Minimal Union-Free Decompositions of Regular Languages*-*

Sergey Afonin and Denis Golomazov

Lomonosov Moscow State University, Institute of Mechanics, Moscow, Russia serg@msu.ru

Abstract. A regular language is called *union-free* if it can be represented by a regular expression that does not contain the union operation. Every regular language can be represented as a finite union of union-free languages (the so-called *union-free decomposition*), but such decomposition is not necessarily unique. We call the number of components in the minimal union-free decomposition of a regular language *the union width* of the regular language. In this paper we prove that the union width of any regular language can be effectively computed and we present an algorithm for constructing a corresponding decomposition. We also study some properties of union-free languages and introduce a new algorithm for checking whether a regular language is union-free.

1 Introduction

Regular expressions are a natural formalism for the representation of regular languages. It is well known that there exist regular languages that can be represented by infinitely many equivalent regular expressions, and a number of "canonical" forms of regular expressions representing a given regular language have been proposed in the literature, such as concatenative decomposition [\[1,](#page-8-0) [2\]](#page-8-1) and union-free decomposition (see e.g. [\[3\]](#page-8-2)). This paper is devoted to the task of finding a minimal union-free decomposition of a regular language. A language is called *union-free* if it can be represented by a regular expression without the usage of the union operation. For example, the language represented by the expression $(a + b^*)^*$ is union-free because there exists an equivalent expression $(a^*b^*)^*$. Union-free languages have been introduced under the name "star-dot" regular" languages by J. Brzozowski in [\[4\]](#page-8-3).

Every regular expression r can be transformed into a regular expression r' in which union operations appear only on the "top level" of the expression, i.e., it takes the following form: $r' = r_1 + \ldots + r_m$, and the regular expressions r_1, \ldots, r_m do not contain the " $+$ " operator (see [\[3\]](#page-8-2)). This means that every regular language can be represented as a finite union of union-free languages. But this decomposition is not necessarily unique: for example, $(a + b)^* = (a^*b^*)^* = \{\varepsilon\} + a^*ba^* + b^*ab^*,$ and these are two different union-free decompositions of the language $(a+b)*$. We

call the minimal number of components in such a representation *the union width* of the regular language and a corresponding decomposition (that is not necessarily unique) is called *a minimal union-free decomposition* of a regular language. In this paper we present an algorithm that computes the union width and constructs a minimal union-free decomposition of a regular language.

The union width of a regular language and corresponding decompositions may be considered as canonical representations of a regular expression, as well as a complexity measure of a regular language [\[5\]](#page-8-4), similar to the restricted star height.

Union-free decompositions play an important role in the algorithm for checking membership of a regular language in a rational subset of a finitely generated semigroup of regular languages with respect to concatenation as a semigroup product. In order to check such membership one should verify that at least one of the distance automata corresponding to the components of an arbitrary unionfree decomposition of a certain regular language is limited. We do not go into the details here (see $[6]$). We will just mention that checking the limitedness property is Pspace-complete [\[7\]](#page-8-6), thus, the number of components in a union-free decomposition is an important parameter influencing membership-checking complexity.

The problem of constructing union-free decompositions of regular languages has also practical applications. In particular, regular languages can be used for a description of the syntactic structure of a programming language [\[8\]](#page-9-1). The concatenation operation corresponds to the sequential continuation, the Kleene star corresponds to loops, and the union operation corresponds to branching. In this context, union-free languages represent sequences of operators that do not contain conditional transitions. Minimal union-free decompositions of regular languages may be useful for simplifying and normalizing such descriptions.

The main result of the current paper is that the union width of a regular language L can be effectively computed, and we present an algorithm that constructs the corresponding decomposition. This result is achieved by using the combinatorial technique we have adopted from [\[2\]](#page-8-1). First we take the set $C(L)$ of all maximum finite concatenations of letters and certain star languages derived from the automaton of L. We prove that $C(L)$ is a finite set and that for every union-free decomposition of L there exists a union-free decomposition of L of the same number of elements that consists of languages from $C(L)$. Consequently, there exists a minimal union-free decomposition that consists of languages from $C(L)$. Thus we can obtain it by examining all the subsets of the finite set $C(L)$.

We also present an algorithm for checking whether a given regular language is union-free. This decidability result is already known (see Theorem [1](#page-2-0) below) but it is based on reduction to the computationally expensive problem of checking limitedness of distance automata, which is Pspace-complete.

The paper has the following structure: Section [2](#page-2-1) provides some basic definitions, Section [3](#page-3-0) presents results concerning general properties of union-free languages, Section [4](#page-6-0) is devoted to the algorithm for finding a minimal union-free decomposition of a regular language, and Section [5](#page-8-7) contains conclusions and ideas for the further work.

2 Preliminaries

Let $\Sigma = \{a_1, \ldots, a_n\}$ be a finite alphabet, $L \subseteq \Sigma^*$ be a regular language and $V = \langle \Sigma, Q, q_0, F, \varphi \rangle$ be the corresponding minimal deterministic finite automaton, where $Q = \{q_1, \ldots, q_m\}$ is the set of all states of V, $q_0 \in Q$ is the initial state, $F \subseteq Q$ is the set of final states and $\varphi : Q \times \Sigma \to Q$ is the transition function of the automaton. Let $M \subseteq \Sigma^*$, $q_1 \in Q$. The definition of the function φ is extended as follows: $\varphi(q_1, M) = \{q \in Q \mid \exists \alpha = \alpha_1 \alpha_2 \cdots \alpha_p \in M \}$ $\varphi(\cdots \varphi(\varphi(q_1,\alpha_1),\alpha_2),\ldots,\alpha_p)=q\}.$

An ordered list of states $\{q_1, \ldots, q_m\}$ $(q_i \in Q)$ is called *a path marked with a* word $w \in \Sigma^*$ iff $w = a_1 \cdots a_{m-1}$ and $\varphi(q_i, a_i) = q_{i+1}, i = 1, \ldots, m-1$. A path in an automaton is called *cycle-free* iff it starts at the initial state q_0 , ends at a final state $q_f \in F$ and does not contain any cycles, i.e., there is no state occurring in the list more than once. It should be noted that by "a cycle-free path in a language" we actually mean a word in the language that is represented by a cycle-free path in the minimal automaton associated with the language.

A language $W \subseteq \Sigma^*$ is called *a star language* iff $W = V^*$ for some $V \subseteq$ Σ∗. A language L is called *union-free* iff it can be represented by a regular expression that contains the star and concatenation operations only, i.e., it takes the following form:

$$
L = S_{01}^* S_{02}^* \cdots S_{0k_0}^* u_1 S_{11}^* \cdots S_{1k_1}^* u_2 \cdots S_{l-1,1}^* \cdots S_{l-1,k_{l-1}}^* u_l S_{l,1}^* \cdots S_{l,k_l}^*,
$$
 (1)

where S_{ij} are regular languages, u_1, \ldots, u_l are non-empty words, and $l \geqslant 0$. We call (1) *a general form* of a union-free language and denote it $GF(L)$.

Let L be a union-free language. We denote $\text{tw}(L)$ the shortest word in L. Proposition [1](#page-3-1) shows that the definition is correct, i.e., there cannot exist two different words of minimum length.

Definition 1. Let L be a regular language. Then a representation $L = L_1 \cup L_2 \cup$ ···∪L*^k is called* a union-free decomposition *of* L *iff* L*ⁱ is a union-free language for all* $i = 1, \ldots, k$ *. The decomposition is called minimal iff there is no other union-free decomposition of* L *with fewer elements.*

Theorem 1 (K. Hashiguchi [\[9\]](#page-9-2)). *Let* L *be a regular language,* $T \subseteq \{ \cdot, \cup, \cdot \}$ *be a subset of the rational language operations (concatenation, union, and star),* and $M = \{M_1, \ldots, M_n\}$ be a finite set of regular languages. Then it is decid*able whether* L *can be constructed from elements of* M *using a finite number of operations from* T *.*

As an immediate corollary we obtain that it is decidable whether a regular language L is union-free, by taking singleton languages as M and $T = \{ \cdot, \cdot \}$.

Let B be a subset of the set of states Q of the automaton $V = \langle \Sigma, Q, q_0, F, \varphi \rangle$. The set of words $\{x \in \Sigma^* \mid \forall q \in B, \varphi(q, x) \in B\}$ is denoted str (B) .

Lemma 1 (J.A. Brzozowski, R. Cohen [\[2\]](#page-8-1)). *Let* $B \subseteq Q$. *Then* str(B) *is a regular star language.*

3 Union-Free Languages

In this section some common properties of union-free languages are studied. In particular, we present an algorithm for checking whether a regular language is union-free.

First, we adduce an example of a union-free language. Its associated finite automaton is shown in Fig. [1\(a\).](#page-3-2) We believe that it is not a simple task to recognize a union-free language by looking at the automaton. For example, the well-known Kleene algorithm constructs a regular expression that contains three union operations on the top level. The language can be represented as $M =$ $S_1^* b S_2^* a S_3^*$ where S_1, S_2 , and S_3 are shown in Fig. [1\(b\),](#page-3-3)[1\(c\),](#page-3-4) and [1\(d\),](#page-3-5) respectively (the initial states of these automata are marked by 1).

In this section we assume that $\Sigma = \{a_1, \ldots, a_n\}$ is a finite alphabet, $L \subseteq \Sigma^*$ is a regular language and $V = \langle \Sigma, Q, q_0, F, \varphi \rangle$ is its associated deterministic finite automaton.

Proposition 1. *Let* L *be a union-free language. Then* tsw(L) *is meaningfully defined, i.e., if* u and v are shortest words in L then $u = v$.

Proof. Suppose $u = u_1 \cdots u_l$, $v = v_1 \cdots v_l$. Consider $GF(L)$. It should have the following form:

$$
L = S_{01}^* S_{02}^* \cdots S_{0k_0}^* u_1 S_{11}^* \cdots S_{1k_1}^* u_2 \cdots S_{l-1,1}^* \cdots S_{l-1,k_{l-1}}^* u_l S_{l,1}^* \cdots S_{l,k_l}^*
$$

.

Since $v \in L$ and length of v is equal to that of u, $v_i = u_i$ for $i = 1, \ldots, l$, hence $u = v$. \Box

Fig. 1. Example of the union-free language $M = S_1^* b S_2^* a S_3^*$

Remark 1. Obviously, the word $u_1 \cdots u_l$ in the general form of a union-free language L is equal to $t \text{sw}(L)$.

Definition 2. *Let* $2^Q = \{B_1, ..., B_k\}$ *. We denote*

$$
B(L) = {\text{str}(B_1), \ldots, \text{str}(B_k)}.
$$

By Lemma [1,](#page-2-3) $B(L)$ is the finite set of regular star languages that can be constructed for every regular language. We now show that for every representation of a subset of L as a product of a prefix language, a star language and a suffix language the star language can be replaced with a language from $B(L)$. Thus we can extend every subset of L by replacing all star languages within it with star languages from the fixed set $B(L)$.

Lemma 2. Let $M \subseteq L$. Then for every representation $M = PR^*T$ there exists *a language* $D \in B(L)$ *so that* $M \subseteq PDT \subseteq L$.

Proof. First it should be noted that we do not consider the automaton associated with M and work only within the automaton for L .

Given a representation $M = PR^*T$ we define

$$
G = \{ q \in Q \mid \exists w \in P, \varphi(q_0, w) = q \}.
$$

Then we denote $\widehat{G} = \{q \in Q \mid \exists w \in P, \varphi(q_0, w) = q\}.$
Then we denote $\widehat{G} = \{q \in Q \mid \forall w \in T \ \varphi(q, w) \in F\}.$ Obviously, $G \subseteq \widehat{G} \subseteq Q.$ Then we denote \hat{G} = We define $D = \text{str}(\hat{G})$ We define $D = str(\widehat{G})$. Taking any words $p \in P$ and $r \in R^*$, we obtain that Then we denote $\widehat{G} = \{q \in Q \mid \forall w \in$
We define $D = \text{str}(\widehat{G})$. Taking any v
 $\varphi(q_0, p) \in G \subseteq \widehat{G}$ and $\varphi(q_0, pr) \in \widehat{G}$ $\varphi(q_0, p) \in G \subseteq \widehat{G}$ and $\varphi(q_0, pr) \in \widehat{G}$, because $\varphi(prt) \in F$ for all $t \in T$. This Then we denote $G = \{q \in Q \mid \forall w \in I \ \ \forall (q, w) \in F \}$. Obviously, $G \subseteq G \subseteq Q$.

We define $D = \text{str}(\widehat{G})$. Taking any words $p \in P$ and $r \in R^*$, we obtain that $\varphi(q_0, p) \in G \subseteq \widehat{G}$ and $\varphi(q_0, pr) \in \widehat{G}$, because $\varphi(prt) \in F$ f $M \subseteq PDT$. $PDT \subseteq L$, because we extend the language R^* to the language D working within the same unmodified automaton for L and therefore cannot obtain a language that contains more words than L does. \Box

Corollary 1. For every representation $L = PR^*T$ there exists a language $D \in$ $B(L)$ *so that* $L = PDT$ *.*

Proof. We consider $M = L$ and apply Lemma [2.](#page-4-0) Then $L \subseteq PDT \subseteq L$ hence $L = PDT$. \Box

Definition 3. *We denote* C(L) *a set of all maximal finite concatenations of languages from* B(L) *and letters such that every concatenation is a subset of* L*. Maximal means that if* C_1, C_2 *are such finite concatenations and* $C_2 \subseteq C_1$ *then we include only the language* C_1 *in* $C(L)$ *.*

Lemma 3. Let $M \subseteq L$, $B_1 \subseteq Q$, $B_2 \subseteq Q$ and $M = P \text{str}(B_1) \text{str}(B_2)T$, where P and T are regular languages. Then $\varphi(q_0, P\, \text{str}(B_1)) \subset \varphi(q_0, P\, \text{str}(B_1)\, \text{str}(B_2))$ *or there exists* $B_3 \subseteq Q$ *such that* $M \subseteq P$ str $(B_3)T \subseteq L$ *.*

Proof. We denote three sets of states: $D_1 = \varphi(q_0, P), D_2 = \varphi(q_0, P \text{str}(B_1)),$ and $D_3 = \varphi(q_0, P \text{str}(B_1) \text{str}(B_2))$. Since $\text{str}(B_1)$ and $\text{str}(B_2)$ contain the empty word, $D_1 \subseteq D_2 \subseteq D_3$. We also obtain that $str(B_1) \subseteq str(D_2)$, because the set $\varphi(q_0, P \operatorname{str}(B_1) \operatorname{str}(B_1)) = \varphi(q_0, P \operatorname{str}(B_1)) = D_2$. Suppose $D_2 = D_3$. This means that $str(B_2) \subseteq str(D_2)$. Therefore, $str(B_1) str(B_2) \subseteq str(D_2)$ and $M =$ $P \text{str}(B_1) \text{str}(B_2) T \subseteq P \text{str}(D_2) T$. Finally, we take $B_3 = D_2$. $P \text{str}(B_3) T \subseteq L$ because we have not modified the automaton for L and still work within it. \Box

Lemma 4. $C(L)$ *is a finite set.*

Proof. Every element in $C(L)$ is a concatenation of star languages and letters. As already mentioned, all the letters concatenated form the shortest word in the language represented by the concatenation. First we limit the number of letters in every concatenation by $|Q| - 1$. We do that as follows: if a concatenation $L_i \in C(L)$ contains more than $|Q| - 1$ letters, we show that there is a language $M_i \in C(L)$ such that $L_i \subseteq M_i$, and we come to a contradiction with the definition of $C(L)$. We show how to effectively construct the language M_i given the language L_i . Suppose $L_i \in C(L)$ and its general form contains more than $|Q| - 1$ letters. This means that $tsw(L_i)$ contains cycles in the automaton for L. Then $tsw(L_i) = u_1v_1 \cdots u_hv_h$, where $u_j \in \Sigma^*$, $v_j \in \Sigma^+$ and every $v_j = v_{j_1} \cdots v_{j_{l_i}}$ $(j = 1, \ldots, h)$ represents a cycle in the path $u_1v_1 \cdots u_hv_h$ in the minimal automaton for L (and every u_j does not contain any cycles). This means that $L_i = L_{u_1} L_{v_1} \cdots L_{u_h} L_{v_h}$ where languages L_{u_i} and L_{v_i} are parts of the general form of L_i corresponding to the words u_j, v_j , respectively. For example, $L_{v_1} = v_{11}S_{p1} \cdots S_{pk_p} v_{12}S_{p+1,1} \cdots S_{p+1,k_{p+1}} v_{13} \cdots v_{1l_1}$. Then we define the language M_i as $M_i = L_{u_1}(L_{v_1})^* \cdots L_{u_h}(L_{v_h})^*$. First, $L_i \subset M_i$. Second, $tsw(M_i) = u_1 \cdots u_h$ and $u_1 \cdots u_h$ represents a cycle-free path in L. Third, $M_i \subseteq L$, because it has been constructed within the automaton for L. This means that $L_i \subset M_i \subseteq L$ and we come to a contradiction, since $C(L)$ contains only maximal languages.

Now we prove that there is only a limited number of star languages between every pair of adjacent letters in every concatenation $M \in C(L)$. For every representation $M = P \text{str}(B_1) \cdots \text{str}(B_k)T$ we apply Lemma [3](#page-4-1) and obtain that either $\varphi(q_0, P \text{str}(B_1)) \subset \varphi(q_0, P \text{str}(B_2)) \subset \ldots \subset \varphi(q_0, P \text{str}(B_k))$ or we can replace the language M with the language M' such that $M \subseteq M'$ and $M' = P \text{str}(D_1) \cdots \text{str}(D_l)$ and

$$
\varphi(q_0, P\operatorname{str}(D_1)) \subset \varphi(q_0, P\operatorname{str}(D_2)) \subset \ldots \subset \varphi(q_0, P\operatorname{str}(D_l)).
$$

In this case $M \notin C(L)$. We conclude that every element in $C(L)$ can be written as a concatenation with not more than $|Q|-1$ star languages between every pair of adjacent letters. These two limitations complete the proof. \Box

Corollary 2. *Let* $M \in C(L)$ *. Then* tsw(M) *represents a cycle-free path in the automaton associated with* L*.*

Proof. Since $M \subseteq L$, tsw $(M) \in L$. Suppose tsw (M) contains cycles in the automaton associated with L. Then applying the procedure described in the proof of Lemma [4](#page-5-0) (which constructs the language M_i using the language L_i), we obtain a language $M' \in C(L)$ such that $M \subset M'$. This means that $M \notin C(L)$ and we get a contradiction. \Box **Corollary 3.** $|C(L)| \le c|Q| (2^{|Q|})^{|Q|-1}$, where c is the number of cycle-free *paths in the automaton associated with* L*.*

Proof. First, we fix a cycle-free path in the automaton associated with L (c) possibilities). Then we fix a position of star languages: since there are not more than $|Q| - 1$ letters, we have $|Q|$ possibilities (because star languages can appear before the first letter and after the last one). Then we choose not more than $|Q|$ −1 languages from $B(L)$ (every language can appear more than once), having $(2^{|Q|})^{|Q|-1}$ possibilities. Finally, we multiply all three expressions and come to the statement of the corollary. \Box

Remark 2. In order to construct $C(L)$ given a language L, we simply take all possible concatenations that contain letters that being concatenated form cycle-free paths in the automaton for L and that contain not more than $|Q| - 1$ languages from $B(L)$ between every pair of letters. Finally, we exclude the languages that are not subsets of L and the languages that are subsets of other languages from the set.

Lemma 5. *Let* L *be a regular language and* $M \subseteq L$ *be a union-free language. Then there exists a language* $C_M \in C(L)$ *such that* $M \subseteq C_M$ *.*

Proof. We take every star language $S^*_{i,j}$ from the general form of M. Thus $M =$ $PS^*_{i,j}T$ where

$$
P = S_{01}^* \cdots S_{0k_0}^* a_1 \cdots S_{i1}^* \cdots S_{i,j-1}^*
$$

and $T = S^*_{i,j+1} \cdots S_{i,k_i} a_{i+1} \cdots a_l S^*_{l,1} S^*_{l,2} \cdots S^*_{l,k_l}$. Then we apply Lemma [2](#page-4-0) and derive that $M \subseteq P$ str $(B_k)T$ where $B_k \in B(L)$. Thus we extended the "unknown" language $S_{i,j}^*$ to the known language $str(B_k)$ from the set $B(L)$. After applying the procedure of extension to each star language in the general form for M, we get a language C_M that is a finite concatenation of languages from $B(L)$ and letters and also an extension of M. Hence $M \subseteq C_M$ and $C_M \in C(L)$. \Box

Theorem 2. *Let* L *be a regular language. Then* L *is a union-free language iff* $L \in C(L)$.

Proof

Necessity. We consider $M = L$ and apply Lemma [5.](#page-6-1) Then there exists a language $C_L \in C(L)$ such that $L \subseteq C_L$. But since all languages from $C(L)$ are subsets of L, $L = C_L$ and hence $L \in C(L)$.

Sufficiency. Suppose $L \in C(L)$ and L is a non-union-free language. Then it cannot be represented as a finite concatenation from $C(L)$ because every concatenation from $C(L)$ only consists of union-free languages (languages from $B(L)$) and letters), and we come to a contradiction. \Box

4 Union-Free Decomposition

Theorem 3. *Let* L *be a regular language. Then there exists an algorithm that results in a minimal union-free decomposition of* $L: L = L_1 \cup L_2 \cup \cdots \cup L_k$ *(the algorithm is described within the proof).*

Proof. To construct a minimal union-free decomposition, we examine all the subsets of $C(L)$ and choose the subset containing a minimum number of languages (among all the subsets) which being added up are equal to L. It should be noted that there is at least one subset containing languages which being added up are equal to L , because there exists at least one union-free decomposition of L and to every component of the decomposition we can apply Lemma [5,](#page-6-1) thus obtaining a decomposition of L into languages from $C(L)$. The final step is to prove that the decomposition obtained is minimal, i.e., there exists no decomposition containing fewer elements than the one we got. Suppose we have such a decomposition $L = N_1 \cup N_2 \cup \cdots \cup N_p$, $p < k$. We take each language N_i $(i = 1, \ldots, p)$ and apply Lemma [5](#page-6-1) to it, getting a union-free language $C_{N_i} \in C(L)$ such that $N_i \subseteq C_{N_i}$. Thus we get the new decomposition $L = C_{N_1} \cup C_{N_2} \cup \cdots \cup C_{N_p}$, $p < k$ and every language C_{N_i} belongs to the set $C(L)$. But since we have already examined all the subsets of $C(L)$, we have examined the subset $\{C_{N_1}, \ldots, C_{N_p}\}$ too, and we must have chosen this subset for the minimal decomposition. This contradiction completes the proof. \Box

Unfortunately, the algorithm for constructing a minimal union-free decomposition of a given regular language L is computationally expensive since it requires checking all the subsets of the set $C(L)$, which can contain up to $c|Q| (2^{|Q|})^{|Q|-1}$ elements, where c is the number of cycle-free paths in the automaton associated with L (see Corollary [3\)](#page-6-2). We believe that there exist more effective algorithms that result in a minimal union-free decomposition of a given regular language. Some ideas on creating such an algorithm are given below.

A promising way of constructing minimal union-free decompositions can be developed using the technique of cutting maximum star languages introduced in [\[2\]](#page-8-1). In short, the technique is as follows. Let L be a regular language. The equation $L = X^*L$ is proved to have the unique maximal solution X_0 (w.r.t. inclusion). Moreover, the equation $L = X_0^* Y$ is proved to have the unique minimal solution Y_0 . To construct a minimal union-free decomposition of L we solve these two equations and obtain the language Y_0 . Then we apply the same procedure to the language Y_0 and get the minimal language Y_1 such that $L = X_0^* X_1^* Y_1$. If the process ends (and it is an open problem, see [\[10\]](#page-9-3)) we either obtain the language $Y_m = \{\varepsilon\}$ (and thus the union-free decomposition $L = X_0^* X_1^* \cdots X_m^*$) or get a language Y_m such that the equation $Y_m = X^*Y_m$ has no non-trivial solutions. In the latter case we check whether all the words in the language Y_m start with the same letter. If it is the case and, for example, all the words in Y_m start with a, we write $Y_m = aY'_m$, $L = X_0^* X_1^* \cdots X_m^* aY'_m$ and apply the procedure described above to the language Y'_m (solve the equation $Y'_m = X^* Y'_m$ etc.). If it is not, and there are words in Y_m that start with different letters, e.g. a_1, \ldots, a_n , we can write $Y_m = Y_{m_1} \cup \cdots \cup Y_{m_n}$ so that every language Y_{m_1}, \ldots, Y_{m_n} contains only words starting with the same letter a_i , $1 \leqslant i \leqslant n$. Then we write $L = X_0^* X_1^* \cdots X_m^* Y_{m_1} \cup X_0^* X_1^* \cdots X_m^* Y_{m_2} \cup \cdots \cup X_0^* X_1^* \cdots X_m^* Y_{m_n}$ and apply the procedure described above to every language Y_{m_1}, \ldots, Y_{m_n} . If the process ends, thus we obtain the union-free decomposition of the language L , which is likely to be minimal, but this is yet to be proved. As already mentioned, another open problem connected with this technique is that the described process of "cutting stars" has not yet been proved to always be finite (see [\[10\]](#page-9-3)).

5 Conclusions and Further Work

In this paper we have presented an algorithm for constructing a minimal unionfree decomposition of a regular language. The algorithm includes an exhaustive search but we tend to think that there exist more effective algorithms that solve the problem.

We have also studied some common properties of union-free languages. In particular, we have presented the new algorithm for checking whether a given language is union-free which can be more effective than the one existing in the field (see $[9, 7]$ $[9, 7]$).

There are some other interesting questions connected with the problems considered. For instance, whether languages that form a minimal union-free decomposition are pairwise disjoint (as sets of words). If it is not always the case, one can consider minimal union-free decompositions that consist of pairwise disjoint languages and ways of constructing them.

Another open problem is connected with star height. Given a star height of a regular language is it possible to construct a minimal union-free decomposition that consists of languages of the same star height?

Acknowledgements. The authors would like to thank the anonymous reviewers for valuable comments. The first author would also like to thank Benedek Nagy for drawing attention to the problem.
