individuals either know or can do when they take part in social practices. This suggests that there is something ethereal about tacit knowledge. It points to it being fluid, temporal, and in motion (Broad 2016) rather than fixed, tangible, and stable. Supporting this conception and through contrasting codified and tacit knowledge, Polanyi (1967), who originally developed the concept of tacit knowledge, described it as that which we know but cannot tell. This in itself raises challenges for vocational teachers in that, as it cannot be told, it is problematic and not straightforward to turn this into learning experiences and teaching materials for students. However, the importance for vocational teachers and their students' learning is captured by Livingstone and Guile (2012) who argue that tacit knowledge is becoming the most important form of knowledge in learning organizations and increasingly so for the production of new knowledge. It is imperative, if teachers are to ensure that their students are conversant with current workplace practices, for them to capture and then recontextualize, for learning contexts, this newly formed tacit knowledge.

The problems of viewing these two forms of knowledge as distinct from each other are often highlighted in the literature, and Guile (2011) suggests that theoretical and practical concepts of knowledge, rather than being separate, have a mediated relation to one another. A practical example of the inherent problems of separating "know that" from "know-how" can be seen in the processes involved in how to teach someone to tie a shoelace; "A brief list of all that is involved in tying a shoelace would overwhelm a learner" Duguid (2012: 151). Rather, the better approach would be to show the person in practical terms how to tie a shoelace and perhaps support this with some theoretical constructs in the form of an aide-memoire or diagrammatic aid. Nevertheless, it is important to distinguish between codified and tacit knowledge and to recognize that both forms of knowledge present distinct problems for vocational teachers in bringing vocational expertise to the classroom settings of students. Emerging from these differing conceptions of vocational knowledge and the interplay between the two frames this chapter by highlighting the complexity of, and thus difficulty in, teachers ensuring that their occupational expertise is maintained.

## **Understanding Vocational Expertise in the Context of Vocational Teachers**

No single theory of learning, professional or otherwise, currently exists. Rather there is a multiplicity of varying and, at times, competing theoretical positions (Russ-Eft 2011). Historically, these have been drawn from psychological positions such as behaviorism and cognitive theory (Billett 2001). More recently, concepts have emerged from social learning theory that recognize the importance of both the social aspects of learning and the importance of situatedness and that of the context in which learning occurs. Influential in this is the work of Lave and Wenger (1991) and their central concept of the vehicle for learning, "communities of practice," in which individuals are shown to be able to learn through participating in shared activity.

These two conceptual approaches for understanding professional learning and the development of expertise have been crystallized into a dichotomy of theorizing, with cognitive psychology contrasted to social theories of learning. As a facet of social learning theory, Pelissier (1991) takes an anthropological approach and examines various dichotomies in the constructions of differences in approaches to, and understandings of, learning within education, drawing the distinction between practice and capacity. Others, however, have challenged this dualism and accept that understanding expertise requires an understanding of the relationship between the mind and social conditions of learning (Billett 2001). This is also encapsulated in the work of Sfard (1998) who suggests two metaphors of learning: learning as acquisition and learning as participation. She warns, however, of the dangers of favoring just one. In the former model, learning is seen as the individualistic learning of facts, knowledge, and skills and in the latter as participation in communities and in social practices. The importance here is that, "Different metaphors may lead to different ways of thinking and to different activities. We may say, therefore, that we live by the metaphors we use" (Sfard 1998: 5). This suggests that the way in which learning is conceptualized will determine the approach taken. It is argued here that in terms of pedagogy for vocational teachers, that aims to ensure the continued development of expertise, participative approaches will serve to be the most effective. Indeed, as discussed earlier, collaborative and thus participative approaches appear to be the most useful way of organizing CPD for teachers. However, to be able to recontextualize this across contexts, new knowledge will need to be internalized so that teachers can recontextualize and transport it from occupational to learning contexts.

## How Vocational Teachers Know

These debates concerning the nature of vocational knowledge and the development of expertise raise interesting ontological and epistemological questions concerning "knowing" and how experts know. Within approaches to understanding knowledge, it is seen to reside either in the heads of individuals (psychological approaches) or within social practices (social constructivist theories). As we have seen from the above, psychological explanations, drawn from cognitive perspectives, view knowledge as being held in the mind of individuals. Social constructivist explanations view it as being situated in contexts, shared between individuals and collaborative groups, and distributed through networks.

Early conceptualizations of tacit knowledge align with psychological theories in viewing knowledge as residing internally within the individual, rather than externally in social practices. Both Canning (2008) and Kotzee (2012) explain that Polanyi, in his development of the concept of tacit knowledge, and Schön (1991), in his use of tacit knowledge in understanding reflective practice, held this position. Eraut (2000) also takes this line and discusses tacit knowledge in terms of personal knowledge. However, as explored above in the discussion of expertise, more recent conceptualizations have shifted understanding of tacit knowledge to a shared social

conceptualization and to view knowledge as a network effect (inter alia, McArdle and Ackland 2007; Fox 2000).

The importance of this discussion for understanding learning and the development of expertise is explored by Collins (2007) who explains that within psychological and somatic approaches, it is generally accepted that learning is seen as independent of context and therefore as transferable, unproblematically, to a range of diverse contexts. However, Hager (2011: 22) states powerfully that, "It seems that skillful practice of occupations is both holistic and significantly contextual, rather than atomistic and context-free." Eraut (2000), even though he suggests that knowledge is held in the minds of individuals, reinforces the importance of context for learning and states that the learning context affects the knowledge acquired and if that knowledge is to be applied in a different context, it will need further learning or recontextualization.

Actor-network theory (ANT) draws knowledge and learning together and views both as highly contextual with learning emerging out of distributed practice networks. One conception takes a geographical position and views learning as, "...activities [that] are organized across space and time and [that] are produced in social practice or within social practices" (Nespor 1994: 1). Similarly, Latour (1986) views knowledge as performative and argues that it is developed in networks through action. It is through engagement within these performative networks that learning occurs. Drawing on sociology of associations, he states, "If a dancer stops dancing, the dance is finished. No inertia will carry the show forward" (Latour 2007: 37). This raises particular issues for vocational pedagogy when these practices take place in occupational sites, geographically separate from classrooms, and taught by vocational teachers who are also in the main divorced from the occupation. The main concern is how these separate geographical locations can be connected in performative ways.

In summary, the conception of vocational teachers' pedagogy presented here suggests that it is highly complex, heterogeneous, and contextual. This suggests that uniform approaches to the CPD of teachers may not be beneficial. Pedagogical approaches used need to enable vocational teachers to connect teaching environments, geographically and conceptually separated from where vocational knowledge is developed in networks, to occupational sites. It is suggested here that nature of vocational knowledge and of the development of expertise should be understood as residing both within these performative networks and in the heads of teachers as they work to learn and develop and then contextualize this for consumption by students in classrooms and learning settings.

---

## Researching Vocational Teachers' Pedagogy

The findings presented here are drawn from a study that sought to understand, in practical terms, the practices that vocational teachers engage with to maintain and develop their vocational expertise. To capture the complexity described above, a material-semiotic approach, actor-network theory (ANT), was adopted. A rallying

call in ANT is to “follow the actor” (inter alia, Latour 1987, 2007 Callon 1986) and led mainly to the use of ethnographic research methodology being used. The initial starting point for the research (see Broad 2013, for further details) was by surveying vocational teachers to begin to understand their approaches to the continued development of expertise once qualified. This was followed with in-depth interviews with vocational teachers and the chairs of two professional associations, the Association of Hairdressers and Therapists (AHT) and the Association of Painting Craft Teachers (APCT). The AHT was subsequently followed through participant observation. Further in-depth interviews were conducted with the AHT teachers and other actors.

## Examining the Pedagogical Approaches Adopted by Vocational Teachers

The research approaches adopted, described in the previous section, enabled the capturing of the pedagogical practices of teachers on the ground, as they happened. Their recollections of their experiences also allowed a deeper and richer understanding to emerge. Key themes emerging was the importance that teachers place in maintaining their expertise, the varied and myriad ways in which they ensured that they kept up-to-date with their specialist vocational area, and the perceptions they held that their activities enhanced the learning experiences of their students.

## The Importance of Occupational Expertise

The maintenance and development of occupational expertise is seen by teachers to be crucial to their teaching role. No matter the subject or occupational area taught, or the contractual arrangements of the teacher, they all stated that it was important to some extent to maintain and develop their vocational expertise, with none of the sample seeing developing occupational expertise as not important. Within this, the majority of 64 (83%) saw it as very important. The remaining 13 (17%) saw it as important (Table 1 below).

This importance is echoed in the amount of time teachers report devoting to CPD activities to maintain their occupational expertise, as opposed to for other reasons. More than half said maintaining and developing occupational expertise was the most frequent reason for CPD activity.

**Table 1** Importance to teachers of maintaining and developing subject expertise

Answer options	Response percent	Response count
Very important	83.1	64
Important	16.9	13
Not very important	0.0	0
Not important at all	0.0	0
Answered question		77

## How Teachers Develop and Refresh Occupational Expertise

Vocational teachers use a range of activities to develop occupational expertise. The first activity reported here, short courses and workshops, was a frequent activity. However, these proved to be either very useful or of little value. Thirty-eight teachers (51%) reported that they had attended short courses and 46 (62%) had attended occupationally relevant workshops, which are short, often half day or 1-day events.

### Courses and Workshops

Often these courses and workshops are viewed as not helpful by teachers because they cannot easily identify commonality between the subject matter of these events and their day-to-day practices as vocational teachers. An example was offered by three teachers in different vocational areas, employed at different colleges of internally provided safeguarding courses. One teacher of painting and decorating found it helpful because of the nature of the students he taught and that there had been “a serious problem” that he did not feel equipped to deal with. The course suggested a range of practical strategies. Two other teachers, one in applied sciences and the other business management, both teaching mature students, found little value in the course. The applied sciences teacher said:

The last one we did as far as I can recall, we spent a lot of time talking about how the new student disciplinary procedures were to be implemented. And, a lot of it was not appropriate [for my subject] anyway because of the nature of our students.

There are difficulties in pitching CPD courses at the appropriate level to teachers who have a wide range of knowledge and experience. It is also problematic when the audience is made up of teachers drawn from a wide range of subjects who also teach their subjects at varying levels. One often used solution is to generalize course content so that it “fits” with as wide a range of circumstances as possible. However, this sets its own challenges, explained again by the applied sciences teacher:

It wasn't really relevant for lots of the stuff I mean bits of it were, but most of it wasn't and it was done in a very fluffy way. Not very specific and bits and pieces like that.

Teachers found value in workshops that enabled them to network with and fold across to the occupational world. Why these courses and workshops are more beneficial than those provided by organizations is that they enable teachers to access expertise. The early years teacher discussed how she was able to listen to Tina Bruce (an academic consultant in early years and childhood studies), who she described as, “One of the leading lights in early years, she is amazing.” The carpentry teacher had attended a week-long course provided by a tool manufacturer on making a Windsor chair which he described as being challenging but rewarding:

But the amount of work you have to do was quite incredible. To have a chair completed from you know, wood. [. . .] And that's a nice incentive and a great push, but they were long days.

He also explained that he was afforded opportunity to learn new techniques which he had not used when working in the occupation:

It was covering techniques that I haven't had experience of myself in my woodworking career, one of them being steam bending. [...] The other part of it too, was wood-turning which I haven't done much of.

### **Learning with Students and Colleagues**

Teachers commonly liaised with manufacturers and in particular learnt alongside students. In response to the survey, 21 (28%) of the teachers learnt from participating in guest speaker events organized for students. The hairdressing teacher at interview and two AHT teachers also described the use of student training events. The construction teacher also explained this use of student training events:

I would much prefer to have people come to them and it's what we have done, had specialists come in, delivering say new technology in laser levels and things like that.

Teachers also independently access manufacturer training. An example was offered by the applied sciences teacher who attends seminars and conferences organized by his professional association where much of the content is supplied by manufacturers:

[named manufacturer] they are going round the country giving free talks [...] So you turn up and listen to that

### **The Use of Professional Associations**

Professional associations play a significant role in the maintenance and development of occupational expertise for teachers. Twenty-six (60%) teachers surveyed were active in a professional association. The activities provide by these include student competitions, seminars, meetings, and specialist occupational publications.

One of the main forums for collaborative learning through professional associations is student competitions and is central activities for both the AHT and the APCT. The benefits for teachers were described by an AHT hairdressing teacher as:

You see the changes and the styles changing and the fashions and the colour trends coming through.

Another AHT hairdressing teacher commented that she always learns something new at hairdressing competitions and explained how these competitions would tend to broaden her experiences of different approaches and techniques and said:

I've not seen that tool used in that way before. So I've taken some photographs and I'm going to go and get that tool when I get back.

She further explained that this form of learning, learning by watching and seeing, complements well the practical nature of the occupation.

Professional associations also offer seminars and meetings, and the ACPT in the main organizes its meetings around CPD events and holds what the ACPT chair described as, “Saturday craft practical weekends,” where manufacturers run workshops on their products and latest decorating techniques. The applied sciences teacher also described evening talks he had attended through his professional association:

That [showing leaflet] is an evening ‘do’ which is promoted by [. . . the] Association and it will be an hour’s talk and we can go down there to the Royal Society of Medicine and we give up an evening to learn about topics

He also described “peer review” events where a group of practitioners would come together to discuss a specific area that they had difficulties with. These were self-selecting and self-organized events that would happen as a one-off or a small series.

## Improving Pedagogic Practice

The key driver for ensuring that vocational expertise is continued to be developed is that vocational teachers consider that it improves their own pedagogic practice and it makes them better teachers. One reason centers on their concerns about their credibility as professionals, within an occupational or subject area. The early years teacher said:

[. . .] because with the teaching, you have got to get it right, because especially at level three and foundation degree, they’ll all go away and say ‘actually I think you’ll find you are wrong’ the law says this or something, so, probably that is a personal challenge as a teacher to get it right.

The applied sciences teacher explained the importance of keeping up-to-date for his teaching. He began by saying that he could, if he wished to, sit back and produce the same materials for his students every year. For him however, it links to his interest in the occupational area. He said, “If you are interested and enthusiastic, you have to take a few opinions on board and you have to inform your students.”

His concern was with being topical and au fait with current industry practices and said:

Because if you don’t know what is going on in industry then you are out of date and if you are out of date, then that is less relevant to your students who you need to pass information on to.

The construction teacher was concerned with how best he could ensure that his students were better prepared for, “the real world” of the construction industry. He could identify very clear links between his ability to do this and him keeping abreast of current trends and new technologies within the occupation. He then linked this to curriculum design and ways of stretching his students’ occupational knowledge and said:

I'm thinking ahead [...] in the second year when they have all the work done, to perhaps do something different, whether it's a bit of veneer work, whether its curved work where you know, we use vacuum bags, or some steam bending [a technique he had recently learnt on a course]

Occupational CPD opportunities also enrich conversations that vocational teachers have with students. The graphic design teacher explained this as, "You can just talk about this nature or that nature of the work." Similarly, the applied science teacher stressed the importance of working within the occupational area and that it enabled more informed discussions with his students. He said, "And it's good to be able to turn round to students and say 'when I was in practice the other day, I saw blah'..." Likewise, the construction teacher could also identify how, through conversations based on his recent CPD experiences, he could improve the experiences of his students. For him, this meant sharing his experiences with the students and entering into professional dialogs by discussing his recent experiences and asking such questions as, "What do you think?"

---

## Discussion: The Pedagogy of Vocational Teachers

This section draws on the findings presented above and explores the defining characteristics of effective vocational teachers' pedagogy, as employed by teachers, to maintain and develop occupational expertise. It is acknowledged here that this is a complicated and complex process because much of what teachers need to access is shared and developed in contexts distant from the contexts they inhabit as teachers. Compounding this for those researching this phenomenon is that their activities are also largely hidden. However, the study presented here has made the practices of vocational teachers as they strive to maintain their expertise visible. In this section, the three elements of effective teacher pedagogy are discussed and examined: (a) teacher agency, (b) relational networks, and (c) hidden pedagogical practices.

### Agency of Vocational Teachers

The findings show that vocational teachers act with agency in identifying opportunities to maintain and refresh their occupational expertise and in shaping the pedagogical approaches to activities. They self-determine these activities based on what opportunities are afford them and those they find value in. They find value in activities that bring them closer to and enable them to engage more fully and firsthand with their original occupation. Returning to understandings of the development of expertise and professional learning, these teachers are adopting and preferring pedagogical approaches that favor active participation and involvement in learning processes. This approach to professional learning is suggested by Boud and Hager (2011: 26) as more potentially useful and argue for, "a shift from use of acquisition and transfer to metaphors, such as participation, construction

and becoming, that imply [...] active involvement...” and link this to concepts of teacher professional agency. They highlight that dominant metaphors of learning, of acquisition, and of transfer turn the focus of professional development from outputs, the benefits, to inputs, the activity. This in turn leads to professional autonomy and agency being somewhat diminished and undermined. Congruent with this, the findings here show that vocational teachers find more benefit in participatory activities, rather than acquisition and sedentary approaches provided for them by employing organizations. They describe these as “fluffy” and not particularly relevant to the own pedagogic practice with their students.

These debates suggest a structure/agency dichotomy in teacher professional pedagogy. The debate, however, is not solely concerned with structure/agency dichotomies but also concerned with networks. Mulcahy and Perillo (2010) remind that agency is distributed across various entities. Vocational teachers are influenced by the networks where vocational knowledge and skills are enacted into being, where they network with the tools, ideas, and mores of the vocational area, and it is to these particular networks that we now turn.

## Relational Networks

In contrast to the pedagogical approaches of organizations in the planning and execution of vocational teachers’ professional development, they find the most benefit in activities that enable them to cross boundaries and to network with their original occupation in authentic and practical ways. The pathways that vocational teachers follow and the networks that they use are multiplicitous and heterogeneous. They vary from teacher to teacher, shaped by the opportunities presented and by their particular development needs. Some of these professional development networks are bounded by the organization with teachers working alongside both students and colleagues to develop expertise. Much of what is shared within organizations is manufacturer knowledge. Within the literature, the use of manufacturer provided opportunities is known, and Lloyd and Payne (2012) report that for hairdressing teachers, manufacturers provide ample opportunities for teachers’ development. The research here shows that teachers also take advantage of opportunities provided by manufacturers for their students. In addition, they also share learning with colleagues when one has attended a manufacturer training event. They network to manufacturers which enables them to connect to new product knowledge and keep abreast of the latest techniques, materials, and tools. On occasion, these manufacturer opportunities take them outwith the organization, to seminars and courses provided by manufacturers and experts.

By far the most important form of networking for maintaining and refreshing occupational expertise is that provided by professional associations. They enable teachers to come together with other teachers, with practitioners, and with experts in the occupational area. Orr (2013: 378), drawing on the work of Wenger, explains that mutual engagement in shared learning ventures enables the sharing of, “shared routines, words, tools, ways of doing things, stories, gestures, symbols, genres,

actions and concepts.” Through this, they are able to take part in the processes of new knowledge production, which, it is contended here, is developed through shared practice, and, to capture this, recontextualizing it for use within their own classrooms and learning sites. They can be seen to be part of a vocational teachers’ extended community of practice. These communities of practice are “. . . in part systems of relations among persons” (Lave and Wenger 1991: 53).

The importance of networking into the original industry has been highlighted by Smith and Rahimi (2011) who report that teachers involved in student competitions state this as one of the key benefits of involvement. These networks mediate between new knowledge and skills and classrooms with the teacher acting as a bridge between the two, bringing them together through their own learning of this new knowledge. This sets up a network of relations that extend beyond the teacher and connects powerfully with the learning and development of their students.

### Issues of Hidden Pedagogy

Emerging from the findings is that teachers perceive that their professional development activities enhance the learning of their students. This happens because these activities develop their pedagogic practice by refreshing the knowledge, skills, and ideas they are able to share with their students. It gives them credibility with students; it helps to maintain their enthusiasm and thus maintains their confidence as vocational experts. Their professional development activities enable them to engage students in discussions about practice which in turn brings them closer to the occupational area they are studying. Through this process, teachers recontextualize vocational knowledge, turning it from a productive to a learning function (Moodie and Wheelahan 2012). This process of recontextualization is a process with inherent complexity and is not a straightforward knowledge transfer from one context to another. Evans et al. (2010) describe the recontextualization process as chains forged by practitioners and as multifaceted pedagogic practice. According to Wheelahan (2007), part of this process of recontextualization is that of selection, and vocational teachers select the knowledge that they carry to vocational learning contexts.

Despite this complexity, the way in which vocational teachers’ professional development is currently conceptualized and understood means that there is a lack of focus by employing organizations on both the development of occupational expertise for teachers and the benefits it presents to vocational students’ learning. This issue however is not constrained to vocational teachers in England. Köpsén and Andersson (2017: 80) found in a study of Swedish vocational teachers’ engagement with vocationally focused CPD that they also faced institution’s barriers to engagement such as “managements’ lack of interest or financial support.” Due to what appear to be insurmountable difficulties, a generic approach tends to be adopted within organizations, with CPD workshops designed to meet a range of pedagogic needs. A potential concern with a generic approach to the development of pedagogic skills is highlighted by Fisher and Webb (2006: 342) who argue that current self-conceptions of teachers are not as “subject” specialists but as “. . . a Jack/Jill of all

trades.” The reason for this is that the activities that teachers engage with to develop their occupational expertise are largely hidden from others. They go about this largely in their own time. They join in with colleagues after teaching has finished. They learn alongside students through collaboratively engaging with manufacturers. They join others outside of the organization and come together through professional associations in self-determined and self-selected communities of practice, sharing new knowledge and skills away from the organization. Nerland and Karseth (2013) in their study of professional associations use the concept of “knowledge work” as a way of describing and understanding how professional associations manage and standardize knowledge in their field. However, the findings presented here strongly suggest that vocational knowledge resists standardization and that the role it serves for vocational teachers is to enable them to access, share, and develop knowledge.

---

## Concluding Remarks

Through exploring how vocational teachers, through their self-determined and self-selecting pedagogical approaches to the maintenance of their vocational expertise, this chapter sheds light on how they manage the in motion and circulatory nature of vocational knowledge. New technologies and new approaches and techniques are continually developed in and through workplace practices. In order to ensure high-quality learning experiences for their students, vocational teachers need to keep abreast of these changes. The chapter began by conceptualizing vocational knowledge, which teachers attempt to capture through their CPD activities, and expertise and professional learning. This illuminated the complexity of vocational knowledge and thus the challenges that teachers face in maintaining their expertise in boundary crossing across geographical contexts and in recontextualizing knowledge from a learning to a productive function.

The findings presented here captured the pedagogical practices of vocational teachers and illuminate the main characteristics of effective pedagogy that are (a) teacher agency, (b) relational networks, and (c) hidden pedagogical practices. Through this, the chapter sets out to inform ways of thinking in relation to how teachers can best be supported in their endeavors to both maintain their vocational expertise and in using this to enhance the learning experiences of their students. It is argued here that those tasked with organizing and supporting the CPD of vocational teachers appreciate the complexity and heterogeneity of practice highlighted here. It is also suggested that the ways in which teachers maintain their expertise, predicated by the theoretical concepts presented here, through the sharing of practice with others, be taken account of when designing learning opportunities for vocational teachers.

## Abstract

Appropriate qualifications and professional development opportunities for vocational education and training (VET) teachers, trainers, and assessors are key to the future success of VET in meeting industry and individual needs. This chapter, based on qualitative analysis of research on the development of

teacher capability and the authors' lived professional experiences, examines the main issues and approaches in the training and development of VET practitioners in Australia. It describes the VET system in Australia and the nature of the VET teaching workforce, documents the history of VET teacher preparation and development, highlights key dilemmas confronting VET teacher education and professional development, draws conclusions, and provides potential ways forward.

The chapter contends that, while the Australian VET system is highly regarded, most of the issues relating to VET teacher development since the 1970s have been exacerbated by sectoral change and remain unresolved. Important and consistent messages from past reports continue to be ignored or not actioned. Yet the lesson learned is that "one size can't fit all" and that, given the diversity and complexity of the VET sector, dual status of its practitioners, and nature of their employment, only a wide variety of well-supported preparation and ongoing development approaches can be the way forward.

## Introduction

This chapter explores teacher education and professional development in the vocational education and training (VET) sector in Australia. It:

- Describes the vocational education system in Australia and the nature of VET teaching workforce.
- Documents the history of VET teacher preparation and development.
- Highlights key issues and dilemmas which confront VET teacher education and professional development at present.
- Draws conclusions and provides some potential ways forward.

The VET sector is seen by governments, society, and industry bodies alike as being important to help sustain, develop, and grow the Australian economy. It provides training to a wide range of industries and occupations at the sub-professional level. VET:

is vital in both preparing Australians to enter the workforce and upskilling them to transition between industries to exploit new employment opportunities (ACCI 2016, p. 4)

and the VET workforce plays "a critical role in helping Australia increase workforce participation, productivity, skills and social inclusion" (Wheelahan and Moodie 2011, p. 14).

VET helps provide people with the skills, knowledge, and personal attributes they need to enter the workforce for the first time, to reenter the workforce, to train or

retrain for a new job, or to broaden or upgrade their skills. It provides opportunities for the development of second-chance education as well as postsecondary initial training and further skills development for those well established in their careers. VET's charter in Australia is wider than in many other countries, with its roles encompassing workforce training and development on the one hand and the promotion of access, social justice, and equality on the other.

Arguably, the quality of vocational education to fulfill this broad "mission" is strongly dependent on the quality and capabilities of its teaching workforce: its practitioners. These capabilities are manifested in two major ways: capabilities in teaching, learning, and assessment as well as vocational currency and a connectedness to their often rapidly changing vocations. Thus, VET practitioners are seen as "dual professionals." Skills Australia (2011, p. 91) has argued for a national VET workforce development strategy, as "the front line of excellence in teaching and learning outcomes is a professional and well-supported VET workforce."

This and similar state and territory- or industry-specific proposals have been supported by others (Smith et al. 2009; Training and Skills Commission 2010; Northern Territory Government 2014; Rasmussen 2016), but not all (Productivity Commission 2011). However, the Australian vocational education sector is complex, with a large number of students and providers, diverse purposes, and a great many sites of delivery. Providing comprehensive initial practitioner education and ongoing professional development is therefore extremely challenging.

---

## The VET System in Australia

Vocational education in Australia includes the formal, nonformal, and informal learning to prepare people for the world of work. The VET sector occupies the territory between compulsory schooling and professional education and has been called the "middle child" of Australian education (CEDA 2016).

Australia's VET sector is made up of public, private, enterprise, community, school, and other providers that deliver formal training programs based on the Australian Qualifications Framework (AQF). The National Centre for Vocational Education Research (NCVER 2017) in Australia estimated that the total VET market in 2016 comprised nearly 4,300 training providers delivering training to approximately 4.2 million learners, both older and young. The great majority of VET providers are private, and small providers predominate. There are also 42 large public (government-owned and operated) providers called Technical and Further Education (TAFE) institutions. In addition to these large public providers, there are six dual-sector institutions nationally, being both a public VET provider and a university. However, a total of 15 universities offer VET programs (NCVER 2017). Put simply, TAFEs are the "department stores" of Australian VET being large and having a wide range of offerings; private VET providers are the "boutique stores" being generally smaller and tending to concentrate in a particular training niche (Guthrie and Clayton 2010).

The basis for vocational training is a series of endorsed Training Packages, overseen by Industry Reference Committees and supported by Skills Service Organisations.

These committees provide the formal channels for considering industry skills requirements for package development and review. Thus, it is said that the sector is “industry-led” and based on a series of endorsed competency standards and qualifications, including those related to formal VET practitioner education.

Vocational education institutions are predominantly regulated by the Australian Skills Quality Authority (ASQA) which quality assures the sector by implementing the Standards for Registered Training Organisations (RTOs). As will be shown later, these VET standards address issues of the initial teaching and learning qualification held and ongoing professional development, including the development of their delivery and assessment skills and the maintenance of vocational currency. However, the requirements of being a “dual professional” are at once complementary and potentially conflicting, and getting the balance right between these two requirements can be problematic.

---

## **VET Practitioner Workforce**

### **Scope and Size**

The phrase “teachers, trainers, and assessors” encompasses the terms VET practitioners, teaching professionals, enterprise trainers and assessors, industry experts, and other vocational education and training professionals (Productivity Commission 2011). Wheelahan and Moodie (2011, p. 4) noted that such terms included those who develop courses and modules and learning and assessment materials and any other term that may be used to describe those engaged in assessing, validating, moderating, training, instructing, and teaching and learning. The key feature which is the core of a practitioner’s role is direct engagement with learners in the development, delivery, and assessment processes associated with vocational education and training (NSSC 2013). However, as Tyler and Dymock (2017) note, the demarcation between those who “teach” and those who “administer and lead” has become increasingly problematic as roles have expanded and practitioners undertake a wider range of roles.

There are few reliable data on the size and nature of the VET practitioner workforce despite calls for more information about it (Skills Australia 2011; Productivity Commission 2011; Guthrie and Every 2013). The most recent estimates put numbers at about 73,400 Technical and Further Education (TAFE) employees and another 150,000 workers who are involved in VET delivery by non-TAFE providers (Productivity Commission 2011), but higher numbers have been suggested by others (e.g., Mlotkowski and Guthrie 2010).

### **Nature of Employment and the Changing Nature of Their Work**

VET teachers, trainers, and assessors are employed under a variety of arrangements and are thus variously “attached” to the sector (Guthrie and Clayton 2010; Guthrie and Every 2013). They are characterized as being older and having high rates of

nonpermanent employment when compared with the general workforce. They may hold multiple jobs within or outside the VET sector.

VET practitioners generally come to the sector in a second or subsequent career as they are normally required to demonstrate industry experience of at least 5 years on hiring. Many nonpermanent VET practitioners would also see their primary employment as outside the sector in industry. Thus, Simons et al. (2009) found that careers in the VET sector are notable for their diversity with “progression” often being measured by promotion or changing modes of employment from hourly paid to contract work to a permanent appointment. Indeed, their career paths are significantly more diverse than those of school teachers or university academics (Tyler and Dymock 2017).

The nature of their work has also changed, expanded, and diversified (NCVER 2004). However, the balance between their roles is context dependent and constantly changing. For example, they may be required to work in an increasing range of contexts – institutions, schools, workplaces, online, and community settings – develop a wide range of relationships with industry, use skills in providing work placements and career advice, and perform a broad range of resource development and administrative and management functions. They may act as consultants to enterprises and help develop customized approaches to training for them (Harris and Simons 2006).

## **Expected Capabilities**

At least three capability frameworks for VET practitioners have been developed in Australia and can be used to assist practitioners to reflect on the capabilities that apply to their particular work role, how they have demonstrated these capabilities, and the evidence that supports the quality of their work. This information can then be used to help plan their professional development and may also be used in performance reviews. The first, by Innovation and Business Skills Australia (IBSA 2013), contains four domains of work concerned with teaching, assessment, industry and community collaboration, and systems and compliance, each of which is broken down into a series of capabilities and six skill areas or ways of working with three distinct levels reflective of experience and expertise. It is the only national capability framework for VET practitioners in Australia. The two others are state-based and were developed, respectively, by the Queensland College of Teachers for the Queensland Government and the LH Martin Institute for the Victorian Government. They are more focused than IBSA’s on the quality of teaching, learning, and assessment.

The capabilities of VET practitioners are developed using three principal forms of learning: formal, nonformal, and informal. Formal learning involves the attainment of a formal qualification or award, while nonformal learning takes place through programs which do not lead to a formal qualification or award but which might be recognized as legitimate forms of learning. Such programs include substantive in-house and other professional development programs, mentoring, project work, and established communities of practice. Informal learning is an important but often

forgotten form of professional education that involves predominantly individual developmental activities and a process of personal and/or group reflections on daily work-related activities (Guthrie and Every 2013).

The issue of what makes a good VET teacher was investigated by Smith and Yasukawa (2017) who reported on the views of VET teachers and students. Their paper forms part of a wider study which aims to find out whether and how higher-level qualifications for VET teachers would improve quality in the Australian VET system. The preliminary findings suggest that not only are expected aspects such as professionalism, disciplinary, and pedagogical knowledge important but also are their relationships with and attitudes toward their students. This suggests that many of the key aspects of a good VET teacher are balanced between their intrinsic personal attributes and those derived from their professional qualifications and experiences. It is therefore likely that any set of capabilities will be a useful but inadequate description of what really makes for effective VET practice.

---

## **Brief History of VET Practitioner Education and Professional Development**

The complexity involved in determining what is appropriate VET teacher education was recognized as far back as 1972 in one of the first comprehensive books on Australian vocational education, *Trade and Technician Education: Principles and Issues*. Hermann et al. (1972, p. 117) wrote that it had “not proved easy” and there were not “likely to be simple solutions to the problems that such courses raise.” Over the nearly five decades since then, VET teacher education has turned full circle – from optimistic beginnings following the Kangan Report in 1974, when programs moved from being mainly in-house within State education departments into higher education. Recent years have witnessed the closure of many degree programs (AQF level 7) in universities and the settling on the default position of a Certificate IV (AQF level 4) as the de facto qualification for all VET practitioners, though there are now indications that this restrictive mandate is opening up from being only the Certificate IV, predominantly offered within the VET system itself, to include also a diploma or higher-level qualification in adult education as alternative qualifications (ASQA 2017a). However, as will be shown later, the quality of delivery continues to be perceived as problematic.

In 1974 the Kangan Report (ACOTAFE 1974) changed the face of vocational education in Australia. It bestowed a new image, status, and clear definition as to its charter and philosophy. Of relevance to this chapter, it found no common pattern of initial technical teacher education in Australia’s states, concluding that “the issue is of great importance to the quality of TAFE” (p. 88). This recommendation led to the Fleming Report (1978), which was the first systemic effort at improving the quality and standing of TAFE teachers. Fleming’s report was notable for recommending a move away from model of teacher education based on that used for schools, arguing that TAFE teachers’ and their students’ needs were different. It was a powerful catalyst for a much-needed boost to TAFE teacher education, which to that time had

been piecemeal and variable. At the end of the 1970s, there were five higher education institutions offering accredited teacher education courses for beginning TAFE teachers.

A series of national conferences on TAFE teacher education reached agreement that the most appropriate level was a 3-year higher education qualification. However, through the 1990s the opening up of the training market, increasing casualization, diversification of the VET practitioner workforce and provider types, and disillusionment with university preparation courses led to the Certificate IV qualification becoming the mandated minimum qualification in 2001.

In 2011, the Productivity Commission (2011) conducted an inquiry into the VET workforce. This report, like the Fleming report, acknowledged that still little was known about the size and characteristics of the VET workforce, this lack being seen as an obstacle to effective VET policy-making and workforce planning. Despite this lack of information, or perhaps because of it, the Commission concluded that the Certificate IV current at that time provided an appropriate, entry-level qualification for VET practitioners but with two important caveats: that it was taught well and that it was seen as the foundation for further capability development. However, the Commission acknowledged that it did not always equip teachers with skills required to deliver VET effectively, it did not completely cover the diversity of roles in VET, its delivery required more supervised learning, and concerns about the quality of that delivery were “long standing, persistent and supported by recent audit evidence” (p. 247). As only a first-level and entry qualification, the Commission recognized that it was not fulfilling its potential as a basis for professional development and that clear options and pathways for study beyond the Certificate IV needed to be available to the sector.

Through the 1990s there had been many types of professional development programs (ANTA 1997). However, the Predl Report (VEETAC 1992) concluded that “much of the staff development [was] *ad hoc* and not necessarily in the best interests of employer and employee.” The National Staff Development Committee which had promoted and funded staff development throughout the VET sector was disbanded in 1996.

The Australian National Training Authority then instituted a national professional development program, “Framing the Future” (later, “Reframing the Future”), in 1997 to explain and facilitate the introduction of the new National Training Framework. But it too was disbanded in 2008, despite its extensive work in establishing 2,298 projects involving an estimated 65,673 participants (Reframing the Future 2008). Instead, governments resolved that responsibility for VET workforce development rested with the states and territories and with individual providers. Since that time, there has been no national and broad-based approach to VET workforce development. Still by 2011, the Productivity Commission was lamenting that “opportunities for professional development beyond the Certificate IV in Training and Assessment within the sector are not adequate” (2011, p. 247).

During this period, there had been an explosion in the number of providers of VET teacher preparation. From 5 institutions in the late 1970s, this number had expanded to 20 universities by 2008. By 2013, around 850 VET providers had

the Certificate IV on scope with nearly 40,000 enrolments. A total of 97 institutions had the Diploma of VET on scope, and enrolments in both these and higher education qualifications were substantially lower than for the Certificate IV: around 1,500 and 2,000 students, respectively (Guthrie and Every 2013). By 2016, however, there had been a notable decline in the numbers of higher education providers and students involved in VET teacher preparation, as universities tightened budgets and closed many of these programs and teaching departments. The reasons for this decline in university-based VET teacher education are many, with both internal and external factors playing their part (Harris 2017). However, two key factors stand out. The first is that university offerings in vocational teacher education have been increasingly perceived as not being as relevant as they had once been (VEETAC 1992, p. 14; Guthrie et al. 2011, p. 24). The second is that the Certificate IV, originally intended for trainers in industry, has increasingly been appropriated by *vocational educational* institutions and mandated by regulators as the de facto qualification for VET teachers. Its introduction and mandating and the increasing casualization of the practitioner workforce have been critical factors in lessening numbers proceeding to VET teacher education at university level. Unfortunately, the minimum often becomes the maximum.

Furthermore, providers of the Certificate IV had to reapply for their registration to deliver the latest version of that qualification because of perceived quality issues and an excessive number of RTOs with the qualification on their scope of registration. As at July 2018, only 83 institutions had the latest version of the certificate on their scope, of which 17 are TAFEs. Potentially, this restricts the availability of even the most basic VET practitioner qualification in the short term. However, the restrictions have involved significant vetting of potential providers in an attempt to assure and improve the quality of delivery.

Quality of VET teaching in this period emerged, not unsurprisingly, as a critical issue (Harris 2015). Around the time of the Productivity Commission's work, a number of research studies were undertaken, and, for a time, it appeared as though VET teacher education and professional development were about to return to their places in the sun following years of relative neglect. One was a review of the quality of VET teaching and teacher qualifications, which recommended establishing a national VET professional body, introducing standards for VET teaching and training and evaluating the quality of teaching through a national student satisfaction survey (Wheelahan and Moodie 2011). Another was the synthesizing work of Guthrie and colleagues fleshing out the background and advocating a range of qualifications to embrace the variety of roles within VET (Guthrie 2010a, b; Guthrie et al. 2011; Guthrie and Every 2013). As well, an Australian Research Council funded project examined whether and how higher-level qualifications for VET teachers could improve quality in the Australian VET system (Smith 2016; Smith and Yasukawa 2017).

Yet the delivery of consistent, high-quality training and assessment continues to be a fundamental concern for government, employers, and students (AWPA 2013; BCA 2017). Even the body that was, until recently, responsible for the Certificate IV, Innovation and Business Skills Australia, labeled quality of delivery as "one of the most enduring issues facing the VET sector" (IBSA 2014, p. 26).

The Australian Government continues to put its faith in regulation. Three sets of clauses in ASQA's User's Guide to its regulatory standards (ASQA 2017a) require that RTOs engage with industry and employers, employ skilled and vocationally current trainers and assessors, and, in the case of providers offering qualifications from the Training and Assessment Training Package, employ more highly qualified experts to teach trainers and assessors. Potentially and collectively, these clauses hold promise for a higher quality of delivery for the prescribed initial VET practitioner qualification and strongly promote the ongoing development of VET's "dual professionals." Nevertheless, there is no prescription in the standards about how, or how often, such maintenance and professional development must occur. However, the approaches used must be "sufficient" and demonstrably so through appropriate evidence. There are a number of other issues and dilemmas which affect the extent to which sound initial and ongoing education and professional development is possible. These are considered below.

---

## Issues and Dilemmas in Australian VET Practitioner Education

### Funding for Professional Development

Some Australian states and territories have provided significant funding for professional development and set up agencies with that remit, including providing scholarships to acquire higher-level teacher/trainer qualifications. However, in most cases, the available funding is now relatively small, and professional development programs are necessarily limited to reactive activities centered on standards, accountability, and efficiency rather than being proactive and focused on developing the wider and deeper sorts of skills and characteristics required of an adaptive and modern VET workforce (Wheelahan and Moodie 2011; Tyler and Dymock 2017). Because the levels of public funding received by RTOs for delivering teaching and training services are often seen as "tight," there may be little surplus available to them to fund professional development and quality improvement after basic operational costs have been met. What professional development funding is available is mainly focused on the needs of higher-level or permanent staff. Thus, the needs of part-time and casual staff, the majority of the VET practitioner workforce, are generally not well supported. The level of practitioner participation in professional development and further education may also be affected by cost (which can be high), the incentives available to encourage participation or impediments that discourage it (e.g., the level of acquired debt from the Higher Education Loan Program for VET teacher education studies or the lack of available tax benefits for undertaking such further study), and thus the perceived level of tangible personal return on the investment of their time and money (Guthrie and Every 2013). This is especially so when practitioners do not identify strongly with their role as a teacher or trainer or when they work for a number of VET providers, and it is therefore unclear which, if any, of those providers should help support their development.

## **Role of Leaders and Managers and Organizational Culture in RTOs**

Leaders and managers of RTOs play a key role in how well professional and workforce development is supported in their institutions. Among other things this requires that they give attention to job design, the qualification profile of their staff, and their access to further and higher levels of vocational or teaching, training, and assessor qualifications. Therefore human resource management practices need to be developed that encourage planned approaches to professional and broader workforce development. This involves developing a workplace culture where teaching staff are challenged; exposed to new ideas; encouraged to learn and learn by doing; able to consolidate their learning by immersion in the professional development process and through active study, reflection, or research; and able to actively network both within and outside their organization. However, Smith and Hawke (2008) claimed that most providers are a long way from these ideals of practice. VET practitioners also see themselves as time-poor and adversely affected by continual and unrelenting processes of change (Simons and Harris 2014).

## **Pressures of Organizational Change**

Clayton et al. (2008) noted the extent and rapidity of changes in RTOs brought about by external pressures from government policies, training imperatives, and various stakeholders, including to be more competitive, businesslike, flexible, innovative, entrepreneurial, and client-focused in a climate that is market driven. In their study of ten public, private, and enterprise RTOs, Clayton and colleagues noted the significant upheavals these changes brought with the consequent difficulties of maintaining a shared and sustained vision coupled with significant levels of change fatigue. They suggested that RTOs, especially larger ones, are also multicultural organizations. Hence professional development needs and emphases may likewise vary considerably, but the importance of workforce development through effective and inclusive professional development, recruitment, induction, and empowerment and the development of the organization's leaders and managers at all levels are key to shaping an effective organizational culture and enabling change. This is done through formal programs as well as less formal approaches such as communities of practice, mentoring, coaching, and networking. However, as already reported, resources to enable professional development are often limited, and so immediate priorities are addressed at the expense of more sustained and effective development activities that are more likely to affect real changes in the quality of practice.

## **Quality of Basic VET Teacher and Trainer Education**

The capability of Australian VET practitioners continues to be the subject of intense debate. Hodge (2014) in his in-depth study of 30 VET practitioners concluded that the way they "understand and use competency standards is of fundamental importance to

the quality and integrity of the Australian VET system” (p. 3). Yet he found that VET practitioners felt ill-equipped to interpret competency standards when developing curriculum. The most extensively synthesized evidence on the quality of VET teaching has been undertaken by Wheelahan and Moodie (2011). They reported that VET is being required to teach a much wider range of learners than ever before and that therefore “Australia will have to . . . further professionalise VET teaching” (p. 14). Their report presented a range of options, models, and proposals on VET teacher preparation, qualifications, and continuing professional development and on ensuring and evaluating the quality of VET teaching and its impact on the VET student experience and outcomes. The Organisation for Economic Co-operation and Development (OECD 2011) also recommended that innovative strategies were necessary to sustain the numbers and skills of the teacher and trainer labor force in providers.

In relation to teacher qualifications, much research has shown (Simons et al. 2006; Clayton 2009; Clayton et al. 2010) that the quality of delivery of the Certificate IV has been highly variable over its various iterations, that VET practitioners themselves have little faith in the certificate (Hodge 2014), and that it remains a focus of scrutiny (NSSC 2013; DET 2016). The recent review of Tyler and Dymock (2017, p. 43) concludes that:

. . . the current process for producing capability and capacity in VET practitioners’ knowledge and skills is questionable. The ability of the Certificate IV in Training and Assessment (TAE) and its equivalents appears to be inadequate for meeting, over a sustained period of time, the articulated understandings relating to assessment, competency interpretation, learner and learning diversity and pedagogical theory and practice, as well as to the supervisory tasks of the position.

There have been ongoing calls for professional development and recognition of a variety of qualifications more appropriate for a range of VET teachers and trainers, rather than a “one-size-fits-all” approach. The Standards for RTOs currently require these providers to ensure that all trainers and assessors undertake professional development. However, what these standards do not specify is a definition for acceptable professional development or a minimum standard.

Regarding assessment, Gillis and Clayton (2013) stated that, despite systematic validation being an essential requirement within the National VET Regulator Standards for Registered Training Organisations, numerous key stakeholders have continued to raise concerns about the quality and consistency of assessment being undertaken by providers. Misko et al. (2014) highlighted concerns over quality and rigor of assessments in VET and suspicions that some providers are taking shortcuts to qualifications. This serves only to raise doubts about credibility of VET qualifications and competence of its graduates. As ASQA (2017b, p. 11) noted in its recent review of course durations:

The review has found the TAE40110 [the mandated VET teaching qualification] to be the Certificate IV qualification with the highest proportion of advertised course durations below 50 per cent of the AQF volume of learning minimum. This presents a significant risk to the entire VET system—as poor-quality delivery of the TAE has a compounding effect on the quality of delivery and assessment for all vocational training in Australia.

In 2016 the Australian Government's Department of Education and Training also highlighted concerns that some providers and their standard of assessment for competencies within particular industry Training Packages had been found to be inadequate. Its report (DET 2016) produced seven recommendations to improve the quality of assessment, four of which related specifically to strengthening the skills of trainers and assessors. Whether these will be sufficient remains to be seen.

## **Access to Higher-Level VET Qualifications and Professional Development**

Australia needs quality VET practitioners who, as well as their occupational expertise, can decipher and creatively interpret Training Packages; understand the psychology and sociology of learning, curriculum design, and evaluation, so as to develop meaningful curricula; know how to teach creatively and imaginatively so as to engage often disengaged learners put off by previous educational experiences; assess effectively; understand how the VET system in which they work is contextually constructed and managed; critically appraise what goes on around them; and so on. What has been, somewhat disparagingly, characterized as a weekend course (or something to be "RPL-ed" through), the Certificate IV, does not, and cannot, do all of these things, at least not to the depth required. That there is underemphasis on teaching and learning in it and it is at only certificate level would suggest that attaining these outcomes may well be beyond its reach.

There is clear need, therefore, for ongoing professional development and experience, both formal and informal, following the completion of the mandated Certificate IV (Harris 2015). However, with declining provision of university-based VET teacher education, continued neglect nationally of professional development, and continuing difficulties in implementing return-to-industry experiences because of such issues as insurance coverage and availability of placements, opportunities for accessing appropriate development remain meager, especially for those not in full-time, permanent employment. Tyler and Dymock's (2017) review of continuing professional development (CPD) has highlighted widespread agreement that CPD is vital for maintaining industry currency and pedagogical expertise, yet there is a lack of a national CPD strategy and the need for a long-term approach rather than one-off initiatives.

## **Maintenance of Vocational Currency**

RTOs are facing the challenge of keeping their VET practitioners vocationally current in an environment of constant change. Thus, vocational currency, or the lack of it, is a critical issue for the sector (Clayton et al. 2013), as providers and practitioners alike seek to maintain, upgrade, or even widen their industry skills and knowledge to ensure that their delivery of training is up-to-date, relevant, based on real-world examples, and tailored to industry needs. VET's learners, too, highly value and respect practitioners with vocational currency (Smith et al. 2009).

Toze and Tierney (2010, pp. 8–9) reported that RTOs and practitioners used a broad range of approaches to maintain currency. These include industry placements; staff exchanges; concurrent employment in industry and the RTO; industry and professional association membership; subscribing to professional journals and publications; talking to students about practices and job roles in their workplaces; networking; undertaking industry specialist visits, industry site visits, and study tours or specific training courses in new equipment or processes; and work shadowing. However, they also identified a range of barriers at the personal, RTO, and industry levels and stated that a balance needed to be struck between maintaining individual currency and that of the whole teaching team. Further, success in maintaining vocational currency requires a joint commitment from both the individual practitioner and the RTO as their employer, but, as Clayton et al. (2013) point out, employers in industry considered that it was not possible for trainers and assessors to keep abreast of every change and confirmed that they struggled to do so themselves.

Clayton et al. (2013) found that the views of ASQA auditors about how currency might be maintained did not align with the view of industry or RTOs. Potentially, this is problematic and can affect the relevance and quality of approaches used as RTOs may feel pressure to comply with perceived regulator views on maintaining vocational currency. The authors acknowledged, however, that auditors noted:

... some confusion in the standards relating to industry currency and competence. They were of the view that there needed to be clarification of the terms and greater consideration of what constituted appropriate evidence of industry currency. (p. 8)

## Effecting Change and Improving Practice

Clayton and Guthrie (2013) examined six reports produced over five decades into VET practitioner education and professional development. They concluded that little was known about the nature of the practitioner workforce and the range of work they do. In addition, there has been too great a focus on the form and content of the initial formal practitioner qualification, while too little attention has been paid to providing comprehensive support to beginning practitioners. This support includes structured training, observation and supervision, collegial support, mentoring, and professional networking. Rasmussen (2016) believes that more emphasis needs to be placed on working across policy borders and developing holistic and nationally based solutions to practitioner education and professional development.

An exacerbating factor is the lack of a national voice for VET practitioners, a professional association, to influence relevant VET policy and to act as a focus for practitioner training and development. Guthrie and Clayton (2012) examined the possibility of establishing a VET professional association (as suggested by Wheelahan and Moodie 2011). They found that there was support for a professional association but its exact nature and functions were more problematic given the high levels of casualization in the practitioner workforce and its “dual professional” nature. They suggested that there had to be a strong value proposition for individual practitioners to encourage comprehensive membership.

In sum, this has meant that practitioner education and professional development have not been properly addressed and recurring issues not resolved because no one body or group appears to have the power to make things happen or to enact comprehensive solutions. Rather, any attempted solutions have been piecemeal or have turned into battles between state/territory and federal governments or a variety of other interest groups over whom, precisely, has the responsibility (Guthrie and Clayton 2012).

---

## Conclusions and Ways Forward

Vocational education and training in Australia have been held in high regard nationally and internationally. A wide range of countries have sent delegations to Australia to explore its approach to VET, seeing it as a world leader and a possible model for their approach, while Skills Australia (2009, p. 42) has stated that “Australia is much admired” for its VET system. The Organisation for Economic Co-operation and Development review concluded that “Australia has a very well developed VET system, which enjoys a high degree of confidence” (Hoeckel et al. 2008, p. 5). Official surveys show high rates of satisfaction among both employers and students with outcomes from VET (Australian Government 2017a, b).

Yet, paradoxically, there is also criticism. The Council of Australian Governments (COAG) highlighted in 2011 the need for “revitalising the National VET System,” with one of its four priorities being “improved quality” (p. 7), and Skills Australia (2011, p. 5) noted that:

The debate over quality is the issue that most troubles VET stakeholders. This review identified the need for a comprehensive package of reforms in the sector’s quality practices, especially in the delivery of teaching and assessment . . . [and including a] greater depth in the professional requirements for practitioners in the sector.

The National Skills Standards Council (2013) also drew attention to the inconsistent quality of training and assessment of registered training organizations, which were undermining the integrity and value of vocational qualifications held by all individual learners and employees. A recent review (Braithwaite 2018) found that the sector has experienced “significant disruptions in recent years” (p. 5) and been “saddled with significant reputational damage” (p. 57) from some poor providers placing VET at risk. In particular, four key issues emerged as concerns for the sector’s future: training quality, teaching professionalism, provider ethics, and student protection and well-being (p. 58). Industry, too, is both a critic and a critical supporter. For example, a joint statement in 2016 by all three of Australia’s peak employer bodies (ACCI, AiG & BCA 2016) suggested that “in recent years employers and industry groups have become concerned that the VET system is deteriorating and that recent attempts at reform have failed to impact on some core issues.” On the other hand, at various times all three of these industry bodies have advocated the importance of, and need for, a strong and viable VET sector.

As this chapter has shown, a series of reports spanning nearly 50 years has raised issues about the nature and quality of practitioner preparation and subsequent development to maintain and build quality. Arguably too, satisfactory responses have still not been found to the issues and questions raised over this period. This chapter concludes that, despite the positive image of the sector, important and consistent messages about practitioner preparation and development from the past have not been comprehensively actioned or even been ignored. And yet there is sound advice in all the reports, and much of what has been recommended in them remains as valid today as it was originally. The following conclusions can therefore be drawn and ways forward proposed.

First, the quality of practitioners and their practice is key to VET success. In VET, trainers and assessors are “the most valuable asset and arguably least cared for resource,” and yet “the quality of the service provided to learners is entirely dependent on the quality and performance of the trainer” (Walker 2012, p. 1). Their job roles are diverse. Thus, there is not, nor should there be, a simple conception of who the sector’s practitioners are, nor should there be simple notions about what their work involves and the qualifications they should hold or the attributes and experiences they need to perform their work. More nuanced and wide-ranging approaches to education and development are required. There are clear moves in that direction from the regulator (ASQA 2017a), particularly in relation to the range of mandated teaching VET qualifications. These will come into force early in 2019.

Second, a wide range of drivers are changing the nature of their work, job roles, and developmental opportunities. Thus, the relevance and quality of initial and further practitioner qualifications and professional development opportunities are critical. The qualifications they can attain need to be of the highest standards possible. Yet the evidence is that the Certificate IV is deficient not only in terms of its content but particularly in the quality of its delivery. This deficiency must be comprehensively addressed, and there is evidence that this is occurring. Nevertheless, this chapter proposes that the answer does not lie in continuing to mandate a single qualification for Australia’s VET practitioners. What is needed is a range of high-quality and flexible awards at a variety of levels, coupled with appropriately balancing requirements for qualifications with the availability of soundly based and high-quality non- and informal professional development opportunities whose value also needs to be more tangibly recognized. At present, these latter are largely piecemeal and, by and large, focused on immediate issues which are most commonly related to compliance matters rather than activities that are more deeply and sustainably concerned with the quality and effectiveness to a practitioner’s delivery and assessment approaches.

Third, there is concern over the viability of a range of available higher education qualifications for VET practitioners. The authors conclude that new approaches to delivery and recognition need to be considered including micro credentials, mini degrees, skill sets, and certifications. There is also a need to debate moving away from an individual institution model of delivery to one that draws on the best available expertise in both the higher education and VET sectors and across a

range of institutions. Such approaches could include the development of learning approaches and programs that are focused on more immediate and practical needs but can be built on progressively to enable a qualification to be attained to increase their appeal to individual practitioners and their RTOs alike.

Fourth, any approach to improving the quality of practitioner education and development needs to be part of a wider and more holistic approach to the issue of quality. At present, there is no one authoritative entity which takes an interest in this area, nor is there a body acting on a mandate to address all the issues that directly and indirectly affect the quality and capabilities of the VET practitioner workforce. Two further matters need attention. Firstly, there is a lack even of the most fundamental data about the nature of the VET workforce nationally, including the qualifications they presently hold and despite a data standard having been developed to collect such data but not implemented. Secondly, there is no national VET workforce development strategy. The authors contend there is a strong case for one and one that is properly supported by all interested stakeholders and appropriately designed and funded. Such an initiative was attempted in 2008 by the (then) National Quality Council and again proposed by Skills Australia 3 years later but never taken up. In addition, mechanisms to support both institutional and personal investment in development of professional capabilities need to be developed and implemented.

Fifth, there is a need to establish the best balance between a casual and a more permanent and sustained workforce based on the business needs of individual RTOs. The issue this raises is the preparedness of institutions and individuals alike to invest in capability development when the perceived return on investment may be seen as questionable for both parties. Ways need to be found to improve the preparedness to invest, including tax benefits for individuals and improved regulatory support and relief for providers prepared to invest in their staff's development. This also raises the issue of the extent to which individual RTOs support the proper induction of new staff and the development of their casual and part-time practitioner staff. Often, such support is not available to such practitioners, even if they make up the predominant proportion of teaching and training staff.

Sixth, there needs to be a strong institutional culture at RTO level supporting professional development, including professional development planning at both the teaching team and individual levels. In addition, this culture needs to encourage and support the development of a sense of professionalism in staff, including the development of capabilities in reflective practice about teaching and assessment approaches and maintaining vocational currency.

Finally, despite much research and many reports over the decades, many of the issues related to improving the quality of VET practitioners' professional practice remain unresolved. None of these issues are easily resolved, and there are no simple solutions or "silver bullets." The Australian VET system has not resolved what the best forms and level of practitioner preparation are nor which forms of ongoing development are most appropriate as well as who should conduct them. What is known is that there is no "one-size-fits-all approach" and that a wide variety of approaches are needed, based on careful planning and underpinned by clear

strategies. There needs to be effective pathways into and through formal qualifications, but also ways by which valid, useful but less formal development, including high-quality mentoring and other support, can be given due credit and recognized for the value they bring to a practitioner's work. This may require the development and endorsement of professional standards, coupled to the development of a range of respected qualifications, credentials, pathways, and recognition frameworks for professional development in all its forms.
