**Abstract.** The stream cipher TPpy has been designed by Biham and Seberry in January 2007 as the strongest member of the Py-family ciphers, after weaknesses in the other members Py, Pypy, Py6 were discovered. One main contribution of the paper is the detection of related-key weaknesses in the Py-family of ciphers including the strongest member TPpy. Under related keys, we show a distinguishing attack on TPpy with data complexity  $2^{192.3}$  which is lower than the previous best known attack on the cipher by a factor of  $2^{88}$ . It is shown that the above attack also works on the other members TPpy, Pypy and Py. A second contribution of the paper is design and analysis of two fast ciphers RCR-64 and RCR-32 which are derived from the TPpy and the TPpy respectively. The performances of the RCR-64 and the RCR-32 are 2.7 cycles/byte and 4.45 cycles/byte on Pentium III (note that the speeds of the ciphers Py, Pypy and RC4 are 2.8, 4.58 and 7.3 cycles/byte). Based on our security analysis, we conjecture that no attacks lower than brute force are possible on the RCR ciphers.

## 1 Introduction

### Timeline – The Py-Family of Ciphers

- **April 2005, Design.** The ciphers Py and Py6, designed by Biham and Seberry, were submitted to the ECRYPT project for analysis and evaluation in the category of software based stream ciphers [4]. The impressive speed

The user thereof uses the information at its sole risk and liability.

of the cipher Py in software (about 2.5 times faster than the RC4) made it one of the fastest and most attractive contestants.

- **March 2006, Attack (at FSE 2006).** Paul, Preneel and Sekar reported distinguishing attacks with  $2^{89.2}$  data and comparable time against the cipher Py [18]. Crowley [7] later reduced the complexity to  $2^{72}$  by employing a Hidden Markov Model.
- **March 2006, Design (at the Rump session of FSE 2006).** A new cipher, namely Pypy, was proposed by the designers to rule out the aforementioned distinguishing attacks on Py [5].
- **May 2006, Attack (presented at Asiacrypt 2006).** Distinguishing attacks were reported against Py6 with  $2^{68}$  data and comparable time by Paul and Preneel [19].
- **October 2006, Attack (presented at Eurocrypt 2007).** Wu and Preneel showed key recovery attacks against the ciphers Py, Pypy, Py6 with chosen IVs. This attack was subsequently improved by Isobe *et al.* [11].
- **January 2007, Design.** Three new ciphers TPy, TPy6, TPypy were proposed by the designers [3]; the ciphers can very well be viewed as the strengthened versions of the previous ciphers Py, Pypy and Py6 where the above attacks should not apply. So far there exist no published attacks on TPy, TPy6 and TPypy.
- **February 2007, Attack.** Sekar, Paul and Preneel published distinguishing attacks on Py, Pypy, TPy and TPypy with data complexities  $2^{281}$  each [23].
- **June 2007, Attack (to be presented at ISC 2007).** Sekar, Paul and Preneel showed new weaknesses in the stream ciphers TPy and Py. Exploiting these weaknesses distinguishing attacks on the ciphers are constructed where the best distinguisher requires  $2^{275}$  data and comparable time.
- **July 2007, Attack and Design (presented at WEWoRC 2007).** Sekar, Paul and Preneel mounted distinguishing attacks on TPy6 and Py6 with  $2^{233}$  data and comparable time each [22]. Moreover, they have modified TPy6 to design two new ciphers TPy6-A and TPy6-B which were claimed to be free from all attacks excluding brute force ones.<sup>1</sup>

**Contribution of the paper.** The list that orders the Py-family of ciphers in terms of increasing security is: Py6→Py→Pypy→TPy6→TPy→TPypy (the strongest). The ciphers are normally used with 32-byte keys and 16-byte initial values (or IV). However, the key size may vary from 1 to 256 bytes and the IV from 1 to 64 bytes. The ciphers were claimed by the designers to be free from related-key and distinguishing attacks [3,4,5].

(i) *Related-key Weaknesses.* One major contribution of the paper is the discovery of related-key attacks due to weaknesses in the key scheduling algorithms of the Py-family of ciphers. The main idea behind a related-key attack is that, the attacker, who chooses a relation  $f$  between a pair of keys  $key_1$  and  $key_2$  (e.g.,  $key_1 = f(key_2)$ ) rather than the actual values of the keys, is able to extract

---

<sup>1</sup> It has been reported very recently that Tsunoo *et al.* showed a distinguishing attack on TPypy with a data complexity of  $2^{199}$  [25].

secret information from a cryptosystem using the relation  $f$  [2,13]. Related-key weakness is a cause for concern in a protocol where key-integrity is not guaranteed or when the keys are generated manually rather than from a pseudorandom number generator [12]. Related-key weaknesses are not new in the literature. The usefulness of such type of attacks was first outlined by Knudsen in [14,15]; since then a good deal of research has been spent on related-key weaknesses on block ciphers [2,12,13,16]. The related-key weaknesses of a block cipher can be translated into attacking hash functions based on that particular block cipher and vice versa [9,10,17,20,26,27].

On the other hand, discovery of related-key weaknesses of stream ciphers is not very common in the literature, mainly due to the heavy operations executed in one-time key-scheduling algorithms compared to the operations performed in iterative block ciphers. However, there is an example where related-key weaknesses of the stream cipher RC4 are used to break the WEP protocol with practical complexity [8]. Furthermore, there is a growing tendency by the designers nowadays to build hash functions from stream ciphers [6] instead of building them from block ciphers. In such attempts, related-key weaknesses of stream ciphers need to be addressed carefully.

In the paper, we show that, when used with the identical IVs of 16 bytes each, if two long keys  $key_1$  and  $key_2$  of 256 bytes each, are related in the following manner,

1.  $key_1[16] \oplus key_2[16] = 1$ ,
2.  $key_1[17] \neq key_2[17]$  and
3.  $key_1[i] = key_2[i] \forall i \notin \{16, 17\}$

then the above relation, exploiting the weaknesses of the key setup algorithms of Py-family of ciphers (i.e., TPpy, TPy, Ppy, Py), propagates through the IV setup algorithms and finally induces biases in the outputs at the 1st and the 3rd rounds. Such related key pairs are used to build a distinguisher for each of the aforementioned ciphers with  $2^{193.7}$  output words and comparable time (note that, in total, there are  $2^{2048}$  such pairs, while our distinguisher needs any  $2^{193.7}$  randomly chosen pairs of keys). This result constitutes the best attack on the strongest member of the Py-family of ciphers TPpy; they are also shown to be effective on the other members TPy, Ppy and Py (see Table 1). These related-key attacks work with any IV-size ranging from 16 to 64 bytes. However, the attack complexities increase with shorter keys. Note that the usage of long keys in the Py-family of ciphers makes it very attractive to be used as fast hash functions (e.g., by replacing of the key with the message). In such cases, these related-key weaknesses can turn out to be serious impediments.

(ii) *The Ciphers RCR-32 and RCR-64.* Finally, we make simple modifications to the ciphers TPpy and TPy to build two new ciphers RCR-32 and RCR-64 respectively. In the modified designs, the key scheduling algorithms of RCR-32 and RCR-64 are identical with those of the TPpy and the TPy. The changes are made *only* to the round functions where *variable rotations* are replaced with *constant rotations*. Our extensive analyses show that the modifications not only

**Table 1.** Attacks on the Py-family of stream ciphers ('X' denotes that the attack does not work)

Attack	Py6	Py	Pypy	TPy6	TPy	TPypy
Crowley [7]	X	$2^{72}$	X	X	$2^{72}$	X
Isobe <i>et al.</i> [11]	X	$2^{24}$	$2^{24}$	X	X	X
Paul <i>et al.</i> [18]	X	$2^{88}$	X	X	$2^{88}$	X
Paul-Preneel [19]	$2^{68}$	X	X	$2^{68}$	X	X
Sekar <i>et al.</i> [21]	X	$2^{275}$	X	X	$2^{275}$	X
Sekar <i>et al.</i> [22]	$2^{233}$	X	X	$2^{233}$	X	X
Sekar <i>et al.</i> [23]	X	$2^{281}$	$2^{281}$	X	$2^{281}$	$2^{281}$
Wu-Preneel [29]	X	$2^{24}$	$2^{24}$	X	X	X
Related key (this paper)	X	$2^{193.7}$	$2^{193.7}$	X	$2^{193.7}$	$2^{193.7}$

free the Py-family ciphers from *all* the existing attacks, it also improves on the performance of the ciphers without exposing them to new weaknesses (see Sect. 5 for an elaborate security analysis). As a result, the cipher RCR-64 goes on to become one of the *the fastest* stream ciphers published in the literature (approximately 2.7 cycles per byte on Pentium III). The names are chosen to reflect the functionalities involved in the ciphers. For example, RCR-64 denotes *Rolling, Constant Rotation and 64 bits output/round*.

## 2 Description of the Stream Ciphers TPy, TPy6, Pypy and Py

Each of the Py-family of ciphers is composed of three parts: (1) a key setup algorithm, (2) an IV setup algorithm and (3) a round function or pseudorandom bit generation algorithm (PRBG). The first two parts are used for the initial one-time mixing of the secret key and the IV. These parts generate a pseudorandom internal state composed of (1) a permutation  $P$  of 256 elements, (2) a 32-bit array  $Y$  of 260 elements and (3) a 32-bit variable  $s$ . The key/IV setup uses two intermediate variables: (1) a fixed permutation of 256 elements denoted by *internal\_permutation* and (2) a variable  $EIV$  whose size is equal to that of the IV. The round function, which is executed iteratively, is used to update the internal state (i.e.,  $P$ ,  $Y$  and  $s$ ) and to generate pseudorandom output bits. The key setup algorithms of the TPy, the TPy6, the Pypy and the Py are identical. Notation for different parts of the four ciphers is provided in Table 2.

Due to space constraints, the  $KS$ , the  $IVS_1$ , the  $IVS_2$ , the  $RF_1$  and the  $RF_2$ , as mentioned in Table 2, are described in the full version of the paper [24]. The details of the algorithms can also be found in [3,4,5].

**Table 2.** Description of the ciphers TPypy, TPy, Pypy and Py

	TPypy	TPy	Pypy	Py
Key Setup	$KS$	$KS$	$KS$	$KS$
IV Setup	$IVS_1$	$IVS_1$	$IVS_2$	$IVS_2$
Round Function	$RF_1$	$RF_2$	$RF_1$	$RF_2$

### 3 Notation and Convention

The notation and the convention followed in the paper are described below.

- The pseudorandom bit generation algorithm of a stream cipher is denoted by PRBG.
- The outputs generated when  $key_1$  and  $key_2$  are used are denoted by  $O$  and  $Z$  respectively.
- $O^a_{(b)}$  (or  $Z^a_{(b)}$ ) denotes the  $b$ th bit ( $b = 0$  is the least significant bit or lsb) of the second output word generated at round  $a$  when  $key_1$  (or  $key_2$ ) is used. We do not use the first output word anywhere in our analysis.
- $P^a_1$ ,  $Y^{a+1}_1$  and  $s^a_1$  are the inputs to the PRBG at round  $a$  when  $key_1$  is used. It is easy to see that when this convention is followed the  $O^a$  takes a simple form:  $O^a = (s \oplus Y^a[-1]) + Y^a[P^a[208]]$ . The same applies to  $key_2$ .
- $Y^a_1[b]$ ,  $P^a_1[b]$  denote the  $b$ th elements of array  $Y^a_1$  and  $P^a_1$  respectively, when  $key_1$  is used.
- $Y^a_1[b]_i$ ,  $P^a_1[b]_i$  denote the  $i$ th bit of  $Y^a_1[b]$ ,  $P^a_1[b]$  respectively.
- The operators ‘+’ and ‘-’ denote *addition modulo  $2^{32}$*  and *subtraction modulo  $2^{32}$*  respectively, except when used with expressions which relate two elements of array  $P$ . In this case they denote *addition and subtraction over  $\mathbb{Z}$* .
- The symbol ‘ $\oplus$ ’ denotes bitwise *exclusive-or*,  $\cap$  denotes set intersection and  $\cup$  denotes set union.

### 4 Related-Key Weaknesses in the Py-Family of Ciphers

We first choose two keys,  $key_1$  and  $key_2$  (each key is 256 bytes long), such that,

**C1.**  $key_1[16] \oplus key_2[16] = 1$  (without loss of generality, assume lsb of  $key_1[16]$  is 1),

**C2.**  $key_1[17] \neq key_2[17]$  and **C3.**  $key_1[i] = key_2[i] \forall i \notin \{16, 17\}$ .

Now we observe that the above relation between the keys can be traced through various parts of the Py-family of ciphers.

#### 4.1 Propagation of the Weaknesses Through the Key Setup Algorithm

For  $key_1$  and  $key_2$ , the values of the variable  $s$  through Algorithm A are tabulated in Table 3. The Algorithm A is a part of the key setup algorithm  $KS$  (described in the full version of the paper [24]).

---

**Algorithm A**

```

for(j=0; j<keysizeb; j++)
{
    s = s + key[j];
    s0 = internal_permutation[s&0xFF];
    s = ROTL32(s, 8) ^ (u32)s0;
}

```

---

**Table 3.** The variable  $s$  after rounds 15, 16 and 17 of Algorithm A

End of round	$s$ (using $key_1$ )	$s$ (using $key_2$ )
15	$s_{1,15}^A$	$s_{2,15}^A = s_{1,15}^A$
16	$s_{1,16}^A$	$s_{2,16}^A = s_{1,16}^A - \delta_1$ (say)
17	$s_{1,17}^A$	$s_{2,17}^A = s_{1,17}^A$ if $key_2[17] = key_1[17] + \delta_1$

If  $x$  is a 32-bit variable, let  $B(x)$  denote the least significant byte of  $x$ . In Table 3,

$$\delta_1 = s_{1,16}^A - s_{2,16}^A \tag{1}$$

$$= ROTL32((s_{1,15}^A + key_1[16]), 8) \oplus ip[B(s_{1,15}^A + key_1[16])] \tag{2}$$

$$- ROTL32((s_{2,15}^A + key_2[16]), 8) \oplus ip[B(s_{2,15}^A + key_2[16])], \tag{3}$$

where  $ip$  denotes *internal\_permutation*.

Now, if  $key_2[17] = key_1[17] + \delta_1$  (call this the event  $D_1$ ), it is observed from Algorithm A that the following equation is satisfied:

$$s_{1,17}^A = s_{2,17}^A.$$

For event  $D_1$  to occur,  $\delta_1$  should be an 8-bit integer. Running simulation, it is determined that

$$Pr[|\delta_1| = 8] \approx \frac{1}{2}.$$

Hence,

$$Pr[D_1] \approx 2^{-9}. \tag{4}$$

If  $s_{1,17}^A = s_{2,17}^A$ , then in the subsequent rounds of Algorithm A, the  $s_1^A$  and  $s_2^A$  remain the same, that is,  $s_{1,k}^A = s_{2,k}^A$ , where  $k = 18, 19, \dots, 255$ .

Given that the  $D_1$  occurs, that is,  $s_1^A = s_2^A$  at the end of Algorithm A, or  $s_{1,255}^A = s_{2,255}^A$ , we now trace the values of  $s$  through Algorithm B which forms

**Algorithm B**

---

```

for(j=0; j<keysizeb; j++)
{
  s = s + key[j];
  s0 = internal_permutation[s&0xFF];
  s ^= ROTL32(s, 8) + (u32)s0;
}

```

---

**Table 4.**  $s$  after rounds 15, 16 and 17 of Algorithm B given event  $D_1$  occurs

End of round	$s$ (using $key_1$ )	$s$ (using $key_2$ )
15	$s_{1,15}^B$	$s_{2,15}^B = s_{1,15}^B$
16	$s_{1,16}^B$	$s_{2,16}^B = s_{1,16}^B - \delta_2$ (say)
17	$s_{1,17}^B$	$s_{2,17}^B = s_{1,17}^B$ if $key_2[17] = key_1[17] + \delta_2$

another part of the key setup. Table 4 compares the values of  $s$  after rounds 15, 16 and 17 of Algorithm B when  $key_1$  and  $key_2$  are used.

In Table 4,

$$\begin{aligned}
\delta_2 &= s_{1,16}^B - s_{2,16}^B \\
&= ROTL32((s_{1,15}^B + key_1[16]), 8) \oplus ip[B(s_{1,15}^B + key_1[16])] \\
&\quad - ROTL32((s_{2,15}^B + key_2[16]), 8) \oplus ip[B(s_{2,15}^B + key_2[16])]. \tag{5}
\end{aligned}$$

Now, given event  $D_1$  occurs, i.e.,  $s_1^A = s_2^A$  at the end of Algorithm A, if  $\delta_2 = \delta_1$  (call this the event  $D_2$ ), we will have  $key_2[17] = key_1[17] + \delta_2$  and hence from Algorithm B, the following equation is satisfied:

$$s_{1,17}^B = s_{2,17}^B.$$

For event  $D_2$  to occur,  $\delta_2$  should be an 8-bit integer. Running simulation, it is determined that

$$Pr[|\delta_2| = 8] \approx \frac{1}{2^{2.4}}.$$

Hence,

$$Pr[D_2|D_1] \approx 2^{-10.4} \Rightarrow Pr[D_2 \cap D_1] \approx Pr[D_1] \cdot 2^{-10.4} \approx 2^{-19.4}. \tag{6}$$

If  $s_{1,17}^B = s_{2,17}^B$ , then in the subsequent rounds of Algorithm B, the  $s_1^B$  and  $s_2^B$  remain the same, that is,  $s_{1,k}^B = s_{2,k}^B$ , where  $k = 18, 19, \dots, 255$ .

Given that the  $D_2 \cap D_1$  occurs, that is,  $s_1^B = s_2^B$  at the end of Algorithm B, or  $s_{1,255}^B = s_{2,255}^B$ , the values of  $s$  and  $Y$  are traced through Algorithm C which

forms the final part of the key setup. In the full version of the paper we compare the values of  $s$  and  $Y$  after rounds 15, 16 and 17 of Algorithm C when  $key_1$  and  $key_2$  are used [24]. Since Algorithm C and the corresponding table have striking similarities with Algorithm A and Table 3, they are described in the full version [24] and we provide only the results of our analysis. Now, given that the event  $D_2 \cap D_1$  occurs, i.e.,  $s_1^B = s_2^B$  at the end of Algorithm B, if  $\delta_3 = \delta_1$  (call this the event  $D_3$ ), we will have  $key_2[17] = key_1[17] + \delta_3$  and hence from Algorithm C, the following equation is satisfied:

$$s_{1,17}^C = s_{2,17}^C.$$

For event  $D_3$  to occur,  $\delta_2$  should be an 8-bit integer. Running simulation, it is determined that

$$Pr[|\delta_3| = 8] \approx \frac{1}{2}.$$

Hence,

$$Pr[D_3|D_2 \cap D_1] \approx 2^{-9} \Rightarrow Pr[D_3 \cap D_2 \cap D_1] \approx Pr[D_2 \cap D_1] \cdot 2^{-9} \approx 2^{-28.4}. (7)$$

If  $s_{1,17}^C = s_{2,17}^C$ , then in the subsequent rounds of Algorithm C, the  $s_1^C$  and  $s_2^C$  remain the same, that is,  $s_{1,k}^C = s_{2,k}^C$ , where  $k = 18, 19, \dots, 255$  and  $Y_1[j] = Y_2[j]$ , where  $j \neq 13$ .

## 4.2 Propagation of the Weaknesses Through the IV Setup

Given that the  $D_3 \cap D_2 \cap D_1$  occurs, i.e.,  $s_1^C = s_2^C$  at the end of Algorithm C, or  $s_{1,255}^C = s_{2,255}^C$ , and  $Y_1[i] = Y_2[i]$  ( $i \neq 13$ ), we now trace the variables  $s$ ,  $Y$ ,  $P$  and  $EIV$  through the first part of the IV setup. We now consider Algorithm D which is a part of the IV setup. It is to be noted that  $s$ ,  $Y$  (obtained after the key setup) and the  $iv$  are the basic elements used in the IV setup to define the  $P$  and the  $EIV$  and to update the  $s$  and the  $Y$ . We now model our attack in such a way that the same IV is used with both the keys. Prior to the execution of Algorithm D, the only elements of array  $Y$  which are used in the first part of the IV setup are  $Y[0]$ ,  $Y[1]$ ,  $Y[YMININD]$  and  $Y[YMAXIND]$ . Since  $Y[13]$  is not used, it follows that  $P_1$  (that is,  $P$  when  $key_1$  is used) and  $P_2$  (that is,  $P$  when  $key_2$  is used) are identical.

---

Algorithm D

```

for(i=0; i<ivsizeb; i++)
{
  s = s + iv[i] + Y(YMININD+i);
  u8 s0 = P(s&0xFF);
  EIV(i) = s0;
  s = ROTL32(s, 8) ^ (u32)s0;
}

```

---

In Algorithm D as well,  $Y[13]$  is not used to update the  $s$  or define the  $EIV$  when the IV is of the recommended size of 16 bytes. For longer IVs, we can induce the first difference in the keys (that is, where the least significant bits alone differ) according to the size of the IV. An example is provided in the full version [24]. It is to be noted that, if the IV-size is  $N$  bytes, the first difference in the keys should be induced nowhere: neither (1) in the first  $N - 1$  bytes (i.e., key bytes 0 to  $N - 1$ ), nor (2) in the last  $N - 3$  bytes (i.e., key bytes  $260 - N$  to 256). Otherwise, it is immaterial as to where the first difference is set (i.e., anywhere

---

**Algorithm E**

```

for(i=0; i<ivsizeb; i++)
{
    s = s + iv[i] + Y(YMAXIND-i);
    /*s = s + EIV((i+ivsizeb-1)mod ivsizeb) + Y(YMAXIND-i); for IVS1.*/
    u8 s0 = P(s&0xFF);
    EIV(i) += s0;
    s = ROTL32(s, 8) ^ (u32)s0;
}

```

---

from byte  $N$  to  $259 - N$ ) – in all the cases, bias induced will be approximately identical (this is established from a large number of experiments).

We now consider Algorithm E. Again,  $Y[13]$  is not used to update the  $s$  or the  $EIV$  (for both  $IVS_1$  and  $IVS_2$ ). Hence, at the end of Algorithm E, we have  $s_1 = s_2$ ,  $EIV_1 = EIV_2$ ,  $P_1 = P_2$  and  $Y_1[i] = Y_2[i]$  (where  $i \neq 13$ ). With this result, we now proceed to the second part of the IV setup.

In the second part of the IV setup (that is, for  $IVS_2$ ), when  $i = 16$  ( $i = 17$  for  $IVS_1$ ), the  $s$  generated using  $key_1$  and  $key_2$  are different due to the difference in  $Y[13]$ . This causes the  $EIV$ s to be different in the following round and hence  $P_1 \neq P_2$ . In the subsequent rounds, the mixing becomes more random with the result that at the end of 260 rounds, we have  $Y_1[j] = Y_2[j]$  where  $j \in \{-3, \dots, 12\}$ .

---

**IV setup part-2**

```

for(i=0; i<260; i++)
{
    u32 x0 = EIV(0) = EIV(0) ^ (s&0xFF);
    rotate(EIV);
    swap(P(0), P(x0));
    rotate(P);
    Y(YMININD)=s=(s ^ Y(YMININD))+Y(x0);
    /*s=ROTL32(s,8)+Y(YMAXIND);
    Y(YMININD)+=s^Y(x0); for IVS1.*/
    rotate(Y);
}

```

---

This result holds only if  $x_0 \neq 13$  when  $i = 0, \dots, 15$ . The probability that this occurs is  $(\frac{255}{256})^{j+4} \approx 1$  when  $j \in \{-3, \dots, 12\}$ . With this result, we now analyze the keystream generation algorithm.

### 4.3 Propagation of the Weaknesses Through the Round Function

Here, we consider only the round function  $RF_1$  (see the full version [24]). The formulas for the lsb of the outputs generated at rounds 1 and 3 when  $key_1$  (the output words are denoted by  $O$ ) and  $key_2$  (the output words are denoted by  $Z$ ) are used are given below.

$$O_{(0)}^1 = s_{1(0)}^1 \oplus Y_1^1[-1]_0 \oplus Y_1^1[P_1^1[208]]_0, \quad (8)$$

$$O_{(0)}^3 = s_{1(0)}^3 \oplus Y_1^3[-1]_0 \oplus Y_1^3[P_1^3[208]]_0, \quad (9)$$

$$Z_{(0)}^1 = s_{2(0)}^1 \oplus Y_2^1[-1]_0 \oplus Y_2^1[P_2^1[208]]_0, \quad (10)$$

$$Z_{(0)}^3 = s_{2(0)}^3 \oplus Y_2^3[-1]_0 \oplus Y_2^3[P_2^3[208]]_0. \quad (11)$$

Let  $C_1, C_2, C_3$  and  $C_4$  denote  $Y_1^1[P_1^1[208]]_0, Y_1^3[P_1^3[208]]_0, Y_2^1[P_2^1[208]]_0$  and  $Y_2^3[P_2^3[208]]_0$  respectively. Each row in Table 5 gives the conditions on the elements of  $P_1$  and  $P_2$  which when simultaneously satisfied gives  $C_1 \oplus C_2 \oplus C_3 \oplus C_4 = 0$ . The corresponding probabilities are also given. From Table 5, it follows that events  $G_2, G_3$  and  $G_4$  can be ignored when compared to  $G_1$ . We now state the following theorem.

**Theorem 1.**  $s_1^1 = s_1^3$  when the following conditions are simultaneously satisfied.

1.  $P_1^2[116] \equiv -18 \pmod{32}$  (event  $E_1$ ),
2.  $P_1^3[116] \equiv -18 \pmod{32}$  (event  $E_2$ ),
3.  $P_1^2[72] = P_1^3[239] + 1$  (event  $E_3$ ),
4.  $P_1^2[239] = P_1^3[72] + 1$  (event  $E_4$ ).

**Proof.** The formulas for  $s_1^2$  and  $s_1^3$  are given below:

$$s_1^2 = ROTL32(s_1^1 + Y_1^2[P_1^2[72]] - Y_1^2[P_1^2[239]], P_1^2[116] + 18 \pmod{32}), \quad (12)$$

$$s_1^3 = ROTL32(s_1^2 + Y_1^3[P_1^3[72]] - Y_1^3[P_1^3[239]], P_1^3[116] + 18 \pmod{32}). \quad (13)$$

Condition 1 (i.e.,  $P_1^2[116] \equiv -18 \pmod{32}$ ) reduces (12) to

$$s_1^2 = s_1^1 + Y_1^2[P_1^2[72]] - Y_1^2[P_1^2[239]].$$

Therefore, (13) becomes

$$s_1^3 = ROTL32(s_1^1 + \sum_{i=2}^3 (Y_1^i[P_1^i[72]] - Y_1^i[P_1^i[239]]), P_1^3[116] + 18 \pmod{32}). \quad (14)$$

Now, condition 3 (i.e.,  $P_1^2[72] = P_1^3[239] + 1$ ) and condition 4 ( $P_1^2[239] = P_1^3[72] + 1$ ) together imply  $\sum_{i=2}^3 (Y_1^i[P_1^i[72]] - Y_1^i[P_1^i[239]]) = 0$  and hence reduce (14) to

$$s_1^3 = ROTL32(s_1^1, P_1^3[116] + 18 \pmod{32}). \quad (15)$$

**Table 5.** When  $G_j$  ( $1 \leq j \leq 4$ ) occurs,  $C_1 \oplus C_2 \oplus C_3 \oplus C_4 = 0$ 

Event	Conditions	Probability	Result
$G_1$	$P_1^1[208] = P_1^3[208] + 2, P_2^1[208] = P_2^3[208] + 2$	$2^{-16}$	$C_1 = C_2, C_3 = C_4$
$G_2$	$P_1^1[208] = P_2^1[208], P_1^1[208], P_2^1[208] \leq 12, P_1^3[208] = P_2^3[208], P_1^3[208], P_2^3[208] \leq 12$	$2^{-24.6}$	$C_1 = C_3, C_2 = C_4$
$G_3$	$P_1^1[208] = P_2^3[208] + 2, 2 \leq P_1^1[208] \leq 12, P_2^3[208] \leq 10, P_2^1[208] = P_1^3[208] + 2, 2 \leq P_2^1[208] \leq 12, P_1^3[208] \leq 10$	$2^{-25.4}$	$C_1 = C_4, C_2 = C_3$
$G_4$	$G_2 \cap G_1$	Negligible ( $\ll 2^{-25}$ )	$C_1 = C_2 = C_3 = C_4$

Now, when event  $E_2$  (that is,  $P_1^3[116] \equiv -18 \pmod{32}$ ) occurs, (15) becomes

$$s_1^3 = ROTL32(s_1^1, 0) = s_1^1. \quad (16)$$

This completes the proof.  $\square$

Now,  $s_1^1 = s_1^3 \Rightarrow s_1^1(0) = s_1^3(0)$  and  $Pr[E_1] \approx Pr[E_2] \approx 2^{-5}$  and  $Pr[E_3] \approx Pr[E_4] \approx 2^{-8}$ . The four events  $E_1, E_2, E_3$  and  $E_4$  are assumed to be independent to facilitate calculation of bias. The actual value without independence assumption is in fact more, making the attack marginally stronger. Hence,  $Pr[E_1 \cap E_2 \cap E_3 \cap E_4] = 2^{-26}$ . Similarly, we have  $s_2^1 = s_2^3$  when the following conditions are simultaneously satisfied.

1.  $P_2^2[116] \equiv -18 \pmod{32}$  (event  $E_5$ ),
2.  $P_2^3[116] \equiv -18 \pmod{32}$  (event  $E_6$ ),
3.  $P_2^2[72] = P_2^3[239] + 1$  (event  $E_7$ ),
4.  $P_2^2[239] = P_2^3[72] + 1$  (event  $E_8$ ).

Again,  $s_2^1 = s_2^3 \Rightarrow s_2^1(0) = s_2^3(0)$  and

$$Pr[\cap_{i=1}^8 E_i] = \frac{1}{2^{52}}. \quad (17)$$

From the analysis in Sect. 4.1 and 4.2, when  $D_3 \cap D_2 \cap D_1$  occurs,  $Y_1^1[j] = Y_2^1[j]$  where  $j \in \{-3, \dots, 12\}$ .  $Y_1^1[i] = Y_2^1[i] \Rightarrow Y_1^1[-1]_0 = Y_2^1[-1]_0$  and  $Y_1^3[-1]_0 = Y_1^1[1]_0 = Y_2^1[1]_0 = Y_2^3[-1]_0$ . Therefore, from equations (8), (9), (10) and (11), we observe that

$$O_{(0)}^1 \oplus O_{(0)}^3 \oplus Z_{(0)}^1 \oplus Z_{(0)}^3 = 0 \quad (18)$$

holds when the following events simultaneously occur.

1.  $D_3 \cap D_2 \cap D_1$ ,
2.  $\cap_{i=1}^8 E_i$  and
3.  $G_1$ .

In the following section, we calculate the probability that (18) is satisfied.

#### 4.4 The Distinguisher

Let  $L$  denote the event  $(\cap_{i=1}^8 E_i) \cap (D_3 \cap D_2 \cap D_1) \cap (G_1)$ . From (7), (17) and Table 5, we get:  $Pr[L] = 2^{-52} \cdot 2^{-28.4} \cdot 2^{-16} = 2^{-96.4}$ . Assuming randomness

of the outputs when event  $L$  does not occur (concluded from a large number of experiments), we have:

$$Pr[O_{(0)}^1 \oplus O_{(0)}^3 \oplus Z_{(0)}^1 \oplus Z_{(0)}^3 = 0] = \frac{1}{2} \left( 1 + \frac{1}{296.4} \right). \tag{19}$$

To compute the number of samples required to establish an optimal distinguisher with advantage greater than 0.5, we use the following equation:

$$n = 0.4624 \cdot \frac{1}{p^2} \tag{20}$$

from [1,18]. Here,  $p = 2^{-97.4}$ . Therefore, the number of samples is  $2^{193.7}$ .

### 4.5 Attacks with Shorter Keys

The related-key attacks described in the previous sections can be applied with shorter keys also. However, the data complexity of the distinguisher increases exponentially as key size decreases. For example, when the key size is 128 bytes, the distinguisher works with  $2^{229.7}$  data and comparable time. For 64-byte key size, the data complexity of the distinguisher is  $2^{247.7}$ .

## 5 New Stream Ciphers – RCR-32 and RCR-64

As mentioned in Sect. 1, in the last couple of years, the Py-family of ciphers have come under several cryptanalytic attacks. In spite of the weaknesses, the ciphers retain some attractive features such as modification of the internal states with clever use of rolling arrays and fast mixing of several arithmetic operations. This motivates us to explore the possibility of designing new ciphers that retain all the good properties of the Py-family and yet are secure against all the existing and new attacks.

In this section, we propose two new ciphers, RCR-32 (*Rolling, Constant Rotation, 32-bit output per round*) and RCR-64 derived from TPpy and Tpy, which are shown to be secure against all the existing attacks on the TPpy and Tpy. The speeds of execution of the RCR-64 and the RCR-32 in software are 2.7 cycles and 4.45 cycles per byte which are better than the performances of the Tpy (2.8 cycles/byte) and the TPpy (4.58 cycles/byte) respectively.

The key/IV setup algorithms of the RCR-64 and the RCR-32 are identical with those of the Tpy and the TPpy. The PRBGs of the RCR-64 and the RCR-32 are also very similar to those of the Tpy and the TPpy. The only changes in the PRBGs are that: the *variable rotation* of the quantity  $s$  is replaced by a *constant rotation* of 19. Single round of RCR-32 and RCR-64 are shown in Algorithm 1.

### 5.1 Security Analysis

Due to restrictions on the page limit, the security analysis has been provided in the full version of the paper [24].

---

**Algorithm 1.** Round functions of RCR-32 and RCR-64

---

**Require:**  $Y[-3, \dots, 256]$ ,  $P[0, \dots, 255]$ , a 32-bit variable  $s$ 

**Ensure:** 64-bit random output (for RCR-64) or 32-bit random output (for RCR-32)

```

/*Update and rotate P*/
1: swap ( $P[0]$ ,  $P[Y[185]\&255]$ );
2: rotate ( $P$ );
/* Update s*/
3:  $s+ = Y[P[72]] - Y[P[239]]$ ;
4:  $s = ROTL32(s, 19)$ ; /*Tweak - the variable  $s$  undergoes a constant, non-zero rotation.*/
/* Output 4 or 8 bytes (the least significant byte first)*/
5: output ( $(ROTL32(s, 25) \oplus Y[256]) + Y[P[26]]$ );/* This step is skipped for RCR-32.*/
6: output ( $(s \oplus Y[-1]) + Y[P[208]]$ );
/* Update and rotate Y*/
7:  $Y[-3] = (ROTL32(s, 14) \oplus Y[-3]) + Y[P[153]]$ ;
8: rotate( $Y$ );

```

---

## 6 Future Work and Conclusion

In this paper, for the first time, we detect weaknesses in the key scheduling algorithms of several members of the Py-family. Precisely, we build distinguishing attacks with data complexities  $2^{193}$  each. Furthermore, we modify the ciphers TPpy and TPy to generate two fast ciphers, namely RCR-32 and RCR-64, in an attempt to rule out all the attacks against the Py-family of ciphers. We conjecture that attacks lower than brute force are not possible on RCR ciphers.

Our present work leaves room for interesting future work. The usage of long keys and IVs (e.g., possibility of 256-byte keys and 64-byte IVs) in RCR ciphers makes them good candidates to be used as hash functions. One can also try to combine a MAC and an encryption algorithm in a single primitive using RCR ciphers. It seems worthwhile to address these issues in future.
