These issues do not result in intractable problems. In the case of new technologies and techniques that are solely harmful, it is unlikely that they will be developed by governments or by companies as enhancements.[4] Either governments will prohibit the use of harmful enhancements or market forces will ensure that harmful enhancements will not be worth developing as people will not wish to purchase them. In the case of harmful-but-pleasurable enhancements or harmful-but-useful enhancements that have both beneficial and negative effects, regulation will be required. It is possible that a class of harmful enhancement technologies would be illegally developed and that problems of addiction similar to contemporary drug problems would arise. Various mood enhancements might develop in this

[4]These techniques are quite likely to be used in the development of weapons, but this is another matter.

problematic way. Yet the prospect of such developments does not create a fatal problem for HET as a whole. The potential for direct harms to individuals makes the case for regulation of the development of HET, not the abandonment of their development.

Loss of Openness to the Unbidden

That argument that HETs are illustrative of human hubris is intriguing. Sandel claims that in developing HET, humanity adopts a stance of mastery and dominion that fails to appreciate the gifted nature of human powers and achievements. The result of this is that enhanced humans no longer access the part of freedom that consists in a persisting negotiation with the given. Firstly, it is essential to ask whether HET would mean humanity was no longer open to the unbidden. Although people might be enhanced, they would still confront many aspects of the world beyond their control from traffic, to other animals, to the movements of the weather. Secondly, it is not clear that not being open to the unbidden, if true, is in fact as morally problematic as Sandel implies. Thirdly, even if it is the case that the stance of mastery and dominion and the loss of openness to the unbidden have undesirable social and moral consequences, it is an open question as to whether these moral problems are outweighed by the moral (and practical) benefits of the adoption of HET. It is at this point that Sandel's approach is most intriguing, as it questions the moral and political framework used to respond to deep issues such as HET. Sandel argues that in order to think about developments such as HET, a moral framework based around individual rights, autonomy, and fairness does not equip contemporary society to address questions about the moral status of nature and about the proper stance of humans towards the given world. The question of the correct moral and political stance to adopt in relation to the world and to HET is an open question, though Sandel is surely correct in pointing out that the debate currently is dominated by a liberal framework. Ultimately, while he has not illustrated that this is necessarily a fatal flaw, he has at least opened out the debate to include issues such as the correct moral stance of humanity to the unbidden and to nature, and whether HET reduces the freedom of humanity to reflect critically on these issues. At the very least, he is persuasive in that further critical reflection on these issues is required.

Review of the Case for Enhancement

Rights

That people should be permitted to improve their lives and their health appears to be a basic right. Given the likelihood of HET being introduced incrementally, it would be very difficult to find a compelling argument to deny people the right to use many of these enhancements. Realistically, a moratorium on the use and development of HET as a whole is not an option due to the widespread use of certain enhancement techniques, such as cosmetic surgery. As such, there exists a presumptive case that

people have rights to use technologies and techniques so long as they do not harm other people. The UNESCO Declaration commits nations to respecting human rights and fundamental freedoms.

That people have rights to use some enhancements does not mean that people have rights to use all enhancements. The extent of these rights is yet to be determined. HET will come in a variety of forms, our rights to use them are not necessarily total – the rights we enjoy now suggest that we ought to be able to benefit from some enhancements though other enhancements may be beyond the limits of these rights. Currently, cosmetic enhancements are permitted, but the use of certain drugs (cocaine, heroin) as mood enhancers is prohibited.

A libertarian view would accept only minimal limitations on rights to use HET. This view, stemming from the Enlightenment tradition of negative liberty, is common amongst advocates. Proponents argue that the right to use enhancement technologies is an extension of our right to reproductive freedom, cognitive liberty, and bodily autonomy. However, it is unclear whether these rights extend to include rights to use HET, despite the assertions of proponents. This outlook would have distributive consequences as rights may trump considerations of distributive justice. A libertarian perspective on justice would argue that if HETs are developed privately and are bought by people using their own (legally and justly acquired) resources, any interventions stopping this are unjustified. This libertarian perspective finds some justification in Article 3 of the Universal Declaration on Bioethics and Human Rights – emphasizing the importance of respecting human dignity, human rights, and fundamental freedoms – but may conflict somewhat with the aims of Article 15 (concerning the sharing of benefits) if libertarian principles of property prevent the sharing of benefits. Libertarians can be expected to favor the benefits of HET being distributed via the free market, which is likely to exclude many. This latter highlights the need to share the benefits resulting from scientific research and its applications. Moreover, the justness of the starting point (of those with access to enhancements) can be questioned.

However, some limitations are likely to be acceptable to libertarians. Reproductive rights, for instance, are likely to be limited by considerations of harm to the child. Certainly, any putative right to genetically alter a future human will most likely be limited by considerations of harm. Nor is it clear that reproductive freedom necessarily includes the right to use novel technologies. These prospective rights to certain HET may be limited by considerations of the effect the institutionalization of such practices will have on the society. People may be limited in how they are permitted to use HET on their own embryos. For instance, sex-selection of embryos is not currently permitted.

As mentioned, however, a broader conception of harms may be considered. The concept of harm need not only concern direct and measurable harms to identifiable individuals. We are now aware, as noted above, of the ways in which our actions might cause indirect harms to other people, by participating in inequitable trade or by negatively affecting the environments necessary for people's subsistence. These harms are not direct in the sense of one person directly harming people

(i.e., by shooting them) but contribute to an overall effect that may be harmful. Global inequality is one such harm (climate change another) in that although individuals in the developed world are not individually and directly causing poverty in the developing world, the global economic and political system in which they partake produces harmful effects. The use of HET by some people will place those without at a relative disadvantage, thus harming them. If these harms are distributed across populations as a result of inequitable historical and political processes, then the harms caused by HET might be considered unjust.

Related to this argument is a concern with human dignity and with positive rights. From the perspective of social justice, a right is not secured unless effective measures are taken to ensure that people are capable of using this right. At times, securing a right of human dignity will require affirmative institutional and material support. For instance, female children might have a right to education, but due to social conditions and historical traditions, they may never receive an education. The development of HET may leave the unenhanced incapable of enjoying rights – for instance, they may find themselves incapable of civil and political participation if these activities require enhancements. Unchosen exclusion from the life of their society would risk undermining the dignity of unenhanced individuals. This suggests that either there is an obligation to ensure that everyone has access to similar HET in order that they can live a life of human dignity or enjoy basic rights, or that the rights to use HET must be limited in situations where their use will undermine the fundamental rights of the unenhanced.

Thus, there are three outstanding problems regarding the rights argument in favor of HET. (1) It is unclear that current rights to reproductive freedom, cognitive liberty, and bodily autonomy extend to HET. (2) If it is acceptable to limit rights due to harms, there is an obligation to consider the indirect yet foreseeable harms that might result from the development of HET under current economic conditions. (3) A positive interpretation of rights might place obligations on states to ensure that all have a relatively equal access to HET when they are required for political and social participation. As noted, the unrestrained societal use of HET may pose threats to the possibility of a life with dignity of those who cannot afford to obtain enhancements or alternatively threats to the rights of those who wish to remain unenhanced.

Improvement and Beneficence

The consequentialist argument in favor of HET is less compelling. However, adopting this approach may have more far-reaching implications than initially considered by Harris and Savulescu. For instance, if there is a moral obligation to ensure that a child has the best possible life, societal biases ought to be taken into account by the parents, i.e., that the child should not be homosexual or have a skin color that a society is biased against. Furthermore, if there is an obligation to have the best possible child that they can have, there may be an obligation to use an embryo created by some other couple, if it is likely to result in a better person.

Moreover, it is not certain that we do have an obligation to be the best we can possibly be, nor is it certain that we are obligated to create the best possible future

people. Firstly, it is not clear what is meant by "best." Enhancements that provide immunities are relatively uncontroversial, but whether there is an obligation to ensure that children have specific skills and talents is debatable. There is no way of knowing whether the skills and talents chosen will count as genuine improvements. An enhancement that improves mathematical ability may be rendered obsolete by advances in computer technologies.

The assumption of an obligation to enhance also results in a number of disquieting implications, as discussed by Sparrow (2011). The obligation to enhance is based on our obligation to be concerned with the welfare (or improvement in general) of future generations. However, upon examination, the consequences of this approach are more far reaching than is immediately apparent. The suggestion is that people should be concerned with acting to promote happiness or welfare in the world and that insofar as enhancements can achieve this, there exists an obligation to pursue them. The most obvious way to guarantee this would be to use HET to manipulate the brain chemistry of everyone so that they all feel happy. There are less fanciful but more disturbing implications too. This obligation would mean that parents in a racist society would have the obligation to ensure their prospective children will fit in to that society, or that in a society in which males are treated better, there exists an obligation to ensure that a child is male. The obligation to enhance in order to increase the well-being of a child might result in a collective-action problem (Singer, 2009), where parents are obliged to ensure that their children are taller, or blonde, or have some other relatively trivial trait that improves their chances of success in life even if this creates problems for the society. Over generations, these individually rational decisions risk producing new problems, i.e., taller people might require more resources, or may have novel health problems, societies might become increasingly homogenous, and research funding might flow disproportionately to profitable but trivial projects. Nor does the line need to be drawn at aesthetic enhancements. It may be beneficial (and hence obligatory according to this reasoning) to ensure that children are patriotic, fearless, or uncurious. The desire of parents to ensure that their children thrive in their society may stymie change within a society if the children are designed to thrive in and respect the norms of the culture of their parents rather than question it. Such a society is likely to stagnate. In certain cases, it might be in the best interests of the child to ensure through pharmaceutical means that they are contented, despite living in wretched conditions. Would a parent be obliged to put their child in Nozick's "experience machine"[5] if their chances of success in life were low enough?

[5]The Experience Machine is a machine in Nozick's thought experiment that would give you any experience you desired. During the time in the machine, the person would have no memory of their previous life or of the external world. They would believe that the experiences they have in the machine are real. The purpose of the thought experiment is, supposedly, to provoke a realization of the importance of something more than just experience – of actually living and of authentic experience. (Nozick, 1974: 42–45)

Indeed this line of reasoning has the result that parents may be obliged to select the best embryo available, even if it is not carrying their own genes but of some other couple's. The consequentialist argument can be taken further to the point that prospective parents ought to be coerced (through direct or indirect means) into ensuring that their children receive enhancements. The existence of unenhanced future people will, as noted above, potentially impose costs on the rest of society. If these costs are high enough, then coercion may be considered justified. Furthermore, if there is soft coercion (due to advertising campaigns, etc.) to obtain enhancements, direct coercion becomes more plausible.

Therefore, the case for there being an obligation to enhance is far from clear. The consequentialist argument runs up against the rights of people to choose not to use enhancements. The obligation to enhance to ensure a child's welfare risks a collective-action problem, in which enhancements could lead to the pursuit of relatively unimportant positional goods that ultimately impose costs on the society as a whole. On top of this, there is a risk of stagnation of the moral and societal development, as the values of the current generation become embedded in the next generation, who would presumably wish (due to their design) to further continue the aesthetic and political trends of their forebears. Finally, there is the disquieting logical conclusion of the argument – that all people would be obliged to use the best embryo available regardless of its provenance.

Moral Enhancement

The concept of moral enhancement is an intriguing development in the discussion of HET. Intuitively, it is appealing. Firstly, we accept that our moral behavior has a biological basis. Our moral intuitions have developed over millions of years of our evolution from our ape-like ancestors to our present state. Yet, there are clearly serious moral issues that we appear incapable of adequately addressing, such as entrenched inequalities and the environmental crisis. These problems are global in scale and have a time-scale of many generations. As such, these problems do not seem to be issues that our evolutionary moral sense is designed to deal with. It is most likely that we have evolved to care for ourselves, close family members, and broader kinsfolk – for those of our genetic heritage. While our political development has meant that the moral circle has expanded, it is not certain that our political institutions are adequate for dealing with the pressing moral issues of global inequality, resource scarcity, and environmental degradation, particularly if we have to take into account the requirements of future generations. Moreover, if we accept that our moral inclinations are the product of evolution, then this lack of concern with distant peoples, future generations, and non human issues is unsurprising. There would have been little evolutionary reason in our history and prehistory for such a broad moral sense (concern with future generations, and distant peoples) to have developed.

If our morality does have a biological basis and we have the technological means and techniques of enhancing it, the initial appeal of the perspective of moral enhancement is obvious. Moral enhancement may result in people who are less greedy, less aggressive, more concerned with addressing global poverty, and more

interested in ameliorating the effects of climate change. The idea that politicians, policy makers, and the judiciary receive moral enhancements is an appealing one. If brain-computer interfaces, pills, or genetic alterations were available to ensure that those in power behaved ethically, they would obviously be of enormous benefit. The benefits to the species over the long term would be enormous if it were possible to ensure that future generations had greater empathy towards each other and towards the natural world.

The environmental crisis can be considered as both a tragedy of the commons and a prisoner's dilemma. A tragedy of the commons describes a scenario in which a common resource (in this case, the biosphere) can be used freely by everyone. Each user, in pursuing their own interests, fails to consider how their actions affect others. Ultimately, the commons becomes depleted and all suffer. However, the gains from exploiting the environment are available immediately, while the costs will be borne by future generations. Moreover, even if nations were to attempt to find some sort of solution to the problem of the commons, they find themselves in a prisoner's dilemma. All parties know that action must be taken to ameliorate the effects of climate change. If the USA (for example), agrees to cut emissions, it loses out competitively to China (for example), and vice versa. The solution to the prisoner's dilemma is, as is well known, cooperation. There are two solutions to the tragedy of the commons – one is to privatize the commons, while the other involves managing the commons and restricting its use. Privatization is not practicable for the biosphere, and, would, in any case have problematic distributive implications. In any case, either solution requires cooperation and long-term planning.

Exhortations to reduce our carbon footprint have not had any significant impact in terms of reducing our harmful impact on the environment. Moral enhancements might theoretically offer a surer method of changing peoples' ways of life. If we take seriously the aims of creating a basically equitable global system and building a political and economic system that is environmentally sustainable, moral enhancements may be a necessity.[6]

Enhancements that make us more willing to cooperate, less willing to betray others, and less materialistic might have to be considered if the biosphere is to be protected, inequalities diminished, and the interests of future generations provided for. If we as a species wish to preserve what is left of the planet's biodiversity, and maintain a climate we find comfortable, moral enhancement might perhaps provide a solution where philosophy, politics, and religion have so far failed. There are, however, a number of difficulties with moral enhancements.

First there is the problem of the indistinctness of moral enhancement. It is not clear what would count as a moral enhancement. There is of course great disagreement over what constitutes a good life or whether such a thing exists. Even within

[6]Persson and Savulescu (2008) argue that due to the perils posed by cognitive enhancement in the shape of our increased ability to do harm, we should not undertake cognitive enhancements without also undertaking moral enhancements.

a single generation, different societies possess quite different versions of the good. The values of Wall Street are very different from the values of a Buddhist monastery. Furthermore, it is not clear which virtues or vices should be enhanced or diminished. Aggression would surely be the appropriate response to witnessing a rape. John Harris (2010) has suggested that the traits that lead to wickedness or immorality are the same traits that are required for the existence of any sort of moral life. Thus, weakening negative traits, such as racism or a propensity to violence, might also weaken positive traits such as kinship ties and drive.

A second problem concerns the obstruction of long-term moral progress. There would be a significant risk that the values of the first generation to adopt moral enhancements would become entrenched in a society and moral progress would become impossible. Many of our current moral values may well appear to be barbaric to future generations just as we view the gladiatorial fights and slavery of Roman antiquity as anathema.

Moreover, there must be doubts about the incentives to take moral enhancements. Assuming that there was agreement on what constituted a moral enhancement, it is not clear why people would want to take or undergo them. The societies that would most benefit from widespread use of moral enhancements are most likely made up of people who will not be amenable to using them. In these societies, strong inclinations to act morally might leave a person vulnerable to being taken advantage of by those lacking that same moral drive. Many parents might not want to enhance children and might consider giving their children moral enhancements to be putting them at a disadvantage in a world in which deceit, self-interest, and greed predominate. Politically, such enhancements might leave policy makers and negotiators at a significant disadvantage. Any individual state could legislate that all people entering public office would be required to make use of moral enhancements, but these politicians would be at a disadvantage in international affairs unless their rivals were also using moral enhancements.

This could be offset by nations requiring that all citizens or all future citizens receive moral enhancements. Requiring that all citizens receive moral enhancements would most likely be seen as a violation of the autonomy of individuals. This would be less of a risk in relation to unborn future generations, who do not yet possess autonomy. The people that would exist after a decision to enhance was made would be entirely different people to the people who would exist after a decision not to enhance was made. Nonetheless, this scenario is still disquieting: It risks turning into an Orwellian nightmare in the hands of oppressive regimes or regimes with a perverted sense of morality (what counts as perverted, of course, depends on one's moral perspective). Once more, however, it is difficult to envisage why a nation would wish to morally enhance its entire populace – nations seem to require a certain measure of aggression in their soldiers, suspicion in their police forces (at least some of the time), and (unofficially at least) deceit in their leaders.

Thus, moral enhancement is both unsettling and appealing. The idea of being designed or pharmaceutically manipulated into doing the right thing is unpleasant. The idea of ensuring that the species as a whole was less aggressive and greedy is

very appealing. Yet, three problems of moral enhancement make its development unlikely. Firstly, there will be disagreements over what counts as a moral enhancements. Secondly, it is hard to see why people would choose to use moral enhancements. Thirdly, the practical difficulties, such as locating and altering neurophysiological processes that promote moral behavior, developing techniques to alter these processes safely, agreeing upon moral ends to promote, and persuading people to use these enhancements, mean that moral enhancements appear to be a very distant prospect.

Conclusion

Proponents of HET envision a world in which people are cleverer, more beautiful, and live longer. Opponents of HET raise significant issues regarding the emergence of greater inequalities as a result of enhancement technologies. We examined arguments for and against HET.

We argued that the threats posed by HET of exacerbating both national and international inequalities are compelling and must be addressed. Furthermore, the threats of direct harms to future generations arising from HET are small and can be dealt with via regulation and oversight. However, the indirect harms to future generations likely to emerge from exacerbated inequalities are more serious and need to be addressed at a global scale. Nonetheless, these threats did not lead us to call for a moratorium on the development of HET, as it is neither realistic nor desirable.

A negative conception of rights (entitlements to non-interference) suggests that limiting non-harmful HET is a breach of our right to improve ourselves. That we have certain rights to improve ourselves seems clear, although the suggested obligation to use enhancements is not persuasive. That our rights should be extended to *some* HET is difficult to dispute, but does not suggest that all forms of enhancement should be permitted. The extent of these rights should be considered in relation to the grave issues of inequality that beset the world. Furthermore, a more positive conception of rights, which would only consider rights as secured when people have the relevant capabilities to use them, also has implications for the development of HET. Over the past number of decades, research has shown that inequalities produce real societal harms. We are now aware that some practices (such as unfair trade agreements, or the production of pollution) or inequitable social arrangements cause real but indirect harms to people. In some cases, these harms prevent people from functioning normally (in a way characteristic of human life), as these harms might include mental distress, starvation, and death. Thus, in order to guarantee a person's rights, it is (arguably) not sufficient to merely not interfere with their pursuit of their autonomously chosen goals, but it is necessary to actively ensure that people are capable, at a minimal level, of pursuing their goals. This interpretation is not uncontroversial – libertarians would fiercely resist it. Furthermore, this understanding of rights has not been dominant (though not entirely absent) in political and economic life over the past two centuries.

Nonetheless, the evidence of real harm occurring as a result of indirect actions must be taken into account.

Concern with future generations is an even greater challenge to the dominant forms of liberal political philosophy and is the subject of much debate. Nonetheless, given that we are aware of the existence of indirect harms, and that we know that future people will be affected by our actions, including how we develop and use HET, it behooves us to consider the effects of our actions on them. This positive conception of rights, along with the argument from indirect harms, and concern for future generations, suggests that there is an obligation to ensure that HET does not exclude anyone from social or political processes.

Finally, we looked at moral enhancements. Proponents claim that moral enhancement could enable future generations to overcome problems resulting from our evolution as an ape species. Our limited rationality, limited sympathy, distrust, and greed must, in the environmental context, be seen as disabilities. They endanger not only other species, but also the environmental foundations of all modern societies. Just as propensities to heart disease, cancers, and dementia are held by those in favor of enhancement to be avoidable ills, the tendency of humans as a species to primarily care about those genetically close to us or who are members of our tribe, to use the natural environment beyond sustainable limits, to compete with each other for positional goods (and thus waste limited resources), and to fail to make long-term (multi-generational) plans can be seen as avoidable ills. Although moral enhancements carry much appeal, unfortunately, they cannot be viewed as a panacea. Their development is speculative, and while it should be pursued, moral enhancements are unlikely to be available early enough to help us confront the urgent moral issues raised both by current inequalities and by the development of HET themselves.

The development of HET has the potential to radically improve the lives of current and future generations. However, while many parts of the world suffer from the effects of environmental degradation, extreme poverty, and lack of food and water, the development of HET appears something of a luxury. The development of HET also risks entrenching existing and harmful inequalities, with negative consequences for future generations. Therefore, although the further pursuit of HET is recommended, it is necessary that this research takes into account and is shaped by an awareness of the harms caused by inequalities, and the risks that both HET and inequalities pose for future generations. Unregulated development of HET is not fit for this purpose. In short, it would be wise to heed Sandel's suggestion and critically reflect on our stance towards nature and towards the social institutions of solidarity as they currently are and as they might be improved or worsened by technological developments such as HET. Exclusive reliance on individual nations to regulate their own development of HET will most likely not adequately address issues of global inequality. Therefore, it is necessary to create a global regulatory system for the development of HET. The UNESCO Universal Declaration on Bioethics and Human Rights, signed by 193 nations, is the first step towards such a global regulatory system.

Fair Trade

39

Nicole Hassoun

Introduction

Historically, Fair Trade proposals have tried to improve the terms of trade to reduce poverty and protect the environment. What does this have to do with bioethics? Perhaps the most obvious answer is that those who are concerned about global health have reason to care about poverty and environmental quality and Fair Trade is one way of ameliorating poverty and protecting the environment. Poverty is probably the biggest public health problem, and both environmental quality and trade have a large impact on the poor. Poor people often lack adequate food, water, shelter, education, and the emotional and social resources necessary for avoiding debilitating illness (Center for Disease Control and Prevention, 2007; Doyle, 2002; Leathers & Foster, 2004; Red Cross, 2007; Woolcock, 2001; World Health Organization, 2007a). The rules of trade can have a large impact on individuals' ability to secure these things. After introducing Fair Trade certification schemas and considering some of the arguments for and against (different kinds of) trade in the literature, this chapter suggests some avenues for further research into new Fair Trade proposals that focus on health, in particular.

Fair Trade-Certified Goods

Although there are many conceptions of fairness, one way of promoting fair trade in practice is to try to improve the lives of poor producers by purchasing "Fair Trade"-certified products. To receive Fair Trade certification, organizations must pay their laborers a living wage and farmers must receive fair prices (FLO-CERT, 2009). Moreover, Fair Trade-certified goods may have to be made in an environmentally sustainable way in safe working conditions. Fair Trade products should not be

DOI 10.1007/978-94-007-2512-6_138,

made with slave or child labor, and workers must have the right to organize (FLO-CERT, 2009).

Some Fair Trade organizations also try to improve poor people's lives by investing in infrastructure (e.g., roads, schools, or hospitals), reducing the length of supply chains, providing credit and technical assistance, and implementing community development projects (FLO-CERT, 2009; World Fair Trade Organization, 2009). Other Fair Trade organizations focus on creating equitable, sustainable trading relationships, increasing market access, improving the capacity of farmers' cooperatives, and raising consumer awareness (International Fair Trade Association, 2008).

Fair Trade markets are growing (Fairtrade Labeling Organization, 2009). In 2000, European countries sold 27 million pounds, or more than 300 million dollars worth, of Fair Trade coffee, and Fair Trade coffee made up 1.2 % of the European market (EFTA, 2001, cited in Raynolds, (2002)). In the USA, Fair Trade coffee was the fastest growing segment of the coffee market (it grew by 79 % in 2000–2001) (McMahon, 2001, cited in Raynolds (2002)). More generally, sales of Fair Trade-certified goods are growing incredibly quickly and amounted to approximately €2.3 billion by 2007 (FLO-CERT, 2009). Tea, sugar, cocoa, spices, honey, bananas, cotton, fruit, handicrafts, wine, and flowers are only some of the Fair Trade goods available for sale. About 7.5 million poor people benefited from Fair Trade projects by 2008 (FLO-CERT, 2009).

The Moral Status of Fair Trade

Some argue that on both deontological and consequentialist moral theories, there is an obligation to purchase Fair Trade-certified goods. Jos Philips suggests, for instance, that Western consumers cannot reasonably reject a duty to purchase Fair Trade goods on the assumption that Fair Trade benefits, but does not harm, the global poor. Philips believes that poor peoples' basic interests are at stake and Westerners do not have to give up much to support Fair Trade. Moreover, he suggests, even if Western consumers have to give up a few luxury goods, this is justifiable, for, as Thomas Pogge argues at more length, the rich often contribute to the plight of poor people (Philips, 2008; Pogge, 2002). Philips does not think that consequentialists should only be concerned with efficiency. He thinks they should also consider individuals' basic interests. Moreover, he argues that even governments may have an obligation to reduce taxes on Fair Trade-certified goods (Philips, 2008).

Some have given arguments that might provide reason to question the traditional Fair Trade movement's desirability. Consider, for instance, Aaron James' argument for free, as opposed to, fair trade (though James is concerned with philosophical conceptions of fairness in trade and not the Fair Trade movement, in particular). James asserts that participation in markets does not, on its own, raise issues of fairness. Questions of fairness only arise within a social relationship that "embeds market relations" in the practice of free trade that "allows and regulates economic interdependence" (James, 2009, 5). When considering the distribution of gains from

trade, he says that only countries can be treated unfairly and they can only be treated unfairly if exchanges are not mutually beneficial to trading partners. (Though, James does qualify his argument a bit to allow that human rights considerations may also have some force.) He says this is because the purpose of free trade is "for countries to mutually increase national income" (James, 2009, 5). As he puts it:

> Egalitarian claims, concerned with relative gains or losses, are held by… countries. For such claims are essentially tied to the type of good the trade relation is intended to create, and the ultimate aim of international market reliance is for countries to mutually increase national income (via productivity-enhancing specialization). (James, 2009, 5)

It seems there is little room for properly fair trade on James' theory.

If, however, the primary aim of free trade should not just be to ensure that countries make mutually beneficial exchanges, James' argument will not go through. Perhaps, for instance, the gains from trade should primarily benefit the least well off globally. Perhaps, if the gains from trade do not benefit the least well off globally, those who can should try to alter or work around these rules (by, e.g., buying Fair Trade-certified goods) (Hassoun, 2009).

Or consider Kurjanska and Risse's argument against Fair Trade. They argue that the case for Fair Trade-certified goods hinges, primarily, on whether or not Fair Trade is part of the best development strategy for poor countries. They do not think Fair Trade is part of the best development strategy, and so, they believe purchasing Fair Trade-certified goods is only acceptable because it does not constitute a large share of the market in traded goods (Kurjanska & Risse, 2008).

Kurjanska and Risse do not, however, argue that the case for purchasing Fair Trade-certified goods hinges, primarily, on whether or not Fair Trade is part of the best development strategy for poor countries. (They do not even specify what kind of development they have in mind.) They just suggest that a roughly Rawlsian account of fairness would support this conclusion. So, if Fair Trade need not promote countries' development, Kurjanska and Risse's argument will not go through (Hassoun, 2011b). Perhaps purchasing Fair Trade goods is justified, or required, if it promotes poor individuals' agency or welfare. This is probably so on some cosmopolitan theories of justice (Hassoun, 2012c).

In any case, the argument Kurjanska and Risse advance for the conclusion that Fair Trade is not part of the best development strategy for poor countries is much weaker than they make out. They rely on anecdotal evidence to support some of their key claims (Hassoun, 2011b). More precisely, they think that Fair Trade may not be the best development strategy because it may induce poor people to specialize in ways that are not in their long-term interests. They try to support this point with the following case:

> In Costa Rica a focus on new exports and eco-tourism allowed for diversification away from coffee and bananas. The export share of non-traditional products rose from 38.6 % in 1982 to 87 % in 2003. Consumers who would have supported Fair Trade with regard to coffee and bananas in Costa Rica would have resisted a shift that *in the long run* turned out for the better (One may even argue that providing opportunities for farmers to transition out of farming improved the lot of those who entered a new more profitable and less volatile sector. Moreover, by decreasing production of bananas, it increased returns for those who

> retained their business. It can be asserted that by providing aid and higher than market price returns to those who can obtain its label, it simultaneously provides incentives for others to continue in or even enter an unprofitable market with hopes to gain access to the limited Fair Trade market). (Kurjanska & Risse, 2008, 28–29)

It is not clear that Costa Rican farmers would have been worse off if they had tried to produce Fair Trade coffee. Even if Kurjanska and Risse are right about Costa Rica, however, Fair Trade may, generally, be part of the best development strategy for poor countries.

Moreover, even if critics of Fair Trade are right and there are only humanitarian reasons to pursue any kind of fair trade, these may be significant. Many poor people may depend, for instance, on Fair Trade for their survival. So, purchasing Fair Trade goods may even be morally required. There is some evidence that Fair Trade is effective in alleviating poverty (Bacon, 2005; Raynolds, 2002). Impact assessments suggest that Fair Trade projects help poor people secure better prices for their products (Imhof & Lee, 2007; McMahon, 2001). There is also evidence that many Fair Trade farmers have more stable incomes, are more organized, and have greater access to credit information and training programs than many traditional farmers (Bacon, 2005; Calo & Wise, 2005; Imhof & Lee, 2007; Milford, 2004, 76; Murray, Raynolds, & Taylor, 2003; Raynolds, 2002; Ronchi, 2000; Taylor, 2002). Fair Trade can help farmers to do better than organic farmers (Bacon, 2005; Calo & Wise, 2005; Imhof & Lee, 2007; Milford, 2004; Ronchi, 2000; Taylor, 2002). Although further, more rigorous, evaluations are necessary, there is evidence that Fair Trade farmers may be less vulnerable to crises and less likely to lose their land than their traditional counterparts (Bacon, 2005, 506). There is also some evidence that Fair Trade can help farmers better educate their children and meet their basic needs for things like food, water, and housing (Bacon, 2005; Hopkins, 2000, cited in Raynolds (2002); Murray et al., 2003; Ruben, 2008). A recent study commissioned by the Center for International Development Issues in the Netherlands even found that Fair Trade can increase market prices and wages for other poor farmers in a region (Hassoun, 2011a; Ruben, 2008).

Extending the Idea of Fair Trade

If purchasing traditional Fair Trade-certified goods is ever praiseworthy, never mind morally required, there is reason for bioethicists to consider ways of extending the idea to more properly medical arenas. One possibility is to embrace a traditional Fair Trade labeling campaign for pharmaceutical products, ensuring that those involved in producing pharmaceutical products (or products made by pharmaceutical companies) can meet their basic needs (Bhutta, 2006).

There may also be reason to consider other kinds of "Fair Trade" proposals that do not focus on poor producers. While most Fair Trade proposals focus on improving the lives of poor producers and workers, others try to prevent companies from employing certain kinds of workers. "Respect: Fair Trade Sports" and "GoodWeave International" focus on eliminating child labor, for instance (GoodWeave International, 2009;

Respect Fair Trade Sports, 2008). If it is legitimate to extend the concept of Fair Trade beyond production processes, Fair Trade labeling organizations might evaluate producers' impact on those poor people they do not employ. So, Fair Trade standards might apply to more producers, even large transnational corporations that do not employ poor people. One idea is to rate pharmaceutical and biotechnology companies based on how their policies impact poor peoples' access to essential drugs and technologies. The best companies, in a given year, might then be Fair Trade certified and allowed to use a Fair Trade label on their products. Socially responsible investment companies could also include in their portfolio Fair Trade-certified companies. Having a Fair Trade certification system for pharmaceutical and biotechnology companies would open the door to all kinds of fruitful social activism including boycotts of poorly rated companies and lobbying of insurance companies to include Fair Trade products in their formularies. Because, for instance, pharmaceutical and biotechnology companies rely, to a large extent, on university research and development, universities might make it a condition of the sale of their licenses that companies agree to abide by Fair Trade standards (Hassoun, 2012a).

Another possibility is to rate competing energy or extractive resource firms. Energy companies that develop, and help poor people secure access to, renewable energy sources might be Fair Trade certified, for example (Hassoun, 2012c). One reason for including such proposals under the umbrella of "Fair Trade" is that that would explain why "antiglobalization" activists *a*nd those in "the global justice movement" argue that Fair Trade provides an alternative to the neoliberal economic policies central to globalization that they reject (Highleyman, 2002).

Whatever one thinks about how one should use the term "Fair Trade," it may be fruitful to consider new ways of incentivizing improvements in global health that are, in some ways, analogous to Fair Trade campaigns. Such *Global Health Impact* campaigns may help combat some of the world's worst health problems. One such problem is that the poor lack the resources to secure the existing drugs and technologies that they desperately need. In 2002, the top ten causes of death in low-income countries included lower respiratory infections, HIV/AIDS, perinatal conditions, diarrheal diseases, malaria, and tuberculosis (WHO, 2007b). Reliable treatments exist for many of these conditions but few poor people can afford the treatments. Less obviously, poor health-related infrastructure can make it hard for the majority of the world's population to secure essential drugs and technologies even if they are cheap or free. In many countries, there are too few clinics and many of the existing clinics are hard to access (Global Health Watch, 2005). Some clinics lack staff, equipment, resources, and personnel. Others lack basic services like consistent electricity (necessary for refrigerating vaccines and other medicines) (Barnard, 2002). Moreover, few existing drugs and technologies address the most prevalent diseases in poor countries. There is a large mismatch between the amount of research and development (R&D) done on health problems in developed countries and the global burden of disease (GBD). Though things have improved recently, only 16 of 1,393 new chemical entities on the market between 1975 and 1999 were for tuberculosis or tropical diseases (Trouiller et al., 2001). "Malaria,

pneumonia, diarrhea, and tuberculosis, which together account for 21 % of the GBD, receive 0.31 % of all public and private funds devoted to health research" (Pogge, 2007). Most of the newly approved drugs are not new molecular entities (NMEs). "In 2002, only 17 of the 78 newly approved drugs were NMEs" (Angell, 2004, 43). And there are many other problems as well.

Consider how rating pharmaceutical companies based on their efforts to extend access to essential medicines to the poor, and providing the best companies with a label (that could say, for instance, that the company is "Promoting Global Health" or "Extending Access"), might address a few of these problems. Once again, the idea is that the best companies, in a given year, will be Global Health Impact certified and be allowed to use a (say) Extending Access label on their products. Highly rated companies, then, have an incentive to use the label to garner a larger share of the market as those engaged in trade and investment often prefer to purchase ethically labeled goods. If even a small percentage of consumers or doctors would prefer products from Extending Access companies, the incentive to use this label could be substantial. Moreover, socially responsible investors could include in their portfolio Extending Access-certified companies. Finally, having an Extending Access certification system for pharmaceutical companies would open the door to all kinds of fruitful social activism including boycotts of poorly rated companies and lobbying of insurance companies to include products from Extending Access companies in their formularies. Because, for instance, pharmaceutical companies rely, to a large extent, on university research and development, universities might make it a condition of the sale of their licenses that any companies holding their technologies must abide by the standards the Global Health Impact rating organization requires companies to meet to be Extending Access certified. None of these possibilities will solve all of the world's health problems, but they might have a significant impact on some of them.

For Global Health Impact certification to be a good idea, the rating system upon which it relies must be objective and output based (Hassoun, 2012a, 2012b). Here the objective is to design a rating system that can incentivize companies to do more R&D on essential medicines in ways that promote global health. Toward this end, companies should be able to impact their rating and, if companies' scores improve, that should improve global health. This requires information on the need for different essential medicines (e.g., disability-adjusted life years – *DALYs* – lost to the diseases they treat) and drug impact (e.g., efficacy) information. The drug's score will be, roughly, Need*Impact. Suppose, for instance, 100 million DALYs are lost per annum to a disease treatable with a drug that reduces the impact of the disease by 80 %, on average. If there are no alternatives, the drug will save 80 million DALYs (100*.8 = 80). If there are alternatives, doing a similar analysis on the second-line drug (or best alternative) will provide the basis for estimating the first-line drug's marginal impact. Companies can then be rated on the basis of their drugs' aggregate contribution to alleviating the global burden of disease (Hassoun, 2012a, b, c).

Moreover, for a Global Health Impact label to be a good idea, there should be some reason to think that people would actually use it. Consider, here, just the

potential impact of an Extending Access label on consumer sales. There are two important questions to answer in considering this impact. First, what percentage of consumers will purchase Extending Access products? Second, what is the size of the market in these things? The most direct way to answer the question "What percentage of consumers will purchase different kinds of labeled products?" would be to do market research on how many people actually purchase products with the label. One way of collecting such data might be to design an appropriate web platform for the project to provide decision makers, companies, and researchers with access to the ultimate ratings of companies on the basis of their products' impact and the comprehensive database of information underlying these ratings. This platform might be made available to consumers via a phone application like Fooducate or the GoodGuide that will let consumers see information about all of the products they scan (see, for instance, http://itunes.apple.com/us/app/fooducate/id398436747?mt = 8 or http://www.goodguide.com/). Scanning the barcode will bring up a web page that provides information about the rating of the company that makes that product. Interested users can learn more about the rating system and the impact of the drugs that the company makes on the basis of which the company is evaluated. Under each drug's rating, the application will explain how the score was calculated and include a link to the database. Such an application will help in gathering market data about what percentage of consumers will base their purchasing decisions on the rating system's results.

To do market research, however, a model rating system must be developed already (though this research can help in fine-tuning the model). In the absence of all the necessary market research, however, one might attempt to determine what percentage of consumers will purchase Extending Access products by considering what percentage of people are willing to engage in other kinds of ethical consumption.

As an indication of what is possible, consider the market in a few ethically labeled products. As noted above, the percentage of the European market in coffee captured by Fair Trade coffee is over 1 % (EFTA 2001, cited in Raynolds (2002)). Though, coffee is not the best-selling Fair Trade product – at least in the UK, bananas top the list (Fair Trade Foundation, 2008):

> Fairtrade coffee now accounts for 20 % of the UK coffee market, well above the 7 % market share registered in France, Europe's second largest market for fair-trade coffee. Fairtrade coffee represents between 3 % and 5 % of the coffee market in Ireland, Luxemburg, the Netherlands, Sweden and Switzerland; between 1 % and 2 % in Austria, Belgium, Denmark, Germany and Norway; and less than 1 % in Finland, Italy and Spain. (Pay, 2009)

The market for other kinds of ethical-labeled products is much larger:

> Organic coffee is estimated to account for about 3 % of the North American coffee market in volume in 2007, while its share in value is slightly higher, since prices for organic coffee are higher than those of conventional coffee. Organic coffee ranked the highest in dollar value among all organic products shipped to North America last year, and it accounted for one-third of all U.S. organic beverage sales. (Pay, 2009)

"Utz Certified coffee accounts for 40 % of the coffee market in the Netherlands" (Pay, 2009).

Moreover, there are other labeling campaigns that have captured a significant market share. Consider, for instance, sales of ENERGY STAR products in the United States. In 2006, 11 % of all washing machines in private homes and 38 % of all of the washers sold were ENERGY STAR certified (US Department of Energy, 2008). The EPA reports that 17 % of new homes now earn the label, and many people buy ENERGY STAR appliances (EPA, 2009). In their 2009 report, the US Department of Energy noted that three out of every ten refrigerators sold are ENERGY STAR certified (US Department of Energy, 2008). This is not to say that the ENERGY STAR label is in all respects a positive model for an Extending Access label. The testing and certification standards are not rigorous enough (Consumerreports.org, 2008). This is something an Extending Access rating system should avoid. The point here is only that a significant proportion of customers are willing to buy ENERGY STAR products.

Similarly, although The Body Shop has been criticized for not doing enough to help the poor (as well as for using chemicals and animal products in their health and beauty lines), they have captured a significant share of the market in developing as well as developed countries (Franklin Research's Insight, 1994). The Body Shop now makes up 3.5 % of the market in local toiletries and cosmetics in Malaysia and aims to acquire 5 % of the market in India (about its share in Hong Kong and Singapore) (Fashion United, 2010; The Star, 2009).

One might worry that consumers will not purchase Extending Access-certified conventional pharmaceutical products because consumer demand for medical goods is very inelastic. When there is no reasonable competitor to a necessary medical item, its Extending Access status may not matter. Patients will not always prefer drugs from highly rated companies. Sometimes there will be one medicine that is best for a particular condition. So, the fact that it comes from a highly rated company may (and probably should) not matter.

This brings one to the second question: What is the size of the market in things that consumers might buy? One way of trying to estimate this is to look at what percentage of drugs is generic or available over the counter. In 2006, 63 % of all prescriptions were for generic drugs (Kesselheim, 2008, 125–39; New York Times, 1986). The market for generic medications alone is over US$20 billion – much larger than the market for almost all Fair Trade products, including coffee (Mullins, Palumbo & Stuart, 2000). Similarly, the market for over the counter medicines was quite large – US$16 billion (Hassoun, 2012a). So if, like The Body Shop, a GHI label can aim to capture 5 % of US$36 billion, this would yield US$1.8 billion worth of incentive for companies to become GHI certified.

Even if poorly rated companies come up with counterfeit labels or try to manipulate the rating system, highly rated companies should support it. If people are educated about what the Extending Access label stands for, it may be trusted and alternatives may look suspicious. If necessary, government regulation (along the lines of the USDA "Organic" standards) may help prevent abuse. Even if the standards are not quite as good as one might like, the USDA does oversee the use of the pesticides and other farming practices that motivated the organic movement in the first place (USDA, 2010).

Finally, it is important to recall the fact that a rating system has many uses beyond providing the basis for a consumer label. Insurance companies or pharmacies might support highly rated companies by including their drugs in their formularies or stores. Policy makers can use the rating system to provide (e.g., tax) incentives to companies that better promote global health. Companies might also use the rating in their public relations campaigns. There is a lot of room for further research.

More recently, a few others have taken up the idea of Global Health Impact labels and proposed a different way of arbitrating between them. Nir Eyal argues, for instance, that it would be a good idea to let consumers vote on which Global Health Impact labels they prefer (or delegate their votes to organizations that they trust). He points to the success of Wikipedia in providing good information on a broad range of topics. He also suggests giving a label to hospitals in developing countries that provide health services to needy communities as well as rich tourists (Eyal, forthcoming).

It is not clear, however, that the way Eyal suggests arbitrating between labels, or his particular proposal for rating hospitals, is a good idea. Consumers may not choose good labels or delegate their votes to those who will. They may delegate their votes to religious health organizations that care only about labels that ensure people will not be offered Plan B or condoms. Further, it is not clear that Eyal's suggested label is feasible or, if implemented, would produce good results. What reason do hospitals have to sign on to the rating system he proposes? Will tourists seeking medical care abroad choose highly rated hospitals? How will people learn of the rating? Will they even have a choice of otherwise comparable health facilities providing the services they require?

Still, there are many other possible ways of deciding which potential labeling schemas a Global Health Impact rating organization should endorse as well as possible bases for Global Health Impact-certified labels. As suggested above, it would be better if an umbrella organization used objective criteria for evaluating potential Global Health Impact labels (and then granted Global Health Impact status to organizations offering ratings systems that can plausibly promote global health). They might consider, for instance, whether (1) the rating system measures actual impact on global health, (2) the organizations being rated can increase their impact, and (3) the rating system will provide these organizations with reason to do so.

Conclusion

This chapter has argued that those who are concerned about global health have at least some reason to promote fair trade by, for example, purchasing Fair Trade-certified goods. Poverty and environmental quality impact global health, and Fair Trade is one way of ameliorating poverty and protecting the environment. Moreover, there are many avenues for further inquiry into what, if anything, fair trade requires and into extending the idea of Fair Trade certification into the medical arena itself. Objective, output-based Global Health Impact labels may be particularly promising ways of encouraging fair trade, and exploring this alternative may open the door to many other ways of improving global health.

Genetic Modification

40

Don Chalmers

Introduction

Genetic modification (GM) involves modern biotechnology techniques to change the genes of an organism, particularly those of plants or animals. Genetic modification may be referred to by the synonyms genetic manipulation and genetic engineering (GE). GM builds on traditional and long-practiced plant or animal breeding techniques, such as tissue culturing propagation, graft cuttings (referred to as "clones" from Greek: *klon*, a twig), and seed selection. In animals, traditional techniques have been selective breeding and artificial insemination. These traditional techniques aim, like modern GM, to identify and develop favorable traits in plants and animals or to restrict or breed out unwanted traits. Modern GM, using recombinant DNA techniques, not only has the capacity to accelerate the time traditionally taken to introduce or eliminate the traits into the modified plants or animals but also to introduce genes from other organisms to produce transgenic organisms or traits.

Scientific development and economic investment in the context of GM have been concentrated in developed nations, which have invested heavily in biotechnology generally and genetics research in particular, as a strategy for their future economic development. Biotechnology is a key component of what has been called the *knowledge-value revolution* (Sakaiya, 1992). Following the agrarian, industrial, and petroleum revolutions, which transformed national economies, many developed nations have invested substantially in research and development, within universities, research centers, and commercial companies. This research and development aims not only to develop new medicines, plant varieties, materials, and products but also to generate the "knowledge value" in patentable inventions or methods. GM plants and animals and biotechnology, in general, have not simply been facilitated by increases in public and private funding. National biotechnology strategies have been accompanied by development tax and financial incentives, access to research tools, security of investment, and new regulations.

Scientific developments in GM have been accompanied by vigorous ethical, legal, and social debates within communities generally. There are fundamental ethical and social values involved in the development of genetic science. Genetic modification of plants and animals has been highly controversial and led to the introduction of regulatory systems in most developed countries. Similarly in human genetics, there have been equally vigorous debates about the dignity of the human embryo, which is the source of embryonic stem cells in those countries, which permit this type of research. Also, in human genetics, the growth in genetic testing has prompted extensive debate about the potential for discrimination based on the results of genetic tests. Part of these ethical legal and social debates about GM has focused on commercialization and raised questions about the fundamental values of science itself. Much of the GM research and development and resulting intellectual property rights are in the hands of private-for-profit companies. Similarly, many public institutions have commercialization policies and plans for their science research. In this modern commercialized research environment, there are concerns that the values and norms of science, which were traditionally expressed as "universalism, collegiality, disinterestedness and organised scepticism" (Merton, 1973), have been radically altered.

Genetic Modification in Animals and Plants

Modern genetic modification (GM) breeding techniques have been refined over the last decades to accelerate the time traditionally taken to introduce or eliminate traits in plants or animals and to introduce genes from other organisms to produce transgenic organisms or traits. So GM can be achieved by modifying the genes of the organism itself or by introducing a gene from another organism. GM techniques are used to identify and introduce favorable traits or to restrict or silence unwanted traits. In traditional plant or animal breeding, a number of cycles may be required to introduce or eliminate a trait or traits. The traditionally bred plant or animal will still retain some of the traits of the original stock.

Modern GM techniques enable genes from one organism to be inserted, rather than bred, into another plant or animal. A genetically modified organism (GMO) is a plant, animal, or other organism that has been changed using GM. A GMO can be created with the following steps: identification of the gene interest; isolation of the gene of interest; amplifying the gene to produce many copies; associating the gene with an appropriate promoter and poly A sequence and insertion into plasmids; multiplying the plasmid in bacteria and recovering the cloned construct for injection; transference of the construct into the recipient tissue, usually fertilized eggs; integration of gene into recipient genome; expression of gene in recipient genome; and inheritance of gene through further generations. Apart from plants with pest or disease resistance, GM techniques aim to develop new plant varieties and animal breeds with improved yield or enhanced nutritional status (BBSRC, 2008). There are also efforts to develop plant varieties with drought resistance and salt tolerance traits. GM also includes the technique of *gene silencing* to reduce the activity of specific genes present in an

organism with the aim of altering the traits of the organism. As an example, some oilseed crops have had GM *gene silencing* for the reduction of oils, which are considered unhealthy. Finally, modern GM is also used as a laboratory research tool in gene discovery, gene interaction, and genetic structure studies.

Many common crops (e.g., soybeans, corn, cotton) have undergone GM research and development. Whereas many European Union members have been critical of and resistant to the use of GM technology and have little GM plantings, there are a number of countries that have taken up GM technology with significant proportions of crop plantings (the USA, Argentina, Brazil, Canada, India, China, Paraguay, and South Africa).

The Scientific Aims of GM

GM techniques have been developed for a variety of reasons. A key aim of GM has been to increase crop productivity to achieve higher yields. In this respect, there are claims that GM offers more reliable avenues for addressing the need to feed the expanding world population, particularly in the third world. One of the other key purposes of GM was to restrict the use of pesticides and other environment-damaging chemicals. As an example, GM cotton was developed for improved insect resistance by introducing a gene from a naturally occurring soil bacterium. The development of GM insect resistant cotton has enabled reductions in the amounts of chemical pesticide spraying required, with a claimed secondary benefit from reduced water run-off pollution from the reduced use of pesticides and other chemicals. In this respect, GM may be a technique to achieve bioremediation of degenerating land or to remediate degraded mining operations. There are claimed benefits for the environment along with pesticide cost savings for the grower. GM also aims not only to increase crop productivity and yields but also to improve crop quality and food value (BBSRC 2008). GM has been used to improve the appearance and color of foods, removal of blemishes on some crops (such as bananas and papaya), or to produce later ripening fruit. GM has been used also to extend the shelf-life display of a number of popular foods (e.g., tomatoes). Finally, there have been research efforts to investigate the GM development of crops suited to global warming and likely increased drought conditions (e.g., salt-tolerant wheat varieties).

GM and the Precautionary Approach

GM has attracted concerns and criticisms based upon claims of the risks involved (Weaver & Morris 2005). These concerns are not new. As recombinant DNA technology developed, scientists themselves recognized the safety concerns about the new technology. The National Academy of Sciences, USA, set up a Committee on Recombinant DNA to assess the biosafety of the technology, and, in 1975, at the Asilomar Conference USA, biosafety in recombinant DNA research was discussed and a precautionary approach to risk initiated scientists attending established biosafety

principles, the first of which required any potential research risks to be a component part of experimental design. The second principle required that effective risk containment measures be implemented, dependent of the level of risk. Asilomar also agreed that certain types of experimentation, particularly recombinant DNA on highly pathogenic organisms (e.g., *E. coli* bacteria), should be prohibited and that a moratorium was required, pending the development of safety standards and procedures. Significantly, Asilomar, by including lawyers and doctors, was a milestone in the public debate about and scrutiny of science and science policy and regulation and took place in the context of the USA *National Research Act* 1974, which established the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research and introduced greater regulation of the approval processes for human research projects. These ethics review procedures have been influential globally.

These basic principles of risk assessment and levels of risk containment remain key features of modern risk assessment and management in trailing GMOs. The precautionary approach to GMOs requires that *known* and *potential* to the environment and human health should be addressed at the outset of any experimentation or trials. The Convention on Biological Diversity (Rio Declaration, 1992) from the United Nations Conference on Environment and Development in Rio de Janeiro Principle 15 states that "in order to protect the environment, the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation." Precautionary measures are required where long-term risks are unknown and scientific certainty may be achieved too late to provide effective responses to environmental threats (Peel, 2005). Some take the precautionary approach to be a *principle*, requiring that experimentation not be undertaken until and *unless* risks can be ascertained and addressed. The precautionary approach, more generally requires that proposes that GM can be undertaken *but* strict risk assessment, review and avoidance procedures must be put in place. In 2000, the *Cartagena Protocol on Biosafety*, building on Principle 15 of the Rio Declaration, required signatory countries to apply the precautionary approach to the transfer, handling, and use of living modified organisms (LMOs).

Risk Assessment and Management

GM raises issues of gene flow from GM crops affecting neighboring properties and possibly surrounding natural and vulnerable ecosystems. There are concerns that GM may create new types of weeds, transfer of gene expression from GMOs through vertical or horizontal gene transfer, possible allergenicity from GM plants and animals, and that the long-term impacts of GMOs are uncertain. For GM development, risk-assessment plans must be prepared before GM laboratory research and any field trials undertaken (Weaver & Morris 2005). The Asilomar principles were taken up by scientists and nations involved with gene technology and similar Recombinant DNA Monitoring Committees established. These *advisory*

committees were gradually replaced by formal statutory authorities. For example, in Australia, the Recombinant DNA Monitoring Committee, established in 1975, was succeeded in 1987 by a Genetic Manipulation Advisory Committee and replaced by a statutory Gene Technology Regulator (Gene Technology Act, 2000).

Schemes for the regulation of genetically modified organisms (GMO) have common features of risk assessment and risk management. The *Cartagena Protocol* aimed to ensure levels of protection for the safe transfer, handling, and use of LMOs from biotechnology, with proper account, was taken to risks to human health. An LMO generally refers to agricultural crops and so is narrower than a GMO. The *Cartagena Protocol* established the foundational principles for the regulatory systems of signatory countries. These systems essentially assess the risk involved with a GMO dealing and require that dealings are *licensed* unless the GMO dealings are an exempt or a low-risk dealing. Risk assessment of the GMO is essentially science based, without assessment of psychological or social conceptions of risk. Many GMO dealings are contained within laboratories, without any release into the environment by field trials. Experimental laboratory dealings, depending on the assessment of risk, will be licensed to be conducted within different levels of security containment standards (physical containment levels, PC1–PC4, depending on risk). The restriction of the GMO to a physical containment facility is a usual license condition. Institutions conducting GMO work must generally undergo an *accreditation* and require their laboratories to be *certified* to ensure the proper physical containment levels are maintained for the GMO work. Institutions must, as part of the accreditation process, have an institutional biosafety committee (IBC) to assess institutional biosafety issues. Where the GMO is to be released into the environment, usually in a field trial, specific licenses are required and a Risk Assessment Management Plan (RAMP) prepared to minimize impact involved with the intentional release of the GMO on human health and environmental safety to minimize the risks. RAMPs vary according to the significance of the risks to safety of people or environment. The RAMP will consider the effect of genetic modification on the original organism, the effect of the modification of toxicity or allergenicity to other organisms, the effect of modification increased weediness, the potential for gene transfer, and the potential for limiting the spread and persistence of the proposed GMO. Applications for licenses involving an intentional release of a GMO will allow opportunities for public consultation and comment, which will inform the development of the specific RAMP. In cases of an intentional release of a GMO, the license will impose RAMP conditions to minimize the risks of contamination and risks to health and safety. Common license conditions require isolation and setting up buffer zones around the trial site, destruction and removal of any plant, canopies over GMO crops to prevent pollen flow, and special harvesting, transport, and storage procedures.

Genetic Modification Ethics

The development of genetic modification of plants in agricultural biotechnology has met with considerable debate and controversy. Supporters of GMOs claim that the technology will improve crop production and yields, reduce the use of

environmentally damaging pesticides, and fulfill a duty to feed increasing third-world populations. Supporters also claim that scientific inquiry and the advancement of knowledge is itself a moral good. By contrast, opponents claim that GMO technology is inherently wrong, GMOs interfere with nature and damage ecosystems, GMOs reduce biodiversity, and GMOs are economically anticompetitive because the market for GMOs has been dominated by a small number of multinational corporations. In fact, much GMO research is conducted within government organizations or universities. Environmental ethics focus on issues of "naturalness" and whether GM technology distorts this natural order. Patenting has also been a major issue in GM plants with concerns about the domination of a small number of multinational corporations holding key patents over major crops (e.g., soybeans, cotton, corn, and canola).

Environmental ethics and the ethics of GM are inchoate and less formalized in comparison with established traditions of ethical debates in human or animal research (Sylvan & Bennett 1994). There are no GM or environment equivalents of human research ethics committees or animal ethics and welfare committees. Where GM involves animals by, for example, the introduction of human genes, animal welfare and ethics issues arise. Respect for animals recognizes animal sentience (sense pain and suffering) (Singer, 1975). This respect is reflected in animal welfare legislation prohibiting cruelty to animals and supported by guidelines regulating animal research. These guidelines generally require researchers in animal experiments to *replace* them, where possible, *reduce* the number involved, and *refine* the project. Respect for animals, specifically in GM projects, reflects concerns about consequences for the welfare of these modified animals and for their possible effects on human and animal health and the environment. These guidelines apply to laboratory animals and to GM production animals.

GM is not a science-only activity but embraces regulatory policy, economics, third-world development, and profound ethical questions. Decisions about applications of GM require scientific assessments of potential and risk to be accompanied by ethical discussion. Therefore, strict scientific analysis of risk is not sufficient for ethical decision making about gene technology (Singer, 1975). Global warming research has revived debates on environmental ethics, which is well recognized in some cultural traditions. In Australia and in New Zealand, government advisory bodies (the Gene Technology Ethics and Community Consultation Committee and Environmental Risk Management Authority, respectively) have developed ethics frameworks in respect of GM technology. These *ethics frameworks* contain general principles (respect for the environment and respect for people, including past, present, and future generations) and specific principles of concern for animal welfare, autonomy, cooperation, cultural identity and pluralism, human rights, human dignity, justice and equality, sustainability, and well-being.

Genetic Modification in Humans

Genetic modification is not a term generally used in relation to humans; however, human genetics is an area of intense research effort, aimed not only at developing

diagnoses and treatments for genetic conditions but also for many common diseases (Burley & Harris, 2004).

Before the advent of modern molecular genetics, genetic information came from family histories, physical appearance, and some chromosomal analysis (e.g., an extra copy of chromosome 21 indicating Down's syndrome). Many genetic conditions were known but not treatable. However, genetic information could inform reproductive choices. Marriage rules on consanguinity, which restricted near relations from marrying, were examples, with restrictions based to degrees of genetic separation. Darwin's *The Origin of Species* proposed that all forms of life are essentially convertible into one another and that each cell had propagating "gemmules" able to attach to other tissue. A second idea of *pangenesis* proposed that these gemmules have natural affinities to select and attach to other tissue. A cousin of Charles Darwin, Francis Galton coined the term *eugenics* in *Inquiries into Human Faculty*, 1883. In 1902, William Bateson in *Mendel's Principles of Heredity* used *genetics* for the study of heredity and its variation, followed by the Danish botanist Wilhelm Johannsen, with the terms "genotype," "phenotype," and "gene." Research work in the 1940s by Oswald Avery and collaborators identified DNA as the molecular material base for genes and chromosomes. James Watson and Francis Crick advanced the analysis of DNA with their publication in 1953 of its molecular structure (building on work by Rosalind Franklin and Maurice Wilkins). Building on chromatography and dye-based techniques (Southern blotting), sequencing techniques became easier, faster, and less expensive with PCR and became more detailed with the Sanger DNA sequencing technique (Kevles & Hood, 1992).

The modern "genome era" has been marked by considerable research activity, much of which is international and collaborative. This work has not only expanded understanding of the molecular genetic code of humans but is also informing and driving efforts to develop diagnoses and treatments of many common diseases and conditions, based on this genetic knowledge. A significant milestone was reached in 2001, with the joint announcement in the journal *Nature* and in *Science* of the publication of the human genome map. The announcement was made by the *Human Genome Project* (HGP), an international publically funded collaborative project, and the private company, Celera Genomics. Based on the mapping work, it was estimated that the total number of human genes was between 30,000 and 40,000. This was a considerable reduction on previous estimates and required a revision of the previous biology doctrine of "one gene for one protein." This announcement also showed a common thread of similarities between the DNA of humans, animals, and plants (Sulston & Ferry, 2004). This was a starting point for further sequencing work and improvements in sequencing technology and bioinformatics. Automation, chip technology, and mass parallel sequencing have exponentially accelerated sequencing toward *Whole Genome Sequencing* (WGS), enabling the systematic identification of genes and the complete sequencing of the genetic code of many plants, animals, humans, and organisms. Equally significantly, the HGP funding included consideration of the ethical, legal, and social issues (ELSI) in the HGP and the establishment of the International Human Genome Organisation (HUGO). The HGP adopted a policy of public release and open access to data after its *Bermuda Declaration* in 1996 with release within 24 h. The HGP and Celera Genomics joint announcement

spawned new disciplines of proteomics (gene identification, protein structure), functional genomics, and transcriptomics (genetic variation, gene expression monitoring) and targeted drug discovery and pharmacogenomics (for treatment of diseases with a genetic component) and new enabling technologies. The HGP has also spawned other major international collaborative projects, like the International HapMap Project and the International Cancer Genome Consortium, which involves some 14 countries each specializing in analysis of specific types of cancers and which has been described as the biggest collaborative international research project since the HGP.

The results from these projects, and others, have enabled medical science to better understand human genetics in relation to health and to translate this understanding into diagnoses and treatments for many common diseases and conditions. The genetic base for many diseases has been understood for some time. The *autosomal dominant disorders* include conditions such as polycystic renal disease, neurofibromatosis, and Huntington's disease. The *autosomal recessive disorders* include sickle cell anemia in certain populations, cystic fibrosis, and phenylketonuria. Similarly, *X-linked disorders* like hemophilia are also well known. However, there are many conditions which are not clearly genetically linked. High incidence conditions, which can also affect family groups, such as cancer, hypertension, diabetes, and heart disease, are *multifactorial* and depend on genetic as well as dietary and environmental factors.

Human Gene Therapy

Advance in development of molecular human genetic research and a better understanding of the genetic bases of some diseases, in the 1980s, encouraged early efforts to consideration of the use of DNA in gene therapy to treat disease by altering a patient's genes. Gene therapy aims to replace defective genes but also to introduce genes as a means to improving cellular function or repair genes. Gene therapy interventions *on* humans have been few. In the 1980s and 1990s, there were high expectations of the promise and potential of gene therapy to modify and treat diseases. These interventions were targeted not on the patient's germ cells but on their somatic cells. By the early 1990s, the director of the National Institutes of Health, USA, advised clinicians to return to the laboratory and improve experimental techniques before undertaking further clinical gene therapy trials (256 *Science*, 808–813), and an editorial in *The Lancet* suggested that the promise of gene therapy had been "over sold" (350 *The Lancet* 9071, 79). The Gelsinger case in the USA in 1999 raised grave ethical questions about gene therapy. A virus vector with modified genes was administered to a teenager, without his father's knowledge or consent to treat his OTC (ornithine transcarbamylase deficiency), which prevented his OTC (ornithine transcarbamylase deficiency, a rare condition, which prevented his liver from metabolizing ammonia). The teenager died, and the FDA inquiry found serious failures to disclose and research ethics breaches, including reports of competing financial interests of the research/medical team in a company with the right to market the tested gene therapies. Slow progress followed in gene therapy protocols with a focus on common diseases of cancer,

diabetes, and heart disease. Some clinical successes in the last decade have revived gene therapy treatment plans for patients with the retinal disease. There have also been animal model tests, as required ethically, with the first approved clinical gene therapy trial in the USA on the X-linked Duchenne muscular dystrophy disease and another first approved trial for adenosine deaminase (ADA) deficiency using autologous cells and Parkinson's disease.

The limited gene therapy trials have been on somatic cells. There is international consensus that gene therapy on germ cells is ethically unacceptable. The *Convention on Human Rights and Biomedicine* of the Council of Europe states that "any intervention seeking to modify the human genome may only be undertaken for preventive, diagnostic or therapeutic purposes and only if its aim is not to introduce any modification in the genome of any descendants" (Article 13). The Group of Advisors on the Ethical Implications of Biotechnology to the European Union (GAEIB) echoed this view and recommended that the germ line therapy techniques be forbidden on humans until there is greater scientific clarity and ethical reevaluation (GAEIB 1994). Internationally, the research ethics guidelines in most countries include restrictions or prohibitions on germ line therapy.

Gene therapy aims to replace defective genes but also to introduce genes as a means to improving cellular function or repairing genes. Research is also focusing on mitochondrial DNA, which is separate from the nuclear DNA of a cell. Mitochondrial DNA provides the energy for cell growth. There are efforts both to target and remove defective mitochondrial DNA, and transfer new DNA, and also to introduce supplementary mitochondrial DNA. Where this research is carried out on a female oocyte, the genetic change is in the germ line and will be passed on to offspring. This research is ethically controversial and is being developed on animal models (Burley & Harris, 2004).

There has been discussion about the possibility of gene therapy developing techniques to enhance human characteristics. Somatic cell gene therapy has proved to be difficult in clinical application, and any serious discussion of enhancement gene therapy must be hypothetical. From time to time, there has been hypothetical discussion that human genetic techniques could offer the opportunity to insert genes for non-disease-related traits, such as intelligence, height, musical ability, and looks. These traits are influenced by the environment and social interaction and are probably also polygenetic, thus extraordinarily complex to alter and, much less, enhance. It is unlikely that enhancement gene therapy will be realized; many human traits may prove to be far too complex to be modified by the introduction of a single gene or group of genes. Some bioethical literature has discussed the ethics of gene enhancement, even though this discussion is not matched by any research activity, much less any clinical application (Buchanan, 2011). Enhancement gene therapy, like germ line gene therapy, is considered ethically controversial.

Regenerative Medicine

Stem cell therapy is built on the knowledge that certain human cells, derived from, as examples, bone marrow, placental tissue, and human embryos, are capable of

replication. Stem cell technology aims to introduce these new replicating cells into damaged tissue as a therapy to treat disease or injury. For this reason, stem cell therapy is a component of the area of what is referred to as "regenerative medicine." The replacement of cells can be viewed as a method of genetic modification for therapeutic purposes. Some stem cell therapies are well established in regenerative medicine and uncontroversial and involve minimal invasive techniques. As examples, whole blood transfusions and bone marrow transplants for particular types of cancers are standard treatments. Stem cell therapy is another area of future promise, which may become a pathway for treatment in diabetes, heart disease, spinal cord injury, Parkinson's, Alzheimer's, diabetes, some cancers, and the production of synthetic blood. Stem cell technology may become a new treatment strategy and delivery method for therapeutic agents for malignant brain tumors. In 2001, the National Academies Committee on the Biological and Biomedical Application of Stem Cell Research stated that stem cell research "offers unprecedented opportunities for developing new medical therapies for debilitating diseases and a new way to explore fundamental questions of biology" (National Academies Committee on the Biological and Biomedical Application of Stem Cell Research, 2001).

Stem cell technology involves a continuing search for reliable sources of regenerative tissue for medical treatments. International public attention was attracted to stem cell research in the late 1990s with the *Dolly* announcement that a somatic cell nuclear transfer procedure (SCNT) had been undertaken at the Roslin Institute in Scotland in 1997. According to the report, a sheep egg had been enucleated and somatic cells from the same sheep (Dolly itself) inserted and a replicated "clone" of the somatic cell developed. This "cloning" procedure built on earlier research work in animal studies. The experiments showed that somatic cells could be differentiated and reset by transferring them to an enucleated oocyte. This indicated that an adult cell could be changed back to a premature pluripotent state. Later scientific work demonstrated that a human pluripotent state was present in human blastocysts (Thomson et al. 1998), and in 2001, the first "cloned" human embryo was reported. Somatic cell nuclear transfer (SCNT), also called cell nuclear replacement (CNR), has developed as an established research area of regenerative medicine for cell replacement. SCNT has a critical advantage over embryonic stem cells. SCNT cells involve the transfer of an individual's own somatic tissues, which means that the modified somatic cells are autologous cell lines, thus avoiding the problems of allogenetic transplants and immuno-rejection. These cells should be compatible with the recipient's immune system. The continuing search for reliable sources of regenerative tissue for medical treatments has moved to iPS cells. There were simultaneous publication of reports of the creation of induced pluripotent stem cells (iPS) from human fibroblasts in Japan (Takahasi & Yamanaka, 2006) and the USA (Thomson). iPS cells show many similarities to pluripotent stem cells as they proliferate indefinitely and appear to differentiate into cells across cell lineages. iPS cells can be derived equally because they can be derived from skin cell biopsies to produce autologous cells for transplant. In addition, parthenogenesis techniques aim to produce stem cell lines of compatible tissue using human oocytes. Much research work lies ahead in the characterization of the differences and similarities between embryonic, SCNT, iPS, and parthenogenic stem cells.

Clinical Applications of Regenerative Medicine

Some stem cell technologies, particularly those involving bone marrow, have been available as standard clinical care for many years. The gradual introduction of stem cell therapies to relieve serious disabilities and diseases will take a number of years of preclinical and clinical research before they are approved. The trials current in the USA can be seen at http://clinicaltrials.gov/.

Like the Asilomar conference, the scientists involved, the International Society for Stem Cell Research (ISSCR) has developed *Guidelines for the Clinical Translation of Stem Cells*, 2008, at www.isscr.org, which propose that clinical trials of stem cells should not be undertaken until there has been rigorous independent assessment of the safety of the procedure. Standards for good manufacturing practice are a necessary precondition to the use of embryonic stem cells in a clinical setting as part of "established" clinical practice. The major ethical issues surrounding stem cells relate to the novelty and safety of the proposed applications. The proposed application must be carefully assessed for risk, that risk properly communicated to the patient and the risk involved and the application properly managed and addressed. Secondly, the application should be subject to independent scientific assessment and ethical review. Thirdly, as with all human research, the risks and benefits should be properly assessed by the independent science and ethics review committees. Fourthly, the risks involved must be carefully communicated and explained to the patient involved so that they can give voluntary consent to involvement in the trial. These ethical principles, including quality control, preclinical work, ethical trials, and ethical evaluation, are consistent with the UNESCO *Declaration on the Human Genome and Human Rights* that "research, treatment and diagnosis affecting an individual's genome shall be undertaken only after rigorous and prior assessment of the potential risks and benefits" with the informed consent of the person and after the research protocols have been submitted for prior review in accordance with relevant research standards and guidelines (Article 5). In view of the innovative aspect of the application, the benefits should not be overstated. This is particularly important as some clinics, in countries with lax or dubious regulatory structures, have advertised treatments of unsubstantiated and unproven effectiveness, raising unrealistic hopes for seriously ill patients with promises of entirely novel and untested therapies.

The Ethics of Regenerative Medicine

Some stem cell technologies, such as bone marrow and whole blood transfusions, are standard clinical practice. These procedures do not arouse bioethical debate. However, like the public debates on genetic modification of plants, the *Dolly* report prompted a worldwide international discussion on the ethics of "cloning" among international organizations, regulatory bodies, and the bioethics community. This report unleashed an avalanche of press comments and academic writings about the potential application of the SCNT process to produce human "clones," sometimes with wildly exaggerated

suggestions that duplicate "clones" of dead children could be brought back. There were also reports of the use of embryonic stem cells for use in drug testing.

The *Dolly* report led to two lines of ethical debate, the first on whether research should be undertaken on human embryos and the second on the possible use of SCNT in assisted reproduction programs (ART). In the first line, human embryo research focused on the moral status of the human embryo and its likely destruction if used in research. Many countries, such as Austria, Ireland, Canada, and the Philippines, banned human embryo research, considering it contrary to human dignity. Interestingly, Germany banned embryo research but allowed stem cell lines to be imported for research. Internationally, the UNESCO *Declaration on the Human Genome and Human Rights* stated that "no research. . .concerning the human genome. . .should prevail over respect for the human rights, fundamental freedoms and human dignity of individuals or. . .groups of people" (Article 10). Arguments based on human dignity recognized that the human embryo may not have human rights but, nevertheless, deserve to be treated with dignity, because early human life represents the fundamental nature and values of a society and transcends individual rights. Human dignity also underpins human rights and places proper limits on research and to avoid its trivialization of values. However, many other countries (e.g., the UK, Finland, Greece, Israel, the Netherlands, Sweden, South Korea, some states in the USA, Australia, Singapore, China, Spain, and Japan) took a utilitarian approach and permitted the use of "surplus" human ART embryos (i.e., not to be used in ART by the parties creating the embryo). These countries weighed utilitarian benefits and harms and preferred the use of excess embryos rather than their destruction. However, these permissive countries all imposed conditions on embryo research. These conditions include strict consent requirements, requirements to explain and justify the intended research purposes, and approval by an IRB/research ethics review committee. Some states in the USA permitted embryo research, but public funds for such research were restricted until the presidential embargo was lifted. Accurately, the President's Commission on Bioethics in the USA described the regulatory landscape on human embryo research as a "patchwork, with authority divided among numerous sources of oversight" (*Reproduction and Responsibility: The Regulation of New Biotechnologies* 204 at 75). This comment applies equally in the international context. No country, however, has approved the creation of human embryos for research purposes.

The second line of debate considered whether SCNT could be used in assisted reproduction programs (ART). Two rather misleading terms developed of "reproductive cloning" and "therapeutic cloning." The former, reproductive cloning, was condemned universally. Article 11 of the UNESCO *Declaration on the Human Genome and Human Rights* stated "practices which are contrary to human dignity, such as the reproductive cloning of human beings, shall not be permitted." This was followed by similar bans on "reproductive cloning" by the WHO General Session and a resolution of the United Nations. Similarly, the Council of Europe added an *Additional Protocol* to its *Convention on Human Rights and Dignity with regard to the application of Biology in Medicine*. The *Protocol on Prohibition on Cloning of Human Beings* states that "any intervention seeking to create a human being genetically identical to another human being, whether living or dead, is prohibited."

There were some comments that reproductive cloning was part of the right to procreate but with little influence.

Significantly, debates about human embryo research do not arise with some stem cell technologies. iPS cells, for example, are not derived from human embryos and will produce autologous transplant cells. This procedure removes much of the moral objection to the use of excess embryos for the production of stem cells. Similarly, parthenogenic stem cells avoid using human embryos but may raise ethical questions about the procedures for women donating their oocytes for research.

Genetic Research for Future Medicines and Treatments

There are considerable efforts to develop medical treatments matched to the specific genetic characteristics of individual patients. This development has been termed "personalized medicine," although it has been long recognized that different people vary in their metabolic responses to the same medicine. Dosing variation in medicines has been standard practice since the 1950s, but what is novel is the link between genetic tests to profile an individual patient to more accurately prescribe specific drugs matched to individual patients. This process is further refining current patient stratification practices by the use of genetic tests to classify patients between those more susceptible to benefit from a particular intervention and those who are unlikely to benefit. As an example, the effectiveness of the drug Herceptin can be indicated by a test identifying the genetic pattern in some women. These have been termed "rational drugs" (Presidents' Council of Advisors of Science and Technology). Personalized medicine also aims to improve current clinical trial procedures of new drugs, especially at Phase II and Phase III stages. Genetic tests may better identify participants who should be excluded from trials as they are unlikely to benefit or may be harmed. This may reduce the number of patients to be recruited. In these ways, the time and cost for the completion of drug trials may be reduced substantially (Presidents' Council of Advisors of Science and Technology, 2008).

Ethical Issues in Human Genetics

Apart from the specific issues of embryo research discussed above, human genetics has attracted considerable bioethical debate. The issues of genetic privacy have been a prominent topic of debate and a subject of a major Australian Law Reform Commission Report (Essentially Yours Report, 96 of 2003). This report also considered genetic research, databases, employment, insurance and law enforcement in relation to human genetics. Genetic privacy was debated and legislation introduced, in the United States (*Genetic Information and Non-discrimination Act*, 2008). Secondly, there have been debates about the introduction of genetic tests and their potential discriminatory application in the workplace, insurance applications, and immigration. Genetic testing debates have also extended to discussion of growing trends for direct-to-customer (DTC) tests and their accuracy and use. Any wider

discussion of publically funded genetic testing would be dependent on evidence of cost benefit, utility, and effectiveness of these tests. Certainly, testing for late-onset conditions would require proper counseling support services to be available and screening of children limited to cases where it is clinically indicated or where some treatment regime is available. Thirdly, GM has involved, in some cases, cross transfer of human, animal, and plant genes. In heart surgery, for example, porcine and bovine tissue replacement heart valves have been used for humans with success. This form of *xenotransplantation* involves cellular and molecular transfer from one species to another and aims to provide a source of human body parts for transplantation. However, xenotransplantation is controversial, and a precautionary approach has been applied to the clinical application of these procedures. A precautionary approach has been taken to avoid risks to the individual patient through hyper-rejection of the GM transplant and to avoid risks to the population through the possibility of introducing animal viruses or new pathogens (xenozoonosis) into human beings. Efforts have been invested in relation to developing genetically modified animals as sources of parts for human transplantation. Regulation of some aspects of xenotransplantation and human genetics should be harmonized internationally. There is a possibility of "xeno-havens" developing in countries with lower standards of regulation. Fourthly, patenting is also an issue in human genetics. Patenting of the human genome attracted international attention in the early 1990s when the USA National Institutes of Health attempted patent partial gene sequences of unknown function. There were also a number of commercial companies involved in what was described as the "patent rush" to patent human gene sequences. The current view is that it is possible to patent gene sequences provided their function is known. Generally, there is a patent exemption for research, and this is generally included in legislation, including the *European Patent Convention*. As noted, there is a general practice for international consortia to release their data publically on open-access websites. Most recently, there has been international discussion on the growth of biobanks, which are essential tools for undertaking genetic research as well as the translation of research findings into clinical applications. Finally, "rights-based" approaches to bioethics have been immensely influential but may not sit comfortably with familial obligations in the context of human genetic information. Movements from rights to duties can be identified in the UNESCO *Declaration on the Human Genome and Human Rights* 2005 expressly referring to a notion of a "practice of solidarity" which states should respect and promote toward individuals, families, and population groups which are particularly vulnerable or affected by disease or disability of a genetic character.

Public Consultation, Engagement, and Trust

Genetic modification in plants, animals, and humans has been accompanied by widespread public comment and debate. Many countries conducted public consultation on GM development, and field trials are usually preceded by formal notification and opportunities for public comment. Apart from formal public consultation

on GM issues, there has been considerable academic research conducted in an attempt to identify public attitudes and opinions. The European Commission has undertaken systematic polling over nearly two decades, publishing annual reports under the title of *Europeans and Biotechnology*. These reports track the broad awareness, perceptions, and opinions in relation to biotechnology for food production (GM food and animal cloning) as well as emerging technologies of nanotechnology biofuels and synthetic technology. More recent reports have also started to track climate change. These reports also track the knowledge of and attitudes toward biobanks and their governance. These reports are rich sources of information about the EU and do not cover the Americas, India, China, or the third world, which have been more receptive, for example, to GM crop plantings. *The Europeans and Biotechnology* has generally supported biotechnology in the areas of medicine, regenerative medicine, and healthcare generally, including genetic tests to identify diseases. There has been less enthusiasm for applications to crops for human consumption. There has also been continuing support to develop GM bacteria to clean pollution. There has been widespread acceptance that the developments of biotechnology in general and GM in particular require public acceptance and trust. Public consultation and engagement enables levels of trust to be investigated.

The EU-based surveys are aligned with surveys in other parts of the world and academic research that public trust is a major component of GM and that public consultation and engagement are important processes in the development in GM, its regulation, and application. In addition, risk assessment processes require public consultation and engagement.

Conclusion

The challenges posed by GM technologies and the scientific research involved are essentially how society is to harness the promise of potential benefits of the technology or research and at the same time minimize or avoid the threat of possible risks from GM. These challenges transcend national boundaries. GM has also transcended the technical scientific aspects and has significant ethical, legal, and social issues, including safety, privacy, and accountability. It is highly desirable that these core international issues should be governed by the same or at least closely harmonized international regulations and standards, including administrative controls, enforceable and voluntary guidelines, and review structures (such as research ethics committees and national bioethics bodies) that apply principles consistent with developing international norms.

The GM horizon has benefited OECD and developed nations. Although there have been significant uptakes in GM crops in many developing nations, the financial benefits have flowed, mainly to developed nations. There is the need for a more equitable distribution of the benefits from the GM knowledge value… The gap between rich and poor nations is widening at an increasing pace. The promise of GM and human genetics "…carries with it extraordinary responsibilities. It is incumbent on both scientists and public servants to ensure that science serves humanity

always, and never the other way round" (Clinton, 1998). The costs involved in many of the developments and applications of this technology may lead inevitably to exclusion of the poor and needy from access to the products. The United Nations Economic and Social Council echoed this view and stated that ". . .[t]here is a general recognition of the need for international cooperation in order to ensure that mankind as a whole, benefits from the life sciences and to prevent them from being used for any purpose other than the good of mankind."

There is a continuing challenge in GM research and development to strike an appropriate balance between the value of scientific freedom and the protection and safety of individuals and the environment. There is also a further continuing challenge of recognizing that science is not purely technical nor value neutral but involves profound ethical, legal, and social issues.

Human Cloning

41

Toivo Maimets and Kristi Lõuk

Introduction

The word "cloning" comes from a Greek word "κλών" (twig) and refers to the agricultural process where a new plant is generated from a twig. Through this asexual multiplication, genetically identical plants can be produced.

"Human reproductive cloning" describes the creation of a human embryo from nuclear DNA sequence of an existing human being in order to implant it into a womb, leading eventually to the birth of an identical human being. The meaning of the word "identical" here is different from that in cloning plants and is even not scientifically entirely correct: to get an identical organism, one also has to copy all the developmental processes involved, in addition to the DNA resource. The long development time of mammals in the mother organism before birth, when many micro- and macroenvironmental effects not directly caused by its own DNA sequence influence the future "outcome," creates a substantial difference between processes of cloning plants and "cloning" mammals. Even monozygous twins are not entirely identical, although they share the same DNA sequence and have passed through a very similar pre-birth developmental environment. However, the term "human reproductive cloning" has been deeply engrained in global discourse and already features in a number of national legislations and international documents and should therefore be kept in use, at least for the time being.

Several sources also use the term "human therapeutic cloning," or, synonymously, "research cloning," the definition of which is rather vague and unclear. It seems that instead of clearly defining it, the term has been used to distinguish "good" from "bad" cloning. It therefore has created a lot of confusion in ethical and legal debates, and, as has been noted by the UNESCO International Bioethics Committee (IBC) *Report on Human Cloning and International Governance* (2009):

"The terminology used in the bioethical debates is misleading and does not adequately describe the technical procedures used (or potentially to be used) today" (p. 7). More specifically, it adds that: "While 'reproductive' is a term that clearly indicates the ultimate intention of the procedure, the term 'therapeutic' fails to clearly define the purpose of the procedure. . ." (p. 6). Therefore defining and, indeed, using the term "therapeutic cloning" is avoided further in this chapter.

Since the birth of the first mammal clone – Dolly the sheep (Wilmut et al., 1997), the issue of human reproductive cloning and the appropriate international system of governance have been triggering off profound reflection and debates at national and international levels, including within the United Nations system. A number of norms have been elaborated at the international and regional levels, which address directly or indirectly the issue of human cloning. Although several attempts have been undertaken to achieve an international ban of human reproductive cloning, this result has not been achieved yet. Therefore, it is possible today to carry on this work in many countries of the world (mostly in underdeveloped countries), which have not introduced the ban. The UN Declarations are not legally binding to the member states, and achieving a consensus for a UN Convention has not been possible so far.

In this chapter, the scientific developments over the last two decades which have created new technical possibilities for human reproductive cloning and an acute need for new ethical and legal reflections on these issues are analyzed. Then the arguments for and against the use of human reproductive cloning are presented. In the last part, the national and international actions (at the level of United Nations and UNESCO) to regulate and govern the issue of human reproductive cloning are described.

Methods for Reproductive Cloning

Embryo Splitting

The first method to clone human embryos was embryo splitting, which was used for human embryos by Jerry Hall and colleagues in 1993 (Kolberg, 1993). Using micromanipulation techniques, it is possible to separate some cells from the early phase embryo, and by injecting them into "empty" natural *zona pellucida* (or an artificial one), recipients achieve normal development of an identical organism. Basically, one can split an embryo even into more than two, whereas genetically identical individuals develop from each portion in the same way that identical (monozygous) twins are formed in nature. This technique has been used to successfully clone embryos and animals.

Tetraploid Complementation

Tetraploid complementation is a technique where two mammalian embryos are combined to form a new embryo (Kaufman & Webb, 1990). Normal mammalian somatic cells are diploid: each chromosome is present in duplicate. The assay starts

with producing a tetraploid cell in which every chromosome exists fourfold. This is done by taking an embryo at the two-cell stage and fusing the two cells by applying an electrical current. The resulting tetraploid cell will continue to divide, and all daughter cells will also be tetraploid. Such a tetraploid embryo can develop normally to the blastocyst stage (an early stage embryo with about 100 cells) and will implant in the wall of the uterus. The tetraploid cells can form the extraembryonic tissue (placenta, etc.) but usually not the tissues of the fetus.

In the tetraploid complementation assay, one now combines such a tetraploid embryo with normal diploid embryonic stem cells (ES) from a different organism. This can be achieved either by direct injection of ES cells into tetraploid embryos or aggregation of ES cells with 4-cell stage tetraploid embryo. ES cells are pluripotent, meaning they are able to produce (through proliferation and differentiation) all cell types of the future organism. The embryo will then develop normally; the fetus is exclusively derived from the ES cells, while the extraembryonic tissues are derived from the tetraploid cells.

Somatic Cell Nuclear Transfer (SCNT)

Somatic cell nuclear transfer (SCNT) is a technique for creating a clonal embryo using an egg cell with a donor nucleus. The nucleus (which contains the organism's DNA, except mitochondrial DNA) of a somatic cell is removed and the rest of the cell discarded. At the same time, the nucleus of an egg cell is removed. The nucleus of the somatic cell is then injected into the enucleated egg cell. Alternatively, the entire donor cell may be fused (using electrical current or chemicals) with the enucleated egg cell. After being inserted into the egg, the somatic cell nucleus is reprogrammed by the egg cell. The egg, now containing the nucleus of a somatic cell, is stimulated to divide. After mitotic divisions in culture, this single cell forms a blastocyst with almost identical DNA to the original organism. The difference from the original organism remains in the content of mitochondrial DNA. Mitochondria are cellular organelles located in cell cytoplasm and carrying their own DNA. Hence, mitochondrial DNA in the new organism comes not from a donor of the nucleus, but from the enucleated egg cell. The technique of transferring a nucleus from a somatic cell into an egg was used to produce Dolly the sheep. The same technique has now been successfully used to clone many animals, including primates. The first SCNT clone of humans was reported recently, although it needed triploid chromosomes (two sets from donor nucleus and one from oocyte) to fully develop into blastocyst and pluripotent ES cells (Noggle et al., 2011).

Induced Pluripotent Cells (iPS): Generation of Embryonic Stem Cell-like Cells

Induced pluripotent stem cells, commonly abbreviated as iPS cells or iPSCs, are a type of pluripotent cells artificially derived from a non-pluripotent cell, typically

an adult or neonatal somatic cell, by inducing a "forced" expression of specific genes. iPSCs were first produced in 2006 from mouse cells and in 2007 from human cells. This has been cited as an important advance in stem cell research, as it may allow researchers to obtain pluripotent stem cells, which are important in research and potentially have therapeutic uses, without the controversial use of embryos. Because iPSCs are developed from the patient's own somatic cells, it was believed that treatment of iPSCs would avoid any immunogenic responses; however, recently this assumption has been challenged (Zhao et al., 2011).

In many aspects, iPS cells are similar to natural stem cells, such as ES cells, but the full extent of this similarity is still under study. Differences between iPS- and blastocyst-derived embryonic stem cells have been reported for gene expression, DNA methylation, and differentiation potential. In addition, reprogramming to iPS cells seems to compromise genomic integrity, introducing de novo mutations and copy number variations.

Since the development of iPS cells, the ethical and legal debates over human reproductive cloning have entered the "post-SCNT era." Until that, the ethical center of the issue was the moral status of human embryo. The destruction of an existing embryo, which was unavoidable for SCNT, was ethically unacceptable for those who believe that human life begins from the moment of conception. It is now possible to use tetraploid complementation and iPS techniques to create new organisms from somatic cells of existing persons turning them first back to the embryonic stem cell stage. Moreover, direct derivation of human sperm cells using iPS technology has been described recently (Yao et al., 2011), and attempts to create mammalian oocytes (Imamura et al., 2010) are in the way. Therefore, the destruction of an existing embryo may be not needed any more for human reproductive cloning. These developments have not, however, ended the ethical debates over the issue (see below).

From the description of these laboratory techniques, which have been tremendously advanced over the last decade, one can make two conclusions important in the context of ethical and legal discussion over human reproductive cloning. First, SCNT is not the only possible method for human cloning – several other techniques are existing and upcoming. Second, there are alternative methods of mammalian reproductive cloning, which do not require destruction of any existing embryos.

Arguments Supporting and Opposing Human Cloning

By using the SCNT technique, the new individual roughly copies the genome (nuclear DNA) of the donor and is not a combined product of two parental genomes, which is the case in regular sexual reproduction. It has been pointed out (Häyry, 2003) that part of the opposition to human cloning has been created by misconceptions about the procedure. The popular belief is that through this process the copies of existing human beings are created. This is not so. "Genetically speaking, it comes very close to creating a later identical twin to an already existing individual. Socially and psychologically speaking, it produces an entirely new individual,

whose biological features just happen to be quite similar to somebody else's" (Häyry, 2003, p. 449).

Sören Holm indicates that the problem is in widely believed genetic essentialism, a concept that a person's character is wholly determined by genes, and in the fact that popular media amplifies this misconception (Holm, 1998).

Following is an overview of the main arguments used in the human reproductive cloning debate.

Arguments Used in Favor of Human Cloning

Reproductive Freedom

This includes not only the familiar right to choose not to reproduce (e.g., by using contraceptives or abortion) but also the right to reproduce. The right to reproductive freedom should therefore include various artificial reproductive technologies, such as *in vitro* fertilization (IVF), surrogacy, or cloning (Brock, 2001). Brock is of the opinion that "the reproductive right relevant to human cloning is a negative right, that is, a right to use assisted reproductive technologies without interference by the government or others when made available by a willing provider" (Brock, 2001, p. 95). "The case for permitting the use of a particular means of reproduction is strongest, however, when that means is necessary for particular individuals to be able to procreate at all" (Brock, 2001, p. 96). Takala underlines that the right to start a family is one of the internationally acclaimed human rights. However, it is not always clear who possesses the right to reproduce – this notion has been interpreted in different ways (Takala, 2005). For example, due to developments in iPS technology it could soon be possible for couples of the same sex to have offspring. Takala also points out that there is no general positive right for everyone to have children, but is of the opinion that in the modern world the right to reproduce has been seen as a liberty right, and therefore it would be plausible to argue that there is no public duty to fund research on human cloning, but nobody should interfere with privately funded attempts to clone humans. Havstad has recently pointed out that commitment to autonomy simultaneously creates an obligation to limit that right appropriately (Havstad, 2010).

Norman Daniels and Dan W. Brock show that there are three main interests and values determining the moral importance of reproductive autonomy. These are self-determination, the contribution to individual good or well-being, and the principle of equality (Buchanan et al., 2001). The interest in self-determination stems from the desire to make decisions about one's life. Such decisions should be based on the values and concepts of good life that one follows and be respected by others. Daniels and Brock specify that the realization of reproductive autonomy means the creation of a new person and the possibility to choose what kind of children one wishes for.

According to Onora O'Neill, the reproductive choice, being important to people, should not be seen as a freedom of expression. She finds that ideals of personal autonomy or self-expression are not good starting points for thinking about

reproduction because the aim of reproduction is to create a dependent being and "reproductive decisions are irresponsible unless those who make them can reasonably offer adequate and lasting care and support for the hoped-for child" (O'Neill, 2002). She is also concerned about confused relationships created through reproductive cloning. No responsible parent, she argues, would want to put a lifelong additional burden of confused relationships on their child. O'Neill finds that a possible solution to this problem would be cloning from the child of the same couple or using oocytes and sperms (genetic material) from strangers. At the same time, Takala has claimed that due to changes in family life, the traditional model with two parents of opposite sexes and their own genetic offspring is outdated. She is of the opinion that "it is the socio-political atmosphere that determines how these methods, and in the future possibly cloning, are used and not the technology that determines the socio-political views" (Takala, 2005). Due to the well-known fact that moral acts are acts in the interest of others, there should be a limit for egoism and self-love in order for the society to be able to function. This means that it is difficult to condone the use of cloning when there are realizable, safer, and simpler methods for reproductive choices. Holm adds that as long as genetic determinism prevails, cloning should not be permitted (1998). There is a real threat that expectations will not be fulfilled and the result would be hard to endure. Indeed, many experiments with cloned animals have shown that the "clones" can differ considerably in both character and appearance. It is important that we set the position of the future possibly cloned human being in the center of the discussions concerning human reproductive cloning. This should help us to better understand the possible negative impacts, such as how life in shadow (Holm) and constant psychological harm (Havstad) may impact the cloned human being.

Relief to the Problem of Infertility

Cloning would allow infertile persons/couples to have biologically related offspring. This purpose of reproductive cloning has been pointed out by the President's Council on Bioethics (PCB, 2002, p. 79). Typical situations in this case would be women producing no functional ova or men producing no sperm (Brock, 2001). Recent work mentioned above provides new solutions to male infertility through the use of iPS cells (Yao et al., 2011). "While the moral right to reproductive freedom creates a presumption that individuals should be free to choose the means of reproduction that best serves their interests and desires, the benefits from human cloning to relieve infertility are greater the more persons there are who cannot overcome their infertility by any other means acceptable to them" (Brock, 2001, p. 98). Although there are other possible solutions, e.g., adoption, it is important for many to be biologically related to the child. It is possible to have a biologically related child with other forms of assisted reproduction. That said, according to Brock, cloning could be accepted only if it is the only means to overcome infertility. The counterargument would be that this is a temporary solution, as the biologically related child may also have fertility problems. Which raises the question of what should be more important – biological ties or the health and quality of the child's life?

Cloning Avoids the Transmission of Diseases

If one partner has a risk of transmitting a serious hereditary disease, cloning could be used in order to avoid the transmission. The avoidance is also possible using other methods than human cloning, but these might be not acceptable as they involve genes from a third party (Brock, 2001). Takala has pointed out the possibility of human cloning to avoid certain mitochondrial diseases (2005). The purpose of avoiding genetic disease is mentioned as one of the main purposes for reproductive cloning also by the Report of the President's Council on Bioethics (PCB, 2002, p. 79).

Cloning Provides Organs and Tissues Necessary for Transplantation

Cloning would solve the problem of finding a donor with matching tissue or acceptable organ. The purpose of obtaining "reject-proof" transplants is also mentioned by the President's Council on Bioethics (PCB, 2002, p. 79). However, if cloning takes place with the sole purpose of saving another human being, this could be criticized based on the categorical imperative by Immanuel Kant. The second formula of the categorical imperative reads: "Act in such a way that you treat humanity, whether in your own person or in the person of another, always as the same time as an end and never simply as a means" (Kant, 1994, p. 36). Brock has, however, indicated that the problem here is more complex, asking why it is considered acceptable to have children with the purpose of not being alone or receiving financial assistance from the state (Brock, 2001).

"Bringing Back" People with Special Meaning

Classical example is the case when parents have lost their child. Parents should, however, take into account that the new child will not replace the lost one, that despite the same genes, this is a new child. Cloning would help to deal with the loss and go on with their lives (Brock, 2001). To "replicate" a loved one is a purpose of human reproductive cloning mentioned by the President's Council on Bioethics (PCB, 2002, p. 80). This argument also triggers the accusation of treating people merely as means, especially when the cloned person is not treated as a person of his/her own, but as a recreation of someone else. Takala brings to our focus that if one does not believe in genetic determinism and instead thinks that a person's uniqueness is a sum of different factors, many of which are nongenetic, then the aim of bringing someone back is wrong as it cannot be done (Takala, 2005). Murray adds that even if cloning would become safe and result in a healthy embryo, the outcome would not be the same person, whose genetic material was used. Moreover, there are no technological solutions to grief: cloning a deceased loved one is not the escape, as science cannot reincarnate the dead (Murray, 2009).

"Bringing Back" People with Great Talents, Character, or Other Qualities

Once again, one should not be fooled by genetic determinism stating that only the genes determine who a person is or what he or she is capable of. Take a hypothetical case of cloning Michael Jordan or Andrew Lloyd Webber (the names of the persons

are changed compared to those used by Dan W. Brock). One should take into account that although persons with great talent may be indeed created, it is not clear how similar they would be in capacities and accomplishments to the ones they were cloned from. The hope for exceptional accomplishment due to cloning is considered to be a reasonable ground for doing so (Brock, 2001). The report of the President's Council on Bioethics also mentions the purpose "to produce individuals of great genius, talent or beauty" (PCB, 2002, p. 80). However, the cloned Michael Jordan might have no interest in playing basketball and become an accountant instead. We should not forget that what made Michael Jordan great was "not merely his physical gifts, but his competitive fire, his determination, his fierce will to win" (Murray, 2009, p. 663).

Arguments Used Against Human Cloning

Human Dignity Objection

UNESCO Universal Declaration on the Human Genome and Human Rights states in article 11 that "practices which are contrary to human dignity, such as reproductive cloning of human beings, shall not be permitted" (UNESCO, 1997). According to the UNU-IAS Report, "the concept of dignity is inherent in foundational UN texts that were written at the end of the World War II when there was political unanimity that abuses of war were against human dignity, and it was accepted that everyone knew what was meant" (Kuppuswamy et al., 2007, p. 9). The report also stresses the need to be clear about the elements of the debate. Careful attention should be paid to understand "whether opposition to cloning stems from concern for human dignity or respect for divine dignity" (Kuppuswamy et al., 2007, p. 11). Takala points out that it is often uncertain what human dignity actually is. According to her "dignity seems to be something that is given to humans by humans" and "dignity could be interpreted to lie in God's perception of us" (Takala, 2005 p. 55). Haugen writes that "the notions of human dignity have been nurtured in the natural law tradition, and subsequently confirmed and developed through the social teaching of the Catholic Church" (Haugen, 2010, p. 207) and that when clarifying the concept, it would be natural to refer to Catholic social ethics.

The Report of the President's Council also has a human dignity objection. The Council states that "Parents beget a child who enters the world exactly as they did – as an unmade gift, not as a product. Children born of this process stand equally beside their progenitors as fellow human beings, not beneath them as made objects. In this way, the uncontrolled beginnings of human procreation endow each new generation and each new individual with the dignity and freedom enjoyed by all who came before" (PCB, 2002, p. 105–106). This has also been mentioned as the "lessening the worth of an individual and respect for human life" objection in the literature. Returning to the wording used in the PCB report, this seems to indicate that begetting creates a child, but by cloning one obtains a made object, a product. This is seen as a violation of Kant's categorical imperative never to treat others merely as means to our ends (the humanity principle). It has been questioned

whether this is a fair objection, (e.g., Steinbock, 2009, p. 659). She is of the opinion that if the technology of cloning were safe, then the cloned child would not be a thing or object but a human being with human dignity, with the same human dignity as any other. It should be noted that what makes a child a product is designing the child (e.g., parents wanting a specific genome). Steinbock finds the idea that human cloning or reproductive technologies can violate human dignity puzzling. She explains that if dignity means acting with formal, grave, and noble bearing, then this sense of dignity has not much to do with the issues of reproduction. Dignity could also be understood in the Kantian sense as a requirement for respect for persons, that people should not be tortured, humiliated, or exploited. Steinbock finds that none of these concepts have anything to do with the ways how children are brought into the world.

According to Takala, it is debatable whether cloning violates the humanity principle any more than any other act of reproduction. She finds that in philosophical literature, arguments derived from the concept of human dignity are inseparable from the idea that we should not treat people as mere means. Takala is of the opinion that if the purpose of reproductive cloning is to "bring back a lost loved one" (Takala, 2005, p. 57) and the person will be treated not as a person of his/her own, then this would constitute treating him/her as a mere means and, therefore, a violation of the humanity principle.

The usage of the notion has raised much criticism. For instance, Ruth Macklin has claimed that dignity is a useless concept and that it means no more than respect for persons or their autonomy (Macklin, 2003). Ashcroft is of the opinion that "it is not immediately obvious whether dignity is something that admits of degrees, whether it is alienable or not from its possessor, whether an assault on dignity or a bearer of dignity is something that destroys dignity or whether it is a sort of insult to dignity" (Ashcroft, 2005, p. 679). Häyry is of the opinion that one cannot settle ethical disputes by stating that something is against human dignity. He gives five interpretations of the concept of dignity and shows that each yields different moral norms. These are the dignity of God, the dignity of reason, the dignity of genes, the dignity of sentient beings, and the dignity of important beings (Häyry, 2003).

Caulfield shows that international instruments rarely provide an operational definition of human dignity, and it is rarely explained whose dignity is infringed in the context of human reproductive cloning (Caulfield, 2003). He stresses that if human dignity is used as a blanket argument against human cloning, then it is much more difficult to reflect about the real risks and benefits. Caulfield and Brownsword are of the opinion that the use of the blanket justification of human dignity marks a departure from the traditional human-rights informed view of human dignity (which is to a large degree manifested in a respect for individual autonomy and self-determination) that has dominated bioethics debates for decades and that the policy-making role of human dignity becomes more questionable when it is used as a form of general condemnation (Caulfield & Brownsword, 2006). They are of the opinion that in a pluralistic society, the possibility should exist to debate all aspects that form the content of human dignity, and that without conceptual clarity, there is a danger that the notion will turn into a rhetorical slogan.

Right to Open Future/Life in Shadow

A cloned person would know or believes he/she knows too much about him/herself. The choices that the earlier person has made would always be present. This might cause the impression that the life has already been lived and determined so that the later person does not have the opportunity to make his/her own choices that would create his/her future (Brock, 2001). Holm points out that if the parents of the clone have a definite picture of how the clone will develop based on the development of the person who was cloned, this will have an impact on how the child will be raised. Whatever the cloned person does, his/her actions will be compared to the ones of the original, so there is no possibility for self-determination and for living one's life the way one wants to live it (Holm, 1998). Takala brings out the "life in shadow" argument: as long as people see clones as shadows of the originals, there is something wrong with human cloning (Takala, 2005). She suggests that a possible way to counter these problems would be to apply the right of genetic ignorance. This is a negative right, meaning that "the right-holder has no duty to know about her own genetic makeup, and that others have a duty not to inform her (against her own wishes). A right like this does not, however, obligate others to actively protect her from the information" (Takala, 2005, p. 62).

Psychological Distress and Harm to the Later Person

Knowing the choices already made by the earlier twin will cause psychological stress and harm, because the later twin may feel that his/her autonomy and freedom are diminished. Adding to it the knowledge of lack of individual uniqueness, the burden of the later twin is even higher. However, this should not be taken as a suggestion that it would be better not to exist at all, which is the only way to avoid these stressful circumstances and psychological harms (Brock, 2001). Holm argues that this harm can be avoided if all clones were adopted anonymously, so there would be no knowledge available to the social parents about the original. He is, however, skeptical about this argument because cloning is attractive to many exactly because of the idealized belief of recreating oneself (Holm, 1998). Havstad's objection to cloning is the threat of psychological harms to clones. These harms could result if the clones were forced to live the lives of those they were cloned from, thus violating their self-determination (Havstad, 2010).

Unacceptable Health Risks to the Clone

The success rate of cloning Dolly the sheep was frustratingly low, less than 1 %, and it has not been considerably improved since then. Clearly, additional animal research should be carried out before one could approve the use of this technique on humans. It is questionable how to make sure that the process of cloning humans is safe and effective and whether the procedure will ever be safe and effective enough to meet the criteria of ethical standards (Brock, 2001). The report of the President's Council on Bioethics "Human Cloning and Human Dignity: Ethical Inquiry" elaborates on the topic of the ethics of human experimentation and details the problems of safety: for the child, the egg donor, and the birth mother (PCB, 2002, p. 87–99). The problem of safety is not a temporary ethical concern, but it is

not an objection to cloning as such (PCB, 2002, p. 96). Takala also argues that in terms of research ethics, research into human cloning cannot be justified because this technique cannot be tested on other mammals due to different reactions in practice. At the same time, no ethics committee would allow controlled trials on human cloning extending after the birth of the cloned person (Takala, 2005). The UNU-IAS Report points out that serious safety concerns apply to reproductive cloning. These are "the current immature state of cloning technology, the possibility of mutations, potential physical harm and general long term health risks" (Kuppuswamy et al., 2007, p. 13).

Human Cloning Would Divert Resources from More Important Medical Needs

The number of cases, where cloning would meet human needs, is relatively limited. Therefore, public funds should not be used to support human cloning and spent for other more pressing medical needs. After all, it is not known how expensive human cloning would be, especially in comparison with other methods to relieve infertility (Brock, 2001). Also it has been argued that funds for human cloning research could be used for more pressing issues such as infant mortality and diseases, e.g., HIV/AIDS (Kuppuswamy et al., 2007, p. 13).

Effect on the Human Gene Pool

Cloning could reduce genetic diversity and hence our capacity to adapt to new environmental conditions. Brock does not consider this to be a realistic concern because human cloning would not be used on a wide enough scale, as people would prefer sexual means of reproduction and maintaining their own biological ties (Brock, 2001). Takala is of the same opinion that cloning would not threaten the human gene pool even if it one day became an acceptable method of reproduction (Takala, 2005). If new developments make it possible to use combined genetic material from both parents, this argument loses its strength even more. This argument can also be seen as a part of the human dignity argument against cloning, as according to the Universal Declaration on Human Genome and Human Rights "human biological diversity is considered a fundamental part of human natural heritage, and diversity is recognized as part of the concept of human dignity" (Kuppuswamy et al., 2007, p. 12).

Moral Status

On the top of the arguments described above, one also has to discuss the issue of moral status. According to Warren (Warren, 2000), to have a moral status means to be morally considerable, or to have a moral standing. Moral agents have moral obligations toward such entities. This means that it is not possible to act or treat them as one pleases, but there is a moral obligation to take into account their needs, interests, and well-being as they have moral importance in their own right. Protecting these entities might benefit us or others, but this is secondary compared to the moral obligation (Warren, 2000).

Warren emphasizes that we need the concept of moral status to establish the entities, objects, and phenomena toward which we have moral obligations. She proposes the idea of many types of moral status, which come in varying degrees of strength. According to Warren, moral agents, sentient human beings who are not moral agents, sentient nonhuman animals, and non-sentient living things – all have legitimate claims to moral consideration. It is to be noted that of all these entities with which we interact, only moral agents have full moral status (based solely upon their mental and behavioral capacities). The rest have moral status, which is partially determined by their social and other relationships to moral agents (Warren, 2000).

However, the concept of moral status does not answer all the questions about the duties of human beings. Many of our duties are not dependent on the moral status of the persons toward whom we have an obligation but also on particular circumstances, e.g., earlier promises, personal connections, a new penal code, or previous wrongdoings, which imply that the harm needs to be compensated.

The concept of moral status represents only very general claims about how moral agents ought to behave toward entities of a particular sort. For example, by postulating that all human beings have a moral right to life and liberty, a claim is made that the moral status of human beings forbids harming them in certain ways if there is no good reason for it. Most interpretations also include the obligation to help in case of need and if there is no risk to oneself. An important feature of the concept of moral status is its generalness – moral status is not ascribed to specific individuals but to members of a group (Warren, 2000).

There are two main reasons why human beings need shared standards and principles of moral status that are based on arguments that most of them can understand and accept. The first is the capacity to do harm (in considerable amount and with the aid of technological advances), and the second is the capacity to care about other living beings (both human and nonhuman) (Warren, 2000).

The latter aspect shows that using merely exterior sanctions, one cannot assure moral actions. This is a notion that values interior sanctions and the inner motivation to be a moral actor. From the positive side, the concept of moral status is a tool, which allows expanding the minimum standards of acceptable behavior. Following lower standards than the minimum is not acceptable. Although one usually does not doubt the equal and full moral status of all human beings, if the focus is on embryos, embryonic stem cells, or induced pluripotent stem cells, there seems to be much less consensus.

It has been shown that if the argument remains at the level of the moral status of the embryo, there are different arguments and opinions (for instance, see the report of President's Council on Bioethics (PCB, 2002, p. 133–149)) and no room for achieving common ground and understanding. As reproductive cloning may become possible without using embryos, the focus here is on iPS cells. The technological developments that led to the production of iPS cells have been seen as an ethical breakthrough: the iPS cells enable the production of human pluripotent stem cells without the need for human oocytes. According to Chan and Harris, the anti-embryo research lobbyers have welcomed iPS cells as a source of "ethical stem

cells," in contrast to the so-called unethical human embryonic stem cells (Chan & Harris, 2008). Hyun draws our attention to the understanding that human iPS cells, if they are truly pluripotent, should be capable of generating also human sex cells. This would mean that ordinary skin cells could be transformed into human sperm and eggs, and this fact could radically alter our common sense notions of human fertility and infertility (Hyun, 2008).

Chan and Harris (2008) argue that it is incorrect to assume that derivation of stem cells without the destruction of embryos solves all the main ethical issues of stem cell research. The significance of the embryo as the starting point of human life and its status of moral relevance seem further threatened when any cell can be programmed to embryonic state. The situation, according to them, is ironic, as those who were concerned about the human embryo and its moral status, welcomed the new developments which may at the same time diminish its status. They elaborate on the status of skin cells reprogrammed to embryonic status and ask whether they are really embryos *in potentio*, just like an embryo is a person *in potentio*. The authors do not provide a direct answer to that, but they point out that those who value the embryo for its potentiality might feel obliged to value all cells that might be reprogrammable for the same reason. They suggest that this kind of thinking will lead to asking whether there is an obligation to release the potential contained in each cell by reprogramming them so that every skin cell can experience its future of value! Their own position is that human embryonic research is ethical as it takes place on embryos less than 14 days old. At that point, an embryo is not a subject of rights or interests and cannot be harmed. Based on analogy, we could draw the conclusion that reprogrammed skin cells cannot be hurt or harmed either.

According to Magill and Naeves, the scientific breakthrough of iPS cells raises a different ethical question: that of the philosophical meaning of cellular development in early human life. "The science of direct nuclear reprogramming may shed light on the ontological status of cells in the early stages of what could become a human foetus and thereby contribute to the justification of research in this controversial field" (Magill & Naeves, 2009, p. 24). Numerous cells in the human body have a biological capacity or natural potential, with appropriate help and supportive circumstances, to become a fetus and possibly be born as an individual person. "Because it is technologically possible to develop a foetus from reprogrammed human cells, the question of their ontological status arises with ensuing ethical implications for research. By ontological status we mean the assignment of either personal or potentially personal life in the sense of having full moral respect" (Magill & Naeves, 2009, p. 26).

Holm argues that no implications for the debate arise from the moral status of the embryo. He is of the opinion that nothing in these research results can affect the positions of the persons who believe they have good arguments for supporting their opinion, being it either that the embryo has no moral status at all or that it has considerable moral status. Holm draws the line between embryonic stem cells (artificially derived from an embryo) and the cells naturally inside a blastocyst. He is of the opinion that "it might mischievously be argued that the results show that every somatic cell is potentially an embryo, thereby constituting a *reductio* of

the moral status argument, because the methods allow the production of pluripotent cells from somatic cells, but the argument is fallacious" (Holm, 2008, p. 63). He stresses that it is important to understand that embryonic stem cells are cells derived from embryos, not embryo cells.

Baerschi and Mauron discuss a property called "reversed potency," i.e., the capability of somatic cells to return to a pluripotent state in a controlled way. This necessitates the reexamination of the role of the traditional concepts of potentiality and capability. Their understanding is that moral status must refer not only to intrinsic properties but also to extrinsic and relational properties (Baerschi & Mauron, 2010). If the focus is only on the intrinsic properties, then the conclusion we have to draw is that all somatic cells are potential persons. The role of relational properties is relevant because these properties affect the emergence of intrinsic properties important for moral status. Moral status of a cell emerges when a cell induced (reversed) to its pluripotency (or totipotency) is placed into uterus. Their understanding is that iPS cell does have a low moral status insofar as they are used in cell therapy in humans and not for producing humans by introducing them into human blastocysts (2010, p. 102).

In the following, the initiatives on both national and international (UN and UNESCO) levels to regulate and govern the issue of human reproductive cloning will be described.

National and Regional Regulations for Human Cloning

Numerous domestic laws and regulations that directly or indirectly prohibit practices that may lead to reproductive human cloning have been in place for many years. A detailed overview of the legislation as in 2009 is available as annex to the *Report of IBC on Human Cloning and International Governance* (IBC, 2009). These national regulations are diverse and reflect different cultural, religious, social, and political backgrounds of different countries. Together they constitute "general principles of international law" under article 38 (3) of the Statute of the International Court of Justice.

At regional level, the Council of Europe has approved *Additional Protocol to the Convention for the Protection of Human Rights and Dignity of the Human Being with regard to the Application of Biology and Medicine, on the Prohibition of Cloning Human Beings* (Council of Europe, 1998). As a convention, this instrument creates binding international law obligations, but only for those State parties that have signed or ratified it. Article 1 of the Additional Protocol enunciates that "any intervention seeking to create a human being genetically identical to another human being, whether living or dead, is prohibited"; and that "for the purpose of this article, the term human being 'genetically identical' to another human being means a human being sharing with another the same nuclear gene set." This definition is ambiguous because the commonly used method of reproductive cloning (SCNT) does not create genetically identical organisms: the content of mitochondrial DNA is different, and there are numerous epigenetic differences and those created by individual developmental processes (see above).

The above-mentioned national and regional regulations cannot be considered as sufficient in addressing the global challenges posed by the contemporary developments related to human cloning for the following reasons:

(a) The norms contained in these instruments pose clear conceptual problems: they are often mutually inconsistent, vague, and expressed in scientifically inaccurate terminology.
(b) The declarations do not constitute international legal obligations enforceable either by states or individuals.
(c) The existing instruments may have unintended consequences of either inhibiting socially valuable medical research or encouraging prohibited practices for profit.

Internal Governance of Human Cloning

The following regulatory acts for international governance of human cloning are in existence today:

Universal Declaration on the Human Genome and Human Rights (UNESCO, 1997). Article 11 of the Declaration states that "Practices which are contrary to human dignity, such as reproductive cloning of human beings, shall not be permitted. States and competent international organizations are invited to co-operate in identifying such practices and in taking, at national or international level, the measures necessary to ensure that the principles set out in this Declaration are respected."

Universal Declaration on Bioethics and Human Rights (UNESCO, 2005). Article 16 specifies that "the impact of life sciences on future generations, including on their genetic constitution, should be given due regard."

United Nations Declaration on Cloning (2005). The Declaration, adopted by the general assembly with a narrow margin (see below), states that "Member States are called upon to prohibit all forms of human cloning inasmuch as they are incompatible with human dignity and the protection of human life." On its face, this norm is broader in scope than that of the UNESCO Declaration (1997) and could cover forms of genetic research that are treated as fully legal by legislation in many domestic legal systems. Moreover, the wording of the document leaves room for very different interpretations of the text, which reflected, in part, the lines of division between different Member States on this issue. The main point of contention was the question of linking the issues of reproductive and nonreproductive cloning, which was not agreeable to many States, who abstained or voted against the Declaration.

World Health Organization Resolutions WHA50.37 (1997) and WHA51.10 (1998). These resolutions, which, again, do not create obligations under international law, call to "foster continued and informed debate and take appropriate steps, including legal and juridical measures, to prohibit cloning for the purpose of replicating human individuals."

In August 2001 in the United Nations General Assembly, the Permanent Missions of France and Germany requested the secretary-general to include

a supplementary item in the agenda of the 56th session entitled *International Convention against the Reproductive Cloning of Human Beings*. An international convention would be, after ratification, legally binding to the Member States. The German representative at the Sixth Committee (legal) of the General Assembly called for the mandate to be "focused, by narrowing down the issue to the cloning of human beings for reproductive purposes in order to win a speedy consensus that would deter irresponsible researchers."

At the same meeting, the observer from the Holy See, however, argued that action must also be taken to prohibit the production of human embryos as suppliers of specialized stem cells. He observed that in the view of the Holy See, embryos have a status equal to human beings, and therefore the destruction of innocent human beings for the purpose of collecting stem cells "constituted even more serious offences against human dignity and the right to life." The irreconcilable differences on the issue of many other forms of human embryo manipulation loosely defined as "research cloning" or "therapeutic cloning" and their linking to the issue of prohibition of human reproductive cloning accompanied all further discussions over this proposal from the French and German delegations.

Almost 4 years later, in the face of the political stalemate, members of the United Nations agreed to abandon efforts to put in place an international convention for the prohibition of human reproductive cloning. The Sixth Committee (legal) of the General Assembly was tasked with drafting a declaration rather than a convention.

The *United Nations Declaration on Human Cloning* was adopted on 8 March 2005 (A/RES/59/280). The Declaration was voted and passed with 84 countries supporting it, 34 countries voting against and 37 abstaining. The wording of the document left room for very different interpretations of the text, which reflected the lines of division between different Member States on this issue. The main point of contention was the question of linking the issues of reproductive and nonreproductive cloning, which was not agreeable to many States, who abstained and voted against the Declaration.

The journal *Nature Cell Biology*, in its editorial "Missed opportunity to ban reproductive cloning" (April 2005) wrote: "At a critical time, the UN has thus failed to send a clear message that human reproductive cloning is unacceptable. It is lamentable that this salient issue has fallen victim to a debate that is driven by political agenda and religion-infused ethics, rather than rational thinking that puts the patient's interests first" (p. 323).

In 2007, the United Nations University Institute of Advanced Studies (UNU-IAS) produced a report entitled *Is Human Reproductive Cloning Inevitable: Future Options for UN Governance*, which summarized up-to-date technical information on cloning, ethical issues accompanying it, and the state of the art of international governance of these issues, specifically analyzing the discussions during the 4 years of United Nations General Assembly debate leading to the voting on the United Nations Declaration of Human Cloning. The report expressed the view that further development of international governance would be needed and envisaged several options along this line. One of possible options to further develop international governance was identified by UNU-IAS as "UNESCO IBC takes up the issue of reproductive and

research cloning, in the context of resolution A/RES/59/280 and also in the context of the Universal Declaration on Bioethics and Human Rights, which was adopted by the General Conference of UNESCO on the 19th of October 2005."

After that, the director-general of the UNESCO expressed his wish that the examination of the UNU report be added as an agenda item for discussion by UNESCO International Bioethics Committee (IBC) at its session(s). At its meeting in January 2008, the Bureau of IBC therefore decided to include the discussion of the UNU report and the issue of human cloning and international governance to the work program of IBC for 2008–2009. The IBC Working Group chaired by professor Toivo Maimets was established, which presented their findings to the IBC. The mandate of the Working Group was ". . .to explore whether there is any scientific, social or political change that would justify a new initiative at the international level, rather than to initiate another ethical and scientific analysis of the issue of human cloning." As a result of their work, the Working Group identified several changes, which would indeed justify new initiatives in the international governance of human cloning:

1. There are new scientific developments, which make the need for international governance more urgent. On one hand, the construction of induced pluripotent stem (iPS) cells and their possible uses has created more technical possibilities for reproductive manipulation of human embryos and hence brings new problems into the debate. Since it has been demonstrated that functional germ cells may be created from embryonic stem cells, this raises the possibility of creating germ cells from somatic cells (via iPS cells) which further blurs the borders between different stages of human development and reproduction. On the other hand, it is clear to scientists that "cloning" in the sense of producing identical human beings is impossible because of differences in developmental and environmental conditions, epigenetic modifications of the DNA involved, etc. In addition, it is scientifically clear that in the current state of technology, reproductive cloning is associated with serious health risks for both women and fetuses.
2. During the last 3 years since the adoption of the United Nations Declaration on Human Cloning, the public sensitivity and awareness of the issues has increased, whereas the information and dissemination of the issues could be improved.
3. Several Member States have recently updated their national regulations of governance of human cloning and embryo research in general, and therefore there is more awareness and information among politicians in these countries.
4. The financing of human embryo research has considerably increased over recent years, whereas more and more multinational commercial private interest is being involved. This is accompanied by international traffic (both legal and illegal) of embryos, eggs, and stem cells.
5. If the argument remains at the level of the moral status of the embryo, there is no room for achieving consensus. Also, as detailed above, reproductive cloning may become possible without using embryos. So there is a clear need to move to ethics of international governance of cloning, where different countries can find agreement, e.g., a ban on reproductive cloning.

Based on these findings, the Working Group was of the position that the issues surrounding human reproductive cloning cannot be ignored, and therefore a focused international dialogue considering a binding instrument against reproductive cloning was needed.

In June 2009, the IBC approved a *Report of IBC on Human Cloning and International Governance*, which was also supported a month later by UNESCO Intergovernmental Bioethics Committee (IGBC).

The IBC agreed with most of the findings of the Working Group. In particular, the Report states that "While the technology required to give birth to a human being by cloning is not yet available, it could be developed in the near future and the existing international non-binding texts relevant to human cloning (i.e., the UNESCO Universal Declaration on the Human Genome and Human Rights of 1997 and the UN Declaration on Human Cloning of 2005) are not sufficient to prevent human reproductive cloning" (IBC, 2009, p. 7).

Proposed by the Working Group, an international ban or moratorium for human reproductive cloning did not, however, find unanimous support from the IBC, neither during the approval of this Report nor at its later 18th session in 2011. Therefore, we are still in a situation where there is no internationally binding regulation of human reproductive cloning, which leaves the doors open to different kinds of "medical tourism" and makes especially vulnerable less developed countries, which have not yet introduced their national regulations. At the same time, technical developments bringing in new possibilities for human cloning are emerging with considerable speed.

Conclusion

Scientific research and technical possibilities for human reproductive cloning have been rapidly developing over the last two decades, and the current progress is even more active. Here the analysis of the present status of these developments and the main arguments speaking for and against the use of human cloning is presented. The most common arguments used in the discussions in support of human cloning are the right to reproductive freedom and the possibility to provide organs and tissues necessary for transplantation. The most common arguments against human cloning are human dignity, psychological harm, and the "life in the shadow" argument. As the new technical developments have brought again to the debates the issue of moral status, the main positions of this topic were also outlined.

The vast majority of countries, which have regulated the issue in their legislation, have supported the arguments against of human reproductive cloning and, therefore, the ban of this activity. There are, however, many countries, especially less developed ones, who have not introduced this position in their laws, which makes them vulnerable to different types of "medical tourism." The international actions at the level of UN and UNESCO have so far been not successful and need to be continued further.

Immigrants and Displaced Persons

42

Lindsey N. Kingston and Christopher P. Morley

Introduction

Migration, whether that entails crossing an international border or fleeing to another part of the same country, often creates vulnerabilities that limit or deny the enjoyment of the human right to health. Even temporary migration may cut a person off from social systems, both formal and informal, which supported them and kept them healthy. Crossing international borders and entering a state where one is not a citizen will often lead to dramatically decreased levels of social support. This may be even more pronounced when a person is crossing a border for the long term (emigrating) and especially when they are moving to flee from violence, oppression, economic degradation, or other negative circumstances. While this vulnerability applies to a number of dimensions, certainly health is high among them. Although a "right to health" has been codified in international law, it is almost always the case that nation-states are ultimately the arbiters of international law (Gostin & Taylor, 2008). It is this fact that leaves those who are not clearly protected as members of a given society without full – or in some cases, any – ability to access the right to health. Migrants, including both those who cross international borders as well as those who are internally displaced across internal regions within a nation-state, are the focus of this entry.

The universal right to health has been identified and described as a right to "the highest attainable standard of health" that can reasonably be afforded, which includes not only a right to healthcare but to social and environmental precursors of health, such as clean food and water, housing, and security (Gostin, 2001;

Kingston, Cohen, & Morley, 2010). The right to health has been codified by international law, under Article 12 of the Universal Declaration of Human Rights (General Assembly of the United Nations, 1948). In general terms, the right to health has been posed as a fundamental issue of distributive justice, which Daniels and others have recognized as "special" in that it protects normal functioning and hence the range of opportunities open to individuals within a given society (Daniels, 2001; Daniels, Kennedy, & Kawachi, 2007; Green, 1983; Moskop, 1983). The focus on justice is particularly poignant when a consideration of the social determinants of health is taken into account, since it is generally true that the less well-off one is within a given context, the poorer one's health tends to be.

Enforcing such a right, however, has been empirically thorny. Within given societies, the argument often becomes one between those who view healthcare and other goods that are associated with health as commodities and those who view these items as public goods. However, most societies tend to provide at least some level of access to healthcare and do so within the parameters established by laws within given jurisdictions that apply principally to established members of the society (i.e., the citizens or otherwise-recognized permanent residents of a nation-state or other political entity). A distinct problem arises when people move across borders.

There are several categories of migrants that warrant consideration. An individual may cross an international border for a variety of reasons, and these reasons matter. A physician or an engineer who emigrates for more lucrative opportunities is certainly not in the same category as a person running from deprivation to a situation in another nation-state that is simply less desperate. Similarly, those who emigrate via documented (i.e., "legal") pathways are often in different empirical circumstances than those who do so "illegally." Economic refugees of any stripe are in many ways different than political or conflict-driven refugees, and the internally displaced person faces different challenges than the international border crosser.

Given these categorical differences as well as the disparity between the moral underpinnings of a right to health and the empirical ability to exercise or realize it, it is necessary to consider the empirical issues that arise in each category. The entry will begin by defining each category and describing the distinct challenges faced by each. The entry will then conclude with a summary discussion of the most pressing ethical issues posed by migrant rights to health and the lack of access many face to this right.

Characteristics

Defining the Right to Health

Article 25 of the 1948 Universal Declaration of Human Rights (UDHR) asserts that "everyone has the right to a standard of living adequate for the health and well-being of himself and his family," including medical care. Article 27 bolsters this

assertion with a statement that all people should "share in scientific advancement and its benefits." This foundation has been built upon since 1948 in a number of international agreements. In 1976, Article 12 of the International Covenant on Economic, Social and Cultural Rights (ICESR) recognized the right to the "highest attainable standard" of health, including the reduction of infant mortality as well as the prevention, treatment, and control of disease. More recently, the 2005 UNESCO Universal Declaration on Bioethics and Human Rights asserted a fundamental human right to "the enjoyment of the highest attainable standard of health," and that "access to quality health care and essential medicines" is required "because health is essential to life itself and must be considered to be a social and human good." Furthermore, the UNESCO Declaration argues that "the promotion of health and social development for their people is a central purpose of governments that all sectors of society share." Approaching health through a human rights frame, then, ultimately serves to elevate healthcare from a market commodity to a basic entitlement.

A central challenge for the protection of health rights is inequality, both at the international and national levels, and this challenge implicates the medical community. As Farmer has noted, "in arguing that health care is a human right, one signs on to a lifetime of work dedicated to erasing double standards for rich and poor. . . It has taken years for the sharp critiques voiced by the poor to begin to work their way into our medical journals and ethical codes." Farmer goes on to argue that "allowing 'market forces' to sculpt the outlines of modern medicine will mean that these unwelcome trends will continue until we are forced to conclude that even the practice of medicine can constitute a human rights abuse"(Farmer, 2003). The impacts of inequality – between the rich and poor, the marginalized and empowered – have become a matter of life and death in many cases, as biomedicine offers revolutionary new therapies that were impossible even a few decades ago. In a system which views health and healthcare as a market commodity, in which healthcare is distributed to those who can afford it, some of the individuals most in need of healthcare will have diminished access. As the following discussion will highlight, vulnerabilities related to migration often limit or deny people access to their right to the health.

Defining Migrant Categories

Immigrants fall into one of three principal legal status groups: naturalized citizens, legal permanent residents, and undocumented immigrants. The term *undocumented immigrants* refers to foreign-born people who reside in a country but are not legally recognized residents. These people are sometimes referred to as *unauthorized immigrants, illegal aliens*, or *illegal immigrants*. As immigration policies within Western countries continue to restrict and delay immigrants' ability to adjust their status, it is likely that undocumented immigration will increase. Many so-called "legal" immigrants, however, either become naturalized citizens in their new country or gain permanent residency status (e.g., procuring a "green card" in the United States) to remain in-country without transferring citizenship. What is

common among these three categories is the fact that immigrants tend to make a relatively autonomous decision to migrate.

On the other hand, a displaced person is someone who has been forced to leave their home, often because of war or the fear of persecution, in what is commonly referred to as *forced migration*. Displaced persons fall into one of two key categories: refugees and internally displaced persons (IDPs). A *refugee* is someone who has fled across international borders and is at risk for persecution or has already been a victim of persecution, in their country of origin. Refugees are protected by various international legal instruments, including the 1951 Convention Relating to the Status of Refugees. The United Nations High Commissioner for Refugees (UNHCR) identified 10.4 million "refugees of concern" in early 2011, with an additional 4.7 million registered refugees living in Palestinian camps throughout the Middle East (UN High Commissioner for Refugees). IDPs are those who have been forced to relocate within the borders of a sovereign state. Although IDPs technically do not migrate, they nevertheless often are cut off from the exercise of a right to health, either because they have left a region or district which administers the right or because the state in which they are trapped is ungovernable, in the grips or a civil conflict, or is otherwise beset by internal strife. In late 2010, the Internal Displacement Monitoring Centre (IDMC) estimated that 27.5 million people had been internally displaced by armed conflict, generalized violence, and human rights violations, an increase of about 400,000 people since the end of 2009 (Internal Displacement Monitoring Centre, 2011). This group is comprised of civilians, mostly women and children, who have been forced to abandon their homes mainly due to conflict and persecution.

In many ways, IDPs are in a worse position, qua rights claimants, than refugees who have crossed an international border. Unlike refugees, who cross state borders and are protected by a strong body of international law, IDPs are often unable to access safeguards and assistance despite having fled their homes for many of the same reasons. Legally, IDPs are under the protection of the state, even though their governments may be responsible for their flight or have proven incapable of helping civilians. The UNHCR notes that governments often view IDPs as enemies during times of civil conflict, and there are no international legal instruments to assist the displaced. General agreements such as the Geneva Convention are difficult to apply, and donors are often reluctant to intervene in domestic conflicts or offer sustained assistance. The UNHCR's Guiding Principles on Internal Displacement outline the rights of IDPs and the responsibilities of governments in accordance with international law, but the nonbinding document does not provide adequate enforcement provisions to be effective. While the refugee is endowed with the right to seek asylum and access assistance, an IDP lacks those options.

Health Challenges

Immigrants

International migration control is at the forefront of Western political debates, and growing anti-immigrant political ideology has resulted in formal obstacles to

immigrant access to health insurance. Within the United States, for example, recent policy changes such as the 1996 Personal Responsibility Work Opportunity Reconciliation Act (PRWORA or "welfare reform") have restricted immigrants' eligibility for federally funded services such as Medicaid, and many state legislatures are considering a record number of anti-immigrant measures that may further restrict immigrants' access to healthcare (Derose, Bahney, Lurie & Escarce, 2009). When President Barack Obama spoke to Congress and the public about his healthcare reform proposal in September 2009, he was sure to emphasize that the proposal would exclude undocumented migrants (thereby eliciting the now-famous "You lie!" interjection). Indeed, the Patient Protection and Affordability Care Act signed months later by Obama does not cover the near 11 million undocumented migrants in the United States (Galarneau, 2011).

Lack of health insurance, whether public or private, is a formal obstacle to health found within immigrant populations in Western countries. A recent pilot project in Montreal, Canada, suggests that access to healthcare is increasingly difficult for undocumented (and often uninsured) families and that this issue has become a national problem within Canada. Both healthcare workers and community organization workers alike reported that many, if not most, patients with "precarious" immigration status presenting with acute health crises had delayed seeking care. Consequences include shortcomings in treatment and poor follow-up for chronic conditions such as hypertension and diabetes, problems of access to treatment for tuberculosis and HIV, worsening mental health problems, and serious complications related to perinatal care (Rousseau et al., 2008). Evidence from the United States supports this trend, linking immigrants' lack of medical insurance with lower quality and quantity of medical care use and with morbidity for adults and children. Noncitizens and their children are less likely to have health insurance and a regular source of care, have lower use than the US born, and be less satisfied with healthcare and more likely to face discrimination when accessing medical services.

Ultimately, immigration status – whether someone is undocumented, naturalized, or a permanent resident – strongly affects access to health insurance or other coverage, especially in public programs. Noncitizens are the least likely to have employer-sponsored insurance, followed by naturalized citizens and the US born, and immigrants tend to work for employers that do not offer health insurance benefits (Derose et al., 2009). However, it is important to note that some undocumented immigrants do receive employer-based health insurance; The Migration Policy Institute estimated that in 2007, 59 % of undocumented adults in the USA had no insurance (four times the rate of US-born adults) while 55 % of their children were uninsured (Galarneau, 2011). In Denmark, for example, a study by Jensen and colleagues examined treatment of migrants by general practitioners and described how undocumented migrants face administrative barriers when trying to access healthcare, with lack of an insurance card limiting access to medical treatment. Respondents to the study explained that undocumented immigrants would not experience the same access to care as a native-born Dane or a regular immigrant and noted that immigrants without insurance cards were usually only treated in "very special circumstances," with most told to contact the emergency

room for treatment that would ordinarily occur in an outpatient primary care setting (Jensen et al., 2011, p. 4).

Following lack of health insurance, many immigrants also lack a regular source of healthcare. In the United States, adults 55 years or older with limited English proficiency are 1.86 times more likely lack a usual source of care than their English-speaking counterparts. Among young adults aged 19–29 years, noncitizens are 1.35 times more likely to report no regular source of care than US citizens. Trends are similar among immigrant children; noncitizen children and those with non-English-speaking parents are two to five times less likely than US-born children and children with English-speaking parents to have a usual source of care outside of the emergency department (Derose et al., 2009). Many undocumented immigrants who do receive health services receive them from "safety-net providers" such as community health centers, public health clinics, emergency departments, and outpatient clinics (Galarneau, 2011). In Denmark, undocumented immigrants do not appear on the National Register of Persons and are therefore unable to formally access general practitioners in the general healthcare system. Although foreign citizens have the right to access emergency services, undocumented immigrants lack access to regular sources of healthcare and are forced to settle for less treatment compared with that of native-born Danes. They have no formal access to further diagnostic facilities and very restricted possibilities of follow-up care, and medical conditions often worsen as immigrants delay treatment until they are ill or injured enough to seek out emergency treatment. Furthermore, undocumented immigrants often cannot access prenatal care, regular supplies of medication for chronic illnesses, and mental healthcare options (Jensen et al., 2011). The experiences of migrants seeking healthcare in the USA and Denmark, as described in the studies cited above, are generally representative of migrants globally and certainly in the health systems of most of the developed world.

In addition to these formal obstacles to health, immigrants also face a variety of informal obstacles such as language barriers. Within the United States, where there are currently few financing mechanisms for implementing national standards for culturally and linguistically appropriate services (Derose et al., 2009), adults with limited English proficiency are more likely than English-proficient speakers to report difficulties getting care, such as long waits and problems getting information or advice by telephone. Language barriers are often related to a substantial reduction in the odds of receiving mental health services. Again, in Denmark, health professionals note that language barriers pose problems for themselves and undocumented immigrants. Healthcare work is complicated when patients cannot describe their symptoms, creating difficulties for the physician and stress for the immigrant. As described by a health professional responding to the study by Jensen et al., "if [the patient] showed up, one would assume that he had an acute need, that he was in real pain, or he thought that it was life threatening. Not being able to get a proper explanation or have his worries interpreted would add to his anxiety and fear" (Jensen et al., 2011).

The foreign born are also more likely to report discrimination and lower quality of healthcare, particularly those with limited language proficiency or those who are

nonnative/majority. Such perceived discrimination discourages some from seeking medical attention or delays treatment. In the USA, parents with limited English skills are more likely than parents who speak English at home to report facing discrimination while seeking care for their children. Undocumented Latinos and those with a green card are more likely to feel that they would receive better care if they were a different race or ethnicity, as well. Perceived quality of care is another factor that sometimes impacts immigrants' access to health. The foreign-born often report lower quality healthcare than the US born, and immigrant respondents in both the United States and Canada have lower odds of reporting excellent quality of care. Immigrants also report dissatisfaction with how much their physician spent time with them or involved them in their own care. Latino and Asian immigrants are also less likely to indicate that their general and mental health services were helpful, compared to their US-born counterparts (Derose et al., 2009).

Other informal barriers to immigrant health involve health practitioners themselves, who struggle with issues related to compensation, referrals and continuing care, and police involvement. Again, the qualitative study of Danish general practitioners and emergency room physicians conducted by Jensen et al. reported that challenges for healthcare professionals could translate into obstacles for immigrant patients (Jensen et al., 2011). The majority of general practitioners, for instance, were uncertain whether they would provide treatment if a patient were unable to pay. In particular, physicians noted that problems would arise if they had to involve finances outside of their own practice, such as the use of laboratory facilities or prescription drugs. One general practitioner responding to the study described that she would refrain from referring undocumented immigrants because she would not be able to assess the financial consequences of this action. Others were hesitant to prescribe medicine for undocumented immigrants, since the patient may not wish to have the prescription made out in his/her own name or may be unable to purchase the prescription at a pharmacy. Finally, some practitioners were unsure about the legal implications of treating undocumented immigrants. Despite this uncertainty, however, the Danish interviewees expressed in general that they would not involve police or authorities to report an undocumented immigrant who contacted them for treatment. It is reasonable to assume, however, that fears of police involvement could keep some undocumented immigrants from seeking medical treatment.

Unsurprisingly, formal and informal obstacles often result in lower levels of healthcare use among immigrants. Existing literature suggests that noncitizens in the United States are less likely than citizens to seek emergency care, see a physician or a nurse, use mental health services, or have a dental visit. In terms of preventative care, immigrants and non-English speakers are less likely to receive cancer screening than the US born, with immigrants at highest risk of underuse. Other types of preventative care seem to follow similar patterns. Spanish-speaking Latinos are half as likely to receive the pneumococcal vaccine and endoscopy compared to US Whites, and foreign-born children (19–35 months old) had similar odds of having adequate vaccination coverage compared to US-born children (Derose et al., 2009).

Refugees

The health-related priorities of the United Nations High Commissioner for Refugees (UNHCR) highlight the most pressing challenges faced by refugees. Currently, the UNHCR provides public health and HIV programs to more than 10 million refugees and other "people of concern," with the aim of reducing mortality and morbidity while addressing root causes of public health concerns. According to a recent report, the UNHCR focuses on three issue areas in order to protect the health rights of refugees living in both camp and urban settings: (1) HIV/AIDS and reproductive care, (2) water, sanitation, and hygiene promotion (WASH), and (3) nutrition and food security. First, the UNHCR recognizes particular concerns related to HIV/AIDS and reproductive health due to instances of gender-based violence and the prevalence of sex work within some refugee communities. Key protection concerns include the need for HIV testing and counseling, which often requires special guidance for medical professionals and patients alike in areas where stigma and discrimination against HIV patients are high. The UNHCR continues to strengthen linkages between reproductive health services and HIV prevention, including offering information to new mothers on issues such as breast feeding and HIV exposure. Health professionals are also encouraged to offer post-rape services, and the number of rape survivors having access to postexposure prophylaxis increased from 53 % in 2008 to 88 % in 2009. The number of survivors having access to emergency contraceptives within 5 days increased from 46 % to 69 %, and access to presumptive treatment for sexually transmitted infections increased from 72 % to 76 % (UN High Commissioner for Refugees, 2009).

Second, the UNHCR stresses that "access to water, sanitation, and hygiene promotion (WASH) is a fundamental human right and essential to life, health, and dignity." The overall objectives of its WASH program are to minimize mortality and morbidity among the displaced as well as to mitigate the resulting impact on local environments including fresh water (UN High Commissioner for Refugees, 2009). A recent outbreak of cholera in Haiti illustrates the importance of clean water and proper sanitation; an outbreak was confirmed in October 2010 following a massive earthquake in January. For a cholera outbreak to occur, two conditions have to be met: (1) there must be significant breaches in the water, sanitation, and hygiene infrastructure used by groups of people, permitting large-scale exposure to food or water contaminated with *Vibrio cholerae* organisms, and (2) cholera must be present in the population. Although cholera had not been documented in Haiti for decades, evidence suggests that UN peacekeepers from Nepal may have reintroduced the disease to Haiti, killing more than 5,000 people. Circumstantial evidence showed that fecal contamination by a riverside peacekeepers' camp initiated the epidemic, with dirty water from a local stream draining into the Artibonite River and reaching local populations (Farmer et al., 2011).

Third, a global economic slowdown on the heels of the 2006–2008 food crisis has negatively impacted refugee health and food security. Refugees and IDPs, who often live in remote and barren areas with limited access to fertile lands and livelihood activities, continue to face nutritional obstacles. The UNHCR, in partnership with the World Food Programme, has recently implemented programs to

improve food assistance delivery to the displaced in this context of increasing financial crisis and resource shortages. In Djibouti, for instance, a postdistribution monitoring system was developed to better understand how refugees use food aid at the household level. In Sudan, agencies worked together to combat high levels of malnutrition through a blanket feeding program for young children. In Uganda, discussions are underway regarding a possible transfer program in lieu of food to improve refugees' market purchasing power and nutritional outcomes (UN High Commissioner for Refugees, 2009).

Resettled refugees experience unique healthcare needs relative to immigrants, but unfortunately much of the existing literature does not adequately address the healthcare experiences of refugees. It is generally acknowledged, however, that the refugee experience and resettlement process partly shape health needs and experiences. In addition to concerns related to healthcare access, refugees may also require access to employment services, shelter, and specialized health services including mental health and counseling. Therefore, refugees may constitute a particularly vulnerable health population with multiple health risks. A Canadian study of healthcare providers conducted by McKeary and colleagues, for example, identified barriers to refugee health including issues of interpretation and language, cultural competency, healthcare coverage, availability of services, isolation, poverty, and transportation issues – some of which were observed regardless of refugee status. Although there is overlap between the obstacles faced by immigrants (as discussed above) and displaced persons, interview respondents consistently stressed that refugees face more and greater barriers than those who entered the country as economic or family class immigrants (McKeary & Newbold, 2010).

In particular, obstacles related to culture – including language, cultural competency, and cultural isolation – are linked to refugee health in Canada. As is often the case with immigrants, language issues often served as a barrier and prohibited patients from making clinical appointments, adequately explaining health concerns and symptoms, following medical instructions and making follow-up appointments. Lack of translation services may delay appropriate care when the need for care is acute, and the presence of interpreters in the examining room may further stress trust relationships between physicians and patients. Refugees may have greater issues with literacy than immigrants, are more likely to have limited command of the English language, or do not have sufficient vocabulary to describe their conditions. Furthermore, refugees may have difficulties finding a health provider that provides culturally competent care and understands the specifics needs of the refugee community. Refugees often need health professionals who are knowledgeable of their experiences, sometimes requiring providers to be aware of cultural difference and have trauma training, and this issue is further compounded by waiting lists and general service shortages. As McKeary and Newbold state, "the story or history of clients is vital, meaning that providers must (conceptually) travel a similar road to that of their refugee clients to understand their health needs." Yet this is highly problematic, due to cultural differences as well as frequent lack of client medical backgrounds and records. Additionally, social and cultural isolation emerges as a barrier to healthcare by restricting interaction within the community

and constraining individuals within their homes. In some cases, isolation is further complicated by transportation availability, gender, and age (McKeary & Newbold, 2010).

Internally Displaced Persons

The World Health Organization (WHO) links the impact of war to the mental health of displaced persons and argues that recognition of the mental health needs of the displaced is emerging but remains poorly addressed. WHO estimates that more than 50 % of the displaced present mental health problems ranging from chronic mental disorders to trauma and distress. In many cases, the effects of war and displacement are compounded with destroyed (or nonexistent) health and mental health infrastructures, including a lack of health professionals. In places such as Afghanistan, Rwanda, and Chechnya, prolonged human destabilization and psychological dysfunction were caused by traumatic events including killings, material losses, torture, and sexual violence. Life in overcrowded camps, deprivations, uncertainty over the future, and disruption of community and social support networks may also lead to mental health concerns among displaced persons (Porter & Haslam, 2005).

Existing (albeit limited) health data suggest that in more than half of countries affected by internal displacement – including practically all African and most Asian countries – IDPs have no access to adequate healthcare. Examples of these situations abound; most of northern Uganda's IDPs, for example, are confined to camps with extremely limited access to healthcare. IDPs in several countries – including Burma (Myanmar), Somalia, the Palestinian territories, and Serbia (Kosovo) – face discrimination in gaining access to healthcare due to ethnicity or restricted freedom of movement (Internal Displacement Monitoring Centre). Iraqi IDPs suffer from a range of health concerns, including gastrointestinal tract illnesses from drinking unclean water, dermatological disease (primarily among children), and the absence of services such as maternal care and treatment for chronic diseases. IDPs must rely on existing health facilities in Iraq, which were neglected under previous regimes and are now plagued by shortages of health professionals, medical supplies, and essential medicines (Morton & Burnham, 2008). Displaced women worldwide face high maternal mortality, unmet needs for family planning, complications following unsafe abortions, and higher vulnerabilities to sexually transmitted disease, including HIV/AIDS (Austin et al., 2008). Although negative health impacts are often found within refugee populations, as well, the availability of international humanitarian aid within refugee camps is often life saving. These options do not exist for IDPs, who must rely on government protections that are simply not offered to them.

NGOs and policy makers are quick to attribute negative health conditions to breakdowns in health services during times of war, lack of state financial resources, and the remote location of IDPs. However, this emphasis on scarce resources and logistics ignores the power dynamics underpinning the nature of displacement in the first place. To better understand this power, one must question why certain people are displaced while others are not as well as consider who are able to access existing resources during times of crisis and who are not. IDPs often represent populations that were the most vulnerable within countries during peacetime,

including members of ethnic and religious minority groups. As noted, governments themselves are often the cause of violence leading to displacement, and many IDPs are viewed as enemies of the very states responsible for their protection. National governments are often unwilling to prioritize the delivery of services to IDPs, leading some critics to call for the creation of a specific international humanitarian agency with a mandate for the provision of services such as healthcare (Salama, Spiegel & Brennan, 2001). In Burma, for example, ethnic minorities such as the Karen and Shan peoples are often targeted as national security threats by the military government (Kingston et al., 2010). People are displaced by coercive measures that drive people from their homes, such as forced labor, extortion, and land confiscation, as well as direct eviction and relocation orders issued by the state. Displacement has also occurred due to state-sponsored development initiatives, which disproportionately impact ethnic communities. In many cases, villagers are forcibly relocated to fenced settlements, or "relocation sites," and villages have been burned down or mined to prevent return. Those who refuse to leave their homes have been treated as legitimate military targets, with many threatened with violence or even shot and killed (Internal Displacement Monitoring Centre, 2009b).

The negative health impacts stemming from abuse of state power in Burma are significant. Malaria (including drug-resistant strains) is a leading cause of death among IDPs in Burma, and its spread is linked to the army's practice of forced displacement and destruction of villages. Food insecurity and malnutrition undermine resistance to chronic diseases, and researchers contend that the country's mortality rates are much higher than official state estimates. Studies within ethnic IDP communities found extremely limited maternal care, with nearly 90 % of women giving birth at home and only 5 % of births happening with the assistance of a skilled attendant. International relief organizations put the infant mortality rate at 91 deaths per every thousand IDP births, compared to a national average of 76 and an average of just 18 in neighboring Thailand. Twenty percent of children in the Karen state of Burma die before their fifth birthday, and it is estimated that one in 12 women dies during childbirth. Conditions of poverty (including lack of shelter and warm clothing, as well as food scarcity) serve to spread and perpetuate illnesses such as gastrointestinal disease and communicable infections, while a lack of healthcare providers and medicines serves to limit access to treatments (Internal Displacement Monitoring Centre, 2009b). Ultimately, the poor health status of IDPs in Burma is intricately linked to the country's human rights context and the negative consequences associated with internal displacement.

Health, Ethics, Immigrants, and Refugees

The largely empirical discussion above should illuminate the marked disparity between international law that defines a "universal" right to health and the practical application of this right. The tension between a right to obtain services and the moral or ethical duty to provide those services is a constant. In many Western countries, polarized debates about immigration and growing anti-immigrant

sentiment have created political obstacles to immigrant healthcare, including policy measures that limit access to health insurance and regular sources of care. In addition to these formal obstacles to health, immigrants also face a variety of informal obstacles which include language barriers, perceived discrimination, perceived lower quality of care, and challenges for health professionals themselves. Within displaced populations, refugees and IDPs face sometimes similar, but often exacerbated, challenges. The health-related priorities of the UNHCR highlight the need for increased HIV/AIDS and reproductive care among refugee populations as well as improved nutrition and food security as well as water, sanitation, and hygiene promotion. Resettled refugees have unique needs that are shaped by the resettlement process itself, often related to cultural differences. Limited data on IDPs suggests that these populations lack access to adequate healthcare and present mental health problems ranging from chronic mental disorders to trauma and distress. In cases such as Burma, IDPs come from already marginalized groups whose human rights are routinely violated by the government.

Unfortunately, there is a relatively weak body of ethical literature on the establishment of health or access to healthcare as an unchallengeable human right. Even within political philosophy, only in the last 20 years have mainstream thinkers in the Western world begun to systematically question the assumption that justice applies only within bounded political communities, thereby making ethical discussions of health rights for immigrants and the displaced possible. In this respect, two dominant approaches have been used to advocate for rights protection: First, pedagogies of reason stress the importance of rationality for persuading privileged groups (in this case, Western governments, medical professionals, hospital administrators, and insurance companies) to uphold universal human rights standards. For example, treating immigrants and the displaced helps to limit the spread of infectious diseases and therefore protects the mainstream, as well as these minority groups. Second, pedagogies of sentiment focus on ethical appeals to upholding human dignity and building an international, rather than national, community (Kahane, 2009). From this perspective, one must accept that all human beings matter and individuals have transnational responsibilities. Therefore, healthcare and other health rights should be provided to immigrants and the displaced simply because they are human, and privileged actors within the international community have a responsibility to protect the rights of those with fewer resources and less political power.

Debate over healthcare reform in the United States, which is often marked by immigration concerns, illustrates the ethical issues inherent to the protection of health rights. In this context, arguments for exclusion and inclusion often center on reason and sentiment. Typically, in the USA, for example, the opponents of including undocumented immigrants in healthcare reform are groups who oppose current US immigration policy and who work toward reducing the number of immigrants in the country. Economic and political arguments dominate citizen-only perspectives, including the leading economic argument that healthcare of undocumented immigrants is a financial burden on US taxpayers. Some exclusionists target healthcare costs of pregnant immigrants whose newborns may serve as

"anchor babies" to bring citizenship to their parents, while others contend that including undocumented immigrants in healthcare reform would encourage more immigration to the USA. Some argue that inclusion would violate core American principles such as individual responsibility and that healthcare is not a priority of undocumented immigrants (Galarneau, 2011).

Arguments for inclusion, on the other hand, often center on very different moral, economic, and public health claims. The moral argument is quite straightforward: Undocumented immigrants are human beings with healthcare needs and the right to health. Economic arguments for inclusion recognize that the undocumented contribute to society through labor, tax payments, and market participation, thereby contributing financially to public benefits despite being ineligible to receive them. Some contend that American free market principles are violated when people are prohibited from purchasing private health insurance, while others argue that such prohibitions will force the undocumented to rely on safety-net providers such as emergency care. Lastly, the central public health argument rests on the reality that any individual's health depends in part on the health of the people around them. Undocumented workers may continue to work when sick, since they often lack paid sick days and job security, and access to health services will limit infection risks within the general public.

The repatriation of uninsured, undocumented immigrants illustrates the ethical tensions inherent to this political debate, and it highlights how the right to health is threatened by anti-immigrant sentiment and financial concerns. In the USA, a new cost-shifting tactic – hospitals transporting uninsured, undocumented immigrants to their native countries – is being used by some medical facilities as a creative solution to ease economic pressures (Bresa, 2010). The story of Luis Alberto Jiménez, an undocumented immigrant living in Florida who suffered devastating injuries in a car crash with a drunken Floridian, highlights the health consequences of repatriation. Although Jiménez's life was initially saved by medical care from Martin Memorial Medical Center at a cost of $1.5 million over several years, the hospital eventually discharged him and transported him to his native Guatemala following a court battle with his guardianship. After being "forcibly returned to his home country," as one hospital administrator described it, Jiménez received no medical care or medication for his extensive injuries, which included a severe traumatic brain injury. His mother described his treatment as "just Alka-Seltzer and a prayer," and his condition rapidly deteriorated with routine violent seizures (Sontag, 2008).

Although federal US laws dictate hospitals' obligations to severely injured and ill patients in the emergency room, there are few provisions for the long-term care of undocumented immigrants; the universal right to health is at odds with the financial concerns of hospital administrators and healthcare providers. The Emergency Medical Treatment and Active Labor Act (EMTALA) requires emergency rooms to stabilize patients irrespective of their legal status or ability to pay, while Medicaid governs reimbursement for emergency medical care. The Medicare Conditions of Participation prohibit hospitals from discharging patients without an appropriate post-hospital-care plan. However, federal US law does not require receiving facilities, such as nursing homes, to accept patients nor does it provide

fund for the long-term care of undocumented immigrants. Corresponding funding mechanisms are inadequate to cover the cost of providing emergency treatment, as required by EMTALA, and there are no federal guidelines that clarify hospitals' obligations to provide poststabilization or long-term care. As a result, many hospital administrators see few options other than "patient dumping" to remain financial viable (Bresa, 2010).

Financial concerns also create obstacles to health among displaced populations and raise ethical dilemmas for healthcare providers. Global financial woes have limited the amount of funding available to humanitarian organizations that provide key health services, and many donors (including governments, corporations, and individuals) have decreased or cut funding to international health causes. Donor governments such as the United States, Germany, Italy, and Spain have reduced or reneged on previous funding commitments and key institutions – including the Global Fund to Fight AIDS, Tuberculosis, and Malaria – now suffer from funding gaps that limit service and programming options. In 2010, some countries were forced to implement 10 % "efficiency cuts" to funds approved in a previous round of grants to conserve funds for future projects. Doctors Without Borders/Médecins Sans Frontières (2010) contends that lack of funding undercuts opportunities to overcome global health threats, and the humanitarian organization recently called on world leaders to continue funding key health initiatives to fight concerns such as communicable diseases and child malnutrition.

For health practitioners operating in the field, the care of refugees and IDPs is further complicated by hostile governments and political volatility. Since governments control borders and may limit humanitarian activities occurring within their territory, many health providers must make the ethical decision to censor their beliefs (such as criticizing leaders who routinely violate the human rights of their citizens) in order to continue safely providing health assistance to the displaced. Several health-based human rights and humanitarian organizations have responded to this ethical dilemma in different ways. The work of the International Committee of the Red Cross (ICRC) is based on the Geneva Conventions of 1949 and emphasizes impartiality. The ICRC plays a neutral role during armed conflict and internal violence, and the organization relies on that impartiality to provide the most comprehensive humanitarian services while protecting the safety of ICRC workers. Doctors Without Borders also focuses on providing independent and impartial assistance, but the humanitarian organization also clearly asserts its right to speak out and bring attention to human rights violations. Its medical teams regularly supply information to the international community, and advocacy campaigns target rights abuses such as recent violations against Hmong refugees in Thailand. Other organizations, such as Physicians for Human Rights (PHR), choose to utilize the medical community's scientific expertise in order to investigate rights violations and raise awareness, rather than to provide health services in the field.

Political tensions often impact the ability of health practitioners to safely provide care to patients in need. For example, the health of Sudanese IDPs was compromised in 2009 when aid workers were expelled from the country in direct

response to international calls for human rights protections. At the beginning of 2009, 2.7 million people of Darfur's total population of six million were internally displaced. Already suffering from the extreme hardships associated with displacement, Darfur's IDPs experienced a significant drop in access to basic life necessities in March when the government expelled 13 international NGOs and revoked the licenses of three Sudanese relief agencies. This decision followed the issuing of an arrest warrant for Sudanese President Omar al-Bashir by the International Criminal Court on charges of crimes against humanity and war crimes. These expulsions meant the withdrawal of 40 % of aid workers and more than half of the total aid delivered to Sudan. Although health access was already difficult for IDPs prior to the expulsion of NGOs, with bureaucratic obstacles imposed by the government delaying some shipments for more than 6 months, the health sector lost significant capacity for mitigating disease outbreaks, treating diseases, and preventing loss of life to health concerns such as meningitis. The closure of health clinics, including mobile clinics in rural areas, left hundreds of thousands of IDPs without access to basic health services (Internal Displacement Monitoring Centre, 2009a).

Conclusion

The discussion above highlights the tension between ethical principles, expressed via international law, and the actual provision of care for individuals who have been displaced due to violence or economic deprivation. At the heart of the issue is the fact that immigrants and refugees are often protected in a bare-minimalist fashion, with no practical guarantor of the right to health in place. This is due to the fact that the nation-state is the main guarantor of the right as it may exist and be practiced. When refugees cross international borders, state governments or nongovernmental organizations may offer healthcare to such individuals due to an overarching moral imperative to do so, to protect their own citizenry from the dangers of unchecked health crises (such as epidemics), or some combination of these and other influences. However, such care is often bare minimum, since its provision necessarily takes away from the provision of services to the existing citizenry. In the case of IDPs, the situation is magnified by the fact that the nation-state in which the internal displacement has occurred has either been expressly unwilling or unable to guarantee the health rights of the displaced.

As noted by Daniels, Gostin, and others, the right to health has been expressed as a right that ought to receive priority given the fact that health is a de facto precursor to the ability to live a functional life and hence to enjoy other rights that might exist. Given the empirical tensions described above, the realization of a right to health is often denied to those who have no nation-state to guarantee access to it for them. The fundamental challenge posed to bioethics by this thorny issue is to balance the right to health against the normative and practical preference by many nation-states to protect the distribution of the services and goods necessary for the maintenance of health for those who are already functioning members of the state – its citizens and recognized permanent residents.

Informed Consent

43

Michèle Stanton-Jean, Hubert Doucet, and Thérèse Leroux

Introduction

This chapter of the compendium takes into account Article 6 of the *Universal Declaration on Bioethics and Human Rights* (2005) that states:

1. Any preventive, diagnostic, and therapeutic medical intervention is only to be carried out with the prior, free, and **informed consent** of the person concerned, based on adequate information. The consent should, where appropriate, be express and may be withdrawn by the person concerned at any time and for any reason without disadvantage or prejudice.
2. Scientific research should only be carried out with the prior, free, express, and **informed consent** of the person concerned. The information should be adequate, provided in a comprehensible form and should include modalities for withdrawal of consent. Consent may be withdrawn by the person concerned at any time and for any reason without any disadvantage or prejudice. Exceptions to this principle should be made only in accordance with ethical and legal standards adopted by States, consistent with the principles and provisions set out in this Declaration, in particular in Article 27, and international human rights law.
3. In appropriate cases of research carried out on a group of persons or a community, additional agreement of the legal representatives of the group or community concerned may be sought. In no case should a collective community agreement or the consent of a community leader or other authority substitute for an individual's **informed consent**.

The requirement for informed consent in research is relatively recent. In the area of clinical research, the obligation to obtain consent from the potential participant is now formalized. In 1947, the Nuremberg Code declared that consent shall be mandatory for research on human beings to protect the dignity and the freedom of the participants. The Helsinki Declaration of the World Medical Association specifies, since the first version in 1964, that this consent must be informed. Furthermore, in medical practice, it would seem that it is in the United States that the word "informed" appeared in 1957 in the *Salgo v. Leland Stanford Jr. University Board of Trustees* judgment in which Justice Bray wrote: "In discussing the element of risk a certain amount of discretion must be employed consistent with the full disclosure of facts necessary to an informed consent." (Salgo v. Leland Stanford Jr. University Board of Trustees, 1957, section 5, Instructions (b) Duty to Disclose, p. 568). The concept is used at the end of a very ambiguous sentence. In juxtaposing disclosure and discretion, Justice Bray opened the door to painful conflicts that are still with us (Katz, 1984, p. 63).

The relationship between "informed" and "discretion" is the basis of the majority of problems encountered today in research and clinical practice. How should the ethical requirement to correctly inform a patient that must receive care or a study participant be completely fulfilled? Up to what point can discretion be evoked to limit the disclosure of information?

Current Context of Informed Consent

It can be said that informed consent is still a crucial element of ethics, although its applications are getting more difficult in a context of globalization and technological developments. The fact that there is now an expanded process of collaborative research including many researchers in the same project and, in the clinical field, a significant growth of information technologies that allow professional associations to share their views on informed consent has given rise to many new questions related to privacy, confidentiality, secondary use, use of data and samples, use of the information for public health purposes, quality of the information provided, and even the right not to know.

By creating a conversation between human beings, specially researchers, living in different regions of the world, where religion, philosophy, physicians' power, and social traditions are different, globalization has, in the field of ethics, increased the complexity of ethical reviews. Consequently, the conclusion that will be reached by Research Ethics Boards on a multinational project can be different from one country to another. For example, the same research project, often benefitting from multiple sources of funding, can be conducted by a team coming from many countries, and carried out in clinical contexts where the ethical reviews are based on different philosophical theories or legal norms. For example, questions raised about consent (individual versus community or family consent), such as privacy, secondary uses can be different and have an impact on the fulfillment of the project. The new technologies by possibly allowing genetic profiling,

and predictive medicine are starting to offer multiple choices to patients and raising the questions of insurability and employability, themes that have an impact on the level of information that should be given and understood by a patient or a participant in research. This complex environment has prompted some lawyers, philosophers, ethicists, scientists to ask themselves if too much emphasis has been put on autonomy and individual rights without paying enough attention to countries where communities and families are the ones who have the power to decide on matters related to medicine and research (Benatar, 2002).

At first glance, giving consent seems to be fairly easy to understand and apply. It is related to a person's agreement to accept a medical intervention or to participate in a project explained by a clinician or a researcher. But the use of this simple tool has, over the years, become more complex for two reasons: On the one hand, the citizens' wish to choose themselves what is best for them and on the other hand, the development of new technologies, applied in clinics and research, has complicated the choices offered to patients or research participants, making it difficult for a person to decide what is best for him or her. For example, preimplantation genetic testing may raise some ethical questions, unpredictable before the test and difficult to explain to parents, who depending on the results, might be faced with multiple scenarios and have to choose between different options like to keep or destroy an embryo. In the research as in the clinical context, citizens do not always trust pharmaceutical companies who want to involve them in clinical trials, or physicians still using a paternalistic decision-making process not taking into consideration the patients' will. The development of new therapies and drugs and the complexification of research in a globalized and culturally diverse world contribute to this mistrust of the patients. This context has had an impact on the development of the patient's right to be fully informed of the risks of any procedures as have many examples of unethical human researches that have also strengthened the importance of informed consent For example, cases have been reported where pharmaceutical companies have offered to provide drugs to participants in clinical trials, stopping the treatments when trials are over.

This is why in the three declarations adopted by the United Nations Educational, Scientific and Cultural Organization (UNESCO) on Bioethics (Universal Declaration on the Human Genome and Human Rights in 1993, International Declaration on Human Genetic Data in 1997, and the Universal Declaration on Bioethics and Human Rights in 2005), the prior free and informed consent is presented as a key component of the respect of human dignity and autonomy of each participant in research. It is generally well accepted that universal and international declarations are helpful and useful for countries to help them achieve more coherence in the drafting of their legislations and guidelines but the devil is in the details, and the application of these universal principles raises a lot of difficult questions. For example, during the drafting process of the *Universal Declaration on Bioethics and Human Rights*, the article on consent was the subject of long and substantial discussions reflecting the willingness to reiterate the importance of free, informed,

and express consent, but also the willingness to take into consideration ethical issues raised by recent scientific developments, cultural diversity, and globalization of research.

What is the Meaning of "Informed" Consent?

What is the meaning of informed consent? What kind of information is appropriate? Is informed consent given once and for all, or should it be an ongoing process where, if needed, patients are recontacted? How does the decision-making process work? Where does the power of the physician stop when he wants to do something that the patient rejects? How should different cultural approaches related to family or community decision-making process be dealt with?

"Article 6 of the *Universal Declaration on Bioethics and Human Rights* states that 'informed consent' is to be 'based on adequate information'. As a general rule, an individual has to receive comprehensible, relevant, structured and individually tailored information that makes it possible for him to reach a decision on whether or not to accept a medical intervention or to participate in scientific research. But it is still necessary to specify what is understood by that." (UNESCO, 2009, p. 15). In the following sections, the current challenges associated with the use of the term "informed" in the consent will be examined.

What is Adequate Information?

Giving and receiving information assumes communication between at least two individuals. Communication is a process filled with pitfalls. Even in everyday life, there are frequently misunderstandings. Understanding information is therefore a complex intellectual exercise beyond simply knowing how to read and write. It requires specific cognitive abilities ranging from understanding words that do not relate to each other to the ability to analyze and synthesize. Researches have been conducted to assess the level of health literacy defined as: "the ability of individuals to access and use health information to make appropriate health decisions and maintain basic health." (Health Literacy in Canada, 2007, p. 3). Five levels have been identified in accordance with difficulty thresholds in understanding information and some examples provided for the each level. We provide here a summary of Categories of Health Activities with some tasks examples related to those categories.

1. Health Promotion (read food and product labels, purchase food, plan exercise regimen); Tasks: purchase food, plan exercise regimen.
2. Health Protection (read articles in newspapers and magazines; understanding air and water quality reports); Tasks: Decide among products options, vote.
3. Disease Prevention (understanding letters related to tests results, understanding postings for inoculations and screening); Tasks: Determine risk, engage in screening or diagnostic tests.

4. Health Care and Maintenance (understanding health history forms, discharge instructions, calculate timing for medicine); Tasks: Describe and measure symptoms, follow directions for medicine labels.
5. System Navigation (understanding application forms, statements of rights and responsibilities, understanding informed consent forms); Tasks: Applications for insurance and benefits and offer informed consent for procedures and studies (Health Literacy Health Literacy in Canada, 2007, pp. 17–19).

The System Navigation level is the most complex and is the one related to bureaucratic demands, application for insurance and other coverage plans, rights and responsibilities and **informed consent forms** for procedures and studies (Health Literacy in Canada, 2007, pp. 17–19). The level of difficulty in which the informed consent is situated posits that it is difficult, if not impossible, for large proportions of the world population to understand what they are agreeing to by giving their "informed" consent. Health literacy in relation to informed consent is a central question. It is well known that people are often shy of saying that, even though they can read, they cannot understand complicated words or long sentences. In fact, imagine the anguish of a patient or a research participant who does not understand the information provided when it is known that, in general, people are embarrassed at the idea of telling someone that they have not understood and that they require further explanation.

In clinical practice, almost everywhere in the world, doctors are not ready or available to explain at length the procedures to follow for a treatment or a surgery whereas in research, potential participants frequently receive very long and technical informed consent forms aimed at protecting research sponsors rather than participants.

Several studies on the level of comprehension of information about treatments, participation in clinical trials, or other type of research have proven that doctors rarely check the type and quantity of information that the patient would like to obtain. As Jefford and Moore wrote in 2008: "Many participants have incomplete understanding of various features of clinical trials. Issues associated with the length, format, and language of documents for written informed consent are common" (Jefford and Moore, 2008, p. 1).

It is therefore understood that people with a low level of literacy who often live in disadvantaged countries are at risk of being exploited. This is why "informed consent needs not only disclosure and a signature, but also promotion of participants' understanding of the research project and the voluntary nature of their decision to participate"(Jefford and Moore, 2008, p. 486). Sharing this point of view implies finding means to provide an information accessible through the use of detailed interviews or aids such as graphics, drawings, cartoons, pictograms, or videos. It must be added that obtaining a written consent does not always mean that an "informed" consent has been obtained.

Variations in the Application of Informed Consent

There is an abundance of literature on the consistent application of the principle of informed consent and the difficulties that it entails. In clinical practice as well as in

research, the information provided may be adequate, relevant, and complete, but the context may present particular challenges due to cultural diversity. Consequently, the decision-making process may vary from one country to another, or even within the same country from one group to another. In clinical practice, these challenges may be related to the health system model in place. If the system is not financed by public funds, a patient may refuse a procedure because it is too expensive even though he understands the benefit of that procedure. In the same vein, a possible participant in research project who understands the risks of that project might accept to participate because he or she will receive free drugs and treatments during the time of the research.

Cases that apply commonly in clinical practice and research in all contexts and cases that require different information and decision-making processes due to cultural diversity will be presented in the following sections. Finally, some questions raised by recent scientific developments and their impact on informed consent will be addressed.

Common Issues

Clinical Cases

Informed Refusal

What happens when a patient refuses treatment? How should the physician react? The following has been proposed by The Canadian Medical Protective Association: "When patients decide against recommended treatment, particularly urgent or medically necessary, discussions about their decision must be conducted with some sensitivity. While recognizing an individual's right to refuse, physicians must at the same time explain the consequences of the refusal without creating a perception of coercion in seeking consent. Refusal of the recommended treatment does not necessarily constitute refusal for all treatments. Reasonable alternatives should be explained in a comprehensible language and offered to the patient" (Canadian Medical Protective Association, 2006, p. 9).

Advanced Care Planning

How should the ideal of informed consent be respected in a context in which longevity increases and the ability to make decisions progressively decreases to nothing? This situation is encountered more and more among seniors. It is therefore possible to use Advanced Care Planning, which "is generally described as a process of planning by an individual for a time when that person does not have the mental capacity to make decisions about his/her own health care or treatment" (Wahl, 2006, p. 1).

The practice of having advanced discussions on the type of care a patient would like to receive depending on their condition and indicating this on an appropriate form occurs in several countries and is more and more encouraged. It is a way to ensure the respect of the patient (Health Canada, 2008). In May 2007, the Collège des

médecins du Québec published a guide to this effect entitled "*La pratique médicale en soins de longue durée*." (Medical practice of long term cares (translation)). For the College, upon admission of a new resident to a nursing home, the health care team must rapidly implement a comprehensive assessment of the health status of the individual and discuss the orientation of care with the latter and his or her family in view of developing a personalized plan of interventions.

Research Cases

Placebo

The use of a placebo in studies can place some participants in a vulnerable position as they will not receive the study treatment. In such a situation, informed consent rules must be followed and participants must be specifically informed of all risks and consequences associated with receiving or not receiving the therapy being tested.

Researches Involving Partial Disclosure

There are cases where, in minimal risks situation, there can be departure from the principle of informed consent. For example, some researches involving social sciences, like psychology or sociology, are designed to understand human responses to experimentally put together situations. "For example, some social science research that critically probes the inner workings of publicly accountable institutions might never be conducted without the limited use of partial disclosure. In some research that uses partial disclosure or deception, participants may not know that they are part of a research project until it is over, or they may be asked to perform a task and told about only one of several elements the researchers are observing." (TCPC, 2010, p. 38). In those cases, the Research Ethics Board has to be reassured that there are no major risks for the participants and that after the research is completed, they will be informed about the project and given an opportunity to refuse consent. These kinds of researches can only be carried out if participants do not know the purpose of the research project and therefore do not give a real informed consent.

Multicenter and International Research

When research conducted in one country includes many centers in its protocol, how should the ethical review be conducted? If many Research Ethics Boards (REBs) are included and give different advices, how should it be managed? Should the informed consent form be the same for every center in order to guarantee that patients are receiving the same information? Who should be accountable?

The difficulties related to multicenter research have been documented in many countries: burden of many ethical reviews, frustration of researchers because of delays, bureaucratic processes, lack of understanding of other's decision-making processes, not enough scientific and expertise available, institutional accountability issues, monitoring difficulties. This issue is being discussed in many countries (Australia, Canada, USA, UK) and different models have been developed, that

share responsibilities in different manners between institutions. The success is however mitigated. No simple solution exists specially in ethics. Not being a hard science, ethics must continue to have contextual flexibility in its application. This is why reaching a consensus on ethical reviews with people coming from different institutions is very difficult to achieve. The development of good governance models seems to be the way to go in the future to achieve coherence and reliability. "A critical element of the Harmonisation of Multi-centre Ethical Review (HoMER) initiative1 is the need for research governance to be understood as comprising distinct elements ranging from the consideration of budgets and insurance, to the management and conduct of scientific and ethics review" (NHMRC, 2011, p. III).

If the research is conducted in many countries, especially with developing countries, it should follow the guidance proposed by the *Universal Declaration on Bioethics and Human Rights* in its article 21 that states: When research is undertaken or otherwise pursued in one or more States (the host State(s)) and funded by a source in another State, such research should be the object of an appropriate level of ethical review in the host State(s) and the State in which the funder is located. This review should be based on ethical and legal standards that are consistent with the principles set out in this Declaration.

Some Specific Contextual Issues

Cultural Diversity

Research Context

Article 6 on consent of the *Universal Declaration on Bioethics and Human Rights* states: "In appropriate cases of research carried out on a group of persons or a community, additional agreement of the legal representatives of the group or community concerned may be sought. In no case should a collective community agreement or the consent of a community leader or other authority substitute for an individual's informed consent." What does this item practically mean?

Countries differ culturally, socially, and politically. In some countries, adequately or misinformed groups' or communities' leaders have the authority to make decisions and give consent for the entire group, completely putting aside information to individual group members, and even if the information is provided, it is difficult to assess the level of understanding of community members. Research conducted on the practice of informed consent in developing countries has revealed the difficulties of meeting the requirements of informed consent and "whether those involved would be able to fully understand and accept information" (Molyneux et al., 2005, p. 451).

There are also cases in which the group comes to agreement based on inadequate information. In Canada, in the 1980s, blood samples were collected from members of the Nuu-chah-nulth Nation for research aimed at discovering whether this population had a genetic predisposition to rheumatic disease. Dr. Richard Ward, who led the project, wrote to the Tribal Council, "We feel that if a proper study is

carried out it will identify all people who have a problem with their joints, and a physiotherapy treatment can be started as a way of helping them" (Ward quoted by Wiwchar, 2004, p. 1). The participants were never informed of the research results or ensuing publications, and the blood samples were only returned to British Columbia in 2004 (Wiwchar, 2004).

Such examples prove that obtaining a meaningful informed consent faces many challenges within certain cultural contexts. As explained, several factors must be taken into account to relay adequate information. For research, the subject must understand the risks and benefits of their participation. In a globalized world where, for example, the delocalization of clinical trials, patent races, and the search for new molecules have already had detrimental effects, it is becoming more and more necessary to be vigilant with respect to the ways in which consent is obtained from participants and patients. Research in culturally different regions, especially in poor settings, is often difficult to undertake as, again, illness conceptions, sharing of power in families and communities, and value systems require an understanding that, for example, the pharmaceutical companies and sponsors do not always have. "Reports of abuses associated with informed consent to research in resource-poor settings consent call attention to global power inequities when research is conducted by investigators sponsored by organizations or pharmaceutical companies from industrialized nations. In a clinical trial of the antibiotic trovafloxacin (Trovan) in the treatment of bacterial meningitis in Kano, Nigeria (Khabir, 2001), researchers working for Pfizer Pharmaceuticals were charged with neglecting to obtain adequate consent." (Marshall, 2007, p. 30).That said, it is important not to fall into a cultural relativism where nothing is common among developed and developing countries but rather to recognize the importance of understanding and respecting communities values and tradition which is essential to the establishment of a strong partnership between all the actors.

Clinical Context

There are several variations in the information and decision-making process in many communities across the world and they take several forms in clinical context with respect to treatment consent. As shown by Fan and Tao, family authority, direction by the physician, and the role of the patient are always present in the medical decision-making process but managed differently in different cultural settings, i.e., the role of the physician and that of the family and the patient may be adapted based on the size of the family, and religious and cultural traditions. The patient will be involved more or less in the decision-making process depending on the familial paradigm in place. For example, in some Asian countries, the family may be informed before the patient of the treatment or procedure to be followed and take the decision to proceed or not. On the contrary, in western countries, the family will be informed by the adult patient who will be the one to take the decision. Depending on the model in place, the family or the patient may decide on their own or the physician may be the one to take the decision (Fan and Tao, 2004).

Vulnerable Persons

Article 8 of the *Universal Declaration on Bioethics and Human Rights* (2005) states:

> "In applying and advancing scientific knowledge, medical practice and associated technologies, human vulnerability should be taken into account. Individuals and groups of special vulnerability should be protected and the personal integrity of such individuals respected."

In its report on this article (2011), the International Bioethics Committee (IBC) states:

> "This Report on article 8 of the Declaration will investigate the scope and content of the principle of respect for human vulnerability and integrity, focusing on special vulnerabilities and taking into account conditions that, more or less directly, impinge upon the capacity to live as a free, autonomous individual and the right to live in a world where significant inequalities in the capacity to meet everyone's basic needs are adequately addressed." For the IBC, this means that: "The principle of informed consent is at risk whenever someone claims to know what is the right thing to do, and insists that his or her decision should prevail over the self-determination of the patient, whether that person is the physician or a family member." (IBC, 2011, p. 1)

According to these definitions, there are several categories of people that may be vulnerable in a given population, more specifically, children and seniors.

Children

The assent of the child poses a certain number of questions. The term "assent" generally refers to the willingness of a child to participate in a research project. Assent is different from consent, as it addresses the limited understanding of a child based on his/her mental capacities and level of maturity and development. If a child is capable of discernment, it is just as essential for the researcher to obtain the assent of the child before including the child in pediatric research as it is to obtain informed consent from the parents.

With children, should the consent of the two parents be mandatory? Who can be defined as a minor by law? The answer to these questions varies from country to country and can be based on legislation or on an assessment of the level of comprehension. But, generally speaking, there is an agreement, among ethicists, that minors should not be excluded from participating in the consent process only based on their age because "the inclusion of children in research advances the commitment to justice in research by improving our knowledge of, and ability to respond to, the unique needs of children throughout their development" (TCPC, 2010, p. 49). But, when a child says no, it is no, and as stated in the Helsinki Declaration: "When a potential research subject who is deemed incompetent is able to give assent to decisions about participation in research, the physician must seek that assent in addition to the consent of the legally authorized representative. The potential subject's dissent should be respected." (WMA, 2008, p. 4) In the case of treatment, if treatment is not required, the opinion of the minor must be taken into consideration.

Seniors

The mental capacity of seniors can be impaired especially when they are affected by neurodegenerative diseases such as the Alzheimer disease. In the case of research on that disease, if the family does not object, should, as it is often happening, sick persons be excluded from research on the ground that they do not have a legal representative who can legally consent?

Even if a person is vulnerable, this does not necessarily mean that they cannot freely consent to participate in the study. It is the ethical framework in place that should insure that their participation is possible or not and well supervised. "Even when the requirements of free, informed and ongoing consent cannot be met, respect for persons requires involving individuals in circumstances of vulnerability in decision making where possible. This may include asking about their feelings regarding participation and/or for their assent" (TCPC, 2010, p. 9).

New Scientific Developments and Informed Consent

The spectacular developments that have arisen over the past decades in genetics, genomics, and nanotechnologies have presented new questions with respect to the application of the principle of informed consent in a globalized world. Over the past years, several authors have examined the questions raised by these new scientific developments vis-a-vis informed consent and its approach focused only on the individual whereas these developments affect families, or even entire populations. Consequently, the individual basis of the informed consent based on autonomy, confidentiality, and the individual decision of the patient is challenged. "The traditional model fails to recognize that an individual is also a social person with a particular historical and socio-cultural context giving that person certain ways of viewing things, as well as a set of values. Each person has their own understanding of who they are, how they and others should be treated as people, and what important relationships need to be honoured. Each individual also has their own views about disease and illness and will face genetic issues with their own level of fears, concerns and questions" (Kegly, 2004, p. 832). In her discussion, Kegley argues that "various perceptions of 'adequate information', that are at the heart of informed consent, are at odds with the complexity of genetic information" (Kegly, 2004, p. 832). The complexity of the new technologies is making it even more difficult to provide adequate information to patients, and sometimes even physicians and genetic counselors are not sufficiently trained in communication skills or even willing to take the time to properly inform the participants.

The Necessity to Obtain Consent in Research Involving Human Tissues and Databanks

The proliferation of databanks and databank sharing has led to an abundance of literature in bioethics to identify and analyze the ethical questions related to the start-up and use of these databanks. Several reports, notices, and statements have attempted to address these issues and propose governing methods.

In research on human tissues samples and databanks, even if the individuals are not directly affected, it is still important to obtain informed consent. If the information identifies participants, a new consent must be obtained. If the donor is deceased, the family or a research ethics board may make the decision to provide or refuse access to the data. To facilitate the use of data, it would be useful, for example, to ask donors to insert a clause to this effect in their last wishes which are often indicated in a will.

The Right to Know or Not to Know

During the last decade, the right to know has been stressed based on the ethical view that the patient has a right to be informed about the risk and benefit of a treatment or a research. Particularly, in genetics, we are now faced with the opposite right: the right not to know. Research findings, or treatments, including incidental results, can more and more reveal diseases that will impact the participants, or their biological families by having strong psychological effects (Andorno, 2004). As Ruth Chadwick explains: "It may not be justifiable to take away hope from a person by exposing them to knowledge that they do not want" (Chadwich, 1997, p. 18). In trying to balance the patient's right with, for example, the impact of different genetic disorders, on the family and on future generations, can it be said that the right not to know is absolute based on the autonomy of the participant? The fact that the participant can refuse to get the information about the results or accept to be informed and refuse to communicate the findings to his relatives raises difficult ethical dilemmas. This is why return of the results should be discussed before the beginning of a research or a treatment and a plan should be designed to manage the information to avoid incomprehension when the results will be known. This right not to know has been recognized by international organizations like The Council of Europe Convention on Human Rights and Biomedicine (1997) and by the UNESCO Universal Declaration on the Human Genome and Human Rights (1997).

In the case of incidental results, i.e., discoveries that are beyond the goals of the research, the management of the information is also a challenge. As discussed by Zawati, Van Ness, and Knoppers (2011), it is almost impossible for the researcher to identify at the outset of a research all the possible findings. International norms that address that topic have been reviewed in that paper and as to the content of the documents analyzed, the authors found that most of them call on researchers to be clear on their practices with their participants at the time of consent concerning incidental findings. The conclusion is that there is a lack of guidance and: "Greater consensus is required on the management of incidental findings in the field of genomics and for a proportionate approach to the responsibilities of all stakeholders involved in this process" (Zawati et al., 2011, p. 8).

There are cases when the right not to know can be restricted. For example, the positive result of a sexually transmitted disease should be told to a patient and discussed with him before the test is performed. Public health interests can also, in some circumstances, limit the right not to know and those circumstances should be well defined by law (Andorno, 2004, p. 437).

Data Ownership

Tissues taken from patients, information obtained in genetic research, medical records are now part of large data and tissues banking process. Biobanks are not new, but, with scientific developments, particularly in the area of genomics, they are now more and more large population and specific disease collections (Luther and Lemmens, 2012). But who owns the data? How much do patients or research participants know about what is done with their data? When a researcher has built a databank or a tissue bank, does he have the right to sell it or to obtain a patent on his discoveries just for himself? Is his institution the owner of the data? If he quits, can he leave with his bank? Does that question need to be raised when the informed consent of patients is asked? And what about conflict of interest? Those are some of the substantial questions being discussed in a global context where researchers and data are moving around the world. Ethicists agree that research centers must provide clear policies on the subject and legal systems must take an interest in this complex question. But how is it possible to do that?

On the question of ownership, it is generally accepted that institutions, not the researcher, is the owner of the data bank and is accountable for its proper management. Some institutions have created registers where they keep a list of the data bank created in their institutions. On the other side, the discoveries that come out from these databanks are the property of the researcher unless there are specific clauses in the consent form that instructs differently.

Secondary Uses

That databanks or the biobanks constitute a very rich platform for future researches. When the data is collected, it is difficult to assess all the possible uses of the data. Should it be mandatory to obtain informed consent for each new research study using the data, or should it suffice to ask a Research Ethics Board (REB) to approve that new research? Or, is it right to forbid a general consent when, for example, a participant wants, after having obtained thorough information, to give his samples as an altruistic gift for the welfare of future generations or accept not to be recontacted if his data are to be used for another research not necessarily linked to the initial research? Whether participants should be recontacted is an unresolved issue. There are two different schools of thought at play about that: individual rights and common good or solidarity. Depending on ethicists' philosophical background, they will adopt one or the other position. Several suggestions have been proposed to respond to these questions, but none of these approaches completely satisfy the ethical rule requirements with respect to informed consent and are often perceived as distortions of the original concept based on autonomy and confidentiality.

Certain avenues aimed at maintaining the information have been explored in order to avoid the difficulties presented by the secondary use of data. For example, in a paper published in 2003, Caulfield, Upshur, and Daar recognized the impossible task of predicting all the possible uses of donated samples. They suggest an authorization model "whereby participants in genetic data banks are able to exercise a certain amount of control over future uses of genetic data. We argue this preserves the autonomy of individuals at the same time as allowing them to give

permission and discretion to researchers for certain types of research" (Caulfield, Upshur and Daar, 2003, p. 1). In that model, informed consent would be required for initial collection and future uses would be done "under a mode of preauthorization." Participants would have to say what uses they agree or do not agree with and this process would be monitored by some sort of overarching governing body.

In 2006, Knoppers and Chadwick wrote, in an important article titled *Human Genetic Research: Emerging Trends in Ethics*, that "the increase in interest in population-based genetic research has led to calls for rethinking the paramount position of the individual in ethics" (Knoppers & Chadwick, 2006, p. 416). They argue that the discoveries in genetics have been accompanied by a shift in emphasis toward new trends in ethics as reciprocity, mutuality, solidarity, citizenry, and universality (Knoppers and Chadwick, 2006). These new trends feed the debate on ethics in different ways either it be on the right to know or not to know, insurance, choices, management of data base, and autonomy versus common good. Those issues can all be related to informed consent and the need to give a clear and comprehensible information to the public.

Relation of This Chapter with the Scope and Article 26 of the Declaration

In this chapter, the challenges faced with using the term "informed" in the process of getting consent from patients and participants in research projects have been examined. Some examples of varied situation where difficulties arise in various clinical or research settings have been provided. The writers of the *Universal Declaration on Bioethics and Human Rights* (UDBHR) were aware of these challenges, most of them having been highlighted during the consultation process. This is why they made sure to specify in Article 26 entitled Interrelation and Complementarity of the principles that: "This Declaration is to be understood as a whole and the principles are to be understood as complementary and interrelated. Each principle is to be considered in the context of the other principles, as appropriate and relevant in the circumstances" (UNESCO 2005).

The Declaration having been drafted to provide "guidance to decisions or practices of individuals, groups, communities, institutions and corporations, public and private" (UNESCO, 2005, Scope) needed to be grounded in a set of principles that can take into account a diversity of international contexts. The role of religion, families, and governments is not the same everywhere and this is why a certain level of flexibility, provided by article 26 of the UDBHR, is important.

Conclusion: Informed Consent Revisited

Informed consent has arisen from the desire to respect the autonomy of the patient and protect them from harm. It is not only a form to be signed. It should be a process

through which health professionals must inform the patient adequately about all the impacts of the procedure or the research project. This is why exchanges between all partners should support the process. Schachter and Fins properly proposed in a paper published in 2008 "a reinvigoration of the doctrine of informed consent in which the physician engages in meaningful and ongoing dialogue with the patient. Ultimately, both the clinician and the patient–physician relationship will benefit as respect for this doctrine serves to facilitate compliance with the doctor's legal obligations, ethical duties, and clinical responsibilities, and, as importantly, enhances the collaborative treatment enterprise" (Schachter and Fins, 2008, p. 1113).

Without denying the value of the actual ethical foundation of the individual informed consent, the collective and globalized dimensions implied by many of the actual researches lead one to think that other principles like solidarity, responsibility, and common good should carry the same weight as autonomy and individual decision.

The questions and the applications that have been discussed in this chapter are only the tip of the iceberg. Indeed, on top of the developments in genetics (genetic testing, population genetic, and prenatal genetic testing), the scientific developments in nanosciences, neurosciences, proteomics, and regenerative medicine will continue to challenge the limits of informed consent. As explained in this chapter, new scientific developments and the globalization of research demand the capacity to innovate. Methods of keeping alive informed consent in every treatment and research should be found and tested. To benefit from science progress and at the same time to protect individuals and especially future generations is a duty for the scientific community.

It is also important to have a clear view of the differences in the application of informed consent theory between clinical and research settings. As explained by Agich in 1998, informed consent in clinical practice can be challenged and analyzed retrospectively in court following a complaint while, in research, the informed consent can be reviewed and discussed during the project (Agich, 1998).

In a globalized world where governing models and the application of laws and guidelines vary from one country to another, some scientists may be tempted to move to countries where the ethical laws and regulations are minimal or not developed at all instead of trying to improve guidelines and norms everywhere. Informed consent must continue to be applied and studied by multidisciplinary and multicultural teams involving health professionals and social scientist. Finally, to obtain a real informed consent, awareness-raising and education strategies as well as public debates should be given much more attention in the elaboration of guidelines and policies at the international and regional levels. New governance models that involve the public in meaningful consultations must be developed. Physicians and scientists must be trained to communicate in plain language with their patients. Most importantly, cultural diversity and pluralism should always be taken into consideration.

Acknowledgments The Canadian Commission for UNESCO generously contributed to the translation of this chapter.

Migration of Health Personnel and Brain Drain

44

Jeremy Snyder

Introduction

Within global bioethics, global inequities in terms of life expectancy, morbidity, and the distribution of health resources have been identified as areas of serious ethical concern. These inequities are caused and compounded by a grossly unequal global distribution of health workers, both between and within countries. In many communities, there are insufficient health human resources to provide primary and preventative care, to distribute new interventions provided by external donors such as antiretroviral drugs to combat the spread of HIV, and, most pressingly, to train future generations of health workers. Thus, these inequities in human welfare are likely to persist or even worsen if the problem of health human resource levels in these areas is not addressed.

This problem is compounded by an ongoing pattern of migration of health workers from relatively low- to high-income countries and from countries with severe health human resource shortfalls to those countries with relatively many health workers. Increasingly, bioethicists have identified this pattern of migration as an ethical concern and have accused a range of players of engaging in serious moral wrongdoing in failing to prevent or even encouraging this pattern of migration to take place (e.g., Eyal & Hurst, 2008; Dwyer, 2007; Benatar, 2007; Eckenwiler, 2009). This chapter begins with a brief background on the effects and causes of health worker migration. While there is wide agreement that this phenomenon is ethically worrisome, there is considerable disagreement as to the nature of the wrongdoing taking place and which parties are engaging in this wrongdoing. Therefore, the next section of this chapter consists of a survey of the range of arguments on the ethical terrain of health worker migration, noting that multiple forms of unethical behavior are likely taking place. In the final section, the chapter surveys policy responses to the problem of health worker migration with discussion of their chances of success and implementation and therefore their ability to address

global inequities in health human resources. As with many cases in global bioethics, the international migration of health workers raises many, serious ethical concerns, but because of its global nature, it is a problem that resists easy solutions.

Background

The numbers of trained health workers are widely disparate between countries and often mirror more general disparities in resources between nations. For example, Africa has an average density of 2.3 health workers per 1,000 population, compared to 4.3 workers for Southeast Asia and 24.8 for the Americas. Perversely, countries with lower health worker density tend to be faced with a disproportionate share of the global disease burden and therefore have a greater need for these health workers (WHO, 2006). This inequality is a source of great ethical concern given that in many countries shortages of trained health workers have resulted in difficulties meeting the basic health needs of their citizens (Snyder, 2010). While more health workers can be trained given adequate facilities and resources, these resources are now lacking in many countries and the training of new health workers can be a time-consuming process (WHO, 2006).

This ethical concern is particularly acute given that shortages of health workers in some regions are exacerbated by a pattern of migration of health workers from relatively disadvantaged to advantaged areas. Health worker migration of this kind increases inequalities in levels of health workers globally and can reduce numbers of these workers in some countries in absolute terms (Anand & Bärnighausen, 2004). In India, for example, trained health worker migration has been an increasing problem, exacerbating already existing shortages of health human resources (Rao, Rao, Kumar, Chatterjee, & Sundararaman, 2011). While these countries often already suffer from limited access to medications, the ability to distribute these resources even when available is further compromised by health worker shortages. Health worker migration can contribute to a vicious cycle of health worker shortages when the best-trained and most experienced workers – who are often those most desirable to potential employers – choose to migrate. These workers serve as mentors and trainers for more inexperienced workers and students, thus undermining the capacity of these countries to replace workers who have migrated (Eyal & Hurst, 2008).

The motivations behind migration is disparate, but some pull factors (drawing workers to certain destinations) and push factors (motivating movement from worker home countries) are frequently cited as behind more recent, problematic worker flows. Push factors for migrants in the public sector in low-income countries include low wage levels at home when compared to the private sector and more economically developed destinations. These workers may also face comparably heavy workloads and more limited workplace support, which can lead to lower job satisfaction over time (Eyal & Hurst, 2008). Pull factors include better wages and working conditions in destination countries and often mirror push factors in source countries (Snyder, 2010).

The decision of any individual health worker whether and where to migrate will be a complex interplay between these push and pull factors and will involve many individualistic considerations. In many cases, it is the knowledge of an opportunity to migrate that factors into the decision to move abroad. Simply allowing the immigration of skilled health workers or even having an immigration system that favors these workers can be considered a passive form of recruitment and raises ethical issues for the destination countries that accept these workers from disadvantaged source countries. In other cases, national health systems or private employers will actively recruit these workers through job fairs, advertisements, or the use of head-hunting firms. These forms of active recruitment may make it more likely that a health worker will migrate abroad, raising distinct ethical concerns. That said, in a globalized setting where networks of health workers are able to easily communicate information about migrating to destination countries through formal and informal networks, the distinction between active and passive recruitment is becoming more blurred, while the harmful effects of health worker migration remain much similar in both cases.

Ethical Issues Raised by Health Worker Migration

The movement of health workers from relatively low- to high-income countries has been associated with a range of ethical concerns, some complimentary and some conflicting. This section surveys the most prominent of these concerns.

Nonbeneficence and Maleficence

The ethical concern with current patterns of health worker migration can be framed in terms of a failure to discharge a duty of beneficence or violation of a duty of nonmaleficence. In the first case, privileged members of wealthy destination countries can be said to have a duty of beneficence to help to reduce the needs and suffering of others throughout the world. As was discussed earlier, lack of adequate numbers of health workers in many source countries leads to considerable preventable suffering and lower levels of welfare than would be the case if there were greater support for and retention of health workers in these countries. By not doing more to rectify this problem, privileged destination and source country members alike fail in this duty of beneficence.

This understanding of the concern with health worker migration is less than satisfying, however. A duty of beneficence is commonly considered to offer some leeway in terms of how it is discharged. Given the many forms of unaddressed need worldwide, it may not be clear why the particular failing to address global health human resource levels should be seen as a failure of a duty of beneficence. Some individuals will have taken other charitable actions to address global poverty, giving them grounds for saying that they have acted beneficently in other cases and discharged the relevant duty. For those who have taken no charitable action

toward addressing others' needs, the failure to act on the need for better access to health human resources is just part of a general failing to act; that is, there is nothing special about access to health workers that could be identified as a failure of beneficence in the face of great, unaddressed global suffering.

Instead, global health worker flows can be framed as a failure of a duty of nonmaleficence on the part of certain members of both source and destination countries. This is because these worker flows should be seen as resulting in not only a failure to benefit the members of these source countries. Rather, they actively make some individuals worse off in absolute terms. As such, the migration of workers, and the encouragement and enablement of such migration, can be considered an act of maleficence. One advantage of this understanding of the moral terrain of health worker migration is that it assigns responsibility to certain actors for the repercussions of their actions – namely, those actors with a causal role in promoting harmful patterns of health worker migration. Whereas a failure of a duty of beneficence is difficult to pinpoint due to actors' discretion in discharging this responsibility, a maleficent act is identified by the specific harm caused by the actions of individuals.

It should be stressed, however, that causally tracing harms to specific actors in these cases may be difficult or impossible. Should a specific health worker migrate from an underserved population, it may be difficult to pinpoint specific persons over the long term who will suffer from this choice, even if it is known that this decision will have negative repercussions at the population level. This problem becomes more difficult as actors are further removed from the decision of the health worker and its impact on individuals in the source country. For example, it will be very difficult at best to quantify the harms caused by the action of a specific recruiter or health system administrator who encourages migration to a source country. And again, this problem is magnified at the level of immigration policy makers, citizens urging their political leaders to increase health human resource levels, and negotiators of global health services trade treaties. This observation is not to deny the negative impact of the choices of these actors but to question whether either a duty of beneficence or nonmaleficence is helpfully illuminating of the forms of wrongdoing for a systemic pattern of harms.

Equity and Justice

A general concern with global health worker migration from low- and middle- to high-income countries can be framed as an issue of health equity. This concern can be explained in terms of a redistribution of wealth from relatively poor countries to relatively wealthy countries. As health human resources have a direct impact on health, these movements can make countries already relatively well prepared to meet the health needs of their citizens better off, directly at the expense of countries that are failing to meet their citizens' basic health needs.

If low- and middle-income countries lack the resources to meet their basic health needs, then it seems perverse for relatively wealthy countries to meet their needs at

the expense of less well-off countries. That is, the actions of wealthy countries would seem to exacerbate already existing inequities in access to health care. Not only would the size of the resource gap increase, but health worker migration can make other countries less well off in absolute terms, undermining goals of providing sufficient global access to health human resources. This concern is triggered whether or not high-income countries actively recruit health workers. Even if there is no structure in place to encourage or facilitate migration by workers from low- and middle-income countries, the pattern of migration is seen as ethically problematic.

These concerns will be heightened when high-income countries have other means available to meet their health human resource needs, for example, by increasing domestic training opportunities. That is, a set of background institutions can be held to be unjust if they leave certain groups without access to a decent minimum of resources when an alternative set of background institutions could have been put into place. Neoliberal structural adjustment policies can be blamed for reducing investment in the health sector, leading to a dearth of training opportunities in high-income countries and poor working conditions in low- and middle-income countries (Benatar, 2007). Low- and middle-income countries find it difficult to resist these structural adjustment programs as they are tied to development loans and development aid in many cases. Therefore, a set of institutions imposed on these countries can be said to lead to unjust distributions of health human resources globally.

Identifying the agents responsible for causing and rectifying these global injustices can be difficult. If single responsible agents are being sought, a few can be identified. These agents would include very high-level government officials responsible for negotiating, passing, and enforcing the neoliberal trade policies that have enabled and encouraged health worker migration. As these individuals have influence on the international socioeconomic structures shaping health worker migration, they can be held causally responsible for creating and maintaining unjust social structures.

But assigning responsibility for global injustices according to the agents who cause these injustices becomes more problematic when we depart from the higher level, systemic causes of health worker migration. Individual recruiters, administrators, and health workers make their decisions against the structural backdrop that creates a set of incentives and options for these individuals. While unjust social structures do not eliminate individual responsibility, it makes it less clear how to assess responsibility for the effects of these individuals' actions. Focus can instead turn to assigning responsibility for altering the global structures that lead to a redistribution of health workers from low- to high-income countries (Eckenwiler, 2009). On this view, a range of actors who are connected to and benefit from these structures can be held responsible for pushing for more just structures and ameliorating some of the negative effects of these structures. This responsibility will vary from actor to actor but will capture a wider range of responsible parties. Thus, not only individuals and workers directly responsible for health human resource distributions are responsible for reforming the global system of trade in health services,

but so too are citizens of destination countries who benefit from these injustices and citizens of source countries who are deeply connected to and implicated by these structures.

Stealing and Exploitation

Health worker migration can also be criticized as a case of stealing or theft by destination countries from source countries for health workers. Substantial resources must be devoted to the training of health workers, including their education, infrastructure to provide practical training opportunities, certification of these workers, and payments to students during periods of training. This investment can be repaid to source countries if health workers remain in the source country for a sufficient period to provide valuable services to the wider community. However, if destination countries allow or promote the relocation of these health workers before their training costs have been recouped, the movement of health human resources is a net loss of resources for the source country. The charge in these cases is that the health human resources do not merely move from one country to another but that they are stolen. This charge is most likely to be placed in circumstances where members of the destination country take steps to actively promote or accommodate workers' migration. In these cases, where the destination country does not act to meet its own needs through local training, appropriation of other countries' health human resources appears to be a deliberate policy (Heath, 2007).

If the charge of theft is to be taken literally, the source country must be understood to lose, without its permission, a resource or property to which it is entitled. Certainly, many source countries actively resist the migration of their trained health workers and see active recruitment by source countries to be unwelcome and inappropriate. It is less clear that these countries have an entitlement to these resources if they have not already contracted with the workers for periods of service to the source country in order to repay the training costs. One concern is that the language of theft in this case tends to obscure the perspective of the worker, who may have a right to migrate and responsibilities to the source country as well (Snyder, 2009).

Similarly, charges of exploitation rest on the idea that destination countries systematically seize resources from low-income-source countries for their own purposes. An analogy can be drawn to other forms of economic exploitation where poorly paid workers create resources of value far beyond what they receive in wages or where low-income countries sell their natural resources while receiving disproportionately little in exchange. Unfair exchanges of this kind will be common against a background of pervasive, global economic injustice (Heath, 2007). This charge similarly can fail to include the perspective of health workers but does have the virtue of depicting health workers from low-income-source countries as a disadvantaged class whose options are limited and controlled by the global economic system. Typically, however, the charge of exploitation is made very loosely in the context of health worker migration and would benefit from more careful development.

Individual Rights

Individual health workers who choose to migrate – or even face overwhelming pressure to do so – tend to emigrate in order to seek better opportunities for themselves and, often, their families. Health workers who migrate can experience higher wage levels, more satisfying working conditions, improved personal safety, and more opportunities for training and advancement (Martínez & Martineau, 1998). Family members who join the health worker abroad can share in many of these advantages, and health workers can provide significant benefits to family in their country of origin through remittances. These remittances can benefit not only those persons to whom they are sent but also have wider positive economic impacts by boosting capital flows into the country. However, these remittances are not directly reinvested into the local health system and cannot be seen as directly making up for the loss of the migrant's skills (Stilwell et al., 2003). While health worker migration creates many negative effects at a population level for members of the worker's country of origin, the benefits for individuals may be significant.

Restrictions on the movement of health workers out of an interest in restricting the loss of these workers may run afoul of freedoms of movement or rights to migrate. Conceptions of these rights vary and not all restrictions on movement should be understood as potentially infringing on the rights of workers. But at the very least, many interventions aimed at dissuading health workers from leaving their countries of origin in order to seek better opportunities for themselves and their families must balance the benefits to the populations of their home countries against the losses and potential rights violations for individual workers.

While the right of health workers to migrate can be pinned to a right to free movement, the selective immigration policies of many destination countries bring into question whether this right is relevant to the implementation of their policies. As many countries tie immigration status to the skills and qualifications of the migrant or the needs of an employer, it is likely that the interests of the source country motivate these policies rather than an interest in protecting a general right to free movement (Benatar, 2007). This is not to say that such a right does not exist; rather, its relevance to the policies of destination countries is unclear, and therefore, it is not clear that a change in these policies would be relevant to the exercise of this right.

Violations of Worker Rights

Health workers stand to personally benefit by migrating to another country and seek employment abroad. However, these workers are also vulnerable to coercion, manipulation, deceit, and other forms of abuse by recruiters and their employers. In some cases, the opportunities abroad, including the existence of a job or terms of employment, may be misrepresented to workers by recruiters. As these recruiters may be paid per individual they recruit – either by the potential employer or the workers themselves – they have an incentive to encourage these workers to migrate and some may exaggerate the opportunities available to workers to do so.

Moreover, workers may be bound to their employers through the terms of their visas, work permits, or licensure in their new home. These arrangements make workers particularly vulnerable to employers who may offer wages and working conditions inferior to those received by local workers. In these cases, questions of equity for migrant workers are raised. Employers can also use the lack of mobility by migrant workers to offer wages and working conditions below what is legally required as workers may find themselves unwilling to challenge their employers out of a fear of being forced to return home. These workers may also be ill-prepared to press their rights if they are unfamiliar with the legal system or dominant language of their new home. Finally, unclear terms of migration may leave migrants unable to find work because of restrictive licensure that leaves them unqualified to work in a position for which they were qualified in their home country. These cases of what is sometimes called "brain waste" can leave workers in a new country with few or no applicable skills, far away from family and social networks, and faced with a much higher cost of living than that back home.

Workers who face these abuses may in the worst cases be made worse off than they would have been had they not migrated abroad in search of work. Other workers may be better off when compared to a baseline of their welfare prior to migrating but worse off than they were promised they would be or would be under more equitable working conditions. In these cases, workers can make the case that they have been exploited by recruiters, employers, or the immigration and employment policies of their new country, despite being better off overall. While exploitation and outright harms of these kinds may be the exception rather than the rule for migrant workers, the choice to migrate creates new vulnerabilities for workers that did not exist previously (Snyder, 2010).

Worker Responsibilities

Workers can be held morally responsible for the negative effects of their decision to migrate. This responsibility will be clearest in cases where the local community has subsidized the worker's education through tuition subsidies, development of the medical infrastructure used in training, and training and employment of medical professionals who serve as teachers and mentors to the worker. In these cases, the worker can be said to owe a debt to the community in light of these resources; the worker who simply migrates without making up this debt transfers resources to another country to which the worker is not entitled (Benatar, 2007).

Even if the worker did not receive considerable public subsidies during training or if these debts have been paid, a worker can be said to have a special responsibility to the local community in light of the worker's connection to this community, the need of the community, or the worker's special ability to aid the community (Snyder, 2009). While there are many people worldwide in need of the services of trained health workers, including in the destination countries to which health workers often migrate, these links to the worker's home community may create

a special responsibility to meet the needs of the members of the worker's home community first. Migration on this view is not a failure to repay a debt but rather a failure to discharge this special responsibility to the worker's home community.

Importantly, however, enforcing a responsibility to workers to remain in their home countries may be unfair to these individuals. As has been discussed, these workers can face a range of challenging working conditions, including low levels of pay, dangerous working conditions, and limited opportunities for advancement. As these workers begin from a disadvantaged position compared to their colleagues in wealthier countries, it may be unfair to demand that they take on particularly stringent responsibilities to address the needs of their own communities when they have alleviated rather than caused this poverty and more advantaged individuals in wealthier parts of the world do comparably little to alleviate global poverty and likely benefit more from global injustices. At the very least, a special responsibility by health workers to care for their local communities must be balanced against the demands faced by and dangers to these workers and placed in a context where all health workers and all individuals have responsibilities to meet the needs of others (Crozier, 2009).

Slowing Destination Country Reforms

As has been observed, a policy of promoting health worker migration can be used by source countries to address perceived shortfalls in health human resource levels, especially in rural and underserved areas. These shortfalls may have been caused by a failure by the destination country to devote adequate resources to training health workers, the loss of health workers to other countries, or a loss of skilled health workers to other employment if health work is perceived as insufficiently rewarding or working condition are too onerous. While the resort to immigrant health workers to meet local staffing shortages has implications for the source country, this policy also can have negative effects on members of the source country. In particular, addressing health human resource levels through migrant workers can act to reduce demands for increased funding for local, sustainable training of health workers and slow reforms that would make working in the health sector more rewarding, especially the caring professions that are historically underpaid relative to other health work. For members of the source country, this slowing of policy changes can deny them the opportunity to enter into training for the health professions. Those already in the health field may find that the influx of migrant workers undercuts their ability to advocate for better working conditions. More generally, the failure to develop sustainable mechanisms for training and retaining health workers can have severe long-term consequences if the destination country later finds itself to be less able to attract migrant workers, a less appealing destination for these workers, or in greater competition with other destination countries for a finite supply of health workers globally (Snyder, 2010).

Policy Responses

Many policy responses have been proposed to attempt to reduce the flow of health workers from low- to high-income countries and to reduce the ill effects of this migration. Given the global scope of this phenomenon, source and destination countries can choose to act unilaterally or engage in multilateral policy responses.

Unilateral Source Country Responses

Source countries for migrants may take a number of steps aimed at forcing students and other workers to remain in their country of origin for a set period of time. A bonding scheme, for example, would require that students complete a period of service to the sponsor of their training before they are allowed to emigrate. Those workers violating the terms of this agreement would be required to pay a significant fee as a means of ensuring that the period of service is completed. Importantly, a bonding scheme of this kind is only likely to be successful if the penalty to the worker is sufficiently high and there are effective mechanisms in place to enforce payment. Moreover, the penalty must be sufficiently high to ensure that potential employers may not simply pay the penalty for the worker (Martineau, Decker, & Bundred, 2004). One weakness of bonding proposals is that they may run contrary to individuals' right to emigrate, though this concern might be overcome if entering into training as a health worker were fully voluntary and any bonding conditions were clear and fully consented to. Even so, restrictions on the movements of health workers may prove counterproductive over the long run if they serve to create friction with workers and worsen working conditions, thus encouraging migration over the long term (Eyal & Hurst, 2008).

Source countries can also improve the working conditions for their citizens, thus reducing the pull of emigration to more economically developed countries. These improvements might include increased wage levels, competitive with those in richer countries when adjusted for cost of living, better equipment and staff to patient ratios in the workplace, and new opportunities for training and research. Of course, the difficulty with these proposals is that low-income-source countries will typically not have the resources to institute these changes – in fact, providing basic health services to their citizens is often challenging. In some cases, donor countries, including those that serve as destination countries for these migrants, have provided funds for salary top-ups for workers and other workplace improvements and training opportunities. However, to reduce the pull of migration, these donations must be sizable and sustained. Given the increased domestic demands of many high-income countries, sustained support of others' health systems is doubtful over the near future.

Source countries can choose to train at least some of their health workers in ways that are locally relevant to the needs of their own citizens, deviating from training foci and standards used in many high-income countries (Eyal & Hurst, 2008). Examples of such training could include a narrower focus on diseases endemic in

the source country and the health needs of its citizens, prescription of less expensive and generic medications available in the source country, and the use of less expensive diagnostic methods including stethoscopes and manual diagnosis. This training would be relevant to the needs of the source country in that it would target the health needs of its citizens and provide training that is responsive to the resource levels of that country's health sector, especially in rural areas. Because this training focus is not directed at the needs and medical resources of high-income countries, these workers would likely not be desirable for recruitment by high-income countries and their certification may not be of the type that allows for easier migration (Eyal & Hurst, 2008). Thus, this solution aims at both meeting the health needs of the source country while reducing the desirability of these workers for destination countries.

One concern that this solution generates is that it endorses a permanent second, lower quality tier of care for low-income countries. That is, the use these workers might imply that low-income countries should settle for levels of training and quality of care that would be unacceptable in higher-income countries. However, this proposal is a pragmatic response to a problem that is undermining the health of many people and a realistic response to the actual resource levels available in low-income countries. Moreover, it can be coupled with continued training of health workers to Western standards for use in district hospitals, while other responses aim to retain these other workers (Eyal & Hurst, 2008).

Unilateral Destination Country Responses

Destination countries can reduce the demand for migrant health workers by increasing the domestic supply of these workers. Critics charge that the health worker "crisis" facing some high-income countries is a product of decisions to fill health worker positions by an active process of recruitment rather than directing the necessary resources toward training new health workers domestically to meet local needs sustainably. Thus, greater levels of local training in high-income countries would both reduce demand for health workers from abroad while arguably addressing an injustice by these countries (Benatar, 2007). While this solution is ethically satisfying and straightforward in its application, it unfortunately may require higher levels of spending on health by these countries or cuts from other sectors, which may be politically unpalatable in some countries.

Similarly, destination countries might make reparations to the source countries from which they recruit health workers. These payments would be targeted at repaying the costs of health worker migration, including the loss of health human resources in these countries (possibly including replacement costs) and the costs of training for these workers. These proposals are hampered by the reality that training new workers takes not only financial resources but also considerable time, meaning that cash remunerations may not fully address the source country's loss. Moreover, as has already been observed, the loss of health workers in some countries has hit particularly hard in those workers who would normally train future generations of

workers, including university and teaching hospital staff. Therefore, source countries may lack more than the financial means of training new health workers. Encouraging destination country workers to train their colleagues abroad can help to address this problem.

Destination countries can also choose to regulate the recruitment of workers within their own borders and to enforce these regulations on private employers and recruiters and public employers such as national health systems. Recruitment policies can take many forms, but requirements could include banning active recruitment of workers through advertisements, attendance at job fairs, or source country visits, limiting active recruitment to countries that have expressed a willingness to have their workers migrate abroad, or requiring employers to limit the migration period of these workers, provide them with additional training, pay some form of compensation to the source country, or exchange workers with the source country. Similarly, the source country could modify its immigration policy so that only workers meeting the above kinds of conditions would be allowed to migrate and, possibly, only as temporary, guest workers. These interventions would all have the aim of placing legal restrictions on health worker migration such that the worst negative effects of this practice, at least, are reduced (Martineau et al., 2004).

Destination countries can also unilaterally create policies meant to guide the hiring of migrant health workers within their own countries. These policies can be crafted by both government agencies and nongovernmental stakeholder groups. For example, the Canadian Nurses Association (2000) has released a position statement on international health worker migration that focuses on licensure and professional development, which are among the key interests of this stakeholder group. These policies tend to set recommendations for members of the stakeholder group but will not typically be binding.

Policies issued by destination country governments are more likely to have the force of law, though these guidelines can be merely advisory as well. One particularly influential unilateral recruitment guideline is the United Kingdom's (UK) *Code of Practice for the International Recruitment of Healthcare Professionals* (Department of Health, 2004). While the code notes the potential benefits of international health worker recruitment, it requires that health workers in economically developing countries not be targeted unless an explicit government-to-government agreement with the UK has been negotiated to guide and set conditions on this recruitment. These workers are to be extended equal protections under the law as local workers and should receive opportunities for training and development. This code is intended to apply to hiring practices within the National Health Service (NHS) and to recruiters supplying employees to the NHS. While the document encourages adoption of the code by all employers, it is not binding on private employers outside of the NHS. Moreover, the code aims only to limit active recruitment of health workers. Passive migration, where migrants travel without the explicit encouragement of recruiters or employers, would not be affected by this code: "Individual healthcare professionals from developing countries, who volunteer themselves by individual, personal application, may be considered for

employment" (Department of Health, 2004, p. 7). As the line between active and passive recruitment can be blurry and knowledge of the UK as a destination for health workers is likely to be widely disseminated among the workforces of developing countries, the efficacy of the code is uncertain.

Multilateral Responses

Health worker migration raises ethical concerns that have been addressed in multilateral policy documents, including the UNESCO *Universal Declaration on Bioethics and Human Rights*. This document includes requirements of solidarity between states in promoting the health and social development of their people, presents health as a fundamental human right, and stresses the equal rights and dignity of all human beings. These requirements could seemingly be met by promoting greater cooperation to reduce the negative effects of health worker migration and overall levels of migration. However, the document also states that the interests of the individual should have priority over the sole interest of society, potentially forbidding attempts at addressing health worker migration by limiting the freedom of workers to migrate (UNESCO, 2005). This tension underscores the difficulty of finding solutions to the problem of health worker migration without violating the rights of affected parties.

Several policy documents have been created aiming at directing a global response to the problem of health worker migration. The World Medical Association (WMA) in 2005 produced a *Resolution on the Healthcare Skills Drain* that affirmed and expanded a 2003 declaration by this same group. The resolution describes the need of high-income destination countries to become self-sufficient in health human resources and for all countries to support and retain their health workers as well as possible given their resources (WMA, 2005). A more recent and potentially influential policy response to the international migration of health workers is the World Health Organization's (WHO) *Global Code of Practice on the International Recruitment of Health Personnel* (WHO, 2010). This code encourages nations to develop sustainable planning for their workforce needs in order not to rely on the migration of health workers in the future. In order to prevent exploitation of workers, the code encourages transparency around working conditions and equal treatment of migrant and domestically trained workers. Opportunities for migrant workers to receive training are also encouraged. In terms of the effects of health worker migration on source countries, the code encourages cooperative steps to ensure that both countries benefit from migration, including skills transfers, development of training facilities in source countries, and promotion of return migration. On this basis, the code discourages recruitment from countries with health worker shortages. Similar guidelines are included in the multilateral and voluntary *Commonwealth Code of Practice for the International Recruitment of Health Workers* (Commonwealth Secretariat, 2003).

As opposed to the UK's *Code of Practice for the International Recruitment of Healthcare Professionals*, the WHO code aims to be applicable across stakeholder

groups, including government agencies, recruiters, and private employers. In this way, active recruitment of health workers within the private sector would be limited as well as in the public sector. However, the WHO code can be criticized as being unlikely to be effective given its voluntary nature. That is, the code encourages member states to adopt it but explicitly states that it is voluntary in nature. Without binding international limitations on health worker migration, especially from low- to high-income countries, there is good reason to question whether even multilateral codes of this kind will influence health worker migration trends (Buchan, 2010). Moreover, as with the UK code, the WHO code reaffirms the right of health workers to freedom of movement and thus focuses on limiting the active recruitment of health workers. Given the extensive number of health workers from low-income countries already overseas, migration will remain highly visible and attractive if push factors for these workers are not addressed.

Conclusion

International health worker migration is associated with a wide range of ethical concerns. While many of these overlapping concerns simply serve to underscore the deeply unethical pattern of migration allowed and promoted by many destination countries, these concerns in some cases would benefit from clearer formulation and may conflict with one another. For example, the rights of health workers to migrate can conflict with the social responsibility of these workers to their source countries. Similarly, a right to adequate health human resource levels in rural areas of wealthy destination countries can conflict with similar needs in source countries. Policy responses to the problem of health worker migration are difficult to implement due to practical challenges. Doing so in ways that help to relieve rather than exacerbate these ethical problems is challenging as well. Continued discussion of the ethical landscape of health worker migration will be helpful to better expand and assess the range of policy responses to this phenomenon and to help reduce the conflict among the many parties seeking better access to health care. Given increased demand for health human resources globally and an aging population in many source and destination countries for health workers, this problem is likely to increase rather than decrease over the short term.

Organ Trafficking and Transplant Tourism

45

Nikola Biller-Andorno and Zümrüt Alpinar

Introduction

Organ trafficking is at the same time a widely known and an elusive subject. Many stories are circulating – some are dismissed as being of little credibility, others have been corroborated by legal investigations. In 2004, the New York Times ran the story of Alberty José da Silva, who lived in a Brazilian slum and sold a kidney for $ 6,000 to a woman from New York. The deal was arranged by Israeli brokers, the operation carried out in South Africa. In 2007, the UK newspaper Daily Mail reported on a British father-of-two who went as a "medical tourist" to the Philippines in the hope of receiving a kidney, after having turned down an offer from a Chinese hospital.

How are such arrangements to be judged morally? Is there a globally shared common moral ground that such judgments can be based on? The past years have witnessed a rather polarized debate on the ethical permissibility of organ sales. The prevailing international prohibition was challenged, mainly from two perspectives: a clinical view invoking the suffering of patients with organ failure, and a philosophical position claiming the vendors' right to an autonomous choice and to a fair deal. Although international policy was reassessed, the prohibition of organ selling was confirmed.

The terminology used to describe cases when people are selling, brokering, or buying kidneys is varied and sometimes confusing or euphemistic. Recently, some definitions have been offered that help clarify what is at stake. *Medical tourism* is a general term signifying a person traveling abroad to receive medical care – in the case of *transplant tourism* an organ for transplantation. *Organ trafficking* has been defined as "the recruitment, transport, transfer, harbouring or receipt of living or deceased person or their organs by means of the threat or use of force or other forms

of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability, or of the giving to, or the receiving by, a third party of payments or benefits to achieve the transfer of control over the potential donor, for the purpose of exploitation by the removal of organs for transplantation" (The Declaration of Istanbul on Organ Trafficking and Transplant Tourism, 2008). Whereas the da Silva case would quite clearly constitute organ trafficking, a medical tourist receiving services at a foreign hospital might also become involved – knowingly or unknowingly – in an organ trafficking arrangement. According to the definition, selling and trading organs are forms of organ trafficking. Sometimes, these are disguised with labels such as "rewarded gifting," "compensation," or "gratuities."

This chapter will proceed with an overview of the ethical debate on organ selling. In a next step, a review of empirical data illuminating the reality of organ trafficking in different contexts will be presented. The final part will describe policy developments in recent years and summarize the current international norms on organ trafficking.

Selling Human Organs: A Controversial Issue in Bioethics

Whereas there is a broad consensus on the ethical unacceptability of exploitative practices, the question if selling organs is morally wrong has prompted different responses. In the following, the major arguments for and against organ selling will be presented (Biller-Andorno & Capron, 2011). Transplant tourism will only be dealt with insofar as it constitutes a form of organ trafficking. Other forms, not involving abusive procurement of organs, trigger rather different questions related to medical tourism in general – such as the effects of the development of luxurious medical tourism sites for the health care of the country's population – and will not be included in this chapter. It will also not address payment for organs from deceased donors, which again leads to a different set of ethical issues, such as the potential for conflicts of interests for relatives.

The debate on whether payment for organs is blameworthy or morally required has been going on at least since the 1990s. A large number of articles have appeared, not only in bioethics publications but also in medical journals. The arguments put forward revolve around central principles of biomedical ethics, the respect for autonomy, human dignity, justice, nonmaleficence, and beneficence.

The Autonomy of the Vendor

Autonomy in decision-making depends on various factors. The person taking the decision must have been appropriately informed about what is involved. Beyond that, the person must be in a position – in terms of education, health status, mental capacity, etc. – to process this information in making a competent choice. This also presumes that the person perceives herself as a moral agent who can take decisions

on her own responsibility. This precondition to autonomy is frequently taken for granted, leading to a misinterpretation of ethical questions. It is misplaced, for instance, to consider wearing a burka an expression of autonomy, if the woman concerned does not perceive herself as someone who has moral rights and is entitled to make choices, including the choice not to comply with a religious rule. In addition to the self-understanding as a moral agent whose views matter, the situation needs to be such that genuine choices are possible; for instance, it does not make sense to talk about an autonomous decision to live in a slum if there is no alternative within reach.

When organ selling is being discussed in abstract terms, these crucial factors become invisible. But there is an enormous moral difference if a well-off professor from an Ivy League university considers the amount of money he would be willing to sell her – somewhat aged – kidney for, or if a desperate woman who gets frequent visits from a debt collector sees herself forced to this step. Organ selling under these circumstances cannot be considered an expression of autonomy but rather an "autonomy-constraining option" (Kerstein, 2009).

It could be argued that in real life many decisions are not ideally autonomous. In the case of donating a liver segment to a loved one, for instance, voluntariness is restricted, too, even if the potential donor is not threatened, forced, or manipulated. It is the simple fact that the alternative would be to watch the beloved person get worse and possibly die before he or she received an organ that is difficult to reconcile with the role as a caring relative and creates a certain pressure. This is why procedural safeguards have been called for that maximize the potential donor's degree of freedom to decline this option (Biller-Andorno, 2011). Such safeguards might be sufficient in the context of altruistic living donation, but they would be insufficient in a context marked by severe poverty, dependency, and violence.

Some have spoken out against restricting poor people's range of options, which is already limited. It was claimed that this was unfair, particularly with a view to all the risks that rich people were allowed to take just for pleasure, such as dangerous sports (Radcliffe-Richards et al., 1998). However, a prohibition of selling in fact does not curtail potential vendors' autonomy – as the decision to sell would likely not have been an autonomous one – but rather aims to protect their choice not to part with an organ in order to cover the basic necessities for themselves and their families.

Human Dignity and Instrumentalization

The prohibition of organ selling in Western countries traditionally rested on a broad consensus that organ selling was obviously and categorically wrong, as it would diminish human dignity (Cohen, 2002). More recently, the use of the concept of human dignity in bioethics has been criticized, so that its role in the organ selling debate merits a closer look.

Interestingly, human dignity can be invoked on both sides of the organ selling debate: It has been argued that organ selling enhances autonomy and therefore human dignity. Paying for organs, it has been stipulated, avoids an abusive

instrumentalization of the organ donor, and offers him or her a fair deal instead. On the other hand, organ selling has been claimed to constrain rather than enhance autonomy, and therefore to use a person who cannot decide otherwise as a means toward the end of obtaining his or her organ for somebody else.

This ambiguity underscores the point that human dignity does not help much to resolve moral questions if it is used as an unspecific, vague notion of mainly rhetorical value. It would allow speaking out against obvious abuse in the form of degrading, fraudulent, or violent treatment – however, there is consensus on the moral unacceptability of such practices anyway. For a stance that argues against organ selling as long as the major moral premise – the autonomy of the vendor's decision – is not realized and insofar as consequences are detrimental to vendors (no sustained benefits, physical harm, etc.), human dignity is not needed as an argument; it does not add anything beyond a reference to the principles of autonomy, beneficence, nonmaleficence, and justice.

Human dignity is also used in a more specific way, frequently referring to Kantian ethics. From this perspective, human beings are considered to have an unconditional and incomparable value by virtue of their rationality. By selling a part of their bodies (which is part of their selves), human beings would turn themselves into things, into their own property. This would be self-contradictory, as one cannot be a person and a thing at the same time. Putting a price on a part of persons (even if it is done by themselves or with their consent) would therefore conflict with their dignity, lowering their status to that of things that come with a price. This, according to Kantian ethics, is nothing one could rationally will. There are also religious interpretations of the concept of human dignity that refer to humans as being created in the image of God. These notions, however, are not universally accepted. There are, for instance, other positions that see nothing wrong with the self-ownership of the human body. Others question the absolute moral status of humans as rational beings. Accordingly, human dignity can be charged with being a vehicle for metaphysical premises that are not shared by everyone.

The role of human dignity in the organ selling debate can be summarized in the following way: If used as an unspecific notion, human dignity has an appellative character, evoking shared concerns about lacking respect for individual autonomy and abusive relationships. Human dignity as a specific, metaphysically rich *terminus technicus* is an essential element for positions, arguing that organ selling is intrinsically wrong. In bioethics, these two different notions are not always clearly distinguished. This can lead to misunderstandings as to the normative content and justification of positions and should be avoided. The current minimal consensus – organ selling is wrong insofar as it is coercive or exploitative – does not necessarily require a reference to human dignity.

Justice and Solidarity

Simplistic arguments in favor of organ selling point to the fact that almost everyone profits from organ transplantation – the recipient, the transplant surgeon,

the hospital, and the pharmaceutical industry that sells immunosuppressive drugs – only the donor is refused to join in the deal. This argument is assuming that donation is bound to a profit motive, which does not capture at least part of living donations. In addition, a market approach to organ donation would raise serious social justice concerns: Encouraging individuals to sell an organ in the case of economic need would remove an incentive to shape social policy such that all can sustain their existence without having resort to such options (Kerstein, 2009). Disguising the exploitation of the poor as an antipaternalistic stance that is concerned with promoting their right to autonomous choices would seem a rather cynical approach. As financial incentives would be of differential interest according to socioeconomic status, the world would be divided into organ buyers and organ sellers (Scheper-Hughes, 2003), with severe consequences regarding social cohesion and solidarity. With organs a commodity available for sale, altruistic donation would likely be further diminished – who would bother a family member if a high-quality organ can be purchased somewhere else?

There is widespread consensus that such a development would not be desirable (UNESCO, 2005, Art. 13). As a response, regulated market models have been suggested that aim to take care of negative social consequences while maintaining the possibility of organ selling in an attempt to increase the number of available organs. As features of a regulated markets, the following have been suggested: confinement to a self-governing geopolitical area; limitation of sellers to residents of that area, who are at the same time eligible to receive organs; a public health agency as the only purchaser, which would also be responsible for fair allocation according to medical criteria; and prices that are attractive to potential vendors (Erin & Harris, 2003).

A regulated market is perceived by some as the superior alternative to black markets which are presumed to prevail anyway (Daar, 2006). Others consider the idea of regionally contained, fair markets illusory, arguing that legitimizing such practices anywhere in the world will lead to exploitation of the underprivileged (Jha & Chugh, 2006), either because such models are copied but implemented in an ethically less exigent way, or because regionally contained markets in a globalized world might quickly resort to outsourcing, which – once the moral qualms about recruiting people through payment are overcome – will provide yet more organs at a cheaper price.

The question if making an organ available to a patient in need should be the subject of a business deal, and if organs are to be considered commodities that one owns and trades at will are fundamental decisions that deeply impact on one's self-understanding and on the social fabric of a society.

Risks and Benefit

Two facts are frequently cited when organ selling is discussed: One is the increasing gap between demand and supply of organs, due to a growing circle of recipients. With the advance of transplantation medicine, patients are now transplanted that

would not have been considered eligible previously, due to their condition, their health status, or other factors. In addition, the number of people needing an organ is increasing, notably in developing countries, for instance, due a rising incidence of renal failure caused by diabetes that comes with a change in diet. The other facts are the low mortality and morbidity risks of kidney donation, if carried out at excellent facilities, as well as the outcome for recipients, which usually experience an improvement in the life expectancy and quality of life as compared to dialysis. Mortality and complication rates are higher for liver segment donors, the other main organ procured through living donation.

In a market setting, quality might suffer if organs come from poor vendors. Depending on the transplantation setting, there might be an additional risk of infections and other complications. As far as the vendor is concerned, those promoting market schemes usually do not doubt that the vendor would benefit through the payment. This is, however, a hypothesis that needs to be scrutinized in the light of empirical data. Another hypothesis that frequently goes unquestioned is the assumption – in fact the major justificatory premise – that paying vendors would result in a net gain of organs. This is certainly true if an unregulated global market is considered. Many people are desperate enough worldwide to willingly part with an organ. However, it is much less certain if a significant number of individuals would be willing to sell an organ in a regulated market in a country with a well-developed social security system. For instance, an exploratory study among Swiss medical students showed that – although many found the idea of being allowed to sell an organ interesting at first sight – almost none of them would have volunteered to vend an organ other than in a situation of financial duress (Rid, Bachmann, Wettstein, & Biller-Andorno, 2009).

Selling Human Organs Under Real-World Conditions

In order to judge the validity of the ethical arguments for and against organ selling, a look at the available empirical data is indispensible. Over the past years, a number of studies have been published, describing the effects of organ selling in different settings (Goyal, Mehta, Schneiderman & Sehgal, 2002; Moazam, Zaman, & Jafarey, 2009; Zargooshi, 2001a, b).

Consequences for Vendors

It could be assumed that those who vend an organ and receive a certain amount of money in exchange would be better off after the sale. The short-time and long-term risks of nephrectomy have been found to be very small in studies published in well-known journals. The psychological effects of vending could be thought to be positive too; after all, the vendor has performed a courageous act that has helped another person survive or to enjoy a better quality of life. Regarding social status, such a person might be considered if not a hero, at least a respectable person, and

acknowledged by his or her loved ones for the sacrifice to ensure better living conditions for the family. The sum received might help to lift a family out of poverty, allowing them to move to another quarter or to start up a small business, leading to long-term, sustainable benefits. This is the utopia that is guiding some voices that speak up in favor of organ markets.

The picture emerging from social science studies is quite different. A cross-sectional study carried out among kidney vendors from Chennai, India, on average 6 years after the sale, found no long-term economic benefit and possibly a deterioration of health (Goyal et al., 2002). Once India implemented a legal prohibition of organ selling, Pakistan emerged as a center for organ trafficking, in particular the cities of Punjab. Quantitative and qualitative studies describe the impact of the sale on vendors' lives (Moazam et al., 2009; Naqvi, Ali, Mazhar, Zafar, & Rizvi, 2007).

The core findings of these studies are similar and reveal that sellers are frequently poor, illiterate, and in a relationship of dependency, such as bonded labor. Their main motivation for the sale was to pay off debts. The amount of money they received was modest (around 1,000 dollars) and frequently less than they had expected. The money was usually used to pay debts or items of daily living such as food or clothing. In many cases, the family income declined after the nephrectomy. The vendors reported a deterioration of health status and ability to work. There was no follow-up care. Most vendors would not recommend selling a kidney to others in a similar situation; many regretted their decision. The scar was perceived as a stigma.

Regulated Markets

Those who argue in favor of organ selling are quick to point out that problematic consequences might be seen in unregulated markets, with vendors being at the mercy of obscure middle men or recipients of higher social status. Iran is to date the only country that has extensive experience with a regulated system, although other countries such as Singapore or the Philippines are experimenting with various forms of incentives as well. In Iran, kidney vendors are recruited by a nongovernmental organization and receive a fixed rate from the state, plus an additional sum that can be negotiated privately between vendor and recipient. This second payment can cause conflict if promises are not kept or if there were misunderstandings about the amount to be paid. Vendors reportedly receive free health care for one year, but there is neither long-term follow-up nor a registry (Zargooshi, 2001a; Rizvi, Naqvi, Zafar, & Ahmed, 2009a). A qualitative study with interviews of kidney vendors confirms the findings reported from India and Pakistan and illustrates poverty as the main cause for the organ sales, and they describe massive anger and frustration with the vendors' dire situation before and after the nephrectomy (Zargooshi, 2001b). The picture that emerges from this study is certainly not one of autonomy, options and choice, but of poverty and despair.

The empirical studies in both unregulated and regulated settings reveal several mistaken assumptions of the organ market proponents: The assessment of risks and benefits unjustifiably extrapolated results from ideal conditions in rich countries. Under less than ideal conditions, risks – in terms of health, psychological effects, and socioeconomic status – are significant and benefits questionable. Second, the idea that financial gain would not take over regarding the motivation for organ selling has not been corroborated. There is no indication that an altruistic motivation is maintained, and the payment seen as an additional nice-to-have. It might not be possible to have it both ways – the motivation will be either mainly altruistic (if no payment is offered) or driven by the financial reward. Finally, the idea that all social strata would act as vendors and recipients has not materialized, at least not in the societies that were studied. Rather, it is the poor who sell, forced by circumstances or in the hope to improve their situation, and they are usually worse off afterward. The problems that have appeared in a regulated system are very similar to those in an unregulated one; regulation thus cannot be considered a quick fix for the problems emerging with paying for organs.

Transplant Tourism

With long waiting lists for organs in many countries, and the easy accessibility of other sites, transplant tourism is an increasing phenomenon. Yet, transplant tourism is not well characterized (Merion et al., 2008). It frequently and in some cases rather openly involves organ trafficking. In any case, transplant tourism undermines a country's ability to provide transplant services for its own population, as resources – in the form of organs, health professionals, or transplant centers – are devoted to patients from other countries (Council of Europe/United Nations, 2009). Packages are offered through websites on the Internet, including the kidney, liver, lung, heart, or pancreas. Organs come either from deceased donors (in China the use of executed prisoners has been a frequently raised issue) or from live vendors. It is difficult to assess the magnitude of transplant tourism. A conservative estimation of around 5% of all recipients in 2005 was offered as number of recipients who underwent commercial organ transplants overseas (Shimazono, 2007).

The label "transplant tourism" focuses the attention on the "tourist" and its well-being. The term has been criticized for its positive, harmless association that glosses over ethical issues. A number of studies have turned to the medical results for recipients. Many times, though not always, medical outcomes were reported to be worse (a higher percentage of transplant failures, postoperative complications, infections, etc.) than the average outcomes in the recipient's country (Cohen, 2009; Rizvi, Naqvi, Zafar, Mazhar et al., 2009b). There has been some controversy as to who would take care of, and in particular pay for, the follow-up care for organ obtained abroad. Although positions differ on this, most would agree that patients should not be penalized by leaving them without appropriate medical care (Schiano & Rhodes, 2010).

A related form of transplant tourism consists in bringing vendors or their organs to the recipient's country or a third country. Some countries, such as China, Pakistan, and the Philippines, have been recognized as "organ-exporting," whereas others are "organ-importing countries," such as Australia, Canada, Israel, Japan, Oman, Saudi Arabia, and the USA (Shimazono, 2007).

The web of international interactions that has unfolded in the context of transplant tourism shows that in a globalized world, a regionally contained market is likely to remain an illusion. Legitimizing profit motives in the procurement of organs will foster different forms of international trading and is likely to exacerbate exploitative practices at a global scale (Budiani-Saberi & Delmonico, 2008).

International Policy on Organ Trafficking

The policy issued by international bodies has always taken a prohibitive stance on organ selling. The prohibition was frequently formulated as a brief, matter-of-fact statement, without any further qualification. The Council of Europe Convention on Human Rights and Biomedicine (1997), for instance, in Chapter VII, Art. 21 stated: "*The human body and its parts shall not, as such, give rise to financial gain.*"

In more recent times, however, this prevailing consensus on the obvious moral wrongness of organ selling was challenged from two sides. One form of criticism came from those who did not question the prohibition of organ selling as prudent policy but were unhappy with its justification. A categorical prohibition of organ selling based on Kantian arguments, it was argued, could not claim to be universally accepted, particularly not in a pluralist global context. Others considered the policy in itself flawed and lobbied for liberalization, allowing the possibility of regulated markets.

In reaction to these charges, policies were revisited, leading in some cases to a more refined justification, yet the prohibition of organ selling remained untouched. In the following, an overview of current international policy will be provided.

Current International Policy

In May 2010, the 63rd World Health Assembly endorsed the *WHO Guiding Principles on Human Cell, Tissue and Organ Transplantation*. At the same time, it urged Member States "to promote the development of systems for the altruistic voluntary non-remunerated donation of cells, tissues and organs" and "to oppose the seeking of financial gain or comparable advantage in transactions involving human body parts, organ trafficking and transplant tourism" (WHO, 63rd World Health Assembly WHA63.22, 2010).

The Guiding Principles address a number of ethical issues of transplantation, among them consent requirements, donation from minors and legally incompetent persons, and the allocation of organs, cells, and tissues. Guiding Principle 5 deals

with organ selling: "*Cells, tissues and organs should only be donated freely, without any monetary payment or other reward of monetary value. Purchasing, or offering to purchase, cells, tissues or organs for transplantation, or their sale by living persons or by the next of kin for deceased persons, should be banned.*" Further, it specifies: "*The prohibition on sale or purchase of cells, tissues and organs does not preclude reimbursing reasonable and verifiable expenses incurred by the donor, including loss of income, or paying the costs of recovering, processing, preserving and supplying human cells, tissues or organs for transplantation.*" (WHO, 2010, Guiding Principle 5).

The Commentary on Guiding Principle 5 explains the rationale for the prohibition: "Payment for cells, tissues and organs is likely to take unfair advantage of the poorest and most vulnerable groups, undermines altruistic donation, and leads to profiteering and human trafficking. Such payment conveys the idea that some persons lack dignity, that they are mere objects to be used by others." The justification thus moves away from categorical claims but refers to the (likely) possibility of exploitation that payment schemes would undeniably bring with them. It also questions the coexistence of altruistic and paid donation and points to the mutual recognition as individuals of equal moral status as a basis of modern societies, which might be put at risk if organ selling was a widely accepted legal option.

In a similar vein, the *Medical Association Statement on Human Organ Donation and Transplantation* (WMA, 2000, 2006) states: "*Financial incentives for providing or obtaining organs for transplantation can be coercive and should be prohibited.*" Again, there is no claim that payment for organs has to be coercive under all circumstances, but the probability of this occurring, especially in a globalized world, suffices to justify a cautious policy.

Implementation

Although clear international guidance provides valuable orientation on normative issues, implementation is frequently a challenge. Like the World Health Organization, UNESCO encourages states in its *Declaration on Bioethics and Human Rights* to "*take appropriate measures, both at the national and international levels, to combat (. . .) illicit traffic in organs*" (UNESCO, 2005, Art 21(5)).

Beyond the commitment of states, professional societies play a crucial role in the promulgation and implementation of the prohibition of organ trafficking. The *Declaration of Istanbul on Organ Trafficking and Transplant Tourism* plays a particularly important role in this regard. Initiated by the Transplantation Society and the International Society of Nephrology, more than 150 representatives of scientific and medical bodies from 78 countries around the world, including government officials, social scientists, and ethicists, gathered in 2008 in Istanbul to jointly draft the document. Explicitly referring to the WHO Guiding Principles, the Declaration states: *Organ trafficking and transplant tourism violate the principles of equity, justice and respect for human dignity and should be prohibited. Because transplant commercialism targets impoverished and otherwise vulnerable donors, it leads*

inexorably to inequity and injustice and should be prohibited. (Principle 6, The Transplantation Society/International Society of Nephrology 2008).

Beyond principles, the Declaration contains concrete proposals and recommendations to deal with the scarcity of organs while combating transplant commercialism. They call for legal and professional frameworks on organ transplantation as well as regulatory oversight systems in every country. Professional societies are encouraged to exclude members who violate the Declaration, and funding sources are required to affirm the Declaration when involved in research or clinical activities in transplantation (Delmonico, 2009). Furthermore, a custodian group has been established that continuously promotes the aims of the Declaration. With their forward-looking approach, those initiating and promoting the Declaration of Istanbul have set up an exemplary collaboration of professionals, international organizations, and governments that can have a significant impact on transplantation practices worldwide.

Conclusion

Payment for organs used to be an unquestioned taboo in international policy. The controversial debate on the justification of such a prohibition has helped to articulate the current consensus on ethically acceptable practices in transplantation. Although there is clearly no support for coercive or exploitative practices, opinions differ on the consequences a regulated market would have. As a scrutiny of the pro-market arguments in the light of empirical data has shown, however, there is no plausibility for the claim that markets, regulated or not, might lead to a win-win situation. Existing evidence suggests vendors would be likely to come from the poor segment of a given society and to experience a further deterioration of their health and socioeconomic status. Altruistic donation could be expected to decline, and any attempt to regionally contain markets might not withstand the dynamics of globalized market forces. The current prohibitive stance is therefore well justified.

Policies today do not necessarily claim that payment for organs needs to be unfair and have negative consequences in each and every case. This does not mean, however, that a market approach would be prudent policy. A micro-fairness approach that focuses on individual transactions is insufficient to address this question. Rather, a perspective is needed that takes real-world conditions – such as asymmetries of power and structural injustice – into account.

A lot has been achieved over the past years: There is a set of clear, up-to-date international rules and a dynamic collaboration of the transplantation community, public health authorities, and governments. Next steps might include the development of a monitoring system that would contribute to a more nuanced understanding of the different forms organ trafficking might take, as well as of locations, quantities, and specific enabling conditions. Encouraging nations to strive for self-sufficiency regarding the procurement of organs might help to counter transplant tourism. Finally, alternatives to an increased reliance on live donation might have to be explored, such as presumed consent for deceased donation, combined with an increased focus on prevention of end-stage organ failure.

Poverty

46

Juha Räikkä

Introduction

Every year, millions of people die prematurely from poverty-related causes such as malaria, lack of clean water, and malnutrition. This makes tens of thousands of deaths per day. Many of those who die are children under the age of five. From an ethical point of view, there is little doubt that extreme poverty is a bad thing and should be eradicated. This view can be defended by various ways, for instance, by referring to the utilitarian doctrine that suffering is a bad thing, or by referring to the golden rule or categorical imperative, or by referring to the view that we all have natural rights against poverty, or by referring to virtue ethics (as virtuous persons try to help those who suffer), or by referring to the UNESCO Universal Declaration on Bioethics and Human Rights. The view that extreme poverty should be eradicated is compatible with the claim that not all people in the planet should enjoy equal living standards. Global egalitarianism is not the issue here, and the view that extreme poverty is a bad thing is a very weak claim that almost everyone can accept. Those who deny it may have environmental concerns in mind and think that extreme poverty is a welcome phenomenon as it kills a lot of people and hence decreases the number of consumers of natural resources. However, it is not clear whether this argument is a *moral* argument at all, and in any case, this chapter is based on the normative assumption that extreme poverty should be eradicated. The real problem is that there is no agreement about what should be done. Not all actions are feasible and productive, and those that are can be ethically doubtful. Extreme poverty raises difficult ethical and philosophical questions. This chapter deals with the following ones. How to define poverty? What is the point of the Millennium Declaration? What is the value of development aid? Can poor countries help themselves? Is poverty possibly based on a self-fulfilling prophecy? How poverty and population growth are related to each other? What should be the role of genetically modified food in the war against extreme poverty? Let us start with the problem of a definition.

Absolute and Relative Poverty

It is customary to distinguish between absolute and relative poverty. Absolute poverty refers to a criterion that is universal and makes international comparisons possible. Relative poverty views poverty as context dependent and is closely related to the assessments of social inequalities. Poverty is related to issues such as health, education, violence, a sense of security, housing conditions, political power, population growth, and hunger. Extreme poverty is seldom voluntary, and people who suffer from extreme poverty cannot always satisfy their basic wants such as a need for food, water, shelter, basic education, minimal medical care, and self-respect.

There is no agreement about the proper definition of poverty in either sense. In the *Encyclopedia of Global Justice* 2011a, b, Teppo Eskelinen writes both about absolute and relative poverty. He points out that definitions of absolute poverty often rely on a certain understanding of basic needs and that this is problematic as we do not know, exactly, what our "basic needs" are. (Eskelinen, 2011a). It is doubtful whether they are *only* biological needs (cf. Gasper, 2004). In practice, the attempts to measure the number of people living in absolute poverty have been based on financial measurements. A poverty line is defined, and persons falling under this line are classified as poor. The most used poverty lines are expressed in US dollars (for instance, $1.08 per day for extreme poverty), and these lines have been defined by the World Bank. As Eskelinen (2011a) points out, the figures do not refer to actual dollars but to purchasing power. Typically, the purpose of poverty reduction is to raise poor people above a poverty line, not to make income distribution more equal or to increase the overall living standards in poor countries. Eskelinen (2011a) argues that this policy is often defended by the ethical argument that absolute poverty generates duties for affluent countries to alleviate poverty, while less severe forms of poverty do not generate similar obligations.

Relative poverty is a context-dependent concept, and a person can be poor in a relative sense while not being poor in an absolute sense. Eskelinen (2011b) argues that relative poverty is seen as a matter of failure of distributive justice, while absolute poverty is seen as a failure of meeting the requirements of basic dignity of human beings or human rights. Both relative poverty and absolute poverty relate to the issues of global justice, but in different ways. Relative poverty can be understood mainly as a psychological concept that refers to people's expectations and desires. When certain goods become common in a society and people are expected to have these goods, then not having them may lead to a feeling of being poor, whether or not the goods in question are, in any meaningful sense, "necessary." Eskelinen (2011b) points out that it is possible that some things become necessities for living in a society and that the inability to acquire such goods is not merely a matter of unmet wants. For example, transportation can be possible by only specific technological solutions, and the failure to access these can lead to relative poverty in a sense which refers to more than mere wants or expectations. Relative property is not merely a psychological concept (Eskelinen, 2011b).

Millennium Declaration

There is no doubt that people are familiar with the fact of extreme poverty. The main purpose of the United Nations' *Millennium Declaration* is to eradicate extreme poverty and hunger (cf. Hutchings, 2010). According to the Declaration, accepted by General Assembly, the goal is "[t]o halve, by the year 2015, the proportion of the world's people whose income is less than one dollar a day and the proportion of people who suffer from hunger and, by the same date, to halve the proportion of people who are unable to reach or to afford safe drinking water."

How can this be done? The Declaration lists, *inter alia*, the following means. The industrialized countries should (1) adopt a policy of duty- and quota-free access for essentially all exports from the least developed countries, (2) implement the enhanced program of debt relief for the heavily indebted poor countries without further delay and agree to cancel all official bilateral debts of those countries in return for their making demonstrable commitments to poverty reduction, and (3) grant more generous development assistance, especially to countries that are genuinely making an effort to apply their resources to poverty reduction.

Critics have argued that the goal of the Declaration is modest. Why is the purpose only to *halve* the number (or the percentage) of people who live in extreme poverty? And why is the time period fifteen years? (The Declaration was made in 2000.) The defenders have replied that more demanding goals would be unrealistic and unfeasible, and perhaps the view is justified, judging from the fact that even the realization of this "modest" goal has turned out to be difficult. It is important to note that the above-mentioned means of eradicating poverty – i.e., (1) fair trade, (2) debt relief, and (3) more intensive development assistance – do not *oblige* any country to carry them out. They are based on every country's voluntary efforts. Fair trade, debt relief, and development assistance are very complex tools, and one can use them counterproductively as the history of development assistance shows. For instance, when a rich country gives grain for a poor country for free it may cause permanent damage to local farmers, agriculture, and food production.

The Value of Development Aid

It is relatively widespread to doubt the value of development assistance. This doubt is often expressed not only in daily debates concerning development aid, but also in academic writing. In his *Despite Good Intentions – Why Development Assistance to the Third World Has Failed* (2003), Thomas W. Dichter argues that it is impossible to eradicate global poverty, because development assistance does not and cannot work properly. Dichter (2003, p. ix) writes that he has "doubts about the value of development assistance" and that he knows of no organization that really accomplishes much in the way of sustained alleviation of poverty or promotes real development or does exactly what it told the public it would do. According to Dichter (2003, p. xi), his "concern is to show not so much *why* development

assistance does not work (. . .) but *how* it does not work" (although the subtitle of the book is the former question). He does, however, have an explanation for the mystery why it does not work – and why it cannot work. The explanation has two, closely linked, parts.

The first part of the explanation is based on the idea that institutions are "slow" – they do not change easily – and that the *development industry* is an institution which changes very slowly, if at all. Dichter (2003, p. 2) asks "[w]hy has an industry that since 1960 has spent over $1.7 trillion on development assistance, by any commonsense cost-benefit calculus, produced negligible results (if not made things worse)?" and points out that "[n]o other large-scale publicly funded effort on such duration could have got away with such poor performance, certainly not in the private sector or even in the ranks of government" (Dichter, 2003, p. 2). Dichter's answer is that aid has become a business whose main stake is its own survival. But this is not to say that organizations or people who work in them have bad intentions. Dichter (2003, p. xiii) writes:

> Most development professionals I have met possess very high ideals about the work they do. But because no one has to date been funded to do development work outside the structure of an organization, those good intentions and ideals get twisted, bent and reshaped. Development professionals have, almost all of us, become caught in the evolution of a set of increasingly self-serving structures whose imperatives, stakes, and incentives have snuck up on us, sometimes so quietly that we have not noticed. If we haven't seen how much those structures limit and compromise development, it's partly because we are in fact so sincere and partly because it is not in our interests to do so.

The second part of the explanation consists of the claim that it is impossible to do anything good by becoming involved in a strange culture and a foreign political system. Development industry denies the validity of this claim or ignores it. One cannot control historical processes. Dichter (2003, p. 7, 9) explains:

> The keys to development increasingly lie in the realm of the policies, laws, and institutions of a society, and to change these requires indirect kinds of approaches – stimulating, fostering, convincing – rather than doing things directly. Why is it, then, that the majority of development assistance organizations continue to "do" things? And why do more and more come into existence every day with funding to do still more things? (. . .) The problems of development are far too complex for any organized and deliberate effort to solve in any lasting way. Development is not a set of obstinate problems the way cancer is but a historical process that cannot really be engineered or controlled.

Dichter's (2003, p. 19) conclusion is pessimistic. According to him, a formally organized, publicly paid for, outsider-driven industry can accomplish "very little." Whatever "few things it may make sense for 'us' to do for 'them', must be done with a light hand. These things, moreover, will have few easily measurable effects, will surely take far *less* money than is presently being applied, and will involve far fewer and much smaller organizations to manage them" (Dichter, 2003, p. 19).

One might argue, however, that Dichter's pessimism is based on an exaggeration. Although it is easy to agree that the development business is growing and that it is often difficult to influence historical processes from outside, it seems clear that even if institutions are "slow," this does not imply that they are unchangeable.

History provides a number of examples of stable institutions which have radically changed structurally – either because of a catastrophe, such as war, or because of intentional external pressure or a radical change in the financial situation. Development industry may well change. It is worth noting that development organizations do *not* get as much money as they are supposed to get. The claim that it is impossible to influence the cultural and political life of a given society from the outside is familiar from the debate on humanitarian interventions, and it seems that the acceptability of the claim should be assessed on case-by-case basis.

It is important to note that no country lives quite separately from others and that influencing the affairs of other countries from outside is something which happens all the time. To say that a development industry intervenes in the political processes of developing countries with no chance of success is to suggest that otherwise those countries are not influenced by the industrialized world and are left untouched. Indeed, Dichter's account seems to be based on the explanation of global poverty that is perhaps the most popular one, namely, the claim that the eradication of severe poverty in the Third World depends largely on their local governments and that wrong decisions explain why the countries are poor. This assumption can be and has been challenged.

Can Poor Countries Help Themselves?

In his article on global order and democracy, published in 2001, Thomas Pogge (2001, p. 333) argues that "our global order plays an important part in sustaining oppression and corruption in the poorer countries." Oppression and corruption, in turn, "cause not only poverty in the developing world, but also moral detachment among the affluent." Pogge is especially concerned about the so-called *international borrowing privilege*, i.e., a right of any Third World government to negotiate loans from international financial markets. He (2001, p. 335) suggests that the "international borrowing privilege has three important negative side effects on the corruption and poverty problems in the developing world." They are as follows: (1) The privilege facilitates borrowing by destructive governments and helps such governments to maintain themselves in power even against near universal popular discontent and opposition. (2) The international borrowing privilege often imposes huge debts accumulated by earlier corrupt regimes upon their democratic successors. It thereby saps the capacity of such democratic governments to implement structural reforms and other political programs. (3) The international borrowing privilege further strengthens the incentives at attempting a coup: whoever succeeds in bringing a preponderance of the means of coercion under his control obtains the borrowing privilege as an additional reward.

How we should try to eradicate poverty? Pogge's main idea is the Global Resource Dividend which, in some respects, resembles the proposal called the Tobin Tax (i.e., a tax for currency transactions in order to collect money for poor countries). According to the Global Resource Dividend, states and their governments shall not have full libertarian property rights with respect to the natural

resources in their territory, but can be required to share a small part of the value of any resources they decide to use or sell. However, Pogge also stresses that the democratic governments of poor countries can do something *themselves*, without complex global redistribution systems such as a Tobin Tax or a Global Resource Dividend. The governments can support democratic development, oppose corruption, and possibly stop the borrowing privilege by local efforts. What is needed is a *constitutional amendment* which says that loans that are borrowed by authoritarian rulers need not be paid back to international banks. In his *World Poverty and Human Rights* (2002, pp. 153–154) Pogge writes that

> There are (. . .) ways of affecting the dispositions of foreign states in ways that would, without violence, reduce the rewards of, and would thereby tend to discourage, an undemocratic takeover. One such measure is a constitutional amendment requiring that debts incurred by future unconstitutional governments – by rulers who will acquire or exercise power in violation of our democratic constitution – must not be serviced at public expense. The idea behind this amendment is to bring it about that successful predators will be able to borrow less, and this at higher rates. If it can achieve this purpose, the amendment would stabilize our fledging democratic order by reducing the payoff associated with a successful coup d'état and thereby weakening the incentives for attempting such a coup in the first place.

Of course, after a successful coup authoritarian rulers can simply declare the amendment suspended, but should they eventually lose power, the democratic government that succeeds them can nonetheless refuse repayment of their debts on the grounds that the coup was illegal (cf. Räikkä, 2006).

Would international banks grant loans to the future authoritarian governments in this situation? According to Pogge (2002, p. 154), they would not. The banks could not be sure that the governments of their home countries would support them in case they did not regain their money. They would know that their governments (i.e., governments of rich democracies) might refuse to help them exactly because of the amendment made by democratic rulers. "Serious public-relations problems, both home and abroad, could arise" if the governments of rich democracies openly supported authoritarian laws above democratic constitution of a poor country. Therefore, if the constitutional amendment were in place, international banks would grant loans only to democratic governments, not to authoritarian rulers. The borrowing privilege – the main cause of corruption and poverty – would be eliminated.

Pogge does not explain why banks of *undemocratic* rich countries would not grant loans to the future authoritarian governments. However, he provides a rather detailed analysis of the constitutional amendment, and he answers other difficult questions such as how to distinguish between democratic and authoritarian governments ("the criterial problem"), and what should be done if the possible authoritarian successors refuse to pay debts of democratic governments ("the tit-for-tat problem"). Pogge (2002, pp. 156–161) argues that we should have (1) a *Democracy Panel* that identifies democratic governments and (2) a *Democracy Fund* that guarantees that debts of democratic governments will always be repaid to international banks. These claims suggest that the functioning of the constitutional amendment is *not* really in the hands of an individual government. Rather, it depends on international support as would be the case with the Tobin Tax or the Global Resource Dividend.

This raises the question whether it is likely that the governments of the powerful rich democracies would readily agree to establish the Democracy Panel and support financially the Democracy Fund. After all, the Democracy Fund would cost much, and rich countries have no incentive to oppose dictators who sell at giveaway prices the natural resources of their land (and keep the money). Pogge admits that some of the governments of the rich democracies would probably object to the constitutional amendment, claiming that it would cause too much instability to international financial systems. In Pogge's (2002, p.160) view, however, this claim is plainly false. The constitutional amendment would engender instability only if rich countries refused to support the necessary institutions related to it, and anyone defending the opposite claim would be seen in a bad light "in the arena of world public opinion." This would reduce pressure by the rich countries against the constitutional amendment.

Pogge's argument seems to rely on the same assumptions as the whole idea of the constitutional amendment, namely, (1) that "public relations" and "public opinion" can have significant effects on the decisions of the governments of rich democracies and (2) that public opinion would condemn actions that contradict democratic development in the poor countries. Pogge argues further that, in fact, the support of the most powerful democratic countries is unnecessary. The Democracy Fund can be financed in another way. He (2002, p.161) writes that the "capital facility needed for the Democracy Fund can be financed through contributions by democratic developing countries, by the more progressive developed democracies, by international organizations, and by contributions from banks and multinational corporations."

Pogge's critics (Räikkä, 2006; Jaggar, 2010) have pointed out that the credibility of this argument depends on how much money is needed to finance the Democracy Fund. If a group of other powerful rich countries oppose the constitutional amendment and the institutions related to it, the Democracy Fund will probably be a very weak and poor organization. It can be argued that international organizations (such as the United Nations and WTO) or banks (such as the IMF and the World Bank) will not give any money to the Democracy Fund, if powerful countries so decide. It is likely that multinational corporations (such as Nokia and Shell) will not endanger their position by opposing world leading countries, and the same is true of "more progressive developed democracies." It is hard to imagine that countries such as Sweden or Norway would strongly support an institution which is explicitly criticized by their powerful allies.

Pogge has recently defended his position for instance in *Politics as Usual* (2010).

Poverty as a Self-Fulfilling Prophecy

There has been a tendency to explain global poverty by referring to the selfishness of the citizens of affluent countries. For instance, in *One World: The Ethics of Globalization* (2002, pp. 152–153), Peter Singer argues that "for many people,

the circle of concern for others stops at the boundaries of their own nation" and that the popular view is that we may, or even should, favor those "of our own kind." An alternative to this view is the idea that the question is about an unfortunate *self-fulfilling prophecy*. The theory states that most people in the affluent countries *believe* that for one reason or another it is practically *impossible* to eradicate poverty, and that this shared belief *itself* may be a cause for why it is practically impossible to eradicate it in the near future. The only cause for global poverty need not be the alleged selfishness of people. It is possible that the main cause is a commonly shared belief that it is impossible to eradicate poverty from the Third World, which influences people's behavior. Behavior that may seem selfish need not be selfish, if it is based on the pessimism regarding the possibilities of success.

There are several reasons why people think that it is practically impossible to get rid of global extreme poverty. Academic literature and daily newspapers are both full of arguments that aim to show that a fight against poverty would be a politically unfeasible project. A person who believes in one or other of these arguments needs not be selfish in any way. The familiar arguments include the following claims:

1. *The Argument Based on Population Growth*. It is impossible to reduce poverty effectively, because increased well-being would cause overpopulation, which in turn would decrease well-being. Famine, diseases, and a high infant mortality rate prevent population growth. There would not be enough food to feed a larger population. Genetically modified organisms that can be used in agriculture will never save people from starving.
2. *The Environmental Argument*. Global equality would cause huge environmental problems. Not everyone in the world can have a car. In the long run, pollution and other environmental problems would make living for human beings impossible, at least in most areas. Therefore, it is practically impossible to eradicate poverty in any meaningful sense.
3. *The Blame Approach*. It is impossible for Western countries to save people in the Third World from starving, because famine and suffering are their own fault. Foreign aid does not work, because the money is used, not for schools, but for dictators' Cadillacs and castles. There is no way of solving military conflicts between local groups and clans, and these conflicts are one of the main reasons for poverty. The idea of exporting democracy from the outside is a joke.
4. *The Not Enough Money Approach*. It is an unfeasible idea that people in the West could really eradicate poverty. This would be impossible because it would be far too expensive, not only in the sense that people would not be happy to give away what they have but in a concrete sense that there simply would not be enough resources to do so. To feed every single person in the world requires not only food – which is not expensive – but also roads, schools, and dozens of local uncorrupted organizations that simply do not exist.
5. *The Argument from Political Realism*. It is impossible to reduce poverty, because nation-states are selfish actors – even if their individual citizens are not. Nation-states would never create international organizations that have

power to really do something for the Third World. Nation-states act on the basis of *political realism*, and they are happy with organizations such as the United Nations, which will never have sufficient power to reduce poverty.

6. *The Technical Argument*. The idea of eradicating poverty from the world is technically unfeasible, at least in the near future. Even if there were enough money and enough political willingness to fight for global equality, it would not work. This is because there are no redistributive structures. To dream of systems such as the Tobin tax is to ignore the fact that redistribution requires not only complex civil servant machinery but also an effective system of sanctions and courts to solve cases. At the moment, we do not have them.
7. *The Argument from Multinational Corporations*. Multinational corporations, by their nature, are largely independent of the political decisions of the nation-states in which they operate, and also of their home countries. Multinational corporations are not interested in reducing poverty. On the contrary, in a sense they are interested in increasing it, because they try to benefit from the poverty in the countries in which they operate. Currently, there is no political way of controlling multinational corporations, and this is why it is practically impossible to reduce poverty or to prevent inequality from increasing.
8. *The Argument from Value Pluralism*. Suppose that rich countries would decide to fight for moderate global equality and redistribute resources. How should those resources be distributed? Should we use Scandinavian standards, or North American, or maybe Saudi Arabian? There are no globally shared standards of (re)distribution, and therefore, there is no chance of distributing them in any way.

The list of arguments for the claim that it is practically impossible to eradicate global poverty is much longer than the list above. What seems common to all these arguments, however, is that they are controversial. (Indeed, one might claim that most of them are plainly false). Even so, it seems clear that they are very popular – judging from the frequency of these arguments.

A self-fulfilling prophecy is a description of the situation that becomes true because of the actions performed as a result of the public acceptance of the prophecy. When an economist presumes that prices will go up in the housing market in the near future and reveals his opinions in public, the result may be that prices will indeed go up – and just because people try to buy a house before the prices do go up. The public announcement and the common acceptance of the prophecy make it come true. The discussion on self-fulfilling prophecies has centered on the difficulty of making predictions in the social sciences. It is hard to make predictions of social life and *test* theories, because predictions influence the data that are supposed to confirm or disprove those theories. Social predictions may possess a reflexive force. They may make themselves true (or untrue).

What could be the route from the widely shared belief that poverty in the Third World is a necessity to the possible fact that it *is* a necessity? There are several possible reasons why the claim that global inequality is unavoidable could be a typical self-fulfilling prophecy. (Cf. Räikkä, 2004). When people believe that it is practically impossible to get rid of global inequality, they might be politically passive in issues related to foreign aid. Perhaps they do not vote for politicians that

are interested in global justice. Perhaps they do not participate in the actions of different nongovernmental organizations that pursue a better world. They could give more donations or join the one percent movement. They could do voluntary work in the poor states. They could take part in an action such as "Sponsor a Child." They could start new organizations that fight against poverty in the Third World. But why should they if such actions are futile? When people believe that poverty is unavoidable, there is little pressure on national governments. And why should governments try to do something which is impossible?

Of course, not all people believe that poverty is a necessity, and there are many active citizens who really try to do *something*. Indeed, the belief that it is practically impossible to get rid of poverty is compatible with the idea that there is much that we can do. Thus, even the majority who seem to accept the *impossibility thesis* may be willing to do something, because they realize that something is better than nothing. But still it may be the case that eradicating poverty from the Third World is extremely difficult mainly because of people's pessimism.

The claim that global inequality can – at least partly – be explained by referring to the unfortunate self-fulfilling prophecy should be distinguished from the claim that people (and states) hesitate to fight against poverty because they are afraid that others will not. The so-called compliance problem, as the latter claim is often called, is important, but it is not directly related to the self-fulfilling prophecies. Rather, the compliance problem provides an alternative way of explaining why people do not do good things even if they would like to.

Poverty and Population Growth

Extreme poverty and population growth are closely related as poverty tends to enlarge family size. The growth of world population raises two kinds of normative questions. First, there are questions of intergenerational justice. How should welfare be distributed across generations? What kind of theoretical framework should we construct to deal with future generations? Second, there are ethical questions of population policy. Since determining the number of people in the world is partly a matter of individual and social choice, it is subject to moral evaluation. What are desirable goals of population policies? Which means are morally acceptable when striving for these goals? How should the burden of achieving a demographic goal be distributed? Questions of intergenerational justice and the ethics of population policies are interrelated in various ways, but it is important to note that intergenerational justice concerns current and *future people*, i.e., people who will live in the future, while the ethics of population policies concern *potential people*, i.e., entities that have the potential to become a person, and *possible people*, i.e., people who will live in the future if we so decide.

Certain population policies have caused serious social and moral problems. Eugenics and sterilization were widely used both in Europe and North America in the twentieth century. Contraceptives have had unknown side effects, and women have not been fully informed of their health risks. Especially in the Third World

countries coercion of women has been a general feature of many population policies. Control-oriented policies have been much more common than service-oriented policies. Compensation payments have linked sterilization and abortion to poverty, highlighting, and increasing social inequality. Certain policies have led to sex selection and to the killing of female newborns. These kinds of problems may suggest that active population policies are morally problematic *per se*, but a *laissez faire* population policy – a policy of nonaction – may cause serious problems too.

In general, there is a relatively good understanding of what should be done to reduce family size in areas of rapid population growth. We may, *inter alia*, try to increase social approval of small families, to cut down the opportunities for children to be productively employed, to make social security available for the elderly, to reduce the costs of contraception, to increase knowledge of contraceptive techniques, to improve social standards involved in the raising of children, to increase the cost of products used by children, to educate young women, to create well-paid jobs for young women, to speed up urbanization, and to impose mandatory education for children where the cost of this education is partly paid by parents. The most effective means to reduce family size would be to eradicate extreme poverty, since poverty causes population growth.

Are coercive population policies ever morally justified? A received view is that ethically acceptable population policies let individuals freely decide the number of their children and that we are permitted to strive for demographic goals only by policies that are noncoercive. However, an argument has been made that if there is no way to slow down the population growth other than using *directly coercive* laws, such laws may be morally justified (Attfield, 1999, p. 128). Those who sympathize with this view emphasize that population growth is inconsistent with the ideals of sustainable development and contributes significantly to environmental, ecological, and social problems in certain areas.

It is not clear whether we should prefer *indirectly coercive* population policies to directly coercive ones if we wished to respect procreative rights. Much depends on the *content* of such indirectly coercive policies. Suppose that there is a law (direct policy) that prohibits having more than two children, but that nothing really happens if one has more than two children. Compare this law to an economic deterrent (indirect policy) that in practice makes it inadvisable to have more than two children. In this case the direct policy seems less problematic than the indirect policy. Consider another example. Suppose there is a law (direct policy) that prohibits having more than three children, and that acting against this law implies heavy penalties. Compare this policy to an economic incentive (indirect policy) that in practice makes it impossible to have more than one child. Again, the direct policy is less problematic than the indirect policy. Compare now a law that restricts the number of children in families (direct policy), and an economic incentive that makes it impossible for poor people to have children and encourages rich people to have them (indirect policy). At least from the point of view of equality, once again the direct policy seems less problematic (cf. Räikkä, 2001).

Population theory has generated a number of philosophical paradoxes and puzzles. A famous puzzle is Derek Parfit's reasoning that classical utilitarianism (i.e., the

"total theory") implies the "Repugnant Conclusion." As formulated by Parfit, the repugnant conclusion is the claim that for "any possible population of at least ten billion people, all with a very high quality of life, there must be some much larger imaginable population whose existence, if other things are equal, would be better, even though its members have lives that are barely worth living." According to (the hedonistic version of) classical utilitarianism, it is a good thing to maximize happiness as long as persons' happiness exceeds their misery and adds to the total sum of happiness on Earth. As long as average happiness declines slowly enough, numbers under classical utilitarianism are encouraged to increase indefinitely no matter how low the average has fallen. But most of us think that this kind of overcrowded world is not the ideal world. There are many ways to react to Parfit's argument. One can simply reject classical utilitarianism, or one may try to show that classical utilitarianism does not lead to the repugnant conclusion or, biting the bullet, one may claim that the repugnant conclusion is not so repugnant. However, it is important to keep in mind that poverty-related overpopulation (and birth control that has followed it) have caused much pain and trouble to individual persons, in particular women. Perhaps philosophers have not always taken seriously the suffering of people.

Extreme Poverty and Genetically Modified Food

A suggestion has been made that we could reduce poverty and the number of unnecessary deaths by the use of genetically modified organisms (GMOs). This view has been supported for instance by the multinational agricultural biotechnology corporation The Monsanto. According to the argument, GM agriculture may (1) produce bigger harvests, (2) make food more nourishing, and (3) make food cheaper in the developing countries. There is no doubt that the problem of poverty should be resolved by political means, but it seems that at the moment there is no feasible political solution. The ethical acceptability of GM agriculture should be evaluated in this context. The defenders of GM agriculture argue that we should try to use *all* possible means to reduce the number of unnecessary deaths. However, there are well-known objections against this proposal (Altieri & Rosset, 2002). Let us list and consider four typical arguments against using GM agriculture in helping the poor.

The first argument is the claim that the major cause of poverty and hunger in the world is not lack of food but unfair distribution. The distribution of the means to acquire food and the actual distribution of what is already available in terms of food is poor. There is, therefore, no need to use GM agriculture. The first argument does not tell whether GM agriculture will be useful in the future. Even if there is enough food now, GM agriculture may be necessary in the future. It is also important to notice that the first objection does not prove that GM agriculture is useless: *if* GM agriculture results in bigger harvests or makes food more nourishing or cheaper, then it may be very helpful.

The second argument claims that gene-altered plants will induce allergies, or rock the delicate balance of nature. Gene-manipulated grain and other species are

living pollutants, the effects of which are beyond anyone's grasp to comprehend. Therefore, GM agriculture should not be used. This objection is based on the assumption that GM food has harmful effects on health or environment. Perhaps this is true, as the European Union stresses the risks of GM agriculture. However, the reasons behind the EU claims may be economic rather than environmental or social. The second objection raises the question whether it is more important to avoid health and environmental risks than to try to save people's lives: if GM agriculture saves five percent of people who would otherwise die, it would save a considerable number of people every day.

The third objection says that genetic engineering means that the poor in rural areas may well become more dependent on the multinational companies who provide seeds to local farmers. Local farmers will lose their own seeds. That is social injustice. Therefore, GM agriculture should be rejected. The third argument reveals one problem that is related to GM agriculture, although one should remember that *all* agriculture have similar consequences in poor countries, at least potentially. (The problem of dependence is related not only to GM agriculture.) A critic might point out that the third objection is based on the suspect ethical assumption that it is more important to oppose social injustice than try to save people's lives. Social injustice is a bad thing, but it need not *kill* anyone.

According to the fourth argument, even if gene technology were to yield bigger harvests, it would not help solve the hunger problem. The causes of underlying hunger are political and economic, they are not technical. Therefore, GM agriculture is futile. This objection shows that, at best, GM technology provides incomplete solutions to hunger and poverty: clean drinking water and cheaper medicines are, *inter alia*, also needed. However, the objection assumes wrongly that political problems cannot have technical solutions. Indeed, it is relatively common in politics that difficult questions are solved by technical means. (For example, new train connections make a change of work place more accessible and so on.) Another point is that the fourth argument is based on a dubious claim that nothing need be done if not everything can be accomplished. Of course, one must try to save one person even if it is impossible to save ten.

It is difficult to say how helpful GM technology in agriculture could be; the future may show that it is not very helpful, at least in eradicating poverty in terms of preventing unnecessary deaths.

Conclusion

Extreme poverty raises many ethical and philosophical questions, even if one agrees that poverty is a bad thing and should be eradicated. As the discussion above shows, many problems are related to the question what kinds of solutions are *feasible*. The notion of feasibility, however, is anything but clear. The evaluation of the feasibility of a certain goal seems to refer to means and processes. One can criticize a political proposal from the point of view of both desirability and feasibility, but quite often the desirability of a goal (such as reduction of poverty)

is taken *for granted* when its feasibility is evaluated. When we estimate the feasibility of the goal, we ask whether we should strive for the goal – now that we know it *is* desirable. There are at least two different attributions based on a lack of feasibility, i.e., judgments that conclude that a certain social ideal is "not realizable." First, it can be said that the realization of a social ideal is strictly and literally impossible and just cannot be implemented in practice. Second, it can be said that there are weak constraints such as economic or cultural facts that make an ideal less feasible than other goals in that their existence makes the achievement of the ideal very difficult and decreases the likelihood of success.

Notice, however, that it can also be said that a social ideal cannot be realized because its realization process would (more or less necessarily) require unjustified (moral) sacrifices. The point of these kinds of judgments is not to say that one cannot realize a given goal or that its realization would be very difficult. Rather, the point is to argue that one *should not* realize the goal, given the moral costs that its realization process would necessarily create. These kinds of judgments may require *moral defense*, but too often they are presented as if they were factual claims that need not be defended normatively. Those who make normative claims should make their reasoning explicit so that their arguments could be evaluated. People who present new proposals have a right to know exactly what are the allegedly unavoidable moral costs that make the ideals unrealizable. If someone argues that eradicating global poverty is unrealistic, then he or she has the burden of proof to show why this is so.

Scientific Misconduct and Research Integrity

47

David B. Resnik

Introduction

In the last two decades, scientists, scholars, policymakers, and members of the public have become increasingly concerned about threats to scientific integrity, such as fraudulent academic research, plagiarism, manipulation, and suppression of data by pharmaceutical companies, academic-industry collaborations, exploitative mentoring of students, abuses of animal and human research subjects, misuse of funds, and lax institutional oversight. Scandals involving unethical research have frequently drawn the attention of the press and politicians. To promote integrity in research in the USA, the National Institutes of Health (NIH) and the National Science Foundation (NSF) have promulgated ethics policies, such as conflict of interest and misconduct rules, and have required graduate and postdoctoral students funded by grants to receive education in responsible conduct of research. Scientific journals, professional associations, and research institutions have also developed ethics guidelines (Shamoo & Resnik, 2009; Steneck, 2007). This entry presents an overview of research ethics, examining the foundations of research ethics, principles for ethical research, common ethical dilemmas in research, research misconduct, famous cases of misconduct or alleged misconduct, and international ethics standards.

Research Ethics and Integrity

General ethics (or morality) consists of the standards of conduct that apply to all people in society, such as the duties to not harm others, to help others, to not steal, to tell the truth, and to keep one's promises (Gert, 2007). Individuals also have special ethical obligations based on their social roles in addition to their general

obligations. For example, parents have an obligation to care for their children. Physicians have an obligation to protect their patients' confidentiality. Scientists also have special obligations based on their social roles. Scientists perform several important social functions, including developing and applying knowledge, educating students, and providing expertise and advice for policymakers and the public. Research ethics is thus a type of applied or professional ethics akin to medical, business, or legal ethics. To act with integrity in research is to act in accordance with ethical principles (Shamoo & Resnik, 2009).

Foundations of Research Ethics

A foundation provides support (or justification) for a larger conceptual structure, such as a theory, political system, or worldview. Research integrity has two distinct foundations. First, research integrity is part of good scientific practice because it is essential for achieving the goals of science and for promoting cooperation and trust among scientists. Data fabrication, falsification, and manipulation lead to falsehoods, errors, and biases that impede the quest for truth, explanatory knowledge, and other goals of research. Refusing to share data, results, and methods or keeping inadequate records can also hinder the advancement of science. Cooperation and trust among scientists is essential to many different aspects of research methodology and practice including collaboration, peer review, publication, and the replication of results. For example, scientists who submit papers for publication must be able to trust that reviewers will not steal their ideas or use data, methods, or results. Second, research integrity makes science accountable to the public by ensuring that scientists adhere to ethical standards and produce socially beneficial results. Scientists who violate ethical standards or produce harmful results betray the public's trust and undermine support for research. Abuses of human or animal research subjects, mismanagement of funds, fraud in academic or industry research, violations of laws and regulations, and other ethical transgressions can weaken the public's trust in science and produce detrimental results that harm individuals, society, or the environment (National Academy of Sciences, 2005; Shamoo & Resnik, 2009; Shrader-Frechette, 1994; Resnik, 1998).

Principles of Research Ethics

Nearly 40 years ago, the prominent sociologist of science Robert Merton (1973) described four norms that govern scientific research: communalism (scientists should share data and results), universalism (all scientists should be able to contribute regardless of race, gender, nationality, or culture), disinterestedness (scientists should not allow their personal or political biases to affect their work), and organized skepticism (scientific claims should be exposed to rigorous criticism). Science historian and philosopher Thomas Kuhn (1977) argued that several values influence scientific judgment and theory-choice, including accuracy, consistency,

generality, simplicity, and fruitfulness. Other philosophers (e.g., Longino, 1990) have argued that slightly different sets of values influence scientific reasoning. Although Merton's and Kuhn's ideas still have considerable influence over the sociology, history, and philosophy or science, they do not provide a clear statement of the ethical principles of science, because they focus mostly on the epistemological aspects of science, such as methodology and theory-choice. Ethical principles of research apply not only to scientific evidence and belief but also to scientific behavior and conduct (Resnik, 1998). Ethical principles are implicit in our understanding of what constitutes good scientific practice and are embodied in professional codes and guidelines, institutional and journal policies, and government rules and regulations (Resnik, 1998). These principles are as follows (Macrina, 2005; National Academy of Sciences, 2005; Shamoo & Resnik, 2009; Steneck, 2007):

- Honesty: Scientists should communicate honestly with each other, research sponsors and institutions, government agencies, and the public.
- Due care: Scientists should avoid careless errors and strive to reduce or control biases in research.
- Openness: Scientists should share data, results, methods, and tools.
- Fair credit: Scientists should allocate credit fairly.
- Respect for peers and students: Scientists should treat their students and colleagues with respect.
- Respect for property: Scientists should respect physical and intellectual property.
- Respect for research subjects: Scientists should show appropriate respect toward human and animal research subjects.
- Respect for the law: Scientists should obey institutional policies and legal rules that apply to their work and promote compliance with policies and rules.
- Nondiscrimination: Scientists should not unfairly discriminate against peers or students.
- Stewardship of resources: Scientists should make effective use of physical, financial, and other resources.
- Social responsibility: Scientists should maximize benefits and minimize harms to society, public health, and the environment.
- Freedom: Scientists should respect the right to freedom of inquiry and debate.

These principles provide general guidance for the conduct of research and imply numerous subsidiary rules and obligations that apply to particular situations. For example, the principle of honesty implies prohibitions against data fabrication and falsification. Due care implies rules for managing conflicts of interest and keeping research records. Fair credit implies rules for assigning authorship on papers and prohibitions against plagiarism. Respect for research subjects implies rules for research with humans, such as standards for obtaining informed consent, protecting subjects from risks, and safeguarding confidentiality. Nondiscrimination implies prohibitions against discrimination in admissions to graduate programs, hiring, or promotion. Respect for the law implies obligations to obey the institutional policies and legal rules pertaining to one's research and to report people who violate policies

or rules. Social responsibility implies duties to educate the public about research, to communicate with the media, and to provide policymakers with expertise and advice (Shamoo & Resnik, 2009).

The principles also imply institutional obligations and responsibilities. Institutions should share data, results, methods, and tools; respect intellectual property; not discriminate; respect freedom; respect research human and animal subjects; obey and enforce the law; practice social responsibility; and make effective use of resources. Research institutions can help to ensure that ethical standards are upheld by developing, promulgating, and enforcing policies that reinforce these standards; by sponsoring education and training in research ethics; by promoting ethical management and leadership; and by auditing and overseeing research (National Academy of Sciences, 2002).

Ethical Dilemmas in Research

Sometimes ethical principles conflict with each other or with other rules or values. When this occurs, researchers face ethical dilemmas, and they must determine the best course of action to take. Some common ethical dilemmas in research are as follows:

- Analyzing data: When researchers analyze data, they often face issues relating to data analysis, such as how to deal with data outliers and missing data, editing data, using statistical methods to draw conclusions from the data, or using digital manipulation programs to represent data. Tensions can occur between honestly presenting all the data in an unbiased fashion and presenting convincing and clear results (Shamoo & Resnik, 2009; Steneck, 2007).
- Sharing data: The obligation to share data sometimes conflicts with other obligations and interests, such as protecting the privacy and confidentiality of human subjects, safeguarding propriety business information and intellectual property rights, following rules concerning classified research, and protecting scientific priority and credit for one's accomplishments. Scientists may use a variety of strategies, such as data sharing and confidentiality agreements, to balance the obligations to share data and protect confidentiality (Shamoo & Resnik, 2009).
- Assigning authorship: Determining who should be an author on a scientific publication can be a difficult decision, because individuals may have different understandings of what counts as a significant contribution. Though journal guidelines can help to resolve some of these questions, it is also helpful to discuss authorship issues at the beginning of a scientific collaboration (Steneck, 2007).
- Conflicts of interest: A conflict of interest in research is a situation in which an investigator has a professional, personal, or financial interest that is likely to affect his or her judgment or conduct. Difficult questions can arise when deciding which types interests should be disclosed and whether some types of conflicts should be prohibited (Macrina, 2005).

- Peer review: Peer review helps to ensure the quality of published research. The most qualified reviewers in a particular field often have vested interests in promoting their own theories or suppressing competing research groups. Ethical dilemmas can arise when deciding how to develop procedures that promote fair and effective review that minimizes bias (Shamoo & Resnik, 2009).
- Intellectual property: Patenting helps to foster scientific and technical innovation, but some argue that some types of biological systems, including organisms, DNA, human and cell lines, should not be patented. Others are concerned that pharmaceutical and biotechnology patents undermine access to affordable medicines (Shamoo & Resnik, 2009).
- Reporting misconduct: The obligation to report suspected misconduct (discussed below) often conflicts with self-interest, since the person who makes an accusation may face professional or personal repercussions, as well as the expenditure of considerable time and effort. Although institutions have rules to protect whistle-blowers against direct retaliation, these rules do not guarantee that those who report misconduct will face no adverse personal consequences, and individuals still face difficult choices when deciding whether to report illegal or unethical activity (Macrina, 2005).
- Human subjects research: Many different ethical dilemmas arise in human subjects research. Most of these dilemmas revolve around the basic tension between advancing scientific research and protecting human rights and well-being. For example, dilemmas can arise when deciding whether placebos should be used in clinical trials. Placebo control groups are often needed to ensure scientific rigor. However, subjects who receive placebos will not receive an effective therapy. Failing to offer an effective treatment to a subject participating in a clinical trial may violate the physician/investigator's duty to benefit his patients (Emanuel et al., 2008).
- Animal research: The most basic ethical question related to animal research is whether it should be conducted at all. Some animal rights activists argue that all animal research is unethical and should be stopped, while proponents of animal research argue that the knowledge generated from animal experiments provides important benefits for human health. Even proponents of animal research acknowledge that difficult issues may arise when experiments that advance biomedical science cause significant pain or suffering to animals (Nuffield Council on Bioethics, 2005).
- Social responsibility: Ethical dilemmas can arise when scientists participate in political debates. Though scientists have a right and an obligation to provide expertise and advice to the public, taking a strong stand on an issue can compromise their objectivity. Dilemmas can also arise when scientists decide whether – and how – to communicate with the media, because journalists may misrepresent research results. Scientists may be tempted to oversimplify their findings in order to ensure that the public receives the proper message (Resnik, 1998).
- Scientific freedom: Some types of scientific research can threaten national security, public health, or society. Ethical dilemmas can arise when deciding whether to restrict the publication or funding of potentially dangerous research (Shamoo & Resnik, 2009).

Dealing with Research Misconduct

Investigators sometimes violate widely accepted ethical standards. Severe violations are classified as research misconduct. Because misconduct can significantly undermine the integrity of research, legal or other penalties may be imposed on individuals who commit misconduct. For example, the Public Health Service (PHS), which funds NIH research, may bar a researcher who commits misconduct under a grant or contract from receiving federal funding. Other federal agencies have similar policies. Institutions may demote, suspend, or fire individuals who commit misconduct. Professional associations may revoke the membership or privileges of individuals who commit misconduct, and journals may require authors to withdraw papers impacted by misconduct. In some cases, researchers who have committed misconduct have also been convicted of criminal charges, such as fraud or misuse of funds (Shamoo & Resnik, 2009).

Because misconduct allegations can lead to serious ramifications for an individual's career, misconduct investigations are legal proceedings in which the accused parties have rights to due process. For example, the PHS' misconduct policies allow the defendant to seek legal counsel, have access to all the evidence presented against him or her, and appeal a finding of misconduct. PHS policies also set specific deadlines for different stages of misconduct proceedings and require all those involved in misconduct proceedings to maintain confidentiality. If an investigator's reputation is harmed as a result of a false allegation of misconduct investigated by an institution, the institution is obligated to compensate the investigator for the damages. NIH policies – and federal and states laws – also protect individuals who make good faith allegations from retaliation (Shamoo & Resnik, 2009).

Under NIH policy, an individual may bring a misconduct allegation to his or her supervisor or institutional official. The allegation will be forwarded to the person who is designated as the research integrity officer (RIO) at the institution, usually a dean, director, or vice president for research. If the RIO determines that misconduct allegation has been made in good faith and it fits the definition of misconduct, then he or she will sequester evidence (such as research records) and appoint an inquiry committee. If the inquiry committee determines there is enough evidence to conduct an investigation, the RIO will appoint an investigation committee. The investigation committee will consider all the evidence and make a formal finding. If the investigation committee finds that the individual has committed misconduct, then it will forward its recommendation to the RIO, who will decide whether to impose any penalties, such as academic demotion or suspension. The institution will also report its findings to the Office of Research Integrity (ORI), which oversees PHS-funded research. The ORI will review the misconduct proceedings and decide whether to impose penalties on the investigator, such as denial of funding. The ORI usually allows institutions to conduct their own investigations, but it may become involved in an investigation at any time if the circumstances warrant. The defendant also has the right to appeal the ORI's findings to an administrative law court (Shamoo & Resnik, 2009).

One of the key policy debates related to misconduct is the definition of misconduct. During the 1980s and 1990s, the PHS defined misconduct as fabrication, falsification, or plagiarism (FFP), or other serious deviations from accepted research practices. For several years, investigators and federal agency officials debated about whether "other serious deviations" should be included in the definition of misconduct, because this category is inherently vague and limitless. Institutions might be required to investigate sexual harassment, property theft, abuse of animal or human subjects, exploitation of students, and many other unethical behaviors if this category were included in the definition. In 2000, the US federal government adopted a definition of misconduct that eliminates the "serious deviations" category and defines misconduct as FFP. Misconduct does not include honest errors or differences of opinion about research methods. Fabrication is defined as making up data or results and recording or reporting them; falsification is manipulating research materials, equipment, or processes, or changing or omitting data or results such that the research is not accurately represented in the research record; and plagiarism is the appropriation of another person's ideas, processes, results, or words without giving appropriate credit (Office of Science and Technology Policy, 2000).

Other countries and private funding agencies have also adopted definitions of misconduct and procedures for investigating and adjudicating misconduct. Though most definitions include FFP, some also include interfering with a misconduct investigation, lying on a résumé or job application, or significantly violating human or animal research regulations (Resnik, 2003).

The incidence of misconduct is thought to be low, though it is difficult to obtain an accurate estimate, due to problems with underreporting or overreporting. Martinson, Anderson, and de Vries (2005) surveyed over 3,000 NIH-funded researchers about various misbehaviors in science; 0.3% (3 out of 1,000) admitted to falsifying or "cooking up" data in the past 3 years. However, this number may be too low, because respondents may not have wanted to admit on an anonymous survey that they have engaged in unethical or illegal behaviors. Swazey, Anderson, and Louis (1993) found that as many as 9% of students and faculty reported direct knowledge of fabrication, falsification, or plagiarism. However, this number may be too high because respondents may not have had sufficient evidence to determine that the behavior they observed was misconduct. Even if the incidence of misconduct is low, it is still a significant problem for the integrity of research, because misconduct can have wide-ranging effects on the accuracy of the research record, trust among scientists, and the public's support for science (National Academy of Sciences, 1995, 2002).

Some investigators subscribe to the "bad apples" theory of research misconduct, which holds that misconduct is committed by a few people who are morally corrupt or psychologically disturbed. However, there is considerable evidence that misconduct is a complex phenomenon caused by a variety of psychological and social factors, such as the pressure to produce results, career ambitions, competition for funding, and poor communication and oversight (National Academy of Sciences, 2002). Misconduct is often committed by people who are not inherently unethical or disturbed but who decide to bend or break the rules of science when faced with stresses and burdens.

Famous Cases of Research Misconduct or Alleged Misconduct

Scientists have recognized that misconduct is a problem in research since at least the nineteenth century. In 1830, the British mathematician and scientist Charles Babbage published an essay titled *The Decline of Science in England* in which he chided his colleagues for fabricating, falsifying, and manipulating data. In 1849, the newly formed American Medical Association formed a committee to investigate fraudulent medical claims (Resnik, 2008).

The first major scandal involving allegations of misconduct took place over several decades in the early twentieth century when Charles Dawson and Arthur Woodward claimed to have found pieces of a skull in the Piltdown gravel bed near Surrey, England, in 1912, which they said was a "missing link" between humans and apes. The skull was controversial from the beginning, however, and many claimed that it was a fabrication which was inconsistent with other hominid fossils. In 1953, physical and chemical tests proved that the skull was not genuine. The upper part of the skull was human, the jaw came from an orangutan, and the teeth were from a chimpanzee. The pieces of the skull had been treated with chemicals to make them appear to be fossils. It is not known who committed the Piltdown forgery, though Dawson is a leading suspect (Resnik, 2008).

A bizarre case of fabrication took place at the prestigious Sloan Kettering Institute in New York in 1974. William Summerlin, a well-known immunologist, had been conducting experiments to prove that tissue rejection can be prevented by culturing tissue prior to transplantation. Summerlin transplanted skin patches from black-haired mice to white-haired mice to prove his hypothesis. While cleaning the animals' cages, a laboratory assistant discovered that the black patches of hair could be washed off by treating them with alcohol. The assistant reported his findings to Summerlin's supervisor, Robert Goode, and Summerlin admitted that he had used a black felt tip pen to produce patches of black hair on the white-haired mice. Summerlin was granted a medical leave of absence and required to retract papers related to his work. The incident had a negative impact on Goode's career as well, even though he was not implicated in the fabrication (Resnik, 2008).

In 1981, a misconduct committee found that John Darsee, a postdoctoral fellow at Harvard Medical School, had fabricated or falsified data on 17 papers and 53 abstracts coauthored with faculty at Harvard, Emory University, and Notre Dame University. Although the committee did not find that any of Darsee's coauthors had committed misconduct, it raised serious questions about their responsibilities, since much of Darsee's fraudulent work would be obvious to a trained expert. All of the papers and abstracts were retracted. Though his career as a researcher was finished, Darsee went on to practice medicine (Resnik, 2008).

A scandal known as the "Baltimore Affair" took place at the Whitehead Institute, a laboratory associated with the Massachusetts Institute of Technology (MIT) and Tufts University, from 1986 to 1996. The scandal involved allegations of fabrication and falsification in a paper reporting the results of NIH-funded research published in the journal *Cell* in 1986. The paper had six coauthors, including Thereza Imanishi-Kari and Nobel Prize–winning molecular biologist

David Baltimore. The authors claimed that they were able to insert genes into laboratory mice zygotes to induce the production of specific antibodies in the offspring. Margot O'Toole, who was a postdoctoral student working under the direction of Imanishi-Kari, had trouble repeating some of the experiments reported in the paper. She asked to look at Imanishi-Kari's laboratory notebooks and found that the data recorded in the notebooks differed significantly from the data in the paper. She reported her suspicions to officials at MIT and Tufts, who launched an investigation. The committees investigating the alleged misconduct found errors in the paper but not misconduct. The paper was retracted in 1991. The Office of Scientific Integrity (which later became the ORI) reviewed the committee's findings and conducted its own investigation. In April 1988, the House Oversight and Investigations Committee also investigated the case during its hearings on fraud in government-funded research. Baltimore testified before the committee and labeled the investigations a "witch hunt" (Resnik, 2008).

The Baltimore Affair, which was splashed all over the front pages of the *New York Times*, continued to make headlines during the 1990s. In 1992, Baltimore resigned his position as President of Rockefeller University as a result of his involvement in the scandal, even though he was never implicated in any research misconduct. In 1994, the ORI determined that Imanishi-Kari had fabricated and falsified data reported in the paper, and Tufts required her to take a leave of absence. However, Imanishi-Kari never admitted to any misconduct, and she appealed the case. In 1996, an appeals panel at the Department of Health and Human Services determined that there was not enough evidence to prove that Imanishi-Kari committed misconduct, and the panel overturned the ORI's findings against her. To this day, Imanishi-Kari maintains that she was guilty of only poor record-keeping (Resnik, 2008).

In 1993, a scandal emerged involving a high-profile clinical trial, the National Surgical Adjuvant Breast and Bowel Project (NSABP). The ORI concluded that Canadian surgeon Roger Poisson had falsified data on 117 patients enrolled in the NSABP. Poisson admitted that he changed data pertaining to inclusion criteria for the study in order to help his patients qualify for advanced medical treatment. The misconduct was discovered by University of Pittsburgh statistician Bernard Fischer, who had published several papers containing the falsified data. Fisher, who was never implicated in any misconduct, reanalyzed the corrected data and found that Poisson's fraudulent work had no effect on the overall results. The NSABP represented an important advance in the treatment of breast cancer because it showed that lumpectomies are effective at treating tumors less than 4 cm in diameter. Fisher sued the NIH for damaging his reputation, because the National Cancer Institute, a branch of the NIH which funded the NSABP, had labeled 148 of Fisher's papers posted on its website with a "scientific misconduct" warning (Resnik, 2008).

In 2002, a scandal rocked the physics community when a misconduct committee determined that Jan Hendrik Schön had faked data on at least 17 publications. The committee found that experimental data sets had been reused in various publications and that graphs had been generated from mathematical functions, not from

data. None of Schön's collaborators were implicated in misconduct, although their responsibility was questioned. Schön lost his position and was required to withdraw the fraudulent papers. The 32-year-old Schön won prizes for being a bright, young investigator and for his work in condensed matter physics and nanotechnology. He worked at the world-renowned Bell Laboratories and was publishing at an astounding rate of a paper every 8 days. His publications appeared in *Science*, *Nature*, *Physical Review Letters*, and other prestigious journals (Resnik, 2003).

In 2005, an investigation by the University of Vermont and ORI found that Eric Poehlman had fabricated and falsified data on 15 grant applications submitted to the NIH between 1992 and 2000 and 17 publications. During this time, Poehlman received $2.9 million in federal funding. Poehlman was a tenured professor at the University of Vermont during the period when the misconduct occurred, but took a position at the University of Montreal while the investigation was under way. Poehlman conducted influential research on women's health. In a highly cited paper on menopause published in the *Annals of Internal Medicine*, most of the experimental subjects did not exist. Poehlman's research assistant, Walter DeNino, brought misconduct allegations against him after discovering inconsistencies in a longitudinal study on aging. During the investigation, Poehlman destroyed evidence, falsified documents, and gave false testimony. After the ORI made its findings against Poehlman, it turned the case over to federal prosecutors, who charged Poehlman with criminal and civil fraud and misuse of funds. In 2006, Poehlman accepted a settlement in which he agreed to serve 1 year and 1 day in jail, pay $180,000 in restitution to the government and $16,000 to DeNino's attorney, retract 10 papers from the literature, and be barred for life from receiving federal funding (Shamoo & Resnik, 2009).

Also in 2005, a high-profile scandal involving stem cell research occurred. Woo Suk Wang and colleagues from Seoul University in South Korea published two papers in *Science* in 2004 and 2005 purporting to show how they produced human embryonic stem cells from an embryo created by transferring a nucleus from a patient's somatic cells into a fertilized egg, which has had its nucleus removed. Tissues grown from stem cells taken from the embryo are less likely to be rejected by the patient because they will have the same genome as the patient. If this finding had been correct, it would have been an important development in stem cell research. Wang was hailed as a hero in South Korea and gained international acclaim. However, problems began to emerge in June 2005, when an informant told *PD Notebook*, a South Korean news show, that the 2005 paper had been faked. *PD Notebook* began investigating Wang. In December 2005, another informant made a posting on a website claiming that images of 9 of the 11 cell lines in the 2005 paper had been duplicated from two other images. A university investigation ensued, which found that all of the data in both papers had been faked. Both papers were retracted and Wang lost his position at Seoul University. In 2009, Wang received a 2-year suspended sentence for embezzlement and bioethics law violations. One of Wang's collaborators on the 2005 paper, Gerald Schatten, a prominent stem cell researcher at the University of Pittsburgh, had received $300,000 in consulting fees for his work on the project. Though Schatten was never implicated in misconduct, many have argued that he neglected his duties as a coauthor because

he was only remotely involved in the research (Shamoo & Resnik, 2009). Newspaper, television, and Internet media outlets provided extensive coverage of the scandal as it unfolded.

International Ethics Standards

As one can see from the Wang case, research integrity is also an international concern. International research collaborations raise a variety of ethical problems and concerns, because investigators from different nations may have different understandings of the standards of conduct and different interpretations of ethical concepts. As noted above, research misconduct may be defined differently in different countries. Other concepts, such as authorship, plagiarism, and conflict of interest, may also have different definitions. Countries may have different understandings of the proper treatment of human and animal research subjects. Because ethical standards may vary, scientists involved in international research should work toward a mutual understanding of the ethical standards that will apply to the collaboration.

Following World War II, countries around the world adopted the first international standard for human research ethics, the Nuremberg Code (1947). Since then, other international codes for research with human subjects have been developed, including the Helsinki Declaration (World Medical Association, 2008) and the Council for International Organizations of Medical Sciences (CIOMS) guidelines (CIOMS, 2002). International standards that address ethical issues beyond research with human subjects were not developed until 2010, when the Second World Conference on Research Integrity drafted the Singapore Statement on Research Integrity. The Singapore Statement addresses all of the major areas of research ethics, including data integrity, data sharing, record keeping, authorship, publication, peer review, conflict of interest, reporting misconduct, communicating with the public, complying with regulations, and social responsibilities. The Singapore Statement also includes four ethical principles: honesty, accountability, professional courtesy and fairness, and good stewardship of scientific resources (World Conference on Research Integrity, 2010).

Conclusion

Integrity is vital to good scientific practice and publicly accountable research. There are a dozen or so well-accepted ethical principles in science, including honesty; openness; due care; fair credit; respect for peers and students, research subjects, and the law; and social responsibility. Scientists and research institutions have obligations to follow ethical principles and to promote integrity in research through education, training, policy development, leadership, and oversight.

Synthetic Biology

48

Gregory E. Kaebnick

Introduction

Synthetic biology is a collection of lines of biological research linked by the common goal of engineering novel biological systems, designing and building them to human specification. The basic idea of altering biological systems has been part of genetic research for several decades, and it has been an explicit part of traditional breeding programs for much longer than that; indeed, the very phrase "synthetic biology" was coined a century ago (Campos, 2009). Contemporary synthetic biology seeks to bring this goal to fruition through the application of new technologies – especially technologies for reading and producing genetic sequences – ideally in a structured way that allows design inputs to be well understood and standardized so that design outcomes can be predictable and efficiently achieved. It has potentially transformative benefits, but it also poses a variety of questions that will be a challenge to evaluate fully and to address in public policies. What is the right balance between risks and potential benefits? How can the risks be managed in light of the complexity of microorganisms and ecosystems? Can a society ensure that the changes wrought by the field are just and environmentally beneficial? Is the idea of engineering living organisms intrinsically troubling? And how are these questions most usefully discussed – how do we ensure that deliberation reflects the global import of synthetic biology, for example? This chapter provides an overview of synthetic biology and then delves into four broad ethical concerns that encompass the questions above.

Overview of the Technology

The overall goal of synthetic biology is to make possible the engineering of novel biological systems that can be used like machines or miniature factories to make products or provide services. Such industrial analogies are inescapable when

talking about synthetic biology, and while they may deflect attention from the fact that synthetic biology is about *living* systems, they capture several key aspects of synthetic biology, including the focus on engineering those systems and on altering them in ways that making engineering easier – standardizing and simplifying them.

Since synthetic biology is fundamentally about bringing the principles of engineering to bear on biology, it is, in principle, not defined in terms of and not limited to any particular kind of biological research or category of organism. In practice, however, the main lines of work in synthetic biology are on microorganisms and have to do with the synthesis and alteration of their genomes.

Types of Synthetic Biology

Exactly what the term "synthetic biology" refers to is contested (Brent, 2004), and various taxonomies can be found to explain the term (Presidential Commission for the Study of Bioethical Issues, 2010), but one or more of three broad lines of work are usually in mind when it is used.

One line, and arguably the line that aims most directly at the goal of integrating biology and engineering, is what Maureen O'Malley et al. have called "DNA-based device construction" (O'Malley, Powell, Davies, & Calvert, 2008). It is exemplified by the construction of "biobricks," made from DNA and other molecules, that can function as standardized and interchangeable parts or tools to perform very specific functions – turning gene production on or off, say, or measuring the concentration of a particular gene product (BioBricks Foundation, 2011). Assembled in sequences and installed in "platform" organisms, these parts would, as proponents describe it, turn that organism into a very specialized tool of sorts. Some proponents would add that the parts should also be well characterized and available to the public. Some other synthetic biologists have expressed doubts, however, about whether standardized genetic sequences are achievable (Kwok, 2010).

In a second line of research, Craig Venter and colleagues at the J. Craig Venter Institute are engaged in what O'Malley et al. have called genome-driven cell engineering. For example, they hope to use synthetic DNA to build a "minimal genome" that contains only the genetic material needed to sustain bacterial life (Gibson et al., 2008). Such a minimal genome might provide a standardized platform that could then be equipped with DNA-based devices. In May 2010, researchers at the J. Craig Venter Institute announced that they had taken a step toward creating a minimal genome by successfully synthesizing the entire genome of the bacterium *Mycoplasma mycoides* (Gibson et al., 2010 To prove that the synthesis was successful, they inserted the genome into a cell of a closely related species, *Mycoplasma capricolum*, resulting in a fully functioning *M. mycoides*.

The development of interchangeable biological parts and of general purpose platform organisms into which the parts could be installed are ideal goals. They are certainly not yet realized, and in practice, they tail off into what is sometimes called "metabolic engineering" – the study and alteration of metabolic processes within existing organisms (Nielsen & Kiesling, 2011). Metabolic engineering frequently

resembles a more advanced form of older lines of gene transfer research, differing in that it can be done faster, on a larger scale, potentially combining genetic sequences from three or more organisms, and with more information about the genetic sequences and the organism into which they are put, and therefore with greater ability to design the resulting organism. Given the links and differences with gene transfer, critics sometimes refer to synthetic biology simply as "extreme genetic engineering" (ETC Group, 2007).

A third line might be cobbled together from what are really distinct lines of research, but are united in that they seek to reinvent the basic mechanisms and materials found in living things. For example, in what is known as minimal cell creation or protocell creation (also the creation of "chemical cells," or "chells"), the goal is to design and build organisms from the ground up, first identifying the basic functions necessary for the simplest forms of life (for example, mechanisms for metabolism, for control, for replication, for organization) and then constructing them from basic parts (Presidential Commission, 2010). The new cells might use chemicals not found in naturally occurring organisms. In principle, the development of protocells could lead to an entirely new biochemistry – a biochemistry that was nonorganic, in that it would not be carbon-based. Additionally, mechanisms for control and replication need not depend on DNA.

Two particularly high-profile examples of new products to which synthetic biology might lead are worth describing in greater detail. The examples both illustrate the science and help ground a discussion of the ethical issues synthetic biology raises.

The Case of Artemisinin

What is sometimes considered the flagship example of synthetic biology is the production of artemisinin, a highly effective but to date comparatively expensive treatment for malaria. Up until now, artemisinin has been extracted from the wormwood plant (*Artemisia annua*), which can be grown in plantations but according to some commentators is not easily grown in the quantities necessary to make artemisinin affordable for widespread treatment. An alternative strategy, developed by a partnership formed between Amyris Biotechnologies, the Institute for One World Health, and the University of California, Berkeley, is to construct a new metabolic pathway, comprised of genes from bacteria, yeast, and wormwood, that allows microorganisms equipped with the pathway to synthesize artemisinic acid, an artemisinin precursor, through a fermentation process (Hale et al., 2007). The pathway was first developed in *Escherichia coli* and then in baker's yeast (*Saccharomyces cerevisiae*). The artemisinic acid produced by the organism can then be processed in the laboratory into artemisinin. (This final step in the production of artemisinin is performed by the wormwood plant, but it has not been recreated in microorganisms.)

As malaria affects hundreds of millions of people globally each year and kills up to one million, the potential health benefits of this application are considerable. The work was initially funded by the Bill and Melinda Gates Foundation, and it has now

been licensed to and further developed by the pharmaceutical company Sanofi-Aventis. Synthetically produced artemisinin is expected to be available in 2012 (Specter, 2009).

The Case of Fuel Production

Research is under way on several fronts to develop organisms that would produce fuel. One line of research is aimed at the development of organisms that can more efficiently process biomass, typically crops such as corn, into biofuels such as ethanol. The organisms considered candidates for ethanol production include *S. cerevisiae* and *Zymomonas mobilis*, which naturally produce ethanol out of glucose, and *E. coli*, which naturally produces a small amount of ethanol but can process a broad variety of substrates (Jang et al., 2012). The research aims to eliminate metabolic pathways that compete with ethanol production, allow the organisms to tolerate higher levels of ethanol, and broaden the range of substrates that the organisms can process. An organism that processed cellulose, which is abundant and cheap, would be especially desirable. Butanol production is also desirable, because butanol has a higher energy density than ethanol, allowing for better gas mileage, and because it has properties similar to gasoline, so that it can replace gasoline in existing engines and in the existing systems for fuel storage and transport. Research on butanol production is under way with *Clostridium*, which produces butanol naturally, and *E. coli* modified with clostridial genes (Jang et al.).

Research is also under way on the development of organisms that produce alkanes (which, depending on the number of carbon atoms, can be used either as gasoline or as diesel or aviation fuel), isoprenoids, and hydrogen (which has an extremely high energy density and produces only water when it burns) (Jang et al.).

Another line of research is on organisms such as algae and cyanobacteria that could produce some of these same kinds of fuel photosynthetically. Biomass from feedstocks would be unnecessary; the inputs might only be carbon dioxide, water, and sunlight. In principle, then, this method of producing fuel could avoid or limit the environmental harms of drilling and transporting oil and of growing feedstocks to produce biomass and also serve as a carbon-fixing process, thereby helping to offset the environmental costs of burning fuel. However, some methods of producing fuels photosynthetically would require a significant investment in equipment (such as greenhouses), land, and water.

Some of these methods are expected to be commercially viable in the next few years; others are longer-term propositions (Presidential Commission, 2010).

Where Synthetic Biology Occurs

The research described above is undertaken primarily by laboratories in major research universities and private industry. As noted, research on the production of

artemisinic acid is a collaborative effort involving a major research university, nonprofit funders, and private companies. Research on biofuels is conducted by the Joint BioEnergy Institute (a public-private research partnership that brings together Lawrence Berkeley, Sandia, and Lawrence Livermore national laboratories along with the University of California campuses of Berkeley and Davis and the Carnegie Institution for Science), the J. Craig Venter Institute (with $600 million in funding from ExxonMobil Corporation), Amyris Biotechnologies (with funding from Crystalsev, a large Brazilian ethanol distributor), and an assortment of start-ups and smaller biotechnology companies.

Some synthetic biologists believe, however, that the *spirit* of synthetic biology is in the research and development that occurs *outside* established academic and commercial facilities – in so-called "garage biology," "outlaw biology," "bio-hacking," or "DIY bio." These terms embrace more than synthetic biology, but synthetic biology is in some ways the most striking example of what can be accomplished in a garage setting, and if synthetic biology is defined as the application to biology of engineering principles, then the goals of synthetic biology are closely affiliated with DIY bio: both aim at the democratization of skills.

Research in DIY bio could veer off in unpredictable and entrepreneurial ways, following the inclinations of the practitioner. Although DIY biologists often aim to develop serious, marketable products–in recent years, projects at the International Genetically Engineered Machines competition, which is structured to imitate and advance amateur biology, have included bacteria that could break down plastic waste in landfills and a form of *E. coli* that could function as a drug delivery system (iGEM, 2010) – they can also experiment with toys, gadgets, and lifestyle products. Amateur biology will be greatly facilitated if extensive catalogs of well-characterized, standard "biobricks" become available, allowing people to order off-the-shelf parts.

Overview of the Ethical Issues

The ethical issues raised by synthetic biology will be familiar, in outline form, to those who have thought about the ethical implications of earlier waves of technology. As with any emerging technology, the ethical issues can be crudely divided into several general categories, having to do, respectively, with the tangible benefits and harms of the technology, with the implications for equality and justice (i.e., the distribution of benefits and harms), with the intrinsic value of limiting human intrusion into nature (aside from any questions about benefits and harms), and with deliberation about the science and its ethical issues. While these issues are already familiar in broad outline, however, they sometimes take particularly interesting and challenging forms with synthetic biology. The potential benefits and harms are uncommonly great, for example, and the issue of human intrusion into nature amounts, with synthetic biology, to concerns about the very idea of synthesizing living organisms.

Benefits and Harms

One tangible benefit of synthetic biology is nonetheless not immediately obvious, as the benefit may be indirect and deferred: synthetic biology provides further insight into the nature of cells and their genetic machinery, which may prove useful years later, and perhaps in ways that cannot be anticipated at the time the research is performed. The work at JCVI on the minimal genome, for example, which is aimed at determining which genes are essential to the cell, also provides insight into what different genes do. Other lines of research in synthetic biology provide insight into the mechanism of basic metabolic processes. Synthetic biology is a way of testing hypotheses: scientists can find out about organisms by designing and actually building systems that are capable of testing those hypotheses.

More obvious tangible benefits have to do with products and services that synthetic organisms could provide. The two examples above give a concrete sense of these benefits, but most in the field believe they are only a beginning and that the practical benefits will be very heterogeneous. Other possible applications include solvents and other industrial materials, high-yield or disease-resistant crops, new kinds of insecticides, food additives, sensors to detect food spoilage, more efficient vaccine production, and environmental remediation.

The primary concerns about synthetic biology are about the risks of deliberate misuse – bioterrorism, that is – and accidental threats to public health and the environment – dubbed "bioerrorism" by some commentators (Caruso, 2008). The risks of deliberate misuse center on the possibility that the technology used to synthesize and engineer useful microorganisms could be used instead to produce pathogens (Garfinkel et al., 2007). Some virus pathogens have already been synthesized. The 1918 Spanish flu virus has been briefly recreated in the laboratory, and in 2002, polio (an RNA virus) was created from a string of DNA that had been produced in a lab (Cello, Paul, & Wimmer, 2002; Tumpey et al., 2005). Eventually, as the synthesis of *M. mycoides* makes clear, it should also be possible to create bacterial pathogens in the laboratory. Further, it should be possible not merely to recreate pathogens but to augment them – not just to bring smallpox back from extinction, for example, but to make it even more virulent. In theory, at least, entirely new pathogens could also be created. Also, in addition to human targets, pathogens could be created to target a nation's crops, livestock, or natural resources.

Merely creating a pathogen is not the only technical hurdle that would have to be overcome to misuse synthetic biology (Mukunda, Oye, & Mohr, 2009). It would also be necessary to grow the pathogen in quantity and then to "weaponize" it. To use a human pathogen against a target, for example, one would need to develop ways of disseminating it so that it is capable of infecting targets in large enough numbers to overcome public health systems. Proponents of the technology argue that terrorists have much better ways of attacking their enemies than with bioweapons, which are still comparatively hard to make and are very hard to control. Once released, they might be expected to hurt those who have released them, and their allies and countries, just as much as or even more than the intended targets. But of course

terrorists are not always rational. For some pathogens, such as flu, the weaponization challenge could be overcome merely by sending infected people–suicide bombers of sorts–into crowded public places.

Public health concerns might be raised by some applications that do not initially appear to have any implications for human health. In principle, for example, modified *E. coli* might escape the environment for which they are intended, display unexpected properties in the new environment, or mutate to acquire them, or either acquire new properties or impart new properties to other microorganisms by means of lateral gene transfer between organisms, developing eventually into an organism that poses a health risk.

Another source of public health concerns is that microorganisms created for use in the human body could turn out to have unintended effects. For example, synthetic biology could be used to engineer the human "microbiome" – the ecosystem of microbes residing in and on the human body. These applications range from medical treatments – transgenic probiotics to treat Crohn's disease and bacteria modified to serve as vaccines, for example – to early examples of human enhancement – bacteria that eliminate body odor, allow people to take up nutrients more efficiently, or maybe even promote good mental health (exploiting the recently discovered connection between mental health and intestinal function), for example (Sachs, 2007). These applications raise questions not only about risks to the particular recipient but also, because bacteria in the microbiome can be passed from one person to another, about public health.

Concerns about possible harms to the environment follow a similar pattern. In principle, just as public health concerns could be raised by applications not intended for use in humans, environmental hazards might be posed by applications that are not intended for release into the environment. Applications that involve algae engineered to produce fuel, for example, might be designed so that the algae were contained inside sealed equipment. Nonetheless, the risk that some would eventually escape into the environment is very high, and then the question is whether they would display unexpected properties or somehow acquire them and pose a threat to other organisms in the environment.

There are some reasons to think that the threat might not be severe. The modified organisms would be designed to spend their energy on something, such as producing excess quantities of hydrocarbons, that would likely put them at an evolutionary disadvantage if they escaped into the field. Moreover, some of their protective mechanisms could be removed, and the genetic complexity that makes for adaptability might be reduced. Deliberately designed fail-safe mechanisms could also be implemented to hamper their survival in the field. Indeed, keeping the organisms separated from the environment may be more important for protecting the organisms than for protecting the environment.

Applications that involve deliberate environmental exposure might pose significantly greater environmental hazards, since the organism would be designed to survive and perhaps reproduce in the field, and once released could never be fully removed from the field. Examples of these applications include organisms

designed for contained but unprotected settings, such as fuel-producing algae grown in open ponds, and organisms intended for uncontained release into the environment. Examples of the latter include bioremediation, such as an engineered form of *Pseudomonas putida* (a soil bacterium) that degrades an organophosphate compound (commonly used as a pesticide) and *E. coli* engineered to degrade the herbicide atrazine (Presidential Commission, 2010).

All of these possible harms are hard to assess. For many of these applications, the likelihood of harm may be very low, but the severity of harm could be very great. Moreover, it may be difficult to gauge either likelihood or severity with great confidence. Because of the complexity of living organisms and because of the possibility of evolution, which for microbes can occur very rapidly and can be facilitated by lateral exchange of genes across species, synthetic biology inherently involves a high level of unpredictability. Also, once organisms invade new environments, they can be extremely difficult to eradicate, and invasive microorganisms would likely be ineradicable. Environmental contamination by living organisms would be very different in this respect from contamination by a chemical spill (Snow, 2011).

At the outset, then, extremely careful analyses are needed of the organisms proposed for commercial application. In testimony to the Presidential Commission for the Study of Bioethical Issues, ecologist Allison Snow offered the following recommendations for thinking about the risks posed by synthetic algae designed to produce fuel: "a good start for micro algae would be to publish professional monographs dealing with the biology and ecology of each species and its close relatives including information about how they reproduce, how they spread, whether they exchange genes with other strains, whether they have been bred to be suicidal, whether they could become more abundant or might die out, and whether they produce any kinds of toxins or other side effects" (Snow, 2011).

DIY biology raises special concerns about benefit and harm. If a DIY form of synthetic biology becomes feasible, then DIY synthetic biology could be practiced by people who are not affiliated with major laboratories and could prove to be hard to monitor and regulate. Also, the people who practice DIY bio often view themselves as a countercultural force, challenging boundaries and resisting control. Amateur biologists maintain that "outlaw" biology need not be "criminal" biology, but they display a certain edginess in their approach to biology and develop applications reflecting that attitude. The DIY mindset encourages trying unheard of things, which might have a multiplier effect on the inherent unpredictability of the living systems they are manipulating.

Different views about the acceptability of synthetic biology may well depend as much on different views about the weight to be given to remote risks as about different views of the likelihood of the risks. Some thought should therefore be given to the underlying philosophical and psychological questions about the perception and weighing of risk. Evaluating a technology involves both factual claims and value claims – claims both about potential outcomes and their likelihood and magnitude and claims about the significance of those scenarios. Bringing out these values is what "evaluating" outcomes means. Among these value considerations are questions about what *counts* as a risk, a cost, or a benefit, how heavily to weigh it,

how much to discount a risk or potential benefit that is low probability or would occur only many years later, and how much more heavily to weigh a potentially catastrophic impact.

The tools used to evaluate outcomes, such as risk assessment and cost-benefit analysis, make assumptions about these issues. Unfortunately, though, the assumptions are often buried and unexamined. Also, risk assessments and economic evaluations frequently focus on outcomes that can be measured easily, which may not adequately reflect what people actually care about most. In short, evaluating outcomes requires value assumptions that often go unexamined. One result is that people may feel that important values have been ignored or suppressed. Public discourse and public policy could therefore benefit from a thorough interdisciplinary inquiry into the role of values in evaluating the potential outcomes of synthetic biology and other emerging technologies.

Equality and Justice

Another kind of concern about synthetic biology has to do with the social distribution of the benefits and harms. In a nutshell, the worry is that the benefits of synthetic biology will accrue to wealthy nations and especially to those who have secured patents on the relevant technological developments, while those in poorer, undeveloped nations are either excluded from the benefits or are actively exploited and harmed, in terms both of the economic effects of synthetic biology and of damage to the environment or public health.

The production of biofuel with synthetic organisms illustrates these concerns sharply. Methods that rely on the processing of substrates collected from biomass would require the cultivation of vast acreage of feedstock crops, possibly with harmful effects in places where these crops might be grown. The feedstocks might replace crops that produce food for humans, for example. "The most productive and accessible biomass," writes a civil society organization called the ETC Group, "is in the global South–exactly where, by 2050, there may be another two billion mouths to feed on lands that (thanks to climate chaos) may yield 20–50 % less" (ETC Group, 2010, p. iii). Industrial-scale production of the feedstocks might also have ramifications for land ownership, water use, and soil quality, all of which are already often under pressure in undeveloped countries (ETC Group, 2007). Giving land over to production of feedstocks might also have bad environmental consequences.

Finally, there is a debate about the environmental benefits of producing fuel from raw materials harvested from plants, since growing the plants itself requires a lot of energy. Synthetic biology aims to make this way of producing fuel much more efficient, notably by turning to more common raw materials and more easily grown feedstocks, but the outcome of this work is still in doubt. Reliance on photosynthetic techniques would obviate the need for feedstocks, but they would still be resource-intensive; in particular, they would probably require a huge supply of water. If the production of fuel through photosynthesis were conducted in arid

locations (which would be attractive because of their plentiful sunlight and because the land might not be considered valuable for other uses), then providing water might worsen water supply problems.

The US Presidential Commission has suggested that synthetic biology might turn out not to exacerbate social disparities. Indeed, it declared, "Much of the optimism surrounding synthetic biology stems directly from its potential to address some of the longstanding, significant problems associated with these disparities. Synthetic biology offers potential applications that may be particularly beneficial to less advantaged populations, including improved quality and access to vaccines against infectious diseases, medications, and fuel sources" (Presidential Commission, 2010, p. 165). Progress on solving long-term environmental harms such as climate change – on the assumption that synthetic biology can be part of a solution – would clearly benefit less advantaged populations, since it is likely that those populations will be disproportionately harmed by those problems.

The concern about justice is also difficult to assess. Partly this is because of uncertainties about the possible outcomes, which include not only the benefits and harms mentioned above but also the long-range and international social and economic consequences of synthetic biology (should the field be as successful as its proponents believe it will be). Additionally, there are questions of values to complicate the assessment. Unsurprisingly, there are starkly different visions of justice at play in synthetic biology. For example, the goal of promoting welfare equally must be traded off to some degree against the value of protecting individual liberty. Some would hold that justice grants the liberty to experiment with emerging technologies in whatever direction one likes, at least to the extent permitted by public safety. Some would also hold that in any adequate understanding of justice, those who have worked to advance the field should benefit disproportionately. Finally, some would also hold that if the financial rewards are curtailed, none of the benefits will be realized.

A second general value question that complicates the assessment of justice is the question of responsibility for ensuring just outcomes. Possible answers range from governments, acting on behalf of citizens, through various categories of private agents. The US Presidential Commission has suggested a broader rendering: "Manufacturers and others seeking to use synthetic biology for commercial activities should ensure that risks and potential benefits to communities and the environment are assessed and managed so that the most serious risks, including long-term impacts, are not unfairly or unnecessarily borne by certain individuals, subgroups, or populations. These efforts should also aim to ensure that the important advances that may result from this research reach those individuals and populations who could most benefit from them" (Presidential Commission, 2010, p. 164).

The very idea that the development of a new technology should be influenced in order to maximize just outcomes is arguably somewhat novel. Technology development has historically not been constrained with this expectation. Thus, another question arises: Is the goal of achieving just outcomes feasible? Or is it better simply to let innovation proceed and to try to address social injustices through other measures? And what sorts of policy mechanisms might appropriately be employed

to advance this goal? Two much-discussed kinds of options include funding decisions, which can influence the directions in which the field advances and therefore the kinds of commercial enterprises it makes possible, and intellectual property policy, which determines control over and access to new developments in the field, and may therefore influence the direction in which the field advances both by affecting the incentive structure for conducting research in the field and by affecting access to the fruits of others' research.

Attitudes Toward "Synthesizing" Living Organisms

A third broad category of concern about synthetic biology is whether the idea of synthesizing organisms raises any intrinsic moral issues. This concern is a recurrent topic for synthetic biology and is probably the most controversial and philosophically difficult of the ethical issues of synthetic biology. Such concerns might tilt in different directions. On the one hand, some will find the idea of synthesizing and engineering organisms, at least in the way done in synthetic biology, intrinsically attractive. They might try to articulate this position by arguing that knowledge and creativity are intrinsically good; synthetic biology, somewhat like astronomy and basic physics, embodies the human drive to understand the world and put one's intelligence to work in it – activities that are good in themselves, apart from the physical benefits they may make possible. Many also feel, however, that the alteration of nature should have limits of some sort; opposition to genetically modified organisms is connected to this feeling, and more than a little of the concern about the environment is rooted in it; the question for them is whether the engineering of living organisms, at least as done in synthetic biology, is morally troubling.

There are several subtly varying ways of articulating this concern in the context of synthetic biology. Perhaps, the most prominent form of the intrinsic concerns about synthetic biology is that the technology reflects and promotes a troubling attitude toward life. In particular, one might object that synthetic biology undermines the specialness of life by showing that life is a purely material phenomenon – a complex combination of ingredients. In the first scholarly article on the ethical issues of synthetic biology, Mildred Cho and coauthors weighed the possibility that, by defining life in terms of DNA, synthetic biology reduces life to a single biological feature and therefore "may threaten the view that life is special" (Cho, Magnus, Caplan, McGee, & The Ethics of Genomics Group, 1999). More recently, Joachim Boldt and Oliver Müller have argued that synthetic biology represents organisms as machine-like artifacts and thereby challenges "the connection between 'life' and 'value'" (Boldt & Müller, 2008). When scientists synthesized the genome of *M. mycoides*, the achievement was heralded by Arthur Caplan as debunking the idea that living things are "endowed with some sort of special power, force or property" (Caplan, 2010).

Conversely, some have worried that synthetic biology represents a troubling attitude about human agency. Boldt and Müller suggest, for example, that with the

advent of synthetic biology, humans no longer merely *manipulate* nature; they become creators or reinventors of nature. The creation of nature might, they continue, lead to overconfidence: it "might lead to an overestimation of how well we understand nature's processes and our own needs and interests and of how best to achieve them" (Boldt & Müller, 2008, p. 388). This kind of worry harks back to a reaction sometimes evoked by earlier forms of genetic engineering, that human beings were "playing God."

Some ways of formulating these concerns – about the denigration of life or the exaltation of human agency – rely on metaphysical claims that are particular to specific traditions and open to various objections. If so, then one problem with them is that they may depend on acceptance of the underlying religious or metaphysical account within which they make sense, and the more robust this account, the less likely it is to be widely shared, and the less traction it will have in public debate.

Alternatively, these concerns can be formulated as merely moral points – as resting on claims about attitudes toward life and human agency and the role that those attitudes play in moral thinking. Still, they face some significant objections. One is that they treat "life" as a very general moral category, bringing together under one heading a variety of different kinds of living things – complex animals (such as mammals), microorganisms, plants, and fungi. But arguably, people tend not to aggregate all living things together when they think about their moral status. Instead, moral distinctions between different kinds are common. Sacredness might be attributed to some but not to all living things. It is worth noting that religious organizations themselves have by and large not voiced objections to synthetic biology per se. The Catholic Church was moderately enthusiastic about the announcement that JVCI had synthesized the genome of *M. mycoides* and successfully transplanted it into another cell: the achievement was, said the church, "a further mark of man's great intelligence, which is God's gift enabling man to better know the created world and therefore to better order it" (BBC Monitoring Europe, 2010).

Moreover, whether synthetic biology is actually tantamount to the creation or synthesis of life, rather than being merely another form of manipulation, is debatable. Most of the actual applications, as described above, amount to something less than the synthesis of living organisms. JCVI described the *M. mycoides* cell it created through genome synthesis as a "synthetic cell," and it also claimed that, because it was slightly altered from wild-type variants, it represented a new species, which they dubbed *M. mycoides JCVI-syn1.0*, but most commentators regard the JCVI achievement as considerably less than a synthetic cell. They argue that JCVI's accomplishment was synthesis of a genome, but that because the genome was inserted into a naturally occurring cell body and because the genome itself also occurs in nature (minus the slight alterations), thinking of the product as a "synthetic cell" is overblown.

Research on protocells and chells, which in some cases aims to devise novel mechanisms and use novel materials for basic cellular functions, would come closer to creating life. Successful creation of a protocell that employs novel and entirely synthesized ingredients would prove that a living thing does not acquire a "special

power, force, or property" only from a previous generation of living things. It would still not prove, however, that living things have no special, nonphysical property. If one believes that living things have such a property, nothing stops one from believing that the property was acquired in the course of the laboratory synthesis; the property might be said, for example, to have been imbued in it directly by God, who sanctioned the synthesis because He saw it as following naturally from the capacity He has given humans "to better know the created world and therefore to better order it."

Another way of articulating intrinsic concerns about synthetic biology would be to argue that the alteration of nature is in general morally troubling. One might hold, for example, that there are competing moral ideals for the relationship between humans and nature: an ideal characterized by a discourse of "altering nature to meet human demands" and an ideal of "adjusting human demands to accommodate nature" (Jennings, 2010, p. 78). The former holds that nature is no more than stuff to be put to human use, while the latter calls on a person to cherish the natural world and limit the harm that humans wreak on it.

Which of these discourses synthetic biology best fits is contestable, however. On the one hand, to the extent that synthetic biology is the "creation of life" or "extreme" genetic engineering, it might be said to fit the discourse of altering nature to meet human demands. To the extent that it is used to resolve environmental problems and perhaps to replace environmentally damaging industrial systems, however, it might be said to fit the discourse of adjusting human demands to accommodate nature. Moreover, given the moral distinctions often drawn between different kinds of living things – humans, other mammals, other vertebrates, invertebrates, plants, fungi, and microorganisms – the fact that synthetic biology is, to date, primarily about the alteration of microorganisms might be reassuring. On the other hand, if synthetic biology turns out to be harmful for the environment, then concerns about the alteration of nature would be strengthened; synthetic biology might then be morally troubling *even if* it appears to be beneficial for human well-being.

Yet, another kind of intrinsic concern that could be associated with synthetic biology is focused on the prospect of human enhancement – that is, on the possibility that some synthetic biology applications might be used to raise human cognition, mood, physical performance, or life span significantly above current species-typical norms. Applications involving human cells could someday raise this kind of concern. As noted above, applications involving the human microbiome could also have an enhancing effect. The objections to these uses would be objections to human enhancement, however, rather than to the genetic manipulation of microorganisms.

Public Deliberation

In addition to substantive questions about benefits and harms, justice, and the intrinsic values connected to synthetic biology are procedural questions about who and how the substantive questions should be addressed. One interesting feature of synthetic biology is that those engaged in the work have also sought to advance –

and perhaps influence – the discussion of the ethical, legal, and social issues that their work raises. One of the first and most salient articles about synthetic biology was written by a group of bioethics scholars brought together in the late 1990s at the request of JCVI to consider the ethics of creating a minimal genome organism. Many other organizations and commentators internationally have also weighed in on the ethical, legal, and social issues of synthetic biology.

Still, there is a widespread sense among these commentators that the discussion about synthetic biology should if anything be still broader. Recently, the US Presidential Commission has argued that policy on synthetic biology (and other emerging biotechnologies) should be guided by "a principle of democratic deliberation" – that is, by "an ongoing, public exchange of ideas, particularly regarding the many topics – in science and elsewhere – in which competing views are advocated" (Presidential Commission, 2010, p. 151). Such an approach is held to foster better decisions – "outcomes that are inclusive, thoughtfully considered, and respectful of competing views," as the Presidential Commission put it. It is also held to be intrinsically attractive – itself a mark of a just society.

Questions remain, however, about how democratic deliberation is best carried out. These include questions about how to ensure that the scientific and economic information that is fed into the deliberative process is accurate and how to ensure that the public's values are adequately represented and respected. The deliberative process could be hijacked either by corporate interests or by "civil society" organizations whose mission is to advocate for public interests; neither may adequately represent the range of public interests, and both might misrepresent the factual claims at stake and unduly influence the deliberative process.

Part of the problem in adequately representing the public's values is that the relevant "public" for most deliberative processes is restricted to the nation that conducted the deliberation, but the relevant "public" for thinking about the ethics of synthetic biology is international. Since synthetic organisms that have been released or escaped into the environment cannot be expected to observe national boundaries, the risks are international. The implications for justice are also clearly international since questions about the distribution of potential benefits and harms are rooted in the first place in concerns that the benefits will accrue to wealthy nations while developing nations are either excluded from those benefits or are actively harmed. And questions about the very idea of synthesizing organisms are also international in flavor, in the same way that questions about human enhancement are international: if one nation permits this step, then in some sense, the human relationship to nature is changed for everybody around the globe. Moreover, if one nation permits it, other nations may find it increasingly difficult to ban it, given economic competition among nations.

Conclusion

Synthetic biology is still in its infancy, leading some in the field to wonder whether ethical questions about it are being raised prematurely. Perhaps society should

await further technical development, this line of reasoning holds, so that the ethical debate can be grounded on more and better information about the field's risks and potential benefits.

Some of the ethical issues outlined above do not depend on better knowledge of the field, however. The intrinsic values connected to the science are a threshold question – an issue that, in principle, should be raised and resolved before the field progresses. To go ahead with the research is to assume that the intrinsic values generate no insuperable objections.

Questions about the benefits and harms of synthetic biology could certainly be handled more confidently if more information were in hand about actual applications. Yet, it is precisely because of the lack of confidence about outcomes that the effort to think about risks and potential benefits should start early. Perhaps the likelihood of harm is indeed as low as some proponents argue, but the severity of harm could be great, and given the complexity and adaptability of living systems, gauging either likelihood or severity with great confidence is very difficult. It is therefore important to make sure that the processes for identifying and evaluating risks and potential benefits in synthetic biology are reliable and then that the mechanisms for oversight are trustworthy.

Questions of equality and justice also require early attention. The goal should be, not just to correct distributive mistakes after they have occurred, but to correct existing distributive mistakes and avoid exacerbating them with new mistakes, and this requires trying to anticipate outcomes and, if possible, encourage lines of work that will produce good outcomes.

Synthetic biology is heralded by some of its proponents as the beginning of a new industrial revolution. If that turns out to be correct, then it will inevitably generate harms, benefits, new economic and social patterns, and perhaps new ways of understanding how humans are related to the natural world. It is therefore imperative to think about it now.

Section VI

Future Perspectives

Future Perspectives

49

Bert Gordijn and Henk A. M. J. ten Have

Introduction

If you wish to think about the future, it is generally worthwhile to look at the past first. The growth of global bioethics – roughly understood as the establishment, analysis, and application of global ethical norms for medicine, healthcare, and the life sciences – seems to have been largely driven by globalization. Leaving out of consideration yet unknown historical contingencies, it does look as if there are currently no compelling reasons to suppose that globalization is likely to collapse any time soon. Rather, it seems more likely that different parts of the world will see yet more integration, interconnectedness, and interdependence as a result of technological developments in general, progress in transportation and telecommunications in particular, the actions of large multinational companies, and the like. As a result, global bioethics is likely to further gain significance. Looking at the steadily increasing number of publications on global bioethics over the last couple of decades (Table 49.1), it seems reasonable to reckon with a further growth of the debate in the near future.

Table 49.1 shows a similar rise since the early 1970s in the number of publications with "global bioethics" and those with the expression "global ethics" in the title. The parallel development of these two categories of publications indicates that the rise of global bioethics is not an isolated development but rather in line with a similar ascent of a global perspective in other areas of ethics (such as business, environmental, and ICT ethics). This, of course, is to be expected supposing the expansion of these fields is similarly and mainly driven by globalization. While it seems therefore reasonable to expect a further buildup of global bioethics, it goes without saying that it is much more difficult to predict any additional future particulars of the field.

1971–1975	1	1

The specific form of global bioethics advanced in this volume is centered on the UNESCO *Universal Declaration on Bioethics and Human Rights*. As a result, it has a principal orientation on human rights discourse. After all, the *Universal Declaration* involves an expansion of international human rights law into the arena of medicine, life sciences, and healthcare (Andorno, 2009). Consequently, the future perspectives of global bioethics, thus framed, are closely connected with the prospects of the human rights tradition itself. Therefore, as this volume's chosen type of global bioethics has thrown in its lot with human rights, this chapter first briefly reviews the history of the human rights tradition. It then takes a more systematic approach as it looks at the relationship between bioethics and human rights in the *Universal Declaration*. In addition, it examines the key pros and cons of global bioethics' close relationship with human rights. Based on these brief historic and systematic surveys, it finally focuses on the path ahead and endeavors to distinguish global bioethics' main challenges in the years to come.

History of Human Rights

Lynn Hunt (2007) argues that epistolary novels, such as Samuel Richardson's *Pamela*; *or*, *Virtue Rewarded* (1740) and *Clarissa*, *or*, *the History of a Young Lady* (1747–1748), and Jean-Jacques Rousseau's *Julie ou la Nouvelle Héloïse* (1761), "the three greatest novels of psychological identification of the eighteenth century" (Hunt, 2007, 39), played an important role in creating a broader acceptance of the idea of natural rights. The form of these novels, with their imaginary letters, added a dimension of immersion to the readers' experience. The latter felt they could directly sympathize with the troubles of the female heroines. Since the protagonists expressed their inner feelings in their letters, the readers could almost directly look into their soul. Hunt argues that these books and other similar eighteenth-century novels helped readers psychologically identify across social divides and appreciate that all humans were basically the same, that is, had a similar "inner core" of emotions, aspirations, and problems (Hunt, 48).

Consequently, people grew more accustomed to thinking of other human beings as equal to themselves. This again facilitated the development and acceptance of the conviction that all humans possess certain unalienable rights (Hunt, 58). "New kinds of reading (and viewing and listening) created new individual experiences (empathy), which in turn made possible new social and political concepts (human rights)" (Hunt, 33–34).

Somewhat later in the eighteenth century, Thomas Jefferson helped shape two key events in the history of human rights (Hunt, 2007, 15–16). Not only was he the main author of the *Declaration of Independence*, adopted by the Continental Congress on July 4, 1776. Subsequently, in 1789, Jefferson helped the Marquis de Lafayette compose a first draft of a document that would later be known as the *Déclaration des droits de l'homme et du citoyen* (Hunt, 16). The following famous sentences of the American Declaration can be seen as anticipating modern human rights (Hunt, 16): "We hold these truths to be self-evident, that all men are created equal, that they are endowed by their Creator with certain unalienable Rights, that among these are Life, Liberty and the pursuit of Happiness" (DoI, 1776). Similarly pivotal passages can be found in the French Declaration (DDC, 1789, Art. 1–2).

However, according to many scholars, the beginning of the human rights tradition lies much farther back in time than the eighteenth century. It is not uncommon to seek the historical roots of human rights either in antiquity or early Christianity (see, e.g., Gordon (2012, 284) who starts his historic sketch with the Code of Hammurabi). From this point of view, the development of human rights or their precursors then proceeds through medieval "natural law," seventeenth- and eighteenth-century "natural and/or unalienable rights" and "rights of man" onto twentieth-century "human rights." Thus from this long-term historical perspective, the eighteenth century is seen not as the enlightened beginning but rather as an age where the human rights tradition galvanizes and gains momentum. After the Enlightenment, the tradition is further pursued in movements such as humanitarianism, feminism, and abolitionism until it finally culminates in the *Universal Declaration of Human Rights* adopted by the United Nations General Assembly on December 10, 1948. The articles of this decisive document are then subsequently elaborated in various international treaties, national constitutions, and the like, thus establishing the current human rights practice.

A recent revisionist historiography challenges this traditional account of the historical development of human rights (Moyn, 2010). In this view, the modern tradition of human rights only starts in the 1970s when it emerges "seemingly from nowhere" (Moyn, 3). The annus mirabilis of the human rights tradition is the year 1977, "a year of shocking and altogether unpredictable prominence of human rights" (Moyn, 121). In January of that year, Charter 77 is published in Czechoslovakia. Next, in that very same month, the American President Jimmy Carter most firmly commits to human rights in his inaugural speech. Subsequently, in May 1977, he gives a key talk on human rights as a pillar of US foreign policy. In fall, finally, the Nobel Peace Prize is awarded to Amnesty International (Moyn, 239). As a result of these and similarly important events, the discourse of human rights surges. This is evidenced by the suddenly enhanced frequency, with which the term

occurs in important media such as the New York Times and the London Times. In 1977, the phrase "human rights" appeared "nearly five times as often as in any prior year in that publication's history. The moral world had changed" (Moyn, 4).

Furthermore, Moyn argues that this change was accidental and unforeseeable (Moyn, 2010, 7). The huge gain in momentum that the international human rights movement experiences in the late 1970s is a response to disenchantment with other grand political ideologies. So human rights pop up by default as the only remaining viable ideological alternative (Moyn, 120–122). Against this backdrop, Moyn criticizes more conventional historians of human rights who approach their subjects "much as church historians treated the Christian religion" (Moyn, 6). Their work respectfully treats the unfolding of the human rights tradition as a long and necessary historical progression of moral improvement. In contrast with this form of "hagiography," Moyn sketches human rights as emerging coincidentally "as the last utopia – one that became powerful and prominent because other visions imploded" (Moyn, 4).

However, Cooper (2010) claims that Moyn, in depicting modern human rights as popping up the 1970s, fails to see a link with earlier nineteenth-century phenomena such as abolitionism and the progress in the laws of war. Though these developments were not focused on human rights discourse, their ambit was truly universal and internationalist. Moyn's account also lacks an explanation of the difference between the Red Cross and modern human rights movements. Most importantly perhaps, Cooper argues that, if pushed to find a recent beginning for human rights, the 1990s, which saw the start of international criminal tribunals and a real boom of human rights organizations, might be even more appropriate than the 1970s. The rather effortless construction of an alternative modern historical trajectory demonstrates the weakness of Moyn's claims (Cooper, 2010). Be that as it may, it is clear that the court is still out on the most appropriate interpretation of the history of human rights.

The Universal Declaration and Human Rights

After World War II, a number of intergovernmental and international organizations, such as the European Council, UNESCO, the WHO, the Council for International Organizations of Medical Sciences, and the World Medical Association, established quite a number of international ethical standards in various areas of bioethics. To varying degrees, these documents are embedded in the human rights tradition and have helped shape the field of global bioethics. The most important ones are the *Declaration of Helsinki* (1964); the *Proposed International Guidelines for Biomedical Research involving Human Subjects* (1982); the *Declaration on the Human Genome and Human Rights* (1997); the *European Convention on Human Rights and Biomedicine* (1997); and the *Universal Declaration on Bioethics and Human Rights* (2005).

The *Universal Declaration on Bioethics and Human Rights* is the first global instrument that endeavors to cover the entire field of bioethics (cf. Andorno, 2007).

It can therefore be regarded as epitomizing global bioethics' recourse to the human rights tradition. It is also, of course, the central set of normative standards referred to in this volume. Within the text of the Declaration, three types of relationships between human rights and bioethics are to be distinguished: (a) human rights as starting point and context of bioethics, (b) human rights as a basic principle of bioethics itself, and (c) human rights as constraint and final authority for bioethics (Ten Have, 2013).

Human Rights as Starting Point and Context

As the title of the *Universal Declaration on Bioethics and Human Rights* suggests, its principles are closely interlocked with human rights. The Preamble of the *Declaration* unambiguously refers to human rights as the context within which ethical issues should be analyzed: "Recognizing that ethical issues [. . .] should be examined with due respect to the dignity of the human person and universal respect for, and observance of human rights and fundamental freedoms" (UNESCO, 2005). The Preamble equally refers to human rights instruments. The context of international human rights law is furthermore emphasized in Article 2.c., which states that one of the aims of the Declaration is: "to promote respect for human dignity and protect human rights, by ensuring respect for the life of human beings, and fundamental freedoms, consistent with international human rights law" (UNESCO).

Human Rights as a Basic Principle

Although an explicit hierarchy of bioethical principles is lacking in the UNESCO Declaration, the very first of its 15 principles refers directly to human dignity and human rights. This might be understood as suggesting a fundamental role of human dignity and human rights in bioethics (Byk, 2007; Nys, 2006).

Human Rights as Constraint and Final Authority

Several times, the Declaration states that its bioethical principles should be interpreted and applied in accordance with international human rights law. The Preamble refers to these constraints in a general way: "Recognizing that this Declaration is to be understood in a manner consistent with domestic and international law in conformity with human rights law" (UNESCO, 2005). The importance of consistency with human rights is repeated more specifically in the following principles: Article 6 (Consent) states that exceptions to the principle of consent can only be made, if they are in line with international human rights law. Article 7 (Persons without the capacity to consent), 9 (Privacy and confidentiality), and 11 (Non-discrimination and non-stigmatization) equally stress compliance with human

rights. In addition, the Declaration advances a few principles that are relatively new in the global bioethics discourse. An example is the principle of respect for cultural diversity and pluralism (Article 12). This is the only principle, for which a constraint is formulated within the text of the principle: Neither cultural diversity nor pluralism should not be invoked to infringe upon human rights or upon any of the other principles. Due to this limitation, this principle can be seen as the weakest one in the Declaration. Another example is the principle of social responsibility and health (Article 14), although it can be regarded as based on the human right to enjoy the highest attainable standard of health (International Bioethics Committee [IBC], 2010). Finally, the last two articles of the Declaration advance further stipulations regarding limitations to both the application and the interpretation of the principles of the document. Article 27 declares that the application of the principles can only be limited subject to three conditions: (1) it must be by law, (2) for specific reasons (public safety, criminal offences, protection of public health, or protection of the rights and freedoms of others), and (3) when the law is consistent with international human rights law. Article 28, finally, states that nothing in the document may be understood as justifying any activity contrary to "human rights, fundamental freedoms and human dignity" (UNESCO, 2005).

Arguments in Favor of a Close Connection of Bioethics and Human Rights

This section and the next one focus on the assessment of the close connection with human rights, as reinforced by the Declaration, from the point of view of global bioethics. The sketches of pros and cons below owe much to earlier analyses and surveys by Andorno (2007, 2008, 2009), Ashcroft (2008, 2010), as well as Gordon (2012). The view in favor of a close link points out that the connection is advantageous for global bioethics in order to tackle important challenges on a worldwide scale. The general argument goes as follows. Due to the global village character of the modern world, much of what goes on in any specific country is thoroughly interwoven with developments in a variety of other countries, sometimes at the other side of the globe. This goes for politics, culture, energy, environmental degradation, entertainment, science, technology, and so forth. As a result, numerous bioethical issues have emerged that are difficult to address adequately by single nation-states. Examples are pandemics, international drug trials, brain drain of healthcare workers and researchers, access to pharmaceuticals, property rights, environmental pollution, and biopiracy. Clearly, as these issues inherently cross national borders, they demand international solutions. Against this backdrop, the appeal to human rights makes a lot of practical sense in order to seek avenues for a more effective global governance of these issues. More specifically, the main advantages of human rights advanced in the literature are the following.

Familiarity and Reputability: Everybody knows human rights. In contrast, other important ethical theories, such as utilitarianism, deontology, and virtue ethics, are usually only known to academic insiders. This broad familiarity gives human rights

an instant edge when it comes to looking for instruments for the establishment, analysis, and application of global ethical norms for medicine, healthcare, and life sciences – the aim of global bioethics (see above). As human rights are firmly embedded in international human rights law, the authority of which is accepted by almost every country on earth, human rights present a commanding discourse that is broadly acknowledged around the world (Andorno, 2009; Baker, 2001; Gordon, 2012). Hence, ". . . casting a debate into human rights terms allows a well-tested and long-established common language, rhetoric and institutional practice to be applied in order to achieve consensus both on the nature of the problem and, ideally, on the form of possible solutions to it" (Ashcroft, 2010, 644).

In addition, human rights generally enjoy a good reputation. Human rights discourse is "the ubiquitous mode of expressing social criticism" (Fenton & Arras, 2010, 128). Human rights are perceived as important, almost self-evidently accepted international normative standards. Accordingly, infringements of human rights are usually condemned as grave and urgent events that demand instant intervention (Gordon, 2012).

Affinity Between Bioethics and Human Rights: Several scholars have observed that there is a certain kinship between bioethics and human rights (Andorno, 2009; Ashcroft, 2008; Gordon, 2012). More particularly, it seems that human rights and public health have important shared concerns focused on improving basic conditions, such as the availability of sufficient drinking water and food, appropriate shelter, and access to rudimentary healthcare. These circumstances are pivotal for health and, more generally, physical, mental, and social well-being (Fenton & Arras, 2010). Therefore, promoting human rights may very well amount to furthering public health (Mann, 1996). In addition, Ashcroft (2010) stresses further commonalities between bioethics and human rights. He regards them as "two alternative forms of governance for the life sciences and medicine" (Ashcroft, 640). They are an answer to "the same social and historical forces and events" (Ashcroft, 642). Annas sees bioethics and human rights as intimately interlocked in the global arena, a situation that will eventually develop into a synthesis between the two (Annas, 2003). Additionally, bioethics and international human rights are held to have similar historical roots: World War II, the Nazi concentration camps, and their follow-up events triggered the establishment of both (Annas, 2004, 2010; Baker, 2001). In addition, Baker sees further significant parallels between the historical development of bioethics and human rights. Both lost influence during the Cold War and regained sway again in the mid-1970s. Both became prominent and broadly known as a result of abandoning their earlier more esoteric philosophical foundations. Both gain support from a variety of organizations, both governmental and nongovernmental (see Baker for more similarities). Finally, many important regulatory frameworks and bioethics policy documents that have been developed in the last few decades do already employ rights terminology (Andorno, 2007, 2009).

Universalism: Human rights can be regarded as entitlements that all human beings are held to have exclusively on the basis of their species membership (Andorno, 2009; Gordon, 2012). Thus when it comes to determining whether an

entity has human rights, being human is the only thing that matters. All other traits, such as geographic location, ethnicity, gender, political outlook, and the like, are indifferent (Andorno, 2008, 2009). In this sense, human rights also rise above cultural diversity. Due to their universality, human rights enable the creation of an appeal to minimal normative standards (Andorno, 2008). Global bioethics needs certain transcultural principles that are universally valid regardless of the differences between sociocultural, philosophical, and religious traditions (Andorno, 2008, 2009; Gordon, 2012).

Flexibility: Human rights, as they occur in the *Universal Declaration on Bioethics and Human Rights*, are to a certain degree compatible with regard to cultural diversity. In other words, although human rights norms claim universality, there might still be local differences in the way in which specific rights or articles are interpreted and implemented (cf. Andorno, 2007, 2008, 2009). In its Preamble, the *Universal Declaration on Bioethics and Human Rights* clearly states that cultural diversity "...as a source of exchange, innovation and creativity, is necessary to humankind and, in this sense, is the common heritage of humanity" (UNESCO, 2005). At the same time, however, it states that cultural diversity may not be called upon "at the expense of human rights and fundamental freedoms" (UNESCO). Accordingly, Article 12 (respect for cultural diversity and pluralism) later points out that the "...importance of cultural diversity and pluralism should be given due regard. However, such considerations are not to be invoked to infringe upon human dignity, human rights and fundamental freedoms, nor upon the principles set out in this Declaration, nor to limit their scope" (UNESCO, Art. 12). Thus cultural diversity is important when it comes to interpreting and implementing the other principles in specific contexts. Nevertheless, as remarked above, respect for cultural diversity and pluralism is the only principle in the Declaration that can never overrule any of the other principles.

Effectiveness and Enforceability: The biographies of people like Václav Havel, Alexander Solzhenitsyn, Aung San Suu Kyi, and Chen Guangcheng demonstrate that violence and cruelty can meet their match. Human rights discourse can effectively transform moral bravery into political clout. In the current stage of the globalization process, it does not seem to be primarily nation-states but rather the activism of a global civil society movement that is effectively enforcing human rights. Something similar seems true in global bioethics, which is a movement of healthcare professionals, scientists, and citizens in general rather than predominantly governments. For bioethicists interested in improving global governance of important ethical issues, in order to become more effective, it is advantageous to link up with the human rights movement, which enjoys substantial support of a global network of powerful international organizations and NGOs. Thus with the help of the human rights movement, bioethics might be able to more effectively influence real-world policies on important issues (Arras & Fenton, 2009; Fenton & Arras, 2010).

In addition, human rights reinforce a link to lawmaking. Bioethics nowadays has expanded over and beyond the confines of the exclusively academic arena. In this regard, Ashcroft makes a useful distinction between "academic bioethics" and

"policy bioethics" (Ashcroft, 2010, 643). Through its focus on and link with policy, bioethics is intimately related to lawmaking, both domestically and internationally. There is also a shift from the domestic realm to the global arena as bioethics is increasingly focused on creating an international legal framework beyond merely domestic concerns. In addition, bioethics is currently more and more regarded as a form of advocacy. Rather than only providing analytical discourse and sophisticated arguments, it is also concerned with the implementation of argumentative strategies in daily practices and the application of policies in concrete circumstances. Recourse to human rights can enforce these forms of advocacy.

An example of the impact of the association of bioethics and human rights is the Trovan case in Nigeria. Following the unjustified experiment of Pfizer in the city of Kano, Nigerian families brought the pharmaceutical company to court in the USA. After an initial dismissal, the judiciary decided in 2009 that Pfizer should be condemned since informed consent is a universal ethical norm, so that not applying this norm is in fact a crime against humanity (Ten Have, 2011).

Arguments Against a Close Connection of Bioethics and Human Rights

Equally, there is also criticism of a close link between bioethics and human rights. According to this view, it is neither necessary nor desirable for bioethics to link up with human rights in theory or practice. On this view, bioethicists would better do without resorting too much to human rights discourse. The main arguments supporting this critical view are the following.

Problems of Human Rights Theory: It may come as no surprise that currently a *communis opinio* concerning the justification of human rights is lacking. Back in the seventeenth and eighteenth centuries, religious approaches were prominent in foundational discussions about "natural rights," "unalienable rights," and the "rights of man." It was usually claimed and fairly broadly accepted that these rights were God-given. In contemporary debates, however, this strategy has lost its self-evidence due to secularization and the truly worldwide scope that modern international human rights are currently meant to cover. Obviously, any successful substantiation of international human rights must aim at convincing not only those people who believe in a God who stipulates rights for human beings. Above and beyond, it must endeavor to include people with other religions or no particular religion whatsoever (cf. Baker, 2001). At present, therefore, it is critical to develop a discourse on the justification of human rights that starts from premises acceptable to everybody. As this has turned out to be a difficult task, current scholarly discussions are dominated by wide ranging and various secular attempts to justify human rights (see Gordon (2012, 285) for references).

However, all these attempts have been criticized resulting in a lack of agreement on the foundation of human rights within the scholarly community. Human dignity, for example, is rejected as a solid foundation of human rights by Schroeder (2012) on the following three grounds. First, with secularization the concept of human

dignity has lost its self-evidence, which it still possessed when it was widely perceived and accepted as an important religious concept. Nowadays referring to dignity as such does not suffice. Instead, it demands further justification. Second, the secular understanding of human dignity by Kant, whereby dignity is the ability of normative self-legislation, excludes many human beings whom we wish to be covered by universal human rights, for instance, incompetent people who have lost their rational capacities. Third, the concept of human dignity seems to provoke more intellectual criticism than the idea of human rights itself, which disqualifies it as an appropriate justification (Schroeder, 2012, 333–334).

Besides the basic problem of the justification of human rights, there are various other more specific theoretical problems such as the anthropocentrism involved in the exclusiveness of human beings as the sole bearers of human rights excluding basic and universal rights for other natural entities (Sakamoto, 1999) and the inability of human rights theory to capture the full complexity of morality and adequately deal with phenomena such as virtue, supererogation, and the good (Benatar, 2006).

Indeed, there is substantial theoretical criticism of human rights within the bioethics community. Ashcroft (2008) argues this is partly due to the fact that most bioethics scholars tend not to have human rights as their fundamental moral theory. Most of them, instead, work either with the dominant four-principle theory, a version of consequentialism or deontology or an eclectic approach. When bioethicists operate with human rights, these are often understood as derivative and not foundational concepts (Ashcroft, 2008).

Impotence: Schroeder (2005) argues that human rights discourse has two important weaknesses. First, the Western idea of human rights itself is feeble and unfamiliar in large parts of the world. Second, the human rights system focuses on rights without substantially considering the corresponding obligations. This might render those rights meaningless. The right to healthcare, for example, lacks meaning "…if nobody exists who can discharge the equivalent obligation" (Schroeder, 222). Against this backdrop, Schroeder argues that non-Western moral frameworks could help out in stressing substantive obligations "not only with reference to other human beings, but also to other living entities" (Schroeder, 222).

Activism's Deleterious Effects on Academic Work: Benatar (2006) argues human rights activism in bioethics may actually undermine the scholarly quality of the field. He argues that while bioethics is essentially an academic endeavor, the human rights movement is focused on social change. Importing human rights discourse into bioethics runs the risk of introducing activism in the field as well. If social activism increasingly drives scholarly activities, merely advancing rights claims may replace or marginalize subtle moral analysis. There is a danger that the activist agenda might instrumentalize scholarship in order to further its goals. Obviously, this would harm bioethics as a sophisticated academic undertaking (Benatar).

Western Imperialism: Sakamoto (1999) argues that Eastern and Western bioethics are substantially different. While in Western bioethics human rights are very important, the appreciation of human rights is "very weak and foreign" in Asia

(Sakamoto, 194). What is more, the very idea of human rights has triggered "moral, ethical and political conflicts among Asian societies" (Sakamoto, 194). Sakamoto identifies further differences between Eastern and Western thinking regarding the role of nature and individualism. Given these differences, a new global bioethics is needed that is more appreciative of the different cultures and moral outlooks. It should not be based on the alleged universality of human rights. Instead, the new global bioethics should harmonize and "bridge over all kinds of ethoses, East and West, South and North" (Sakamoto, 197).

Although Sakamoto states that he advocates a form of "value relativism" (Sakamoto, 1999, 196), his argument does not seem to be explicitly based on relativist premises. From a harsh relativist point of view, the observation that there are countless distinctive moral traditions, lifestyles, and cultures does not only seriously challenge the universality claim of our current set of human rights. Rather it might challenge any global bioethics with universal normative aspirations. If ethical norms are regarded as valid only in specific linguistic, historical, and cultural contexts, it might be difficult to establish universal standards that transgress different cultures, unless some moral common denominator can be found that happens to be valid everywhere as a matter of historic and cultural contingency.

So while proponents of human rights regard them as universally binding basic rights, relativists tend to disagree, even though all governments or members of the UN have adopted international human rights law as a guiding framework for policy-making. The latter circumstance can be explained as the result of Western domination and instrumentalization of the UN system, according to the opponents of human rights. From this point of view, the current human rights system can be regarded as an attempt of the West to impose human rights on non-Western cultures where they might be experienced as foreign.

Future Challenges

This chapter does not aim to systematically assess the merits of the different scholarly positions sketched above in the brief accounts of human rights historiography and the debate about the role of human rights in bioethics. Instead, it attempts to use the above accounts as a background against which to formulate global bioethics' most important challenges in the coming years ahead.

Combining Practical Engagement and Theoretical Commitment

The brief systematic survey shows that the pros and cons of using human rights within global bioethics are still very much subject to debate. Reviewing the arguments, it is difficult to avoid the impression of the ambivalent character of global bioethics. On the one hand, there seems to be a gap between the rather philosophically inclined academic bioethics scene and the more activist human rights movement. While the latter seems focused on social change, the former

sometimes gives the impression of mainly seeking intellectual elucidation of moral quandaries. On the other hand, through globalization the bioethical discourse seems to have expanded out of the esoteric academic arena as well. Even at a local level, bioethicists are often concerned with policy-making in healthcare institutions and consultation in clinical settings. This connection to policy-making is yet stronger at national and international levels where bioethicists are involved in a wide range of activities that go beyond the exclusive domain of academic enquiry.

As this *Handbook of Global Bioethics* evolves around the UNESCO *Universal Declaration on Bioethics and Human Rights*, it clearly engages with the human rights tradition as a pivotal means of communicating and implementing ethical standards on a global scale. The consideration that human rights represent a well-known, reputable, and effective framework is decisive in picking this moral framework to feature prominently within global bioethics. Admittedly, on the view that global bioethics should merely stick to reflecting about the world, without any attempt at improving it, the utility argument in favor of invoking human rights fails to make a dent. However, the editors of this volume believe global bioethics should attempt to be more ambitious and aim for social change next to elucidating and establishing moral truths.

This handbook looks at the way bioethics has developed in a variety of countries worldwide and explores the main ethical challenges through the prism of the UNESCO *Universal Declaration on Bioethics and Human Rights*. In the years ahead, it will be pivotal to further develop a global bioethics that aims at improving social conditions and combining an activist agenda with scholarly research and moral reflection. This stance implies that further serious scholarly work should be done in order to adequately answer claims about flaws in human rights theory. Additional high quality work is needed, which should be focused not only on the philosophical foundations and justifications of human rights but also on more specific "downstream features" of the theoretical human rights framework. That being said, it should not be forgotten, of course, that the other main ethical theories and traditions such as utilitarianism, virtue theory, and deontology are not free either of alleged flaws or of controversial disputes about their philosophical justification. International human rights theory, however, as the youngest contender among these ethical traditions, has some catching up to do in terms of philosophical solidification and analysis of its main theoretical features and concepts. Activists might sometimes seem hesitant toward philosophical explorations of the foundations and basic concepts of human rights, perhaps fearing that too many critical reflections might shed uncomfortable doubts on the normative standards themselves and lessen their impact in practical settings. In the long run, however, serious attempts to get human rights theory on par with its main theoretical competitors will likely solidify the human rights tradition (cf. Arras & Fenton, 2009). Raising the bar in the scholarly arena might, for example, fence off harms and damage from all too easy attacks. On the other hand, scholarly disputes should not be an excuse for abstaining from practical interventions. One cannot argue that practical action is impossible as long as there is no comprehensive consensus on foundations and all the pivotal concepts. In numerous countries, there are important ethical issues

"on the ground" that require decisions in conditions of uncertainty. As long as bioethicists are pondering and analyzing, others – for example, pharmaceutical companies and governments – will simply continue with their current policies or lack thereof as usual.

Promoting Education, Capacity Building, and Protection

Despite the fact that in some countries bioethics has achieved a strong institutional base and a high level of sophistication, in many other countries it has clearly not yet reached a full-fledged state of development. This is demonstrated in this work's survey of the state of bioethics in a large variety of different countries. Indeed, it should here be noted that the list of countries featuring in this volume involves a positive selection bias, since – for obvious reasons – countries without any noteworthy bioethics infrastructure could not be included. In the years ahead, the editors hope to enlarge the number of countries listed in future editions of the *Handbook of Global Bioethics*.

Be that as it may, efforts are needed to strengthen the state of bioethics in most countries worldwide, so that global ethical standards might be more effectively communicated and implemented. As said, human rights and their institutional mechanisms do currently seem to be the strongest implement for social change available to global bioethics. Yet the above-mentioned argument about the "impotence" of human rights should be a reminder that human rights' impact can and should indeed still be reinforced. In the area of medicine, healthcare, and the life sciences, this can be done by promotion of bioethics education and capacity building.

Thus it is important to improve bioethics education worldwide. Also, it is essential to remain critical toward existing methods of bioethics education, promote the development of alternative approaches, and develop more sophisticated ways of assessing the effectiveness of different teaching methods. Finally, there should be a better-organized exchange of teaching experiences in various educational settings. Sometimes bioethics teachers tend to be too secretive about their teaching programs. However, openness and mutual exchange are important so that academics who wish to set up new bioethics programs or improve existing ones do not have to reinvent the wheel continually. NGOs, universities, and intergovernmental organization such as UNESCO are already constructively involved in a range of international activities focused on bioethics curriculum development, designing teaching materials, and the training of bioethics teachers (Ten Have, 2008). These are exciting new initiatives that must be further expanded.

In addition, as set out in Article 19, the *Universal Declaration on Bioethics and Human Rights* advocates the establishment, promotion, and support of "independent, multidisciplinary and pluralist ethics committees." These are crucial platforms for bioethical debate, education, and policy advice (Article 19). The majority of countries worldwide still lack any noteworthy experience with these committees or have not yet established them in the first place. Consequently, it is

pivotal that the establishment and operations of these future bioethics committees in countries with an underdeveloped bioethics infrastructure be promoted and supported (Article 19).

Finally, the implementation of global bioethics requires the development of various levels of protection, especially in developing countries where individuals and populations are increasingly vulnerable due to globalization and appropriate guidelines and effective legislation are often absent. In order to protect defenseless and weak people, serious efforts should be undertaken to develop and apply appropriate legal frameworks in the area of bioethics.

Exploring Alternative Theoretical and Practical Approaches

The concise historical survey above features a mainstream account, according to which human rights have roots rather far away in the past. On this view, the development of the human rights tradition is a long process of moral improvement, whereby moral truths have gradually become clearer until they begin to really trickle through in the Age of Enlightenment. Progress then continues until, after World War II, humanity finally learns its lesson. Human rights are now set up in a serious way and crystallized into a solid foundation for modern international relations. Alternatively, according to a revisionist historical account, the international human rights tradition only really starts off in any significant way in the 1970s. International human rights begin to flourish by accident after dominant other ideologies had collapsed (Moyn, 2010, 7). On this view, development of human rights is a far cry from any necessary unfolding of moral truth. Instead, it is affected by historical twists of fate. Extrapolating from the traditional historical account it might seem reasonably safe to assume that human rights will further expand, as different people around the earth will more broadly accept their moral truth. On the alternative account, however, it is less self-evident to expect that the human rights tradition will survive the vagaries of world history in the twenty-first century. "Human rights were born as the last utopia – but one day another may appear" (Moyn, 2010, 10).

As the court is still out on the appropriate historical view as well as the likely future development of the human rights tradition, it is prudent for global bioethics not to put all its eggs in one basket. Instead, it should explore a variety of alternative theoretical and practical approaches to further its cause. The fact that the human rights framework currently seems the strongest vehicle for social change might hinge on precarious historical contingencies. Thus global bioethicists should not feel too self-confident and self-congratulatory when linking up with the human rights tradition in order to avoid that their endeavors might be swept away together with the latter, once the next ideology takes over as the new foundation of international relations. Fortunately, as this volume shows, a wider theoretical focus is available, for example, through the perspective of communitarianism, the link with environmental ethics, and the international law concept of the common heritage of humankind.

Conclusion

The goals for future global bioethics are ambitious. It goes without saying that it should focus on excellent intellectual scrutiny. However, academic reflection should not be an end in itself. Global bioethics should also aim to have a positive effect on the world. For this reason, this volume endorses human rights as the strongest vehicle for social change currently available to global bioethics. Combining a theoretical commitment with practical engagement implies the following: On the intellectual front, global bioethics should focus on further philosophical solidification and analysis of the foundations and basic concepts of human rights theory. On the practical front, it should promote ethics education, capacity building, and protection. In following this two-thronged approach, however, global bioethics should also avoid dogmatism and keep an eye open for exploration of alternative theoretical and practical approaches that are not integral to the international human rights system.

Introduction

The history of bioethics as it has been known was more an account of the events giving rise to this discipline in the Anglo-Saxon world, particularly in the United States, and later, of the attempts at establishing stages in the historic development of bioethics in Latin America, which described the reactions to the arrival of the bioethical paradigm – basically born and developed in the United States – in the region (Rodriguez del Pozo & Mainetti, 2009; Lolas, 2002). These have been accounts geared to deconstructing what appears to be a linear history.

It is well known that ethical problems related to human life and health are generated within a specific historical and cultural context, and it is essential to relate to this particular environment to understand the way in which these problems are apprehended, discussed, or decided on. For its part, institutional development has also accompanied the arrival and expansion of a "discourse" that is establishing itself in a specific milieu. For example, a fact to be taken into account is that, at the time when minority movements started to appear in North American society demanding the right to recognition of their differences (which for many has been an inflection point in the birth of bioethics), one of the darkest periods of its history was beginning in Argentina. The interruption of democratic processes in many countries of the region coincided with the explosion of the autonomist movement in the United States, something that should not be overlooked when considering the history of the ethics of life and human health.

These accounts of the ways in which Anglo-American bioethical discourse was understood in the region are of great interest. However, it is essential to consider at least three aspects when discussing the history of bioethics in Latin America and in Argentina in particular.

In the first place, the socio-political context in which the discipline started to be developed should be considered, in particular, the right to freedom, to life, to health, and the freedom of conscience, expression and movement. Secondly, the economic, social, and sanitary conditions within the country need to be taken into account, observed in the exercise of the right to health and accessibility of health services and in the enormous inequitable gap prevailing in Argentina between the different regions and social classes. Poverty, inequity, and exclusion are conditions which, in addition to being ethical problems in themselves, necessarily cut across all the ethical problems emerging in the field of life and human health. This is the framework in which the central issues of bioethics must be considered, such as the value of life, dignity in death, respect for freedom of conscience and of choice (reflected in informed consent), equity and justice in the distribution of the goods and benefits of development. It is difficult to consider the fulfillment of values and application of principles proposed by bioethics in the framework of political conditions of oppression and extreme violation of human rights and basic freedom. It will be equally difficult if these values and principles are not related to the enforcement of social, economic, and cultural rights and, in particular, to the way in which the right to health can be exercised in the communities' real and concrete life.

The third aspect to be taken into account is the influence of the religious and historical cultural tradition in the development of an ethos for the region and for Argentina in particular (Tealdi, 2008). It is important to remember that the Catholic Church has had, and continues to have, an enormous influence on debates on ethical issues, in particular those related with the beginning and end of life. In the first place that influence is on medical ethos but also an enormous political influence, which, in many cases, has led to regulatory projects being postponed or changed (e.g., those on sexual and reproductive health, abortion, and issues regarding the end of life), and finally, in the judiciary field, as will be seen in many of the rulings by judges.

In their revision of the stages of development of bioethics in Latin America, Rodriguez del Pozo and Mainetti (2009) talk about the "bioethical revolution," and this would seem to coincide with a political-historical time in which human rights were apprehended by civil society, internalizing the sense of belonging of these rights to concrete practices and, therefore, the possibility of effectively demanding them when they could not be exercised. It was also the time when basic freedom crystallized in a social practice that, for this same reason, made it possible to have a critical outlook, reflect on the history, talk, and voice opinions and take free decisions in a pluralistic and democratic environment. It was around the year 2000 that a critical revision could be made of the Anglo-American model that had been transferred to Argentina uncritically in the 1990s. This model very shortly showed itself unable to respond to the complex ethical conflicts emerging from life and health in a region with great inequities that required new answers. In this way, the revolution was not only an academic one. Certainly, this standpoint removes bioethics from the academic shelf, to place it in the context of applied ethics which seems to be the richest way of looking at its history, as a reflection on social practices, individual acts, and the ways that *ethos* adopts in this specific location.

Bioethics as a program for social reform (Cecchetto, 1996), as a new discourse, is a bioethics linked to social practices and expresses as a result of a movement that is growing, self-creating, and establishing itself. Its field of study concerns the ethical aspects of life and human health and, therefore, cannot be indifferent to those lives ending before their time because of lack of satisfaction of their basic needs, such as food, or lives ending as a result of violence, injustice, or exclusion. The death of innocent people for social, political, or religious reasons is an example of a lack of respect for life and is an expression of the way in which people live and die in each society.

There is no doubt about the debt to write a history of Latin American bioethics, as in fact it happened with North American bioethics (Jonsen, 1998). It should start with the debates that arose with the conquest of America about the rationality of the indigenous people and the state of nature (Gracia, 1989, pp. 128–130). Saving this debt, the account of Argentine bioethics was only possible with the reestablishment of democracy and several years later was able to achieve a wider academic development toward the end of the 1990s and, more strongly in the twenty-first century, following almost 20 years of democracy in full force but crossed by three economic

crises that decimated the country. The last crisis in 2001, which was not only economic but also institutional, left over 40 % of the population under the poverty line. This background has affected in different ways the manner in which bioethics developed in the country, its institutional growth, its regulatory swings, and its difficulties to progress in the normative field.

The Institutional Framework in Argentina

A representative, republican, and federal government system is in force in the Argentine Republic based on the institutional organization of the 1853 Constitution and its subsequent amendments in 1860, 1866, 1898, 1957, and 1994. The Federal State comprises 23 provinces and the Autonomous City of Buenos Aires. Each of these has its own local constitution and conserves all the power and authority not expressly delegated to the national government, in accordance with a republican and representative government system respecting the declaration of rights and guarantees set out in the National Constitution. The country has 40+ million inhabitants and is placed among the region's medium-income countries. It is the second largest country in Latin America.

Some Background Information and Stakeholders Who Took the First Steps

Bioethics first saw the light in Argentina and also in Latin America at the Institute for Medical Humanities of the Dr. José María Mainetti Foundation for the Progress of Medicine, established in 1969. Shortly after, the Editorial *Quirón* was created, producing the first journal to publish bioethical contents in the country. This was followed by the creation of the Medical Humanities Chair at the School of Medicine at the University of La Plata, thus starting the stage of bioethics "assimilation" (Mainetti, 2010) with the organization of the first courses given by guest lecturers, particularly from US centers. But it was only in 1985 with the creation of the Program for Bioethical Research that the national situation was approached from a *comparative* bioethical standpoint (Mainetti, 1990). In 1986, the National Bioethics Reference Center was established, subsequently becoming the Latin American Bioethics School (ELABE) in 1990, reporting to the Mainetti Foundation and located in the City of La Plata. This was an academic extension project with a regional scope. Its president was José Alberto Mainetti, and Juan Carlos Tealdi was its director for almost 10 years. In 1989, the Mainetti Foundation organized the First Course on Health Ethics Committees with the aim of training future coordinators for these committees. Later, more specialized international courses in bioethics were organized, providing a high-level training to many of the pioneers in bioethics from other fields and provinces in the country.

By this time, there were around five Health Ethics Committees (HECs) among them those established in the Buenos Aires Clínicas Hospital (created in 1984),

the Italian Hospital's Neonatology Service (1984), the La Plata Excellence Center for Cancer (1987), and the Mendoza Hospital Emilio Civit (1989), later renamed the Humberto Notti Hospital (Tealdi, 1995). Subsequently many other committees arose in hospitals in the Province and City of Buenos Aires and in the Provinces of Córdoba, Santa Fe, and Mendoza (Vidal, 2008). ELABE coordinated the operation of the Regional Network of HECs, which for almost a decade gathered efforts at different levels and was headed subsequently by the president of the civil association Bio & Sur, Juan Carlos Tealdi.

Another center of importance was the one created related to the University of Mar del Plata with the Bioethics Commission set up in 1989 following a proposal by Pedro F. Hooft and Justo Zanier. From this initiative arose the degree course for Specialization in Bioethics at the University of Mar del Plata, which started in 1991 with a postgraduate course in bioethics and was later in 1994 reformulated as the Advanced Program for Research in Bioethics. The Bioethics Committee of the Private Community Hospital, PCH (established in 1995) contributed closely to this project and from 1984, had a Deonto-thanatology Committee and a section for palliative medicine, in which Jorge Manzini – a recognized specialist in end of life issues – participated. Presently, it also has a very rigorous research ethics committee (the institutional council for the revision of research studies (CIREI-HPC)). It was an initiative of the PCH Committee that led to the establishment of the Network of Bioethical Institutions of the Southeast of the Province of Buenos Aires, with 12 other institutions from Mar del Plata, Tandil, Bahía Blanca, and Necochea, in which many bioethics specialists from the Province of Buenos Aires took part. The Ethics Committee of the Inter-zone Acute Hospital also played an enormous role. The late Sergio Cecchetto, a well-known bioethicist, was part of this committee and of its numerous contributions to Argentine bioethics, particularly through the presentations of cases greatly contributing to jurisprudence. Likewise, other HECs in this network participated extensively in various activities that took place at that time.

In 1993, FLACSO (the Latin American School of Social Science) established a Certificate of Higher Studies in Bioethics. Presently, it is known as the Bioethics Program, under the direction of Florencia Luna. This school offers an educational program (which will be discussed below), develops a research program, and has been producing the Journal "Perspectivas Bioéticas" since 1996. In 1994, the International Association of Bioethics' Second World Congress took place in Buenos Aires, in collaboration with ELABE under the presidency of Juan Carlos Tealdi. This congress was an encouragement to national bioethics and led to encounters with voices from central countries and also from other countries of the region. In 1995, the Argentine Bioethics Association was created gathering most of the bioethicists working in the country at that time. Since then, it held an annual meeting where different voices and views met over several years.

It would be impossible to refer to all the people who took the first steps in Buenos Aires and in the rest of the country to develop this discipline. It must be said that many of them generated bioethics in their centers or provinces and were later followed by others who created new initiatives.

At the University of Buenos Aires, the Faculty of Law relied on the impulse of academics such as the late Gladys Mackinson from the Gioja Institute and the Bioethics Chair, one of the first in this subject in the country, and Salvador Bergel with the UNESCO Chair in Bioethics since 1994, developing considerable activities in the field known as *biolaw*. Mention should also be made of other lawyers like Luis Niño, Estela Maris Martinez, and Nelly Minyersky, who made a fruitful contribution to providing grounds from a philosophy of law for different subjects. They were later followed by other bioethicists such as Eduardo Tinant (La Plata) and Ignacio Maglio (Bs As), among others, who continued contributing to this task. Some philosophers such as Maria Julia Bertomeu, Maria Luisa Pfeiffer, and the late Sergio Cecchetto, among others, were there from the start working on issues of fundamental bioethics, close to ELABE and later at other academic centers.

Toward the end of the 1990s, the Ethics Committee of the Argentine Society of Intensive Care was set up, with the presence of two well-known referents, Carlos Gherardi and Francisco Maglio who contributed a lot to Argentine bioethics in terms of decision-making in end of life situations, among other issues.

Outside Buenos Aires, many experts developed not only local work but also became involved with initiatives at the national level that arose from Buenos Aires. It should be mentioned that at the end of 1999, there were over 200 Ethics Committees (both HECs and Research Ethics Committees (RECs)) in the whole country, as compared to the four existing 10 years earlier (EULABOR, 2005). These had mostly arisen spontaneously from the initiative of small groups of people.

From Bahía Blanca, the contribution of the bioethicists Norberto Cragno and Agustín Estévez was very considerable, giving vitality to the launching of bioethics on a local and national level.

In the Provinces of Rio Negro and Neuquén, the work of Luis Justo and Andrea Macías has been enormous. There, a Bioethics Chair was set up at the National University of Comahue (UNC) and the Provincial Network of Bioethics Committees by the Ministry of Health in Neuquén among many other activities. The network was established within a health model geared to primary health care starting toward the end of the year 2000, giving it a different profile and involving community participation. The project was a joint venture between the Provincial Bioethics Development Program and the Chair of Bioethics of UNC's School of Medicine (Justo & Macias, 2002).

In the Province of Santa Fe, Silvia Brussino was a pioneer in this discipline at an academic level, working systematically from the University of El Litoral, as well as from a lot of other places like the Bioethics Committee of the Iturraspe Hospital in the City of Santa Fe, established in 1994. Elisa Dibarbora, from the Faculty of Law of the National University of Rosario and the Bioethics Commission of the College of Physicians, was a promoter of bioethics in the province.

In the Province of Córdoba, Susana Vidal from the Bioethics Area of the Ministry of Health started her activities in 1994, continuing in 1996 with the establishment of the HECs Provincial Network (Vidal, 1998), and subsequently

with the project for biomedical research ethics, which went through many difficulties as did the various provincial commissions set up over the years. In 2001, the Bioethics Center of the Catholic University of Córdoba was created by the Rector's Resolution N° 289/01 under the leadership of Armando Andruet who has since developed many activities in the province. Over the past few years, the Province of Jujuy has launched a development initiative from the Ministry of Health, involving HECs and RECs under the initiative of Paz Bossio. The Province of Mendoza started its activities in the 1990s, with Marta Fracapani from the Faculty of Medicine of the University of Mendoza and the above-mentioned HECs, with the invaluable inputs of Aída Kemelmajer de Carlucci from the Faculty of Law and the High Court of Justice. Currently, all the provinces have developed some type of bioethics capacity, either committees or other activities of varying quality.

For their part, the RECs have had a complex history. To start off with, the ethics research evaluation was developed in some provinces and in the City of Buenos Aires by the HECs themselves, and as will be seen, it has only been over the past 10 years that these two types of committees have started to work separately. However, many committees still fulfill both functions in the City and Province of Buenos Aires and in some provincial commissions.

It should also be mentioned that there were at least three attempts at setting up National Bioethics Commissions in the country that ended in failure. The first attempt was made by the Ministry of Health of the Nation (MH) in 1992 and the second in 1998 by the Presidential Decree No. 426/1998, the National Commission for Biomedical Ethics, that operated in the MH and that was dissolved 2 years later as part of a scandal within academic institutions. Finally, the third was a proposal made in 2006 by the MH, which did not come to fruition. There are other more specific commissions: the National Committee for Ethics in Science and Technology set up in 2001 in the context of the Nation's Ministry of Education, Science and Technology of the time. Likewise, the Ethics and Human Rights Council in Biomedical Research was set up by Resolution n° 050/04 in the Secretary of Human Rights (Ministry of Justice and Human Rights). Finally, the Nation's Ministry of Justice and Human Rights Resolution 666/2011 was made public during 2011, creating the National Council for Bioethics and Human Rights, which it is envisaged will start to function in 2012.

Biomedical Research and Regulations in Argentina

Addressing research ethics in Argentina requires looking at the shape the model of biomedical research has acquired in the country over the past years. In this respect, it may be stated without the fear of committing a misjudgment that one must analyze a dual scenario: first the regulative scenario (always marked by a path of progress and setbacks related to conflicts of interest, particularly interests of economic and sectorial nature), and, secondly, a scenario not linked to the regulatory frameworks, of enormously heterogeneous practices.

The Regulatory Framework

Since 1997, Argentina has a regime of Good Clinical Practices in Pharmacological Research Studies, Provision 5330/97 of the National Administration for Drugs, Food and Technology (ANMAT) reporting to the Ministry of Health, with provisions that must be fulfilled by researchers and promoters undertaking research in which human beings are involved in the country. This was a technical regulation, which barely alluded to the ethical aspects of research and made no reference to the problems already present at international discussions on the subject. However, it established as mandatory that studies must be approved by an Ethics Committee and by the Teaching and Research Committee of the center where the research was to take place. It also established the responsibility of ANMAT regarding approval, control and monitoring of studies and the obligations of researchers and sponsors. Initially, this regulation had strong repercussions and represented a breath of fresh air for the new situation generated by multinational research that had been growing in an exponential way in the country during the 1990s, without much control. There is no doubt that the provision was insufficient vis-à-vis the growing development of research in the country and went unmodified until a few years ago when it was improved through various amendments. It was only in 2005 that *Provision 690* was adopted, formalizing the procedure for ANMAT to undertake inspections of Clinical Trials.

In 2007, Resolution No. 1490 was adopted as the "Guide for Good Clinical Practices in Research on Human Beings" (Ministry of Public Health, 2007), which adapts internationally accepted ethical and scientific standards to the Argentine situation regarding the design, implementation, recording, and reporting of experimental and nonexperimental studies carried out on human beings (Ugalde & Homedes, 2012a). One year later, Provision 6550 (ANMAT, 2008a) was adopted, strengthening points related with the functions of RECs and further advancing in the requirements for informed consent (IC) among others. Provision 1067 (ANMAT, 2008b) and Resolution 102 (Ministry of Health, 2009) advance on the report on Serious and Unexpected Adverse Reactions to Medication (ANMAT, 2008, Annex I) and establish the Registry for Clinical Trials on Human Beings, which so far had been inexistent on a national level. Finally, Provision 6677 (ANMAT, 2010) adopted in 2010 repealed Provisions 5330/97, 1067/08, and 6550/08 and became the reference document for undertaking clinical tests in the country, taking as a framework of reference international standards established by good clinical practice standards.

Some provinces, such as Córdoba and the Autonomous City of Buenos Aires, have followed their own paths on some occasions removing themselves from national regulations and making further progress regarding requisites to be demanded. A brief summary will be made further on.

Biomedical Research Practices

The 1990s marked Argentina with the emergence of new and more complex research at various centers in the country, mostly of a multinational nature and

funded by pharmaceutical industry. Although the regulatory framework was being progressively implemented, events took place that marked the development of research on a national level. Some of these events warrant a detailed examination and no doubt are among the reasons why low- and medium-income countries are exposed to greater and more complex risks in multinational research (Lorenzo et al., 2009) also showing the need for a stricter control of researchers and local institutions, both centers and hospitals, in addition to ethics committees. Homedes and Ugalde have written a detailed report on ethically questionable situations in the ethics of research in Argentina (Ugalde & Homedes, 2012a). Some of the cases described in this text show that not only did irregularities take place during research processes in public hospitals and on vulnerable populations (such as those carried out on children in the Province of Córdoba) but also various studies detected scientific fraud, corruption, and bad ethical behavior by the researchers. The judge's ruling on the claim made by ANMAT has become public recently (November 2011) sentencing the laboratory and researchers of a multicenter study of vaccines on children (COMPASS Study) aimed at assessing the effectiveness of a vaccine for the prevention of pneumonia and middle ear caused by a pneumococcal infection, to pay a fine. The study took place in three Argentine provinces on low-income populations and "irregularities in the procedure for selection and entry of some participants (were detected) related with errors in the procedure to obtain the informed consent of parents or tutors or the lack of compliance with criteria for the inclusion of participants" (ANMAT, 2012). In the many interviews carried out, failure to comply with procedure IC, signatures of illiterate patients or underage patients, and irregularities regarding witnesses for the signature of the document were detected.

Additionally, not only economic but also political influences have been found in the development of regulatory processes and in the approval of protocols of dubious benefit to the communities involved (Ugalde & Homedes, 2012b). A very notorious case was that regarding the claim lodged by the Nation's Ombudsman (Mondino, 2003, p. 67) on research on clinical oncology carried out in the country between 1998 and 2002 and was presented at a congress of the *American Society of Clinical Oncology* (ASCO). Serious anomalies were detected in these studies, such as studies carried out without informed consent (IC), or without the approval of the REC, showing the lack of control by the responsible bodies and the enormous difficulty to gather data on studies carried out in the country. Another case was detected at the Buenos Aires Naval Hospital (Deyoung & Nelson, 2000) regarding the so-called GUARDIAN Study (Guard During Ischemia Against Necrosis – with cariporide), in which very serious irregularities were found in the IC process. There were false ICs (80 of the 137 cases recruited), lack of knowledge on the part of the patients that this was research, and also forgery of the tests. The study was carried out between 1997 and 1998, and it was the laboratory itself that denounced that the signatures of some of the consents had been forged and that various medical histories, X-ray, and electrocardiograms had been replicated with the aim of "inventing" patients. Researchers received 2700 USD for each patient and had to meet certain "deadlines." The claim led to a criminal court case against the

researchers, the institution, and the laboratory sponsoring the study regarding the death of some of the patients. However, causality between the study and the deaths could not be proven, and finally, the case was dropped and the doctors continue to exercise their profession.

Problems that have been cross-cutting in international debates since the end of the 1990s, such as double ethical standards in multinational research, provision of post-research treatment, and the exploitation of vulnerable populations, although identified in numerous case studies carried out in the country, have not been the center of the debate among RECs until the time they make their assessments. They would seem to be more worried with primary issues related with good research practices, researchers' conduct, subject insurances, and how public funds are used when biomedical research is conducted in low-income populations and in public institutions.

Another issue causing great concern is the problem of the independence of ethics research committees (Vidal, 2004) that have only recently been taken more seriously with the establishment of the national registry and progressive accreditation of these committees. Increasingly in the provinces, the approval of studies by a local or institutional committee is being demanded. This requirement has broken up a circuit that had been operating since the 1990s for the approval of studies by a few private committees, known as "independent committees" located in Buenos Aires, that assessed studies being carried out all over the country and collected fees. They lacked any national public institutional monitoring system and provided assessment and follow-up of a doubtful quality while the studies were taking place (Gonorazky, 2008). Accreditation systems will doubtlessly raise the quality of the committees and lessen conflicts of interest insofar as the criteria demanded are rigorous. In the model described so far, researchers played a complementary role, sometimes as mere patient recruiters, and did not participate in research design and, in most cases, were not part of the final publication either. The number of medical researchers has grown from 961 in 1998 to 3,974 in 2005, which is more related to their capacity to enroll patients rather than their scientific and professional qualities (EULABOR, 2005). On some occasions, they have become actively resistant to the implementation of standards or regulations, in particular if these are restrictive, for fear of losing a source of income in a country that has been hard hit by economic crises, or of losing a certain degree of so-called prestige granted by being part of these protocols.

The City of Buenos Aires

The 1990s saw the first steps in regulating this issue. In 1999 within Basic Health Law N^{o} 153, the Health Research Council was created, entrusted with authorizing and monitoring all research in the public subsector in agreement with the guidelines set out in national and international documents regarding bioethics. The standard underscores the need for informed consent, and progress is made in terms of financial participation by the health institution where the research projects are being carried out. Several years later, Resolution N^{o} 1125/SS/2003, amended by

Resolution N° 1914/SS/2003, approved requisites and procedure applicable to research projects in hospitals depending on the Government of the Autonomous City of Buenos Aires (GCBA), thus decentralizing the assessment function and setting up a Central Committee for Bioethics in Health Research, which started to operate on a central level (Perelis et al., 2012).

In 2006, the Report by the General Auditor of the City of Buenos Aires was published on "Management of Research Projects in Public Hospitals – Period 2006," that covered 30 of the 33 hospitals reporting to the GCBA (Perelis et al., 2012). This report showed the precarious way in which assessments had been made so far with a high degree of heterogeneity in quality and defects in the procedure for assessing protocols. No standard criteria for the RECs were available, and, in many cases, IC standards for participants had not been respected. As a starting point to deal with this situation, Law N° 3301 of 2009 was adopted: "Protection of the Rights of Subjects in Health Research" (Law 3301, Ciudad Autónoma de Bs As., 2009). The law governs the regime for clinical research applied to human beings being undertaken in the City of Buenos Aires. In addition to the usual requisites, it includes the need to consider the relevance to the community of the research. It also requires, in all cases, insurances for research undertaken with private sponsoring in favor of the subjects. Finally, the law also establishes a system for accreditation of the RECs (Resolution N° 1012/GCABA/MSGC/08; 2011), a research registry, and a network with other stakeholders, thus completing the support involved in a system of research ethics evaluation for the city.

The Province of Buenos Aires

Since 1990, the Province of Buenos Aires has been implementing the first project to regulate this matter in the country (Law 11044/1990), which was very complete and innovative at a time when the whole of Latin America was practically virgin of regulations. This law took several years to be enacted, but finally, this was done by Regulatory Decree 3.385/08 Pcia. Bs As, a couple of years ago. It applies to public and private subsectors, by the Ministry of Health through the Joint Health Research Commission. The law is a little complex, creating two types of committees for the assessment of health research, separating ethical aspects from design and methodology (technical quality and scientific merit) and establishing that, on the basis of its findings, it is the person responsible for the institution who will give the final authorization for its implementation. It also establishes the cases in which research must be assessed by the central Ethics Committee (created by Resolution 4107. MS. Pcia. Bs As) as well as all the procedure that must be carried out for ethics assessment.

Province of Córdoba

In 2001, a project was implemented in the Province of Cordoba for the creation of a provincial system for ethics research evaluation, through one of the most rigorous

regulations in the country (Res: 729/02). The resolution created a Health Research Ethics Commission (COEIS), proposed criteria for the evaluation of biomedical research and to accredit RECs. In 2003, the regulation was amended, and the commission was dissolved by a political decision. A commission established by the then Minister of Health only comprising researchers was left in charge of assessing protocols, with flexibility in the criteria to set up the RECs, as in the rest of the country. The provincial regulation has been amended three more times with changes in the authorities and different types of negotiations among the sectors of interest involved: researchers, directors of private centers, political authorities, members of private committees, etc. Currently, a provincial law is in force, adopted in 2009 (Law 9694, 2009), establishing the System for Assessment, Registry and Monitoring of Health Research (SERFIS). The system comprises: (a) the ethical assessment of health research and (b) registry and monitoring of this research. It establishes the Council for Ethical Assessment of Health Research (CoEIS) and establishes its functions, which already existed in the previous resolution. In spite of establishing a registry of RECs, the criteria are not included in the text of the law. This regulation proved to be more flexible than the original resolution 729 regarding some of its points. However, it implements a system for registering researches and the RECs and also provides the way of their control. Furthermore, it maintains as a right of the patient some points that had not been considered in other regulations such as: (a) to receive the best diagnosis, preventive and therapeutic method existing when participating in research, particularly when this involves the use of a placebo and (b) access to the best diagnosis, and preventive or therapeutic method identified by the research.

Other Provinces

Other provinces are progressively advancing in the creation of regulations regarding the demands generated by increasing research and the need to adapt to national standards.

In the Province of Santa Fe, the Provincial Commission for Bioethics was created only a few months ago by Resolution 1084/2011 from the Ministry of Health, aimed at regulating the activities of biomedical research in public and private health services, from the standpoint of public health and the protection of the rights of research subjects. The Province of Neuquén has also adopted a regulation creating a Provincial Bioethics Commission and has a few RECs, mainly in private institutions. Likewise, in other provinces, such as Jujuy, Misiones (Law 4334), the Chaco (Law 4781), and Chubut (Decree 932/03), provincial commissions have been established and are systematizing the system for assessing biomedical research.

Ethical Issues at the Beginning of Life

Ethical issues regarding the beginning of life, as mentioned above, have been characterized in Argentina by a gap between legal standards, public policies, and

social practices. The 1980s, with the arrival of democracy, gave rise to a certain degree of opening regarding the decrees established by the military dictatorship's which had a clear trend toward the prohibition of contraception and the promotion of pronatalist policies of population growth. In 1985, Argentine ratified the Convention on the Elimination of All Forms of Discrimination against Women (CEDAW), new decrees were adopted and other previous ones repealed, and various proposals for a national law were proposed including Sexual and Reproductive Rights (SRR) as a matter of human rights and health policy.

The 1994 constitutional reform incorporated into the National Constitution international treaties and a proposal was made for a bill on a "National Program for Responsible Procreation" (Cecchetto, 1999). Nevertheless, the trend during the 1990s was set by: (a) provincial fragmentation of conflicts (on the basis of the country's federal division) and (b) judicial involvement in medical practices (participation by judges in decisions regarding contraception of various types, tubal ligation, requests for authorization to carry out an abortion under circumstances foreseen in the national law, etc.). In this way, justice made an "interpretation" of the formulations established by international treaties and declarations, according to subjective criteria. All these events coincided with the advent of a strongly neoliberal government in the country during the 1990s.

In 2002, Law 25673 established the National Program for Sexual Health and Responsible Procreation, enacted in May 2003 (Decree 1282/03). This program was a step forward regarding this issue and set out very important and wide objectives. For the first time, this law ensured access to a wide range of contraceptive methods (including intrauterine and copper devices) through public health services. However, shortly after, it became apparent that the situation in the provinces was complex. Under the federal system, they have to adhere to national laws explicitly, and therefore, there was a great degree of heterogeneity in their regulations, with a variability of criteria in the courts, numerous appeals lodged for different reasons, and the continuous use of "conscientious objection" on the part of doctors in complying with the law, particularly of those working in public health services. All this led to the national law progressively losing force.

By 2006, the situation in the 23 Argentine provinces and in the City of Buenos Aires was as follows: 17 had sanctioned laws on sexual and reproductive health, two only had an adhesion to the national law (Santa Cruz and La Rioja), and five had no regulations in this matter (Catamarca, Formosa, Santiago del Estero, Tucumán and San Juan) (Schuster & Garcia Jurado, 2006). Since then, the work carried out by many NGOs has been intense in the field of women's rights and particularly Sexual and Reproduction Rights, promoting that they can effectively be demanded and that women can achieve a true appropriation of these rights.

In the case of surgical contraception, in 2006, the Argentine Congress adopted Law 26.130-2006 on the regime for surgical contraception for men and women. This law has appeared after many years during which these practices were governed by the doctors' and judges' personal positions (Cecchetto, Urbandt & Bostiancic, 2007) and, in many cases, under the influence of religious groups, without

consideration of men and women's rights to decide on their own bodies. Even today, it may be stated – without any fear of error – that medical doctors and legal operators continue to give this law restrictive interpretations in the different jurisdictions.

Abortion

The debate on abortion in Argentina, as in most of the countries of the region, is fraught with socioeconomic and religious issues. In general, these lead to deep rifts in society, with double ethical standards among social classes and in the country's various regions.

Article 86 of the Criminal Code establishes prohibition of abortion with two exceptions that have given rise to various interpretations of the law: "abortion practiced by a qualified medical doctor with the consent of the pregnant woman is not a punishable offence: 1º If it has been done to avoid danger to the life or health of the mother and if this danger cannot be avoided by other means. 2º If the pregnancy is the result of rape or of indecent assault on an imbecile or demented woman."

Prohibition of abortion in Argentina has led to a double morality, particularly affecting underprivileged social groups and, especially, young women. That is, although abortion is prohibited in Argentina, women from the upper parts of society have the opportunity to make abortions in the country by paying high amounts of money to private clinics, while this is not an option for women belonging to the poorest sector of society. The rate of teenage mothers is high in low socioeconomic sectors and in some regions of the country (e.g., the average number of children per woman in Misiones is 3.2, in Santiago del Estero it is 3, while the national average is 2.3). In 2006, in the northeast region, 73 % of births were to mothers who had not finished secondary school. There is no doubt that these differences are related with educational levels, access to contraceptive methods and efficient health services.

In the City of Buenos Aires for every 1,000 teenage girls, 17.6 are mothers, while in the Chaco, this figure reaches 44.12. The case of maternal mortality is similar, with very different rates in the various geographic zones. Twenty-nine percent of the causes of maternal mortality are related to complications following abortions. In the City of Buenos Aires, the maternal mortality rate is 18 maternal deaths per 100,000 live births and rises to 165 maternal deaths per 100,000 live births in the Province of Jujuy. Seventy percent of these deaths take place in jurisdictions representing 40 % of the total number of births, in the poorest provinces of the country.

The number of illegal abortions carried out in the country per year is a sample of the deficiency of clear policies in this regard. It is estimated that some 700,000 illegal abortions are carried out per year in Argentina. Morbidity per abortion is established on the basis of releases from public establishments. Between 1990 and the year 2000, the figure increased by 46 % (78,894 releases) corresponding to the national average; however, in some provinces, the average is greater.

The situation is even more serious, if account is taken of the cases, in which even if abortion is not penalized, there are numerous obstacles before the doctors can carry out the abortion. In most cases, they request legal authorization for fear of legal proceedings against them, and in many cases, the judges take so long in coming up with the sentence that the decision arrives seriously delayed, if ever.

Over the past few years, the debate has been stepped up regarding abortions in the case of fetuses with pathologies making extrauterine life incompatible (in particular anencephaly). Dozens of petitions taken to the courts have ended in decisions making couples wait beyond the point establishing "viability" (week 24 of pregnancy) to authorize induced birth. These situations cause great suffering to the parents and involve enormous expenses in the legal process.

In 2011, a bill was submitted, extending the exceptions to penalizing abortion. The bill was only debated by the Commission for Criminal Matters of the Chamber of Deputies, and they did not reach a decision. The other commissions involved (health and family) did not want to address it, and on finalizing the session, the bill's parliamentary status was lost. Finally, in March 2012, the Supreme Court of Justice gave a ruling on the interpretation of this article, which represents an important step forward, allowing abortion in the case of rape.

Assisted Fertilization and Treatment of Cryopreserved Embryos

In spite of the fact that so far there is no legislation regarding the cryopreserved embryos stored in the banks of assisted fertilization centers, these practices are carried out in the country's main cities under the highest standards and with the best technologies. Numerous bills have been frustrated by the same questionings as set out in the beginning. In the first place, the debate on the status of the embryo has been the center of this discussion. Selection of the embryo before implantation has also been debated, although methods for prenatal diagnosis are available and, in many cases, used. Many of the centers affirm that they do not select embryos in a preimplanting way and that the embryos that are not implanted are offered up for "donation" (Luna, 2004). These issues open up enormous conflicts that cannot be gone into here. Unfortunately, no prompt solution is apparent. However, the lack of legislation in this respect obviously leaves the various parties participating in this process completely unprotected and those carrying out technical procedures in complete liberty.

Ethical Issues at the End of Life

Ethical issues related with the end of life have been on the country's bioethical agenda for several years now. Together with issues on the beginning of life, they are probably among the most controversial points in which progress has been difficult with regard to adopting regulatory measures. A regulatory framework would enable doctors to take decisions without fear of court cases being brought against them for

"mala praxis" and that would provide patients with a framework in which their decisions about the way in which they want to die are respected. Although academic debates on euthanasia and assisted suicide have been very rich, they have not been reflected in concrete projects for legislating on these issues. Most of the debates have addressed the decisions to be taken regarding patients with serious health deterioration and bad prognoses, in particular, situations of life support withdrawal (LSW) for seriously ill patients, for persons in a permanent vegetative state (PVS), or persons with progressive neurological disorders. Civil society has been involved in these debates in an interesting way through an enormous amount of articles in the daily press. However, they have not all given the issues an equally serious treatment, because of the enormous variability in the use of terminology, sometimes creating great confusion.

A particular issue that continues to occupy the legal system is requests for LSW by family members of patients who are incapable of taking their own decisions and who are suffering from permanent lack or deficiency of awareness, such as in the case of PVS or in some progressively incapacitating neurological diseases. When considering the arguments put forth in the courts by provincial and national judges in the resolution of these cases, it is evident that they mix elements taken from national and international jurisprudence with personal and, in some cases, religious convictions. Such convictions should not be included in court rulings in a country where religious freedom is safeguarded by the constitution. A clear reflection of the disassociation between the academic debate and the arguments put forth by judges can be seen in the ruling of the Supreme Court of Justice of the Province of Buenos Aires, where for the past 2 years the husband of a women in PVS has asked the legal system for the suspension of hydration and food (Gherardi, 2007). In the court ruling, the judges repeatedly quoted the report drawn up by the Minor and Incapable Peoples' Advisor who, in his description of the case, speaks of "the Creator" and the "parable of the talents" concluding "Hope of a Miracle must be kept. Love and faith will always demand rest in a heroic heart. This heroism may lie in knowing how to wait for God's time, which we know are not man's time" (S.MDC, SC BUENOS AIRES, 09/02/2005).

In 1999, the Ethics Committee of the Argentine Society of Intensive Care had already made recommendations in this respect in its "Guidelines and recommendations for the withdrawal and/or abstention of life support methods" (Comite de Bioetica de la Sati, 1999). These recommendations emphasize that the primary source of authorization for the decision to treat or not to treat comes from the patient and that this is independent from the nature of the disease and its evolution, while establishing that "the existence of a living will or advance directive made out by the patient (. . .) should be a priority to be respected independently from the opinion of the doctor (health care team) and of the family" (Comite de Bioetica de la Sati, 1999). Given that this fundamentally refers to patients in a critical condition, it establishes that "taking the decision on abstention or withdrawal of life support methods in a health care environment such as Intensive Care Services, generally depend on medical initiative, save for cases in which an advance directive exists" (Comite de Bioetica de la Sati, 1999). The recommendations also establish the

circumstances under which the medical team can suggest the possibility of abstaining or withdrawing life support (Comite de Bioetica de la Sati, 1999):

(a) When there is no evidence of having obtained the effectiveness sought (absence of response in the substitution of an organ or function), or events exist making it possible to presume that this effectiveness will not be obtained in the future
(b) When it is only maintenance and prolongation of a permanent and irreversible state of unconsciousness (e.g., PVS)
(c) When suffering is inevitable and disproportionate to the expected medical benefits
(d) When the opinion of the patient on the eventuality of such a circumstance in the case of a preexisting chronic disease is known without any shadow of doubt (personal report, by the family doctor if applicable or by a family member)
(e) When an irreversible state is manifest in the clinical case due to the successive collapse of vital organs, leading to the conclusion that the use of more and greater procedures will not be in the best interests of the patient

In spite of having these guidelines, today many of these points are still the subject of debate.

The debate on advance directives (ADs) or living wills prepared by adults with capacity has been a little more auspicious (Manzini & Tinant, 2008). A very abundant number of bills have been prepared under the name of "Death with Dignity," and they usually include all these aspects, rejection of treatment, abstention or LSW, decisions for patients without capacity, and the validity of ADs. But for diverse reasons, most of them have gone no further than parliamentary debates. There is a wealth of literature on this issue, addressed with great seriousness by academic circles. There are also different recommendations, from improvements in the doctor-patient relationship, in an attempt to have these decisions taken within this context, with the support of ethics committees and without involving the judicial system, to the creation a public registry of ADs on the basis of a document to be drawn up before a notary public.

Since 2009, Argentina has a Law (26529) regarding the rights of patients in their relationship with the medical profession. This has made progress in what is understood to be the autonomy of will, such as the right to accept or reject certain therapies or medical or biological procedures, with or without stating the cause. This is important because although there already existed jurisprudence on the rejection of treatment in a very much commented-on ruling of the year 1995 ("Parodi Case"), at the time of making decisions, difficulties still continue. The law emphatically defends patients' rights to decide on their integrity, dignity, autonomy, freedom, and personal values. It also refers to the right to reject treatments and, at the same time, legally endorses ADs in the case of capacitated adults.

However, it does not go into the issue of patients without capacity nor on abstention or LSW. In all cases, it discards any indication leading the doctor to "the practice of euthanasia." In 2011, a bill to amend the present law was submitted, in which issues relating to LSW and suspension of food and nutrients to unconscious patients were addressed. It also included a long explanation on AD.

Likewise, it included the provision of palliative care as a right of all patients. A bill was also submitted that year in the City of Buenos Aires, taking a very important step forward in this respect, in particular concerning LSW and a clear definition of what is understood as support (including food and nutrition). The law also makes an important clarification regarding conscientious objection, establishing that it must be done by health professionals on adopting the law, that it must cover public and private areas, and that it is only acceptable in the case that another medical professional is also involved. It also clarifies that institutions cannot put forth this argument: conscientious objection is an individual act.

Only two provinces have legislation on Death with Dignity, Río Negro (Law B 4264 adopted in 2007 and enacted in 2009) and Neuquén, while Córdoba (2003), Buenos Aires (2004), Tucumán, Mendoza, and the National Congress (2004) have submitted several bills, some that are still waiting to be dealt with, but they all open up a path regarding these issues. The Río Negro law defends the "right to a quality of life and to the dignity of terminal patients." The regulation includes patients suffering from irreversible, incurable diseases or who are in a terminal state caused by pathologies leading to death, those that have an uncertain ending or if death is estimated to take place within a short lapse of time.

Finally, progress has been made regarding palliative care (PC) and treatment of pains. Already in 2000, the National Program for Quality Guarantees established Standards for the Organization and Operation of Palliative Care, approved by Resolution N° 643/00 of the Nation's Ministry of Health. PC is included within the Obligatory Medical Program set out in accordance with Resolution 939/00 of the Nation's Ministry of Health, establishing the basic benefits that all citizens must have access to. At all events, and particularly in public health services, the benefit is still precarious and in no way homogeneous in the various parts of the country. Pain-killers for terminal patients are still a difficult issue, and some "barriers" are prevalent with regard to making opiates available. One of these barriers is the low prescription by physicians. The probable reasons behind this are not taking into account the importance of pain, the wrong understanding of the use of opiates, or, ultimately, the fear of side effects. A second barrier is related to the bureaucracy enforced by the authorities in relation to the provision of drugs in trying to prevent them from being used for other purposes (drugs abuse), and finally, a third barrier is related with some patients' own myths about the use of morphine and other analgesics (the use is related to drug dependence) (Mertnoff, 2008).

Terminal palliative sedation continues to be the center of enormous debate, as has been seen in the case of MG in the national news only 1 year ago (Carbajal, 2011). The case involves a teenager of 19 who suffers from a degenerative disease of the nervous system that has no cure. She is currently in a deteriorating state, and she has asked the court to be provided terminal palliative sedation, a request that had been rejected, both by her physicians and the HEC. Increasingly, decisions regarding so-called "terminal" patients are taken in the context of the professional-patient or family relationship, but this is not the case of innumerable different cases, where the courts seem to be the mechanism to solve these problems.

Bioethics Education

It has been said, quite rightly, that the development of bioethics can also be measured in terms of the number of experts and events taking place, such as congresses, meetings, seminars, etc. In this respect, Argentina has produced much, although of varying quality.

The issue of bioethics education has been a concern since the start when the first steps were taken in ELABE as already mentioned. Since then, many universities have taken up the issue of bioethics education as something that cannot be put off, particularly by the Schools of Medicine and Health Sciences. However, this was done to a lesser degree by the Law Schools and practically not at all by other academic disciplines. There are many initiatives in undergraduate and postgraduate education; however, it should be said that there is a great degree of heterogeneity in their content and in their achievements. No consensus has been reached on these issues as would be essential when designing a Bioethics Chair and consequently diversity is enormous.

Here will be mentioned only a few of the numerous postgraduate degree courses, some of which have been maintained over time, particularly with regard to master's degrees or specialization courses.

The Bioethics Master Degree Program at the National University of Cuyo in the Province of Mendoza arose from a partnership between the Faculty of Medical Science and the Bioethics Program of the Pan American Health Organization (PAHO/OMS). It was based on the master degree created under the same program in Chile University under the responsibility of Diego Gracia Guillén from Spain (Pfeiffer & Belli, 2012). Another experience that has managed to survive over time is the Master Degree in Legal Bioethics at the Faculty of Legal and Social Science at the National University of La Plata, which started operating in 2006 and has continued uninterruptedly to this date, under the direction of Eduardo Tinant. The Argentine Pontifical Catholic University (UCA) has had a Master's Degree Course in Biomedical Ethics for 12 full years with a religious dimension. The University of the Argentine Social Museum (UMSA) has a Master's Degree Course in Bioethical and Legal Aspects of Health, mainly pertaining to biomedical research issues and legal matters in this field, not only of a national but also of an international nature. Since 2005, the National University of Cordoba has a Master's Degree Course in Bioethics that started to be reformulated as from 2011. At its start, it was organized following the PAHO Bioethics Program like the University of Mendoza, with a strong stamp of Anglo-Saxon bioethics (Pfeiffer & Belli, 2012). Currently, it is undergoing a deep change.

There are numerous postgraduate courses. Particular mention should be made of the pioneer nature of the Chair for Medical Humanities of the Faculty of Medical Sciences, National University of La Plata, set up in 1980 (mentioned above).

The courses of the Permanent Education Program in Bioethics (PEPB) are an initiative launched in 2006 for the whole of Latin America and the Caribbean by a group of experts from the Province of Cordoba, endorsed by the UNESCO's Regional Bioethics Program (Montevideo Office) under the aegis of Latin American and Caribbean Bioethics Network (Redbioética UNESCO) (Vidal, 2010). Two 240-h

courses are Internet based and given through distance learning. One course is on Research Ethics on Human Beings and the other on Clinical and Social Bioethics (fifth and sixth editions, respectively). The courses have so far contributed to the training over 160 Argentine professionals in Bioethics.

The Latin American School of Social Science (FLACSO) presently offers a Higher Diploma and Specialization in Bioethics, obtained by following four courses, either by distance learning or face-to-face teaching lasting for a total of 190 h. Since 1999, FLACSO Argentina is hosting the Training Program in Research Ethics, funded by the Fogarty International Center of the National Institutes of Health, USA.

Many other initiatives are being developed in the country differing in qualities and results, and with different approaches.

Conclusions

Presently in Argentina, there is no organization that unites all the bioethicists. Different approaches, conflicting positions with regard to recent Argentine history and other less noble conflicts, such as simply struggles for power, have led to an enormous fragmentation in developments. The initial fascination with the bioethics from the First World countries somewhat ignored the need to join efforts started by ELABE and later the Argentine Association of Bioethics. Very shortly, various types of personal interests and group interests overcame the need to carry out a national program or to establish an association joining all the Argentines working seriously on this issue.

Regarding the concrete issues addressed in this paper, the distance between the development of regulations and practices showed very clearly that there are obstacles of different types in establishing national regulations. Regarding research ethics, the need to have a national system of research ethics evaluation is evident. This would avoid the enormous heterogeneity in the way of assessing research in the country and the way in which RECs are set up and function. This field continues to show double standards regarding the protection of participants' rights in the various locations and among the different social classes in the country. Something similar occurs with regard to Sexual and Reproductive Rights. There is a wide gap with regard to a full enforcement of these rights, primarily regarding the disparity between the text of the legislation and what is set out in international treaties. Secondly, there is a need to have public policies that will enforce the text of the law through concrete actions, for example, by allocating funds and resources for its implementation. Finally, the population's and particularly women's and teenagers' full access to these programs needs to be ensured. In this area, there is no doubt that a deep cultural change must take place, in which social practices can be modified without any type of interference or censorship by power or by religious groups. The ethical issues concerning the end of life are in a similar situation, like other related issues. Finally, bioethics education in the country is growing, but the great heterogeneity of programs regarding objectives, content, methods, and results shows the need to establish some minimum areas of consensus on what can be expected from each level of teaching.

Over the past few years, Argentina has been going through a time of true transformation in an attempt to lessen the gaps of inequity, double standards and particularly the gap existing between regulations and social practices, as the best reflection of a public moral and where peoples' convictions, ideals, and expectations are brought into being. Perhaps it is time for a deep sincerity and acknowledgement in this respect and for the application of public policies aimed at strengthening the protection of the rights of vulnerable people and groups such as research subjects, women, people who are dying, old people, and many other social groups who are in need not only of protection but of being respected for their decisions in the framework of pluralism and freedom that democracy offers.

Don Chalmers

Donald Chalmers is a distinguished professor of law and director of the Centre for Law and Genetics, University of Tasmania.

Foundation fellow of the Australian Academy of Law, chair of the Gene Technology Ethics and Community Consultative Committee, and chair of the Data Access Committee of the International Cancer Genome Consortium. Chair of the National Health and Medical Research Council (NHMRC) Australian Health Ethics Committee, 1994–2000, and deputy chair of the Embryo Research Licensing Committee, 2002–2012.

Introduction

Australia has an established record and tradition in bioethical debates, particularly focused on in vitro fertilization (IVF), healthcare, and human research ethics issues (Singer & Kuhse, 2006). Some of Australia's leading bioethicists have argued that the growth of bioethics in Australia may have an "ambivalent genealogy" but was stimulated by changes in technology, particularly IVF techniques and the need to develop new frameworks beyond traditional medical ethics (Irvine, Kerridge, & Komesaroff, 2011). Bioethics has been central to debates on human research ethics. Australia was one of the first signatories of the *Declaration of Helsinki*. The National Health and Medical Research Council (NHMRC) followed this up with human research ethics guidelines in the early 1980s (*Statement on Human Experimentation*) and requirements for all publicly funded research organizations to observe these guidelines. Australia has not experienced any medical research crisis incidents, like the United States Tuskegee revelations (Jonsen, 1998). Australia has had major ethical debates about research ethics as well as termination of pregnancy, IVF (now more commonly referred to as assisted reproductive technology, ART) and surrogacy (Freckelton & Petersen, 2006), Aboriginal and Torres Strait Islander health, medical indemnity, human embryo research, and genetic privacy. Australia has also debated the development of animal welfare and research ethics, building on the seminal and groundbreaking work on animal ethics and protection by Peter Singer (Singer, 1975). In addition, genetic modification of plants and animals (Sylvan & Bennett, 1994) was a major public debate during the 1990s and early 2000s with the introduction of a GMO regulatory framework for the development of biotechnology in Australia. The *Australian Biotechnology: A National Strategy* published in 2000 expressed a national commitment to safeguarding human health and environment protection, in developing the benefits of biotechnology for the community.

Bioethics Development

Modern bioethical development in Australia can be marked by "two epistemological breaks away from well-established biomedical technologies and traditional approaches to ethics" (Irvine et al., 2011, at 245). With respect to biomedical technologies, debates on IVF were prominent in Australia (Singer & Wells, 1984). The IVF debates in the state of Victoria in the early 1980s, which preceded Professor Waller's influential and pioneering reports on IVF, donor gametes, and surrogacy, shaped the national bioethical IVF debates that continue through the decade. These debates involved the churches, feminist scholars, and the community in public opportunities to express opinions on IVF to official government enquiries (Freckelton & Petersen, 2006, Chapter 10). These debates have been generally spirited but respectful of opposing views. The IVF debates extended into embryonic stem cell debates in later decades (Dodds & Ankeny, 2006; Oakley, 2002).

While principles of medical ethics were, and remain, significant starting points in bioethical debates, it has been argued that "...ordinary ethical and social and principles and categories simply [could not] cope with the novel issues raised by the manufacture of totally new living organisms by genetic engineering, the creation of live human embryos outside their mothers' bodies..." (Charlesworth, 1989, at 15). Nevertheless, Australian bioethics have been significantly influenced and shaped by the principles of medical ethics. The World Medical Association drafted and published the influential *Declaration of Helsinki* on ethical standards in medical research. Members of the Australian medical profession promoted its signature and implementation in the NHMRC's first *Statement on Human Experimentation*, in 1976. The ethical principles of patient consent and autonomy, medical beneficence, duty of confidentiality, best interest of the patient, and standard of care are recognized and expressed in the Australian Medical Association *Code of Ethics*. In addition, specialist colleges also have supplementary codes, for example, the Royal Australian and New Zealand College of Psychiatrists Code of Ethics in Principle 1 states that the practitioner should have "respect for the essential humanity and dignity of each of their patients." Standards of medical care and ethics were principally matters for the profession before bioethics "border crossings" (Annas, 2004) by others, including the legal profession, bioethics scholars and the range of administrators, health economists and healthcare advocacy, and consumer groups.

The term "bioethics" was coined in the United States (Reich, 1982; Jonsen, 1998; Tristram, 1995) and American scholars have been influential in the development of bioethics in Australia, but the emphases of many of the big-issue debates on IVF and embryonic stem cells have included uniquely national concerns about funding and regulation (Ankeny, 2003; Chalmers and Nicol, 2003). The neologism "bioethics" is an exegesis of philosophical and, more particularly, medical ethics. The Belmont Report (National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research and *Report Ethical Principles and Guidelines for the Protection of Human Subjects of Research*, 1978) established three basic principles (respect for persons, beneficence, and justice) as the cornerstones for the regulation of research on humans. These principles have been influential and extended not only to researchers but into the clinical research setting (Beauchamp & Childress, 1973, who propose four principles: autonomy, beneficence, non-malfeasance, and justice). These principles were quoted in the NHMRC *National Statement on Ethical Conduct in Research Involving Humans*, 1999, and the current *National Statement on Ethical Conduct in Human Research* 2007 in references to researcher integrity, respect for persons, beneficence, and justice. However, some Australian hospitals had ethics-type committees discussing end-of-life treatments and other ethical dilemmas before the Belmont Report.

Another influential source of Australian bioethics can be traced to the principles embedded in the span of international human rights conventions and declarations. Both the *National Statement on Ethical Conduct in Human Research*, 2007, and the *National Framework of Ethical Principles in Gene Technology* make reference to

relevant international conventions and declarations. In fact, the UNESCO declared in 2003 "modern bioethics is indisputably founded on the pedestal of the values enshrined in the Universal Declaration of Human Rights" (UNESCO IBC, 2003). There are a many significant international instruments that position human rights within healthcare (e.g., World Medical Association *Declaration of Helsinki*; Council of Europe *Convention for the Protection of Human Rights and Dignity of the Human Being with regard to the application of Biology and Medicine*, 1996 (the *Bioethics Convention*); UNESCO *Universal Declaration of the Human Genome and Human Rights*, 1997). The UNESCO view is consistent with the view that modern bioethics can be traced historically to the horrors of the Holocaust, the Nuremberg trials, and the formulation of the Universal Declaration of Human Rights after the Second World War. The ten principles in the *Nuremberg Code* were the emphatic response to the inhumane experimentation conducted in Nazi concentration camps (Annas & Grodin, 1992). Of the ten principles of the *Nuremberg Code*, the most important provided that the "voluntary consent of the human subject is absolutely essential" and these principles were republished in the regularly revised World Medical Association *Declaration of Helsinki* on ethical requirements in medical research. There has been a proliferation of international instruments of *direct* application to bioethics. For example, the UNESCO *Universal Declaration on the Human Genome and Human Rights* 1997 deals with standards in genetic research and nondiscrimination based on genetic characteristics as well as the requirement of genetic privacy. The UNESCO *Universal Declaration on Bioethics and Human Rights* 2005 declares that its scope is "ethical issues related to medicine, life sciences and associated technologies as applied to human beings" and makes an explicit connection between human rights and modern bioethical approaches to not only healthcare but also the environment. The key underlying principles, in the provisions of these international conventions, are autonomy, beneficence and justice, but also human rights (Beyleveld & Brownsword, 2001). The *Universal Declaration of Bioethics and Human Rights*, however, is a non-binding instrument that aims to provide principles to guide signatory states in the formulation of bioethics legislation policies, as well as to promote respect for human dignity and to protect human rights; foster dialogue about bioethics issues; to promote equitable access to medical scientific and technological developments; and, finally, to stress the importance of biodiversity (Article 2). Notably, the declaration continues this wider view of bioethics in requiring respect for human dignity and human rights; the minimization of harm to patients and research participants; autonomy individual responsibility, inform consent to medical treatment and research; special protections for the incapacitated; privacy and confidentiality; equality, justice, and equity; nondiscrimination; cultural diversity; solidarity and cooperation; social responsibility in health; benefit sharing from scientific research; protection of future generations; and protection of the environment, biosphere, and biodiversity (Articles 3–17). In addition to the formal conventions, declarations, and treaties, there has been increasing internationalization of research, which has led a number of official agencies to develop harmonized standards. For example, in the area of clinical trials, the International

Conference of Harmonisation has produced standard *Guidelines for Good Clinical Practice* (CPMP/ICH: 1995). Similarly, the WHO and the Council for International Organizations of Medical Sciences (CIOMS) published ethical guidelines on human research, which also deal with the conduct of researchers in developing countries.

There is obviously considerable overlap between these "epistemological" approaches, which means that the boundaries between Australian bioethics, health law, and human rights are permeable, and "border crossings are common" (Annas, 2004). The utilitarian analysis of assessing the benefits promised by a proposed practice is outweighed by its possible harms is commonly invoked in Australian bioethical debates. Arguably, the UNESCO *Universal Declaration on Bioethics and Human Rights* has encouraged wider scholarly bioethical debates beyond individual autonomy and beneficence to more communitarian values encapsulated in "benefit sharing, solidarity and human dignity."

Governmental Institutional Development

Australia has considered many key bioethical issues, which have been debated in parliaments and parliamentary enquiries, by formal agencies, and among a broad range of bioethics centers and scholars (Charlesworth, 1993; Kasimba & Singer, 1989). These debates have involved the community, churches (Oakley, 2002), as well as the legal profession, administrators, health economists and healthcare advocacy, and consumer groups (Singer & Kuhse, 2006). Bioethical debate in parliaments and formal agencies is a significant characteristic of Australian bioethics. The NHMRC has played such a significant role in bioethical discussion in Australia and in the preparation of key guidelines in health research, particularly the *National Statement on Ethical Conduct in Human Research*. The NHMRC has a legal requirement to present guidelines for health research for formal public consultation and comment before publication. A unique two-stage public consultation process was set up, during the Commonwealth Parliament Senate Debates on the NHMRC legislation in 1992. This two-stage public consultation (stage one – comments on the proposed topic and stage two – comments on the actual draft guidelines themselves) was originally inserted to avoid perceived concerns that NHMRC guidelines were too "in-house" and medically biased. This public consultation is mandatory and requires any NHMRC committee to have, according to the legislation, "due regard" to all the submissions received. The NHMRC is required to give "genuine consideration to the material" according to the decision *Tobacco Institute of Australia Ltd v NHMRC* (1996 142 ALR 1). In this case, the TIA sued the NHMRC for failure to consider its copious submission. The TIA prevented the NHMRC from publishing its report on the effects of passive smoking on health, which was later issued as an information paper. Public consultation is an established process for the NHMRC. Apart from the NHMRC, the Australian Law Reform Commission (ALRC, Kirby, 1983) has conducted some important bioethical debates in relation to human tissue and genetic privacy.

Current Bioethics Infrastructure

The bioethical debates in Australia were stimulated by the creation of new centers particularly the first, the Monash Centre for Human Bioethics (Singer & Kuhse, 2006). Other centers have been established within universities, hospitals, and specialist bioethics centers. However, Australian bioethics is marked by significant government involvement through formal parliamentary public consultations, within official government bodies, particularly the NHMRC and its Australian Health Ethics Committee (AHEC) (Kasimba & Singer, 1989). Other bodies have made contributions to Australian bioethics, such as the NHMRC Animal Welfare Committee (AWC), Australian Law Reform Commission (ALRC), and Gene Technology Ethics and Community Consultative Committee (GTECCC). These bioethical debates are not confined to academia but have influenced public debate, government policy development, and, not infrequently, legal regulation (Freckelton & Petersen, 2006).

The National Health and Medical Research Council (NHMRC)

The NHMRC has been the peak Australian funding body for health and medical research (at http://www.nhmrc.gov.au/) since its establishment in 1937. The NHMRC is also responsible for medical research ethics and animal ethics. The NHMRC is an independent advisory body, which has a number of functions including inquiring and issuing guidelines on the improvement of health; the prevention, diagnosis, and treatment of disease; the provision of healthcare; and public health research and medical research. The NHMRC was established under the federal National Health and Medical Research Council Act 1992 with a principal committee, the AHEC, which is a multidisciplinary committee and develops and issues guidelines on health and medical research as well as promotes community debate on ethical issues. The AHEC's most important guidelines are the *National Statement on Ethical Conduct in Human Research*, 2007 (the *National Statement*), which is approved by Universities Australia and other research funding organizations, and represent a comprehensive national framework for ethics in human research. The AHEC reported on human cloning to the Federal Government in the 1990s. Following the joint ALRC and AHEC Report No. 96, *Essentially Yours*, a new specialist *Human Genetics Advisory Committee* (HGAC) was established within the NHMRC to advise on the developments in genetics in relation to human health including genetic privacy. The HGAC was also tasked with overseeing the developments in personalized medicine and biobanks. The NHMRC *Animal Welfare Committee* (AWC) advises on issues relating to the conduct and ethics on the use of animals for scientific purposes. The Australian *Code of Practice for the Care and Use of Animals for Scientific Purposes* requires Animal Ethics Committees (AEC) to ensure animal care and welfare in research. This Code of Practice sets out the general principles for the care and use of animals for scientific purposes, including the responsibilities of investigators and

institutions, and the use of replacement, reduction, and refinement techniques wherever possible. Where genetic modification involves animals, the Code of Practice specifies principles of conduct relating to the welfare of laboratory animals used to develop genetically modified animals and the genetic modification of production animals. Animal ethics has not received the same attention in bioethical debate in comparison with human research (Singer, 1975).

Bioethics Centers

Apart from the NHMRC, a number of established university-, hospital-, and church-based bioethics centers operate in Australia, which not only promote bioethical debate but often involved in presenting submissions to official enquiries and government bodies. The following is an illustrative and not comprehensive list of these centers. The Monash Centre for Human Bioethics, established by Peter Singer in 1980, is Australia's first established bioethics center. The Centre conducts seminars and education graduate programs and a range of specialized health programs. The state of Victoria had many leading IVF scientists, and the Centre produced work in ethical theory, reproductive ethics, end-of-life decision-making, and the development of utilitarian and virtue-based approaches to ethics. The Monash Centre for Ethics in Medicine and Society was established in 2001 in the Monash University Faculty of Medicine, Nursing and Health Sciences. The Centre is responsible for the development and conducts of teaching at undergraduate and postgraduate levels, fosters research in ethics and values in relation to medicine and society, and maintains a clinical ethics service at the Alfred Hospital.

The Southern Cross Bioethics Institute was established in 1987, in Adelaide by an independent provider of care and accommodation for Australia's older people. The Southern Cross Bioethics Institute adheres to universal human values, human rights, and the laws of humanity, including the inviolable and inalienable right to life of every member of the human family, whatever the age, status, or ability of that member, from conception to natural death.

There are some leading Catholic centers in Australia. The Plunkett Centre for Ethics is a center within the Australian Catholic University (ACU) and St. Vincent's & Mater Health, Sydney. The Centre was established in 1992 to promote the values of compassion and fellowship, intellectual and professional excellence, and fairness and justice. Its primary focus is on the realization of these values in the provision and the allocation of healthcare, from a Catholic perspective. The Caroline Chisholm Centre for Health Ethics also has a Catholic perspective and was established in 1995 with the aim of responding to the demand from Catholic hospitals' "for greater understanding and advice on ethical issues in healthcare."

The Centre for Applied Philosophy and Public Ethics (CAPPE) is a Special Research Centre, spanning a number of universities, and established in 2000. CAPPE has received competitive grant funding and claims to be the world's largest concentration of applied philosophers. CAPPE aims to assist members of the

community to make more ethically informed choices by making available resources in philosophical theory as well as other relevant information about empirical research and statements of fundamental human rights in international instruments on human rights. The Centre for Values, Ethics and the Law in Medicine (VELiM) is a bioethics center in the University of Sydney, established in 1995 to stimulate interaction and dialogue between the disciplines of medicine and science, public health, philosophy, ethics and bioethics, sociology, social linguistics, psychology, history, and law. The Centre for Law and Genetics based at the University of Tasmania was established in 1995 and specializes in research on the legal, ethical, and social issues arising from developments in genetic technology. The Centre has made regular submissions to ALRC and parliamentary enquiries and collaborates with related international centers. The St James Ethics Centre is independent and was established in 1989 and operates nationally and abroad. The Centre is unique and offers ethics assistance and advice to the community, public institutions, and not-for-profit companies. The Centre offers ethics education and training services and also consulting services.

The Australasian Association of Bioethics and Health Law (AABHL) is Australia and New Zealand's leading organization and aims to advance the study of bioethics and health law in Australasia by increasing public awareness, promoting public debate, and supporting scholarship (at http://aabhl.org/). Members come from many disciplines including medicine, nursing, law, ethics, philosophy, healthcare administration, allied health, and complementary healthcare. AABHL encourages discussion on bioethical issues and holds annual conferences and state-based activities. The AABHL is recognized uniquely in legislation as one of the bodies to be consulted when new appointments are made to the NHMRC Embryo Research Licensing Committee. The AABHL was formed in 2009 by a merger of the Australasian Bioethics Association and the Australian and New Zealand Institute of Health Law and Ethics, both established in the early 1990s. The AABHL, this body publishes an official, well-established and refereed international journal (*Journal of Bioethical Enquiry*).

Formal bioethics training, particularly at the graduate level, is offered through some of the centers mentioned above. As examples, at both Sydney University and Monash, full bioethics programs from the graduate certificate level to masters and to doctoral levels are offered. Sydney University offers these programs through its Centre for Values, Ethics and the Law in Medicine and at Monash University at its Centre for Human Bioethics. A number of other short courses are offered by many universities not only these mentioned.

Australian Law Reform Commission (ALRC)

The ALRC is the national law reform body. The ALRC undertakes public consultation on all its references. The joint ALRC and AHEC inquiry on genetic privacy that led to the report *Essentially Yours* (Report 96, 2003) was widely acknowledged, and Francis Collins, current head of the US National Institutes of Health,

described it as "a truly phenomenal job, placing Australia ahead of what the rest of the world is doing." The report made recommendations across the spectrum of activities in human genetics from healthcare, genetic testing, discrimination in employment and insurance, DNA fingerprinting, and parentage testing to human genetic databases and tissue collections. This body received over 300 formal submissions and held public consultation meetings throughout the country. This wide public consultation and the resulting public engagement of the various stakeholders in genetic research practice, development, commercialization, and government was a classic example of Justice Kirby's "Australian style" of law reform engagement (Kirby, 1983). The ALRC also produced one of the world's first reports on the complex ethical issues involved in human tissue in its report, *Human Tissue Transplants* (Report No. 7 ALRC 1977), which made recommendations about the collection and use of cadaveric and living donors.

Gene Technology Ethics and Community Consultative Committee (GTECCC)

Under the Gene Technology Regulatory Scheme (the *Gene Technology Act*), 2000, a regulatory framework for the licensing of dealings with genetically modified organisms (GMOs) was established in Australia. The regulatory scheme includes a comprehensive consultation process for any dealing with a GMO. GTECCC advises on the ethical issues in relation to GMOs and gene technology and has drawn up a *National Framework of Ethical Principles in Gene Technology*. This framework was developed after public consultation.

Major Bioethics Issues and Discussions

Assisted Reproductive Technology (ART) Australia was an early pioneer in in vitro fertilization (IVF), more commonly referred to now as assisted reproductive technology (ART). The first birth from a frozen embryo occurred in Australia. Australia was also very active in discussing the ethical legal and social impact of ART. The debates on ART and surrogacy involved churches and feminist groups and arguments about inter alia reproductive choice, autonomy, beneficence, exploitation, and commercialization (Charlesworth, 1993). ART created a major nationwide public debate in the 1980s (Singer & Wells, 1984) and was followed by debates on embryo experimentation and surrogacy. The Australian state of Victoria produced the first ART legislation in the world (*Infertility (Medical Procedures) Act* 1984), based on Professor Waller's reports on IVF, in the same year as the UK *Report of the Committee of Enquiry into Human Fertilisation and Embryology*, 1984 (Cmnd 9314, the Warnock Report). The pioneering Waller reports were the first in Australia and were followed by some 17 other Australian reports on ART. This near avalanche of Australian reports on ART included a Commonwealth Senate Select Committee report on Human Embryo Experimentation in Australia

and a report by the Family Law Council, *Creating Children: A uniform approach to the law and practice of reproductive technology in Australia*, both in the same year, 1985. These reports led to the establishment the first Australian bioethics body, the *National Bioethics Consultative Committee* (NBCC), to develop "a more coordinated national approach" towards ART in Australia. The NBCC was limited to issues of artificial conception and was requested to consider and made recommendations in the area of human embryo experimentation. The NBCC was multidisciplinary and for 4 years produced a number of reports (on donor gametes, access to information, surrogacy, counseling, and human embryo experimentation) before its amalgamation into the new AHEC, within the NHMRC. All the Australian states and territories introduced legislation recognizing the status of ART children as the child of the gamete recipient and not the gamete donor. This in turn raised legal and ethical questions about the right to access donor information. There was much debate about donor anonymity and whether a child reaching his/her majority was entitled to *identifying* or *non-identifying* information on any gamete donor. These issues were widely discussed and the Victorian Act also established the principle of access to *identifying* information, subject to the consent of the donor and the child's parents. Other states and territories took less prescriptive approaches. Access to ART programs was also a major aspect of the ART debates. Initially, ART was generally restricted to married heterosexual couples, but following challenges in the courts, on the basis of discrimination against single-sex couples (*JM v QFG, GK and State of Queensland* [1997] QSC 206) or single parents (*Pearce v SA Health Commission* (1996) 66 SASR), access was extended. There was also considerable debate about regulatory frameworks in Australia. Three states (Victoria, Western Australia, and South Australia) introduced specific ART legislation dealing with the broad range of issues, but the other states and territories relied on guidelines, developed by the Fertility Society of Australia and the AHEC (Freckelton & Petersen, 2006).

Surrogacy Surrogacy generated considerable debate in Australia. The NBCC, in the late 1980s, conducted public hearings on surrogacy and published a report in 1990. The churches and feminist groups were united in vehement opposition to any step towards recognition of surrogacy arrangements. Professor Waller in Victoria, while publishing recommendations against surrogacy, recognized that "altruistic" surrogacy, for example, between sisters could be envisaged. The early view was that surrogate motherhood was unacceptable. Gradually, the distinction between altruistic surrogacy and commercial-for-fee surrogacy was drawn. All states and territories in Australia prohibited commercial surrogacy in legislation but either recognized or did not prohibit altruistic surrogacy (Freckelton & Petersen, 2006). More recently, some jurisdictions in Australia permit noncommercial surrogacy, under restricted circumstances. The Australian Capital Territory introduced their *Parentage Act 2004*, which supports altruistic surrogacy by allowing parenting orders that transfer parental rights to the "commissioning" parents. A gradual acceptance of noncommercial surrogacy led to the Australian Attorneys-General proposing a national model to harmonize the various state and territory rules on surrogacy in 2009.

Prenatal and Preimplantation Genetic Diagnosis Both prenatal and preimplantation procedures have been controversial, with bioethical debate including considerations of abortion and embryo destruction. Prenatal procedures of amniocentesis and chorionic villus sampling test the developing fetus and may lead to a parental decision to abort the developing fetus, if a serious genetic condition is identified. More recently, preimplantation genetic diagnosis (PGD) of an embryo has been debated. Arguably, PGD offers an earlier opportunity for clinicians to identify embryos considered unsuitable for transfer and implantations, rather than the prenatal tests of amniocentesis or chorionic villus sampling. Australian guidelines (*NHMRC Ethical Guidelines on the Use of Assisted Reproductive Technology in Clinical Practice and Research*, 2007) accept PGD for medical reasons to identify embryos affected by an inheritable genetic condition. PGD for nonmedical reasons is generally considered ethically unacceptable, but the current NHMRC guidelines are expressed with ambivalence and state that it is generally to be disapproved, but "pending further community discussion." PGD is also possible in Australia for the so-called savior-sibling circumstance. PGD has been widely debated in Australia and raises serious ethical issues where it is for the purposes of sex selection, but this is not acceptable under the NHMRC guidelines. However, a leading Australian ART clinic advertises the availability of this procedure overseas in an associate overseas clinic in Thailand. The potential for PGD to become more widely used as genetic testing improves likely (Freckelton & Petersen, 2006, Chapter 11).

Research on Human Embryos Research on embryos remains a controversial bioethical issue in Australia (Dodds & Ankeny, 2006). The AHEC report, *Scientific, Ethical and Regulatory Considerations Relevant to Cloning Human Beings*, 1998, endorsed the Article 11 prohibition on human cloning in the *Declaration on the Human Genome and Human Rights*, which declared the procedure against human dignity. This AHEC report was referred to the Commonwealth of Australia, House of Representatives Select Committee, which undertook extensive public consultation before parliamentary debates on the *Human Embryo Research Act*, which were some of the longest in Australian history and focused on the dignity of the human embryo, the use of surplus human embryos in ART, and the scientific and therapeutic opportunities of embryo research, but only under strictly controlled licensing arrangements (Chalmers and Nicol, 2003). Human dignity was a common theme in these national and parliamentary debates on human cloning (and more recent debates about patenting of human DNA). In contradistinction to rights to individual autonomy to research or procreate, references to human dignity were expressed in terms of a *constraint* on pursuing research inquiry and setting ethical limits in biotechnology, beyond arguments about scientific safety of the procedures (Singer, Kuhse, Buckle, Dawson, & Kasimba, 1992). The *Prohibition of Human Cloning Act* 2002 prohibited cloning for reproductive purposes. The *Human Embryo Research Act* 2002 permitted limited research on surplus ART embryos, provided a license was issued by a special NHMRC Embryo Research Licensing Committee, established by the Act. The AHEC report, like its counterpart, the National Bioethics Advisory Council in the United States and the eventual United

Nations resolution against human cloning in 2005, was careful to distinguish between the use of cloning for human reproductive purposes and the use of embryos for a source for stem cells for therapeutic purposes (although terms "reproductive" and "therapeutic" cloning should probably never have entered the bioethics lexicon). The AHEC report cautioned that any regulatory action undertaken to prohibit creating a child by SCNT should be careful not to interfere with important areas of stem cell scientific research (Capps & Campbell, 2010).

Research Governance There has been much Australian bioethical scholarship on human research governance and the protection of participants in health research. Australia ratified the Declaration of Helsinki in 1965. This was an important symbolic act that was later realized by the introduction of research ethics committees to review the ethical aspects of experiments on humans. Some ethics committees operated in Australia in the 1960s and these influenced the development of the national ethics review system. A major response to the *Declaration of Helsinki* was the drafting of Australia's first guidelines on human experimentation, *Statement on Human Experimentation*, 1976, prepared by the Medical Research Advisory Committee of the NHMRC. Australia has had a comparatively creditable record of ethical research involving humans and has not experienced any medical research crisis incidents, like the United States Tuskegee revelations documented in Professor Beecher's New England Journal of Medicine article (Vol 274: 1354–60). However, Australia's record is not unblemished, and an Australian Government report into unsatisfactory aspects of the collection, manufacture, and injection of human growth hormone (Report of *Inquiry into the Use of Pituitary Derived Hormones in Australia and Creutzfeldt-Jakob Disease* AGPS, Canberra, 1994) recommended that aspects of the research structure be reassessed. Two other incidents in the 1950s, concerning the inclusion of orphans and State wards in vaccine trials conducted and, secondly, the experimental use of estrogens to reduce the height of "tall girls" were considered in the revision of research ethics in the 1990s that led to the introduction of the *National Statement on Ethical Conduct in Research Involving Humans* in 1999. This National Statement was drafted with careful consideration of the codes of ethical research practice developed in other countries, particularly the influential United States Federal Code of Research Practice, the Canadian Tri-Council Code, and the ethical guidelines of the United Kingdom and New Zealand. In addition, a number of international guidelines were examined, particularly the *International Ethical Guidelines for Bioethical Research involving Human Subjects*, published in 1993 by the WHO and Council of International Organizations of Medical Research (CIOMS) and the International Conference of Harmonisations (Guidelines for Good Clinical Practice (CPMP/ICH: 1995)).

The *National Statement on Ethical Conduct in Human Research* 2007 focused on "governance" arrangements for Human Research Ethics Committees (HREC), particularly with respect to institutional legal responsibilities, resourcing, monitoring of research, complaints handling, and accountability. As in other countries, Australia has shifted the focus from the HREC to the responsibilities of research institutions to ensure the integrity, safety, and ethical standards of research

under their control. Key governance issues include the proper functional roles of the HREC and the institution, the expedited review of "low risk" type research, the facilitation of single ethics review for multicenter research, ongoing training for REC members, and independent complaints mechanism to receive and handle complaints from research participants. Formal accreditation has not been introduced for HRECs in Australia but they are required to complete formal compliance reports annually, which are sent to the AHEC. A national system for accrediting HRECs involved in multicenter research (HoMER, Harmonisation Multi-Centre Ethical Review) has been set up. Within research governance, the accountability of researchers has been strengthened in the *Australian Code for the Responsible Conduct of Research*, 2007, which, like the *National Statement*, has been endorsed by all the leading research funders and research institutions in Australia. This Code deals with conflicts of interest in research, which, like elsewhere in the world, has been seriously discussed in Australia. In view of increasing commercialization and private funding of research, there are challenges to traditional ideas of impartiality and independence in research. Detecting and avoiding conflicts of interest are critical to public trust. This Code and the *National Statement* 2007 require researchers to disclose conflicting or competing interests and all sponsorships to be openly declared. A conflict generally excludes the conflicted researcher but an ethics committee may advice on how to "manage" a competing interests. Generally, competing interests are not disclosed to research participants.

Clinical trials are a critical aspect of medical research to assess the safety and efficacy of drugs and devices. The major debates in Australia about clinical trials have focused on the regulatory scheme for clinical trials. Until the 1990s, the national Therapeutic Goods Administration (TGA) administered the centralized system of drug and device assessment. This centralized system was replaced by a devolved Clinical Trials Notification scheme (CTN) under which trials could be conducted in large hospitals or research centers after notification and with the approval of the TGA. The CTN scheme proved very popular and almost all clinical trials are conducted under this scheme, which places additional responsibility on institutions and their RECs. Apart from the scientific design and results from clinical trials, the bioethical issues of recruitment, consent, monitoring, use of placebos, and competing commercial interests attract scholarly consideration.

Human Genetic Research In the 1990s, debates focussed especially on medical research and the emergence of the ethical, legal, and social issues (ELSI) around the Human Genome Project and human genetic research. The ethics of human genetic research was a major focus of the work of the AHEC during the 1990s. Consultation with the public and the Human Genetics Society of Australia (HGSA) led to the development of Guidelines *for Genetic Registers and Associated Genetic Materials* and *Guidelines for Ethical Review of Research Proposals for Human Somatic Cell Gene Therapy and Related Therapies*. The former provided guidance on the operation of genetic registers on the collection, use, and access to this material. The guidelines also deal with aspects of recruitment and storage of genetic material. The latter provided guidance to HRECs that dealt with gene therapy applications.

Australia became one of the first countries, the 1999 version of the *National Statement*, to include a specific set of ethical principles on human genetic research. Guidelines on somatic cell gene therapy (SCGT) provided higher-level advice by specialist committee wherever SCGT was considered. In Australia, as in many other countries, the genomics revolution raised the need for best practice ethical and legal regulation. The increasing volume of genetic research and the creation of specific genetic databases raise concerns about genetic privacy led to a reference by the Commonwealth Attorney-General to the AHEC and the ALRC jointly to consider the issue of genetic privacy, discussed below.

Research Involving Indigenous Communities Research on Aboriginal and Torres Islander peoples (ATSI) has at times been controversial with concerns that ATSI may not have been respected and protected and their genuine consent to research confirmed. ATSI peoples have some of the worst health statistics within the Australian population. Specific guidelines on ATSI research (*Guidelines on Ethical Matters in Aboriginal and Torres Straight Islander Health Research*) were debated and discussed and introduced as interim guidelines by the NHMRC in 1991. These guidelines stressed the need for respect for cultural differences and identity. These interim guidelines were replaced with the NHMRC *Values and Ethics: Guidelines on Ethical Matters in Aboriginal and Torres Straight Islander Health Research* in 2003. These guidelines emphasize the need for ethical conduct between researchers and the community to eliminate difference blindness to promote trust through six basic values of spirit and integrity: reciprocity, respect, equality, survival, protection, and responsibility. The concept of community consent as well as individual consent is recognized. The idea of justice in healthcare certainly extends beyond the individual. Justice has been a key principle in discussions not only about research but also about improving ATSI health and just access to equitable healthcare services.

Privacy has become a major bioethical issue with the expansion of electronic medical records and larger-scale epidemiological research. With the advent of genetic testing and research, privacy came to the forefront of public debate in Australia. Originally, concerns about privacy focused on credit ratings and government records. These were originally covered by Commonwealth legislation, which established Information Privacy Principles based on the original OECD standards in 1980. The ALRC and AHEC were asked to consider concerns about genetic privacy and the possible misuse of genetic information by insurance companies, employers, or immigration department. Over a nearly 3-year period, public consultation was conducted and a major report entitled *Essentially Yours* (Report 96, 2003) was published with recommendations on protecting genetic privacy and in the context of human research, specific recommendations on biobanks, and the conduct of human genetic research. A decade later, developments in personalized medicine in both the clinic and the laboratory necessitate continuing reevaluation of the reforms recommended in *Essentially Yours*, some of which have yet to be implemented. *Essentially Yours* recommended the harmonization of all federal and state health privacy legislation applying to genetics in Australia. Privacy remains an issue for bioethical debate as the national Health *Connect*

electronic health records initiative in unrolled, which will link all government, hospital, and doctor health records.

Medical Care and Informed Consent The standards of healthcare in diagnosis and treatments of patients by medical practitioners has been a major and continuing focus of the bioethical research agenda and frequently appear in articles in the leading *Journal of Law and Medicine*. There is established case law in relation to doctrines of informed consent and the duty to warn in the doctor/patient relationship. The High Court of Australia, in a leading decision of *Rogers v Whitaker* (1992) 175 CLR 479, decided that in cases of disclosure of information to patients, it was not for the doctor to decide what risks should be disclosed but what the reasonable patient was likely to attach significance if warned of the risk. This brought Australian law into line with the US and Canadian case law. Australia, like other countries, experienced a severe insurance crisis in the early 2000s. This general insurance problem extended to the collapse of a major private medical insurer and steeply rising medical insurance premiums. This so-called medical indemnity crisis prompted the Commonwealth Government to appoint a senior judge to review the position (the Ipp Review Committee). The Ipp Report recommended changes to standard of care required by law of medical practitioners. National legislation was introduced clarifying doctors' duties of care to patients in cases of medical negligence claims. Essentially, doctors are required to disclose risks that they know are relevant to their patients and to exercise the reasonable care expected of a medical practitioner of their standing. In Australia there has been considerable bioethical debate around the treatment of minors, the aged, the chronically ill, the mentally ill, and the mentally disabled. In all these cases, issues of competence, consent, duties of medical practitioners, and other medical carers arise. Where children, the aged, the disabled, or the mentally impaired are treated, the rules of consent are varied and surrogate consent may be valid for research. In addition, the courts have a protective jurisdiction and Australia also has specific guardianship legislation.

End-of-Life Decisions and Euthanasia Australia, like most western nations, has a rapidly aging population and there has been consistent debate about end-of-life medical care. In the *Human Tissue Acts* in all the states and territories, a revised legal definition of death was adopted, implementing the test of the irreversible cessation of all brain function (brain death). The introduction of this test and the issue of organ transplantation were widely discussed in ALRC report on *Human Tissue* in 1977. The validity of this test is generally accepted but still debated among some religious groups. This certification of death from a medical and legal standard enabled human organ transplantation to be facilitated has been accompanied by voluntary choice to end one's life. Human dignity has been invoked as one of the main arguments in end-of-life medical care and in the euthanasia debates. Dying with dignity has been widely discussed and was the topic of a parliament of Victoria inquiry into *Options for Dying with Dignity*, 1987. Later, South Australia introduced a *Natural Death Act* in 1993 as did the Northern Territory in 1998, which allowed a person of 18 years or older to sign a notice of direction preventing the administration of extraordinary medical measures to prolong life, in the case of

terminal illnesses. From time to time, other states have had vigorous debates about similar legislation. Some states have introduced medical treatment acts which allow refusals of treatment, except palliative care, and the making of enduring powers of attorney, allowing the attorney to make medical decisions on behalf of the incompetent patient. These advance directives (sometimes loosely called "living wills") are generally well accepted, provided that the advance directive or enduring power of attorney of statutory notice is properly understood, respected, and properly and independently witnessed (Otlowski, 1997). The expression "dying with dignity" encapsulates these discussions and has promoted wider public bioethical debate on dignified and humane palliative care at the end of life. The idea of dignity harm has been extended into discussions about a possible duty for medical practitioners to provide pain relief and palliative care to enable a person to have a dignified end of life.

Future Challenges

Healthcare Generally As a developed country with high-quality healthcare services, there are regular debates about the rising costs of healthcare, access to specific medicines, and the uniquely Australian arguments on the delivery of healthcare by the states and territories or the Federal Commonwealth Government. Two topics are often discussed with respect to the costs of healthcare and access by indigenous Australians. The Commonwealth Government, through its national Medicare scheme, pays 85% of scheduled fees, and this gap and the costs of private healthcare are regularly discussed. Secondly, the Commonwealth, through its pharmaceutical benefits scheme (PBS), pays subsidies for scheduled drugs, and the question of inclusion on this schedule is regularly debated. While most Australians enjoy access and the benefits of an excellent healthcare system, Aboriginal and Torres Islander peoples (ATSI) do not share the same access and benefits to equitable healthcare services. This is a continuing healthcare, equity, and bioethical challenge in Australia.

Human Tissue For the first time, the *National Statement* 1999 included principles for the use of human tissue in research. These guidelines were included as a response to public concerns and reactions to overseas reports about the possible misuse of human tissue samples in medical research. The research uses of human tissue raise legal as well as ethical compliance issues. Samples were defined to include diagnostic, statutory, (e.g., coroner's inquiry), and research samples but did not include fetal, reproductive, or autopsy tissue. Research institutions were requested to develop policies for research on tissues related to the source, nature, cultural sensitivity, and reason for collection in the purpose for the research. Generally, consent is required for the use of a person's tissue. Where there is follow-up research, the new research should be presented for new approval by an HREC. Bioethics has also embraced discussion on commercialization of human tissue. The legislation on organ transplants prohibits the sale of human organs, though there are unregulated markets in some countries in breach of the WHO resolution against this practice. There has also been discussion, including an ALRC report and parliamentary enquiry into the patenting of

human DNA (*Genes and Ingenuity* report 99, 2004). Similarly, the EC directive on the *Legal Protection of Biotechnological Inventions* (98/44) stated that "patent law must be applied so as to respect the fundamental principles safeguarding the dignity and integrity of the person (Recital 16)." The human dignity arguments are generally phrased in terms of a limit on the commodification of the human body. The argument runs that human DNA is unique and it is not legally possible to own body parts. The general position in law is that the human body cannot be owned. This has not prevented claims for the patenting of DNA sequences rather than entire genomes. Medical advances in organ transplantation have not been matched by an increase in the availability of organs for transplant in Australia. Recognizing this, the Federal Government promoted legislation to establish a new Organ Transplantation and Tissue Donation Authority in 2009, as part of the National Reform Agenda. The Authority's role is to establish, in partnership with the Australian states and territories as well as the clinicians, consumers, and the community, a nationally coordinated approach to organ and tissue donation for transplantation. The aim is to "deliver a highly effective national organ and tissue donation system" and there has been measurable progress towards achieving this aim, according to the annual donation statistics. Organ transplantation will remain a key medical and bioethical issue for the future.

Personalized Medicine The "genome era" and the increased knowledge base in genetic research aim to translate into improved drug development and healthcare applications. There is a growing understanding of individual variations in genetic profiles, and as a result, diagnosis and treatment are becoming more "personalized" and less generic. In 2008, the US President's Council of Advisors on Science and Technology ("PCAST") published a comprehensive report entitled *Priorities for Personalized Medicine*, which defined personalized medicine as the "tailoring of medical treatment to the specific characteristics of each patient" (http://www.whitehouse.gov/files/documents/ostp/. . ./pcast_report_v2.pdf). However this report was also careful to point out that personalized medicine does not actually mean the development and creation of drugs that are entirely unique to an individual patient. Personalized medicine does not differ greatly from the current strategies of drug companies that stratify populations into categories that respond or do not respond to treatment, and in this sense, personalized medicine is not new. Nevertheless, the systematic use of molecular and clinical information to optimize treatment of a particular patient is novel (Nuffield Council on Bioethics, *Medical Profiling and Online Medicine: The Ethics of 'Personalised Healthcare' in a Consumer Age*, 2010) (<http://www.nuffieldbioethics.org/personalised-healthcare-0>). There are high expectations for personalized medicine, particularly its capacity to match drugs more effectively to individual patients by using genetic tests that will indicate the best treatment for a patient with less guess work and trial and error; minimize adverse drug reactions; move generally towards preventative medicine through the use of genetic tests that indicate late-onset conditions; improve clinical trials, especially at phases II and III, the most expensive phases, by enrolling fewer participants in order to reliably measure safety and efficacy; and reduce

the overall costs of medicines. These aims raise bioethical issues for debate. In addition, biobanks are recognized as essential tools for genetic research and the development of personalized medicine. Large-scale collections offer opportunities to researchers to undertake genetics testing and soon whole genome sequencing (WGS) to advance identification of genetic causes of many diseases. Although these large biobanks are staggeringly expensive, they can be linked to more efficiently carry out focused and concentrated research, for example, the International Cancer Genome Consortium links biobanks in 14 countries, each specializing in allocated common cancers with a name of sharing all data to advance understanding of genetic aspects of these cancers. Biobanks are also recognized as essential tools for translating biomedical research into healthcare improvements. Australia has also participated in the international debates on biobanking and the need for fully informed participant recruitment, confidentiality and privacy of samples, public trust, public access to anonymized data, and the overall governance of biobanks (Dillner, 2011). Genetic research generally and the growing use of genetic biobanks are being accompanied by discussion on benefit sharing from these common community resources.

Summary Conclusions

Australia may have an "ambivalent genealogy" in bioethics but it has an established record and tradition in bioethical debates, particularly focused on in vitro fertilization, healthcare, human research ethics issues, human embryo research, and genetic privacy. Australia has also debated the development of animal welfare and research ethics, building on the seminal and groundbreaking work of Peter Singer. Bioethical debate in parliaments and formal agencies is a significant characteristic of Australian bioethics. In addition, Australian bioethical debate is conducted with reference to global bioethics, international conventions and declarations, and international literature. In an increasingly globalized research environment, where Australian research is influenced, and hopefully, influences overseas research, bioethical issues undergo "border crossings." Looking to the future, it is unlikely that bioethics debates can continue at the atomistic, individual level of right, and the UNESCO declarations, most recently in the *Universal Declaration on Bioethics and Human Rights*, may promote wider debates about communitarian values of "benefit sharing, solidarity and human dignity," which are within bioethical dialogue.

H.A.M.J. ten Have, B. Gordijn (eds.), *Handbook of Global Bioethics*,
DOI 10.1007/978-94-007-2512-6_6,

Introduction

At the end of March 1997, the then President of the International Association of Bioethics (IAB), Alastair Campbell, visited Brazil at the invitation of the Brazilian Society of Bioethics. Firstly, he attended the Second Brazilian Congress of Bioethics, which was held in Brasília, "an architecturally planned capital and representative piece of artistic design" (Campbell, 1998, p. 01). Following this, he got to know São Paulo, where he participated in an International Seminar on Clinical Bioethics, which took place at the public hospital of Heliópolis, the biggest "favela" or shantytown in the biggest industrial and population center of South America. On his return to Great Britain, he wrote an emotional editorial in the issue of IAB News of that European spring, recounting what he had seen and felt during his trip. One of the paragraphs went like this: "When I left Brazil after a short visit, I felt especially grateful to my hosts, not only for their friendly and insuperable hospitality, but also for bringing out how much I have now started to perceive the nature of bioethics. I was able to see for myself how difficult it is to maintain a public healthcare service with minimal resources and huge problems of poverty. I could also see the developmental challenge of massive urbanization without an adequate infrastructure to maintain it. In the midst of all of this, I got to know people who were determined to build bioethics with the capacity to make a special difference to healthcare in their country and for the quality of its development" (Campbell, 1998 p. 02). The trip to Brazil further strengthened Campbell's conviction that he should fight for bioethics to return to the course initially traced out by Van Rensselaer Potter in 1970–1971 (Potter, 1971) and reinforced by the same author in 1988 through an organic and continuing work (and not just an isolated and time-limited study); in other words, for the objectives that came to sustain the proposal that was specifically called Global Bioethics (Potter, 1988).

Like the contradictions cited in the preceding paragraph, the thematic bioethics agenda for the twenty-first century follows two historically equidistant reference points: those relating to biotechnoscientific advances – "emerging situations," and others, derived from repetitive situations and the acute social inequalities observed worldwide – "persistent situations." In this manner, like what happens on a worldwide scale, this paradoxical phenomenon is also reproduced in Brazil, in strong colors, even though the country has undergone a significant improvement over the last 10 years, with the elevation of no fewer than 36 million people into the so-called middle class (more than 20 % of Brazil's population). In the specific case of Potter's global bioethics, the topic of biodiversity is of singular importance for Brazil, since the country's interests in the fields of environmental equilibrium are enormous. No less than 22 % of the planet's plant species are found in Brazil, while 1 g of Amazon rainforest contains approximately 10,000 microorganisms, just to have an idea of the magnitude of the subject of biodiversity in this country.

For those who are unfamiliar with Brazil, it is not easy to understand it. It comprises around 8.5 million square kilometers of flat and fertile land; more than 190 million inhabitants born through an extraordinarily rich mixture; and the eighth

largest GDP (gross domestic product) in the world. Alongside this, despite the significant improvements over recent years, its social indicators are among the most critical in Latin America, and its wealth distribution is one of the most unequal on the planet. While 80–100 babies out of every 1,000 live births will die in some needy areas of the northern and northeastern regions, this rate comes very close to an exemplary number of ten in the southeastern and southern regions. Thus, despite the significant changes recorded over the last decade, Brazil in 2012 is a country living with one foot in the nineteenth century and the other in the twenty-first. In contrast with having a national company that is the world's biggest producer of latest-generation medium-sized commercial airplanes (of up to 110 seats) and being the country with the world's greatest mastery of the technology for oil extraction from deep sea locations, and furthermore having the capacity to perform multiple organ transplants and to be a pioneer in discovering the human genome sequencing relating to malignant tumors in different anatomical areas, more than 18 million people who are still completely excluded from this recent process of evolution and development coexist in the fields and, especially, on the periphery of Brazil's major cities (Garrafa, 2010).

Between achievements and problems, the profound contradictions cited and the consequences derived from them form an inseparable part of the work of Brazilian scholars and researchers who have chosen to follow the difficult paths of bioethics. Brazil's contradictory realities, thus, not only require very hard intellectual exercise from its bioethicists but also further sharpen the conflicts that are observed in relation to individual versus collective rights; personal autonomy versus public fairness; participation versus omission in relation to social problems; beneficence versus equity; what is known as charity versus the true meaning of critical solidarity; establishment of theoretical limits versus practical control for investigations; freedom versus responsibility in relation to what is produced; and so on.

Bioethics Development and Current Bioethics Infrastructure

Brazilian bioethics developed relatively late, only emerging organically in the 1990s. A few isolated initiatives took place prior to this but without significant impact. On the other hand, there is no starting point or specific historical reference point for its development. On the contrary, some separate events went on taking place and, at the same time, causing positive repercussions with regard to publicizing and spreading the discipline (Garrafa, 2000). At the start of 1993, for example, the journal *Bioética* was created (http://revistabioetica.cfm.org.br/index.php/revista_bioetica/index), with a regular editorial committee, sponsored by the Federal Medical Council. This journal is indexed internationally and has maintained rigorous periodicity until today, initially every 6 months and more recently every 4 months (three issues per year). There are now another two regular scientific journals on bioethics: the *Revista Brasileira de Bioética* (RBB) (http://www.rbbioetica.com.br/rbb/), sponsored by the Brazilian Society of Bioethics, which has been published since 2005 under the responsibility of the Postgraduate

Program (master's and doctoral degrees) of the UNESCO Chair of Bioethics of the University of Brasília (http://bioetica.catedraunesco.unb.br); and *Bioethikòs* (http://www.saocamilo-sp.br/novo/publicacoes/publicacaoRevista.php?rev=b), published since 2007 by the São Camilo University Center, in São Paulo. Many other Brazilian scientific journals also frequently publish bioethics papers, especially those within the field of public health, such as *Revista de Saúde Pública*, *Cadernos de Saúde Pública*, *Ciência & Saúde Coletiva*, and *Saúde em Debate*, as well as the *Revista da Associação Médica Brasileira*.

In 1995, at a meeting convened by a group of around 20 Brazilian bioethics specialists, which was held at the Oscar Freire Institute of the School of Medicine of the University of São Paulo, the Brazilian Society of Bioethics (BSB) was founded. Today, the BSB has more than 800 associates and it has already held nine national congresses: 1996 (São Paulo); 1998 (Brasília); 2000 (Porto Alegre); 2002 (Brasília, jointly with the Sixth World Congress of the IAB); 2004 (Recife); 2005 (Foz do Iguaçú); 2007 (São Paulo); 2009 (Búzios, Rio de Janeiro); and 2011 (Brasilia). At the most recent events, the number of congress participants has ranged from 500 to 900. The BSB now has regional sections in 11 of the 26 Brazilian states plus the Federal District. Its board is elected by a direct vote among all the associates, and the board's mandate is 2 years. The BSB has an Internet website through which the board communicates and sends out news periodically to the associates (http://www.sbbioetica.com.br), as well as including texts of scientific interest.

In 1996, the National Health Council, a body linked to the Brazilian Ministry of Health, created the National Research Ethics Committee (CONEP), which has the task of regulating and controlling research on human beings within Brazilian national territory. Prior to this, federal legislation relating on this topic already existed, although compliance with it was lax. Since the creation of CONEP, the subject of ethic control in the research with human beings has started to be approached with the required rigor and today, Brazil has more than 600 local research ethics committees that are functioning regularly in universities, hospitals, and other public and private institutions. With regard to formal public matters, it should also be noted that there is a National Technical Committee for Biosafety (CTNBio), which is linked to the Ministry of Science and Technology and which, through a bill of law approved by the National Congress, has the task of analyzing, mediating, and regulating issues relating to research on and use of genetically modified organisms, including patent topics, transgenic foods, animal and plant cloning, and other similar matters.

Differing from large numbers of other countries around the world, including in Latin America, Brazil still does not have a National Bioethics Council. Rather than create its Council by means of a fragile Presidential Decree or even a Ministerial Decree (since this would allow a successor government from the opposition to cancel it), the country decided to follow the slower but safer path of implementing its Council through the legislature. Bill of Law No. 6032 has been under discussion in the National Congress since October 2005, when it was submitted by the then President Luiz Inácio Lula da Silva following hard work to construct a democratic proposal that would include participation by bioethics

specialists, jurists, and scientific specialists, as well as from the organized public, which participated massively in the public consultative hearings that were held in six important cities in different geographical regions of the country (Porto Alegre, São Paulo, Rio de Janeiro, Recife, Manaus, and Brasília). Currently, the bill is under a "special regime of urgency" in the National Congress, waiting for all the political parties to nominate their representatives for renewing it (Garrafa & Tenhave, 2010).

In an isolated manner and unfortunately very slowly, Institutional Clinical Bioethics Committees have started to be created. Concerned about this, the BSB and the Federal Medical Council organized the First Brazilian Congress of Clinical Bioethics in conjunction with the Ninth Brazilian Congress of Bioethics in September 2011, with the specific objective of stimulating creation of bodies of this type in this country. Some pioneering examples of such bodies have existed since the 1980s and 1990s (such as the committees in the university hospitals – Hospital das Clínicas – of Porto Alegre and São Paulo and in the National Cancer Institute in Rio de Janeiro), but these are very little for a country of the dimensions and population of Brazil.

Finally, one final important historical date needs to be specially mentioned: the holding of the Sixth World Congress of Bioethics in Brasília in October 2002, which brought together more than 1,400 participants from 62 different countries. This was the biggest congress that has ever been organized so far, anywhere in the world, and its official theme was "Bioethics, Power, and Injustice." In other words, following the Fourth World Congress, which was held in Tokyo, Japan, in 1998, and dealt with Potter's "Global Bioethics" (and moved somewhat away from exclusively biomedical topics), the event in Brasília definitively expanded the international work field of the discipline from specific biomedical themes to social and sanitary themes, thereby politicizing the international bioethics agenda with topics that until then had only been dealt with tangentially and occasionally (Garrafa & Pessini, 2003).

It needs to be recorded that during the Congress in Brasília, a group of Latin American researchers held a meeting in parallel to this event, at which it was decided to create the Latin American and Caribbean Bioethics Network (Redbioética). This action was subsequently consolidated with support from UNESCO on May 2nd of the following year (2003), at another parallel seminar, this time at a Human Genome Project meeting in Cancún, Mexico. This network, under the initial presidency of a Brazilian researcher (2003–2010) and with active participation from key players, particularly from Argentina, Bolivia, Brazil again, Chile, Colombia, Cuba, Dominican Republic, and Mexico, has since then come to have a decisive role in new epistemological and practical proposals for bioethics in this region, and even within the wider international context. Furthermore, Redbioética has held four congresses, published six books, held many subregional meetings, and run distance-learning improvement courses for interested individuals from all Latin American countries and some in the Caribbean. It has shown decisive action in relation to how it has followed international struggles, in the sense of inclusion of health topics (access to healthcare and medications), social topics

(poverty, vulnerability, and discrimination), and environmental topics (the right to clean water and pure oxygen and respect for biodiversity and the terrestrial ecosystem), in the text of UNESCO's Universal Declaration on Bioethics and Human Rights (Garrafa, 2010). Since this chapter aims to explain the development of bioethics in Brazil, it is also essential to signal the leading role of the Brazilian delegation in the discussions held at UNESCO, in Paris, in 2005, directed toward constructing the abovementioned declaration. Through approval of this document, which was formally homologated at a meeting held at the Brazilian Ministry of Foreign Relations, this declaration from then on came to dictate the new conceptual course of Brazilian bioethics (Barbosa, 2006).

Major Bioethics Issues and Discussions

During its first years of life, Brazilian bioethics took the reference point of the so-called principlism of the United States, based on its four supposedly universal principles: autonomy, beneficence, non-maleficence, and justice (Garrafa, 2005a). For example, resolution No. 196 of 1996, issued by the Brazilian National Health Council, which regulates research on human beings in this country and is still in force today, at the beginning of 2012, is based on a structure that absolutely follows this reference point. Nonetheless, this panorama is starting to change, especially in academic circles, coming from research groups dedicated to public and collective health in the second half of the 1990s and more widely since the Sixth World Congress of 2002 and its influence on the scientific associates of the BSB. Although many peripheral groups of lesser scientific importance have continued to use principlism as the guiding doctrine for their actions, especially in isolated disciplines within the field of health sciences, research centers that are more significant in terms of academic production have started to seek their own paths toward facing the bioethics topics and conflicts that have been detected in this country.

Through this, new proposals have emerged as alternatives to principlism and other, more traditional theoretical currents within bioethics (casuistry, contractualism, and bioethics of virtues). Among them, intervention bioethics, protection bioethics, and liberation theology bioethics need to be particularly cited, because of their prominence and especially because of their continuing presence in studies and publications. There is, without doubt, a wide theoretical and practical path that has already started vigorously and is being constructed through the proposals mentioned here, but it is interesting to see that they all coincide with regard to respect for moral pluralism and defense of the interests of weaker and more vulnerable individuals. This observation seems to demonstrate that the basic sources of inspiration for the "new Brazilian bioethics" lie in contextualization of the country's realities and its social exclusion, and defense of active citizenship (Oliveira, Villapouca, & Barroso, 2005).

There are three ways to explain this "unusual" line followed by Brazilian bioethics toward constructing its own autonomous course within bioethics,

especially among its more representative academic research groups: (1) The advanced levels of politicization of the country since the military dictatorship (1964–1985), with development of a strong sense of public commitment toward healthcare, as made explicit in the 1988 constitution ("Healthcare is everyone's right and the state has a duty to provide/bestow it"), and as reflected in the construction of the national bioethics, given that many of its representatives have been involved in these movements (Porto & Garrafa, 2011). (2) The holding of the Sixth World Congress of Bioethics in Brasilia that, in addition to having a theme that was ahead of its time (Bioethics, Power, and Injustice), gave rise to the creation of UNESCO's Redbioética, which has had a strong influence on the context discussed here. (3) The particular content and sense of UNESCO's Universal Declaration on Bioethics and Human Rights, in which, as already stated, Brazil had an especially important role; the proposition and content of this Declaration had direct repercussions on Brazilian bioethics, as will be seen in the next section.

UNESCO's Universal Declaration on Bioethics and Human Rights (2005) and its Impact on Brazilian Bioethics

Immediately after the Sixth World Congress, which was held together with the Fourth Brazilian Congress, at the end of 2002, bioethics started to experience a new impulse in Brazil. While on the one hand its development since then has generally always followed the course of public health in the country, these paths expanded and broadened from this date onward. In addition to dedication within this discipline to the usual topics of biotechnoscientific fields, of which many have a quantitative methodological basis (in the research fields of genetics, assisted reproduction, organ and tissue transplantation, end of life, etc.), other projects and lines of research have also started to focus on some persistent topics within Brazilian realities and have begun to use qualitative methodological tools that until now have preferentially been directed toward the field of social sciences.

This academic movement has opened the doors to a growing number of published papers that have started to center their efforts on social topics, such as exclusion, different forms of discrimination, poverty, access to healthcare, environmental problems, and so on.

When UNESCO's Redbioética was preparing to participate in a meeting in Buenos Aires convened by the Argentine government, in November 2004, anticipating strongly critical discussion about the conservative biomedical content that was being constructed around UNESCO's Bioethics Declaration, the Brazilian Bioethics Society sent three representatives – F. R. Schramm, J. E. Siqueira, and V. Garrafa. Together with researchers from another 11 Latin American countries, plus the host country of the meeting, these representatives signed the "Charter of Buenos Aires," which demanded a Declaration that was more forceful and politicized, and which would explicitly include health, social, and environmental topics. This "Charter" was decisive in the discussions of UNESCO's IBC that took place at

the beginning of 2005, toward reaching the content that is now known and homologated by 191 countries, through a memorable Assembly that was held in Paris in October of the same year (Garrafa, 2010).

Less than 1 year after this homologation, the Brazilian government (with support and intensive participation from the BSB and UNESCO's regional office) organized a formal seminar with cabinet ministers and more than 400 participants. On this occasion, the country's commitment toward the content of the Declaration was explicitly reinforced (Barbosa, 2006). From that occasion until now, starting from these reference points and other of importance within the national context, bioethics has had an expansion of a more organic nature within Brazilian public institutions, in ministerial work, and in universities. The number of books published within the field of bioethics has increased, along with a growing proportion of specialization monographs and a proportionally smaller number of master's dissertations and doctoral theses, which have been recorded from among the several hundred postgraduate programs in the fields of biomedical and health sciences, juridical sciences, and social sciences that exist in Brazil.

Particular Lines of Research and Epistemological Proposals

A study conducted by Oliveira, Villapouca, and Barroso (2005) presents some epistemological considerations about Brazilian bioethics from the point of view of tendencies whose theories are mainly based on the social, economics, and cultural context of the country. They pointed specially three schools to show that the emergence of a scientific community of bioethics researches, in terms of Thomas Kuhn's scientific theory (Kuhn, 2003), might be a reality in Brazil. The study provided confirmation that particular epistemological trends existed in the bioethics developed in the country, with specially defined paradigms, that is, with theoretical construction that, through a capacity to resolve problems that the scientific community considered important – specially in the fields of public health and poverty-social exclusion (Garrafa, 2005a) – acquired specific status in relation to other theories within the same field. These have been worked on organically By their authors/research groups and have repeatedly been mentioned in the regional and international academic literature: intervention bioethics, protection bioethics, and liberation theology bioethics. The authors (Garrafa & Porto, 2003; Schramm, 2003; Fabri-Dos-Anjos, 1996) used the methodology of reference points from a model containing a "discipline matrix" (a set of consensual elements from a given group of scientists) and "examples" (the concrete solution to a problem that was adopted in a shared manner by the members of the scientific community, for example, to resolve a problem of priority in the share of insufficient resources in public health, and concluded from this that all the trends reported had a convergent foundation in the theories of Brazil's socioeconomic and cultural context). In the following, a brief summary of these three bioethical lines or schools is presented.

School of Intervention Bioethics (IB)

Taking the reference point of criticism of the theoretical and practical insufficiency of principlism for managing health and social macro-problems, IB advocates that only greater depth of analysis of these issues, with new epistemological constructions appropriate for these characteristics, would be able to contribute toward building bioethical thinking that identified with developing countries (Garrafa & Porto, 2003; Porto & Garrafa, 2005). IB rejects uncritical and context-free importation of ethical theories from outside and proposes theoretical formulations that are appropriate for the contingencies of the so-called peripheral countries with severe problems of social exclusion (Garrafa, 2005a). It divides the field into two large thematic groups, with a historical basis: (a) Emerging Situations, resulting from the scientific and technological development observed over recent decades (genome research, organ and tissue transplantations, cell therapy, reproductive technologies, etc.); (b) Persistent Situations, which have been repeatedly occurring from ancient times until today (social exclusion, hunger, discrimination and stigmatization, environmental pollution, access to quality healthcare services, abortion, euthanasia, etc.).

IB also advocates that the state should have a regulatory role in relation to defending the most vulnerable segments of the population. Taking the basis of a proposal for utilitarian and consequential action, which advocates that the most appropriate ethical decisions for resolving the problems are those that benefit the greatest number of individuals, for the longest time possible, and result in the best collective consequences, IB furthermore proposes mutual collective action in situations or cases in which the state does not have a material or practical capability to resolve such problems. Nevertheless, IB emphasizes that such mutual action cannot be a replacement for the public commitments inherent to the state (Nascimento & Garrafa, 2011). IB argues in favor of lay bioethics that respects the moral pluralism that exists in contemporary human societies, governed by the reference point of liberty, but still without moving away from certain basic characteristics, such as protection for excluded individuals, affirmation of the state's role, and respect for human and environmental rights.

Moreover, IB uses two other basic delineations: the finite nature of natural resources and studies on corporeality relating to the feelings of pleasure and pain. In relation to the first of these premises, IB emphasizes the need for replacement of proposals to develop at any cost with proposals for controlled and sustainable development, thus stimulating the creation of a consumer society that relates to the obligation to constantly replace the world's renewable resources. On the other hand, regarding the feelings of pleasure and pain, although these can be perceived by everyone and a relationship line can be indicated, they are felt completely differently by rich people and poor people. These are considered by IB to be somatic regulatory markers for individual and collective quality-of-life value guidance. Other indicators used by IB, in situations of expanded regional proposals for more appropriate replacement or use of the principle of autonomy, especially in a collective and society-based sense, are empowerment, liberation, and

emancipation (Garrafa, 2005b). More recently, through stimulation from social sciences, IB has also started to expand its studies in relation to the concept of colonialism, thereby seeking to deepen its critical regional roots so as to become disentangled from the negative and obscure side of the inheritance from Euro-American colonization and globalization at any cost (Nascimento & Garrafa, 2011).

School of Protection Bioethics (PB)

PB is based on the fact that the state's role is to protect the physical integrity and assets of all individuals who are inside its territory. Nevertheless, it emphasizes that with the arrival of the so-called welfare state, the state's provisions have expanded: PB considers that not only does the state have a duty regarding public liberty, but also it needs to ensure that its citizens can have the so-called social benefits (Schramm & Kottow, 2001). Even though PB recognizes the importance for bioethics of the "solidarity principle" and "ethics of responsibility," proposed respectively by Lévinas and Jonas, it advocates that these two reference points have insufficient capacity to work on the state's role in relation to the weakest and most needy segments of the population.

PB also makes criticisms regarding the predominant currents of Anglo-American bioethics, in relation to the prominence place on the physician-patient relationship and the theory of the four principles of Beauchamp and Childress. It underscores that, with such proposals, essential themes like public health end up relegated to a secondary position, since the so-called principlist bioethics does not have theoretical contributions capable of facing up to the dilemmas within this sphere. In this respect, PB proposes that the state has to take on obligations within the field of public health on the basis of its social responsibility, while differentiating these actions from paternalism, given that according to PB, state agents only act in relation to healthcare policies in conformity with previously agreed collective decisions (Schramm, 2003).

This proposal starts from the prerequisite that health is essential for quality of life and, for this reason, it is indispensable for the development of personal potential. Despite the importance of state action for achieving what is proposed, PB emphasizes the need to respect the axiological plurality that is present in modern society and to incorporate lay morality. PB can be defined as lay bioethics that has the task of protecting the most unprotected individuals, with the aim of achieving social justice.

School of Liberation Theology Bioethics (LTB)

Brazilian bioethics has been greatly influenced by the so-called liberation theology, which sees God as the great creator of the world and sees humans as co-creators and responsible for their own conduct, for their full lives. This school proposes a relationship between Latin American Catholic theological concepts

and bioethics (Fabri-Dos-Anjos, 1996). According to LTB, there is a "mystic" that prepares bioethics, taking this to be the hidden reasons and motivations that sustain the criteria, arguments, proposed attitudes, and norms of bioethics; this is also understood as the ideals, utopian projections, or hopes of the theories (Fabri-Dos-Anjos, 2000a).

The advances of science and technology and their reflections within contemporary society are also a concern for this theoretical school, starting from new interpretations of the meanings and the particular direction of life, as well as the relationships between human beings and between humans and the environment. Along this line of ideas, according to theologians, and differing from what occurs with the majority of scholars who are dedicated to other fields of knowledge, bioethicists are touched with a special sense of justice, solidarity, and humanism, through their virtuosity (Fabri-Dos-Anjos, 2000a).

LTB divides bioethics issues into three interrelated dimensions: mini-social, midi-social, and macro-social. The first takes into account interpersonal and family relationships; the second, institutional and group initiatives (risk groups, research subject, etc.); and the last, large structures and systems of social life, such as public activities within the field of healthcare. The school of LTB makes the very particular interpretation that Brazil and the other countries of Latin America are fertile ground for its attention because of the social inequalities of these countries; in this sense, its main focus is on poor individuals and populations, interpreted as those of greatest vulnerability within society.

Postgraduate Programs

In accordance with the requirements of the Ministry of Education, there are two formal types of postgraduate program in Brazil: the so-called *Lato Sensu* (broad sense) programs, which consist of medium-duration specialization courses (with a legal minimum of 360 classroom hours); and the *Stricto Sensu* (strict sense) programs, which consist of master's courses (with a minimum of 1 year and a maximum of 2 years) and doctoral courses (with a minimum of 2 years and a maximum of 4 years).

The first Lato Sensu postgraduate program developed in Brazil was conducted by the UNESCO Chair of Bioethics at the University of Brasília. This started in 1998 and continues to be regularly offered every year between March and December. Through the 13 years in which it has so far been conducted, this course of approximately 400 classroom hours has trained 320 specialists, with a mean of 25 students per year. Similar courses within the category of "specialization" are offered, although without regular periodicity, in the following institutions: State University of Londrina, Paraná; School of Medicine of the University of São Paulo – Oscar Freire Institute; Federal University of Lavras, Minas Gerais (distance learning); São Paulo Institute of Bioethical and Legal Studies, São Paulo; Bioethics and Biolaw, Ribeirão Preto, São Paulo; Pontifical Catholic University of Rio de Janeiro; Pontifical Catholic University of Paraná, Curitiba (offered only once);

Pontifical Catholic University of Rio Grande do Sul, Porto Alegre (started recently); plus another course offered by a private institution in the city of Teresina, state of Piauí, in the northeastern region of the country, also without regular periodicity. Another traditional course, albeit directed especially toward the religious topic of "Bioethics and Pastoral Care of Health," has been offered since the 1990s at the São Camilo University Center, in São Paulo.

Today, there are three Stricto Sensu postgraduate programs on bioethics with regularized registration in the Brazilian Ministry of Education. The first regular program at master's level started only in 2005, at the São Camilo University Center, in São Paulo, which subsequently, in 2010, expanded its activities to doctoral level. Prior to this, the existence of a large number of isolated dissertations defended within the field of bioethics had already been recorded, starting in the 1990s. These were presented within different academic programs with broader specifications, such as Healthcare Sciences, Medical Sciences, Social Sciences, Law, and others, in which bioethics had a specific presence as an area of concentration or at least as a line of research offered by these programs.

In turn, the first regular doctoral program in bioethics was offered, together with a master's program, from 2008 onward, by the UNESCO Chair of Bioethics of the Department of Public Health, School of Health Sciences, University of Brasília. This program has regularly had around 60 students, of whom 40 at master's level and 20 at doctoral level. More recently, in 2010, a consortium of four institutions in Rio de Janeiro (Federal University of Rio de Janeiro, Oswaldo Cruz Foundation, Fluminense Federal University, and State University of Rio de Janeiro) started to offer the third program every year: a new program at master's and doctoral levels on Applied Bioethics and Ethics.

A good explanatory study on the situation of bioethics activities offered at Stricto Sensu postgraduate level in Brazil was recently presented by Figueiredo through doctoral research developed within the Health Sciences Program of the University of Brasília (Figueiredo & Garrafa, 2010; Figueiredo, 2011). This study evaluated 199 postgraduate programs registered in the Ministry of Education as being of interdisciplinary nature and another 691 master's and doctoral courses within the field of health. In addition to the three programs mentioned above that are destined specifically for training master's and doctoral students in bioethics, 163 courses (23.6 %) offer disciplines of bioethics within their programs, another 32 (4.6 %) have bioethics modules, and a further 36 (5.2 %) provide teaching conducted solely through the deontological tradition. Figueiredo's study also shows that federal public institutions concentrate the greatest number of courses with disciplines of bioethics, with an average of 25 classroom hours, within which the conceptual reference point is almost entirely the principalist theory of bioethics. This study concluded that postgraduate programs on bioethics are at the construction stage in Brazil, since despite the existence of three regular programs that already offer specific master's and doctoral courses on bioethics in this country, 460 (66.6 %) of the 691 course examined within the field of health did not offer disciplines relating to ethics or bioethics (Figueiredo, 2011).

Future Challenges

The contradictory social realities have made it necessary for "Brazilian bioethics" to seek alternatives to the traditional theories. Although principlism has been the springboard for this field in Brazil and still exerts a certain hegemony within the national academic context, especially among groups with less academic depth, an intellectual reaction movement has now been constructed, against the simple context-free nature of ethical proposals or "packages" that have been imported without any critical filtering, from developed countries. The proposed Brazilian theories presented here are still under construction and should not be understood as an "affront" or "scientific disobedience" to the traditionally constituted theories, but as an attempt to search in a contextualized manner for appropriate moral responses to this country's specific problems.

As stated at the outset of this chapter, bioethics development in Brazil started late, and only now are different postgraduate programs beginning to take place organically. The observed evolution over this historical period of development is the result or a dynamic process that is making up for the lost time. In this respect, it is essential to have exchanges with neighboring countries within the Latin American community, with the objective of developing closer and more workable relationships in order to search for common or similar solutions for problems that are often the same.

Conclusion

Perhaps the best interpretation of the importance of bioethics for Brazil in the twenty-first century is provided by Fabri-dos-Anjos. In a valuable essay on this topic starting from what this author called the "cultural and humanitarian context," he stated that in the midst of many social inequalities, Brazil had found that bioethics provided an important space for developing criticisms and concrete proposals toward constructing and ensuring a better future: "Bioethical perspectives are important in Brazil and for Brazil" (Fabri-Dos-Anjos, 2000b – p 45). Campbell's generous words were prophetic; his reflections served as stimulus and assurance for Brazilian bioethics to start to view its problems through its own eyes and not through others' eyes, and to think about these problems with its own brains and not from ideas formed by brains that were alien to its real sociocultural context, no matter how reliable these eyes and how friendly these brains may have been.

Bioethics Development

History of Bioethics in Bulgaria

The history of Bulgarian medical ethics and deontology is closely related to the cultural history. In ancient times, the emergence and development of ethical norms was related to the habits, customs, and traditions of different ethnic groups. Religious beliefs played an important role. Care for the ill and the elderly was

DOI 10.1007/978-94-007-2512-6_7,

a sacred duty of ancient Bulgarians. Works of Hippocrates, Democritus, Galen, and Aristotle were well known, and Hippocratic principles were followed in medicine. The period between the thirteenth and eighteenth centuries marked a decline in all areas of life, including medicine. Traditions and moral norms were partially preserved and developed in the abbeys. During the Renaissance, a humanistic attitude toward the ill was proclaimed. Several works on ethical issues were written by Bulgarian physicians.

In 1901, the Bulgarian Physicians' Association (BPA) was established and, in 1904, the first ethical guidelines for physicians were adopted. In 1905, the Bulgarian Dental Association (BDA) was set up. Both associations have always been the main actors in regulating and strengthening the ethical norms in medical and dental practice.

In 1918, the Medical Faculty at the University of Sofia was established and the Hippocratic Oath became obligatory for all graduating physicians. Deontology was officially included in the undergraduate curriculum in medicine.

During the Communist period (1945–1989) medical science developed quickly and many changes in the system occurred. Initially, medical ethics was underestimated and deontology teaching was excluded from the curriculum. Some ethics was included in the discipline "Organization of health care" and deontology was transformed into a part of teaching in Forensic medicine.

In 1947, the existence and activities of the BPA were prohibited by law and, in 1952, the Hippocratic Oath was abolished as well. During the totalitarian period, there was a belief that specific ethical regulation in medicine was not necessary. Moral values in society – socialist values – were considered enough.

A change in thought occurred in the 1970s, and issues of physicians' ethics and deontology began to be seen as of theoretical and practical importance (Radanov, 2004). In 1973, the Moral Code of Bulgarian physicians was adopted. The code advances ethical norms such as physician's duties and obligations to the patients; maintenance and improvement of professional qualification; relations between physicians and other health professionals. At that time futile attempts to introduce the Hippocratic Oath were made. However, as a result of the strong Russian influence on all areas of life, the content of the Russian Oath was adopted in lieu of the Hippocratic Oath.

In 1988, Professor Vasil Prodanov, former director of the Institute of Philosophy at the Bulgarian Academy of Science, published the book titled, *Bioethics*, which was considered the first monograph on the topic in the Eastern European ethical literature (Prodanov, 2001).

In 1990, the BPA and the BDA were restored after 43 years of nonexistence. The legitimacy and independence of both associations became apparent in 1998 with the adoption of the law concerning professional organizations of physicians and dentists (State Gazette, №83/21.07.1998).

In 2000, the new Code of Professional Ethics of Physicians was adopted (State Gazette, №79/29.09.2000). In 2006, the Code of Professional Ethics of the Physicians in Dental Medicine in the Republic of Bulgaria was also adopted (State Gazette, №34/25.04.2006).

The ethical norms were also developed by the Bulgarian Association of Professionals in Health Care. The Code of Ethics (2003) was approved to guide the ethical behavior of nurses, midwives, and other health professionals (http://www.nursing-bg.com).

Major Actors and Forces

Since bioethics studies and research activities are spread throughout medical and philosophical institutions, it is difficult to encompass all professionals working and contributing to the field. Specific names of the main contributors are cited below.

Major Concerns

Although ethics in Bulgaria has developed greatly during the last decades, it is still associated with deontology. Laypeople as well as many health professionals continue to believe that ethics is mainly about the relationships between physician and patient and developing rules of professional conduct. This conceptual framework is not rejected in contemporary ethics but new issues are of importance as well: development of codes of research ethics, regulations for the protection of human subjects in research, the social and moral consequences of research, formulation of public policy guidelines for clinical care, allocation of health care resources, and patient access to health care services.

Resources

Medical ethics was introduced as a separate subject in undergraduate medical education in 1991, and since 1996 medical ethics has been taught in all medical colleges. At each medical university study materials had to be prepared in the absence of a comprehensive ethics textbook. In 1995, the first textbook on medical ethics, edited by Tzekomir Vodenicharov, was published (Vodenicharov, Mitova, & Gateva, 1995). In 2001, a team from the Medical University of Pleven published a textbook on medical ethics designed for medical students and students of other health professions (Grancharova, Aleksandrova, & Velkova, 2001). Silviya Aleksandrova developed this work further, and in 2007 she published a comprehensive textbook on the subject. In 2010, a textbook on bioethics and a book with case studies and practical assignments for medical students were published (Aleksandrova-Yankulovska, 2010a, 2010b). Sashka Popova and Tzekomir Vodenicharov from the Faculty of Public Health at the Medical University of Sofia published medical ethics textbooks in 2004 and 2010 (Vodenicharov, & Popova, 2010). Christina Jivkova from the Medical University of Sofia published a textbook, titled *Biomedical Ethics* (2002), designed for medical students. Darina Zinovieva and Petko Salchev developed materials on patients' rights (1998).

Additionally, study materials were developed by colleagues from the Medical Faculty at Trakia University in Stara Zagora (Marinova & Dimitrova, 1993), from the Medical University of Plovdiv (Liochkova et al., 1994), and from the Medical University of Varna (Kerekovska, 2005).

In 2011, the Faculty of Philosophy at Sofia University "St. Kliment Ochridski" initiated the first master's degree program in bioethics under the title "Integrative Bioethics" (http://www.phls.uni-sofia.bg/display.php). The program is designed for bachelor's and master's degree students in philosophy, sociology, political sciences, psychology, medicine, law, and theology. It is focused on ethical problems in the biosciences and medicine. The program aims to encourage bioethical research. Graduates will obtain a master's degree in philosophy in integrative bioethics.

In 2004, Assya Pascalev founded the Bulgarian Centre of Bioethics in Sofia. The Centre is an independent, nongovernmental organization, the mission of which is to promote the development and application of bioethics in Bulgaria. Its areas of concern include biomedical ethics, research ethics, the ethics of biotechnology, animal welfare, and agricultural ethics (http://www.bio-ethics.net/en).

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

Ethics is studied as a separate discipline in all Bulgarian medical universities. Ethics courses are taught in different years of undergraduate medical education. At Trakia University in Stara Zagora, the course is placed in the second semester (first year of study). At the Medical University of Pleven, it is taught during the fourth semester (second year). At the Medical University of Varna, the course takes place in the fifth semester (third year). Teaching hours also vary from 30 (15 lecture hours and 15 h of seminars) to 45 (15 lecture hours and 30 h of seminars). The basic topics included in the curriculum are as follows:

- Introduction to ethics with definition of basic terms
- Methods and theories of ethics
- Ethical codes
- Confidentiality
- Models of physician-patient relationships
- Informed consent
- Rights of patients
- Reproductive ethics
- Ethical problems in the end of life – care of terminally ill, palliative care, euthanasia
- Research ethics
- Ethical problems of organ and tissue transplantation
- Justice and resource allocation
- Public health ethics

In 2010, a new program was initiated at the Medical University of Pleven: Bioethics for students specializing in public health protection and control. The course focuses on public health ethics, environmental ethics, and ethical issues of new technologies.

Medical ethics is also included in the curricula of all other health professions, including nurses, midwives, laboratory technicians, and X-ray technicians. According to the state requirements for these specialties, the course of "Medical Ethics and Deontology" consists of 30 teaching hours.

Interesting postgraduate ethics courses have been prepared by different medical universities. The course "Ethical Problems in Medical Practice," consisting of 30 teaching hours, is offered at the Medical University of Pleven by Silviya Aleksandrova. The course "Informed Consent in Medical Practice," consisting of 15 teaching hours, is conducted at Trakia University, Stara Zagora, by Svetlana Dimitrova.

Ethics courses are also included in the philosophical programs of Sofia University "St. Kliment Ochridski": Introduction to Ethics (a required course), and Bioethics: Values and Normative Problems around Human Life (an elective course) (http://www.phls.uni-sofia.bg/).

Bioethics Committees

In the Bulgarian Health Act, adopted in 2004, Chapter 7, Part IV is dedicated to medical research involving human subjects. Here the requirement for prior approval of the research protocol by an ethics committee is stipulated. This requirement is also stated in the law of medicinal products in human medicine (2007), according to which every medical institution conducting research should establish an ethics committee. Following this law, 195 research ethics committees were officially registered.

Ethics committees have been established in scientific institutions performing experiments with human beings – in medical universities and hospitals. In scientific institutions, the ethics committees deal mainly with nontherapeutic research and moral problems of these institutions. Research ethics committees in hospitals mainly oversee the therapeutic experimentation of new drugs. Standard procedures for ethical review of experimental protocols have been developed and adopted.

In 2005, Sylvia Tomova published a paper called "Research Ethics Committees in Bulgaria," which was included in a review titled *Research Ethics Committees, Data Protection and Medical Research in European Countries*.

In addition to research ethics committees, ethics committees have been established in all medical professional bodies on national and regional levels: the Bulgarian Physician Association, the Bulgarian Dental Association, and the Bulgarian Association of Health Professionals. On the national level, there is an ethics committee dealing with issues around transplantation.

Expert Bodies and Centers

Bulgaria participated in the European Information Network – Ethics in Medicine and Biotechnology project (EURETH). The aim of project was to develop an information network and a knowledge base in the field of European ethics in medicine and biotechnology, making relevant sources, value-added information, and related legal sources available to academics, researchers, bioethical professionals, decision-makers, and consumers. Several institutions and organizations involved in bioethics in Bulgaria were identified (http://www.medun.acad.bg/cmb_htm/EURETH_NET/Bg_institutions.htm):

- The Bulgarian Physician Association (BPA), which adopted its code of professional ethics in 2000 (State Gazette, №79/29.09.2000). Additionally, according to the law of professional organizations, the Bulgarian Medical Association has responsibility for controlling adherence to ethical norms in medical practice and imposing penalties on physicians. The BPA is also responsible for developing guidelines for good medical practice. These control functions are implemented through the ethics committees.
- The Ministry of Health. The official site of the Bulgarian Ministry of Health publishes all health legislation documents regulating health care and medical ethics.
- The Bulgarian Psychiatric Association
- The Bulgarian Centre for Bioethics
- The Index Foundation–Health is a nonprofit organization, working on the promotion and protection of patients' rights in Bulgaria through research and analysis of the European and international law, dissemination of best practices, creation of databases, raising awareness on patients' rights, consulting services, creation of complaints procedures, and bringing into being an ombudsman in health.
- Bioetika.org is a team of medical, ethical, and legal experts, working at the Medical University of Sofia, who intend to research attitudes toward some ethical and legal problems in biomedical practice.
- The Association for European Integration and Human Rights is an association of practicing jurists united by the idea of exercising law in the public interest and establishing human rights as a fundamental value of civil society in Bulgaria.
- The bioethics website of the bioethics club of the Faculty of Philosophy of Sofia University "St. Kliment Ochridski." This is an informative website designed mainly for students (http://philosophy-bioethics.eu/).
- The Bulgarian national patients' organization. Being concerned with patients' rights, the organization hosted a conference on "Health Inequalities in the New EU Member States: Policy Makers and Patients – Creating the Change" in September 2012.
- The "Intimate with the Nature Society" is a nonprofit volunteer organization for animal protection and welfare. The society organizes campaigns, provides legal help and humane education, and deals with complaints and signals.

- Animal Rescue Sofia
- The Bulgarian Society for Animal Protection and Preservation

Additionally, the EURETH project identified Bulgarian libraries, that have materials concerning the topic "Ethics and Bioethics" at their disposal.

Relevant Legislation

In 2004, the Bulgarian Health Act (BHA) was adopted. In addition to the main articles concerning the health system as a whole, some ethical issues were tackled as well. Chapter 2 of Part III is dedicated to patients' rights. Lots of similarities can be found between the rights declared in the BHA and the Lisbon Declaration of the World Medical Association on the Rights of the Patient, that is, the right to accessible and good-quality medical care without discrimination, the right to a second opinion, the right to confidentiality, the right to palliative care, and the right to give informed consent. Other relevant legislation is mentioned in the discussion of the major bioethics issues and discussions below as appropriate.

Public Debate Activities

Because there is no national ethical journal, ethics discourse usually takes place in philosophical journals and in the media. There have been debates accompanying the proposals for legalization of euthanasia and surrogacy. As for organized events, in 2008, the Bulgarian Centre for Bioethics organized a National Bioethics Conference, "Expanding Patients' Rights through Advance Directives for Health Care: Towards a Joint European Platform."

Also significant was the International Round Table Discussion "Organ Donation in Europe: Challenges, Opportunities and Exchange of Good Practices," organized by the Bulgarian Centre for Bioethics in October 2010. The event was attended by experts from the EU member countries, including members of the European forum ELPAT (Ethical, Legal and Psychosocial Aspect of Transplantation) and Bulgarian experts from Aleksandrovska Hospital, Lozenets Hospital, the Association of Patients with Kidney Diseases, Medical University of Pleven, and the School of Divinity, Sofia University, and by representatives of the media.

Major Bioethics Issues and Discussions

Beginning of Life

Being a secular country for decades, issues regarding the beginning of life have been rarely discussed in Bulgaria. A team of colleagues from Stara Zagora studied the opinions of medical students in Trakia University about moral acceptability of abortion (Marinova et al., 2007). Their results supported the pro-choice view on

abortion. Most of the respondents accepted abortion in case of medical indications, rape, or incest. Lower support was declared with regard to the abortion on social indications.

As for the Bulgarian law on abortion, it allowed the latter with some limitations during the Communist period and was liberalized even more after that period. Presently, every woman can opt for abortion until the 12th week of gestation, providing there are no contraindications to the abortion and she is competent to make a decision. After that period, an abortion is still possible until the 20th week of gestation if there is a medical indication such as a diagnosed genetic disease (State Gazette, 1990, 2000).

A few papers on sex preselection have been discussed at scientific meetings. Silviya Aleksandrova reviewed this debate in "Ethical Aspects of Sex Preselection" (2006).

End of Life

Considering the aging process in Bulgaria, issues of care for the terminally ill have recently been focused on. Moreover, the country has witnessed a boom in establishment of hospices in recent years. Different educational courses in the clinical aspects of terminal care have been organized. Additionally, ethical issues in palliative care have been discussed. At the Medical University of Pleven, a special course on "Management and Ethics of Hospice Care" was introduced in 2002. The following various topics are covered in the course:

- Preconditions for the emergence of palliative care
- Organisational forms of hospices
- Hospice care teams
- Ethical problems in palliative care: ethical principles in palliative care; communication and truth telling; withholding and withdrawing treatment; justice in resource allocation; research in palliative care; team work
- Psycho-social problems in palliative care – spiritual and religious problems, psychological distress, care of the relatives
- Philosophy of palliative care; the concept of "good death"

Death is not much discussed in Bulgarian society due to the secularization and the deeply rooted views of death as a medical failure. A few papers (mainly philosophical) tried to open discussion on the topic. Vasil Kolev (2000) wrote about the concept of death in modern medical technologies. Polina Balkanska (2005) discussed death from the perspective of the geronto-psychological practice. In 2002, Silviya Aleksandrova published a paper called, "How and When the Death Begins and What Is the Appropriate Way of Care for Dying?" Later, she reported findings of her studies on the idea of "good death." The author studied the concept of "good death" among the personnel of hospices, the relatives of terminally ill patients, and students of different medical specialties (Aleksandrova, 2009). More than half of the respondents (50.5 %) associated a death without pain and suffering with "good death." Next were the ideas of "good death" as death during

sleep and sudden death. The author analyzed interesting differences in the concept of "good death" within different age groups. She also compared medical students' ideas of "good death" of before and after ethical discussions on the issue. Additionally, the author studied the idea of "good death" for people with a real experience of death in their family as well as for health care professionals and people without any real encounter with death.

With the introduction of the concept of patient autonomy, informed consent, patients' rights, and advance directives appeared in Bulgaria, too. Advance directives were introduced in a document in 2002 as part of the clinical path for terminally ill patients with cancer. Studies by researchers from the Medical University of Pleven showed that the opinions of practitioners about the advance directive are negative. Practitioners perceive it more as an obstacle in relationships with their patients than as a useful tool in decision-making (Aleksandrova-Yankulovska, Grancharova, & Vekov, 2011).

In 2011, the legalization of euthanasia was discussed in the Bulgarian Parliament. The legal proposal stipulated that euthanasia should be performed on written request of the patient. In case of an incompetent patient, his or her relatives should be able to request euthanasia on the patient's behalf and the request could be granted accordingly if all relatives supported it. All requests are to be discussed in a special committee of five members, three of whom should be physicians. The other two members should be lawyers. There was an idea of holding a referendum on the issue, but in July 2011 the law was rejected unanimously by the Parliament.

Euthanasia was discussed by a variety of professionals in Bulgaria – philosophers (Kaneva, 2006), ethicists (Aleksandrova, 2008), and forensic medicine physicians (Lisaev, 1999).

Health and Disease

In Professor V. Prodanov's book, *Bioethics* (1988), there is a chapter called "Health and Disease" in which the moral meanings of these two concepts are discussed.

One of the great doctrines put in place over the last half century to ensure patients' self-determination is the requirement for informed consent. After the initial confusion, both health professionals and patients have become used to the concept of informed consent. The Bulgarian Health Act (2004) pays special attention to informed consent. Every medical procedure should be done only after obtaining informed consent from the patient. He or she should be informed about the diagnosis, the aim of the treatment, available alternatives, expected results and the prognosis, potential risks, side effects, and the health risk in case of treatment refusal. Surgical procedures and other medical interventions, which are life-saving, can be performed without a patient's explicit informed consent. In case of incompetent patients, consent is obtained from the legally entitled representative. Profound studies on informed consent in medical practice were done by Svetlana Dimitrova (2003) in her monograph, "Informed Consent in Medical Practice."

When discussing health, disease, and patients' care, the issue of patients' rights emerges. In the Bulgarian Health Act (2004), patients' rights are well formulated in Chapter III. In 2012, the preparation of specific law on patients' rights was begun. A working group of the health commission of the parliament was established to prepare the proposal of this act.

Health Care System, Access to Health Care

Since the end of the Communist period, the Bulgarian health care system changed from a state monopoly to a health insurance system. Accordingly, the issue of justice in health care provision has been discussed, and debates are ongoing on about what type of services should be covered by insurance, how insurance taxes should be calculated, what fee per visit should be paid by the insured patients, and so on. These debates have been led mainly by the media. In an attempt to provide a fair solution to waiting list for primary health care, some recommendations were adopted: patients with chronic diseases in need of prescription renewals should appoint their meeting in advance; emergency cases should be served at any time without waiting; pregnant women and babies under 1 year of age should also be served with priority.

Traditional Medicine

Traditional medicine has not entered the discourse on bioethics in Bulgaria. However, abuses of patients' trust have been often discussed in the media. In Chapter VI of the Bulgarian Health Act (2004), some requirements concerning traditional healers were adopted in order to protect patients and guarantee a certain quality of this type of care. The healers should have at least a high school education and have completed four semesters in medical university.

Genetics

Chapter IV in the Bulgarian Health Act (2004) deals with genetic health and genetic research. Genetic materials can be obtained only after written informed consent is given by the subject. Genetic testing on incompetent persons is possible only after approval is given by the local ethics committee. People cannot be discriminated on the basis of genetic test results. Genetic data are personal and should not be accessible to employers and insurance companies.

Stanka Hristova's book, *Ethics in the Era of Biotechnologies* (2009), discusses ethical problems in the sequencing of the human genome, the rights and property of genetic information, genetic discrimination, among other topics. Assya Pascalev (2003) also contributed to this topic, focusing on ethical dilemmas caused by genetically modified foods.

Reproductive Medicine

Recently there have been several interesting developments in the area of reproductive ethics in Bulgaria. In 2004, the regulations regarding assisted reproduction were officially included into the Bulgarian Health Act (Chapter 4). Soon after that, in 2007, the Ministry of Health issued a special decree about activities in the area of assisted reproduction (State Gazette, №55/06.07.2007). There was a discourse on whether assisted reproduction should be covered by health insurance. Finally, it was not included in the insurance package, but in 2009 the government established a special fund called "Assisted Reproduction." Although an age limit was established, allowing assisted reproduction only to women until the age of 43, in 2010 a successful procedure was performed on a 62-year-old mother. This case was widely debated in the light of the mother's age and the related ethical problems. One year later, the age limit for in vitro fertilization with a woman's own ova was revoked, but at the same time a new limit, 51 years, was set for IVF with a donor's ova. New debates over discrimination based on the age of the mother have led to a proposal of amendments to the regulation. In May 2012, an individual assessment of every female candidate for assisted reproduction was proposed. The age criterion was replaced by the menopause criterion. Ethical issues brought up as a result of the application of new reproductive technologies were discussed by Silviya Aleksandrova (2006a) in a comprehensive paper published in *Asklepios – International Annual of History and General Theory of Medicine*. The moral status of the embryo also was an issue of discussion in several other papers (Hristova, 1997; Todorov, 2006). Stanka Hristova published a book about cloning in 1999, titled *From Frankenstein till Dolly. Morality and Procreation.* An overview of the debate over human cloning was presented by Christina Jivkova in the book *Cloning* (2002).

Ethical aspects of surrogate motherhood have been discussed cautiously in a few papers. In 2004, Silviya Aleksandrova published an overview paper titled, "Should surrogate motherhood be prohibited?," long before the issue of surrogacy legalization was raised. In October 2011, the act on surrogacy was discussed in Parliament. It prohibited direct payments to the surrogate mother and allowed only reimbursement of expenditures during her pregnancy and recovery period after the delivery. The surrogate mother should be a Bulgarian citizen between 21 and 43 years of age with at least one child of her own. She should be in good physical and mental health and should not be a surrogate mother more than twice. The surrogate mother should not be the donor of the ova at the same time. The law is still under revision.

Medical Research

The Bulgarian Health Act (Chapter VII) deals with medical research involving human subjects. The principles declared in the act are consistent with the generally recognized ethical principles of medical research according to the Helsinki declaration. The requirement to obtain written informed consent prior to the initiation of the research is stated in it. Incompetent people should not be involved in medical

research. The researcher should be qualified in the areas of medicine, dental medicine, biology, pharmacology, or biochemistry. Research projects should be approved by a local ethics committee before their initiation. The ethics committee should monitor the conduct of the research.

Additional laws regulating medical research include the law on medicinal products in human medicine (2007), the decree on regulation of good clinical practice rules (2007), the decree on regulation of clinical experiments of drugs involving human subjects (2000), the law on vetting activities and the regulation about the minimal requirements for the protection and humane handling of experimental animals (2005).

Public Health

In 2010, one of the plenary lectures at the Jubilee Scientific Conference on the subject "Public Health in 21st Century," held at the Medical University of Pleven, was "Ethics in Public Health," delivered by Professor Marcel Verweij, editor of the journal *Public Health Ethics*. His speech has inspired the subsequent debates. Other relevant works include the following: Silviya Aleksandrova (2007b) presented a literature review, "Ethics and Public Health," at a national conference on "Ethics in Bulgarian Health Care." At the same conference, Valeri Lichev gave a speech, "Economic Constraint for Healthy Lifestyle," in which he discussed the economic measures undertaken by the government to limit smoking through increasing the price of cigarettes. This issue launched a great debate in the country, much larger than the debates about euthanasia and surrogacy. The protests of tobacco producers and lobbyists led to the partial adoption of only some restrictions, like the separation of places for smokers and non-smokers. It took a long time until the ban on smoking in public places was finally adopted in May 2012.

Infectious Diseases

Infectious disease control is described in the Bulgarian Health Act, Chapter V (2004). The measures are obligatory and are justified by the public benefit: obligatory immunizations, obligatory notification and registration of infectious diseases, and obligatory isolation and hospitalization for 13 diseases. There is no specific publication on the ethical issues regarding infectious disease control.

Transplantation Medicine and Organ Donation

Transplantation medicine is typically related to many ethical debates that are mainly focused on resource allocation problems.

Many ethical papers have been published focusing on different aspects of transplantation. Darina Zinovieva (2003) focused mainly on legal issues in

relation to transplantation. Assya Pascalev presented several papers on transplantation at the national conference on "Ethics in Bulgarian Health Care," where she discussed the importance of how informed consent for donation is stipulated in the law (2007). In 2010, at the Jubilee scientific conference of the Medical University of Pleven on "Public Health in the 21st Century," Pascalev presented ethical challenges with regard to unrelated living organ donation. Ethical problems of organ donation and tissue transplantation were the topic of doctoral studies as well.

The law on transplantation and organ donation was last amended in 2011. There was a radical change in the law that was adopted in 2009 in relation to the informed choice of potential donors. In the first version of the law (2003), there was a requirement for registered consent of the donor before death. However, the limited number of Bulgarian citizens who registered such consent fostered the debate and increased the pressure for change of legislation. As a result, the opposite prerequisite for donation was adopted, that is, the absence of explicit refusal for organ donation. The law also clarifies the conditions for living donation, it prohibits payments for organs as well as advertisements for organ donations, and it is detailed with regard to informed consent requirements.

Emerging Technologies

In the course of the development of new bio- and information technologies, some research and debate was initiated among philosophers, ethicists, and other specialists in the field. Stanka Hristova, in her book *Ethics in the Era of Biotechnologies* (2009), pays special attention to the ethical problems of nanotechnologies. Other authors, not specifically trained in ethics, have covered problems of protection of the patients' rights with the introduction of the basic elements of e-health, such as the electronic health dossier, the electronic health card, and electronic prescriptions (Mircheva, 2009).

Intensive Care

There is not much research concerning ethical aspects of intensive care. Nikola Ivanov and Nikolaj Kolev (2007) wrote the book *Intensive Therapy in Internal Diseases*, in which they present and analyze in detail patients' rights, informed consent, confidentiality, transplantation, professional duties, and legal responsibilities in intensive care of internal diseases.

Palliative Care

Palliative care was introduced relatively recently in Bulgaria. The first hospices were established in the late 1990s. Ethical discourse has focused on patient's

autonomy and truth-telling (Aleksandrova, 2007a; Jordanov and Stefanov, 2008), the introduction of advanced directives (Aleksandrova-Yankulovska et al., 2011), the concept of "good death," and the relationship between palliative care and euthanasia (Aleksandrova, 2008). Separate publications have appeared on the philosophical aspects of pain (Kaneva, 2007; Mihailov, 2007).

Care for the Elderly

In 2008, in Plovdiv, the Hasumi International Research Foundation-Bulgaria organized a scientific meeting titled "Elderly – Life with Future." Specialists from different areas as well as politicians were invited to discuss ways of improving the life of the elderly and enhancing their social support. Palliative care issues were touched on and an active discussion was held on the involvement of the Orthodox Church in care. Issues of care for the elderly are often discussed in the media and social politics but not so much in the academic ethical debate.

Chronic Diseases

In 2005, the Bulgarian Psychosomatic Society organized a conference in Plovdiv called "Ethical and Spiritual Aspects of Medical and Social Activities in Chronically Ill Patients" in collaboration with the Department of Health Care at the Medical University of Plovdiv. Mariana Liochkova and V. Mihaylova presented on chronic pain (2005). L. Gateva, G. Petrova, and Iv. Salabasheva (2005) underlined the challenges with regard to care for chronically and terminally ill patients.

Psychiatric Care

A separate chapter of the Bulgarian Health Act deals with mental health and psychiatric care. Psychiatric treatment cannot be imposed upon anyone unless within legally defined situations. They cannot be initiated on the basis of family, professional, or other conflicts. Patients' stays in psychiatric institutions should be shortened and the limitation of personal freedom should be reduced. Patients in acute situations, presenting a danger to themselves and to others, can be temporarily restricted for 6 h. If a patient's condition requires longer restriction, the institutional manager should decide about that and should inform the relatives. In case of necessary psychiatric care (obligatory hospitalization), the manager of the institution should appeal to the court for this decision (BHA, 2004, Chapter V).

Legal and ethical issues regarding patients with epilepsy have been discussed by Silviya Aleksandrova and Plamen Bozinov (2005).

Pediatric Care

New ideas for the physician-patient relationships in pediatric care, particularly in the treatment of terminally ill children, were presented by Silviya Aleksandrova at the tenth Congress of the European Association for Palliative Care, which took place in June 2007 in Budapest. The author discussed the direct approach to the ill child versus the family-centred approach, where the diagnosis is communicated to the parents and they talk to the child later on, with or without the assistance of the physician.

Emergency Care

At the conference titled "Ethics in Bulgarian Health Care," held in 2007 in Sofia, Dr. Spas Spaskov, the former executive director of the emergency care center "Pirogov," spoke about ethical problems in emergency care. He underlined the problems of recourse allocation as well as the responsibility people have for their own health. These problems are often debated in the media, but they have not entered the ethical discourse on a philosophical level.

General Practice

There are not many works on ethical problems related to general practice in Bulgaria. Svetlana Dimitrova studied the implementation of informed consent in general practice, and her results showed little familiarity of physicians with the concept or its legal regulation. The physicians who were surveyed had problematic opinions about the importance of the understanding by patients of the information they were provided. Most respondents preferred to inform their patients about the consequences of their refusal rather than to clarify alternative treatments and the chances of success (Dimitrova et al., 2007). Other discussions have been mainly targeted at organizational problems in general practice with little relation to the ethical discourse.

Health Promotion and Education

Some ethical issues relevant to promoting health have been mentioned earlier under the heading "Public Health."

Scientific and Professional Integrity, Conflict of Interest, Corruption

There are issues of professional conduct in the area of expertise of ethics committees. Ethics committees have been established at the Bulgarian Physicians' Association, the Bulgarian Dental Association, and the Bulgarian Association of Health Professionals. At an institutional level, there are also ethical committees at

universities and hospitals that are separate from the Institutional Review Boards. These committees develop ethical codes and guidelines for good clinical and scientific practice and monitor adherence by practitioners. They are also involved in settling conflicts of interests. A special standard procedure for authorship has been developed by the Ethics Committee of the Medical University of Pleven.

Future Challenges

The greatest challenge to the development of bioethics in Bulgaria is the establishment of collaboration between different professionals involved in bioethical research and teaching. Currently, some scientific events are organized and bioethical publications are released without adequate publicity promotion so that all colleagues in the field can benefit from them. A national ethics society or network would be of tremendous importance for furthering better collaboration among professionals with ethics expertise and for facilitating the public debate on bioethical issues. Another important need is the development of a national bioethics literature database.

Bulgaria does not stand apart from recent medical technology developments and related bioethical issues. Genetic tests, for example, are still not widely applied, but the accompanying ethical issues are recognized. Geneticists as well as other physicians, confronting genetic diseases in their practice, must deal with complex ethical dilemmas in genetic counseling. Consequently, there is a need for development of good clinical ethics consultation services.

Summary Conclusion

In Bulgaria, the field of bioethics has followed recent developments and has had its own national achievements. Bulgarian philosophers produced works in bioethics in the late 1980s, and a decade later physicians began to be trained in different ethics educational programs abroad. Thus, a good foundation for future bioethics development in the country has been built. However, bioethics is still perceived mainly as theoretical knowledge and remains to be incorporated more effectively into clinical practice.

Jacques Simpore

Birth and Development of Bioethics in Burkina Faso

In Burkina Faso, there are four structures of bioethics or ethics committees: the Catholic National Bioethics Committee (CNBC), the National Committee of Ethics (NEC), the Ethics Committee for Health Research (ECHR), and the National Biosecurity Agency (NBA). These structures that are working in the field of ethics have had various sponsors. They were born in different circumstances and at different times and have had different but complementary goals and fields of application.

The Catholic National Bioethics Committee (CNBC)

When and How Has Bioethics Committee Started?

This committee was born in 1998 in Ouagadougou under the inspiration of the Episcopal Conference of Burkina Faso and Niger. Indeed, facing the many challenges of social life and the progress of science and biomedicine, the bishops asked Professor Jacques Simporé to constitute a team of resource persons and work for thorough reflections on these problems of ethics and bioethics. That was how it was organized in 1999 the first National Congress of Bioethics. About 550 participants attended this conference, coming from Burkina Faso and neighboring countries such as Benin, Niger, and Mali. Participants stem from all levels and occupations (university professors, doctors, pharmacists, biologists, nurses, bishops, religious people, priests, economists, psychologists, sociologists, theologians, and philosophers). The topics discussed during these 3 days were general bioethics and methodology, African cultures and sexuality, bioethics and sexuality, bioethics and the beginning of life, identity and status of the human embryo, abortion, ethics and law, canonical references on abortion, bioethics and clinical experimentation of drugs on man, drugs in Burkina Faso, epidemiological data and the fight against AIDS in Burkina Faso, psychiatry and risk behavior, and, finally, bioethics in the terminal stage of life.

In 2007 the second congress of bioethics was organized with the topic "Together for the Promotion of an authentic culture of life." This conference was placed under the patronage of their Excellencies Mr. Bédouma Alain Yoda, Minister of State and Minister of Health, and Bishop Seraphim Rouamba, President of the Burkina/Niger Episcopal Conference. It also gathered 550 participants from the Vatican, Italy, Belgium, France, Benin, Cote d'Ivoire, Cameroon, Niger, Mali, Togo, Portugal, Morocco, Spain, Ghana and Burkina Faso.

What Have Been the Major Actors/Forces of This Committee?

The Catholic National Bioethics Committee (CNBC) composed of 16 members is a multidisciplinary team: jurists, bioethicists, moralists, philosophers, theologians, economists, biologists (biochemists, geneticists), pharmacists (pharmacognosy), doctors (pathologists, dermatologists, venereologists, obstetricians), and nurses.

What Have Been Their Major Concerns Over Time?

Their major concerns over time were to train, educate, to sensitize, and enlighten the populations and the leaders on the new problems raised by bioethics.

What Resources (Books, Programs, Media, Networks, and Societies) Have Been Developed?

During these years, the Catholic National Bioethics Committee (CNBC) has organized numerous conferences and debates on bioethics issues. Some lectures have been published as books; others are published on the Web site: www.cerbafaso.org. This committee has also hosted several debates on the national television and private radio stations. It is also currently developing a program for "a master's degree in applied ethics."

What Were the Steps/Measures (Policies and Legislation, Infrastructure, Teaching Programs, Committee, etc.) Taken?

The committee is a structure of the civil society, unrelated to the government; it does not dictate civil law but teaches, educates, and trains through lectures and writings published for the general public.

The National Ethics Committee (NEC)

When and How Has This Bioethics Committee Started?

The National Ethics Committee (NEC) has been created by Article 4 of the President of the Council of Ministers, the President of Burkina Faso (2001), presidential Decree 2001-278/PRES/PM of June 8, 2001 (OJ N 27 2001). This National Ethics Committee was established following the major sociopolitical events that occurred in the late 1990s in Burkina Faso. Indeed, there was a new and unprecedented strong social and political crisis from 1998 to 2000 in the country of "honest men." This committee's mission was to calm the social and political situation that was troubled by sordid assassination. The objectives of the National Ethics Committee was to be an observatory of the Burkinabe society; to ensure the preservation of republican and secular values at the moral, cultural, and human levels; and to propose and to suggest any measures for the preservation of good citizenship and morality in public and social life.

Who Have Been the Major Actors/Strengths?

According to Article 4 of the Presidential Decree of June 8, 2001 2001-278/PRES/PM (JON 27 2001), the National Ethics Committee is composed as follows:

- Three representatives of traditional and religious authorities appointed by the presidium of the National Day of Forgiveness
- Three representatives of the great control bodies of the state (Court of Audit, Inspector General of State, Ombudsman of Burkina Faso)
- Three high-ranking persons appointed by the President of Burkina Faso
- Members of the National Ethics Committee are chosen for their integrity and their sense of duty. They are appointed by decree for a 5-year nonrenewable mandate.

What Have Been Their Major Concerns Over Time?

The major concerns of the National Ethics Committee were to fight against corruption, to awaken a sense of civic responsibility among citizens, and to build a bridge of mediation between the parties of the opposition and the government in order to reestablish social peace in Burkina Faso.

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Social Bodies)?

Since its inception (June 8, 2001) and installation (March 14, 2002), the committee was able to develop and enforce initiatives in many activities. According to its President, who is the Ouidi Naaba (traditional chief, minister of the Emperor

of the Mossi), the methodology that was used included meeting, listening, exchanging, and consulting, both in urban areas and in the provinces. This enabled them to produce three reports: the first report presents the current state of ethics in Burkina Faso; the second relates to more specific areas of the general administration, education, and health; and the third deals with ethics and politics. The National Ethics Committee organized in 2006, after 5 years of its existence, a special forum for ethics review in Burkina Faso. This forum was designed to measure the impact of the ethics committee on social peace. During this conference, the committee welcomed the positive management effort of the city, depoliticization of the military and administrative structures, complete communalization, the establishment of decentralized and deconcentrated structures, etc. However, the committee was concerned about the persistence of phenomena such as insecurity, corruption, and impunity.

What Have Been the Steps/Measures (Policies and Legislation, Infrastructure, Teaching Programs, Committee, etc.) that Have Been Taken?

The committee also developed draft codes of ethics in education, health, financial and general administration, defense, and security.

The Ethics Committee for Health Research (ECHR)

When and How Has This Bioethics Committee Started?

By Decree No. 2002 of November 21, President of the Council of Ministers, the President of Burkina Faso, 2002 536/PRES/MS/MESSRS, the Ethics Committee for Health Research (ECHR) was established. Subsequently, joint order Minister of Health, 2004/147/MS/MESSRS on the organization and functioning of the Ethics Committee for Health Research in Burkina Faso were signed. At the dawn of the year 2000, antiretroviral (ARV) drugs were still very expensive when many people infected with HIV died of AIDS in Burkina Faso. In this period, several types of pharmaco-clinical experiments took place: autohemotherapy of HIV, herbal medicine of HIV, research of vaccine against HIV, and so on. Certainly, health research, mainly on HIV, is an important component of the fight against HIV/AIDS. These social science and biomedical researches contribute not only to a better understanding of issues related to the access to quality care but also to providing new and more effective approaches in health issues. Faced with these conditions in health research, with possible bias, it was proposed to the Government of Burkina Faso to fill the legal vacuum by creating this committee in 2002 in order to regulate generally all health research in Burkina Faso. Thus, according to the Decree No. 2002 of November 21, 2002 536/PRES/MS/MESSRS, the Board of the Ethics Committee for Health Research (ECHR) has the following specific objectives:

- To analyze and evaluate all proposed health research in Burkina
- To state an opinion on compliance with the code of ethics and research protocols and issue a certificate of ethics prior to any authorization of health research
- To monitor compliance with ethical principles in the conduct of research

- To arbitrate any disputes of ethical issues arising from the implementation of health research
- To promote the ethics of health research in Burkina
- To develop a code of ethics for health research in Burkina Faso and revise it when necessary

What Have Been the Major Actors/Strengths?

According to Article 5 of the Presidential Decree No. 2002 of November 21, 2002 536/PRES/MS/MESSRS, the Ethics Committee for Health Research (ECHR) is composed of nine members:

- Three (3) representatives of the Ministry of Health
- Two (2) representatives of the Ministry of Animal Resources
- One (1) representative of the Ministry for Human Rights
- One (1) representative of the College of Physicians and Dentists
- One (1) representative of the College of Pharmacists of Burkina Faso
- Members of the Ethics Committee for Health Research (ECHR) are appointed by decree for terms of three (3) years renewable once. They enjoy complete independence in the performance of their duties (Article 6).

What Have Been Their Major Concerns Over Time?

The major concerns of the Ethics Committee for Health Research were to ensure that ethical standards for health research are met in Burkina Faso. In addition, they have to analyze and evaluate all research projects, to issue an opinion, and to promote research ethics. One major concern is the oversight of research projects implemented. The work load is so heavy and the members of the ECHR cannot find time for oversight.

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

Over the years, the Ethics Committee for Health Research (ECHR) met regularly to evaluate numerous research projects and to allow their implementation. It has also developed a framework and standards for the writing and presenting of research projects.

What Have Been the Steps/Measures Taken (Policies and Legislation, Infrastructure, Teaching Programs, Committee, etc.)?

According to joint order 2004/147/MS/MESSRS, sections 22–23, no projects for health research can be undertaken in Burkina Faso without the certificate of ethics issued by the Ethics Committee for Health Research. In addition, the committee's opinions are published in an annual report sent to the Minister of Health. The committee is currently developing legal standards for health research in Burkina Faso and has also organized training sessions on the writing of ethical research. Nevertheless, there is an important issue that it means to develop: the teaching of research ethics. On another hand, we are looking forward to have institutional ethics

review board (IRB) in research centers. Norms and standards to establish such IRBs are under development.

The National Biosafety Agency (NBA)

When and How Has This Bioethics Committee Started?

Since the dawn of the 2000s, biotechnology has become a hot topic in Burkina Faso with the cultivation of genetically modified cotton (DMC) or Bt cotton (Bacillus thuringiensis). After the experiment conducted from 2003 to 2008, Burkina Faso, the eleventh country in the world to adopt biotechnology, hopes to take advantage and leverage in order to ensure food security for its populations while protecting its environment U. S. Agency for International Development (2006), [www.assaid.gov]. In the context of exploitation of transgenic products, Burkina Faso ratified by Decree No. 2003-208-/PRES/PM/MAECR/MFB/MECV signed on April 25, 2003 the Cartagena Protocol on Biosafety. In July 2003, without designing an appropriate regulatory framework for the protection of its populations and environment from risks associated with genetically modified organisms, Burkina Faso became the first country in West Africa to test transgenic cotton. However, delivery of authorization for this confined field trial was based on prior work by a scientific board. This experimental phase was carried out in an opaque manner without substantial actions to inform and sensitize people on the subject. It was not until June 2004 that a beginning of regularization was initiated with the establishment of a legislative framework through the adoption of national rules for safety in biotechnology, with Decree No. 2004-262 / PRES / PM / / MECV / MAHRH / MS of 18 June 2004, which represents a significant step forward in the field of regulation of GMOs in Burkina Faso.

Subsequently, at the institutional level, a national authority on biosafety was created which is the National Biosafety Agency (NBA). Its three organs are the National Biosafety Scientific Committee (NBSC), the Internal Biosafety Scientists Committees (IBSC), and the National Biosafety Observatory (NBO). Safety in biotechnology would be all the measures taken to reduce or eliminate the potential risks arising from the development of modern biotechnology and the use of its products. A national framework for safety in biotechnology is a set of political, policy, institutional, legal, and regulatory instrument requirements established for the transfer, handling, or safe use of genetically modified organisms (GMOs) and products that are derived, in accordance with such instruments.

What Have Been Their Major Actors/Strengths?

National rules for safety in biotechnology were developed, and the following authorities are charged as far as they are concerned with the implementation of these standards related to biosafety:

- The Minister of Agriculture, Water, and Fisheries
- The Minister of the Environment and Quality of Life
- The Minister of Secondary and Higher Education and Scientific Research

- The Minister of Health
- The Minister of Animal Resources
- The Minister of Trade, Enterprise Promotion, and Handicrafts
- The Minister of Justice

On the technical side, the three bodies – the National Biosafety Scientific Committee (NBSC), the Internal Biosafety Scientists Committees (IBSC), and the National Biosafety Observatory (NBO) – helped to establish biosafety for products of transgenesis in Burkina Faso.

What Have Been Their Major Concerns Over Time?

The major concerns of the National Biosafety Agency (NBA) were:

- To ensure the strict application of the provisions stated for legislative and regulatory matters, including ensuring compliance with best biotechnological practice research in secluded or open areas
- To ensure that risk assessment and management are made
- To monitor and evaluate
- To sensitize the public for a respect of the practices and obligations under these rules
- To make decisions in a sovereign manner in consultation with the public, concerning applications for research on GMOs, their voluntary dissemination in nature, and their marketing

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

In legal terms, Burkina Faso has developed in 2004 national rules for safety in biotechnology, which aimed at helping to ensure an adequate level of protection for the transfer, handling, and safe use of genetically modified organisms. In 2006, the law on the security system in biotechnology has been adopted. This is a set of legal regulations for genetically modified organisms and derived products. Many reports and training programs, many educational conferences, and several standards were established to entrench the culture of biosafety in Burkina Faso.

According to Article 30 of the law governing the biotechnology security in Burkina Faso [The National Assembly, 2006. Law on security in biotechnology in Burkina Faso; National Biosafety Committee, 2005], an authorization can only be issued if the work:

- Will benefit the country without causing risks or harm to human health, animal, biological diversity, and the environment
- Will contribute to sustainable development
- Does not harm the socioeconomic environment
- Does not violate the rules of ethics

Thus, the present Law No. 005-2006/AN of March 17, 2006 determines the conditions for the use of genetically modified organisms and their products in Burkina Faso. In addition, the laws and decrees that follow were taken by the Government of Burkina Faso with a view to directly or indirectly promoting the objectives of the Convention on Biological Diversity (CBD):

- Law N° 005/97/ADP of 30 January 1997 on the Code of Environment in Burkina Faso and its Decree of 17 July 2001 N°2001-342/PRES /PM/MEE
- Law N° 006/97/ADP of 31 January 1997 on Forest Code in Burkina Faso
- Law N° 034-2002/AN of 14 November 2002 guidance law on pastoralism in Burkina Faso
- Law N° 002-2001/AN of 8 February 2001, on the management of water
- Law N° 023/97/II / AN of 4 December 1997 on the Code of Mining in Burkina Faso
- The Law on the Control of Pesticide. Law N° 41/96/ADP, 08/11/1996 amended by Law N° 006/98/AN of 26/03/1998
- Law N° 23/94/ADP, 19/05/1994, on health code
- Law N° 055 / AN of December 21, 2004, with the general code of local government in Burkina Faso
- Law N° 010-2006/AN of March 31, 2006, on the regulation on plant seeds in Burkina Faso
- Decree 2004-262/PRES/PM / / MECV / MAHRH / MS of 18 June 2004 regulating safety in modern biotechnology in Burkina Faso
- Law on the National Strategy for Genetic Improvement in Burkina Faso (in the stage of adoption)
- Decree N° 2001-342/PRES/PM /MEE of 17 July 2001 on the scope of application, content and procedure of study, and the instructions on environmental impact

What Have Been the Steps/Measures (Policies and Legislation, Infrastructure, Teaching Programs, Committee, etc.) that Were Taken?

The National Biosafety Agency (NBA) developed a communication strategy based on defining different target groups. Activities, topics, and means of communication used are identified, taking into account the specificity of each target group. Apart from communication, NBA organized training on the risks of voluntary and involuntary dissemination and on biosafety measures to be implemented in case of accidental dissemination. It has also published documents and developed standards on biosafety (Table 54.1).

Current Infrastructure in Bioethics

Teaching of Bioethics at University and Other Levels

Some members of the CNBC (Catholic National Bioethics Committee) such as Professors Jean-Baptiste Nikiema and Jacques Simporé and Doctors Joseph Sawadogo and Francis Sedgo teach bioethics in several African universities:

- At the University of Ouagadougou (UO)
- At University St. Thomas Aquinas (USTA)
- At the University Unit of Bobo-Dioulasso (UUB / WAUA)
- At the Biomolecular Research Center Pietro Annigoni, CERBA
- At the University of Lome (Togo)

Table 54.1 Summary table on the establishment of ethics committees and their objectives

Committees	Date of creation	Decree of creation	Name of president	Goals
CNBC	25 May 1998	N°2011CEBN-VIII-24/135	Prof. Jacques Simpore	Train, educate, sensitize, and promote the teaching of bioethics in Burkina Faso to help build the social peace, to promote solidarity, and strengthen human rights in Burkina Faso
NEC	08 June 2001	n°2001-278/PRES/PM	Dr. Tinga Douamba Ouidi Naaba	Being an observatory of society to ensure the protection of secular and republican values and propose measures for the preservation of civic and moral standards of public and social life in Burkina Faso
ECHR	21 November 2002	N°2002-536/PRES/MS/MESSRS	Dr. Bocar Kouyate	To analyze and evaluate all projects in health research in Burkina, to state an opinion on compliance with the code of ethics, to issue a certificate of ethical approval prior to any research promoting the ethics of health research in Burkina
NBA	2005	Decret 2005-040/PRES/PM/MECV du 03 Février 2005 portant organization du Ministère de l'Environnement et du Cadre de Vie	Pr. Chantal Yvette Zoungrana Kabore	To review applications for imports, exports, and uses of genetically modified organisms (GMOs) and products, to issue license for the marketing of food products containing GMOs, to carry out inspections and to carry out technical audits of structures through research on GMOs and products, to ensure compliance of the laboratory and field work on GMOs and derivative with national biosafety rules, and to inform and to educate public and encourage their participation in the decision-making process

CNBC, Catholic National Bioethics Committee
NEC, National Ethics Committee
ECHR, Ethics Committee for Health Research
NBA, National Biosafety Agency

- At the University of Abidjan (Ivory Coast)
- At the St. Thomas d'Aquin Institute for the Theology of development of Yamoussoukro (ISTAY) (Ivory Coast)
- At the University of Brescia in Italy
- At the High Seminary Colleges of Koumi and Lavigerie, in Burkina Faso

The lessons are mainly related to research ethics, biosafety, medical ethics, ethics and social policy, pharmaco-clinical experiments, and morality in general. The lessons take place at all levels: 1st, 2nd, and 6th year of medicine, in 2nd year of the faculty of sciences of life and earth, for master's and doctorate cycles. In addition, numerous workshops, congresses, and conferences on bioethics are held periodically by the CNBC for students and the general population.

Bioethics Committees

In Burkina Faso, there are, as mentioned above, four types of bioethics or ethics committees: the Catholic National Bioethics Committee (CNBC), the National Ethics Committee (NEC), the Committee of Ethics in Health Research (ECHR), and the National Biosecurity Agency (NBA). Each committee works according to its action plan in accordance with the objectives dictated when it was created.

Expert Bodies/Centers

Each committee has its headquarters and structures of its own. But the activities of these committees may be held in several structures or centers: universities, institutes, research centers, training centers, and seminaries.

Relevant Legislation

The National Ethics Committee (NEC), the Ethics Committee for Health Research (ECHR), and the National Biosecurity Agency (NBA) are empowered to create civil standards for the Government of Burkina Faso. The Catholic National Bioethics Committee (CNBC) can suggest ethical standards for the Burkina/Niger Episcopal Conference of the Catholic Church.

Public Debate Activities

When required all four ethics committees in Burkina Faso organize conferences and debates (see Table 54.2). The following topics of bioethics or ethics are often discussed at these conferences and debates: the beginning and end of life, customs and traditions (female circumcision, wife inheritance, and sororities), diseases (AIDS, malaria, genetic diseases, and cancers), traditional medicine (herbal

Table 54.2 Summary of activities of institutions working in the field of bioethics

Committees	Objectives	Publications	Teaching/ training	Conferences	Research authorization	Legislation
CNBC	Social ethics and political science	Publications	Many university courses	Performs numerous lectures	–	–
NEC	Social and political ethics, social peace	–	–	Conducts conferences	–	Propose laws
ECHR	Scientific research	–	–	–	Propose laws	Issue permissions
NBA	Biosafety	Many publications	-Training for members of national biosafety framework (CSNB, NBO, NBA); extension agents for cotton production	Performs many lectures	Gives practitioner	Implement laws

medicine), palliative care, corruption, citizenship, medical ethics, business ethics, and social and political ethics.

Major Bioethics Issues and Discussions

Main Issues in Bioethics and Discussions Faced by the Ethics Committees

Each committee has its specificities, its general purpose, and specific goals.

National Catholic Bioethics Committee (CNBC)

Beginning of Life

The Catholic National Bioethics Committee organizes congress, conferences, workshops, and discussions on the early life. The themes that are developed include the following:

- Sexuality
- Natural or artificial fertilization
- Genetic manipulation of the preimplanted embryo

- Eugenics,
- The voluntary termination of pregnancy (abortion)
- Identity and status of the human embryos
- The culture of life and AIDS (Simpore et al., 2011)

In this sense, for example, the following presentations and publications have been made:

- African Culture and Sexuality (Sanon, 1999)
- Bioethics and Sexuality (Sedgo, 1999)
- Bioethics and the Beginning of Life: Birth Control and Prenatal diagnosis (Pignatelli, 1999)
- Identity and Status of the Human Embryo (Flore, 1999)
- Abortion: Ethics and Law (Sawadogo, 1999)
- Canonical Benchmarks on Abortion (Ouedraogo, 1999)
- The New Frontiers of Genetics and the Risk of Eugenics (Simpore, 2010)

End of life

The National Catholic Bioethics Committee also addressed in presentations that it organized the topic of the end of life: euthanasia, dysthanasia, the dignity of the dying person, the quality of human life, bioethics, and the terminal stage of life.

Other Topics

The CNBC also has developed the themes of gender, traditional medicine, problems related to genetics, biomedical research, infectious diseases, African anthropology, the personalism in Africa (Simpore, 2004), bioethics, and human rights culture in Africa (Sawadogo, 2007).

Ethics Committee for Health Research (ECHR)

The ECHR, whose mission is to analyze and evaluate all research projects in Burkina health, addresses all the issues of health. However, conscious of not being omniscient, the committee appealed to any persons or corporation, for its jurisdiction, whenever necessary, in an advisory capacity. Note that so far, the committee does not develop and does not publish a theme related to the beginning and end of life, genetics, reproductive medicine, medical research, palliative care, and infectious diseases.

The National Ethics Committee (NEC)

The NEC is the observatory of society in Burkina Faso. Thus, by its functions, it ensures the preservation of republican and secular values in the moral, cultural, and human matters. It is also responsible for proposing and suggesting any measures for the preservation of civic responsibility and the morality of public and social life. Therefore, the policy of the NEC aims primarily at stimulating peace and social

justice, to fight against corruption, promote good citizenship, patriotism, good governance, and human rights. The conferences and public debates that it organizes relate primarily to these themes.

The National Biosafety Agency

The NBA, meanwhile, develops themes of discussions and debates related to biosafety in basic scientific research, food security, and environmental security. Indeed, the use of genetically modified organisms generates both hopes and fears within the general public, and, therefore, is the origin of controversial public debate. Based on state's funds through the Programme d'Appui aux Filières Agro-Sylvo-Pastorales (PAFASP) and supports from other partners such as US Agency for International Development (USAID), under the West African Cotton Incentive Program aimed at Strengthening the Cotton Sector in West and Central Africa (WACIP) in 2010, NBA struggles to strengthen its capacity and fully play its role by carrying out several important activities:

- Training on control and inspection of sites containing GMO
- Training on Biosafety-Clearing House (searching information on GMO) for members of the National Biosafety Framework, educational institutions (including professional schools), and professional workers such as customs officers and phytosanitary agents
- Training of 60 members of the National Biosafety Framework structures in evaluation and management for Biosafety
- 6 workshops of sensitization to raise awareness on Biosafety in six regions or a number of 3,658 participants
- Workshops of sensitization for decision makers (Conseil Economique et Social), opinion leaders (religious people)
- Open days of the agency, focused primarily on youth, with the participation of 8,000 students and secondary schools pupils in Ouagadougou and Bobo-Dioulasso
- Training on the content of the law in favor of 555 extension agents in cotton production and media workers (communicators)
- The translation of excerpts of the law on security system in biotechnology in three national languages or more than 10,000 copies distributed to producers
- Their wide dissemination in local languages on local radio antennas.

Future Challenges

In the Field of Bioethics Infrastructure: Need for Legislation, Ethics Committees, Ethics Education

In Burkina Faso, in the field of bioethics infrastructure, it is necessary to develop standards and strong laws against certain obsolete and outdated practices such as cutting of sex organs of girls (the phenomenon of female circumcision),

polygamy, sorority, and witchcraft (the murder of old women falsely accused by people of their village to be soul eaters). Some issues such as impunity, poor governance, and the heinous crimes are a real challenge for Burkina Faso. It would be an urgent need to educate and train people about the realities that hinder the country's progress towards peace and social harmony.

In the Field of New and Emerging Issues

In Burkina Faso and Africa in general, there are many new and emerging issues such as management of biotechnology products (transgenic organisms), biodiversity, conservation and protection of nature, the patenting of genes (markers or DNA sequences), bioterrorism, ICT, emerging diseases (HIV, AIDS, cancer, new deadly flu, and fatal hemorrhagic fevers that rise up from time to time), the issue of stem cells and their possible therapeutic use, and the standards and laws that guide and indicate clearly the way forward.

Summary/Conclusions

In this chapter topics such as birth, development, challenges, and perspectives of bioethics in Burkina Faso have been exposed. The promotion of ethics has been achieved through the action of the four structures that work in the field of ethics: the Ethics Committee for Health Research (ECHR), the National Ethics Committee (NEC), the Catholic National Bioethics Committee (CNBC), and the National Biosafety Agency (NBA). The challenges in the field of bioethics are enormous. From the beginning to the end of life through social and political ethics, human rights, corruption, good governance, social justice, emerging infectious diseases, biotechnology, gene therapy, to the science of the genome, transcriptome and proteome, man, facing 1000 challenges, is expected to act with a double-edged sword. Thus, the future of humanity seems to be in the hands of scientists who will handle almost freely, life. One thing is certain, in this early twenty-first century, the culture has become less theoretical and more pragmatic, and the fulfillment of human hopes today more than ever goes through science and its practical implications whose consequences are going to challenge the very basis of the civilization. The first challenge of genetic engineering, biotechnology is the dizzying pace of its own progress. How surprising to see the scientists themselves dizzy when they feel being authors and actors of this incredible development? The most immediate danger threatening the researchers is to believe that everything is allowed in this rat race. The search goes from conquest to conquest in biotechnology, and some scientists are convinced: there cannot and should not be any limits to their activity, progress itself justifying everything. With this regard, having dismissed the criticism prompted by a bioethics assessment, scientist mentality has succeeded in having many people accept the idea that what is technically feasible is automatically acceptable. However, everyone is now aware: science without conscience and

without wisdom is but the ruin of the soul and the deprivation of mankind. All errors are not forgiving. Could not an error of genetic manipulation cause monsters, imaginary beings? Would not this type of error cost much to humanity in terms of biological, anthropological, cultural, psychological, and social matters? But should one resign and let themselves be invaded by those fears without trying to distinguish what is ethically feasible from what is hazardous and therefore adventurous? No matter the precautions taken by the researchers, they will never get zero risks in biotechnology. There is always a risk, however, nothing ventured, nothing gained. But you have to know how well to risk. To do this, after evaluating, weighing everything against the integral good of man and the cosmos, you have to know how to risk it. The worst does not always occur. And perhaps countless fears might not even materialize. Still, in the criticisms about the performance and prospects of biotechnology, fears and expectations are inextricably intertwined and interwoven to make one believe that the human being, with his or her elusive and impenetrable ideas, is both actor and protagonist of a new booming biotechnology.

Godfrey B. Tangwa

Introduction

Cameroon, a former German colony (1884–1914) and subsequently a United Nations mandated territory entrusted partly to France and partly to Great Britain, is a Central African country with a population of approximately 20 million inhabitants (EDS, 2004) of which about 50 % are youth. Cameroon is a multiethnic, multicultural, and multilingual country (Tangwa, 1999), having English and French as its official languages, with French clearly predominating. The section of Cameroon that had come under French administration (about ¾ of the total

DOI 10.1007/978-94-007-2512-6_9,

population and land mass), following the departure of its German colonizers in 1914, had its independence in January 1960, while that under British administration (about ¼ of the total population and land mass) had its own independence in October 1961 at the same time that it reunified, following an 11 February 1961 United Nations–conducted plebiscite, with the French section. Cameroon shares territorial boundaries with the following other African countries: Nigeria, Chad, Central African Republic, Republic of the Congo (Brazzaville), Gabon, and Equatorial Guinea. Because of its great representative diversity, Cameroon is often referred to as "Africa in Miniature." The country has enjoyed political stability since the mid 1960s but the governing system is not easy to characterize using objective data and parameters. It might be described as a dictatorship slowly attempting to transform into a democracy. Cameroon's current ruler has been in power continuously for three decades and counting, in spite (or perhaps because) of the existence of over 200 opposition political parties and regular "democratic" elections. Cameroon is a country of many contradictions. It has remarkable biodiversity and enormous material and human resources, yet it ranks among the less developed of sub-Saharan African countries. The road infrastructure has experienced little change or improvement in the last three decades; youth unemployment and underemployment combined, by conservative estimates, is around 30 % and electricity and pipe-borne water are a luxury in nearly all of its towns and villages; urbanization and rural–urban migration have been quite intensive in the last three decades and several towns now have a population of over one million inhabitants; and yet, none of Cameroon's cities, including the capital city, Yaounde, has street names, let alone street numbers; and yet again, Cameroon's political elite count among the wealthiest and most highly educated on the African continent.

Disease Burden

Cameroon's great diversities and representativeness can be said to extend to the disease profile of the country. As in most other African countries south of the Sahara, a number of both communicable and noncommunicable diseases are endemic in Cameroon, of which malaria, drug-resistant tuberculosis, and HIV/AIDS are currently a major concern in the health sector because of their high prevalence and deadly nature. According to the Global Health Observatory of the World Health Organization (www.afro.who.int/index.php?option=com_docman&task=doc_download&gid=26&Itemid=2111, accessed 24 April 2011), 17.1 % of the population of Cameroon live below the poverty line (less than $1 a day). The infant mortality rate stands at 87 per 1,000 live births and the under 5 mortality rate at 149 per 1,000 live births. The major causes of death in children under 5 include neonatal-related causes, malaria, pneumonia, and diarrhea. The maternal mortality ratio for Cameroon is 730 per 100,000 live births.

This disease profile shows clearly some of the disease burden of Cameroon that should be the concern of public health authorities and researchers alike. For most of

the diseases mentioned above, the public health authorities in Cameroon do have long-term programs aimed at eradication or at least containment and general improvement of the situation, and there has been a significant increase in health research activity in the country in the last two decades or so, during which time a number of advanced medical technologies, such as endoscopic surgery or in vitro fertilization (Tangwa, 2002, p. 56), have been experimented or introduced. But the whole health situation of Cameroon raises ethical problems and challenges at several levels that may not be quite evident for the time being. For example, the introduction of sophisticated expensive technologies in a few urban centers of a country where potable water is still a rarity and where primary health-care diseases like cholera and meningitis still exist in epidemic proportions, or carrying out diverse intensive medical researches on human beings in a situation where prior ethical review of such research, let alone research governance and regulation, are still problematic (Tangwa & Munung, 2011) clearly raise ethical problems and challenges that need immediate and sustained attention.

Overview of the State of Bioethics

Like most developing countries, Cameroon is still in the process of embracing modern concepts and practice of bioethics, and the rate of progress is rather modest. Despite the multidisciplinary nature of bioethics, very few academic institutions in Cameroon have embraced it as a permanent subject on the curriculum and there are very few initiatives with an interest solely in bioethics. The increased incidence of health-related research, progress in molecular biology, research on genetically modified organisms (GMOs), particularly in the agricultural sector, the presence of fertility clinics, etc., have so far failed to generate or stimulate in Cameroon the sort of lively discourse, controversies, and debates that could lead to appropriate regulation and legislation as have been witnessed in other countries.

Traditional medical ethics is the only branch of bioethics with which many medical professionals in Cameroon are somewhat familiar. The first medical school in Cameroon (Centre Universitaire des Sciences de la Santé – CUSS) was created in 1969. Today (2012) a number of medical schools, both public and private, exist in different higher institutions of learning. But the contact of medical students with bioethics in Cameroon, up to the present, is more or less limited to the occasional lecture or seminar and those portions of traditional medical ethics related to the Hippocratic and Nightingalean Codes. At graduation, students of the Faculty of Medicine and Biomedical Sciences of the University of Yaounde 1 (formerly CUSS) take the following oath:

> *En présence des maitres de cette école, de mes chers condisciples et devant l'effigie d'Hippocrate. Je promets et je jure d'être fidele aux lois de l'honneur et la probité dans l'exercice de la médecine. Je donnerai mes soins gratuits à l'indigent et n'exigerai jamais un salaire au-dessus de mon travail. Je ne permettrai pas que des considérations de religion, de nation, de race viennent s'interposer entre mon devoir et mes patients. Admis à l'intérieur des maisons, mes yeux ne verront pas ce qui s'y passe, ma langue*

taira les secrets qui me seront confiés et mon état ne servira pas à corrompre les mœurs ou à favoriser le crime. Respectueux et reconnaissant envers mes maîtres, je rendrai à leurs enfants l'instruction que j'ai reçue de leur père. Que les hommes m'accordent leur estime si je suis fidele à mes promesses: Que je sois couvert d'opprobre et méprisé de mes condisciples si j'y manque!

In the presence of the teachers of this school, my dear fellow students and in front of Hippocrates' effigy, I promise and swear to be loyal to the laws of honour and probity in the practice of medicine. I will freely care for the poor and will never demand pay that exceeds my work. I will not allow matters of religion, nation and race to interfere with my duty and my patients. If I get into a house, my eyes will not see what is happening there, my tongue will not reveal the secrets which are confided to me and my presence will neither break manners nor favour crime. Respectful and grateful to my teachers, I will impart to their offspring the knowledge I have acquired from their father. May people respect me if I keep my promises: May opprobrium be heaped on me and my fellow students despise me if I fail! [English translation by the translation unit of the AMANET Sub-Hub (ASH), Yaounde].

The version of the Florence Nightingale Oath, as modified by the Cameroon Nurses Association and which is read by nurses during convocation ceremonies reads:

I solemnly swear before GOD and in the presence of this assembly, to faithfully carry out and fulfill the duties of my profession. I shall not willfully take or administer any dangerous drug. I shall do my best to improve the level of my profession.

I shall keep in total confidence anything private that will be confided to me and all the secrets of the family, as well as those of the services made known to me. I shall do my best to faithfully collaborate with other members of the health team and see to the well-being of those left under my care.

So help me God

Even as attempted adaptations and modernized versions, the text of these Codes harbor many archaic elements and important gaps that would surely have been addressed were there adequate consciousness of the current global state of the art of medical ethics, nursing ethics, or bioethics in general. It is instructive to compare the version of the Hippocratic Oath above with, for example, the version used by the Faculty of Medicine of the University of Bristol, UK, or that written in 1964 by Louis Lansagna, academic Dean of the School of Medicine, Tufts University, used by many other medical schools the world over. These other adaptations are succinct and free from both archaic ideas and language.

Biotechnology, molecular biology, bioinformatics, and genetic and genomic studies are not completely unknown in Cameroon, as they have recently been introduced at several institutions in connection with programs or projects in the health, agriculture, or environmental sectors. Some Cameroonian researchers and research institutions are taking the initiative in some of these novel and important fields of research, either alone or in collaboration with northern colleagues and institutions, as can be gleaned from some of the publications emanating from the country.

However, these novel fields of research raise equally novel ethical problems and challenges. There are, for example, ethical questions and issues that are related to research that uses bioinformatics tools (Marturano, 2009a, b) and others that are

related to genetic and genomic research (De Vries et al., 2011; Dubochet, 2009; Roche, 2009; Trinidad et al., 2010). Some of these problems, in the case of Cameroon, have recently been highlighted in a published paper on the ethical aspects of human genetic studies in sub-Saharan Africa (Wonkam, Kenfack, Muna, & Ouwe-Missi-Oukem-Boyer, 2011).

In 2003, Cameroon's Ministry of Environment and Nature Protection proposed a law (Law N° 2003/006 of 21 April 2003) that had been adopted by Cameroon's Parliament or National Assembly. This law focuses on "Safety Regulations Governing Modern Biotechnology in Cameroon" and has as main objectives the following:

- To regulate the safety, development, use, manipulation, and cross-border movement of genetically modified organisms that may negatively affect human and animal health, biodiversity, and the environment
- To ensure safety and ethics in modern biotechnological research and development and lay down the procedure for cross-border movement of genetically modified organisms
- To provide mechanisms for assessing, managing, communicating, and controlling the risks inherent in the use of genetically modified organisms or those having new traits as a result of modern biotechnological activity that may negatively affect the environment. . . ."

This law addresses a number of issues in the area of biotechnology including a chapter on "Approval and Authorization." This section states that any research activity, development, production, or manipulation of genetically modified organisms (GMOs) shall be subject to approval by a competent national administration whose decisions are taken within a national committee made up of services and concerned bodies. The "competent national administration" and the "national committee" are not specified nor are the "collaborating services" named. In any case, this law covers only the agricultural domain and does not address genetic technology and manipulations in the domain of human health and health research. Moreover, it is not evident that this law is enforced and it is doubtful that the majority of researchers and users of GMOs in Cameroon are even aware of the existence of this law.

A section of the above law addresses the socioeconomic concerns connected with the use of GMOs. It requires that, before the deliberate release of GMOs into the environment, a thorough study of their ethical and socioeconomic impact on the local population be conducted by a competent authority. This shows, at least, some general awareness that ethical issues/problems are linked with biotechnology but the method and detailed procedures for dealing with them are nowhere specified.

Assisted Reproduction

The WHO estimates that one in four of ever-married women of reproductive age in most developing countries are infertile because of primary or secondary infertility (WHO-DHS, 2004). However, the country statistics for Cameroon fails to report on the infertility rate of the country and rather reports on the fertility rate, which stands at

approximately five children per woman in 2004 (http://www.afro.who.int/index.php?option=com_docman&task=doc_download&gid=26&Itemid=2111). The problem of infertility in Cameroon and Africa in general is an important one especially as people increasingly are taking biological parenthood much more seriously than in the traditional past. This poses social pressures on infertile couples, often leading to a frantic desire to have their own biological child(ren) by all means. In Africa, infertility is considered a curse and having children is still the main reason for marriage and a good reason for polygamy (Tangwa, 2002). As a result, some Cameroonians would surely be celebrating the discovery of in vitro fertilization. Generally speaking, assisted reproduction is not new in the Cameroon context, as it is an important cultural aspect of most tribes or ethnicities. However, this is assisted reproduction mostly in the form of, say, a brother or close relative helping an impotent or infertile kindred by having children for him with his wife or a wife getting a second wife for her husband, if she believes herself to be responsible for their childlessness (Tangwa, 2008). However, "in vitro fertilization," "frozen gametes," "surrogate mother," "hired womb," and "postmortem parenthood" remain new concepts and vocabularies almost unheard of by many in Cameroon. Though the treatment of infertility is not yet included in Cameroon's health priorities, Cameroon witnessed the introduction of a fertility clinic in the health sector as early as 1972 and, by 14 April 1998, the first success story of clinically assisted reproduction was registered with the birth of Tommy, the first "test tube" baby born in the central African subregion (http://www.cliniqueodyssee.com/2fivpress.htm – accessed 29 April 2011).

It is interesting to note that IVF, for example, which has generated so much debate and even litigation in other parts of the world, could be so quietly introduced in Cameroon. Although IVF certainly solves an important societal problem (infertility), it raises a plethora of ethical concerns, especially for traditional cultures, ranging across considerations related to artificiality, justice, autonomy, risk/benefit ratio, status of the embryo, etc., awareness of which would be incompatible with indifference. At the moment, the law in Cameroon remains silent on these issues and there is little or no discussion on the ethics of these technologies. Some of the reasons for this state of affairs may be related to the fact that such discussion would traditionally be considered taboo in some areas and, in any case, IVF is a service that is unaffordable to the vast majority of those who may need it.

Health Research Ethics

As of 2010, research studies on HIV/AIDS in Cameroon had given rise to a total of 2011 scientific publications (which is partly attributable to the fact that there exist a variety of HIV strains in Cameroon (Peeters, Toure-Kane, & Nkengasong, 2003) which the international research community finds fascinating. However, health-related research in Cameroon is not limited to HIV but includes other communicable and noncommunicable diseases, as most of these diseases are endemic in Cameroon. Most of this health-related research is, however, externally funded (Nyasse, 2005).

With the ever increasing research activity going on in Cameroon (Tangwa, 2007), one would expect that research ethics should also be gaining ground in the country. And, compared to the other branches of bioethics, research ethics can indeed be said to be relatively more developed in Cameroon, but still in general terms rather rudimentary, when compared to the state of research ethics in the developed world or in other African countries, such as South Africa, Ghana, Kenya, or Tanzania. Currently, there are initiatives aimed at building capacity in research ethics for both members of research ethics committees and researchers involved in health-related research. Most of the training in research ethics in Cameroon has been done directly or indirectly (through funding) by the African Malaria Network Trust (AMANET) and the European and Developing Countries Clinical Trials Partnership (EDCTP). A recent Initiative, the Central African Network for Tuberculosis, HIV/AIDS and Malaria (CANTAM) has as one of its objectives to build capacity in clinical trials and ethics in the Central African subregion. Other initiatives concerned with capacity building in research ethics include the Cameroon Bioethics Initiative (CAMBIN), the Cameroon Bioethics Society (CBS), and the Reseau sur l'éthique, le Droit et le SIDA, (REDS), Cameroon.

But in spite of these efforts at capacity building in research ethics and awareness creation, Cameroon's Minister of Public Health, as recently as February 2011, in a circular letter addressed to all stakeholders in health research, could justifiably still open his letter with the following statement:

"Mon attention a été attirée sur le fait que malgré les différentes instructions relatives à la mise en oeuvre de projets de recherche en santé au Cameroun, un grand nombre d'activités de recherche continuent d'être menées dans vos différentes structures sans autorisation préalable du MINSANTE." [My attention has been drawn to the fact that, in spite of the various instructions regarding the implementation of health research projects in Cameroon, a good number of research activities continue to be carried out in your various structures without the prior authorization of the Ministry of Health]. (Lettre-Circulaire No. D36-13/LC/MINSANTE/SG/DROS/YC). The minister here is, of course, primarily concerned about administrative authorization of health research, but this should go hand in glove with ethics clearance, which is even more important for such research, but things are evidently not yet perfectly united in Cameroon for a human-subjects research environment free from serious ethical concerns. Efforts are currently underway in the Ministry of Public Health to formulate clearer guidelines related to the creation and functioning of research ethics committees which fall under its administrative jurisdiction. But, while this is a very welcome development, it is in principle still a far cry from what is urgently needed, namely, overall country regulation and guidance of biomedical research, especially human subjects research (Tangwa & Munung, 2011).

Animal Ethics

Very little or nothing is heard about animal ethics in Cameroon in spite of the fact that a number of research laboratories use animals such as mice, rats, rabbits, and

nonhuman primates for experimental purposes. There are no animal research ethics committees in Cameroon, and human research ethics committees are scarcely ever concerned about the welfare of animals used in research.

However, some Cameroon-based researchers in the biosciences are increasingly using methods like computer simulations and bacteria and cell culture techniques, and a few laboratories are already working toward the production of monoclonal antibodies (Cho-Ngwa, Daggfeldt, Titanji, & Gronvik, 2005) which could help in reducing the need for animals in research. Based on this, it could be said that researchers in Cameroon are gradually moving toward promoting the 3R principle (Replacement, Reduction, and Refinement) which features among the principles of good clinical practice (GCP).

Training in Bioethics

Currently there are no academic institutions that provide formal training in research ethics in Cameroon and the majority of researchers and members of Research Ethics Committees (RECs) have to rely on web-based courses or workshops and seminars to obtain training in research ethics (Ateudjieu et al., 2009; Nyika et al., 2009). There is, therefore, only very nominal training in bioethics in Cameroon, most of which is focused on health research ethics. Such training is predominantly in the form of workshops or symposia, usually lasting 1–5 days. The target group has predominantly been members of RECs, though a few have targeted investigators or members of drug regulatory bodies. Long-term (greater than a month) training in research ethics is atypical in Cameroon (Tangwa & Munung, 2011). An intensive 2-week course for preclinical and clinical medical students at the Faculty of Medicine and Biomedical Sciences (FMBS), University of Yaounde 1, introduced as part of a cooperation program with the University of Geneva, ran for a few years but floundered on organizational and communication problems and the lack of appropriate interest by the Faculty authorities. Recently, the University of Dschang introduced a course in research ethics to be taught to students in the biological sciences involved in research, but whether such initiative will be sustainable and how it may evolve remains to be seen, especially as it is not evident that the University disposes of qualified teachers for such a course.

Research in Bioethics

There are few empirical studies on bioethics in Cameroon and these mostly are concerned with research ethics. The primary focus has been on assessing the needs or identifying training gaps of RECs (Ateudjieu et al., 2009; Nyika et al., 2009), while a few others have focused on the failed tenofovir trials of the early 1990s in Cameroon (Mack, Robinson, Macqueen, Moffett, & Johnson, 2010). Other researchers have used a bibliometric approach to assess adherence by scientists in

Cameroon to some basic research ethics requirements (Munung, Che, Ouwe-Missi-Oukem-Boyer, & Tangwa, 2011a; Wonkam et al., 2011) and publication ethics in Cameroon journals (Nchangwi, Asahngwa, & Che, 2009). Besides the few empirical studies in bioethics, there exist few academic writings on bioethics in Cameroon. These have mostly been authored by students (theses and dissertations written as partial requirements for obtaining an academic qualification in the university) and researchers (books, book sections, journal articles) in the humanities faculties of universities. The bibliography on bioethics in Cameroon is therefore rather small at present.

Current Bioethics Infrastructure

There are very few structures in Cameroon which can be said to be wholly or partly dedicated to bioethics issues. In fact, most of the structures that exist are in the form of research ethics committees, created in response to the needs of various researchers and research institutions but most of which are not officially recognized let alone accredited by the government. Aside from RECs, there exist a few nongovernmental and not-for-profit organizations dedicated to bioethics issues. These organizations usually have very little funding for their activities as a consequence of which their actions and sphere of influence is rather limited. The activities of these organizations vary but are mostly geared toward sensitization through training workshops or seminars and publications in journals, magazines, and newspapers. Some of these organizations are briefly highlighted below.

Cameroon Bioethics Initiative (CAMBIN)

CAMBIN was created in 2005 and officially recognized in 2006. It is the Cameroon chapter of the Pan African Bioethics Initiative (PABIN). CAMBIN is a not-for-profit, non-governmental, non-political and non-discriminatory, multidisciplinary association with official seat in Yaoundé. The overall objective of CAMBIN is to enable the development of bioethics in Cameroon with the main focus on capacity building and empowerment in biomedical research, through the promotion of research ethics. CAMBIN equally shares the goals and objectives of PABIN and coordinates its activities in such a way as to foster the development of biomedical research through the promotion of bioethics in Africa (Tangwa & Munung, 2011). CAMBIN is equally involved in empirical research in bioethics, organization of training workshops and sessions in bioethics and active participation in bioethics debates in the country. CAMBIN has a research ethics review and consultancy committee, which in addition to reviewing research protocols also provides consultancy services for biomedical research and ethical review of research in Cameroon and the Central African subregion. The administrative structure of CAMBIN is made up of the General Assembly, the Executive Council and the Ethics Review and Consultancy Committee. Membership into

the organization is open to all persons and institutions interested in bioethics. The current membership of the institution which stands at about 75, is divided into three categories: ordinary members, institutional members, and honorary members. The academic background of its current membership is diverse and is mostly in the biosciences, social sciences/humanities, clinical sciences, law and engineering.

Since its creation in 2005, CAMBIN has registered a number of successes in the area of capacity building through the organization of training workshops for members of research ethics committees as well as for researchers. In recent years CAMBIN has teamed up with AMANET and CANTAM to conduct capacity-building in health research ethics in central Africa for members of ethics review committees and medical products regulatory authorities. The research arm of CAMBIN has recently also become active and is involved in empirical research in bioethics which has led to a number articles in international peer-reviewed journals (Munung, et al., 2011a; Nchangwi et al., 2009; Tangwa & Munung, 2011) and presentations (oral and poster) in international scientific meetings (Munung, Tangwa, Che, Vidal, & Ouwe-Missi-Oukem-Boyer, 2011b; Ouwe-Missi-Oukem-Boyer, Nyika, Munung, Tangwa, & Ntoumi, 2011).

The major setbacks to the daily operation of the organization have been the lack of adequate legislation governing research and bioethics in Cameroon as a whole and the fact that there is very limited funding available for its activities.

Cameroon Bioethics Society (CBS)

Created in 1995, the Cameroon Bioethics Society (CBS) is, perhaps, the earliest nongovernmental and apolitical organization solely interested in bioethics issues. The mission of the CBS, according to its own report, is to promote information and debates on ethics and morality of life and health and also to organize meetings on scientific and cultural issues on bioethics. Its activities involve promoting specialized studies in the field of Public Health and Human Rights, continuous training of health professionals and members of Ethics Committees, the provision of scientific documentation of high quality, generating interest in bioethics within the scientific community in Africa, promoting the development of ethics and bioethics research in Africa with particular emphasis on African perceptions of bioethics, increasing scientific capacity for multidimensional ethics review and public health in Africa (Cameroon Bioethics Society and the Public Health and Bioethics Research Centre. Report of the Cameroon Bioethics Society, 1990–2008). The CBS has in the past years organized some training workshops in research ethics. It does not, however, seem to have been very active in recent years.

Reseau sur l'éthique, le Droit et le SIDA (REDS), Cameroon

REDS is the Cameroon branch of the African Network on AIDS, Ethics and Human Rights, better known by its French appellation: Réseau Africain sur l'Ethique,

le Droit et le VIH. REDS Cameroon has its headquarters in Yaoundé and is an activist group, created in 1998 and officially legalized in 2000. The main mission of this organization is to advance knowledge and improve education in the ethical and legal fields and to promote actions and measures that respect especially human rights in the fight against HIV/AIDS in Cameroon. The current areas of intervention of REDS include public policy and human rights, ethics and biomedical research, clinical ethics, resource mobilization, and direct aid, including legal and judicial assistance for persons living with HIV/AIDS (PLWHA) and their relatives.

In 2005, together with eight other organizations, REDS set up an interassociative working group on biomedical research in Cameroon (GTIA), whose objectives consist of effective and appropriate ethical review of research protocols especially on HIV-related research; ensuring that sloppy and unethical research does not go through unnoticed; participating in the protection of persons recruited as research participants in biomedical research; helping researchers and research agencies in optimizing their research protocols and acting as a watchdog for research studies carried out in Cameroon (Yomgne, 2008, 2009b).

REDS participated actively in the attempt at protecting research participants that were recruited in the controversial Tenofovir trials in the early 1990s in Cameroon. However, REDS Cameroon admits a couple of challenges and these include the fact that GTIA is yet to convince many researchers and research agencies of their ability to be neutral and to protect the ideas of researchers who submit their research proposals for review (Yomgne, 2009b).

The presence of these nongovernmental, bioethics-related organizations in Cameroon has helped to spark up some bioethics discussions, if not debates, in the country. Of particular note here are current discussions within the Ministry of Public Health to better organize health research and research regulation within the ministry, including the creation of a more credible nation-wide ethics review committee, subsequent to, if not perhaps consequent on, the critiquing of the "national ethics committee" (Tangwa & Munung, 2011).

Current Bioethics Issues, Discussions, and Debates

As already stated, research ethics is relatively more advanced in Cameroon when compared to other branches of bioethics. Accordingly, the majority of bioethics issues, discussions, and debates in Cameroon occur around research ethics. Nevertheless, very little progress has been made even in the area of research ethics. As a matter of fact, most of the discussions and debates on research ethics began after the Tenofovir trials were suspended in Cameroon and Cambodia. A couple of workshops to build the capacity of researchers and members of RECs in research ethics have been organized in Cameroon, mostly with foreign institutions taking the lead and/or footing the bill. There is very little effort in terms of funding from the government of Cameroon to build capacity in research ethics. The initiative to organize training is taken by some nongovernmental organizations with very little

funding or with funding from international organizations. Consequently, the level of research ethics in Cameroon is still rather embryonic. Very few members of research ethics committees have even basic training in research ethics (Ateudjieu et al., 2009), while many investigators, graduates, and medical students have only the most rudimentary notions about research ethics.

There are a good number of research ethics committees in Cameroon though, for the time being, only two – the National Ethics Committee (NEC) and the Ethics Committee of the Chantal Biya International Reference Centre (CIRCB) – are officially recognized by the Ministry of Public Health which is charged with the approval or recognition of RECs in Cameroon. Researchers in Cameroon have in the past years obtained or at any rate documented research ethics approval from a plethora of RECs and IRBs in Cameroon (Munung et al., 2011a). In 1987, there existed just one ethics committee in Cameroon and by 2009 the number had greatly increased. It is arguable if "unrecognized" RECs in Cameroon, some of which conform fully to international standards and regulations, should continue to exist unrecognized. In this regard, some of the RECs/IRBs have submitted files to the Ministry of Public Health requesting official recognition though, till date, a decision on their official status is yet to be obtained. In the meantime, these RECs continue to review research protocols in spite of the uncertainty and lack of clarity regarding their official status. The state of RECs in Cameroon thus remains rather controversial (Tangwa & Munung, 2011) when compared to other countries like South Africa, Kenya, Ghana, Tanzania, or Nigeria that have a clear system of accreditation of RECs.

The status of Cameroon's National Ethics Committee (NEC) remains contentious and has been a topic of debate amongst individuals and groups/organizations involved in research and bioethics in Cameroon. Though the government of Cameroon created the first research ethics committee in 1987, the committee had no specific appellation as the text of creation referred to it simply as "an ethics committee." Today, there exists a National Ethics Committee (NEC) in Cameroon, which is assumed to be the ethics committee that was created in 1987, though its mode of operation, membership, financing, and accommodation appear to be very different from what is stated in the 1987 ministerial decision creating the first ethics committee (Tangwa & Munung, 2011). There exists no ministerial decision creating or explicitly recognizing the National Ethics Committee (NEC) of Cameroon as it is today, whereas there does exist one creating the ethics committee of the CIRCB. There have been calls on the authorities to create a national ethics committee, which, Tangwa and Munung (2011) proposed, should have the status of an overseeing body as is the case with some other national ethics committees elsewhere. In an era of increased scientific research in the country and ongoing debates on bioethics worldwide, coupled with the high incidence of scientific misconduct globally, it is important and urgent that such a situation be rapidly regularized to meet up with the global challenges of scientific research.

Equally significant is the fact that both government-recognized ethics committees are located in Yaoundé, Cameroon's administrative capital, whereas research is going on in universities and research institutions located in many other parts of the

country. It has been urged that the government should move quickly to recognize credible IRBs/RECs, in the interest of facilitating research review, as the current situation could easily lead researchers to consider ethics review as a bottleneck to research. None of the RECs in Cameroon receives any funding from the government despite the fact that the 1987 ministerial decision clearly stated that funding for the ethics committee that was created was to be the responsibility of the government of Cameroon. All the existing RECs in the country therefore seek external funding, charge fees for review, or rely on the generous contributions of their members. Overall, there is no national framework for the operation of RECs in Cameroon and the current situation appears rather chaotic (Tangwa & Munung, 2011).

Concerning the legal and administrative underpinnings of research ethics or bioethics, there exist, in addition to a single law governing modern biotechnology (Law No. 2003/006 of 21 April 2003), only two "ministerial decisions" pertaining to research ethics in Cameroon. The very first of these decisions was signed in 1987 creating an ethics committee and the second in 2009 stating conditions for obtaining administrative approval for research studies. Outside of these, recourse has to be made to the general criminal law or the constitution to find a legal basis for arguments in research ethics or bioethics in Cameroon.

The Tenofovir Trial in Cameroon

The controversies surrounding the tenofovir trials have been among the liveliest in the area of research ethics in recent times in sub-Saharan Africa.

The tenofovir trials were carried out not only in Cameroon but also in Cambodia and other countries. They were carried out on commercial sex workers and were prematurely suspended in February 2005, after a Paris-based organization – Act Up-Paris – criticized the trials on ethical grounds. Some studies have attributed the failure of the trial to insufficient media preparation and understanding of the study (Mack et al., 2010; Mills et al., 2005), while some hold that there were substantive ethical problems in the way the trials were conducted in Cameroon (Munday, Lubangi, Mukandu, & Leyens, 2006). The trial sought to recruit approximately 400 commercial sex workers in Cameroon as research participants. The research protocol for the trial had been reviewed and approved by the National Ethics Committee of Cameroon. Several reasons have been advanced for the failure of the trial in Cameroon, including inadequate access to care for sero-converters, participants not sufficiently informed of risks, inadequate number of staff, exploitation of study participants, and unethical study design (Mills et al., 2005). Trial documents pertaining to research participants such as informed consent forms were only in English whereas the city of Douala where the trial was taking place is predominantly French speaking. There was also no provision for future access to tenofovir for trial participants (Yomgne, 2009a) in case the trial was successful. Follow-up studies by the team of REDS (Yomgne, 2009a) indicate that, though the National Ethics Committee of Cameroon had approved the trial, it was unable to

conduct visits to the trial site, owing to lack of funds. According to the REDS team, which had interviews with some officials involved in or, in some other way, connected to the tenofovir trial:

- The president of Cameroon's National Ethics Committee did not recall if the protocol made reference to medical care for sero-converters, did not offer female condoms, or made provision for future access to tenofovir, should it be found effective. He nonetheless noted that he was informed that care was to be provided to participants who sero-converted during the course of the trial.
- The principal investigator (PI) of the study agreed there was no French version of the trial documents and that the provision of the female condom was not included in the trial protocol, but, however, he argued that potential participants were not familiar with the female condom and that incorrect use of the female condom could only help in increasing their exposure to HIV infection. He promised to ensure that trial documents were translated into French and to discuss the other issues raised with Family Health International (the sponsor of the trial).
- An official responsible for oversight of HIV/AIDS trials in the National HIV/AIDS Committee of Cameroon said he was not aware of the planned trial.

Following the controversies surrounding the trial, France 2, a Paris-based television station aired a program on "what the pharmaceutical companies don't tell us" (Yomgne, 2009a). This was closely followed by demonstrations that condemned the trial (Tangwa & Munung, 2011). The trial coordinator noted that though he had been interviewed by France 2, his interview was greatly censored while the Cameroon minister of public health announced that the study was quite ethical (Yomgne, 2009a). In his write up, Yomgne (2009a) further noted that the investigations of the National Medical Council of Cameroon showed that there were both administrative and legal gaps in the conduct of the study.

The tenofovir trials could have provided insights about a potential microbicide for HIV prevention, an initiative with important implications for developing countries. However, owing to administrative and ethical shortcomings, in addition to poor media coverage and rumors, a potentially important study was prematurely suspended in Cameroon.

Future Outlook and Challenges for Bioethics in Cameroon

The current state of bioethics in Cameroon poses a whole lot of challenges. Its growth and development are not matched by the global growth and trends in bioethics and health research as a whole. The current lack of interest in research ethics by government and policy makers has been a serious handicap in the growth of bioethics in Cameroon. For research ethics and bioethics as a whole to develop firm roots in the country, the government needs to participate in and to encourage bioethics initiatives in the country. Such interest should go beyond taking part in opening ceremonies for bioethics workshops. Policy makers should be able to

follow up and execute recommendations reached at such workshops and to provide the necessary conditions for those who have been trained to practice bioethics in their various institutions.

Overall, there exist as already stated three regulations related to bioethics and research ethics in Cameroon and two of these are in the form of "ministerial decisions." Only one (the law governing modern biotechnology) has passed through Cameroon's law-making body (the national assembly or parliament). Though the presence of these regulations can be said to be proof of government's efforts to promote bioethics, they are clearly still quite inadequate in the face of current global challenges in bioethics. For such laws to be comprehensive and effective, a wide range of different kinds of expertise drawn from several fields including bioethics, the biosciences, medicine, law, and the humanities need to be sought in the conception and drafting of such regulations. The government of Cameroon therefore has the challenge of ensuring that adequate regulations and laws on bioethics are put in place, for Cameroon to be able to meet up with some of the ethical challenges arising from the rapid progress in the bio-sciences, the health sciences, and health research.

Many authors have identified the need for African countries to draw up regulations that govern health-related research in their various countries. The recommendations are that such country-specific laws should be guided by international guidelines but should take into account the local, cultural, legal, and medical situation of each country (Chima, 2006). Chima (2006) further argues that such regulations should address issues of local research ethics committees, standard of care, informed consent, and compensation for injuries that are sustained through participation in any sponsored research. However, the current focus and emphasis on regulation in bioethics in Africa has been on the development of regulations governing biomedical research in Africa. Africa, and Cameroon in particular, needs to draw up guidelines that go beyond biomedical research. Such guidelines should address issues pertaining to all forms of research involving the use of humans as research participants as well as other bioethics-related issues like animals in research, end of life decisions, routine medical care, in vitro fertilization, the use of genetically modified organisms, reproductive health, access to essential drugs, intellectual property rights, and global health training.

Access to essential medicines which has even been described as a basic human right is at the center of bioethics discussions around the globe. The WHO defines essential medicines as medicines that satisfy the priority health-care needs of the population and are selected with due regard to public health relevance, evidence on efficacy and safety, and comparative cost-effectiveness. Thus, essential medicines are intended to be available within the context of functioning health systems at all times in adequate amounts, in the appropriate dosage forms, with assured quality and adequate information, and at a price the individual and the community can afford (http://www.who.int/topics/essential_medicines/en/).

In Cameroon, essential medicines are sold at relatively reasonable prices in the pro-pharmacies located in public hospitals and there is a National Centre for Essential Drug Supply that is charged with the responsibility of supplying these

drugs to hospital pharmacies. Provision of essential drugs in pro-pharmacies has been possible thanks to international aid such as that of Merck and Co. Inc. (which provides Ivermectin free of charge for the treatment of onchocerciasis), the Global Fund, and the Clinton Foundation that subvention antiretroviral drugs. Recently (2011), the Cameroon government has also announced that treatment for uncomplicated malaria in children below 5 years will be provided free of charge. However, all these measures are not yet adequate or sustainable. Most Cameroonians do not use public hospitals for a variety of reasons, including, but not limited to, poverty, inaccessibility owing to the horrible condition of the roads infrastructure, and studies have shown that many people in Cameroon buy drugs from sources other than the pro-pharmacies located in public hospitals (Chana & Bradley, 2011). And, in spite of international and local efforts, Cameroon is one of the African countries yet to achieve universal treatment for HIV/AIDS. The government of Cameroon is evidently still facing the task of providing accessible and affordable health care to its 20 million inhabitants.

Education in bioethics is, for the time being, the most important precondition for the promotion of bioethics in Cameroon. Training in bioethics in Cameroon has mostly been in the form of short-term training (1–5 days) and it has in most cases been focused on research ethics for members of ethics review committees. Overall, there has been a general apathy toward introducing courses in bioethics in the curriculum of universities in Cameroon. This situation needs to evolve if the growing needs for human capacity building in bioethics in Cameroon are to be met.

The tendency in training in bioethics in Africa and Cameroon in particular has been to focus on individuals in the biomedical sciences. However, with the current global situation in bioethics and the fact that bioethics is by its very nature multidisciplinary, there is a need to train students across a wider range of disciplines relevant to bioethics and to encourage them to take up research and professional careers in bioethics. It is only with such approach that adequate human capacity in bioethics can in the long run be achieved in Cameroon.

Conclusion

Cameroon is in many ways a very remarkable country with enormous potential in many domains. Given its remarkable bio and other diversities, its material and human resources, its disease profile, and even available local expertise, Cameroon is a country where all aspects of bioethics should be exciting and flourishing. But, while the main outlines of bioethics activities are indeed present and visible, they are evidently underdeveloped. The underlying fundamental reasons for this situation of underdevelopment must be linked to the overarching politico-administrative-economic system of the country, because other mainly Francophone countries operating similar systems, especially in the same central African subregion, present very similar profiles. Innovative efforts at capacity building in bioethics need to be experimented in Cameroon and other Francophone countries, especially of the central African subregion.

Bioethics Development

When and How Has Bioethics Started?

The launch of the Bioethics Centre at the *Institut de recherches cliniques* de Montréal in November 1976 essentially represented the birth of bioethics in Canada. It was the initiative of Dr. Jacques Genest, founder of the *Institut*, who believed that his research center needed to have within it an ethics "laboratory" that would foster interdisciplinary discussion on the moral and social issues posed by developments in biomedicine. David J. Roy, philosopher and theologian, was the center's first director.

Who Have Been the Major Actors/Forces?

The creation of the Centre for Bioethics was not an isolated event (see section "When and How Has Bioethics Started?"). During the same period, other organizations were interested in certain biomedical ethical issues.

In 1978, the Medical Research Council of Canada (MRC) published its first ethical standards for research with human participants (Medical Research Council of Canada [MRC], 1978). It obliged universities receiving grants from it to put in place local research ethics committees. The MRC played a determining role in the development of research ethics in Canada.

The Law Reform Commission of Canada (LRCC), a federal government agency founded in 1971, played a major role in the study of the new biomedical ethical issues emerging at the time. From the beginning, it placed great importance on these subjects and created a section called "Protection of Life." and published various documents that were authoritative in the areas involved.

Other centers were established later and had a major influence on the development of bioethics in this country like the University of Toronto *Joint Centre for Bioethics* founded in 1995, the *John Dossetor Health Ethics Centre* at the University of Alberta where activities in bioethics started in 1985 and the *Centre de recherche en droit public* (CRDP) of the Faculty of Law at the *Université de Montréal*, founded in 1962 which began in the early 1980s to develop a large bioethics sector.

In the 1970s, names appeared of people who can be considered pioneers of bioethics in Canada. These scholars wrote articles, produced collective works, or played an official role in one of the organizations mentioned. In ethics per se, the names of David J. Roy, Edward W. Keyserlingk, Guy Durand, Benjamin Freedman, Abyann Lynch, Susan Sherwin, Guy Bourgeault, Barry Hoffmaster, Eike-Henner Kluge, and Hubert Doucet are worth mentioning.

What Have Been the Major Concerns Over Time?

In the early days of bioethics, attention was on the following questions:

The first actors were called on to specify the nature of this new field. Many physicians held that traditional medical ethics and professional ethics were sufficient to resolve the issues raised by the extraordinary advances in biomedicine. Philosophers wondered about the pertinence of this new form of ethics, which related to concrete cases rather than fundamental issues. Theologians, concerned with concrete behaviors, were more involved in this field. The tensions in the early 1980s over the creation of a Canadian association of people interested in bioethics are evidence of the differences in points of view on the very nature of this new field.

When the Medical Research Council published its first guidelines on research ethics (MRC, 1978), there was a lack of consensus on the new requirements for researchers, on the creation of local ethics committees, on the presence of lay people on the committees reviewing scientific projects, and on the obligation imposed on researchers to obtain the participant's consent.

Debate raged over abortion in the 1970s, owing to, among other things, the various proceedings brought against Dr. Henry Morgentaler, a pro-choice advocate who challenged abortion law in Canada, but this question did not really capture the attention of the emerging bioethics community. Rather than being interested in the issue of the freedom of women, bioethics was concerned about the condition of the fetuses and of children with congenital malformations. Discrimination against disabled persons was at the heart of the debate, since fetal malformation was the reason for rejection of the fetus. Another concern at the time was the sterilization of persons with a mental disability. A quasi-consensus in favor of authorizing sterilization in this context had developed, following the LRCC document *Sterilization*: *Implications for Mentally Retarded and Mentally Ill Persons* (Law Reform Commission of Canada [LRCC], 1979). A Supreme Court decision in 1986 opposing this trend puts an end to the discussions.

With regard to end-of-life issues, interest was on the appropriateness of treatment withdrawal that could lead to the patient's death. The focus was on two points: the criteria for withholding and withdrawing treatment and the responsibility for decision-making. Consent was a central issue in the debate.

These subjects are still being debated, although their content has undergone major changes. Other topics have been discussed and only those not addressed in the section "Major Bioethics Issues and Discussions" will be addressed here.

There were a lot of debates in clinical ethics (the term "clinical ethics" was born in the late 1970s) on the role of ethicists in ethical consultation and on the mandate of the clinical ethics committees that were formed in hospitals during the same period.

The AIDS pandemic gave rise to fierce debate about such things as the care to be provided, the policies to be promoted, the social behaviors to be encouraged, and the types of research to be put in place.

The tainted blood scandal which, in Canada, conducted to the infection of 30,000 Canadians because the Red Cross, the federal, the provincial, and the territorial governments did not act fast enough to control the spread of HIV led to the establishment in 1993 of a Royal Commission of Inquiry chaired by Judge Horace Krever that revealed the challenges faced by the various health organizations of the period and the weaknesses in the blood system management (Royal Commission of Inquiry on the Blood System (Krever Commission), 1997). Following the Report, Canadian Blood Services and Hema-Quebec were established in 1998. Resource allocation remains the central issue at the heart of all the health debates. In the 1970s and 1980s, discussions on the lack of resources focused more on the importance of increasing resources by developing drugs, injecting more money into the system, or educating the public on the need for more organ donation. Beginning in the early 1990s, due to the economic context, the question becomes the following: What system should be developed, given the cost of services and the limits of the ability to pay? (Evans, 2002).

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

Among the monographs that contributed to the debate on ethical issues in Canada during the 1970s were the working documents and reports of the Law Reform Commission of Canada (Protection of Life Series) and a series of four works, in French, published by the *Centre de bioéthique of the Institut de recherches cliniques de Montréal* (IRCM), affiliated with the Université de Montréal (Centre de Bioethique, 1979, 1980a, b, 1982). Moreover, *Biomedical Ethics in Canada* by John R. Williams (1986), which provides an overview of the field during this period, is a very useful reference work.

What Have Been the Steps/Measures Taken (Policies, Legislation, Infrastructures, Teaching Programs, Committees, etc.)?

Canada's initial approach was to promote ethical reflection and the self-regulation of relationships in the health-care sector and in the development of the biological sciences. This ethical reflection mainly occurred within the academic milieu, professional associations, and religious groups. Overtime, professional health associations adopted codes of ethics, and in 1978, the Medical Research Council of Canada published a guide for research involving human subjects (MRC, 1978).

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

The database of the Association of Universities and Colleges of Canada provides a list of bioethics programs currently offered in Canada (Association of Universities and Colleges of Canada [AUCC], 2013). It is interesting to note that, even at the graduate level, only the Université de Montréal, University of Toronto, and Dalhousie University use the term "bioethics" to describe their programs. The University of Ottawa, for example, offers an Honors BA with a major or specialization in Ethics and Society, while the University of Guelph offers a BA minor in Ethics in Life Science, which could appear broader in scope than a traditional bioethics program. The Université de Sherbrooke and Université Laval have chosen the term "applied ethics" and Mc Gill University has a Biomedical Ethics Unit. Students can also obtain a diploma or degree with a bioethics component (certificate, Bachelor of Arts, or Bachelor of Science with a minor or major). In these cases, the courses are offered by faculties of arts and sciences, philosophy, and religious studies or as part of joint programs involving various biomedical science faculties, such as medicine, nursing, and pharmacy, and faculties of health administration, social sciences, philosophy, law, and religious studies. In addition, bioethics courses are included in the curricula of health science faculties such as medicine, nursing, and pharmacy. There are two universities offering PhD in bioethics and four offering an MA degree.

Bioethics Committees

Canada does not have a national bioethics committee. The province of Quebec is the only one to have established an ethics commission for science and technology, including biomedicine. In Canada, local research ethics committees and health-care committees have developed substantially since the 1980s. Other types of ethics committees have also been put in place, according to the needs of organizations (e.g., professional associations, institutional associations, and policy institutes). Two types of committee will be discussed here: research ethics boards (REBs) and clinical ethics committees (CECs).

A research ethics board (REB) is required in all Canadian institutions that conduct research involving human subjects and receive funding from one of the three research agencies – the Social Sciences and Humanities Research Council (SSHRC), the Canadian Institutes of Health Research (CIHR), and the Natural Sciences and Engineering Research Council of Canada (NSERC) which are run by the federal government.

The Tri-Council Policy Statement (TCPS, 2010) sets out the responsibilities and composition of REBs, which must provide an ethics review and approval, before the work commences, of "(a) research involving living human participants; (b) research involving human biological materials, as well as human embryos,

fetuses, fetal tissue, reproductive materials and stem cells. This applies to materials derived from living and deceased individuals" (TCPS, 2010, p. 15). The mandate of the REB is to "review the ethical acceptability of research on behalf of the institution, including approving, rejecting, proposing modifications to, or terminating any proposed or ongoing research involving humans" (TCPS, 2010, p. 69). Private companies that do not receive funding from federal granting agencies are not subject to the TCPS. However, their projects involving new drug development such as clinical trials must be reviewed by an independent ethics committee, according to Health Canada's Food and Drug Regulations.

In 1997, Health Canada adopted Guidance E-6 of the International Conference on Harmonisation of Technical Requirements for the Registration of Pharmaceuticals for Human Use (Health Canada, 1997). This has resulted in the formation of private REBs. Despite certain criticisms, the independence and competency of these private ethics boards are generally recognized.

Health-care facilities have a second ethics committee known as a bioethics committee, a clinical ethics committee (CEC), or simply an ethics committee. The private, not-for-profit, independent organization Accreditation Canada, which measures the performance of health-care and social service organizations against national standards of excellence, has in recent years required organizations to establish an ethics framework that could take the form of a committee (Accreditation Canada, 2013).

Since the early 1980s, when the first committees were established, their mandate has remained essentially unchanged (Doucet, 1985). Despite their evolution over the past 30 years, a recent study on clinical ethics committees in Canadian hospitals confirmed a high degree of stability (Gaudine, Thorne, LeFort, & Lamb, 2010). In general, CECs do not have decision-making powers but act in an advisory capacity.

Although research ethics boards and bioethics committees are firmly established in Canadian health-care facilities, they are the subject of frequent debate. A common criticism is that REBs are not sufficiently aware of realities on the ground and tend to focus too much on the finer points of law and not enough on research participants' ability to understand. In addition, research has changed substantially since REBs were first introduced, with projects being carried out by researchers from different institutions and countries. How, in this context, should multi-jurisdictional research be reviewed at the local level? In some provinces, the answer has been to create provincial ethics boards, like in Alberta with the Health Research Ethics Board (HREB) (University of Alberta, 2013).

As far as CECs are concerned, many feel that ethics consultations on difficult cases should be carried out in collaboration with all parties concerned. In such instances, the CEC seems inefficient, particularly since certain professionals see it as a court of law. A common difficulty for both types of ethics committee has to do with the presence of a community member. While it would not be acceptable to exclude these members from ethics committees, the exact nature of their contribution and the expertise they require remain somewhat unclear.

Expert Bodies/Centers

Canada does not have a national bioethics commission. Quebec is the only province to have a science and technology ethics commission, the *Commission de l'éthique en sciences et en technologie* whose primary mission is to encourage open, pluralistic, and ongoing reflection on the ethical issues associated with scientific and technological activity.

The federal health department created the Health Canada Centre of Expertise in Bioethics which is dedicated to promoting and advancing bioethics in Canada. This is achieved by providing service, information, and a platform for collaboration on bioethics issues within the Government of Canada. The Centre of Expertise in Bioethics is an initiative of Health Canada to integrate ethical principles into public policy, regulation, health promotion activities, and health programs.

As part of a collaborative effort to promote the ethical conduct of research involving human subjects, Canada's three federal research agencies, CIHR, NSERC, and SSHRC, created in 2001 the Interagency Advisory Panel on Research Ethics (PRE), which develops, interprets, and implements the *Tri-Council Policy Statement*: *Ethical Conduct for Research Involving Humans* (TCPS). Finally, a list of academic centers with primary or significant activity in the area of bioethics is available on the website of the Canadian Bioethics Society.

Relevant Legislation

Canada has no federal legislation specifically devoted to bioethics or aimed at establishing a national bioethics commission. However, depending on the activity sector or social issue in question, legislators might consider it appropriate to intervene. New reproductive technologies, for example, are regulated by the 2004 *Assisted Human Reproduction Act* (AHRA). Section 2 of the act evokes ethical values and principles (AHRA, 2004, Sect. 2).

Any sponsor seeking to conduct a clinical trial in Canada involving a therapeutic product must adhere to the *Food and Drugs Act* and associated regulations specifically aiming at protecting human subjects who participate in clinical trials (Health Canada, 2012 *Food and Drug Regulations*, Part C, Division 5).

Since health care in Canada is a shared jurisdiction among the federal, provincial, and territorial governments, some ethical issues applying to nurses and physicians come under provincial and territorial laws. In addition, the protection of vulnerable populations, such as those with a mental disability, falls under specific provincial and territorial legislation.

Public Debate Activities

Canada does not have a national infrastructure specifically devoted to public consultation on bioethics issues. However, when faced with certain potentially

contentious issues, the federal health department has held national public consultations, for instance, on xenotransplantation and on the appropriate use of placebos in clinical trials. In the province of Quebec, the *Commission de l'éthique en science et en technologie* held public consultations as part of its examination of specific issues and also gathered public opinion through online surveys like Online Public Consultation on Assisted Procreation. Canadian researchers can use various forms of public consultation during the course of their research projects, including public debate. There are also research teams who are specifically interested in evaluating citizen participation.

Other

A number of Canadian organizations encourage and participate in debates on bioethical issues. Some granting agencies fund research on topics related to bioethics, while groups and associations promote discussion among individuals interested in these issues.

The Canadian Institutes of Health Research (CIHR), the major federal funding agency for health sciences, is mandated by the parliament to "foster the discussion of ethical issues and the application of ethical principles to health research" as well as "monitor, analyze and evaluate issues, including ethical issues, pertaining to health and health research" (CIHR, ACT, 2000, 4 g, 5d).

Genome Canada, a not-for-profit organization established in 2000, is mandated by the Canadian government to develop and implement a national strategy for supporting large-scale genomics and proteomics research projects, for the benefit of all Canadians. Genome Canada encourages reflection on ethical issues raised by genetic and human genome research by requiring, as a funding condition, that ethical, legal, and social aspects be integrated into all genomics research funded.

Among the various groups promoting discussion in the field of bioethics, the following have made noteworthy contributions: the Canadian Bioethics Society, the Provincial Health Ethics Network (PHEN) of Alberta, and the Quebec Ne3LS network who has, since 2011, funded research on the ethical, environmental, economic, legal, and social aspects of nanotechnology development.

Major Bioethics Issues and Discussions

Beginning of Life

The issue of the beginning of life has been addressed from a number of angles and in relation to various situations. The debate began with the various legal proceedings against Dr. Henry Morgentaler who performed abortions, contrary to the regulations defined by the Criminal Code of Canada. In 1988, the Supreme Court of Canada declared the Canadian law on abortion unconstitutional. On August 8, 1989, the same court recognized that the fetus, regardless of its stage of

development, does not have the legal status of a person either under Canadian common law or under the Quebec Civil Code. From that perspective, a termination of pregnancy could be performed, even if the age of the fetus made it completely viable. The court's interpretation still governs Canadian abortion practice, but requests for third-trimester abortions, although rare, are the subject of much debate in specialized hospitals (CHU Sainte-Justine (Centre hospitalier universitaire mère-enfant), 2007).

With advances in neonatology, discussions regarding beginning-of-life decisions have increased. In the 1970s, new issues arose that were discussed at one of the first bioethics meetings in Canada. At a 1976 symposium, the following questions were addressed: Are all of these babies to be given the most active treatment regardless of the results this treatment will produce? If no, should some babies be allowed to die? Helped to die? How should the decisions be made? In any event, whose notion of life worth living is decisive? (Roy, 1978) In the present context, the Canadian Paediatric Society, the statements of which are the product of collective work, is recognized as the authority on that matter.

Developments in the field of medically assisted reproduction have also given rise to intense debate on the beginning-of-life issue. One of the most controversial subjects relates to the status of the embryo. Does the handling of the embryo required by these technologies respect the embryo? Is the embryo to be seen as a simple biological product? Is it already a human being? What respect is it owed?

End of Life

Since the late 1970s, end-of-life care has been studied from several angles. Initially, three main questions fed the debate.

Question 1: Is it permissible to withhold or withdraw treatment? The theme of quality of life, at the heart of the current debate, was early on very important (Keyserlingk, 1979). Some felt that all available medical means had to be used to respect the sanctity of life.

Question 2: Who should make the decision to withhold or withdraw treatment or to continue or discontinue therapy? Should it be the doctor, family, or patient? The various stakeholders concerned soon reached a consensus: doctors should make the recommendation and competent patients should make the decision, except in emergency situations.

Question 3: On what criteria should such a decision be based? When a patient is competent, the decision has to be based on respect for the person's autonomy because it is the patient who must decide whether the treatment poses serious personal risks, regardless of whether another person has a different opinion. The Civil Code of Québec clearly recognizes this moral perspective. In 1992, Justice Dufour referred to the Code in granting Nancy B.'s request for the withdrawal of the artificial respirator that was keeping her alive, without which she could only survive a few hours (Dickens, 1993). This judgment has set a precedent in Canada. Other criteria must also be taken into account. As noted

by the Law Reform Commission of Canada in its working paper *Euthanasia, aiding suicide and cessation of treatment* (1982), "considerations of quality of life can be legitimate factors in decision-making" (LRCC, 1982, p. 38). A number of citizens might fear that quality-of-life criteria will open the door to discrimination against vulnerable individuals whom society tends to disregard. That is why it is important to put in place rules to protect the interests of incompetent patients as well as patients who are recognized as legally competent but whose vulnerability puts them at a risk of being left out of the decision-making process. The process itself is considered a criterion. It was in this spirit that, in 1984 and 1995, the Canadian Medical Association, the Canadian Nurses Association, the Canadian Healthcare Association, and the Catholic Health Association of Canada issued guidelines for health-care providers working with patients in the terminal phase. These guidelines emphasized the need to establish quality communication among all concerned (Canadian Healthcare et al., 1995).

Two further questions have since been added to the original three that characterized the ethical debate on end-of-life care. The first is related to palliative care (see subsection "End of Life" in the section "Major Bioethics Issues and Discussions") and the second to dying with dignity.

Canadians are still deeply concerned about the issue of dying with dignity. In the past few years, euthanasia and physician-assisted suicide have occupied a central position in public debates. Despite the Supreme Court's refusal to allow assisted suicide in the 1993 Sue Rodriguez case (Rodriguez, 1993), calls for changes to the law and the decriminalization of euthanasia have multiplied. The same court will no doubt soon have to revisit Canadian laws that criminalize euthanasia and assisted suicide, since various Canadian courts are currently deliberating such cases. In 2009, the Quebec National Assembly created the Select Committee on Dying with Dignity to hold a province-wide consultation on end-of-life issues. The two topics that dominated the debate were the autonomy of competent patients and the dignity of individuals suffering from a disease. The committee's report was tabled in March 2012 (Select Committee on Dying with Dignity, 2012) and was followed by another report that was in charge of proposing the content of a legislation that would permit doctor-assisted dying, under very strict conditions (QUEBEC, 2013).

Health and Disease

The WHO definition of health which includes the social aspects of health marks a shift from a disease-driven to a holistic approach. Although the discussion around health in Canada is often linked to disease, there has always been strong support for the WHO definition.

In fact, the WHO definition served as an inspiration for the 1974 Lalonde report, named after Canada's health minister at the time (Government of Canada, 1981). This report put forward a comprehensive notion of health based on four key elements: human biology, environment, lifestyle, and health-care organization. It is considered one of the founding documents of health promotion. At the time of its

publication, the report gave rise to numerous discussions around ethical issues. One of the concerns was that the government was shifting its responsibility from health care to individuals who did not have healthy lifestyles. By putting the accent on lifestyles and individual risk factors, was the government not ignoring the impact of social and economic factors?

The definition also led to the development of numerous actions and therapies designed to promote overall well-being. While many Canadians recognize the limitations of modern medicine, it continues to be the dominant model, transforming the various problems of human life into medically treatable diseases. Pathologies that were nonexistent in the past are today recognized by the health system. This is the case with conditions such as infertility. Viagra is another good example of this tendency, as are certain cosmetic procedures aimed at reconstructing the human body in cases where individuals do not feel good about themselves. A negative body image is seen as a form of disease for which medicine has a cure. A final example is the steady rise in diagnoses and drug prescriptions for mental health issues, including depression and attention disorders. This situation has created a number of ethical challenges in different sectors of society (CEST, 2009b).

Health-Care System, Access to Health Care

In Canada, where the health-care system is a shared jurisdiction between the federal and provincial/territorial governments, the first province to have a publicly funded health-care system was Saskatchewan in 1946. Today, the health-care system is governed by the *Canada Health Act*, adopted in 1985. The federal government monitors the application of the act which is based on five criteria: universality, portability, comprehensiveness, accessibility, and public administration (Canada Health Act, 1985). The federal government transfers money to the provinces for health-related matters and can reduce the funding amount if provinces do not fully implement the act. The ten provinces and three territories are the key providers of health care. They are responsible for planning, financing, and evaluating the provision of hospital care, negotiating the salaries of health-care professionals, as well as fees for physician services. As a result, each provincial insurance plan differs in terms of how far public insurance coverage is extended beyond medically necessary hospital and physician services. All hospital costs are reimbursed, but costs outside hospitals, such as home care and pharmacare, are not automatically refunded.

Since its inception, this system has been the pride of Canadians. At present, the health-care system is facing major management challenges: overcrowded emergency wards, a shortage of family physicians and nurses, inadequate home care, and surgery delays. In response to these problems, provincial governments have established commissions or working groups to examine and make recommendations on the system, its administration, resource allocation models, and service delivery. At the federal level, the government established the Royal Commission on

the future of Health Care in Canada (Romanow Commission) in April 2001. The commission tabled its report *Building on Value*: *The Future of Health Care in Canada* in April 2002. The report included 47 costed recommendations (Royal Commission on the Future of Health Care in Canada (Romanov Commission), 2002).

Resource allocation models are currently under discussion as are issues related to the cost of an aging population. However, a report released by the Canadian Institute for Health Information (CIHI) noted that "population ageing is a cost driver of modest importance relative to other drivers" and that "After hospitals, physicians represent the second-largest category of public-sector health care spending" (Canadian Institute for Health Information [CIHI], 2011, n.p.).

In their search for answers, some researchers have proposed a new, integrated governance model necessitated by the fact that, over the past few years, there has been a move from a hospital-centered model to a model where the hospital is just one component of a complex network (Leatt et al., 2000). For the time being, it is difficult to say where the Canadian health-care system is headed and where it will end up. Some researchers are calling for a move from a focus on health care to a focus on health, paying more attention to the determinants of health. The provision of health-care services to every citizen, based on the values of justice and solidarity, is considered an important part of Canadian identity. Whether this mindset will continue into the future remains to be seen.

Traditional Medicine

The *Report of the Royal Commission on Aboriginal Peoples* (1996) defined traditional healing as "practices designed to promote mental, physical and spiritual well-being that are based on beliefs which go back to the time before the spread of western, 'scientific' bio-medicine. When Aboriginal people in Canada talk about traditional healing, they include a wide range of activities, from physical cures using herbal medicines and other remedies, to the promotion of psychological and spiritual well-being using ceremony, counselling and the accumulated wisdom of the elders" (Royal Commission on Aboriginal People (Erasmus-Dusseault Commission), 1996, p. 348).

The creation of the Institute of Aboriginal Peoples' Health (IAPH) within the Canadian Institutes of Health Research confirms the government's interest in traditional medicine. In a slightly different vein, medicinal plants, which are becoming increasingly popular in the West, are a very lucrative form of traditional medicine and Health Canada maintains a registry of approved.

A 2010 IPSOS Reid survey revealed that 73 % of Canadians regularly use natural health products such as vitamins and minerals, medicinal plants, and homeopathic remedies. The sale of over 1,400 traditional Chinese medicines is authorized in Canada. Recognizing their unique nature, the Canadian government recently created an advisory committee on traditional Chinese medicines with the

mandate to provide Health Canada's Natural Health Products Directorate with advice on current and emerging issues related to traditional Chinese medicines, such as the importation, sale, and use of those medicines in Canada.

Genetics

Since the discovery of the structure of DNA in 1953, followed by the Human Genome Project, there has been an explosion of research in the field of human genetics. As in many countries, human genetics in Canada does not have a glorious past. In the early twentieth century, there was a eugenics movement in the provinces of Alberta and British Columbia, each of which enacted a *Sexual Sterilization Act*, which allowed for the screening and sterilization of mentally disabled persons (Eugenics Archives, n.d.). In research, abuses were committed against Aboriginal population. For example, in the 1980s, blood samples were collected from members of the Nuu-chah-nulth Nation for research aimed at discovering whether this population had a genetic predisposition to rheumatic disease. The participants were never informed of the research results or ensuing publications (Wiwchar, David, 2004).

In Canada, human genetics has generated a lot of interest, particularly among researchers in the province of Quebec, home to several pioneers in the field. This interest is due in part to the presence of a founder effect in the Quebec population, especially in the Saguenay–Lac-Saint-Jean region, where settlement patterns favored genetic homogeneity and the prevalence of certain traits (Laberge & Dallaire 1967).

Clinical Genetics

As a result of the development of assisted reproduction techniques, databanks, and genetic testing to screen for risk factors or vulnerabilities before birth or later on in life, Canadians now have access to a variety of new services. The science of genetics has also been used to screen for risk factors in specific ethnic groups (e.g., sickle-cell anemia and Tay–Sachs disease). However, the accessibility and variety of genetic tests have also increased the complexity of related ethical issues. Canadians have started asking questions about the reliability of consent obtained from patients in clinical settings and the effects these tests may have on privacy, families, and individuals' insurability and employability (Commission de l'éthique en science et en technologie [CEST], 2003).

Genomics and Population Genetics

In Canada, there are several guidelines for genetic research and clinical work, the main one being the *Tri-Council Policy Statement*: *Ethical Conduct for Research Involving Humans*, published in 2010 (TCPS, 2010).

The main ethical issues related to human genetics in both research and clinical settings are tied to the collection, storage, and use of genetic data. The development of biobanks has raised new questions for ethics review boards, which need to

know whether consenting participants are fully aware of the planned retention and secondary use of the data. For example, for the CARTaGENE project in Quebec, a total of 20,000 participants were recruited in the first phase, and the project is now a well-coded open resource for researchers seeking to use collected data to conduct studies on various aspects of genetics.

There are also the issues of preimplantation genetic diagnosis, stem cell research, personalized medicine, unforeseen effects of tests and research, and the quality of information provided to patients and research participants.

Reproductive Medicine

In the 1980s, women's groups and health organizations campaigned in favor of a national debate on assisted reproduction. In reaction to this mobilizing movement, in 1989, Canadian authorities launched an extensive consulting process by implementing the Royal Commission on New Reproductive Technologies which issued its report in 1993. The debates went on for more than 10 years before the adoption, in 2004, of *An Act respecting assisted human reproduction and related research* (Canada 2004). Further, discussions on the management of assisted reproduction have been pursued; for example, the *Commission québé coise de l'éthique en science et en technologie* issued in 2009 a report on that matter (CEST, 2009a).

With regard to the Canadian situation, three main debates have captured the attention of the public: the anonymity of gamete donations, reproductive tourism, and surrogacy, as well as free access to assisted reproduction services.

When developing the Canadian law, the requirement for federal leadership and consistent legislation across the country was repeatedly affirmed. In this regard, the coming into force of the law on *Processing and Distribution of Semen for Assisted Conception Regulations* (Canada, 1996) constituted a first step toward the legislative framework of assisted reproduction by the federal government. It also demonstrated the desire to ensure conformity with quality and control measures with respect to sperm donations across the Canadian territory.

The question of free access to assisted reproduction care raises several issues. The free access would help reduce the number of multiple pregnancies. Another issue was related to the "right" to a child for people who cannot have a child to a natural way. What is the limit of reproductive autonomy with respect to free assisted reproductive care? For example, the Quebec program also includes preimplantation genetic diagnosis (PGD). This can only be done on embryos for the sole purpose of identifying severe monogenic diseases and chromosomal abnormalities.

In summary, assisted reproduction raises issues where the borders of ethics and rights are often interwoven.

Medical Research

In Canada, there has been a considerable evolution in the design of research aimed at improving population health. Up until the 1990s, such research was referred to as "medical research" and was overseen by the federal Medical Research Council (MRC). The MRC was replaced in 2000 by the Canadian Institutes of Health Research (CIHR) who are now funding research projects that cover all aspects of health; from cellular communications to health-care economics, CIHR integrates research through a unique interdisciplinary structure made up of 13 "virtual" institute networks of researchers brought together to focus on important health problems. This change in approach has made it possible not only to expand the field of health research but also to introduce new research methodologies. Quantitative methodologies, which are essential for the advancement of biomedicine, have been complemented by qualitative methodologies. This shift has considerably added to the body of knowledge in health-care services.

The shift in perspective is today widely recognized and these changes have had an impact on research ethics. Since 1998, researchers applying for grant from governmental agencies and whose work involves human subjects must abide by the ethical guidelines, known as the *Tri-Council Policy Statement* that aims to ensure that all types of research involving human subjects are reviewed in a manner that is systematic and adapted to the chosen methodology (TCPS, 2010).

This approach does not please all researchers. A number of epidemiologists, for example, do not see how the review process concerns them, since their area of research is not focused on individuals but on groups and populations (Doucet, 2002). In other situations, both researchers and research ethics boards have expressed a degree of uneasiness (Doucet, 2002; Trudel & Jean, 2010).

Despite considerable progress, as reflected in the CIHR approach, mutual understanding among health research disciplines has not yet been fully achieved. Although some research agencies require project proposals to include an ethical component, they do not yet require an interdisciplinary dialogue involving the social sciences, for example, which take a broader view of the issues and future of our society than the field of bioethics.

Public Health

In *The Future of Public Health in Canada*: *Developing a Public Health System for the twenty-first Century*, the Canadian Institutes of Health Research define public health as "the combination of sciences, skills, and beliefs that is directed to the maintenance and improvement of the health of all the people through collective or social actions"(CIHR, 2003).

Three national organizations strongly advocate bringing ethics into the public health domain: the Public Health Agency of Canada, the Institute of Population and

Public Health of the Canadian Institutes of Health Research, and the National Collaborating Centres for Public Health. Viehbeck and her colleagues provide an overview of these agencies and their respective activities (Viehbeck, Melnychuk, McDougall et al., 2011). While each has its distinctive characteristics, all share the same objective: to protect and promote the health and safety of all Canadians.

National Collaborating Centres for Public Health

The six National Collaborating Centres (NCCs) for Public Health, created in 2005, aim to promote and improve the use of scientific research and other knowledge to strengthen public health practices and policies in Canada. To this end, the National Collaborating Centre for Healthy Public Policy published a preliminary inventory of public health ethics (PHE) researchers and educators across the country in order to forge ties among PHE practitioners, researchers, and policy makers This initiative responds to a growing interest in the relatively new field of public health ethics, which encourages interdisciplinary dialogue and collaboration about collective interventions aimed at protecting and promoting the health of groups and populations. In Canada, as elsewhere, public health challenges often involve a clash between individual and collective approaches.

Infectious Diseases

Although health care in Canada falls under provincial jurisdiction, responsibility for public health is shared by all levels of government. The federal government has been responsible for monitoring infectious disease threats across national borders since the Spanish flu pandemic of 1918. Currently, the federal government plays an important role in the following areas: quarantine legislation and programs, the control of pathogens, and emergency and pandemic preparedness. The prevention and control of infectious diseases in the provinces and territories fall under their respective jurisdictions.

Interest in public health ethics has grown following recent crises involving infectious agents, such as the tainted blood scandal, the occurrence of severe acute respiratory syndrome (SARS) and the A(H1N1) influenza pandemic.

The prevention of infectious diseases was the target of the first public health measures. Some infectious diseases must be disclosed in order for the authorities to assess their spread and take appropriate action. The notion of isolating infected persons, limiting their movement, or recommending (or requiring) immunization of the population brings individual rights into sharp conflict with societal rights. Other principles that come into play are respect for privacy and individual autonomy, as well as solidarity, reciprocity, the common good, and quality of life in society. In some circumstances, it is justified to infringe on an individual's rights for the public good.

Transplantation Medicine and Organ Donation

The rules in Canada regarding organ donation (living or cadaveric) are clear: explicit consent is required. However, the ways in which this consent is expressed vary, depending on whether the donor is an adult or a minor and on the type of donation (living or deceased).

The values underlying organ donation and allocation are solidarity, altruism, and respect for the dignity and autonomy of the person, as well as efficiency, fairness, and justice. The degree of emphasis placed on each of the latter three values in standard organ allocation procedures depends on organ types.

Since organ transplantation is part of physicians' therapeutic arsenal, and medical practice falls under provincial jurisdiction, certain provincial or regional organizations have a mandate to promote organ donation or to allocate recovered organs.

Moreover, the medical care team in charge of patients requiring a transplant is responsible for registering them on the waiting list. This decision is usually made by a multidisciplinary team.

Cadaveric Donation

In Canada, cadaveric donors outnumber living donors. Until quite recently, organs were only retrieved once neurological death had been confirmed. Now, four provinces (British Columbia, Ontario, Quebec, and Nova Scotia) are retrieving organs for donation following cardiac death, which is defined as the irreversible absence of circulatory and respiratory function. This new approach was the subject of national recommendations which are based on the following core values and ethical principles: respect for the life and dignity of all individuals, optimal end-of-life care that respects the holistic well-being of the dying patient, respect for patient autonomy, support for the grieving family and loved ones, public trust and avoidance of actual and perceived conflicts of interest, and, finally, respect for professional integrity (Shemie, Sam et al., 2006). While organ donations following cardiac death are on the rise, the numbers remain low.

Donation after cardiocirculatory death (DCD) raises the issue of determination of death. In addition, the protocol put in place will have an impact on the family of the dying patient, since the organs must be retrieved as soon as possible to preserve their quality, leaving little time for last goodbyes. All of these issues were the subject of extensive deliberation by the *Commission de l'éthique en science et en technologie* (CEST), which issued a position statement titled *Organ Donation and Transplantation*: *Ethical Dilemmas Due to Shortage* (CEST, 2004).

In the context of cadaveric donation, anonymity between the recipient and the donor's family must be maintained. In 2009, Transplant Québec's ethics committee reiterated this position in its *Avis sur la question de l'anonymat des échanges entre les donneurs ou leurs proches et les receveurs* (Comité d'éthique de transplant Québec, 2009).

Living Donation

Until recently, this form of organ donation almost exclusively occurred within families, mainly for immunological reasons. However, the development of improved antirejection drugs has now made it possible for patients to receive an organ from a living donor to whom they are not biologically related. Specific rules have been put in place to prevent the exploitation of vulnerable populations such as children and incompetent adults. To promote living organ donation, certain provinces such as British Columbia, Ontario, and more recently, Quebec have decided to reimburse expenses incurred by donors so they are not unduly penalized.

In November 2010, the Living Donor Paired Exchange (LDPE) registry conducted a paired exchange which, for the first time, included patients and donors from across Canada. The LDPE facilitates kidney donations through exchanges between incompatible donor/recipient pairs. Since its creation in 2009, the registry has facilitated in 2 years the transplantation of 75 kidneys.

In response to the growing demand for organs, Health Canada has looked into xenotransplantation as a possible avenue. For the time being, however, this approach has been ruled out, following a public consultation held in 2000 and 2001 by the Canadian Public Health Association. It is important to underscore that although there is general opposition to organ trafficking, some Canadians are going to other countries to get transplantation.

Emerging Technologies (Nanotechnology, Information Technology, etc.)

Over the past few decades, emerging technologies have helped change research and medical practice considerably. This growth in information and communication technologies was made possible by developments in devices related to informatics, microscopy, engineering, and nanotechnologies. With the advances promised by the convergence of a number of video, telephone, computer, Internet, and scanner technologies come ethical issues that, while not necessarily new, have to be examined from a different angle.

Study of the applications and issues connected with emerging technologies is complex, since jurisdiction over health is shared in Canada and the strategies therefore vary from one province to another.

Nanotechnologies

Nanotechnology is a good example of a technology that has come out of the convergence of information, biotechnologies, and cognitive sciences. In Canada, as early as 1999, the Canadian Institute for Advanced Research launched its advanced microelectronics program. In the years that followed, there were many developments in this field.

In 2003, the Canadian Institutes of Health Research started up a research program on regenerative medicine and nanomedicine that included a section on biomedicine and biotechnology.

With regard to ethics, in 2006, the *Quebec Commission de l'éthique de la science et de la technologie* produced a position statement, *Ethics and nanotechnology: A basis for action* (CEST, 2006). In the same vein, in 2011, following the production of an action plan, Quebec officially launched Ne^3LS, a knowledge network on the ethical, environmental, economic, legal, and social aspects of nanotechnologies. The main objective of this network is to foster the development of nanotechnology research activities.

The capacity of nanotechnology applied to regenerative medicine opens windows on improved health and increased longevity for human beings, but how far should we go in that direction? This question is being addressed in Canada, as in a number of other countries, by researchers in the humanities and social sciences. Those researchers are analyzing the possible applications of nanotechnologies to diagnostics and treatments, as well as to regenerative medicine, and are trying to determine whether the enthusiasm over them is justified and whether, to some extent, the wool is being pulled over consumers' eyes (Caulfield, Timothy, 2011).

Personal Health Records

The possibility of using technology to build and transmit patients' personal records is another application of the emerging technologies that is researched in Canada. It offers indisputable advantages in terms of speed of access to the data. However, it can lead to breaches of confidentiality and invasions of privacy. There is also a risk that it will help focus medicine and resources on the individual, and not on the needs of the community, leading to a displacement of the health system costs.

Embryonic Stem Cells

In 2002, the Canadian Institutes of Health Research published guidelines for human pluripotent stem cell research (CIHR, 2010). The guidelines emphasized that stem cell research must be based on the following guiding principles: health benefits for Canadians; free and informed consent, provided voluntarily and with full disclosure of all information relevant to the consent; respect for privacy and confidentiality; and no direct or indirect payment for tissues collected for stem cell research and no financial incentives. These guidelines announced the creation of a stem cell research oversight committee and of a registry of stem cell lines generated in Canada. These guidelines were reviewed in 2006, 2007, and 2010. In March 2004, the *Assisted Human Reproduction Act* came into force and applies to the obtaining of stem cells from human embryos and allows the use of unwanted embryos, but not research on germ lines.

Neurosciences

The development of medical imaging research and the increase in health professionals' and researchers' access to scanners have created great hope for treatment of, among other things, mental illness and cerebral palsy. However, this exploration of the brain may also lead to shifts in directions that, again, may cross certain boundaries and interfere with research subjects' and patients' autonomy.

Neuroethics, which is aimed at the study of these issues, has developed in a number of Canadian provinces, for example, there are the National Core for Neuroethics at the University of British Columbia, the Neuroethics New Emerging Team (NET) at Dalhousie University, and the Neuroethics Research Unit at the Institut de recherches cliniques de Montréal. In addition, at the Canadian Institutes of Health Research, there is the Institute of Neurosciences, Mental Health and Addiction (INMHA), which provides financial assistance for neuroethics research.

Intensive Care

Intensive care plays a key role in modern medicine. Its successes pose considerable challenges to practitioners in the field. The ethics sections of many Canadian critical care societies "have proposed a number of policies describing the goals of intensive care unit (ICU) care and providing broad guidance on the diagnoses and physiological criteria that would mandate using the specialized skill and technologies of an ICU environment" (Hawryluck, Bouali, & Meth, 2011, pp. 254–262).

Although it has been clearly established, both ethically and legally, that there is no distinction between withholding and withdrawing treatment, the same is not true at a practical level. In all situations where the life of an individual is at stake, cultural, religious, family, and personal values come to the fore and interact with medical criteria, making the form and content of communication critically important. To date, the policies "do not provide any definitive guidance in the difficult decision making faced by clinicians" (Hawryluck et al., 2011, p. 262).

Another broadly debated issue in Canada is that of resource allocation. ICUs often have insufficient beds to meet the demand. In addition, ICU costs are extremely high, and the development of increasingly sophisticated technology is only driving them higher. Ethical discussions here tend to revolve around two questions: Must we ration intensive care services and refuse to start or continue futile treatments? Nurses play a critical role in intensive care units. Their work is extremely demanding, on both a technical and human level. They often find themselves in a difficult position, because they have to enforce decisions in which they played no part. The most common example is when a decision is made to withdraw treatment, with all of the ensuing implications for the patient and family. Such situations cause a great deal of distress for many nurses (Pauls, McRae, Campbell, & Dungey, 2004).

Palliative Care

The concept of palliative care originated in Montreal in 1973, when Dr. Balfour Mount introduced at the university-based Royal Victoria Hospital the "hospice care" approach. Mount believed that, with its potential to change prevailing attitudes, hospice care would be a boon to all patients receiving end-of-life care in hospital. The debate continues (Senate of Canada, 2010).

When palliative care was first introduced, there was extensive debate around various ethical issues like pain control. The first concerned pain control. Few hospitals run palliative care units, and reports have consistently emphasized the shortage of beds for this type of care. In some parts of the country, there is a move toward building hospices. The focus of palliative care is on achieving comfort and ensuring respect for the person nearing death and maximizing quality of life for the patient, family, and loved ones. In current debates on the decriminalization of euthanasia and assisted suicide, some authors propose seeing palliative care as one stage in a continuum of care that could include euthanasia (Collège des Médecins du Québec, 2009). For others, such an approach undermines the basic philosophy behind palliative care.

Care for the Elderly

Care of the elderly is becoming a major source of concern in Canada. It is impossible to discuss the challenges faced by the country's various health systems without mentioning the burden of the aging population. Will care of the elderly cause health costs to skyrocket? The answer provided by the Canadian Institute for Health Information (CIHI, 2011, pp. 15–20) is far more nuanced: the pressure of aging on health costs is moderate compared to other factors such as inflation, technologies, and salary increases.

In her study on the evolving care needs of older Canadians, gerontologist Neena Chappell (2011) notes that when health fails, care is increasingly provided by unpaid family and friends, more often women than men. Caring for people with chronic conditions (particularly dementia) is often stressful for caregivers, who might be seniors themselves. It is therefore important to develop policies that support the needs of informal caregivers and to make provision for formal long-term home care. Chappell calls for a reexamination of the assumption that "medical care is the most appropriate means to ensure the health of an ageing population" (Chappell & Neena, 2011, p. 1).

A second problem concerns treatments provided to the elderly. The question of upper age limits for treatment is the subject of frequent debate among caregivers and the general public. The discussions reflect our views on aging. For years, the refusal to offer treatments to people who had reached a certain age was based purely on the fact of aging. This position is no longer tenable: the person's health condition is now the determining factor. Acute care for certain illnesses is certainly provided, but is the patient's age taken into account?

Care for the elderly is developing in a fairly paradoxical manner. Concurrent with ageism is the fight against aging. Signs of ageism include a tendency in certain settings to infantilize the elderly, to qualify hospitalized patients in long-term care as "bed blockers," and to move older patients to the bottom of the waiting list for a medical procedure. The fight against aging is a rapidly growing trend, spurred by the development of new technologies. A number of scientists see aging as a painful biological decline that can be controlled through regenerative medicine.

Although the potential of biomedical gerontology research is unknown, it has become a key focus of scientific endeavor and has the potential to extend the average lifespan.

To prevent situations of discontinuation of therapy or aggressive medical intervention, organizations overseeing the practice of medicine and citizen groups are now promoting advance care planning (Health Canada, 2008). The procedure involves discussing with the patient and loved ones the type of care the person would like to receive in the event they become incapable of providing informed consent.

Chronic Diseases

The burden of chronic illness is increasing dramatically in Canada. The current health-care system, which was designed to handle short-term illnesses, injuries, and infections, cannot meet the care needs of the growing number of Canadians living with chronic and complex medical conditions. According to the Health Council of Canada, "The burden of chronic health conditions on Canadians, the health care system, and our economy is enormous and growing. Canadians with chronic conditions account for over 70 % of all nights spent in hospital" (Health Council of Canada, 2008).

Canada's public health-care system does not cover long-term care. The *Canada Health Act*, which was adopted in 1984 replaced various laws dating back to the 1960s, covers only "medically necessary services." There is therefore no national coverage of chronic care. Services delivered to patients with chronic conditions fall entirely under provincial jurisdiction and vary widely from one province to another.

Since the 1980s, approaches to chronic conditions have changed substantially. The new perspective "represents patients as analysts of their chronic illnesses experiences, articulates disease management within the context of a more general life management and, more recently, depicts patients as active agents in attaining a desired outcome" (Paterson & Thorne, 1998, p. 73).

Psychiatric Care

Toward the mid-nineteenth century, there was a move across Canada to improve the treatment and living conditions of the "insane." However, the social role of psychiatry was primarily to protect society against the risks of deviance posed by mentally ill patients. In addition, the rights and dignity of institutionalized patients were barely respected. One has only to think of what happened during the 1950s and early 1960s at the Allan Memorial Institute in Montreal, where Dr. Ewen Cameron was investigating a "psychic driving" treatment for depression (partially funded by the CIA), which consisted of massive amounts of electroconvulsive therapy, heavy sedation, and endlessly repeated tape-recorded voices. Many patients did not respond to this treatment and some suffered irreversible damage. The revelation

of these treatments had a major impact on the development of research ethics in Canada.

Debates around deinstitutionalization in the 1960s reflected the profound changes occurring in the mental health field at the time. Several factors explain the transformation of psychiatry. There was, of course, the shift from large asylums to community psychiatric services, supported by the advent of psychopharmaceuticals. These drugs significantly advanced the treatment of psychotic disorders but also led to major debates on optimal therapeutic approaches in mental health care. The process of deinstitutionalization was also inseparable from the growing civil rights movement throughout the West (Davis, Simon, 2006). These three factors played a major role in shaping existing psychiatric practices in Canada.

The therapeutic objectives at the outset of deinstitutionalization included improved access to services adapted to patients' needs, more favorable treatment in the community, and maximum social integration. However, 40 years later, the public perception is that this policy was largely borne of fiscal and legal necessity and not of logically analyzed mental health considerations. Critics charge that mentally ill patients have simply been released onto the streets. According to some studies, the policy of deinstitutionalization has not been implemented consistently across geographical areas and does not articulate either the conditions under which full implementation would exist or the expected outcomes from successful implementation (Barnes & Toews, 1983).

The question of how best to organize psychiatric care and mental health programs is still under discussion in Canada. The final report of the Ontario Legislative Assembly's Select Committee on Mental Health and Addictions, tabled in 2010, shows the challenge of developing programs tailored to the needs of different clienteles (Select Committee on Mental Health and Addictions, 2010).

More than in any other medical specialty, the epistemologies informing mental health care have major consequences for the patient. Depending on whether a biomedical or biopsychosocial model is adopted, the treatment and care provided to the patient will be completely different. The person of the patient is not viewed the same way. Canada has adopted the second model. The goal of mental health promotion for people with mental illness is "to ensure that these individuals have power, choice and control over their lives and mental health, and that their communities have the strength and capacity to support individual empowerment and recovery" (Public Health Agency of Canada, 2005).

In Canada and throughout the world, there has been a marked increase in the prescription of psychotropic drugs and in the diagnosis of certain mental disorders. At the same time, it has been noted in recent years that healthy people are using this type of medication to enhance their intellectual and job performance. As noted by the Commission de l'éthique en science et en technologie du Québec, "Western societies are experiencing the medicalization of events, emotions and things that are not necessarily part of the biomedical field. In medicalizing life events, this phenomenon promotes the expanded 'non-traditional' use of medications" (CEST, 2009b, p. xviii). The medical field is now more aware of mental health issues, but it is also helping to promote ideal notions of performance and normalcy.

Pediatric Care

Children occupied an important place in the first Canadian bioethical debates. The decisions to be made concerning newborns born prematurely or with congenital defects prompted debate on the obligation to continue or stop treatment. Since then, in both neonatology and other areas of pediatrics, advancement of knowledge and discussion has led to the establishment of rules on which there is generally consensus when a decision must be made to start, continue, or stop treating a severely ill child (Harrison, 2004). It is up to the parents to make the decision. However, they must base the decision on the child's best interests, which are not always easy to identify. In the case of a major disagreement, where it is believed that the parents' decision is not in the child's best interests, the institution may go to court to resolve the conflict – for example, when the parents of a Jehovah's Witness refuse a blood transfusion when it is considered the only way to save the child's life.

In recent years, children have become active participants in their care, with legal and ethical development of informed consent and recognition for the role of the patient in decision-making. In most Canadian jurisdictions, it is now recognized that adolescents can give independent consent for reproductive health services. When children lack legal force to give informed consent, health-care providers are strongly invited to ask them for their assent. This approach is the same in research with children and adolescents (TCPS, 2010, pp. 43–45).

Particular attention is now paid to new concerns regarding treatments for severely ill children. One relates to advance care planning, which requires "effective communication to clarify the goals of care and establish agreement on what treatments may or may not be appropriate to achieve these goals, including resuscitative and palliative measures" (Tsai, 2008, p. 791). Another issue relates to the conditions for the ethical acceptability of withholding or withdrawing artificial nutrition and hydration. Concerning the latter, the Bioethics Committee of the Canadian Paediatric Society has raised two questions. In some specific cases, may withholding or withdrawing artificial nutrition and hydration be considered as part of a palliative care plan? Since artificial nutrition and hydration are "medically assisted" or "medically provided" nutrition and hydration, should they not be considered on the same basis as any other treatment? (Tsai & Canadian Paediatric Society, 2011) Another ethical issue in pediatrics is related to the fact that many parents are opposed to the immunization programs put in place by the public health authorities and pediatricians' associations. They oppose them out of concern for their children's well-being, while the programs are designed to protect public health (MacDonald & Pickering, 2009).

Cases of abuse are another occasion of tension between parents and professionals working in the health sector. Here, the question of parental authority arises. Is it absolute? Under what conditions can it be diminished or even nullified? The guidance documents produced in that connection put forward some principles that are not specifically defined as ethical principles, even though that is what they are. The child's best interest is affirmed in them as a basic principle, but respect for

parents is also affirmed as follows: "While the needs of the child are paramount, all interactions must take into account diversity with respect to family, culture, language and abilities" (CPS, 2007, p. 6).

Emergency Care

Emergency care immediately evokes the image of a hospital emergency department (ED). It also refers to the job of paramedics and the measures put in place to protect the public in cases of infectious disease such as the H1N1 outbreak. Each of these practices has its own ethical requirements tied to the different settings and situations in which health-care professionals operate.

In Canada's major cities, hospital EDs is often overcrowded. The emergency team has to decide whether to refuse new patients by redirecting ambulances to other hospitals in the city. Evidently, this increases risks to patients' health and life. However, admitting new patients to overcrowded departments will affect those already admitted, who may not be able to receive the care they need. In ethical terms, what is the legal duty of the hospital and physicians to provide care to patients in such circumstances? (Walker, 2002). For many, behind this first question lies another, more basic question, related to both ethics and management. For many years, it has been said that "the cause of ED overcrowding generally lies outside the ED. Efforts to maximize ED efficiency are important, but overcrowding is a symptom of system failure" (CAEP, 2001, p. 83).

The work of emergency health-care professionals is different from the one done by their colleagues working in other hospital units. This context also casts classic ethical questions in a different light. What to do when a patient refuses recommended care, without which his or her life cannot be saved? How to interpret the advance directives of a patient whose decision-making capacity is temporarily impaired as a result of an accident? (Pauls et al., 2004).

Paramedics, formerly referred to as ambulance attendants, are another face of emergency care. In most Canadian provinces, they are considered health-care professionals. One of the difficult situations faced by them is how to deal with homeless people when they have urgent health problems and respond within a reasonable time frame especially in rural areas.

General Practice

In Canada, general practice "is the branch of medicine concerned with providing care (known as 'primary and continuing care') to patients irrespective of their age, sex or type of problem. General practice is also known as 'family practice'" (McWhinney, 2012). General practitioners are supposed to know their patients well and to be able to identify health problems early on.

General practitioners are faced with an aging population, the feminization of the profession (female physicians wanting to spend time with their family), and

a growing corpus of knowledge generated by the development of science and technology. In response to these challenges, the medical establishment has authorized GPs to receive assistance from specialized nurse practitioners ("super-nurses") who are able to carry out certain procedures that were formerly limited to physicians. Models like capitation or family physician teams have also been implemented in some provinces to ensure the population has ongoing access to health care. On the knowledge front, the provinces have tried out different models to promote knowledge sharing. One of these is the concept of "community of practice," borrowed from the business sector. This model has been applied in various ways and has received mixed reviews in Canada (Lee et al., 2009).

Health Promotion and Education

Since hosting the first International Conference for Health Promotion in November 1986, Canada has played a leading role in health promotion. Given this fact, it is not surprising that health promotion occupies a central position in a number of national health initiatives and strategies. These strategies clearly demonstrate the need to combine approaches, propose interdependent strategies, and encourage partners to promote behavioral changes aimed at improving population health. Tobacco use is not the only behavior the authorities would like to cut down. Alcoholism, overweight, and physical inactivity are also drawing the attention of those who want to promote better health among all Canadians, irrespective of their age, gender, ethnic background, or social status. The ultimate goal is to encourage healthy behaviors, a guarantee of well-being. However, the adoption of a legal framework raises questions about the state's interference in private life on the pretext of seeking to modify people's behavior for their own good.

Scientific and Professional Integrity, Conflict of Interest, Corruption

As in many countries, the research context has changed dramatically over the past 20 years. It has become very competitive and global and is funded by both the public and private sectors. Consequently, the pressure on researchers to produce results has been growing. The rapprochement between the pharmaceutical sector and the public sector increases the likelihood of conflicts between researchers and sponsors in clinical settings and in publications.

One well-known instance in Canada is the Olivieri case. In 1996, she came to believe, during the clinical trials she was performing, that an experimental iron-chelating drug (deferiprone) in patients with thalassemia was losing efficacy and causing serious adverse effects. At that time, "it was possible for clinical investigators to sign contracts with industrial sponsors for research trials containing provisions that protected the sponsors' interests, but not the public interest or the safety of trial participants [. . .]. The academic freedom of an investigator to publish

adverse findings and inform the scientific community could be at issue" (Thompson, Baird, & Downie, 2001, p. 3).

The case became public in 1998, when Olivieri published her findings. She lost her position and then received the support of the Canadian Association for University Teachers (CAUT). CAUT became involved in 1999 and commissioned a report defending academic freedom and scientific integrity (Thompson et al., 2001). Olivieri got her job back and has become an icon of scientific integrity across the world.

In Canada, publication guidelines have been reviewed recently. In 2009, the *Canadian Medical Association Journal* revised its policy with a view to strengthening the credibility of medical literature (Stanbrook et al., 2009). Researchers are required to declare their conflicts of interest to a Research Ethics Board (REB) when they are submitting a research project. Since 1994, researchers and universities have also been required to follow policies developed by the *Tri-Council*.

In 2009, the Canadian Minister of Industry asked the Council of Canadian Academies to conduct an assessment of research integrity in Canada, and in 2010, the Expert Panel on Research Integrity published its report entitled *Honesty*, *Accountability*, *and Trust*: *Fostering Research Integrity in Canada*. It provides the best overview of the history and the current status of research integrity in Canada. The Expert Panel recommended the creation of a Canadian Council for Research Integrity (Research Integrity & Council of Canadian Academies, 2010).

Following the Expert Panel Report and a consultation process, the Canadian granting agencies issued, in December 2011, a new framework entitled *Tri-Agency Framework*: *Responsible Conduct of Research*. This new framework is an umbrella document that describes agency policies and requirements related to applying for and managing agency funds, performing research, and disseminating results. It also outlines the process that institutions and agencies follow in the event of an allegation of a breach of agency policy (Panel on Responsible Conduct of Research, 2011).

Relations with Industry and Donors/Sponsors

There are close ties between industry and health both in biomedical research and clinical activities in the health services network.

In recent decades, medical research has become increasingly dependent on industry financial support. Universities encourage their members to enter into partnerships with industry to finance research. Government funding agencies insist on permanent ties with the private sector to ensure knowledge transfers and facilitate the marketing of products resulting from the research. As a result, there is an increasing emphasis in biomedical sciences on applied research, to the detriment of basic research. These situations can lead to conflicts of interest related to financial affiliation between researchers and industry.

The Canadian Medical Association (CMA) has a policy titled *Guidelines for Physicians in Interactions with Industry* (Canadian Medical Association [CMA], 2007).

Canada's Research-Based Pharmaceutical Companies (Rx&D), a national association representing over 50 companies, has echoed the concerns of the Canadian Medical Association by adopting a Code of Ethical Practices with chapters on the various aspects of the relationship between the pharmaceutical industry and health-care providers (Rx&D, 2012).

Future Challenges

In the Field of Bioethics Infrastructures (Need for Legislation, Ethics Committees, Ethics Education, etc.)

In Canada, the development of laws and the implementation of new infrastructures (ethics committees or ethics education programs) are always tributary to the distribution of power between provinces, territories, and the federal government. Health being a shared jurisdiction and education a provincial jurisdiction (there is no National Education Ministry). Therefore, the challenge is, and will be in the future, to proceed with federal–provincial negotiations for everything related to the legislation or the harmonization of bioethical practices. Generally, the federal government and provinces have agreed upon frameworks and standards that can be implemented differently in the provinces and territories. Bioethics, which is a part of health, is managed in the same way. Therefore, if a national accreditation system must be put into place, the provinces must hold prior consultation on its administration. Otherwise, if there is a dispute, the cause may end up in Supreme Court, as was the case with assisted reproduction.

The challenge remains to ensure that the frameworks and practices do not differ too much from one jurisdiction to another in order to prevent the exodus of researchers that would benefit more from working in a less severe jurisdiction with respect to management.

In the Field of New and Emerging Issues

Although in Canada they may vary from one province to another, the main challenges in the field of new and emerging issues are as follows:

Multiculturalism

Canada is a country of immigrants, and most of its regions promote multicultural policies. This context explains some of the bioethical debates taking place in this country. To combine respect for diversity with common citizenship, the Supreme Court of Canada uses a criterion it calls "reasonable accommodation."

Being a country where Francophones and Anglophones coexist, as well as aboriginal communities and several multicultural communities, it is often difficult to resolve ethical and bioethical issues when developing legislations and practices, particularly in a clinical setting. Without wanting to fall into cultural relativism

allowing everyone to do what they want, Canada seeks to establish practices in order to accommodate everyone, which is not easy and renders the decision-making process rather difficult for health stakeholders and bioethicists.

Sharing of Power

The increased interest of citizens about their health and the possibilities offered on line continue to solicit medical power. The paternalism of doctors is challenged more and more and the patient–doctor relationship must change in order that there is a more equal relationship between them. Feminist bioethics, with the work of Susan Sherwin, marked the bioethics discourse in Canada and helped expand narrative ethics. The future challenge will be to continue this work and train future doctors in this practice. Lastly, the development and expansion of new professions, such as clinical nurses, occupational therapists, and psychotherapists, have also contributed to challenging medical power and requiring more participatory approaches with respect to making decisions.

Citizen Participation

Citizen consultation on several questions has been instrumental in Canada for a long time in making decisions about several issues. Bioethics is no exception and several citizen consultations and forums have taken place over the past few years. The future challenge is to evaluate when to consult the public (Jean, Deleury, Duquet et al., 2007) and whether or not these mechanisms attain their goals or if they are merely tools for seeking credibility of the decision or a form of assent in face of the proposed solution.

Bioethics as a Disciplinary Field

In Canada, contrary to other countries, bioethics encompasses several clinical and research disciplines. Social sciences are considered as being part of the definition of bioethics, as well as health sciences. However, despite appeals for interdisciplinarity, there remain several barriers to overcome before this idea becomes a reality.

Discussions on an approach based on universal principles versus local principles have been held in Canada. Decisions made on principlism are often challenged when other decision-making techniques based on question contextualization or human rights or narrativity are proposed.

Collective Disasters

Given that bioethics is traditionally focused on the individual, it is difficult to examine the questions at the population level. The emergence of infectious diseases in recent years, such as AIDS and H1N1, and the possibility of bioterrorism pose the question of public health and common good. Policies and practices that limit the freedom of individuals are sometime needed.

Questions About End of Life

These questions that include palliative care and euthanasia or organ transplant are largely discussed in Canada and several working groups have recently discussed the

matter. In the years to come, this challenge will surely be a part of the discussions on the allocation of health resources, home care, and the use of new technologies.

New Technologies

New technologies have led to promising research and practice possibilities. Accordingly, in Canada and around the world, these possibilities have given rise to enormous hope for improving or even curing cancer or Parkinson's disease or Alzheimer's disease. The possibility of creating population databanks has opened the possibility of their use in public health in order to target the cohorts of people susceptible of having certain diseases. However, all of this has raised questions about privacy, discrimination, the right not to know, and the risk of no longer obtaining insurance or employment. In Canada, there is no law that requires the nonuse of genetic profiles by insurance or employment applicants. Insurance companies cannot request genetic tests but can ask whether or not the person wanting to be insured has undergone the tests. The challenge would be to determine the best way to find a solution to this practice because possible predictive medicine research participants, for example, can refuse for fear of being prevented from being insured.

For each new innovation, critical evaluations of all applications must be carried out in order to evaluate the risks and the benefits. Researchers and clinicians will require an ethical conscience that goes beyond the submission of a question or project to an ethics committee.

Globalization

Most of the challenges that have been raised for Canada include a global justice aspect. In effect, Canada, although pockets of poverty exist, remains a rich country where taking poor countries into consideration is not always a concern. One of the major challenges that Canada will have to overcome is its participation in global justice. Will it be ready to allocate a percentage of its resources to the physical and mental well-being of the citizens of less fortunate countries? Will it be ready to contribute to the education of researchers in these countries?

At a time when drugs or surgeries help Canadians have a healthier life, one might wonder whether or not their individual concerns will prevail over their traditional solidarity.

Summary and Conclusion

The challenges explained in the section with respect to this question constitute Canada's agenda for the future of bioethics development in this country. The issues related to the sharing of skills within the Canadian federation and its proximity to the United States forced Canada to constantly strive to develop high-quality researches and clinical practices while respecting the dignity of its citizens.

The Canadian Commission for UNESCO, Health Canada, and the *Commission de l'éthique en science et en technologie du Québec* generously contributed to the translation of this chapter.

ideas about medicine and human life. Without a doubt, these new technologies and skills give people more power than ever: seriously ill persons can be cured by organ transplantation or other treatments and infertile couples can have babies by assisted reproductive technologies. However, in the field of medicine that is intimately connected with life quality and human dignity, limitations still exist, particularly in the context of modern civilized society. How decisions are made in this context in a justifiable and moral manner requires precaution and prudence. The word *bioethics* was coined by Van Rensselaer Potter in 1971 in his book *Bioethics: Bridge to Future*. Later, the implications of this terminology changed from its original use by Potter, though people still use *bioethics* to refer to a new, multidimensional research including biology, medicine, anthropology, sociology, life science, and moral philosophy. The United States took the lead, with the founding of The Hastings Center in 1969 and the Kennedy Institute of Ethics in 1971. This resulted in the rise of bioethics as an interdisciplinary subject in the 1970s.

Development of Bioethics in China

In the early 1980s, new technologies and concepts such as artificial insemination (AI), assisted reproductive technologies (ART), and euthanasia were introduced in China and ethical discussion began concurrently. Thus, bioethics, as a new phase of medical ethics, emerged in China nearly 30 years ago. Professors Renzong Qiu, Zhizheng Du, Ruicong, Peng, Zhaoxiong He, Hongzhu Zhang, Benfu Li, and Dapu Shi were the first generation of scholars who introduced bioethics and have been the major disseminators and researchers in the field of bioethics and medical ethics in China since then. Whereas, in the West, bioethics referred to a new field devoted to human survival and improvement of life quality (Callahan, 1995, p. 250), Chinese scholars placed it in the domain of the much older field of medical ethics. They considered bioethics as an extension of medical ethics (Qiu, 1987, p. 6), as bioethics was closely related to the application and use of advanced biomedical technologies. Gradually, bioethics has become more independent, with a broader scope than medical ethics. Scholars began to emphasize that bioethics and medical ethics should not be taken as two unrelated branches of learning; rather, bioethics is both the heir to and the further development of of medical ethics (Du, 2000, p. 155). With regard to several topics, the distinction between bioethics and medical ethics no longer exists.

The development of bioethics in China is partly driven by the same factors as in Western countries, however, it has its unique background. The rapid progress of life science and medical technologies has directly motivated the rise of bioethics, and, in addition, philosophers and ethical researchers became more interested in practical issues, which lead to the development of bioethics from a theoretical perspective. At the same time, a number of practical problems caused people to consider ethical issues in a more comprehensive and focused way. Two remarkable events in particular too place in China in the 1980s that not only initiated the public

discussion but have also been the direct cause of people's interest in bioethics. One was the development of artificial insemination (AI) technology and the legal cases concerning the use of AI, and the other was the case of the first patient who asked for euthanasia in Shaanxi Province in 1986. In 1988, Professor Qiu and his colleagues organized the first national symposia on Euthanasia and Assisted Reproductive Technologies in Shanghai and Yueyang (Hunan province), respectively.

The major concerns of Chinese bioethics, as well as medical ethics, have broadened significantly during the past three decades. Besides issues like the physician-patient relationship, it is reasonable to say that bioethics research in China began by mainly focusing on both ends of the life span – the ethical implications of assisted reproductive technologies and the ethical problems or dilemmas surrounding euthanasia. Now, nearly 30 years later, these problems remain vivid and active in the discourse of bioethics in China, even though the discussion and research go far beyond them, including clinical ethics, research ethics, public health ethics, genethics, neuroethics, and emerging technologies like stem cell research and biobanking.

Current Bioethics Infrastructure

During 30 years' development, bioethics research in China has been fruitful. First and foremost, a series of textbooks and monographs have been published. The first textbook of medical ethics after the Cultural Revolution was *Outlines of Medical Ethics*, edited by Zhizheng Du in 1985. Renzong Qiu published a textbook titled *Bioethics* in 1987, which was the first book that systematically introduced Western bioethics in China. Zhaoxiong He's *History of Chinese Medical Morality*, published in 1988, introduced the development of medical ethics in China. Benfu Li published the *Textbook of Medical Ethics*, which is still widely used by medical universities, in 1996. Another influential book, *Collections of Chinese and Foreign Medical Moral Standards*, published by Hongzhu Zhang in 2000, contains a full and accurate understanding of moral codes. The *Encyclopedia of China Medicine* (*Medical Ethics volume*), chiefly edited by Zhizheng Du, is due for publication in 201•. Other books, like *The Review of Chinese Medical Humanities*, are becoming increasingly influential. There are significant translated works in bioethics as well. Shen Liu translated Singer's *Practical Ethics* in 2005; Ruiping Fan translated the *Foundations of Bioethics* (H. Tristram Engelhardt, Jr., second edition) in 2006. The translation of the *Classic Cases in Medical Ethics* (fourth edition) was published by Jingbao Nie and Linying Hu in 2010, and *Intervention and Reflection: Basic Issues in Medical Ethics* was translated by Xia Lin in the same year.

Influential journals appeared, witnessing and contributing to the development of bioethics in China. *Medicine and Philosophy* (started in 1980) and *Chinese Journal of Medical Ethics* (started in 1988) have played an indispensable role in the promotion of ethical research and public debate in China. Other journals such as *Medicine and Society, Research of Natural Dialectics, Morality and Civilization, Philosophy Trend*, and *Medical Education*, are also influential. Over the past three

decades, these journals have played an increasingly significant role in disseminating the knowledge of bioethics in China. Many research projects and theses on euthanasia, human embryonic stem cell research, and reform of health policy have been published.

Several societies and associations related to bioethics were founded at various levels in China. One of the most prominent is the Medical Ethics Society, founded in 1988 as a branch of the Chinese Medical Association (CMA). In July 2011, the 16th Annual Symposium of the Medical Ethics Society, held in Liaoning Province, was regarded as one of the most important platforms for Chinese experts in medical ethics and bioethics. The Chinese Bioethics Society, founded in 2007 under the auspices of the Chinese Society for Dialectics of Nature/Philosophy of Nature, Science and Technology, has been organizing the annual National Bioethics Conference since 2007. Over 4 years, a number of scholars, experts, and researchers from mainland China, Hong Kong, and Taiwan worked together to study ethical problems in the fields of stem cell research, public health ethics, animal research ethics, and biomedical research involving human subjects. One landmark particularly worth mentioning was the eighth World Congress of Bioethics, held in Beijing in 2006. Bioethicists from all over the world came to Beijing and exchanged their investigations on public health ethics and health policy, life science technology and research ethics, clinical ethics and medical professionalism, bioethics, culture, religion, and human rights (Li, 2006, pp. 11–15). Other organizations, such as the Chinese Medical Doctor Association (CMDA, founded in 2002), established the Morality Construction Committee, which is responsible for promoting theoretical research in medical ethics and providing ethical consultation for medical professionals. This committee issued the Chinese edition of the Physician Charter in June, 2011. This Charter declared six principles as health professional behavior norms: (1) Be equal and beneficent; (2) Patient's interest first; (3) Be sincere and trustworthy; (4) Diligence and prudence; (5) Honesty and justice, and (6) Lifelong learning to be competent.

A number of bioethics centers and medical ethics centers were established in universities and institutions. To date, the Chinese academy of medical science and Peking Union Medical College in Beijing, Fudan University in Shanghai, Huazhong University of Science and Technology in Wuhan, Shandong University in Ji'nan, Southern University in Nanjing, and Peking University Health Science Center have established bioethics centers and medical ethics center as platforms for further communication and for national and international exchange.

Along with the development of resources mentioned above, crucial steps have been taken in regard to teaching and training programs in China. Medical ethics courses are required by the Ministry of Education in all medical universities, and bioethical courses are provided in some comprehensive universities. Recently, a growing number of universities, medical colleges, and particularly their young scholars have engaged in bioethics, investigating cutting-edge issues, including human reproductive cloning, human embryonic stem cell research, and the Genome Project. The bioethics courses and lectures are more abundant now than 20 years ago, not only because new content and cases have been added, but also because the

interaction between teachers and students has become more active and flexible. In recent years, a credit-based continuing medical education system has been introduced, accompanied by some international collaboration programs (e.g., the cooperation between China and the School of Public Health, Harvard University).

The development of bioethics in different areas of China varies greatly. For some issues, Chinese scholars have reached their unique opinions, while others are still under discussion. So far, China has developed legislation and regulations about ART and gene research, organ transplantation, public health, stem cell research and human subject protection in biomedical research. Related regulations include (but not limited to) *Ethical Guidelines on ART and Sperm Bank* (Ministry of Health in 2001, 2003 Revised); *Quality Management Regulations on Drug Clinical Trial* (*GCP*, State Food and Drug Administration in 1999, 2003 Updated); *Ethical Guidelines for Human Embryonic Stem Cell Research* (MOH and Ministry of Science and Technology in 2003); *Regulations of Coping with Public Health Affairs Outbreak* (Central Government in 2003); *Ethical Guidelines of Research on Human Fetus Stem Cell* (MOH and MOST in 2004)*; Regulations of Human Organ Transplantation* (Central Government in 2007); *Regulations on Ethical Reviews of Biomedical Research Involving Human Subjects* (MOH in 2007); *Management Rules on Clinical Practice of Medical Technology* (MOH in 2009); and *Guidelines for Ethical Review of Clinical Drug Trials* (SFDA in 2010).

Bioethics in Taiwan and Hong Kong also experienced rapid progress during this period. Professor Shui Chuen Lee is the leading scholar in Taiwan who initiated bioethics research. He published *Confucian Bioethics* in 1999, and many theses like *Confucian Perspective on Some Issues of Bioethics* (Nobuhiko Takase ed., 2000, pp. 113–120); *The Reappraisal of the Foundation of Bioethics: A Confucian Perspective* (Julia Tao Lai Po-Wah ed., 2002, pp. 179–193); and *A Confucian Evaluation of Embryonic Stem Cell Research and the Moral Status of Human Embryos* (Shui Chuen Lee ed. 2007, pp. 149–157). In addition, mainland scholars regularly visit Taiwan to participate in international seminars on bioethics. In Hong Kong, Ruiping Fan and his colleagues are making an effort to construct Chinese bioethics by exploring sources from traditional Chinese philosophy and social values. Hong Kong Baptist University founded a Center for Applied Ethics in 1992 and has so far organized four symposiums on Chinese Bioethics Construction and Summer Class on Sino-American Perspectives in Bioethics to provide training for young scholars in China. Fan also published his book *Contemporary Confucian Bioethics* in 2010, in which he attempts to establish a framework for Chinese bioethics in the context of Confucianism.

Main Characteristics of Bioethics in China

Virtue, as a particular dimension of personality, is infiltrated into every aspect of people's lives, especially in the field of medicine. China has a long (5,000 year) history of civilization that is closely connected with ethics and morality and deeply rooted in Confucianism, Taoism, and Buddhism. Benevolence (*Ren*), the core

foundation of Confucianism for nearly 2,000 years, has advocated that good people always love others and get along well with others. Mencius (another leading Confucian philosopher) claimed that people had an inborn nature of humanity, which implies that all people have four senses: a sense of compassion, a sense of shame, a sense of respect, and a sense of distinguishing right and wrong. When time comes, anyone can be a sage after proper cultivation by the social life.

Such fundamental beliefs are rooted in every aspect of Chinese society, including medicine, which formed the most remarkable feature of the Chinese physician: a virtuous personality. In ancient China, doctors, also called "Confucian physicians," bear the goal of curing the sick and saving the dying. Sun Simiao (581–682 A.D.) stated in his book *Da Yi Jing Cheng* (*The Refined Sincerity of the Great Physician*) that the great physician was not only competent in his medical skills but also endowed with noble morality and compassion. People should be treated equally on the basis of their sickness and medical condition regardless of their social status, wealth, age and race, education, or whether they were friends. Shigong Chen (1555–1636 A.D., Ming Dynasty) illustrated the famous "five commandments and ten requirements" in the only standard Chinese work collected in the appendix of the *Encyclopedia of Bioethics* (first edition), Volume 5 for physicians, and claimed that the first requirement for somebody to become a doctor was to understand Confucianism before learning medical knowledge and skills, so that being a virtuous person comes before being a competent physician. Another physician during the Ming Dynasty named Tingxian Gong reiterated the same idea in his *Ten Requirements for Physicians;* and added a benevolent heart before understanding Confucianism (Li, 1996, p. 14). Thus, in its long history, China has a tradition concerning the moralities of professionals, mainly at the individual level.

Furthermore, the family is the basic unit of Chinese society, and the special value place on family by Confucianism contributed tremendously to forming the special physician-patient relationship pattern in China that remains as something cherished by Chinese people. These duties and values also play an extraordinary role in some prominent ethical problems like informed consent and truth-telling in the context of medicine. Medical decision making in China usually involves three stakeholders: doctor, patient, and family member. Such a model can be protective for patients on the one hand, and harmful in some circumstances on the other hand.

The introduction of bioethics from Western countries substantially broadened the ethical discussions in China. In the last 20 or 30 years, Chinese scholars learned much from Western countries in the area of bioethics concerning topics and theoretical resources. The four principles (autonomy, beneficence, nonmaleficence, and justice) were first introduced by Renzong Qiu in the 1980s, and have been widely used both in the discussion and justification of various bioethical issues ever since. China is a community-based and family-oriented society, respecting collective decisions more than single individual's decisions, which makes the situation and concrete problems much more complicated.

Major Bioethical Issues in China

Chinese bioethics shares topics and problems with Western countries in clinical ethics, research ethics, public health ethics, and other related areas. Some issues are widely debated, such as the physician-patient relationship (PPR), ART, euthanasia, organ transplantation, health policy and health resources distribution, human subject protection, and related leading-edge technologies like genetic engineering, human embryonic stem cell research, therapeutic cloning, and food safety.

Physician-Patient Relationship (PPR)

In China, the PPR has its own pattern and historical origin. When PPR is mentioned in China, it actually refers to the relationship among the physician, the patient, and the patient's family members, and primarily the relationship between the physician and the patient' family. This special Chinese physician–patient–patient family model of the PPR is deeply rooted in the long history and social values of China. On the one hand, family support, both material and emotional, is crucial for every patient not only because the family pays the medical cost, but also because the emotional support, to some extent, helps the patient to overcome the disease. Family engagement also makes things more complex and controversial.

The deteriorated PPR in China today is one of the most serious problems in bioethics research, theoretically and practically. The decrease of trust between health professionals and patient/patient family makes PPR not only an issue in medical ethics but also a social problem. More legal cases go to court, and in some extreme conditions, patients have even wounded or killed their physicians. The reasons for such a fragile PPR in China are multidimensional. Take the example of a big hospital: from the perspective of doctors, the imbalanced patient/physician ratio cannot guarantee enough time for physicians to treat their patients carefully enough. The heavy financial burden of outpatients (nowadays the government is taking efforts to cover as much as possible, and this is helping to make PPR harmonious) is usually among the major reasons, inasmuch as patients spend everything they have and still find no hope for cure. In addition, defensive medicine in China is also a problem. Afraid of being sued or bearing some other responsibilities, many physicians take the way of defensive medicine when treating patients, which seriously affects the quality of health services. Moreover, some physicians devote so much time to their own scientific research or other personal concerns that it conflicts with their professional obligations. From the patients' point of view, awareness of their personal rights has increased rapidly in recent years, coinciding with the collapse of traditional authority of physicians. The improvements to the health service and related health infrastructures are far from satisfying the patients' needs medically and nonmedically, resulting in difficulties accessing health services and high costs. According to one national survey carried out in 2010, about 50 % of patients would give a "red envelope" (filled with money or other kinds of gifts) to their physician in order to purchase their "special care" and "higher quality treatments" (Kong & Du, 2011, pp. 34–37). At the administration

level, there are some more fundamental reasons for this development. First and foremost is that the health system in China still needs more improvement to guarantee, at a bottom line, decent minimum health services and health equity.

All the factors above contribute to make the PPR in China a vicious circle. Adoption of comprehensive measures to enhance related reform based on the real situation is urgently needed.

Beginning-of-Life Issues

In China, artificial abortion is not as controversial as in Western countries because of its particular cultural background, social beliefs, and moral intuition. Even when there are debates, people are more concerned about the morality of behavior than the moral status of embryos. Some surveys showed that many Chinese people do not regard abortion as an ethical issue. This can be attributed to the traditional idea that human life begins just after birth. Another reason is closely related to birth control and the one child policy in China that started in the 1980s (Cong, 2003, pp. 239–260).

Interestingly, the issues regarding the beginning of life, especially ethical problems of assisted reproductive technologies (ART), are receiving more attention. A number of problems have been debated in China surrounding ART. In 1978, the world's first test-tube baby, Louise Brown, was born. The first legal case of AID happened in Shanghai in 1987 and initiated the public ethical discussion of ART in China. One year later, the first Chinese test-tube baby on the mainland was born in Beijing. Since then, assisted reproductive technology has developed continuously. In the beginning, some opponents argued that AI violated the nature of human reproduction and destroyed marriage, which was considered as one of the most significant relationships among people. Others suggested such a technique could enhance family happiness for some infertile couples without doing any harm to others. With in vitro fertilization and embryo transfer (IVF-ET), the primary issue was its difficulty in identifying the "parents" of a baby under the culture of addressing blood relationship. Meanwhile, some scholars held seminars and symposia to discuss problems systematically. Nevertheless, the toughest challenges that accompany ART are not the debates described above that conflict with Chinese moral intuitions. There are much more radical and controversial ethical problems, for example, the problems evoked by surrogate mothers were closely linked with women's rights and social justice; and whether IVF embryos have the same moral status as normal embryos before transfer.

After years of discussion, the Ministry of Health (MOH) promulgated *Technical Regulations of ART; Basic Standards and Technical Regulations of Human Sperm Bank; Ethical Rules for ART and Human Sperm Bank* in 2001 and revised them in 2003, to regulate the application of such technologies, guarantee its safety, and protect the welfare of Chinese people. The advantage of ART is that it helps infertile couples to have their own child; however, seven specified ethical principles, including the principles of informed consent, descendant protection, social public welfare, confidentiality, commercialization prevention, and ethical supervision, should be implemented. Some cases that have occurred in ART clinics

came under discussion, for example, families requesting for a surrogate mother for various reasons, and parents requesting to take sperm out for AI after their son died in an accident.

End-of-Life Issues

Euthanasia, which means dying with dignity and without suffering, was a big issue in Chinese society a decade ago. Chinese people generally hesitate to talk about death. The direct cause of such debates in China was the first euthanasia case that happened in Hanzhong City, Shaanxi Province, in 1986. Mrs. Xia was hospitalized for her liver disease on June 23, 1986, and diagnosed with liver cirrhotic ascites, hepatic encephalopathy, and exudative ulcer and bedsores. She felt better after some treatment; however, her condition worsened on June 27 and she suffered pain and anxiety. On the morning of June 28, she fell into a coma. Her son Wang knew that it was impossible to cure her and asked for help from the physician Pu. Finally, Pu prescribed 100 ml chlorphomazine after Wang signed on the prescription to take all responsibilities. Xia died in the early morning of June 29. Xia's death raised fierce public debate. In September, Wang and Pu were arrested by the police for causing the death of Xia. Then after 14 months of investigation, Wang and Pu were accused of intentional homicide. Since there was no prior case or legislation, the court finally considered that the direct cause of Xia's death was her liver disease rather than the chlorphomazine, and pronounced in 1992 that the accused were not guilty. The legal case lasted for 5 years, and Wang and Pu were arrested and released many times as there was no evidence or any related regulations to refer for such cases.

The discussion continued even after the final verdict. Today in China, there is still no consensus on euthanasia, and there is less discussion on euthanasia than there was a decade ago. At both ends of the spectrum of arguments, some radical views reject any kind of euthanasia in the name of professional ethics violation and illegality, while other views support euthanasia unconditionally only for relief of suffering for people with incurable diseases. However, people have their own reasons for being for or against euthanasia. Reasons like the right to die, human dignity and quality of life, and efficient use of scarce health resources all provide justification for endorsement of euthanasia. On the other side, people argue that euthanasia conflicts with medical professional ethics that concern saving lives above all else; moreover, there may be some miracles or possibilities for cure in the future, and informed consent given by the patient in these cases might be unreliable.

In recent years, some representatives participating in the National People's Congress have tried to propose euthanasia legislation, but such proposals have been rejected. Legislation regarding euthanasia still has a long way to go in China. Given the imperfections of the Chinese Health System and the Social Security System, it is hard to identify and guarantee the voluntariness of informed consent. Financial factors, as well as family decision-making patterns, make informed consent in China more complex than in other countries, especially for uneducated, poor, and older vulnerable persons. Furthermore, such discussion is also mixed with numerous disputes surrounding the death standard and newborns with birth defects.

Along with the debates of euthanasia legislation, the issue of whether brain death should be regarded as the death standard is another unresolved issue. According to the basic principles of nonmaleficence, beneficence, autonomy, and justice, the first dimension of the brain death issue is a scientific and medical problem, that is, whether or not brain death means the end of life. However, in the context of organ transplantation and health resource allocation, brain death is far beyond a scientific problem. Another concern is whether people should accept the concept of "brain death" and why should they give up the traditional concept of heart death (Qiu, 2004, pp. 30–33). Since the 1990s, some scholars in China have worked on promoting legislation of brain death; however, the impediment is not the scientific evidence and knowledge but the culture norms and acceptance by the public; thus, brain death remains controversial. In addition, a lack of trust in the Chinese physician-patient relationship is one of the main obstacles to accepting brain death in China (Hu, 2008, pp. 20–22). Another reason for not accepting brain death in China is related to ethical worries around organ transplantation, though the relationship between brain death and organ transplantation is to some extent exaggerated.

Organ Transplantation

The first successful transplantation of a kidney in China took place in 1974, followed by a liver in 1978 and a heart in 1978. As in other countries around the world, organ transplantation in China faces common problems, such as serious lack of donor organs, disparities in distribution of organ resources, and long-term complications resulting from imperfections in transplant techniques. In 1999, a doctor in Beijing removed the eyeballs of a dead body without informed consent or authorization to treat another patient, which caused strong debate and reflection in both the medical and legal professions. It was unethical but no proper regulations existed to cope with it. To regulate human organ transplantation and to protect the rights of citizens, the Chinese Central Government promulgated in 2007 *Regulations of Human Organ Transplantation*, which regulated that the basic principle of organ donation should be voluntary and freely consented to. The living donor must be at least 18 years old and all the living donations should be submitted for review and approval by an ethics committee. If a dead person has not expressed any opinion on the donation his or her organs before the death, a spouse, adult children, or parents can make the decision in their stead on written forms.

In recently years, organ transplantation in China has become more controversial. It has become a social and legal problem. A criminal case in Hebei Province in 2006 shocked all of China. A 40-year-old beggar was murdered and five of his organs (two kidneys, liver, spleen, and pancreas) were taken by the murderers to be sold on the black market, via the Internet. One hospital was involved in the surgery. After the "operation," a physician suspected that they might be involved in a murder and called the police. The murderer was sentenced to death in 2007; the physicians involved were not punished because they came to court as witness (Xinhua Net, August 21, 2007). Though it was an extreme case, it raised a series of ethical problems related to organ transplantation in China.

Infectious Disease and Public Health

Infectious disease research in China has mainly focused on disease prevention and related ethical problems invoked in the control strategies. In 1989, the *Communicable Disease Control Act* (revised in 2004) was passed to regulate the administration of infectious prevention and control. In the case of AIDS, which first appeared in China in 1985, Prof. Renzong Qiu began his exploration of the ethical problems of AIDS prevention and treatment in the 1990s. He claimed that AIDS was not like other public health problems; its infectious mechanism and susceptible population had their own features, so the first step in AIDS control was the transformation of traditional concepts about infectious diseases (Qiu, 2010, pp. 224–226). He also promoted in the following research theses respect and preventing discrimination and stigmatization of those testing HIV positive: *AIDS Prevention and Behavior Change: Protect Public Health and Individual Rights* (1993, pp. 129–135); *Ethical AND Policy Issues in HIV/AIDS Prevention in China; Recommendations on Legal Reform of HIV/AIDS Prevention and Control* (2003, pp. 121–139). In 2006, the Chinese central government issued its regulations on AIDS prevention and control.

In China, public health research was put on the agenda immediately after the outbreak of SARS in 2003. The SARS epidemic alerted people of the significance of public health as the gatekeeper to guarantee health at a population level. It is widely accepted that it is government's responsibility to play a major role, including health education and improvement and regulating people's unhealthy lifestyles and behaviors. However, the government itself cannot bear the burden alone. Citizens cannot passively wait for legislation to assure an equal distribution of health resources and outcomes, nor should they ask for help without taking any actions. Public health requires solidarity and cooperation among different bodies, societies, and organizations. In addition, one thing worth mentioning is that the *Regulations of Coping with Public Health Affairs Outbreak* issued by the central government in 2003 strongly emphasized the network of collaboration among different levels of governments and health administrations. In 2011, Prof. Benfu Li and his research team submitted their report, *The Framework of Public Health Ethics and Public Health Research Review* to the Ministry of Health (MOH). Some core values were clarified and suggested in the report, such as protection of vulnerable people, individual compensation, proper interventions, public participation, solidarity, and prevention, as guidelines to regulate the public health practices.

Human Genome Research and Emerging Technologies

China founded the new Human Genome Research and Ethical, Legal and Social Implication Committee when the Human Genome Research made its vital achievement in 1999. Since then, the HGR and related ethical problems were widely discussed in China. Scholars mainly focused on international cooperation and informed consent. The most controversial case was a project carried out in Anhui Province by an investigator at the School of Public Health, Harvard University. The researchers took blood samples from peasants and transferred some samples to the US without government permission. Though there were debates from different

sides, it was the consensus that there must be fully informed consent in genetic research to guarantee the rights and deserved benefit. When it comes to international genetic research, the collection and transfer of genetic resources and samples must comply with the *Interim Measures for the Administration of Human Genetic Resources* issued in 1998. Besides the importance of informed consent, three other principles should be stressed: (1) principle of respect, not only for the autonomous individuals, but also the procedure of informed consent; (2) principle of beneficence, fully inform the possible harm and risks, constructing a fair evaluation system to assure the rights of vulnerable ones; and (3) principle of justice, calling for fair benefit/burden sharing and independent supervision.

Human embryonic stem cell research is currently another controversial cutting edge issue. In China, the MOH and MOST issued *Ethical Guidelines for Human Embryonic Stem Cell Research* in 2003. It is crucial for people to use such technologies in an appropriate way. Thus, the guidelines stipulate that human embryonic stem cell research must follow three basic norms: (1) the in vitro culture period of blastosphere cannot be more than 14 days before fertilization or transfers happened; (2) such human blastula cannot implant into any human or animal reproductive system; and (3) hybridization between human germ cells and other species' is prohibited. The guidelines also announced that all such research should be reviewed by an independent ethical committee made up of biologists, lawyers, sociologists, and scholars in related fields. During the process of conducting research, investigators should focus on informed consent, making sure the informed consent was signed voluntarily and the privacy is protected.

As for other emerging technologies, the study of ethical issues in China focused on areas of human-nonhuman animal mix embryo research, biobanks, neuroscience, synthetic, and convergent technology. Chinese scholars published a number of essays to illustrate such issues, including *Ethical Issues in High-Techs of Life Science* (Qiu, 2001, pp. 20–27) and *Ethical Issues in the Biomedical Frontier* (Qiu, 2006, pp. 449–455).

Healthcare Reform

On March 18, 2009, China formally launched its new health reform. The reform aimed to provide primary health services to all citizens and guarantee full access with the basic strategy of taking fairness as priority to construct the primary health service system. The five priorities of reformation concentrated on (1) construction of a health insurance system with full coverage; (2) setting up a national essential drug system; (3) perfection of the health service system at the basic levels; (4) popularizing the primary public health services; and (5) promoting the reform of public hospitals. After 2 years' efforts, nearly 95 % of the citizens were covered by health insurance; the national essential drug system efficiently reduced drug prices by 30–40 %; the infrastructure of health services at the basic level was enhanced by the investment of the central government; ten packages of public health services were provide freely to citizens, and 17 cities were designated to carry out public hospital reformation. However, many challenges remain. First, urbanization and industrialization combined with ecological problems created

a complicated context for Chinese healthcare reform. Second, as a rapidly aging country, chronic diseases severely threaten the health of Chinese population; particularly, the morbidity of noncommunicable chronic diseases (NCD) is constantly increasing and constitutes one main reason for mortality. Third, the Chinese health system itself is problematic, which to some degree impedes the reform.

Lessons learned from the previous health reform initiated in 1980s indicated that the intensified health disparities were among the crucial indicators of its failure. Today, social justice is one of the basic values treasured all over the world. People have the right to health and the government bears the duty of safeguarding health, at least providing the decent minimum health services for all the citizens. Though it is still too early to evaluate the new health reform in China, some ethical standards have been developed as indicators to justify whether or not the reformation succeeds. These criteria are accessibility of health services, the appropriateness of health needs, sharing of benefits and burdens, efficiency, responsibility, and alternative choices (Qiu, 2010, p. 264).

One pilot pioneering reform effort in China that deserves mention is the implementation of Shenmu "free health care" carried out by the county government of Shenmu, Shaanxi Province. All citizens of Shenmu county covered by health insurance can access primary health care for free. Health insurance funding, social donations, and local government together pay the financial cost for this system. For hospitalization expenses, they set up an up-pay system of 200RMB at the village level and 400RMB at the county level, which means that the government pays the balance for a patient's inpatient fees. This effort attracted broad interest and triggered fierce debates in China. The Medical Ethics Society of CMA held a symposium at Shenmu in 2010 specifically to discuss its creative work in health reform. Meanwhile, journals, such as *Chinese Medical Ethics*, published a series of multidimensional research essays on the Shenmu health system.

Human Subject Protection

Since the 1980s, international research cooperation, for example, between China and the US, has been set up in large medical universities, hospitals, and public health research institutions. Peking University Health Science Center (PUHSC) was one of the entities that started the cooperation with US Centers for Disease Control (CDC) in 1989 (on the folic acid project). In the same year, PUHSC established the first institutional review board (IRB) in China specifically for this research project. Since then, IRBs have rapidly developed in China.

In the last three decades, many large hospitals and medical universities in China set up their own IRBs to review biomedical research protocols involving human subjects to protect the rights and the welfare of subjects, as well as to guarantee the quality of investigations. Especially in the areas of clinical drug/medical device trials, ART, human embryonic stem cell research, and organ transplantation, ethical review by IRBs is required by laws and regulations. At the provincial level, the Shanghai Health Bureau is one of the pioneers in setting up ethical committees (ECs). More importantly, at the national level, the MOH established the *Ethical*

Committee of Biomedical Research Involving Human Subject in 1998, later renamed the *Medical Ethical Expert Committee MOH* in 2000.

The legislation in research ethics has improved significantly. In 1999, the State Food and Drug Administration (SFDA) issued *Good Clinical Practice*, which regarded ethical committees and informed consent forms as the principal measures to protect the rights of human subjects in clinical trials; China's GCP was revised in 2003. In 2007, the MOH issued *Ethical Review Regulations for Biomedical Research Involving Human Subject*. This regulation pointed out that at least five IRB members should have different scientific and nonscientific backgrounds. The principles of ethical review were: (1) respect the autonomy and decision of the subjects; (2) the safety, health and right of the subjects always come above any other scientific and social benefit; (3) release or avoid the financial burden of the subjects during the research; (4) respect the privacy and confidentiality; (5) make sure compensation is available should hurt or harm happen; (6) pay special attention to vulnerable populations, including minors, pregnant women, mentally retarded persons and patients, prisoners, the poor, and uneducated people. In addition, SFDA published *Guidelines for Ethical Review of Clinical Drug Trials* in 2010, which illustrated in more detail norms about ethical review of clinical drug and medical device trials.

Another noteworthy activity was that Peking University launched its Human Research Protection Program (PKU HRPP) on October 18, 2010. It is the first HRPP in China. As human research protection becomes more complicated in the context of collaborative global health research, it is necessary to go further to ask for more collaboration and a comprehensive network for protecting research subjects.

Conflict of Interest

In 2001, Jeffrey Kahn from the University of Minnesota and Renzong Qiu published articles on COI in the *Journal of Medicine and Philosophy*, which might be the earliest literature in China discussing and introducing COI in medical research. To date, there are about 30 theses on COI in domestic medical research. Existing research, however, mainly focuses on the introduction of research development and cases in Western countries. With regard to academic discussion, COI is one of the themes in the annual China-US Conference on Medical Professionalism organized by the Center for China-US Medical Professionalism, PUHSC since 2006. Distinguished bioethicists, physicians, and health administrators from China and the US participate in this conference regularly to discuss COI problems and their management.

Challenges

It is undisputable that, during the past three decades, the research of bioethics in China has greatly advanced. However, China still faces some tough challenges that not only concern concrete leading-edge issues, but also the construction of bioethics appropriately in Chinese style.

The first challenge is the institutionalization of bioethics research outcomes, especially legislation of controversial issues in China. As mentioned before, there are a few laws and regulations in China to set the standard norms and basic principles in particular fields, such as ART, stem cell research, organ transplantation, and human subject protection, however, some unaddressed areas still call for more attention. It is unacceptable to simply complain the lag in legislation for brain death as a death standard in China or strike repeated comparisons with the progress abroad without taking any actions to verify and justify the real problems in Chinese society. However, no laws or regulations can solve everything once and forever since new technologies are constantly emerging and changing, which leads to new difficulties and unanticipated problems. Thus, it is necessary to keep in mind that the laws should be flexible and updated appropriately in time.

The second challenge is that Chinese scholars must be more active and engaged in order to solve practical problems in everyday life. Take human subject protection as an example: more attention should be paid to the capacity building of IRBs in China. This means not only establishing such committees in institutions, organizations, and administrations where it is necessary; but also building institutional capacity. Presently, IRBs in China mainly focus on biomedical research, like clinical drug/device trials; public health research and social behavior research are severely overlooked. Another issue is the variation in the quality of ethical review in China from one committee to another; most work is limited to initial review rather than continuing review or quality assurance. This can be attributed to the lack of a systematic training program in China for IRBs to enhance their qualification and capacity. Meanwhile, the lack of proper incentives provides another account.

Third, a reasonable multidisciplinary bioethics curriculum is necessary at the national level of professional training in China. Nearly 30 years ago, medical ethics courses were carried out in some medical universities, and during the last two decades, an increasing number of bioethics courses have been made available. However, there is no formulated bioethics curriculum yet. Graduate students who major in bioethics study in the department of philosophy (e.g., Peking University), the School of Humanities, and the School of Public Health. For example, in China, no School of Public Health (except PUHSC) has ever offered a public health ethics curriculum.

Fourth, the future development of bioethics is intimately combined with the unique mission of bioethics research in the context of China. The mission of bioethics is to explore local bioethical issues and to try to find solutions. It is time to make further efforts to articulate bioethics and medical ethics in China (Du, 2010, pp. 1–5), which would be very helpful to advance not only problem solving but also theoretical development. Moreover, "patient interest comes first" should be treated seriously and emphasized.

The fifth and most important challenge is the lack of effective mechanisms or channels to guarantee the transformation between theoretical research outcomes and legislation/policy. It is deeply affected by the quality of investigations, the operational pattern of social structures, and, more radically, ideas of administration, all of which determine that bioethics scholars cannot handle it alone. Thus, it is

necessary that more researchers with diverse knowledge backgrounds engage in bioethics research in China. Meanwhile, more public engagement, involvement, dialogues, exchanges, and collaborations are urgently needed. Most recently, gene-trans food has attracted public attention, sparking hot debates on whether China should adopt a policy regarding use such kinds of modified seeds and on other related issues. Mutual understanding is hindered due to the lack of platforms for dialogue.

Conclusion

In two or three decades' time, scholars have set up the basic framework of bioethics in China and initiated national and international dialogue. This discussion touched upon a variety of issues, including fundamental arguments at both ends of life, concerns about the quality of human life and well-being, and some reflections on the limitations of human power and creativity. More importantly, the nature of bioethics determines its problem-based research methodology. Thus, bioethics is not philosophical pondering confined to an ivory tower, but is closely connected with real life and human welfare.

China has a long tradition of medical ethics and medical humanities that has significantly impacted its medical professional codes. It is definitely true that China shares fundamental values, such as beneficence, respect, treating patient equally, and doing no harm. Sometimes, unique Chinese thinking has meant that China has developed its own ways and styles of implementing such values. Take "respect," for example: one of the most effective ways is to emphasize "informed consent" in practice. The Western style focuses more on the individual, whereas in China decisions are always made by the whole family or by some family members. In the context of bioethics discussions, the final consequence and the procedure jointly make the justification for its rightness. The same issue may have different implications in different situations, like artificial abortion in China and Western countries. Therefore, examining issues in a broader context is important.

Above all, at the global level, on the one hand, Chinese scholars must develop their own ethical discourses in bioethics research to confront the particular problems China faces. On the other hand, being part of humankind, people still need to work together globally to find common ways and common values instead of addressing only some particular points. Only then people can understand each other better.

Mónica Rincón

Introduction

Bioethics in Colombia began through ethical reflection in medicine and spread to other disciplines. A desire to disseminate bioethics is evidenced by its presence in teaching, assistance, and research by means of a plural and interdisciplinary orientation. Human problems and/or information affecting or having something to do with life in the widest sense possible have been discussed publicly in different environments, while diverse stances have been openly exposed and confronted in

order to find feasible solutions to these issues by favoring the exchange of new knowledge in harmony with a pluralist and right-respecting society determined to pursue the good of all.

Bioethics Development

It is possible to trace some manifestations of ethical concern in Colombia back to 1960, in professionals' writings published in newspapers and journals. Dr. Fernando Sanchez-Torres is an example; his articles began to appear in 1954, and many of them made reference to matters that were not limited to professional ethics for physicians but aimed at extending over wider horizons (Mendoza-Vega, 2002). In retrospect, Dr. Sanchez asserts how the ethical implications of organ transplantation, human reproduction, patients with terminal conditions, abortion, and AIDS began to be discussed (Sanchez, 1994).

In 1954, the Colombian Medical Federation approved a moral code for medicine, but it was seldom used. Later, however, with the increasing number of schools of medicine and the emergence of new technologies, the same Federation proposed to the Colombian Congress a new code to be enacted. After extensive debates, both the Chamber of Deputies and the Senate passed Act [*Ley*] 23 of 1981, "whereby rules regarding medical ethics are issued." This Act establishes that "the teaching of medical ethics at the Faculties of Medicine is obligatory."

This is why, in 1987, the Colombian Association of Faculties of Medicine (ASCOFAME) created a program aimed at teaching ethics to medical students and training professors in teaching this subject. Act [*Ley*] 23 awakened a strong interest for medical ethics since its promulgation and, in 1988, the work "Ética Médica y Bioética. Principales Problemas" (Medical Ethics and Bioethics. Major Problems) was published. Previously, only one book existed, under the title of *Deontología Médica General* (Sánchez, 1994).

In the city of Bogotá, the Nueva Granada Military University (UMNG) has been a pioneer in bioethics development since 1998, at both national and international levels. The principle of bioethical development at the UMNG was born when the medical ethics chair was initiated by the Jesuit priest Father Alfonso Llano SJ., followed by Dr. Gustavo García C. After many years, this chair was reassumed by professors Fabio Garzón, Maria Mercedes Hackspiel, Cristian Galvis, and Mónica Rincón R., who initiated the trans-curricular bioethics chair at the Faculties of Medicine and Biology (García, 1999).

The Colombian School of Medicine (currently El Bosque University) started its bioethics activities in 1976. Dr. Jaime Escobar-Triana, as head of the first intensive care unit in the country at the San Juan de Dios Hospital in Bogotá, carried out jointly with the surgery department of the National University's Faculty of Medicine the first seminars relating to patients' rights, dignified death, and end-of-life decision making.

Subsequently, with respect to physicians' attitudes vis-à-vis the dying patient (*actitud del médico ante el paciente moribundo*), these aspects were developed

at the Colombian Gastroenterology Society, the Colombian Surgery Association, and the University of El Rosario's Faculty of Medicine.

The initial history of bioethics at the University of Rosario can be traced to the initiation of the chair of holistic ethics and bioethics at the Faculty of Medicine, led by Dr. Juan Mendoza-Vega, and particularly aimed at training undergraduate medical students. Subsequently, other health science programs have integrated bioethical instruction into their undergraduate curricula. In 2002, the *Centro Interinstitucional de Estudios en Bioética* (inter-institutional centre for bioethics studies) was founded, led by Dr. Ana Isabel Gómez, and with the involvement of teachers of the School of Medicine and Health Sciences.

At La Sabana University, bioethics was included in the program since the beginning of the Faculty of Medicine, with Professors Pablo Arango and Pedro José Sarmiento-Medina. The Bioethics Institute (BI) at Pontifical Javeriana University (PUJ) was created in 1997 and is oriented towards research, teaching, and advising in the field of bioethics.

In 1989, Jesuit priest Father Gilberto Cely began the first interdisciplinary bioethics seminar at the Faculty of Sciences. His work focuses on ethical and political problems arising in the clinical setting, public health, and the environment. The main functions of the seminar are research and teaching developed through involvement in investigative interfaculty seminars. Specialization and a master's degree in bioethics, and the rendering of services through courses in undergraduate and postgraduate programs have been specially developed by the Faculties of Basic Sciences, Odontology, and Medicine, among others, for research and ethical reflection on issues affecting life in its broadest sense.

Since its creation, the Institute has had different directors, beginning with Father Alfonso Llano-Escobar (1997–2005), and followed by Germán Calderón (2005–2007), Father Gilberto Cely (2007–2010), Eduardo Rueda (October–December 2011), and Dr. Guillermo Hoyos-Vasquez (from 2010 to present).

At the National University of Colombia, in the early 1990s, Professors Nelly Garzón and Beatriz Peña introduced the subjects of ethics and bioethics in postgraduate programs in the Faculty of Nursing. The Faculty began to carry out systematic work on this matter, and a course in bioethics has been taught there for more than 15 years.

In 1986 in Medellin, the country's second major city, Father Guillermo León Zuleta, upon completing his studies in bioethics in Paris at the Louis Pasteur Institute, under an agreement with the Borja Bioethics Institute, was engaged as chaplain of the Faculty of Medicine of the Pontifical Bolivariana University (UPB) and was placed in charge of coordination of the medical ethics area. In 1987, the first bioethics syllabus at this Faculty was structured to become one of the first programs in the country. At that time, medical ethics shifted to medical bioethics. Subsequently, this work would be supported by physician Carlos Alberto de Jesús Gómez, a permanent guest at the Inter-sector Committee of Bioethics created by the former Colombian President Andres Pastrana's Decree 1101 of 2001.

In the field of bioethics, the main actors and institutions in Colombia have been, in the city of Bogota, the Nueva Granada Military University, El Bosque University,

the Pontifical Javeriana University, La Sabana University, the University of Rosario, and the National University of Colombia; and in Medellin with Pontifical Bolivariana University and other institutions; in also in cities such as Barranquilla, Bucaramanga, Florencia, Manizales, Cali, and Cartagena, among others.

Resources Developed

The UMNG has been organizing bioethics congresses since 2001, some of them jointly with the University of Rosario and the National Bioethics Centre (CENALBE).

Table 58.1 shows data regarding the organization of events in bioethics.

El Bosque University organizes annual seminars through its bioethics program, with the involvement of distinguished researchers and academics. The main topics discussed include quality of life, teaching bioethics, human rights, allocation of resources, global bioethics, armed conflict, technology, science, and social perspectives in bioethics – dignity, integrity, and vulnerable populations, among others, seeking to reflect on the problems facing the country and their relationship to the field of bioethics. These efforts seek to bring the scientific community to develop strategies for solutions through bioethics.

The University of Rosario, together with the UMG and the National Bioethics Association ["Asociación Nacional de Bioética"] (ANALBE), has carried out three international congresses. The International Bioethics and Sanitary Law Congress was held with the Pontifical Javeriana University (PUJ). With the Foundation in Favour of the Right to a Dignified Death [*Fundación Proderecho a Morir Dignamente*] (Mendoza-Vega, 2002), an event on the Limitation of the Therapeutic Effort took place in association with the Children's Heart Foundation [*Fundación Cardioinfantil*], as well as many other training activities dealing with end-of-life matters in different Colombian cities. With ANALBE, forums, public debates, and cine-forums have been held to discuss current issues such as conscientious objection, organ transplantation, abortions, the so-called savior siblings or donor babies

[*bebés medicamento*], and euthanasia, among others. La Sabana University offers training courses in subjects such as hospital ethics committees, research, and various bioethics issues such as informed consent, doctor-patient relationship, confidentiality, palliative care, and pain management.

The UMNG's bioethics program has three types of publications resulting from its research:

A journal is published: *Revista Latinoamericana de Bioética* (*Latin-American Journal of Bioethics*) started in 2001. It is the first bioethics journal in Colombia, and the second in Latin America.

Dr. Fabio Garzón is the creator and editor of this publication. In addition, he is the first bioethicist in Colombia to publish an interactive bioethics book.

The mission of this journal is to publish original articles based on bioethics research in the form of an interdisciplinary dialogue, in order to disclose them to the modern university community and other people interested in new advances and applications of bioethics in different fields.

This publication is bi-annual. To date, it has produced 20 issues and 172 articles dealing with research, reflection, and review of various subjects. It has more than 60 bioethicists on its various committees and has been indexed in 7 databases (Publindex B, Latindex, Redalyc, Dialnet, Ebsco, Bireme-Lilacs, and Scielo). Table 58.2 lists the titles of the journal's 20 issues.

There are two book collections: the *Pedagogical and Humanistic Collection* and the *Bioethics Collection*. The mission of the former is to publish the research

outcomes of its teachers' and professors' in matters such as education, ethics, pedagogy, didactics, humanities, and their bond with bioethics (Table 58.3).

The *Bioethics Collection* publishes the outcomes of its teachers' and professors' research dealing with applied ethics and bioethics, in an interdisciplinary dialogue with other areas of knowledge (Table 58.4).

In El Bosque University, the bioethics program publications gather works, studies, and research carried out by students, teachers, and professors, as well as the contributions of both national and foreign authors in order to encourage an interdisciplinary multi (inter-trans) dialogue. The following collections are available: the Bios and Ethos Collection (28 volumes); the Pedagogy and Bioethics Collection (10 booklets); the Bios and Oikos Collection (9 issues); the *Colombian Bioethics Journal* (*Revista Colombiana de Bioethics*) (12 issues); and a bi-annual Bioethics, Science, Technology, and Society bulletin (12 issues) (Ovalle, Escobar, & Aristizabal, 2010).

The University of Rosario has published several books with an emphasis on education – *Bioethics and Education: Research Problems and Proposals*; *What Is Research in Bioethics*; *Bioethics and Research Training; Education in Bioethics*; *and Teaching Bioethics: Why, How and Why?* Another aspect requiring investigation relates to training and education in the faculties related to the field of health, including the following topics: medical ethics and relevance of training; ethics for medical professionals and citizens; requirements for doctors today and projections for the future; bioethical implications of the processes of vocational training in physiotherapy, speech therapy, and occupational therapy; and teaching of bioethics in medical schools in the Western and Eastern international experience. This University is affiliated with ANALBE, and Dr. Juan Mendoza-Vega, head of the Faculty of Medicine, presides over the Foundation for the Right to a Dignified Death ("Fundación Proderecho a Morir Dignamente").

La Sabana University publishes *Revista Persona y Bioética* (*Journal of Person and Bioethics*), created in 2001 and available on the web. To date, with the contributions of world-renowned authors, more than 36 issues have been published. The journal deals with a broad array of topics, from clinical bioethics to the doctor-patient relationship and the beginning of human life, as well as assisted reproduction techniques, end-of-life matters, and other subjects such as palliative care, dysthanasia, environmental problems and ecology, and other subjects relating to biomedical research.

The National University of Colombia has been involved in publications on subjects such as modern bioethics, social responsibility in health, ethics in research

with animals, ethics and odontology, a Latin American bioethics dictionary, and fundamentals of bioethics, among others.

Anamnesis Revista de Bioética (*Anamnesis Journal of Bioethics*) of the Pontifical Javeriana University (PUJ) is a publication first created in 2007 as the *Clinical Bioethics and Philosophy of Medicine Bulletin* by the initiative of the group of researchers in clinical bioethics and philosophy of medicine coordinated by Eduardo Díaz and Fernando Suárez. Notwithstanding its beginning focus on biomedical subjects, *Anamnesis* has become PUJ's bioethics journal, published bi-annually, providing alternative and critical space for debate in bioethics and similar fields in Colombia; it accepts a variety of contributions. The objective of this publication is to offer quality articles in a flexible and accessible format to all those expecting either to be well informed or wishing to take part in debates dealing with bioethics.

Revista Selecciones de Bioética (*Journal Bioethics Selections*), founded in 2002, was the first journal with a selection of articles on bioethics or relevant to bioethics originally published in other national and international journals. It was first sponsored by the PUJ's IB and CENALBE, and it became CENALBE's publication exclusively beginning with number 16; to date, 18 issues have been published. Its present director is Father Alfonso Llano.

In Cali, it was Father Gilberto Osorio who introduced subjects dealing with bioethics and produced, as a study text, some of his lectures under the title of "El Significado de la Bioética en las Instituciones de Salud" (The Meaning of Bioethics in Health Institutions), published by the University of El Valle's Faculty of Health.

Associations

Colombian Institute of Bioethical Studies (ICEB)

In 1986, Dr. Fernando Sanchez-Torres, who had been serving as dean at the Faculty of Medicine in the National University of Colombia and then as its rector, side by side with a group of well-known professionals recognized for their work in medical ethics and deeply interested in bioethics matters, created the Colombian Institute of Bioethical Studies ("Instituto Colombiano de Estudios Bioéticos") – ICEB (Sanchez, 1990).

Colombian Bioethics Centre (CECOLBE)

In 1988, Father Guillermo León Zuleta and Father Jose Emilio Lema; physicians Ramón Cordoba, Norman Harry Hinestrosa, Mario Montoya-Toro, Carlos Gómez-Fajardo, and Jorge Humberto Echeverri; psychologist Luis Fernando Velasquez; and attorney William Botero created a group devoted to the study of bioethics and providing advice in this discipline jointly with teaching and research activities. Under the name of

the Colombian Bioethics Centre (*Centro Colombiano de Bioética*) – CECOLBE, the group later headed the creation of the Colombian Association of Bioethics Institutions (ASOCOLBE). In 2000, ASAIBE, the Association of Bioethics Institutions of the Department (geographic and administrative region) of Antioquia was organized.

Colombian Association of Bioethics Institutions

In June 1998, the creation of the Colombian Association of Bioethics Institutions (ASOCOLBE) was discussed. In July 1999, Father Alfonso Llano called a meeting for all those interested in belonging to the National Association and proceeded to appoint its advising board. In November 1999, the National Colombian Federation of Bioethics and Ethics Institutions (FENCIBE) was founded.

Cenalbe

In 1990, while working at ASCOFAME, Father Llano created CENALBE. This national bioethics center has been at all times concerned with the study and spread of bioethics in and outside Colombia. CENALBE, which is today associated with the Bioethics Institute of the Pontifical Javeriana University – PUJ, contributed to the foundation of ANALBE and the establishment of the Inter-sector Bioethics Committee created by presidential decree in June 2001.

Felaibe

En 1991, CENALBE decided to organize a Latin American Federation of Bioethics Institutions (FELAIBE), more oriented to promote the creation of institutes and centers in all the regional countries to federate those not yet existing. In order to make FELAIBE known, CENALBE organized forums and meetings in several countries of the American continent and the Caribbean.

In 1995, FELAIBE began organizing Latin American bioethics congresses for the purpose of publicizing and promoting them. The first took place in Sao Paulo, Brazil, in 1995, and the second was held at Bogotá, Colombia, in 1998, with 1,050 attendees, followed by a third congress in Panama City in 2000, and a fourth in Puerto Rico in 2003 (Llano, 2007).

Colombian Research Academy for Bioethics (ACIB)

The ACIB was created in 2000 by a group of teaching staff from El Bosque University for the purpose of promoting research in the field of bioethics.

Inter-institutional Centre of Studies in Bioethics and Medical Law

This center was created in 2002 by a group of professionals from Rosario University and professors from other universities.

Colombian Ethics and Bioethics Foundation (FUCEB)

FUCEB was founded in 2009 by a group of teaching staff from La Sabana University, and presided over by Dr. Mario Fernando Figueroa. Their first concerns in the field of bioethics turned around the human genome (genetics), in vitro fertilization, cloning, AIDS, and medical ethics matters dealt with in terms of medical bioethics (informed consent, professional secrecy, confidentiality, and clinical history, among others).

Current Bioethics Infrastructure

Bioethics Education

The UMNG work team carries out the following activities:

Teaching at the Undergraduate Level: Bioethics has become the transversal axis of the social medicine area at the Faculty of Medicine. The outstanding work of María Mercedes Hackspiel on the Values Committee and the preparation of the *Cartilla de Valores* (values handbook) is worth noting. Likewise, in the Applied Biology Program it is possible to take part via the Bioethics Seminar; in addition, elective subjects in the field of bioethics are offered to all programs in the different faculties of this university.

Teaching at Postgraduate Levels: This includes bioethics subjects and seminars in 42 medical specialties and, in addition, seminars in the University Teaching Specialization Program. Bioethics is part of a line of research in the master's degree program in education. Work is being done in the structuring of the bioethics doctoral program to be submitted with official entities for evaluation and approval in 2012.

El Bosque University has had a specialization program in bioethics since 1995 and a master degree's program since 2001. In 1997, the teaching of bioethics was extended to 22,568 teachers having followed the various distance education specializations in the different Colombian regions. Subjects of interest to bioethicists have been introduced in faculties such as medicine, odontology, psychology, nursing, administration, education, and environmental, industrial, electronic, and systems engineering. The bioethics doctorate program, the first of its nature in the country, began in 2006, conducted by Dr. Jaime Escobar. Also the specialization and master's degree programs were the first of their kind. The doctorate program consolidates a long experience in the training of professionals in the field of bioethics; it aims at broadening and developing knowledge and practices for the

solution of ethical problems in a pluralistic and interdisciplinary manner; it empowers students as researchers in the area of bioethics and trains them in both theoretical and in-depth conceptual insight and practical application. Doctoral students' research theses and dissertations deal with topics such as autonomy in pregnant adolescent girls; rescuing wild fauna; private and public school education in bioethics; biofuel bioethics; and introspection in the mentally ill to examine their decision-making ability. One hundred and sixty professionals in different disciplines have obtained master's degrees in bioethics; 296 have completed their specialization, and 5 have been conferred PhD degrees (November 2011). The University of Rosario has extended its teaching action not only to the undergraduate medicine program but also to new undergraduate and postgraduate curricular areas, among which the following programs are worth mentioning: undergraduate biomedical engineering, psychology, and nursing; PhD in biomedical sciences; master's degrees in public health, genetic health administration, biomedical sciences, occupational health, and public health.

La Sabana University offers a 12-month semi-residential specialization in bioethics, including residential classes (3 days per month). To this date, seven cohorts with around 100 professionals in different areas have completed this program. Likewise, medical-surgical specialization with more than 150 physicians under training offers 40-h instruction in clinical bioethics.

The National University of Colombia has a bioethics network as its sole institutional referent in this field, consisting of both internal and external members who have become involved via meetings or through the web page. It is fundamentally aimed at promoting respectful and well-argued dialogue among participants, allowing for the emergence of particularly citizen-oriented stances based on the different training angles where there is no predominance or power of any of the areas of knowledge involved, because there is a constant concept construction where new categories and views unlikely to be experienced in other scenarios can be shaped.

At the National University of Colombia, the creation of ethics committees has shown a contextual dynamic with the institution's public and open nature, making it changing, episodic, and at times ambiguous in its decisions and actions. In 1996, a proposal for the creation of an institutional research ethics committee was submitted by the Research and Scientific Development Committee to the Academic Council, the highest governing body, this proposal not having been welcome by the collegiate body.

This situation led the National University to organize ad hoc committees from time to time in order to answer to notices of meetings – particularly from *Colciencias* – until 2002 when, thanks to the bioethics network itself, the Institutional Research Ethics Committee was finally created.

By the first decade of the twenty-first century, the Faculty of Medicine's Ethics Committee, as well as those of the Biotechnology Institute, the Faculty of Nursing, Odontology, Human Sciences, and Veterinary Medicine had already been introduced.

At present, there is a network integrated by nine faculty committees, including the Medellin headquarters. Its institutional committee was organized in 2008, and

there is a central committee of a normative nature for its creation purposes; in exceptional cases, it becomes a second instance for all those requiring it with relation to the functioning of area or faculty committees.

In the early 1990s, the Pontifical Bolivariana University, aside from medical bioethics, began to work with environmental bioethics, research bioethics, theological bioethics, fundamental bioethics, and biolaw by offering bioethics and biolaw courses and degrees (*Diplomaturas*).

At the Pontifical Javeriana Univesity (PUJ) Bioethics Institute, bioethics is being consolidated towards the articulation of the three tasks – research, teaching, and services – with a more secular orientation so as to approach bioethics mainly in relation to Colombian society and problems, without excluding regional and world issues.

All teachers and professors have either master's degrees or doctorates in diverse areas of knowledge, such as philosophy, medicine, sociology, biology, law, nursing, economics, anthropology, or theology.

The master's degree in bioethics program has been offered at the Bioethics Institute since 2008. Its main purpose is to train scholars and researchers with sound philosophical and scientific foundations, and engage in the generation, transfer, appropriation, and application of bioethics in such a way that, as an academic community, they may contribute to the development of knowledge and an ethical-moral attitude reflecting on the associated public policies, along with the search for solutions to practical problems in the field of bioethics.

Linking students' research projects with the Institute's research lines is a priority. In close cooperation with professors of different universities and CENALBE, Father Alfonso Llano conducted in 1998 the first PUJ's postgraduate specialization in bioethics program. The general objective of this specialization is to establish bioethics both conceptually and virtually as a practical knowledge in its shaping process, supported with discourse and interdisciplinary practice so that students may obtain the conceptual tools required and become involved in a qualified manner.

Elective undergraduate courses include general and/or basic bioethics; environmental bioethics; bioethics and animals; ecological and environmental bioethics; health, risk and technology, and clinical bioethics (these courses are open to different undergraduate programs).

For postgraduate students, master's and PhD degrees are available in the Faculty of Sciences and Basic Bioethics applied to biological sciences.

The Bioethics Institute offers graduate and continuing education courses as a response to several institutions' requests. With an important practical component, these courses meet needs in research ethics training with human beings and good clinical practices, as well as bioethics committees, clinical ethics decision-making, ethical and legal aspects in biobanking, introduction to bioethics, and specific courses for medical specialties, among others.

Bioethics training services have been provided to professionals in several companies in the area of health, and also to school students and governmental social service institutions. Likewise, bioethics training has been offered to students at

other universities at national and international levels. Starting in 2010, debates on bioethics have been carried out to encourage reflection and discussion.

A radio show called, *En Clave Bioética* (literally: In Bioethics Key) was created in 2011 as a way to focus on bioethics issues and/or problems, particularly in the university community. *En Clave Bioética* is a means to understand concepts likely to be analyzed and applied to modern societal problems from diverse disciplines. At the same time, *En Clave Bioética* offers a deliberative point of view with respect to a problem or relevant topic.

Institute professors also take part in diverse academic events at which the results of their researches, studies, and reflections in the field of bioethics are presented.

Bioethics Research

UMNG teachers/researchers are qualified in different disciplines: the areas of health, social sciences, and human sciences, along with biological sciences, the different engineering branches, and administrative and economic sciences, always with an emphasis on bioethical matters and concern for life care in all its aspects. The university's research group (bioethics group) has organized networks with several organizations and institutions in order to create, develop, and carry out research projects jointly with prestigious national and international institutions. A team of interdisciplinary teacher/researches is devoted to research and intellectual production, many with more than 20 years of working in bioethics at educational institutions and other entities, particularly in the area of health. They belong to national and international bioethics associations (listed below), and some are both pioneers and founders of other associations, like the ICEB, attached to the National Academy of Bioethics, or FELAIBE.

A fundamental axis of the bioethics program at El Bosque University is the development of investigative activity, which includes, in addition to research, the creation, organization, and functioning of committees in the different university divisions, such as the Institutional Ethics and Research Committee and the Ethics Research Committee of El Bosque University Clinic, as well as active involvement in the creation of the National Bioethics Council, by the Colombian Congress Act ["Ley"], 1374 of 2010. The "Bioética, ciencias de la vida" (literally: Bioethics, life sciences") research group was endorsed by Colciencias in 2008, and rated under Category A; currently, it belongs in Category C (Bioethics Department, El Bosque University, 2002).

At the University of Rosario, the Education Research Group, in the Bioethics and Medicine Law research line, works in bioethics education, patient safety, and genetics. Likewise, it has a science, technology, and professional research group dealing with humanities, health professional training, and medical professionalism.

The PUJ's Bioethics Institute supports a bioethics research group whose purpose is to develop philosophical explorations of the moral acceptability of diverse courses of biomedical, biotechnological and environmental action, apart from the critical development of social and institutional processes upon which hegemonic

practices depend and, therefore, are ethically unacceptable in these domains. The group's organizational basis includes four research lines, which, in turn, are manage projects including clinical bioethics and medicine philosophy; environmental bioethics, ethics, bioethics, and social sciences; and bioethics and multiculturalism. The Bioethics Documentation Centre ("Centro de Documentación en Bioética") is part of the Javeriana University Bibliographic System. Its mission consists of supporting bioethics teaching, research, and diffusion work carried out by the Institute within the PUJ and nationwide. It seeks to be acknowledged as a Model Bioethics-Specialized Information Unit at the national level, and is equipped with basic bibliographic material complementing bioethics development at the international level and the thematic interests of a well-rounded bioethics program in accordance with the cultural context. Also, given the recent emergence of bioethics and its accelerated theoretical-practical development worldwide, it is not yet possible to talk univocally of a single knowledge matter or of a single specific and unique research method. Therefore, development of new knowledge is necessary, but is only possible through research training and investigative practice. Some research sources in this new field of knowledge come from other disciplines and sciences like biochemistry, genetics, medicine, ethics, philosophy, law, theology, economics, politics, education, and social sciences, among others. These research sources provide essential theoretical and methodological support for a complex reality where diverse and multiple problems converge, all requiring study and a wide interdisciplinary discussion of valorative nature, particularly in the ethical and biopolitical environment.

Bioethics Legislation

In Colombia, only at the turn of the twenty-first century, bioethics began to be given political importance. A bill was submitted in 2000 by Senator Carlos Corsi-Otalora, but it was not passed by the Colombian Congress. A year later, however, former Colombian President Andres Pastrana issued Decree 1101 of 2001, published in the official journal "Diario Oficial" number 44,450 of 9 June 2001, "whereby the Inter-Sector Bioethics Commission is created and its members appointed."

The Universal Declaration on Human Genome and Human Rights, adopted by the General Conference of UNESCO on 11 November 1997, called on the world's states to take all appropriate measures to promote conditions conducive to the free exercise of research on the human genome and to consider the ethical, legal, social, and economic investigations. Beginning with the 18th World Medical Assembly in June 1964 and subsequently ratified by the 29th and 35th Assemblies World Medical in Tokyo and Venice in October 1975 and October 1983, respectively, the "Helsinki Declaration" document was adopted, containing a series of recommendations to health professionals engaged in biomedical research and setting forth rules to be observed as a guide in human studies. As a result of recent advances made in biomedical and biotechnology, there is a need for a multidisciplinary committee of the highest professional level to advise governments worldwide and provide conceptual tools from an ethical-philosophical perspective to reflect on, analyze, and guide

decision-making posed by these sciences. The eighth article of Law 10 of 1990, which is organized by the National Health System, and the fifth article of the Law 60 of 1993, which established rules on organic division of powers, determine, through the Ministry of Health, the rules binding the entities comprising the system.

The Inter-Sector Commission on Bioethics is the consultative and advisory body of the national government under the Ministry of Health. Its charge is research and analysis of public policy issues related to the protection of human life when doing research, development, and publication of scientific and technological knowledge. The tasks set were as follows: Formulate and submit to the government a document that comprehensively addresses the analysis of the ethical questions posed by scientific and technological advances involving human beings and make recommendations to reconcile the freedom of research with respect to human dignity. The document will also analyze the existing legislation on the matter and propose a policy framework to develop ethical principles that should guide research in humans, and the desirability of creating an Advisory Council on Bioethics with binding decisions for the scientific community and society in general. Similarly, the advisory body will recommend what the government must do directly or indirectly with ethical issues arising from scientific research and provide advice and recommendations on matters relating to the ethical implications of intervention and research into the human genome, cloning, biomedical research, in vitro fertilization, transplantation of organs and tissues, xenotransplantation, and with individuals and special communities, especially ethnic minorities, children, and the disabled; research using human cadavers and animals is also included. The advisory body also will prepare reports or opinions on ethical issues arising in the activity of clinical bioethics and research committees, in support of hospitals in the country.

Act ["Ley"], 1374 de 2010 January 8 created "the National Bioethics Council,"; articles 3 and 4 of the Act are regulated by COLCIENCIAS. The entity produced a draft for the introduction of a decree in compliance with this mandate, which was socialized in regions of the country prior to submission to the Colombian President (Bioethics Department, El Bosque University, 2009). "Developing actions leading to the promotion of Education in Bioethics and the society's involvement in the debate of related subjects" (Act ["Ley"], 1374 of 2010, Art. 5, paragraph h.) is one of the functions of the National Bioethics Council (CNB).

The following juridical rules relate to bioethics subjects:

The 1991 Political Constitution of Colombia, where characteristic bioethical matters can be identified, such as life and human dignity, scientifically assisted procreation, health, the environment, and so forth.

Ministry of Health Resolution No. 8430 of October 4 1993, "Whereby the scientific, technical and administrative rules required in health research are established." The enactment of Law 100 in 1993 (which amended the previous National Health System, in force since 1976, and established the current Social Security System in Health (SHSS)) sought to carry out the mandates on health and social security in the Colombian population referred to in Title 2 of the Constitution promulgated in 1991. One of the main foundations of this Act is the goal of increased health care coverage for the Colombian population.

Judgment C-239 de 1997 on euthanasia: Colombia, constituted as a unitary state of law, is pluralistic and based on respect for human dignity. Just as the Constitution gives everyone the right to free development of his personality, no other restrictions than those imposed by the rights of others and the legal system, as the person is recognized by the supreme law as an autonomous moral subject, which means that each person who must choose the principles and moral values that should govern their conduct. The State then is assumed as capable of deciding about good and evil, without the State can legitimately be replaced in this radical decision. Thus, pluralism is a necessary consequence. This implies, of course, the paths drawn, goals set, and decision made regarding what meaning must be given to life, conferred by a Supreme Being or Nature, are among many possible options. A person can judge that life is sacred, invoking religious morality (possibly also of more than one interpretation), considered a valuable good (not sacred), or may not even value it as a good. "The right to life is inviolable." Clearly, if life is a right, no one can legitimately deprive one of life against their will, but any person can freely choose between life and death; when a person chooses to keep still, that is a way to exercise their freedom of movement. If life is enshrined as a right, not as a duty, a person can legitimately continue to live or to stop their life course.

Decree 1546 of 4 August 1998: "Whereby Acts ["Leyes] 9 of 1970 and 73 of 1988 are partially regulated with respect to the obtainment, donation, preservation, storage, transportation, destination and final disposal of anatomic components and procedures for transplantation thereof on human beings, and the minimal conditions required for the functioning of Reproductive Biomedicine Units, Centres or the like are adopted."

The purpose of Reproductive Biomedicine Units is to provide health services in the area of reproductive biomedicine accordance with the principles of quality, timeliness, and logical-scientific rationality. Any program of reproductive biomedicine should ensure the selection of healthy donors and absence of genetic alterations involving risk of congenital anomalies, for as long as the donors remain active in the program.

Ministry of Health Resolution 3199 of 6 August 1998 (which supplements Decree 1546 of 1998): "Whereby technical, scientific and administrative rules for the functioning of Anatomic Component Banks in the Reproductive Biomedicine units, centres or the like are established and other provisions issued." This decree established the functions of transplant ethics committees; the information to be submitted by the agency for the coordination officer; the national network of donation and transplants of anatomical components; health and personnel requirements for these procedures; the production, extraction, and conservation of anatomical parts; and health requirements of the units of reproductive biomedicine. Several teachers and professors have participated on the working board in the preparation of a new medical ethics code and the regulation of organ transplantations.

Act ["Ley"] 599 of 2000 (Criminal Code) in Chapter VIII, "On Genetic Manipulation," typifies as criminal conduct the following: genetic engineering, defined as gene manipulation with purposes other than treatment, diagnosis, or scientific

research relating to the field of biology, genetics and medicine, aimed at relieving suffering and improving the health of the person and of humanity (art. 132); repeatability of human beings by cloning or other procedures (art. 133); and human ovule fecundation for purposes other than human procreation.

Act ["Ley"] 1412 of 19 October 2010: "Whereby the free of cost performance of the procedure of cutting, tying and cauterising vas deferens, known as vasectomy, and Fallopian tubes ligation as means to encourage responsible paternity and maternity are authorised and promoted."

One of the most controversial topics to be debated in Colombia has been abortion. Judgment C-355 of 2006, Judgment T-209 of 2008, Judgment T-388 of 2009, and Judgment T-585 of 2010 were related to this issue. On 10 May 2006, the Constitutional Court of Colombia put forth a landmark ruling in favor of human rights of women. By Judgment C-355/06 of 10 May 2006, the Plenary of the Constitutional Court decriminalized abortion in three circumstances: (a) where the continued pregnancy endangers the life or health of a woman, certified by a physician; (b) where there is severe malformation of the fetus that makes life unviable, certified by a physician; (c) when the pregnancy is the result of conduct, duly reported, constituting rape or sexual intercourse without consent, abusive or artificial insemination or transfer of the fertilized egg without consent, or incest.

Bioethics Committees

At the Military University, the bioethics group took part in the Faculty's Research Committee, integrating the Doctorate in Bioethics Project. Some teacher/researchers are involved in other bioethics committees at health institutions in Bogotá, including the Hospital Ethics and Research Ethics Committees of the International Sanitas Organisation (2000–2010), the Ethics and Surveillance Commission of the Association for Clinical Research in Colombia (1998–2008), the Hospital Ethics Committee of the ("Fundación Cardioinfantil"), and the Children's Heart Foundation.

At the National University of Colombia, the creation of ethics committees has shown a contextual dynamics with the institution's public and open nature, making it changing, episodic, and at times ambiguous in its decisions and actions. In 1996, a proposal for the creation of an institutional research ethics committee was submitted by the Research and Scientific Development Committee to the Academic Council, the highest governing body, this proposal not having been welcome by the collegiate body. This situation led the National University to organize ad hoc committees from time to time in order to answer to notices of meetings, particularly from Colciencias, until 2002 when, thanks to the Bioethics Network itself, the Institutional Research Ethics Committee was finally created. During the 2000s, the Faculty of Medicine's Ethics Committee, as well as the committees of the Biotechnology Institute, the Faculty of Nursing, Odontology, Human Sciences and Veterinary Medicine, had already been introduced.

At present, there is a network incorporating nine faculty committees, including the Medellin headquarters. Its institutional committee was organized in 2008, and there is also a central committee of normative nature for its creation purposes; In exceptional cases, exists at the central level to the Vice Rectory of Research a committee that is normative, and has the purpose to be the second instance for those who require in relation to the operation of the area committees or faculty.

Major Bioethics Issues and Discussions

Different Colombian representatives have taken part in the discussion of major bioethics matters through several academic initiatives, public debate, assistance and research activities, and publications, as described below. Some of the issues are detailed below.

Abortion decriminalization in special circumstances was the topic leading to one of the most intense debates held about the beginning of life in Colombia. In 1975, Senator Ivan Lopez-Botero submitted the first bill in the country *whereby the therapeutic interruption of pregnancy is regulated*. This bill was shelved by the Colombian Congress and, after several failed legislative attempts to succeed in achieving this objective, it was finally passed by the Constitutional Court of Colombia under Judgment C-355 of 2006.

The end-of-life debate began in 1979 with the creation of the *Fundación Solidaridad Humanitaria*, which changed its name in 1983 to the *Fundación Pro Derecho a Morir Dignamente* (Foundation in Favour of the Right to a Dignified Death).

The debate became increasingly intense with the pronouncement of Judgment C-239 in 1997 on euthanasia, which has been previously discussed. Subsequently, several bills attempting to legalize both euthanasia and assisted suicide have been submitted and shelved.

With respect to the health system, the debate on this subject began some years prior to the issuance of Act [*Ley*] 100 of 1993, when the need to change the existing health model was exposed, in order to increase health care coverage for the Colombian population.

With regard to reproductive medicine, the Colombian Fertility and Sterility Society was created 1977; among its founders is gynecologist Elkin Lucena, a pioneer of assisted human reproduction in Latin America and founder and director of the Colombian Fertility and Sterility Centre. There is some debate about assisted human reproduction techniques and the ethical quality of their use, relating as well to the beginning of life, embryo selection, the so-called neo-eugenics or new eugenics, or liberal eugenics, among other ethical objections.

Colombia wished to be at the forefront of bioethics, thus different educational institutions, especially those in the field of health, are constantly integrating their programs of study and their committees the possibility of the study and practice of bioethics. Today in Colombia, health care ethics committees and research ethics committees are required by the government and are evidence of quality in health care.

Future Challenges

There is currently too much noncoordinated activity, and sometimes duplication of functions is combined with non-unified human and economic action.

> There is a tendency to copy foreign efforts; for example, many themes and developments in bioethics are mere duplicates of North American and Spanish proposals. New subjects are omitted and scarcely treated from an endogenous perspective and for regional problems not taken into account in foreign proposals.
>
> Latin American governments, as in Colombia, are usually concerned about urgent situations relating to public order, economy, and public service crises. . .
>
> But they do not pay attention nor give any thought to financing, legislating and instituting National Councils in Bioethics aimed at advising politicians about how humans should treat each other or how humans should treat today's threatened life and nature. (Llano, 2007, p. 57)

There is a strong wish to continue to promote the teaching and study of bioethics from the early school years through the highest levels of instruction, and with the institutional recognition and support they deserve.

Conclusion

Bioethics leaders in Colombia have tried to encourage the study of bioethics by different faculties and promote training at both undergraduate and postgraduate levels. They also have carried out instruction and research activities through renowned national and international publications, active involvement in health institutions' research and hospital ethics committees. Public debates and the formulation of juridical rules, the creation of associations, institutes and networks, as well as participation in federations and societies at national and international levels have increased in Colombia.

The introduction of specialization and master's degrees in bioethics in different universities are worth mentioning, as well as a doctorate program and others currently under a consolidation process for the multiplication and training of researchers.

In the future, an interdisciplinary and holistic approach to human life and the environment is expected (Schmidt & Garzón, 2006). In Colombia today, the objective is to join the efforts of the various institutions doing work in bioethics in order to achieve a sounder integration of knowledge through scientific activities, public debates, and research.

The first Congresses and public debates have already taken place jointly with the different universities. Nonetheless, all those currently involved in bioethics expect to further consolidate the work they are carrying out.

Acknowledgments The author wishes to thank the invaluable help received in the preparation of this paper from: Gustavo García, Alfonso Llano, Fabio Garzón, Fernando Sanchez-Torres, Juan Mendoza-Vega, Ana Isabel Gómez, Jaime Escobar, Gloria Naranjo, Pablo Arango, Carmen Alicia Cardozo de Martínez, Afife Mrad de Osorio, Jose Edwin Cuellar, Diana P. Martínez, and Pilar García.

59

Evariste B. Likinda

Introduction

Bioethics debate is currently widespread all over the world. The adoption by the United Nations Educational, Scientific and Cultural Organization (UNESCO) of the Universal Declaration on Bioethics and Human Rights could be considered as a milestone assigned to be a reference for the whole humanity, with regard to the respect of human dignity and human rights in the specific field of health care, biomedical research, clinical practice, or even medical education.

E.B. Likinda
Chief of Department of Surgery, University Hospital Centre of Mbandaka, Mbandaka, Equateur, Democratic Republic of the Congo

H.A.M.J. ten Have, B. Gordijn (eds.), *Handbook of Global Bioethics*,
DOI 10.1007/978-94-007-2512-6_13,

On the understanding that ethics relates to moral conduct, it is widely influenced by variation between cultures, religious beliefs, and mentalities as diverse as the existing peoples in the world. The hierarchy of values does not seem unequivocal at first.

This disparity in the value scale could partly be due to the large rift separating industrialized countries and those which are aspiring to development, with regard to scientific and technological progress. Diverse perspectives coexist side to side, but more and more often, they confront each other in a globalized world. On the one side, there are people who have mastered mysteries of science and give impression to have the best life conditions, and on the other side, those who are yearning for development and better life; and all that in the same world which, thanks to increased power of communications, is being globalized.

As bioethics concerns matters relating to human dignity, all of the earth inhabitants are inevitably sooner or later assigned to enter this debate; solidarity of all human being is at stake, anywhere one could be in the planet. However, even if problems like disease, sterility, old age, and death are common human realities, the way for them to be solved could vary according to place and time circumstances. Any situation will, indeed, be perceived by different observers from their own particular vantage points, which is focusing on what they consider important. Where the peoples of poor countries such as the Democratic Republic of Congo are concerned, it would make sense for their participation in what is now supposedly a global debate, to emphasize some issues important to them.

The chapter is meant to be a synthetic picture showing how bioethics activities are undertaken, seen, and have evolved since the concept's inception until now in the Democratic Republic of Congo (DRC), while trying to foresee future challenges.

Development in an Academic Framework

Medical Ethics Education

In 1968, the Zairian (Congolese at present) legislature issued a law decree based on the constitution, providing terms of reference and procedures of the Ordre des Médecins (National Medical Council). Then in 1970, a second decree affixed the code of medical ethics. This code is inspired by the International code of medical ethics adopted by the World Medical Association (WMA). Later the Ordre des Médecins has become member of the WMA which has already treated some bioethics issues like *informed consent* emphasized in the Declaration of Helsinki, as it concerns the medical researches involving human subjects.

Since this period, medical ethics education has been introduced into DRC university faculties of medicine. One faculty members, Professor G. Kabakele, an orthopedic surgeon, was in charge of this matter. A manual designed for medical students' ethics education was written by Likinda (2001b), a neurosurgeon and former secretary of the Congolese Medical Council. This book entitled "Principes

de Déontologie Médicale" is essentially focused on the regulation of medical practice, relying on a code established in a juridical text that physicians, nurses, and other health professionals have to respect without giving rise to a debate. It is a compendium of rules of conduct towards patients.

Previously the same author had written "La faute médicale" (Likinda, 2001a), essays on malpractice in which he tackled subjects like abortion and euthanasia, both absolutely prohibited by criminal law in DRC. As the Congolese health minister was the guest of honor at the book presentation ceremony, the author took the opportunity to propose the creation, by government, of a national bioethics committee, emphasizing the last aim of the book. In fact, it seems clear that the questioning raised by subjects like abortion, euthanasia, artificial insemination, and other medical methods made possible by the development of scientific knowledge and new technological progress relating to it pushes the limits of the only ethical code regulating the medical profession. A need to extend the debate has become evident.

Bioethics Classes and Academic Works

By 1987, a bioethics class was already included in the course of theology and philosophy students of Catholic Faculties of Kinshasa (at present, Catholic University of Congo). In the same year, this university institution organized the 16th Semaine Théologique (theology week) with the theme "Christian ethics and African societies"; some bioethics items were placed on the meeting agenda. The first academic dissertation on a bioethics topic entitled "Artificial insemination. Approach to a biomedical ethics" (1987) was written by Muyengo S., a Roman Catholic priest, one of the students of the same university, for a theology degree. Later, he prepared a thesis at the University of Toulouse on "The Status of a Human Embryo. A Fundamental Ethical Issue" (*Du statut de l'embryon humain. Problème de fondement de l'éthique*) (1997). Returning home as professor of moral theology, he successively published "Introduction to Bioethics" (*Introduction à la bioéthique*) (1999) and then "Ethics and Genetic Engineering" (*Ethique et génie génétique*) (2003).

More recently, two theses related to bioethics subjects were written up: "The Fight against Reproductive Crime in DRC" by N. Mvaka (2011), an outline of criminal policies applicable to a bioethics matter, and "Philosophie et prévention du VIH/Sida en Afrique. La pauvreté éthique comme source de persistence des comportements à risque par le VIH," a thesis treated by F. Munday (2010).

Social Context and Questioning

Bioethics has been gaining public interest. Information about unceasing advances made in the field of medicine is generously given by the media, particularly in genetic engineering and innovations in biotechnology. In certain places, some

intellectual initiatives have been formed as discussion forums to debate the main bioethics topics each time they are diffused by the media. This was the case, for example, when the Dutch Parliament adopted the law legitimating euthanasia and even when human cloning was demonstrated to be possible after the birth of Dolly.

At the moment bioethics issues began to raise intellectuals' interest, the suggestion was raised to create an organ in charge of reflection on bioethics questions. Meanwhile, the country was experiencing indescribable and multifaceted socio-economic, politico-military, and humanitarian crises; the country was put through a sustained civil war in its eastern provinces. Subjects such as bioethics were among the last concerns of public authorities focused on reestablishing minimum conditions for a secure life in society. Moreover, strictly speaking, the country was not until then facing problematic dilemmas such as whether or not to permit genetic engineering research, human cloning, organ transplantations, etc. So, on several conference occasions, the question was turned around: What is the propriety, the relevance, and the urgency of bioethics debate in a society where people are still dying from hunger, unsafe water, malaria, and other infectious diseases that would be perfectly curable if medical resources were available, in a country badly under-medicalized, where expectant mothers have no access whatsoever to prenatal care and give birth without medical assistance because there are no adequate medical facilities or competent medical personnel in their area? To sum up, the majority of the population is languishing in poverty. The country is struggling with poverty-related problems that require resolute policies, if they are to be solved. There admittedly are problems into which basic research could be carried out, in order to improve scientific understanding, but in practice, all that is sometimes needed to enhance the people's well-being and promote human dignity are some logistics and a modicum of organization. The country is still in the elementary phase of its search for solutions in the struggle for survival. How to improve the conditions of human beings in this situation is surely the first ethical question that must be raised, a socio-ethical question rather than a bioethical one, if we concede that by definition, bioethics is related to life sciences. Given this picture, to delve into the issues raised by technical and scientific progresses might seem like mere intellectual indulgence that is very far from offering any prospect of practical solutions to the real problems of society.

Institution of Bioethics Structures

National Bioethics Committee (NBC)

Probably because of these above-mentioned reasons among others, institutionalizing a bioethics committee was not seen as an urgent necessity to the eyes of the public authorities getting bogged down in other priorities dictated by the crisis. While the government, given this crisis, delayed its action, a private initiative arose, bringing together a panel of intellectuals from different fields, who already were

used to meet for informal bioethics debate, and they began to discuss the possibility of establishing an advisory organ in charge of providing advice on bioethical problems for adequate legislation, fostering debate, education, and public awareness, contributing eventually to the preparation of guidelines. Indeed in the meantime, without involving a true genetic engineering, there were already some cases where procreation has taken place outside the womb; in a private center of in vitro fertilization, test tube babies have been born in Kinshasa since 2002, which reveals the ease of technology transfer in our time and the necessity of appropriate legislation. These sorts of technology applications, underway in the field of medically assisted procreation, take place in a complete legal vacuum. So that a legislator might make laws in full knowledge of the facts, formalizing an institution was also motivated by the necessity to effectively participate in the world debate. So the informal group drafted a statute for the National Bioethics Committee (NBC) and submitted it to the Minister of Education who chairs the National Commission to the United Nations Educational, Scientific and Cultural Organization (UNESCO), a United Nations specialized agency with a role conducting the said world debate. The Education Minister's agreement (2003) allowed the so-established NBC to play the role of bioethics adviser and to represent the DRC at international meetings concerning bioethics issues.

The NBC is a multidisciplinary and pluralist organ made up of 17 members from different fields (medicine, law, philosophy, theology, sociology, communication, etc.). The multidisciplinary and pluralist nature of bioethics speaks for itself; it is actually evident that no one, not even a scientist, could monopolize for oneself bioethics debate relying only his manner of living and thinking. If, indeed, technical aspects of biology and medicine fall unquestionably within the competence of these disciplines' practitioners, these could not solve by themselves ethics questions relating to use of the said techniques. Bioethics questions are proving to be so much more complex that a proper analysis could not be reduced to a limited view: it is not wise to exclude someone from discussion. Bioethics debate has to make the best of the multiplicity of links between individuals with different angles and diverse interests, but living in the same society; its method has become established as a collective research, each one taking part with his comprehension of existence (Likinda, 2006).

National Committee of Health Ethics (CNES)

In another area, a branch of the University of North Carolina (from the United States of America) planning to undertake biomedical research in DRC, aware of international guidelines, suggested to the DRC Health Minister to form a research ethics committee to be responsible for analyzing and conferring an advice on the research protocols before their implementation. That is how a ministerial decree (2007) gave birth to the National Health Ethics Committee, an independent, multidisciplinary, and pluralist committee whose members are appointed by the ministry.

Bioethics Education Structures

In the aim of promoting bioethics education so that it be widespread over the country, and even over Africa, the NBC of the DRC organized, with UNESCO support, a workshop (July 2009) bringing together the experts who lecture on ethics at French-speaking universities of Central Africa and Madagascar so that they could jointly review the different teaching programs with a view to mutual enrichment and possible harmonization. Some other initiatives have started since the last decade and are currently organizing bioethics courses, seminars, workshops, conferences, and public debates. Some are listed below:

(a) The International Center of Bioethics in Francophone Africa (CIBAF, Kinshasa School of Public Health)
(b) The Circle of Bioethics Study of the Catholic University of Congo (Kinshasa)
(c) The Center of Medical Ethics and Bioethics of the University of Mbandaka (Mbandaka)
(d) The Center of Training and Health Support (CEFA, Kinshasa)

Committees' Activities

NBC Members' Education and Public Awareness

Right from the start, before it could even begin to issue opinions, the NBC had to engage in a major operation to obtain information on the issues involved in what is emerging paradigm. The aim was to obtain as much knowledge as possible on bioethics and enhance capacity in the committee so that the committee would efficiently grasp the essence of the ethical matters raised.

The NBC made efforts to implement a communication campaign by publishing a review entitled *C'est quoi la bioéthique?* (What is bioethics?), a sort of glossary which, for each bioethics concept, gives the definition, what made it problematic, and notably the ethics questions it raises, where the discussion remains open. The aim is to bring readers to assess elements on each subject, to form his own opinion or, if he already has one, to compare it with others, and finally to participate more usefully in bioethics debate.

Conferences and seminars as well as television programs have been organized with the same objective to lead more people to know what it is to analyze and to participate in a dialogue on bioethics issues.

Public Debate Before UNESCO Consultation

At the outset, the members of the NBC have made a big effort of communicating on the meaning of the concept bioethics and all that is at stake. Aiming to bring the contribution of the DRC to the global consultation within UNESCO within

the time frame of process of developing international norms on bioethics, the NBC also organized some public opinion studies and seminars just so as to generate a contribution to the international debate sufficiently representative of the national opinion.

Research Protocols Examination by the NCHE

Meanwhile, the NCHE members had been appointed by the health minister; they are in charge of examining research protocols before implementation; in doing so, they must carefully take into account aspects like informed consent, security of research participants, possible risks, and expected benefits.

Contributing to Assisting Bioethics Committee (ABC) Project of UNESCO

The president of the NBC participates in the ABC project as an expert. By means of this UNESCO project, ABC experts are helping in the earliest phases of establishing national bioethics committees in some countries, and once established, the experts also assist NBC members to implement their actions.

Objectives and Priority Themes

Education

Looking back to just a few years ago, bioethics was an academic subject, treated in a limited way by just a few people in a small circle (the philosophy faculty); the term "bioethics" was familiar neither to public at large or politics figures nor even to university experts. Particular emphasis has therefore to be placed on ethical education. It rapidly turned out necessary for everyone to become informed on ethics issues related to biotechnology development. So there is cause to consider that a great deal of efforts should be devoted not only to place bioethics courses on the education syllabus in universities but also to adapt it for secondary and down to primary school.

Public Awareness

Bioethics has to cease being limited as if it were an academic matter for expert's concern. The debate on bioethics topics has to be generalized. It seems useful to increase public awareness of its issues, by removing barriers within which scientific and technology experts are often locked, whereas ordinary people, indeed, perceive and reason, perhaps in an insufficiently structured manner, at times a casting back

for some values that give a sense to their existence. This openness to the public has a sense only if there can be a thorough popularization and social appropriation of scientific knowledge. Whereas "bioethics for all" certainly requires academic's effort to raise the level of debate and avoid pitfalls, its process also needs more democracy, attracting greater interest of people who therefore not only need to be honestly well informed but also need to give their opinion. Scientific research will play, indeed, its real role only if the men and women, the first and foremost concerned, appropriate it as part of dialogue with researchers about issues and possible consequences relating to science and technology. After all, it is the public that is supposed to benefit from advances in science and technology.

In this approach, media is proving to be an indispensable tool for public awareness; it is, though, of the utmost importance to try to have harmonization of views and in every way with journalists who are the professionals of communication and so very useful for assuring that messages are passed to the public according to their proper sense, without exaggeration or omission. Seminars organized with journalists permit them to progressively perceive what is at stake in bioethics issues; with such knowledge, the journalists will better communicate information.

Popularization of bioethics issues also has to take into account the problem of language understood by those whom the message is intended for, bioethics being no more reserved to academicians, technologists, or their institutions and having become a concern for everyone: not only those who speak and understand French or English but also those who speak other native languages which are not taught at school or at university. An effort is therefore to be done for translating messages into many languages. In DRC, for example, despite the fact that French is the official language, only a few people can use it and even fewer speak English.

Socio-ethics or Bioethics

Bioethics activities in a country like DRC must be first of all a social ethics. It could not be understandable to delve into real ethics issues where the majority of people languish in darkness and poverty. Bioethics activities would not be useful if they do not take into account the public's capacities. For example, it will be an illusion to expect some efficiency in public health planning, while many are illiterate. And how should one fight effectively against AIDS or other sexually transmittable infections where many of the men and women are illiterate and when hunger dictates sexual behavior? How should one improve relations between physicians and patients when citizens ignore and have negligible experience of asserting their elementary rights?

In the strictest sense suggested by its etymology, bioethics should refer to ethics issues arising from the invasive application of biomedical technologies. This development has, indeed, raised a lot of problematic questioning in terms of human values. What is at stake here is ethics or morality concerning human life. Bioethics is here reduced to a minimalist definition concerning "morality study in the field of human life" (Reich, 1994). In this scenario, bioethics is defined as

biomedical ethics. It considers all medical practices and techniques taking place at the beginning of life (contraception, abortion, prenatal diagnosis, medically assisted procreation, cloning), during the course of life (researches on embryonic cells, psychiatric diseases, experiments on human beings), and at the end of life (euthanasia, patients in persistent coma).

The more extensive definition refers to "systematic study of human conduct in the field of life and health sciences, examined in the light of human values and morale principles" (Peeters, 2007). In addition to human and other livings beings (animal and vegetal), the biosphere is taken into account, in so much as it provides the conditions of their harmonious existence (air, water, earth). In this definition, bioethics goes beyond the frontiers of human medicine. Medical questions, demographic problems, environmental issues are in question; all are examined with reference to moral values and principles.

The current sense of the concept bioethics suggests a comprehension of reality in a more extended perspective, in every sense of the word. The Universal Declaration on Bioethics and Human Rights includes effectively a vast field of application consisting of diverse issues; questions of peace, solidarity, and cooperation; distributive justice and equity; future generations; social responsibility; and health; in brief, in addition to biomedical and environmental subjects, social questions and even government systems are concerned. Bioethics is defined here in the widest sense, that is to say all scientific interventions in life in general. It is examined from every angles, biotechnological as well as social. Bioethics, far from being limited to the ethics consequences of scientific and biotechnological advances, extends to social problems which are to be taken into account as a primary concerns in a country like DRC. The main challenge of bioethics activity here and now will be to consider social matters on its agenda. So people of countries like DRC should recognize themselves in these issues, because their critical ethics problems are of social nature. At the very beginning of the bioethics debate in DRC, the same question kept coming up at every conference, as the first ethical question that must be raised: How should bioethics improve the conditions of human beings in the elementary phase of their search of solutions in the struggle for survival? Problems centered on social themes such as malnutrition and resource allocations in the context of scarcity, unemployment, literacy training, life conditions in prison, social security, refugees, and war are part of bioethics, but they have a particular specificity: they have roots in social issues. Value conflicts around life here are expressed as socio- rather than bio-terms. As a result, in this sociocultural context, bioethics is meant to be a field of multidisciplinary reflection concerning entire life conditions. It is also a question for government. For example, it could be that a prevention program for some diseases is to be implemented; despite the fact that people are abandoned and the government fails to keep its obligations on public health, it should be important and indispensable to undertake some initiatives so as to establish the preconditions for the efficient delivery of the prevention project; restoring peace, prompting democracy, encouraging distributive justice and sense of common good, and setting up community structures able to arouse, organize, and manage solidarity and generosity within a state would all certainly help.

Vigilance for Appropriate Legislation

In spite of bad conditions of social life, without involving true genetic engineering, a great deal of biomedical research is now being conducted in DRC; some projects are initiated in the developed world and are conducted at any given time in a number of countries, particularly in Africa. Population groups there are thus affected as human subjects in clinical trials or other studies. Vigilance is therefore required: it would be unacceptable for research institutions or pharmaceutical firms to carry out clinical experiments on human subjects without applying the same rules of ethics and risk reduction as is expected in developed countries. In DRC, there is a risk that research participants may not be in a position to provide informed consent due to the lack of their independent capacity to evaluate the associated risks and benefits in the form of medical care during the trials.

It is also to be feared that, in a situation of widespread deprivation, poor people may easily be turned into guinea pigs, with ethically unacceptable experiments being performed on them for some payment. In other cases, these experimental subjects may simply be excluded from realizing even remote benefits. Impoverished people have risked participating on trials of vaccines or drugs despite that, once the drug or the vaccine is developed, they would not have the financial possibility to buy the product that they have contributed to develop (De Castro, 2001). Moreover, some tested techniques may be unashamed luxuries and their development squanders huge resources: only a few people would derive small benefit from them, while many men and women will not gain any advantage and tested subjects suffer risks and side effects.

Another example is the following: Media reports have revealed also that human organs are being traded illegally in various places; the victims of these sorts of affairs are, in general, poor people. Public vigilance has therefore to be aroused given the possible risk of devaluing and even marketing of life. Even in research locally initiated, the history of the country included experiments where the respect of ethical rules should have been problematic to say the least. In fact, in the year 1987, two physicians, Lurhuma (Congolese) and Shaffik (Egyptian) had to test a drug occasionally named MM1 (Mobutu-Mubarak) against AIDS virus; it was reported that 200 soldiers, although healthy, had been designated by president Mobutu as participants in this experiment without a real informed consent. Groups like soldiers may, indeed, be considered as vulnerable because they could be prone to subtle pressure especially under a totalitarian government.

Even though the resources and infrastructures are not currently available to undertake biotechnological engineering, the experts of research ethics committees must be able to keep abreast of the outcomes of scientific work and give them their proper place among global concerns, concerns for policy-makers and concerns for public opinion. It is important for them to strive not only to understand the issues involved in technical and scientific progress but also to anticipate its future directions. Where clinical trials are concerned, they must not only look out for the well-being and safety of their subjects but also – and vitally – ensure that the research undertaken is truly in line with the priorities of the populations concerned.

Every cloud has a silver lining, an adage says. Poverty and underdevelopment give advantage to know in advance what has happened elsewhere; in full knowledge of the facts, people could think about an innovation before it reaches them. There is no doubt that development will reach these countries with globalization; maybe bioethics debate and, why not, laws will precede biotechnologies. In bioethics approach of life problems, the big challenge here in Africa is to know how to receive science and technology without diluting essential of anthropologic values deeply rooted in cultures and traditions. Attention has to be drawn to what it means to answer bioethics questioning: the answer should not hurt conscience and coherently fit the sense of human which is to be preserved or promoted, the signification or the belief of what persons are. Such an answer to questions raised by such practice or research protocol should not contain the risk of transforming the image that people have of the human being and the basis of the respect due to him? A method which apparently comes up against a limited or individual need, even concerning health, should not contradict fundamental ethics and social ideals, should not it risk being destructive for familiar links and favorable to social collapse?

Participation in the World Debate

Endless Extent of Technical Possibilities

In the past, culture and religion imposed taboos. Values and morale were philosophically and theologically stable as immutable truths. Value bases were referred to transcendence. At present, genetic engineering has shaken this confidence. For example, the capacity to work with embryonic cells has given rise to a lot of promises that organs can regenerate. Human cloning has overtaken the step of technical difficulties so that only ethics questioning remains in discussion. Human genome deciphering has paved the way for not only predictive medicine and genetic therapy but also the possibility of genetically modified organisms, including for the species *Homo sapiens*. All of these technical and scientific realities give the endless extent of possibilities open at present to human power. Biotechnology advances have a real influence on the evolution of mentalities, to the extent that one could say they are moving out of the thinking field. All that becomes technically possible tends to become feasible for an effective application and even for a legitimate claim.

Ambiguity of Progress

It is not about discrediting science and technology. Everyone agrees that science and technology have to aim for human well-being, happiness, and prosperity. Actually, scientific progress has significantly improved the human conditions so that people have longer and better life today. Since the time of our understanding of harmful effects of the atomic bomb, however, no one can have a naïve confidence in all possibilities offered by science. Innovations are often made without anticipation of their consequences. Many technical

exploits have been applauded as progress, but then have been revealed dangerous afterwards. Indeed, supposed progress was the cause of the crisis of mad cow disease; cows, naturally herbivorous, were nourished with meat powder; once a number of cows were ill, they transmitted a spongiform encephalopathy to humans; then, in the distress caused by this situation, bovine populations have unfortunately been decimated (Muyengo, 2004). The growth hormone scandal in France or the StarLink affairs in the USA are likewise well known. Humanity should have understood the necessity of maintaining a sustained vigilance about possible excessive dangers.

Universality is nowadays the key word of bioethics. After having been philosophers', theologians', and physicians' concern, bioethics has later aroused lawyers' interest. Then it, more and more, turned public's attention to its questioning. And at present, the debate is a world concern; the world in its entirety. Globalization is made easier by increased power of communications. Geographic or national barriers are systematically broken down, mentalities tossed, problems universalized, and values standardized. There is cause to fear that this globalization be unilateral, too much empowering those who have mastered science and technology. There is a natural inclination to place inventors and promoters of progresses in a position of authoritative superiority; there is then a risk to give in too easily in each area of debate, seeking the easy way out consisting in breaking off the debate in advance, considering as decisive the arguments put forward by holders of technological and scientific powers: "it is so done in Europe or in USA*;* it is lawful*;* it is therefore legitimate," as sometimes they say. And yet, those who master technical and scientific powers are like holders of weapons of mass destruction; they know very well their complicated tools and mechanisms and how exactly to use them, but they are not necessarily the best placed to know that these arms should precisely and simply have not to be used; they do not have the monopoly to assess the acceptability of actions relating to these arms, according to global human values. Nowadays, while offering beneficial perspectives of improving human life conditions, biotechnological power exceeds by far, in potential nuisance, the devastating capacity of nuclear arms. Today, technology and science result from improvement of knowledge in detail of a given sector of activity: things are studied in depth, giving rise to working efficacy in a closed system. This is mechanic rationality, via hyper specialization. And yet, a compartmentalized knowledge and enclosed rationality could not be omniscient; it brings lots of knowledge, but seems to have trouble understanding multidisciplinary problems and recognizing fundamental and global issues. A real rationality would not ignore the anthropologic complexities. Global rationality has to take in consideration the subjectivity, affectivity, and the part of myth which are integral part of the human mind (Morin, 2007).

Universality and Common Destiny of Humanity

In this stage of history, humanity needs an exceptional wisdom to determine the best possible understanding of human responsibility in the world and to know what could be reasonably done and what could, eventually, not be undertaken. It is time to face the challenge of planetary complexity and recognize ambivalences and

contradictions present in all fields. Wisdom means the crucial realization of solidarity among humans and the planetary community of destiny. Climatic changes have fortunately obliged that every earth inhabitant rediscovers to be on board of the same boat, whose motors derived from human science and technology seem to be out of control. The problem is to establish the control of these engines by ethics. The destruction of the ozone layer, for example, due to excess of industrialization, affects people of forest living without the least product of civilization and of whom are required not to exploit forests for their survival, in favor of the whole humanity. So development admittedly brings scientific, technical, medical, and social progresses, but it also brings biosphere destruction, cultural destruction, and new inequalities and constraints (Morin, 2007). As well as equity problems at stake here, it is essential to realize that the common destiny of humanity has no more to be left in the hands of the one and only Western rationality which seems to become established as the only system of thinking. It therefore would seem wise to consider the problems from every point of view. It is about seeing with our heart as well as thinking with our head, as they say. Instead of assisting, it is an assignment for each people to contribute with its culture, philosophy, and religion which are not to be brushed aside with the back of one's hand, because they constitute the common sense acquired and developed for ages by intuitive understanding, for a responsible management of life and the survival of humanity, through future generations.

Fundamental Humans Values

In this global approach, Congolese people as well as Africans in general have got some difficulties when it comes to dialogue with others on some essential bioethics questions like the respect of human life, human dignity, and consequently human rights. The notion of human rights is today the most shared concept to which infallibly peoples agree. The concept of human rights is closely attached to the one of human dignity in the Universal Declaration on Bioethics and Human Rights. The possibility of equivocal interpretation of human dignity has made that a concrete content has been attributed to it in law terminology, in other words, in terms of obligations. Human rights are rights any living human being is entitled to enjoy, without any other condition than to exist as a human being. This principle is equally applicable to all humans, is not to be gained because of some merit, and cannot be lost because of some failure. However, when the issue is about making precise who is a human being, the concept seems to become equivocal. Each one speaks about human being and his rights while evading essential questions which require coherent answers as basic reference for everyone on the required respect.

In DRC as well as in Africa in general, human being and human life constitute the criterion for every moral judgment (Ngoma, 1994). All acts which contribute to the promotion, the protection, and the conservation of life are morally good acts; (Munday, 1982) on the other hand, all acts damaging individual or community life are considered as morally bad (Mujinya, 1969). The respect of human life is therefore the first norm guiding human acts. It is by the yardstick of human life and human being that the value of other values is measured. Being human appears as fundamental value. Human life is to be protected from the moment it gives sign of life (Muyengo, 2012).

Embryo Status and Abortion

The fundamental question to know if the embryo could be considered as a human being is fairly an academic question, coming close to be a theoretical debate. For an African, even the most cultured, the answer to such a question is, of course, obvious. What else should be found in a pregnant woman's womb apart from a child, that is to say a human being? The concept of embryo is neglected in Africa (Nothomb, 1992); the question is treated nowhere but within the framework of human life. Reflections on the embryo throw back into doubt a whole of anthropology from which results an anthropocentric morality where a child is a gift; he is not to be accepted or refused when he is smoldering. His reason for living has another root than only the willingness of his parents (Eggen, 1996). Parenthood is horizontal as well as vertical; there are vertical links between the invisible world (God, ancestors), therefore a transcendental dimension, and the visible one (group, family). Even in the West where debate on the status of the embryo has taken place, the question is sparked off by new powers that humans had acquired at present in the field of medicine. Even the best understanding of human biology, as deeply as to the molecular scale, would not be possible without putting into perspective the embryo's dignity, it is also the same light that biotechnologies throw on the embryo and his potentialities impose to considering him again, to respect him simply as a full human being. Reticence about the human status of the embryo seems to be driven by utilitarianism. The status of the embryo would be treated in the framework of Kant's doctrine according to which the human person must be considered as an end, not as an object or a means to reach some objectives; he is not to be regarded in terms of value, profitability, or utility, but is to be considered in terms of dignity and humanity.

Whatever has been said about a woman's rights, abortion is quite a scandal for Africans because it contradicts the vocation of woman whose mission is to give and to promote life. Even if a woman has recourse to such an extreme, she is aware of the bad act she commits according to the value of life; she does not throw back into doubt the anthropologic statute of the child she is carrying, neither she claims some right on her body and liberty to match against the child rights. She just is sorry to find herself in a fait accompli which prompts her to such a regrettable act. The fait accompli could be social (misery), moral (incest or rape), or psychological (fear or shame). So the debate here does not concern only the use of a technique, but rather the conception, the ideology, and the aspirations on which are based values and motivated choices (Muyengo, 2012). In DRC, abortion is prohibited by law, in keeping of DRC Constitution which stipulates that human life is sacred from its beginning. According to the Maputo protocol relating to women rights, adopted on the 11 June 2003, in the second ordinary session of the African Union, states have to protect the woman's reproductive rights, especially in authorizing abortion in case of sexual violation, incest, and when pregnancy endangers mental or physical health of the mother or the fetus. Abortion, being considered as a fundamental right in the protocol in question, is proposed to all African governments for ratification (Peeters, 2007); until then, DRC had not ratified it. On June 2009,

without any public consultation, or even debate in the Parliament, the president of DRC did nevertheless sign the protocol at issue, and hardly on the sly. That caused general outcry and protest marches, primarily from Congolese women, when by some indiscretion the fact was revealed to the public knowledge.

These are questions essentially about giving a sense to the respect of life and persons, to the human dignity and values, and giving coherence to the concept of human rights. On these questions, there are real difficulties to dialogue with Westerners who, without taking account of other cultural or religious a priori assumptions, impose outlines in which they would make acts like abortion widespread.

Autonomy and Community

In Africa, life is individual as well as communal. All education system aims to link human to human by multiple solidarity relations for vital social requirements. Any individualistic or egocentric attitude is counted as one of a number of social sins. So, in addition to murder which is an objective and direct infringement to life, disagreeable welcome, incitement to discord, theft, and adultery are considered as serious moral faults (Tshama lenga, 1980). In Africa, the concept of human life becomes exhausted in a perspective of union which means community, unity. The participation in a same life constitutes the fundamental basis of all customs among most African people. Life is led in family and clan community where are united reciprocal influences. Each individual feels that one has a kind of obligation to add his link in the chain. Autonomy is always understood in the social framework linking individual to the community in which family is the important element where human life is conceived and would optimally fulfill its potential; autonomy cannot in this context be proposed as a supreme rule, because community is sometimes entitled to protect an individual despite himself. Africans find it strange that the claim of autonomy is sometimes excessively emphasized, giving the impression of parallels with concepts of individualism or egocentrism, and yet, no individual liberty could withstand sacrificing the bases of human rights. Concerns for maintaining social stability and public order are among collective values which could serve as a protective shield for human rights; favoring individual interest could contribute to disturb the same individual liberty if such a balance is sacrificed. There are in each society collective interests which are to be safeguarded for the good of each constituent individual. The preservation of such collective interests, although exceptionally sacrificed in the name of human rights, may nevertheless generally be the best rampart to preserve the same rights (Terre & Lequette, 1994). Moreover, with all of today's knowledge acquired on the human genome, even our concepts like free and informed consent may sometimes need redefinition; indeed, knowing that genetic data relating to one individual person could concern also his blood relations, one could wonder if someone's right to participate freely as subject in a genetic research would not affect the privacy rights of his brothers and sisters, parents, or progeny who would be reluctant to be part of such study.

Conclusion

The irresistible advances of scientific knowledge in biology and medicine as well as associated technologies have given rise to a real ambiguity: on the one hand, biotechnology developments undeniably offer admirable perspectives of improving human life and health conditions; scientific and technical progress can help human well-being, happiness and prosperity, especially humankind's fight against the suffering generated by diseases. On the other hand, several new serious and difficult questions call out to the conscience. There are distinctly perceptible breaches infringing the most precious principles a human may hold dear, that is to say life and dignity, the sense he attaches to his existence, and the signification he gives to his destiny. These questions apply to several sectors of life, ethics, law, social, cultural, and human rights, and have given rise to bioethics.

In the Democratic Republic of Congo (DRC) like in other African developing countries, bioethics topics have begun to be seen as a relevant, especially in the light of broadcasted news about unceasing scientific advances and innovative biotechnologies. The country, indeed, is still on the fringes of biotechnology experiments.

In spite of unfavorable socioeconomic conditions characterized by poverty, DRC has been among the first in Africa to be concerned about bioethics issues. A bioethics class existed already on 1987, the first thesis on this matter has been written up by a Congolese on 1997, and a private initiative to create a National Bioethics Committee had taken place on 2001.

Facing the reality consisting in a lack of the state-of-the-art biotechnology, the outdated state of medical infrastructures, the mentality, the intellectual level, and the social status of many among the people, bioethics questions are posed first in terms of social problems. Value conflicts around life here are now expressed in term of poverty. It is good that the current definition of bioethics, as it is brought out by the Universal Declaration on Bioethics and Human Rights, has a more extended perspective including social problems at the root of value conflicts.

Nevertheless, African people, sooner or later, are about to confront the same bioethics problems as people from industrialized countries are facing; indeed, transfer of technology is growing, whether it could be done through cross-border researcher or by research centers set up by Northern countries. There is a great deal of research now conducted in developing countries like DRC. It is feared that, in a situation of widespread deprivation, poor people, not being well informed on their rights, may easily be turned into guinea pigs, with ethically unacceptable experiments being performed on them for some undue financial incentives.

Globalization reveals how all earth's inhabitants are in the same boat. It does not really matter which place one lives on the planet; today, the destiny of humanity must be seen as a whole. Because it concerns everyone, it is not to be left to the discretion of those who master arcane aspects of science. New human powers have to be carefully managed, taking into account all wisdom people all over the world have acquired and developed, including by common sense and intuitive understanding. In this connection, Africans have something to bring at the table.

Ana Borovečki

Introduction

In Croatia, the impetus for the developments in the field of bioethics were the changes in the political system. Croatia used to be a part of the former Socialist Federative Republic of Yugoslavia. In the 1990s, the socialist political paradigm was abandoned and the democratic changes began. Thus, Croatia entered the same process as the other countries in the Region of East, Central, and Southeast Europe. The transition from a socialist to a democratic society for Croatia was further complicated by the Serbian aggression and the war experienced in the 1990s (Borovecki, ten Have, & Oreskovic, 2004).

Bioethics Development

In Croatia, the subject of medical ethics, or bioethics, was introduced into the curriculum in the early 1990s at the medical schools of the University of Rijeka and the University of Zagreb. With the advent of the new political changes came the changes in the concept of a subject of medical ethics, which was until that time scarcely taught, mainly as a few hour lecture and seminar at the Zagreb School of Medicine. Moreover, the previously taught obligatory subject of Marxism was abandoned leaving a place for the introduction of a new course in the medical curriculum. Further impetus for the development of bioethics in Croatia was created by the Hastings Centre, especially Daniel Callahan, who through the program of exchange invited several teachers from medical schools of Zagreb and Rijeka for a visit to the Hastings Centre providing them later on with additional materials for the development of future courses in bioethics. Croatian scholars were invited to the Hastings Center in the United States; they came from various disciplines. Some of them decided to take this opportunity to reinvent themselves as teachers of a new discipline leaving behind their past teaching experiences and subjects. However, this encounter with the Hastings Centre was not the first one for Croatian scholars interested in the subject of bioethics. In the 1980s, the Andrija Stampar School of Public Health, School of Medicine, University of Zagreb, introduced an annual workshop at the Interuniversity Centre in Dubrovnik called *Human Rights and Medicine*. There with the cold war still present and the former Socialist Federative Republic of Yugoslavia being more open than other socialist countries at that time, both scholars from the East and the West had an opportunity to meet and exchange their ideas and some of the founders of the Hastings Centre were present at those discussions. Moreover, the *Yugoslav Centre for Medical Ethics* was established at the Andrija Stampar School of Public Health, School of Medicine, University of Zagreb in the 1980s, which was active until the 1990s. Furthermore, a column dedicated to medical ethics was introduced in *Liječnički vjesnik*, the oldest medical journal still published in Croatia at the beginning of the 1980s. These developments, started by Professor Slobodan Lang, although not entirely devoid of the influences of the ideological background present at that time in the former Socialist Federative Republic of Yugoslavia, were important for the development of the field of bioethics in Croatia. In 2010, the Zagreb School of Medicine founded the *Centre for Communication Skills, Palliative Medicine and Medical Ethic*s (Nicholson, 2004; Borovecki et al., 2004).

It comes as no surprise that with these influences new courses of bioethics emerged in Croatia in the1990s. Almost at the same time in the curricula of the Schools of Medicine at the University of Zagreb and at the University of Rijeka new courses were introduced dealing with ethical issues in medicine. The course at the University of Rijeka was started by Professor Ivan Šegota, a former teacher of social sciences whose ideological background was linked to social sciences ideas rooted deeply in the frameworks present in the former Socialist Federative Republic of Yugoslavia. He reinvented himself as a teacher and started a new discipline through the development of the course and subsequent books dedicated to the issues

of bioethics. His work is mainly influenced by the work of Van Rensselaer Potter. The new course was elective. It was at first called *Hippocratic Oath Today* in 1991. Later, in 1992, when the course became an obligatory course in the curriculum, it was called *Medical Ethics*. In 1993, an elective course *Introduction to Bioethics* was introduced. The School of Medicine in Rijeka also briefly published a journal called *Ethics and Medicine* (*Etika i medicina*) (1993–1994), and in 1999 started to publish a students' journal *Bioethics Notebooks* (*Bioetičke sveske*) (still published today). The first PhD in the field of bioethics was also defended at University of Rijeka at the School of Medicine (Gosić, 2000; Zagorac & Jurić, 2008).

The course at the School of Medicine at the University of Zagreb was introduced by Professor Niko Zurak (neurologist by training), Professor Gordna Pavleković (a GP and a public health expert) and Professor Zvonko Šošić (a public health expert). This course was called "Medical Ethics" and its founders were oriented more toward medical practice itself and the problems that emerged in this context, with a critical approach to Van Rensselaer Potter's concept of bioethics, which some of them strongly rejected. Later in two other schools of medicine in Osijek and Split that used to be part of Zagreb School of Medicine the subjects connected with ethical issues in medicine became a part of their curricula as well (Zurak, Derezic, & Pavlekovic, 1999; Zurak, 2007).

Significant influence on the field of bioethics came also through the clinical trials implementation, which began in 1970s with the creation of the so-called commissions for drugs. These committees were the first institutional review boards, which were established for the purpose of joint Croatian-international clinical research projects in main clinical and teaching hospitals in Croatia. Just before their foundation, in order to get well-trained members of such committees, a new postgraduate and specialty training was introduced – clinical pharmacology, and the first department of clinical pharmacology was founded at Zagreb University Medical Centre. As a part of training in clinical pharmacology, courses were introduced dealing with good clinical practice and research ethics issues. Although, at that time some legal provisions concerning medical research were put in place, the majority of professional and ethical decision making concerning approval of clinical trials was left for the committees to decide upon. The main figure in these developments was Professor Božidar Vrhovac, an internal medicine specialist and a founder of the field of clinical pharmacology in Croatia (Borovečki, Francetić, & Mujkić, 2010).

The second phase of the development of research ethics structures began in the 1990s, during the period of transition in Croatia. With the changes within political structures came the changes in education as well as the development of ethics. This shift toward a more an institutional approach can be observed in the legal provisions from that period. In the 1990s, the legal requirements for the work of ethics committees changed. The establishment of ethics committees became required by law, with articles 51 and 52 of the 1997 Law on Health Protection devoted to setting the framework for their duties. The further development of the field of research ethics and the development of ethics committees in Croatia came about in the year 2003 with the implementation of the European Directive 2001/20/EC. One of the

principles set by the Directive was the introduction of a single ethics review opinion for multicenter trails for each member state of the European Union. Prior to 2003, the review of clinical trials in Croatia was done locally by an ethics committee in each healthcare institution. Such approach created a lot of problems and conflicts of interest. In 2003, Croatia decided to follow the recommendations of the Directive and established centralized review of clinical trials. Also under the influence of the Directive in 2003, the new Law on Drugs and Medical Products was implemented. This law was implemented in order to regulate all the activities connected with marketing, production, and research of drugs and medical devices (Vitezić, Lovrek, & Tomić, 2009; Borovečki, Babić- Bosanac, & ten Have, 2010).

The Croatian Academy of Sciences and Arts also played a major role in the introduction of bioethics in Croatian scientific discourse in the 1990s. Professor Biserka Belicza, a historian of medicine who was a head of the *Division for the History of Medical Sciences* at the *Institute for the History and Philosophy of Sciences at Croatian Academy of Sciences and Arts*, with help from the Hastings Center and UNESCO, soon became actively involved in this field, organizing several conferences in Croatia and establishing the *Committee for Biomedical Ethics of the Croatian Academy of Sciences and Arts*. She also served as the Croatian representative at UNESCO's *International Bioethics Committee* (Fatović- Fernečić, 2005).

In the 1990s, Professor Ante Čović, a professor of ethics at the faculty of philosophy in Zagreb, became more and more interested in bioethics. He soon started to publish articles on the subject in the journal of the Croatian Philosophical Society, *Filozofska istraživanja*, and in *Synthesis philosophica*. In 2001, the Croatian Philosophical Society in cooperation with the Croatian Bioethics Society started, a today well-established series of symposia *Lošinj Days of Bioethics* and in cooperation with Bochum University in Germany the *South East European Bioethical Forum*. Professor Čović soon became interested in forming a new concept of bioethics, which he called "integrative bioethics." Integrative bioethics tries to expand the methodological field of bioethics. It dismisses the concept of bioethics as a science or a scientific discipline. It is against the narrowing of bioethics to a version of (bio) medical ethics or to a subdiscipline of applied philosophical ethics. Integrative bioethics is, therefore, an interdisciplinary field of dialogue and encounter of humanities, social, natural, and technical sciences, but also an extra scientific field, where different worldviews and cultural perspectives meet in an open dialogue, and approach the issues of life as a whole with an integrative bioethical sensibility. Professor Čović, in cooperation with partners in Bonn, Bochum, and Eichstätt in Germany and with the help of Zagreb University, founded the Referral Center for Bioethics in South East Europe. With these efforts from the Croatian Philosophical Society bioethics also became a part of curricula of students of philosophy at the faculties of philosophy in Zagreb, Rijeka, Split, Osijek, and Zadar (Zagorac & Jurić, 2008; Čović, Gosić, & Tomašević, 2009).

At the Catholic Theological Faculty of the University of Zagreb bioethics also became an important feature, at first in the works of Professor Marijan Valković

who wrote one of the first reports on bioethics in Croatia (Valković, 1997). In addition, his successor Professor Tonči Matulić contributed significantly to bioethics, especially through his work entitled *Bioethics*, which is written from a theological and philosophical perspective (Matulić, 2001). Early on other Catholic Theological Faculties in Đakovo and Split also introduced subjects connected with ethical issues in medicine.

Another pioneer in bioethics was Professor Valentin Pozaić, a Jesuit scholar (Pozaić, 1992) who with Professor Marijan Valković, was one of the main theological scholars involved in this subject. His work is also very significant. He published numerous publications related to different topics in bioethics. Later, he became a professor at Faculty of Philosophy of the Society of Jesus where he founded the *Centre for Bioethics*, which is a member of the European Association of Centres of Medical Ethics (EACME), and the *Centre for Business Ethics* at the Philosophical and Theological Institute of the Society of Jesus. Both centers have significant collections of relevant literature in the fields of bioethics and business ethics.

The legal profession also contributed to the development of bioethics. In the 1980s and 1990s, Professor Zvonimir Šaparović and Professor Ksenija Turković, experts in criminal law at Zagreb Faculty of Law, wrote several papers on ethics issues in medicine. Furthermore, Professor Vjekoslav Miličić, an expert in the field of general theory of the law and the state at Zagreb Faculty of Law, wrote a book on deontology of the medical profession. Professor Mira Alinčić and later Professor Dubravka Hrabar, experts in family law at Zagreb Faculty of Law, wrote several papers in connection to the issues of artificial procreation and were also involved in drafting several proposals for laws covering this field. In 2009, the *Unit for Bioethics and Law* was founded at the Faculty of Law, University of Zagreb, as a local unit of the UNESCO Chair established in Haifa, Israel. Professor Nenad Hlača, an expert in family law at Faculty of Law at the University of Rijeka, was together with Dr. Dubravka Šimonović the first to translate the Oviedo Convention in Croatian. He also wrote several papers on different bioethics issues. Other faculties of law in Split and Osijek also made contributions to the field of bioethics. The Faculty of Law at the University of Split, for example, founded the *Centre for Medical Law*. In 2009, they started a postgraduate specialist course *Medical Law*, where a variety of bioethics issues are discussed and taught.

Dr. Dubravka Šimonović, an expert in family law and human rights issues, gave probably the most important international contribution to the field of bioethics. She was vice-president and later president of the *Steering Committee on Bioethics of the Council of Europe (CDBI)*, where she was actively involved in drafting several important legal instruments (Šimonović & Borovečki, 2009).

In conclusion, the development of bioethics in Croatia took many roots and approaches making the foundation of the new discipline an interesting journey for everyone involved in this field.

Current Bioethics Infrastructure

Teaching Bioethics

Currently, bioethics courses are taught at all four Schools of Medicine in Zagreb, Rijeka, Osijek, and Split on an undergraduate and postgraduate level. At nursing schools, bioethics courses are also taught at undergraduate level. Bioethics courses are taught at the catholic theological faculties in Croatia in Zagreb, Split, and Đakovo as a part of the course in ethics and moral theology or as separate bioethics courses on an undergraduate and postgraduate level. At the Philosophical Faculty of the Society of Jesus in Zagreb, which organizes its teaching in cooperation with the Faculty of Croatian Studies, the number of bioethics courses on undergraduate and postgraduate level, are also part of curriculum. Bioethics courses are taught at protestant theological faculties in Zagreb and Osijek. At the faculties of humanities and social sciences at Zagreb, Rijeka, Osijek, Zadar, and Split bioethics courses are part of the curriculum on an undergraduate level. Finally, law schools in Zagreb, Rijeka, Split, and Osijek are also actively involved in bioethics education on an undergraduate and postgraduate level.

Ethics Committees

In Croatia, as mentioned above, the first steps toward bioethics institutionalization of ethics committees began in the 1970s with the creation of the so-called "commissions for drugs," which were established for the purpose of joint Croatian-international clinical research projects.

In the 1990s, ethics committees became required by law, with articles 51 and 52 of the 1997 Law on Health Protection devoted to setting the framework for their duties. According to this law, each healthcare institution in Croatia should have an ethics committee consisting of five members, two of whom should be from outside the medical field. Committee functions include:

- Following the implementation of ethical principles of the medical profession
- Approving research activities (protocols) within the health institution
- Overseeing drug and medical device trials
- Overseeing organ procurement
- Solving other ethical issues in the health institution

From this description it is clear that at that time, Croatia had a mixed type of ethics committees in healthcare institutions. Ethics committees performed functions of both Institutional Review Boards (IRBs) and Healthcare Ethics Committees (HECs).

In 2001, the National Bioethics Committee for Medicine of the Government of the Republic of Croatia was founded. This independent advisory and multidisciplinary body is involved in policymaking, education, and debates on ethical issues on the national level. This committee consists of 20 members having different fields of expertise and coming from a variety of institutions. So far the membership of the National Bioethics Committee for Medicine of the Government

of the Republic of Croatia had changed twice. The presence of the committee in public debates and its activities varied depending on the activity and interests of its members.

In 2002, the National Bioethics Committee conducted research on the functioning of Croatian ethics committees. Of particular interest were the number of members, the structure of membership, themes discussed during meetings, reports drafted, the number of meetings to date, policies, and guidelines. Excluding pharmacies and homecare institutions, 241 healthcare institutions took part in the study. Of the participating healthcare institutions, 111 reported having an ethics committee. The response rate was between 100 % and 75 %, depending on the type of the institution (100 % response rate for clinical hospitals, 91 % for regional and local general hospitals, 80 % for clinics and polyclinics, 75 % for medical faculties, and approximately 77 % for all other healthcare institutions, including public health institutes, primary care facilities, and ER facilities). Ethics committees tend to have five to ten members as required by law (though two did not state the number of members, four only have three members, and two have four members). All committees have physicians as members, and 34 committees include a nurse. Only one committee had a philosopher. Almost all committees stated that reviewing research protocols was their main task, though some dealt with other issues as well, mainly concerning "the promotion of the ethical values in their institutions." In 19 institutions, a "commission for drugs" also reviewed clinical protocols, which created additional confusion about the tasks of ethics committees.

In 2003, a new version of the Law on drugs was implemented. This meant significant changes in the work of ethics committees. According to this law, the review of research protocols for clinical trials has now been transferred to the independent central research ethics committee at the *Croatian Agency for Drugs and Medical Devices*. However, the new versions of the Law on Healthcare Protection in 2008 did not significantly change the work of ethics committees in healthcare institutions. They still have the following functions:

- Monitoring implementation of ethical and deontological principles of healthcare profession in the everyday work of healthcare institution
- Approving research activities (protocols) within the health institution
- Overseeing organ procurement of parts of human body after dissection for medical, research, and teaching purpose
- Solving other ethical issues in the health institution

However, the new Law on Healthcare Protection from 2008 introduced the balance between sexes in the membership structure. The membership now has to have 40 % of the members of ethics committee of the opposite sex.

In 2007, with the implementation of the new Law on drugs, the central research ethics committee became responsible for issuing opinions on non-interventional trials as well. This centralization of the review of research protocols in Croatia made the process of review more expedient. Moreover, this prevented having several committees on the local level concurrently reviewing the same research protocol and giving different opinions about it. Furthermore, this centralized approach fosters impartiality and avoids local pressure groups influencing the

review process. Finally, this approach helps to bring together the best experts in one committee, which is especially important in smaller countries, like Croatia.

The majority of the faculties in Croatia now have an ethics committee. These committees are in charge of the review of proposed research projects at these institutions and they also deal with the issues of academic integrity. Ethics committees at the Croatian Medical Chamber and the Croatian Medical Association, the Croatian Dental Chamber, the Croatian Pharmacists' Chamber, and the Croatian Chamber of Biochemists and some other professional associations, deal primarily with deontological values and issues of the specific professions they represent. They do not function in a research oversight capacity (Borovečki, ten Have, & Orešković, 2009).

Expert Bodies/Centers

One of important centers in the field of bioethics in Croatia is the *Centre for Bioethics* at Philosophical and Theological Institute of the Society of Jesus in Zagreb. The center is member of EACME (the European Association of Centres of Medical Ethics). There is also the *Centre for Business Ethics* at the Philosophical and Theological Institute of the Society of Jesus in Zagreb. It has a significant collection of literature from the field of bioethics and is involved in organizing meetings and publication of the books from the field of bioethics.

At Medical School, University of Zagreb, a new *Centre for Communication Skills, Palliative Medicine and Medical Ethics* has been established in 2010. The Centre is also actively involved in the organization of different meetings and educational workshop and plans to publish books for the three fields covered in its work.

At the Faculty of Law University of Zagreb there is the *Unit for Bioethics and Law*. The unit is part of chain of units connected to the UNESCO Chair in Bioethics in Haifa, Israel which is dedicated to bioethics education. Its main work is connected to the organization of symposia and translation of the UNESCO Chair in Bioethics' publications into the Croatian language.

The *Referral Centre for Bioethics in South East Europe*, Faculty of Social Sciences and Humanities, University of Zagreb was established in cooperation with partners in Bonn, Bochum, and Eichstätt in Germany. It has a significant collection of publications from the field of bioethics from the countries of South East Europe and is involved in organization of several important annual meeting and events.

At the Faculty of Law, University of Split there is the *Centre for Medical Law* which has a significant collection of publication from the fields of medical law and bioethics.

Relevant Legislation

The *Code of Medical Ethics and Deontology of the Croatian Medical Association, Croatian Medical Chamber, and Croatian Dental Chamber* (Kodeks medicinske etike i deontologije Hrvatske liječničke komore, Hrvatske stomatološke komore i,

Hrvatskog liječničkog zbora) is an important document for all members of the medical and dental professions in Croatia. There used to be separate ethical codes issued by the Croatian Medical Association, by the Croatian Medical Chamber, and by the Croatian Dental Chamber. Their content was basically the same. In 2006, the three organizations decided to have a joint code.

The *Law on Medical Profession* (Zakon o liječništvu, 2003) regulates the major interprofessional relationships of medical profession and the relationship between the physicians and society.

The *Law on the Protection of Patients' Rights* (Zakon o zaštiti prava pacijenata, 2004) regulates the relationship between physician and patients and promotes implementation and protection of patients' rights.

The *Law on Procurement and Transplantation of Human Body Parts for the Purpose of Therapeutic Procedures* (Zakon o uzimanju i presađivanju dijelova ljudskog tijela u svrhu liječenja, 2004) regulates the field of transplantation of organs and human tissues in Croatia. Croatia has an opt-out system. Those who do not want to be donors have to inform the GPs about it and the GPs then send this information to a central registry.

The *Law on the Ratification of the Convention on the Protection of Human Rights and Dignity of Human Being with regard to the Application of Biology and Medicine*: *Convention on Human Rights and Medicine* (Zakon o potvrđivanju Konvencije o zaštiti ljudskih prava i dostojanstva ljudskog bića u pogledu primjene biologije i medicine: Konvencije o ljudskim pravima i biomedicine, 2003). The law represents the ratification of the Oviedo convention by Croatian parliament thus introducing the Convention into the legal system of Croatia. The Oviedo Convention has become a legal instrument that is above all Croatian laws; all laws had to be adjusted to comply with the Convention.

The *Law on the Protection of Persons with Mental Disorders* (Zakon o zaštiti osoba s duševnim smetnjama, 1997) regulates the rights of persons with mental disorders and the procedures for involuntary hospitalization.

The *Law on Drugs* (Zakon o lijekovima, 2007) regulates the fields of clinical trials, drug production, and marketing policies. *The Guidelines on Clinical Trials and Good Clinical Practice* (Pravilnik o kliničkim ispitivanjima i dobroj kliničkoj praksi, 2007) is a bylaw of the Law on Drugs that elaborates in details clinical trials approval, execution, and monitoring.

The *Law on Animal Protection* (Zakon o zaštiti životinja, 2006) deals with animal protection in general but has several paragraphs dedicated to the protection of animals used for experimentation.

The *Law on Healthcare Protection* (Zakon o zdravstvenoj zaštiti, 2008) deals with the organization of healthcare in Croatia, but also has several paragraphs dedicated to the patient information procedures and establishment of ethics committees in healthcare institutions.

The *Criminal Law* (Kazneni zakon, 2005) has several paragraphs dedicated to the issues of medical laibility, prohibition of active and passive euthanasia, infanticide, and prevention of deliberate spread of dangerous infectious diseases.

The *Law on Health Measures for the Promotion of the Right on Freedom and Decision-making about Birth*, (Zakon o zdravstvenim mjerama za ostvarivanje prava na slobodu i odlučivanje o rađanju djece, 1978) regulates the contraception measures and abortion in Croatia. The abortion is allowed until the 10th week of pregnancy. After the 10th week of pregnancy all abortion requests are evaluated by special commissions. The abortion can be also performed upon the request of minor not younger than 16 years of age.

The *Ethical Code for the Research on Children* (Etički kodeks istraživanja s djecom, Ajduković & Kolesar, 2003) gives basic ethical guidelines for research on children.

The *Law on the Protection of Personal Data* (Zakon o zaštiti osobnih podataka, 2008) deals with protection of all personal data thus also with the protection of medical data.

The *Law on Protection against Discrimination* (Zakon o suzbijanju diskriminacije, 2008) deals with protection against of all sorts of discrimination including the discrimination based on one's genetic heritage.

The *Law on Medical Procreation* (Zakon o medicinski pomognutoj oplodnji, 2012) regulates the field of artificial procreation in Croatia.

Public Debate Activities

Public debate activities are done through public lectures often held in public libraries, symposia organized by Croatian Medical Association, Croatian Medical Chamber, Croatian Philosophical Society, Croatian Bioethical Society, Croatian Catholic Medical Society, among others, different students' organizations, religious organization, political parties' media. Special radio programs and special TV programs are also made to encourage public debate on different bioethical issues and to educate general public. Those are done usually in collaboration with academia as a part of educational programs. The members of the National Bioethics Committee for Medicine of the Government of the Republic of Croatia sometimes participate in public debates but this is very rare.

Other

The following journals publish contributions from the field of bioethics:

The *Croatian Medical Journal* is a Current Contents (CC) indexed journal published six times a year. CMJ owners are four Croatian Medical Schools (University Osijek, Rijeka, Split, and Zagreb). The journal was founded in 1953 as Acta Facultatis Medicae Zagrabiensis and later changed its name to Croatian Medical Journal. It is the official journal of the World Association of Croatian Physicians (WACP), Academy of Medical Sciences of Croatia (AMSC), Forum for Public Health in South Eastern Europe (EPH-SEE), International Society for Applied Biological Sciences (ISABS), and Croatian Centre for Global Health. It publishes papers from all fields of medicine including bioethics and medical humanities.

Synthesis Philosophica is a CC indexed journal published twice a year by the Croatian Philosophic Society. The journal publishes papers from different fields of philosophy including ethics and bioethics.

Društvena Istraživanja is a journal for general social issues, embracing complete thematic and disciplinary openness. It publishes four times a year papers in different social disciplines (sociology, psychology, political science, psychiatry, history, law, economics, demography, linguistics, etc.). In addition, it publishes work that transcends the frontiers of individual disciplines. Papers are subject to anonymous review procedures. The journal is indexed in Current Contents – Social and Behavioral Sciences, Social Sciences.

Prolegomena is a journal published two times a year by the Society for the Promotion of Philosophy. It regularly publishes papers from different fields of philosophy including ethics and bioethics. The journal is cited in Arts & Humanities Citation Index, Current Contents/Arts & Humanities, Dietrich's Index Philosophicus, Humanities International Index, International Bibliography of Book Reviews of Scholarly Literature in the Humanities and Social Sciences, International Bibliography of Periodical Literature in the Humanities and Social Sciences, The Philosopher's Index, Scopus.

Bogoslovska smotra is a journal published four times a year by the Catholic Theological Faculty, University of Zagreb. This is one of the oldest scientific journals in Croatia. It publishes papers on different theological and philosophical issues including the issues from the field of Bioethics. It is indexed in Religious and Theological Abstracts (Myerstown, USA), Elenchus of Biblical Bibliography (Rim, Italy), Ephemerides Theologicae Lovanienses (Louvain, Belgium).

Liječnički vjesnik is a journal of the Croatian Medical Association indexed in MEDLINE/Index Medicus, EMBASE/EXCERPTA MEDICA. It publishes four issues a year. This journal publishes papers from all fields of medical ethics on regular basis including bioethics.

Filozofska istraživanja is a journal cited in Arts and Humanities Citation Index and The Philosopher's Index. The journal is published four times a year by the Croatian Philosophic Society. It regularly publishes papers from different fields of philosophy including ethics and bioethics.

JAHR (*Annual of Department of Social Sciences and Medical Humanities at University of Rijeka Faculty of Medicine*) is published twice a year by the Department for Social and Humanistic Studies, School of Medicine, University of Rijeka. The journal contributions come from the fields of ethics, bioethics, history and philosophy of sciences, sociology, cultural anthropology, theology, law.

Croatian Journal of Philosophy is a peer-reviewed journal with a primary focus on original philosophical work in analytic philosophy in Central Europe. It was established in 2001 and has a particular strength in the philosophy of linguistics. Articles and reviews from Croatia, Slovenia, Hungary, and other countries are published along with contributions from Western Europe and the USA. The journal is published three times per year in Croatia by KruZak and from time to time publishes papers dealing with bioethical issues.

European Journal of Analytic Philosophy is published four times a year by Faculty of Philosophy, University of Rijeka. It regularly publishes papers from different fields of philosophy including ethics and bioethics.

Socijalna ekologija is a journal published three times a year. It publishes theoretical, empirical, and methodological papers within the scope of social ecology, as well as other scientific disciplines related to the area of environmental sociology. The journal is scientific in nature and publishes papers acceptable to variety of readership including papers dealing with bioethical issues.

Zbornik Pravnog fakulteta Sveučilišta u Rijeci is a journal published twice a year by the Faculty of Law, University of Rijeka. The journal publishes papers from the field of law including medical law and bioethics.

Zbornik Pravnog fakulteta Sveučilišta u Splitu is a journal published four times a year by the Faculty of Law, University of Split. The journal is indexed in Current Legal Theory, Index to Foreign Legal Periodicals. The journal publishes papers from the field of law including medical law and bioethics.

Zbornik Pravnog fakulteta Sveučilišta u Zagreb is a journal published six times a year by the Faculty of Law, University of Zagreb. The journal is indexed in Index to foreign legal periodicals, Drant – Droits antiques, Kriminologija in kazensko pravosodje – CRIM, Scopus, and Worldwide Political Science Abstracts. The journal publishes papers from the field of law including medical law and bioethics.

Major Bioethics Issues and Discussions

The debate concerning DNR orders emerges from time to time in professional circles. There are still no clear guidelines in Croatia for the implementation of DNR orders. Since do-not-resuscitate decision making is left to the individual physician, families are seldom involved in decision making. The Croatian Society of Intensive Care medicine has been discussing the issue of the introduction of DNR orders and was trying to find appropriate ways for their introduction. The discussion is only done among their members and with other physicians without the introduction of the problem to general public.

Patients' rights are also widely discussed. The most outspoken about the issue are different NGOs that deal with the protection of the patients' rights. In Croatia, there are several important patients' rights NGOs. The most outspoken about the issue are *Croatian Association for the Promotion of Patients' Rights* (*Hrvatska udruga za promicanje prava pacijenata*) from Split and *Patient Today* (*Pacijent danas*) from Rijeka. The NGOs are not satisfied with the current Law on the protection of patients' rights especially with the extremely complicated procedure for patients' complaints. For the sake of realizing, protecting, and promoting patients' rights, Article 30 of this Act prescribes the obligation of founding a commission to protect patients' rights in each unit of regional self-government (county commissions), while at a state level, Article 38, paragraph 1 prescribes the obligation of the ministry responsible for health care to found a National Commission to protect and promote patients' rights (the Commission of the

Ministry of Health and Social Welfare of the Republic of Croatia). The county commissions, which have five members who are patients, NGOs and experts in the field of protection of patients' rights (Article 32), carry out the following work. They monitor violations of individual patients' rights and propose measures to protect and promote patients' rights in their area, that is, their county, report without delay to the Commission of the Ministry of Health and Social Welfare on cases of serious violations of patients' rights, report to the public on violations of patients' rights, and submit an annual report on their work to the county assembly (Article 33), while at a state level, Article 38, paragraph 1 prescribes the obligation of the ministry responsible for health care to found a National Commission to protect and promote patients' rights (the Commission of the Ministry of Health and Social Welfare of the Republic of Croatia). The procedure of protection of patients' rights before a county commission begins with a complaint by a patient who believes that one of his/her rights as established by this Act has been violated. The patient may express the complaint verbally or in writing to the head of the health institution which offered the specific health service. If the head of the health institution does not inform the patient of measures taken following the complaint within 8 days or if he/she is not satisfied with the measures taken, the patient has the right to file a complaint with the competent county commission. This commission is obliged to inform the patient within no more than 15 days of all the measures taken following his/her complaint. The county commission also has the right of access to premises where health care is provided and the right to inspect how patients' rights are being realized in individual health institutions. The commission is obliged to write a report about the inspections it undertakes, which it must send within no more than 8 days to the competent inspection service (health or sanitary), or the body that supervises the work of health workers, that is the bodies of individual vocational chambers in the health service (the Croatian Medical Chamber, the Croatian Dental Chamber, the Croatian Chamber of Nurses, the Croatian Chamber of Pharmacists and the Croatian Chamber of Medical Biochemists). These bodies are obliged to report within 3 days of receiving the report, and in urgent cases without delay, to the commission on the action taken. If the competent body (inspection service or chamber) on the basis of the procedure undertaken has a reasonable suspicion that a misdemeanor or criminal offense has been committed by the violation of the patient's right, it is obliged to file a misdemeanor or criminal report, without delay and no later than within 30 days, and report to the commission on the outcome of the procedure. The commission will inform the patient about the outcome within 8 days. This procedure is extremely complicated and many complaints are not properly addressed. Possible changes that could establish, for example, an ombudsman system would be more appropriate for the Croatian situation according to the views of some NGOs and some legal experts who undertook the studies of the implementation of the Law. Moreover, a study performed into the work of county commissions found out that their members are often confused about the tasks of commission. The commissions themselves are not really sure what their role is, so they frequently deal with the complaints of the patients related to health insurance rights instead of patients' rights. Even more confusing is the issue of

patient decision making. Article 16 of the Law on the Protection of Patients' Rights from 2004 states that the patient can refuse medical treatment except when such refusal can jeopardize either the patient's health and life or other peoples' health and life. However, in article 22 of the Law on the Health Protection from 2008 one can refuse medical treatment and medical examinations except when such refusal can jeopardize the life and health of other people. Therefore, even if the refusal can jeopardize one's own life or health one can refuse a medical treatment. Here, we have two different approaches to the same issues that are part of two different laws. These discrepancies should be corrected (Borovecki et al., 2011).

In 2009, Croatia implemented the Law on Medical Fertilization (Zakon o medicinskoj oplodnji, 2009). This law stirred a significant public debate, since it was one of the most restrictive in Europe. The law allowed the freezing of female egg cells but not the freezing of embryos. This meant that in vitro fertilization was performed with defrosted female egg cells and then only three embryos were implanted and created. Some of the medical circles were not happy with this solution arguing that such a procedure has no proven efficacy and that the implantation of defrosted embryos is a better procedure. This was supported by a number of NGOs. However, other medical professionals who were performing the procedures according to this law claim that the success rate of such procedures was rather good. The Law did not allow surrogate motherhood, heterologous donation of gametes of both parents or embryo donation. It allowed in vitro fertilization for heterosexual common law couples and legally married couples. It did not allow the creation of embryos for research purposes. A child conceived by medical procreation did have a right to know the donor of eggs or sperm, if the latter had given their consent that their identity could be revealed. Before this law Croatia had no law on medical procreation. Thus, a huge number of surplus embryos had been created in this period for artificial procreation purposes that had been frozen. It is not clear what will become of these embryos.

At the end of 2011, new general elections were held in Croatia and there was a change of government. The new government decided in 2012 to create a new law that would regulate the field of artificial procreation called the Law on Medically Assisted Fertilization (Zakon o medicinski pomognutoj oplodnji, 2012). There has been a huge public debate on this law that was of short duration since the government was pressing the issue and wanted to bring changes to the field of artificial procreation as soon as possible. The new law now allows the freezing of embryos instead of freezing of eggs; medical procreation is also allowed to single women and not only to couples. All religious communities and a number of NGOs were against the implementation of this law. There were calls for a referendum on the law but the government did not want to organize a referendum on this issue.

Croatia is extremely successful in organ donation and transplantation. It has an opt-out system of organ donation and it is a member of Eurotransplant. Croatia is the third country in the world in the number of organ donors. Nowadays, there are not many ethical issues that are being discussed in this field.

Palliative care and palliative care institutions although a part of healthcare legal provisions are still not yet implemented into Croatian healthcare system.

Although palliative care institutions are to be implemented on primary healthcare level, so far there is only one established in Zagreb. The palliative movement in Croatia has a long history. It was started by the efforts of Professor Anica Jušić, a neurologist (Jušić, 1999). Several palliative care workshops and courses are held every year. There is a discussion on the need to extend and improve palliative care services and introduce a palliative care education on undergraduate and postgraduate level. Although there is a constant lack of financial resources in the healthcare system the advocates for the improvement of palliative care are trying hard to bring about the changes within the existing healthcare structures. So far there is the initiative coming from the Catholic Church that is now being involved in building hospices.

Croatia has a long tradition of medical research and recently a good legislation governing this field (see the section on "Ethics Committees"). However, there are still several issues that need to be legally solved. Genetic research is not well addressed in existing legal provisions, as well as the issue of bio-banking. Creating changes that can facilitate the establishment of bio-banks have been made in the Law on Procurement and Transplantation of Human Body Parts for the Purpose of Therapeutic Procedures. However, further efforts are needed in this direction. There is currently a debate among medical researchers regarding the use of archived medical data and tissues in medical research. In Croatia there is no specific regulation regarding this area and the majority of the material archived was collected during medical procedures in hospitals without obtaining the explicit consent of the patients for their use in research purpose. Now, one tries to resolve this situation by the introduction of new informed consent practices that will involve also asking of the patient for consent that his/her medical material collected for health purposes can be used for research purposes since Croatia is now more and more participating in the EU projects. It is clear that special attention needs to be paid to genetic research on archived medical material.

The protection of persons with mental disorders is governed by the Law on the Protection of Persons with Mental Disorders. Involuntary hospitalization is permitted but patients can only be held in a hospital without court procedure for no more than 72 h. After the court decision of involuntarily commitment the case of the patient should be reevaluated within 30 days. After that period the commitment can be extended up to 6 months and then reevaluated. A lot has been done in relation to the de-stigmatization of persons with mental disorders. However, there are still some high profile publicized cases involving psychiatric patients who have been either released and committed crimes or held in psychiatric hospitals without clear diagnostic evidence and public is often discussing whether existing legal provisions could be improved to avoid such situations in the future.

Within the healthcare setting except for the better implementation of the Law on the Protection of Patients' Rights, special attention has recently been placed on the issue of transparency and length of waiting lists. There have been several efforts to shorten the waiting lists. The issue of the rising costs of drugs was also addressed and the government has made several changes to lower the drug prices and to make more transparent the relationship between physicians and drug industry. Some propositions

made by the government in debates over this issue involve the establishment of funds for physicians' education in order to avoid the direct payment of medical conference participation to physicians who often do not even actively participate. The idea is to send with this money only those physicians who have a poster or oral presentation at a scientific conference and to make the process transparent.

Future Challenges

There is a need for further development of bioethics education especially on the postgraduate level. Some of the existing legal provisions will have to be amended, especially the Law on the Protection of Patients' Rights, because its current implementation is causing many problems. The issues of genetic testing, research, and bio-banks need to be further looked into with a view to the development of additional legal frameworks that might cover these issues.

Conclusion

The development of bioethics has gone a long way in Croatia. However, there are still some challenges ahead. Nevertheless, one can conclude that the state of the development of the field of bioethics is on a satisfactory level. Other countries who share a somewhat similar path of history and development can learn a lot and the Croatian experience can help others in their development of the field of bioethics.

Linda Nielsen and Berit Faber

Introduction

This chapter about bioethics in Denmark focuses on specific Danish characteristics. These are the early start of a bioethics debate, legislation, and councils; the independence of the councils and the parliamentarians voting on ethical issues; the introduction and extraordinary importance of laymen as part of the bioethical debate and decisions; and the strong focus on debate and educational tools.

DOI 10.1007/978-94-007-2512-6_16,

In the following the development of bioethics, the bioethics infrastructure, major bioethics issues at the moment, and the challenges for the future are outlined followed by a conclusion.

Development of Danish Bioethics

Denmark has a history of being one of the "first movers" on the agenda of bioethics, encouraged by important persons advocating for introducing bioethics in a number of ways.

The *Scientific Ethical Committee System* in Denmark was introduced on a voluntary basis as an initiative of biomedical researchers, among whom Professor Povl Riis was the main initiator. It is the responsibility of the committee system on biomedical health research ethics to ensure that from a research ethical point of view, biomedical health research projects are carried out in a responsible manner and that the rights, safety, and well-being of trial subjects participating in such biomedical research projects are protected, while at the same time possibilities are being created for the development of new, valuable knowledge. The basis of the Danish system was the Nuremberg Code and the Declaration of Helsinki, and the first committees were set up in the late 1970s and the early 1980s. Since 1980 Denmark has had a coherent, nationwide committee system with common guidelines and statutes. The scientific ethical committees are examples of an outcome of a democratic dialogue and cooperation between experts and the rest of society.

In order to assess the need for legislation in the area of bioethics,the Danish Ministry of Interior Affairs established two commissions: The Commission for Gene Technology in 1983 and in 1984 the Commission on Ethical Problems regarding in vitro fertilization, artificial insemination, and fetal diagnostics. The commissions were given the task to investigate the need for regulation of safety issues and of ethical issues.

At this time an intense debate in the media about the rapid development in the field of reproductive technologies captured the public. In October 1984 the Committee on Ethical Problems regarding in vitro fertilization, artificial insemination, and fetal diagnostics submitted its report: "The Price of Progress" in which it suggested that a central ethical council for the health services should be created by law. A large majority in the Danish Parliament passed the bill on the establishment of ethics council and the regulation of certain biomedical trials in June 1987. The purpose of the act was to secure that advice and information concerning ethical problems arisen from the development in artificial procreation in the health service and in the biomedical field was given to the Danish Parliament, the government, and the public in general. The result of these deliberations was the establishment of *the Danish Council of Ethics*. In 1987 a special committee in the Danish Parliament was set up with the sole purpose of safeguarding the close relations between the Danish Parliament and the Council of Ethics. The parliamentary committee has a certain influence on the composition of the Council of Ethics and appoints

a certain number of its members. Furthermore, the parliamentary committee follows the work of the council and can also ask the council to treat certain topics within its terms of reference.

The Danish Technology Board was set up as a statutory body in 1986. The purpose was to disseminate knowledge about technology, its possibilities, and its effects on people, on society, and on the environment. The *Danish Board of Technology* was established as an independent body by the Danish Parliament in 1995 and is the successor of the Technology Board.

The issue of artificial reproduction was subject to intense scientific, ethical, political, and public debate in the 1990s, and assisted reproduction is still subject to debate in Denmark. In 1984 the report "The Price of Progress" from the Ministry of Interior Affairs the Committee on Ethical Problems regarding in vitro fertilization, artificial insemination, and fetal diagnostics had drawn the conclusion that no specific legislation measures were needed in the area, but recommended that an independent ethical council for health care services would be established.

But the ethical dilemmas in connection with the research and the use of artificial reproduction grew stronger. In 1997 the first *Act on Artificial Reproduction* was adopted in Denmark. One of the more controversial areas of debate was and is the access to assisted reproduction of single and lesbian women. This is an issue that is still a very controversial one. In the deliberations on the ethical, scientific, and health-care-related questions to assisted reproduction, the Danish Council of Ethics has played and still plays an important role.

The *Danish Committees on Scientific Dishonesty (DCSD)* were set up in the fall of 1992, initially for a 3-year trial period. Back in the 1950s there was a controversial case of scientific dishonesty in a medical doctor's thesis. This case among some of the cases from the USA made a huge impression on quite a few of the newly educated medical doctors from that generation. Over the years the need for establishing a system for dealing with cases of scientific dishonesty grew. In 1992 a working group with prominent Danish medical researchers as Povl Riis, Daniel Andersen, Torben Clausen, and Niels Axelsen among its members issued a report on scientific dishonesty. (Professor Dr. Med. Povl Riis and former deputy chairman Daniel Andersen have in the annual report from 1996 of the Danish Committees on Scientific Dishonesty given a layout of the historic background for creating the first Danish committee for scientific dishonesty). The conclusion was that Denmark could benefit from a central committee based on a voluntary initiative from medical researchers in order to ensure scientific integrity. In order to ensure the legal rights of the parties involved, it was deemed essential to make a qualified judge the chairman of the committee. The committees' mandate comprised only the area of human medical research. In 1995 it was decided to establish the committee on a permanent basis, and in 1998 the decision was taken to broaden the scope beyond the medical field, including natural sciences, social sciences, and humanities, thus establishing 3 committees on scientific dishonesty.

The Danish Committees on Scientific Dishonesty (DCSD) deal with complaints regarding dishonesty in research.

A case can be brought to the committees as a complaint. It is also possible to have a case processed in order to be cleared of accusations of scientific dishonesty.

Each of the three committees comprises one chair and six members.

The members are recognized researchers who have been officially appointed by the Danish Minister for Science, Technology and Innovation after hearings conducted by the Danish Council for Independent Research.

The joint chair for the three committees is a high court judge who is appointed by the minister.

Current Danish Bioethics Infrastructure

The Danish Council of Ethics

The Danish Council of Ethics was set up in 1988. The council's main functions today are to give advice to legislators and the government and to create public debate on issues pertaining to biotechnology, which affect human life, nature, the environment, and food. The council also covers all ethical issues related to the health care sector.

The Danish Council of Ethics has contributed in developing the public debate by setting up public consultations and debates about ethical questions relating to new technologies within medicine. The council aims at communicating ethical dilemmas relating to biotechnology, the use of natural resources, environmental issues and the area of human health to Parliament, the government, and the health care sector, and to lay people.

According to the current law (Act No. 440 of June 9, 2004), the Danish Council of Ethics consists of 17 members chosen from a mixture of specialists and lay people. Nine members are chosen by a parliamentary committee whose task is to follow the work of the council. In addition, 4 members are chosen by the Minister for Health; 1 member is chosen by the Minister for Environmental Affairs; 1 member is chosen by the Minister for Food, Agriculture and Fisheries; 1 member is chosen by the Minister for Science, Technology and Development; and 1 member is chosen by the Minister for Business.

When the Minister for Health appoints the members, the minister must ensure that lay people as well as experts are represented in the council and that there is equal representation of men and women in the council leaving the possibility for either 9 men and 8 women or 9 women and 8 men as members.

The chairman of the council is chosen by the parliamentary committee and is appointed by the Minister for Health. Members and chairman are appointed for a 3-year period and can be reelected for one more period.

The government has no instructional powers toward the Danish Council of Ethics, and likewise the government has no obligation to follow the recommendations of the council. The funding is provided by government, but the council chooses the topics itself and works independently. The council is providing advice but has no competence to make any forms of binding decisions.

The Danish Board of Technology

The task of the Danish Board of Technology is to promote the ongoing discussion about technology, to evaluate technology, and to advise the Danish Parliament and other governmental bodies in matters pertaining to technology.

One of the "inventions" of the Danish Board of Technology was the "consensus conferences," where a number of lay people are "informed and educated" regarding a specific topic, having an opportunity to ask a number of presentations and questions to experts. Based on this, they form an opinion, which is presented to the politicians and the public.

Every year, after a specific stipulation in the nation's "Finance Law," the Danish Board of Technology receives an annual subsidy of around 10 million Danish kroner. The Ministry of Research is the supervising authority for the board, and the Parliament's Research Committee is the board's steady liaison to the parliament. Once a year, an annual report is submitted to the parliament and the government.

On November 15, 2011, it was announced that a bill is prepared in order to close down the board due to a set of really difficult negotiations on the national budget for research and innovation next year. In this connection the public funding of the Board of Technology of 10 mio. Danish kr. is to be withdrawn in order to reach an agreement on a 1 billion DKK (140 million €) extra research budget. Currently a bill has been drafted in order to terminate the Board of Technology. From Wednesday the 20th June 2012 and onwords the Board of Tehcnology has been restructured into a foundation. The Danish Board of Technology Foundation will be a new, non-profit organization that will continue the work of the Danish Board of Technology. At this moment it is not known whether the Board of Technology will be closed down, or whether the activities of the board will be carried on in a different setting.

The Danish Committees on Health Research Ethics

In Denmark research projects involving human beings or any kind of human tissue, and cells need authorization from a regional ethics committee. See the present Danish Act (Act No. 593 of June 14, 2011, on Research Ethics Review of Health Research Projects). According to the newest English translation of the law from the Danish Ministry of Health, the Danish Scientific Ethical Committees are now translated the Committees on Health Research Ethics. The law implements the principles from the EU directive 21/2001.

The Danish Scientific Ethical Committees are characterized by a high representation of lay members.

The *appointment* procedure is as follows: A regional county council appoints the regional health research ethics committees for a 4-year period. The county council can appoint one or more regional health research ethics committees within its geographical area. A regional health research ethics committee shall consist of at least 7 members and at most 11 members. Three to five members must be active in

the area of biomedical science, and the rest of the members of the committee must be lay members. The members can be reappointed for 2–4-year periods.

The National Committee on Health Research Ethics consists of 13 members: The chairman is appointed by the Minister for Health. Two members are appointed by the Minister for Health after joint recommendation from the board of the Danish Council for Strategic Research and the Danish Council for Independent Research. Five members are appointed by the Minister for Health in collaboration with the Minister for Science, Technology and Development after a public call for candidates. Five members are appointed after recommendation from the county regions. When recommending candidates for the committee, an equal number of men and women must be recommended. When the committee is appointed, an equal representation of men and women must be ensured – so because the uneven number of members you can either have is 7 women and 6 men as members, or 7 men and 6 women as members. The committee must consist of members representing both biomedical health research areas and lay members. The chairman must represent public research interests and public educational activities, health research ethics, and general cultural or social interests that are important for the committee's work. The members cannot hold a seat in the parliament or in a county council. The members are appointed for a period of 4 years and can be reappointed for 2 terms.

According to the act, the medical researcher is responsible for the scientific and bioethical quality of the research project. The medical researcher in charge of the trial must apply for authorization from the regional health research ethics committee in the area in which the investigator is operating. The application should conform with the "Guidelines about notification etc. of a biomedical research project to the committee system on biomedical research ethics." According to Act No. 593 of June 14, 2011, on Research Ethics Review of Health Research Projects, the medical researcher responsible for the research project applying for authorization must send the application to the regional health research ethics committee in the area in which the investigator is operating.

It is the responsibility of the Scientific Ethical Committee System to ensure that research projects are carried out in a responsible manner in accordance with the ethical principles of biomedical research and to ensure that the rights, safety, and well-being of trial subjects participating in biomedical research projects are protected. At the same time research projects should provide possibilities for the development of new, valuable knowledge or the deepening and evaluation of existing biomedical knowledge.

The Danish Act on the Scientific Ethical Committee System lays down the legal framework for the scientific ethical assessment of research projects in overall terms. The requirement of informed consent is entirely fundamental to the rules governing the scientific ethical assessment of research projects and to the committee system.

In June 2011 the Danish Parliament adopted a new act amending the act on the Scientific Research Ethics Committee System (Act No. 593 of June 14, 2011, on Research Ethics Review of Health Research Projects entering into force on January 1, 2012). The act lays down new rules for the composition of the committees,

the collaboration between the regional committees, and the national committee. Furthermore, new regulations for the mandate of the ethics committees are stipulated in the areas of inspection of biomedical research trials, quality, and evaluation. The internal collaboration among the research ethics committees and the external collaboration with other stakeholders such as universities, researchers, hospitals, and governmental and regional stakeholders have been elaborated in the act. The other amendments are mostly elaborations and precisions to regulations of the previous act.

The Danish Committees on Scientific Dishonesty

The task of the Danish Committees on Scientific Dishonesty is to make binding decisions. Therefore, it is important that the academic requirements of members and the chairmanship satisfy the need for both trained decisions makers and experts in the fields of biomedical research in question.

One chairperson, who must be a high court judge, chairs the Committees on Scientific Dishonesty.

In addition to the chairperson, each committee consists of six members and the same number of alternates who may only deputize on any member's absence and only for the full consideration of a case. The members shall all be recognized researchers, who between them cover all areas of scientific research. The alternates are appointed after the same criteria as the members.

The chairperson is appointed by the Minister for Science, Technology and Innovation. The members and the alternates are appointed by the minister in their personal capacities following a hearing conducted by the Danish Council for Independent Research. The chairperson, the members, and the alternates are appointed for a period of 4 years and are eligible for reappointment for a period of no more than 2 years.

Based on the experience from the area of medical research, it was in 1998 decided to create three committees on scientific dishonesty covering a broader range of the scientific fields: In the Danish Executive Order No. 933 of 15 December 1998, the Board of the Danish Research Councils was given the mandate to create three committees on scientific dishonesty within Danish research:

1. A committee for research in natural science, agricultural and veterinary science, and technical science
2. A committee for research in health and medical science
3. A committee for research in social science and the humanities

The committees shall jointly determine the remit of each of the three committees set out in the executive order. The demarcation lines are specified in committees' rules of procedure.

To the committees was appointed a joint chairperson – a judge – one of whose tasks was to ensure uniformity in the statements made across the different fields of research.

In the Act from 2003 (Danish Act No. 405 of 28 May 2003 on Research Advice), it was stated that a revision should take place in the 2007–2008 session of the Danish Parliament on the basis of an evaluation of the advice provided by the

research advisory system concerning support for research training. The revision process was planned to take place in the first part of 2008. The Danish Agency for Science, Technology and Innovation and the Danish Ministry for Science, Technology and Innovation prepared the bill.

Major Bioethics Issues and Discussions at the Moment

The Danish Council of Ethics

The council has two main functions: (1) To offer advice to the Danish Parliament and the Ministry of Health and Interior Affairs on ethical problems arising from the development of new technologies and treatments in health care and (2) to inform the public and to promote public debate and public dialogue on ethical issues in the field of human health. The original wording of Section 1 in the act, stating that the council should "carry out its work on the basis of the assumption that human life takes it beginning at the moment of fertilization" (Section 1 of the Act of the Danish Council of Ethics (440/2004)), was changed by the government in the revision of the act in 2004 to the following wording: "Respect for the integrity and dignity of the human being also encompasses the early phases of human life, including fertilized human eggs and embryos" (reference). Thus, the debate on when life begins has changed. It is still being debated from time to time, but is not as controversial as it was in the beginning and as it is in many other countries.

The Danish Council of Ethics has among other themes dealt with the following issues:

- Priority setting in health service
- Medical euthanasia
- Health science information banks
- Treatment of psychiatric patients
- Prenatal diagnostics; examination of fetuses and fertilized ova for disposition to illness
- Organ transplantation
- Priority setting in biomedical research
- Legal aspects concerning the problems of demented patients
- Man or mouse? – ethical implications of stem cell research
- Microinsemination and preimplantation genetic diagnosis
- Medical enhancement
- Utility, ethics, and belief in connection with the release of genetically modified plants

The Danish Regulation on Assisted Reproduction

The Danish Council of Ethics, the Scientific Ethical Committees, and the Danish Board of Technology have dealt with the ethical issues of assisted reproduction in

several reports and conferences during the 1990s. In 1996 the bill on artificial fertilization was introduced in the Danish Parliament. Because the bill dealt with ethical issues, the members of parliament were allowed to vote in accordance with their conscience and were not subjected to the otherwise strict party discipline. This resulted in a fairly big amount of questions to the Minister of Health and amendments to the bill. As a result the bill was not passed in the Danish Parliament before May 1997.

The present act from 2006 (Act No 923/2006) which is the newest revision of the former act stipulates that the act is applicable for medicinal treatment, diagnostics, and research that is conducted by a medical doctor or under the responsibility of a medical doctor, where a pregnancy is induced in a woman in other ways than between sexual intercourse between a woman and a man. The act restricts the offer of medically assisted artificial reproduction to single women with no children and couples with no children of their own. There is though a possibility to be treated in order to have more children within a period of 5 years if the woman/couple has stored frozen fertilized eggs (Section 15).

Prohibitions against treatment are set out in a number of situations:

1. Assisted reproduction cannot take place unless it is with the view of uniting a genetically unmodified ovum with a genetically unmodified sperm cell.
2. It is prohibited to implant identical unfertilized or fertilized ova in one or more women with the view of inducing pregnancy.
3. A pregnancy must not be induced unless the ovum stems from the woman who is giving birth to the child or the sperm stems from her partner.
4. Assisted reproduction must not take place in the case where the woman giving birth to the child is older than 45 years.
5. The fertilized egg's further development cannot take place outside the uterus of a woman.
6. It is prohibited to use ovaries from aborted female embryos, stillborn baby girls, or deceased women.
7. It is prohibited to transplant ovaries to a woman with the aim of curing infertility.
8. It is prohibited to sell, promote commercialization, or in any other way to participate in the commercialization of unfertilized and fertilized human ova.
9. It is prohibited to perform a treatment of assisted reproduction in the case of surrogacy.
10. It is not permitted to export a fertilized ovum.

The act also lays down *restrictions* in the following cases:

1. It is prohibited to apply new treatments of assisted reproduction before the Minister for Health has authorized them. Before authorizing a new treatment, ethical and health care issues shall be taken into account.
2. Choosing the child's sex can only be permitted, if it is done in order to prevent a serious hereditary disease.
3. Genetic diagnostic techniques can only be performed on fertilized eggs in cases where there is a known and substantially heightened risk that the child will develop a serious hereditary disease.

4. Preimplantation diagnostics can be allowed by the heath authorities in the case, where consideration for a child with a serious hereditary illness in the family requires this.
5. Assisted reproduction with human sperm cells that have been manipulated can only be carried out under the supervision of a medical doctor.

If the medical doctor responsible for the treatment deems it likely that there is clear doubt as to whether the woman/couple is capable of taking care of the child after birth, the doctor shall reject treatment of the woman/couple. If the doctor deems it likely that there is reason to doubt the ability of the woman/couple to take care of the child after birth, the doctor shall get a second opinion seeking competent evaluation of the situation if the woman/couple agrees to this. If the woman/couple do not agree, the doctor shall refuse treatment.

The following types of *research* are *prohibited*:

1. Research with the aim of producing genetic identical individuals
2. Research with the aim of producing individuals by merging genetic different embryos or parts of embryos before they are implanted in the uterus
3. Research with the aim of producing chimeras
4. Research with the aim of developing a human individual in a nonhuman uterus

Only certain types of research on assisted reproduction can be carried out and only after authorization from a Scientific Ethical Committee:

1. Research with the aim of improving IVF techniques
2. Research with the aim of improving techniques of preimplantation diagnosis in order to ascertain a serious hereditary disease
3. Research on fertilized eggs and stem cells with the aim of gaining new knowledge in order to better the treatment of illnesses in human beings

The Danish Medicines Agency and the committee system coordinated by the Danish Central Scientific Ethical Committee operate a parallel procedure for authorization of biomedical research projects involving clinical trials of non-approved medicinal products. The Danish Medicines Agency grants the final permission for such projects. According to this system of bipartite decision-making competency, it is the Danish Medicines Agency that makes the final decision on any authorization to commence trials on medicinal products involving human subjects. The Agency's decisions must be made on the basis of a recommendation from the committee system. Given that it is the committee system that has the sole authority to conduct a scientifically based ethical evaluation of a prospective biomedical trial, the committee's recommendation is in effect binding on the Medicines Agency as regards the scientific component of ethical evaluations.

This bipartite decision-making mandate entails liaison, and this takes the form of a coordinating committee of representatives from each of the two bodies. In recent years cooperation between the two bodies has been devoted largely to the EU draft directive on good clinical practice (GCP Directive), in which representatives of both the Danish Medicines Agency and the Danish Central Scientific Ethical Committee participated in the EU talks.

Collaboration in *gene* therapy has been on the agenda. In 1999 there was a case in the county of Aarhus concerning a research project involving gene therapy on human subjects as part of a study of the treatment of patients suffering from hepatic cancer.

The Danish Committees on Health Research Ethics

The main tasks of the Scientific Ethical Committee System are as follows:

1. The protection of the trial subjects: their integrity, rights, and safety
2. The establishing and maintaining of ethical criteria for high-quality biomedical research
3. The control function with regard to monitoring the approved trials
4. The task of maintaining the dialogue on research ethics in the field of biomedicine with researchers, other stakeholders, and the public

Regard for the individual always precedes regard for the advancement of scientific knowledge. That is an internationally recognized basic principle. The main aim of the Danish system of Scientific Ethics Committees is to apply these two seemingly incongruent principles in their work of evaluating biomedical research projects.

Another aspect of the committees' work is the follow-up control on research projects. The executive order and guideline on biomedical trials cover all phases of biomedical research, including regulation of those projects approved. Researchers should basically be self-regulating, in ethical terms, providing a guarantee in terms of ethical revue. Formalized control by the committees will have a preventive effect. Overall, the Scientific Ethical Committees operate in the cross field between research and ethics.

The committees act as gatekeepers and safeguards, so the process of gaining new scientific ground within biomedical research will not get off track. Respect for the individual always weighs more heavily than regard for science. Thus, the Danish legislation on biomedical research authorization covers a wide spectrum, from planning to implementing and completing a biomedical research project.

Informed consent is the cornerstone of the protection and must meet specific criteria: The trial subjects' participation must be absolutely voluntary. Informed consent must be given in writing. Trial subjects' consent must be explicit.

Trials with legally incompetent trial subjects and other vulnerable groups such as trial subjects who because of age or reduced physical or mental abilities due to depression, age, mental deficiencies, or similar conditions are incapable of giving informed consent to participation in a research project require special precautions.

The persons participating in the research project must be informed of the following: the aim of the trial, all possible side effects, all known risks associated with the trial, and drawbacks and inconveniences that participation is voluntary and that they can always withdraw from the trial again, at any time. A special layman's résumé of the research project must always be written.

Scientific Dishonesty

The *provisions* regarding the Danish Committees on Scientific Dishonesty (DCSD) are now laid down in regulation from 2010 (Pursuant to Chapter 7, Section 31–34 of the Danish Act No.1064 of September 14, 2010). According to the Act on Research Advice, the Minister for Science, Technology and Innovation is given the mandate to establish the Danish Committees on Scientific Dishonesty. The scope of the committees is to ensure the scientific integrity of Danish research. The task of the Danish Committees on Scientific Dishonesty is to consider cases involving complaints of scientific dishonesty in cases of public research or research projects receiving public financial grants.

The *definition* that determines the committees' remit is as follows:

By the term "scientific dishonesty" is meant intentional or grossly negligent conduct in the form of falsification, plagiarism, nondisclosure, or any similar conduct involving undue misrepresentation of a person's own scientific work and/or scientific results. This includes the following:

1. Undisclosed fabrication and construction of data or substitution with fictitious data
2. Undisclosed selective or surreptitious discarding of the person's own undesired results
3. Undisclosed unusual and misleading use of statistical methods
4. Undisclosed biased or distorted interpretation of the person's own results and conclusions
5. Plagiarism of other persons' results or publications
6. A false credit given to the author or authors, misrepresentation of title or workplace
7. Submission of incorrect information about scientific qualifications

The committees are however not entitled to consider cases involving the validity or truth of scientific theories or cases involving the research quality of a scientific product.

The mandate of the committees is specified in the regulation. According to this, DCSD can only deal with cases in which the defendant has been scientifically trained. The executive order does not give a definition of the implications of this training requirement in detail. Furthermore, the committees will not be able to deal with cases in which a researcher deals with fields of research other than his or her own. The researcher must either have had the scientific product published in Denmark, have compiled the product in connection with employment/commercial activities in Denmark, have received or applied for a subsidy from the Danish public authorities to compile the product, or be associated closely to Denmark in other ways.

DCSD is only to deal with cases where the person filing a complaint can be regarded as a party to the case under the rules of the Danish Public Administration Act. As a result, only persons with a substantial individual interest in the outcome of the case can file a complaint.

The committees have an opportunity to take up cases by their own initiative, if they are of social interest or of importance to human or animal health, and there is a justified assumption of scientific dishonesty.

The *types of* cases that the Committees on Scientific Dishonesty may consider are cases involving complaints about individuals or groups of individuals. In cases involving complaints about groups of individuals, however, the committees may only use their authority to employ sanctions, if the clarification of the case leads to clarification of who is responsible for the conduct. The committees may also consider cases involving complaints about an application filed with a view to applying for a grant from public research funds.

The *sanctions* include a variety of reactions. In cases where scientific dishonesty is ascertained by the Committees on Scientific Dishonesty, the committees shall make a statement expressing criticism. At the same time, the committees may do the following:

1. Inform the defendant's employer if the party in question is employed as a researcher.
2. Recommend that the scientific project concerned be withdrawn.
3. Inform the relevant public authority supervising the area.
4. Make out a police report where a punishable offense is involved.
5. At the special request of an employing authority, state their views on the degree of scientific dishonesty.

The committees shall state their views on the degree of scientific dishonesty ascertained and on its importance to the scientific message in the scientific product concerned.

The committees may shelve cases under subsection hereof if the committees find the scientific dishonesty ascertained only to be of little importance to the scientific message in the product.

Challenges for the Years to Come

It is well known that it may be difficult to foresee future developments in research. Some 10 years ago the most difficult ethical dilemmas were thought to be found in the area of xenotransplantation. There was a heated debate on the issue, and there was also raising concerns about the risks for spreading diseases between animals and humans. Now, 10 years later, xenotransplantation does not seem to be the area of main concern from a bioethical viewpoint, maybe because the technology has not evolved as quickly as first expected or maybe the ethical qualms that were voiced by the public but a halt to the interest of the scientists' motivation in moving forward. It is very difficult to assess what factors have played the decisive part in determining the fate of the advancement or decline of a technology.

In the future development of bioethics, one of the areas that might raise new questions could very well be the issue of enhancement of the human body and brain. Another yet equally important focus of attention is the areas of risk assessment, risk

evaluation, and risk communication that might prove to be areas that need further development and deliberation in bioethics. Likewise converging technologies combining nanotechnology, biotechnology, ICT, and cognitive science can be expected to raise new questions on how to deal with the ethical issues these new possibilities will raise. These trends are not specific for the Danish situation and will not be explored further here.

In the following some challenges regarding the setup of bioethical bodies are reflected upon, including the need for cooperation between the different councils, the need for independence and autonomy of the bioethics committees, the pros and cons of the efforts to reach consensus in the ethics committees, and the role of lay people.

Cooperation Between the Different Councils and Boards

There has been a need to establish cooperation among the various Danish administrative units assigned to address ethical concerns. The following gives examples of such cooperation between some of the councils and boards dealing with bioethical issues in Denmark.

In Denmark closer cooperation and coordination has been implemented between councils and boards working with questions of bioethics as related to human health, animals, and biotechnology. This cooperation was for a period centralized in BIOSAM, which was a joint body of representatives from the Central Scientific Ethical Committee, the Council of Ethics, the Danish Board of Technology, the Animal Ethics Council, and the Animal Experimentation Inspectorate and which liaises on ethical issues associated with biotechnology research and the application of biotechnology, including cloning and the genetic transformation of mammals. BIOSAM also contributed to making the parliament and the public aware of new developments in research in, and the application of, biotechnology.

Two councils, *the Danish Council of Ethics and the Animal Ethics Council*, have similarly, over recent years, cooperated more closely, by holding joint information meetings. Additionally, a particular joint focus has been directed at the question of cloning. Thus, in 2000, the Danish Council of Ethics published a discussion paper, dealing principally with issues concerning technologies for tissue and organ propagation and the future potential for the genetic manipulation of humans and animals.

In accordance with the Act on the Scientific Ethics Committee System and the Act on the Danish Council of Ethics, the *Central Scientific Ethical Committee and the Danish Council of Ethics* are required jointly to address the more fundamental ethical issues concerning biomedicine. Over the past decade or so, the cooperation between the two bodies has resulted in the holding of information meetings in which representatives of the two bodies have exchanged information about the work. Furthermore, in recent years, there has been closer cooperation between the Central Scientific Ethical Committee and the Danish Council of Ethics, which, among other things, has given rise to joint events, in which both bodies have planned and implemented the joint initiatives.

According to this system of bipartite decision-making competency, it is the Danish Medicines Agency that makes the final decision on any authorization to commence trials on medicinal products involving human subjects. The agency's decisions must be made on the basis of a recommendation from the committee system. Given that it is the committee system that has the sole authority to conduct a scientifically based ethical evaluation of a prospective biomedical trial, the committee's recommendation is in effect binding on the Medicines Agency as regards the scientific component of ethical evaluations. This bipartite decision-making mandate entails liaison, and this takes the form of a coordinating committee of representatives from each of the two bodies.

The "Aarhus Case" revealed the need to establish interdisciplinary collaboration among the authorities mandated to grant authorizations for clinical trials involving gene therapy. Trials of gene therapy involving human subjects involve major environmental, epidemiological, and ethical aspects. In response to this sequence of events, a coordinating committee was appointed by the Danish Medicines Agency for the purpose of promoting dialogue among the authorities responsible for granting the various authorizations. The coordinating committee, made up of representatives from the Danish National Board of Health, the Danish Medicines Agency, the Danish Central Scientific Ethical Committee, the Danish Forest and Nature Agency, and the Danish Labour Inspectorate, attends to the authorization of human clinical trials involving gene therapy.

Regarding the local committees on biomedical research, there is an aim to ensure that there is minimal inconsistency within a single area and between one area and the next. The same issue may arise among regional authorization bodies, for example, meaning that practices may vary in different national regions. This coherency would seem appropriate in the light of the fact that local variation should be acknowledged, whereas in terms of equality this may appear less reasonable. One essential concern is to avoid any dispute over authority among the various bodies appointed and prevent overlap and the duplication of effort this might give rise to. In this respect it is important to establish actively cooperating bodies. This need also emerges from the fact that many of the ethical issues addressed touch on multiple concerns that may need to be addressed by separate committees. The need for interdisciplinarity and cooperation is therefore pronounced in the Danish system. The challenge is finding the right balance between the different committees, to avoid overlap, to secure exchange of information and experiences, and to use their expertise – jointly regarding bioethics and separately regarding their specific topics.

Independence and Autonomy of the Bioethics Committees

It is often emphasized that it is of the utmost importance for ethics committees to be independent. Only in this way can they meet the need for information and debate in a way that comprises an objective stance on current regulation and prevailing opinion, even when this is at odds with the position held by government and parliament, for example.

It has been the Danish policy to establish independent bodies of this nature – at the national level – and to furnish them with sufficient financial resources to allow them to act in an advisory and debate-promoting capacity.

The challenge is to make sure that the crucial independence and autonomy is maintained and secured – and to furnish them with sufficient financial resources to allow them to act in an advisory and debate – promoting capacity.

Is Consensus a Requirement for Ethical Deliberation?

The Danish Council of Ethics has often been confronted with the demand for consensus. The difference between the desire to achieve consensus or not is based on a weighing of advantages and drawbacks.

The advantages of consensus would appear to be that the greater the level of agreement presented by a given ethics committee, the greater will be its prospects of bringing influence to bear on the regulators.

The drawbacks are that such a committee will thereby forfeit much of its impetus, since controversial issues and/or principles are usually the very aspects that make consensus difficult to achieve. It may therefore be more helpful to furnish the decision makers with detailed information as to where any dispute might arise and which ethical principles may be assessed and weighed differently such that the decision makers will have the best possible basis of information at their disposal to assist their deliberations. The Danish Council of Ethics will usually choose the latter strategy in formulating its opinions and advice.

The Composition of the Bioethics Committees: Especially Lay People

Expert representation comprises groups of expert delegates representing the disciplines concerned, for example, biotechnology, biomedicine, philosophy and ethics, law, sociology, and psychology along with other disciplines as required.

The advantages of having such representation are a means of securing comprehensive and well-founded academic expertise for the advisory and decision-making services rendered by the various committees. In this context *interdisciplinarity* is crucial, since under this concept the representatives of different disciplines can meet and discuss ethical issues as a means of familiarizing themselves with each other's terminology, culture, and scientific traditions. This then serves to promote mutual understanding among different scientific domains.

It is essential that the concept of expert representation is not defined too narrowly and that careful consideration is given to which experts will be the most appropriate, especially with regard to the need to include sociologists, anthropologists, psychologists, and other social scientists.

The drawbacks of establishing forums comprised exclusively of experts are that they may have a tendency to become somewhat introverted in their choice of issues and mode of discourse. Communication with the public and decision makers

may be hampered by the fact that many academics have no particular tradition for opening their debates up so as to make them accessible and comprehensible to the general public.

Lay representation involves delegations made up as "counterweights" to (academic) experts. The reflection and knowledge possessed by lay people serves to complement the more abstract and generalizing insights of academic experts and thereby contributes to a more balanced foundation for decision-making than if all decisions were made solely by such experts.. The findings of consensus conferences have been that ordinary, motivated citizens are capable of acquiring and analyzing complex scientific information and of drawing their own, independent conclusions. In the consensus conference model, the use of lay people may be understood as drawing a parallel with jury service in the administration of justice. The experts could be compared to the witnesses summoned before a court; the panel with the jurors, who, after hearing the expert testimonies, withdraw to formulate their collective response to the conference issues, informed by the presentations of the experts and their own common sense.

Denmark maintains a large body of lay people in its ethics committees. The involvement of lay people is already a time-honored component of the Danish judicial system, the purpose of which is to ensure that the public's sense of justice is reflected in criminal procedure. In addition, the involvement of lay people occurs in public governance, for example, in central tax administration in Scandinavia. The "worldly wisdom" possessed by lay people serves to complement the more abstract and generalizing insights of academic experts and thereby contributes to a more balanced foundation for decision-making than if all decisions were made solely by such experts.

The *advantages* of drawing on the services of lay people are, among other things, that they have a confidence-building function, whereby the link with general public opinion and common sense may be sustained. Lay people thus serve to contribute an element of "wisdom," which ensures that account is taken of the opinions and convictions that exist as implicit tenets in the values embraced by a population. This should also be considered in the light of the fact that lay people are perfectly capable of acquiring objective and valid insights and that scientific experts are just as susceptible as lay people to subjectivity and personal factors. Moreover, the involvement of lay people serves a democratic function in that it exercises the principle of autonomy and counteracts the formation of unintended power bases. This serves to establish what might be termed a "bottom-up" element in decision-making processes, just as it ensures dialogue on the issues that the public finds to be important, and ensures that the concerns deliberated are communicated to the public in a way that is comprehensible to the "man on the street," and which thereby contributes to social and democratic learning processes. The subjective and personal factors brought into play by lay delegates will thus be incorporated in consultations on the issues that present themselves for discussion.

The *drawbacks* of retaining the services of lay people include the risk that they may become "overqualified" in connection with their involvement and

representative services to expert bodies. A failure to take special account of the fact that the role of lay people is precisely to provide the originally intended safeguards and to approach the issues from new angles might mean that the values and culture of the academic experts might come to dominate the agenda such that the lay element is at risk of being "held hostage" by expert opinion. It should therefore be ensured that the views held by lay representatives are allowed to evolve freely and that "down-to-earth" opinions are not compromised. Further problems may arise if extensive lay participation displaces the volume of experts deemed necessary without excessively swelling the ranks of the organization.

Political participation in debate-generating activities will often be useful; the problem being that politicians tend to be reluctant to get involved at an early stage in issues that may be regarded as "dangerous" or "awkward" to take a public stance on. In relation to ethics committees, one purpose of which is to serve as an advisory function, it is doubtful whether political participation would be of value.

The advantages are that this ensures a "direct line" to the political domain, which in turn ensures that the advisory element dominates and that the political domain becomes accustomed to discussing difficult ethical issues in greater depth.

The drawbacks may be that politicians run the risk of backing a given opinion prematurely, which again may pose further problems. The risk is also that the political level engages too early in the process, when it may be more helpful if the debate can proceed in the absence of political interests.

The retention of lay services is often endorsed in relation to debate models proper, which refer to public debate in various forums, etc. However, it is important that the lay contingent and generalized debate are also employed in relation to scientific ethical committee systems in which actual authorization of biomedical research projects is effected, since these committees do not necessarily consider broader ethical implications involving general societal concerns and regard for future generations. Such aspects may play an important role in connection with deliberations on research projects seeking to employ technologies such as xeno-transplantation, stem cell research, and cloning of human cells. Deliberations on the broader ethical implications of such projects should therefore be ensured by retaining the services of lay people in scientific ethical committee systems and by incorporation of the debate model proper.

The question of the term in which lay people should serve has also been debated. The fact that it takes time for lay people to familiarize themselves with complex issues speaks in favor of an extended period of service. In contrast, the fact that it may be necessary at times to "inject" fresh opinions and new participants into the debate speaks in favor of a rather more limited period of service. The latter argument would seem to be the more persuasive.

Conclusion

In Denmark bioethics has been on the agenda for many years, and the Danish Councils of Ethics and other ethical bodies have obtained considerable knowledge

and experience. The strategy of having a two-pronged approach to debating and solving bioethical dilemmas has been prevalent for the last 20 years.

Four basic principles are playing important roles in the content of the ethical debate:

1. The ethical principle of *economic and qualitative benefit* is occasionally comprised by preconditions dictating the balancing of the risks against the benefits of carrying out a given bio-project.
2. *The principles of autonomy, dignity, integrity, and vulnerability* are assured in the scientifically based ethical authorization system in the shape of the requirement concerning informed consent.
3. *Just distribution of benefits and burdens* is also an important principle
4. *Codetermination and openness* form the basis for the debate models in the various formats.

The involvement of lay people in the decision-making process on developing ethical principles and in the authorization of biomedical trials on humans has shown the Danish affinity for incorporating input from "bottom-up processes" like consensus conferences as well as the "top-down processes" from expert groups and committees in the legislation process. A guess based on the growing user-generated input into societal deliberation on bioethical issues will be that the influence from bottom-up processes will be even more prevalent in the future. It is encouraging to find that these principles are becoming more widespread all the time and have now also been identified with great emphasis by the EU in the form of a drive for "proactive civic responsibility." The principles of openness and codetermination are procedural requirements in which there seems to be a growing need for implementation in the legislation process.

One *conclusion* on the views presented here might be that it is vital to ensure broad interdisciplinary expert representation – possibly complemented by a panel of academic advisers who may be consulted on specific matters – but that there may equally be a need to ensure lay representation, both in the democratization instruments designed to generate debate and in ethics committees, whether these serve an advisory or controlling function. This ensures an open, transparent system, as well as a counterweight, to prevent medico-professional and research-based interests from dominating in relation to the mechanisms for protection that may be deemed equally important. At the same time this promotes valuable dialogue between experts and lay people. In this context it is important that lay people are provided with sufficient, readily comprehensible information such that they may render their services on a sufficiently well-informed basis, being appraised of the technical data.

A more *general conclusion* may be that compared to the global picture the expectation would be that Denmark represents a country with a quite exhaustive bioethical infrastructure and bioethical regulations and that some experiences can be drawn from this period. One of the crucial aspects is the securing of an independent and autonomous bioethics council, which can initiate and secure thorough public debate with information and outspoken opinions from a number of people with different backgrounds and different views, presenting decision makers with a solid ground for their important decisions in the matters of bioethics and biolaw.

Andres Peralta-Cornielle

Introduction

Personal experience has taught me that for the development of the discipline of bioethics, there are important factors that must converge. Those are:

- Involvement of people attuned to their moral principles
- Understanding that a sustainable future of humanity requires the well-being of society
- Creating organizational and institutional structures to guarantee permanence

A. Peralta-Cornielle
Professor Medical Ethics, O&M Dominican University, Medical School, Santo Domingo, Dominican Republic

H.A.M.J. ten Have, B. Gordijn (eds.), *Handbook of Global Bioethics*,
DOI 10.1007/978-94-007-2512-6_17,

- Providing adequate academic capacity, in both the epistemological and hermeneutic perspectives of bioethics, to those responsible of teaching its fundamentals
- Designing an agenda to promote harmonious coexistence, in mutual respect, for all strata of society
- Implementing programs to teach moral values at all school levels
- Involving of all levels of government in every step of development or implementation
- Ensuring interinstitutional relationships to expand its field of influence
- Promoting international collaboration in the search of multicultural understanding for its implementation
- Educating the population about its fundamental principles to make this new knowledge available to every citizen

On writing this chapter, the above factors are used as a guide since all of them are essential to the development of bioethics in every human environment or activity.

Development of Bioethics

Activities to promote the discipline of bioethics in the Dominican Republic started on July 1988, with the collaboration of the Pan-American Health Organization (PAHO/WHO) and the consultancy of Dr. Eduardo Del Caño, who promoted a series of meetings with physicians, lawyers, nurses, public health specialists, ecologists, and university faculty. During a second consultancy in November 1991, a second multidisciplinary workgroup was formed with faculty from five different universities and the country's Association of Catholic Physicians.

The organizational work culminated in March 1992 with the workshop *Ethics in Health and Quality of Life* held at Universidad Nacional Pedro Henriquez Ureña with 200 professionals in attendance.

Simultaneously the Association of Catholic Physicians, together with two catholic universities, promoted a series of talks and conferences and organized the First National Bioethics conference in May 1992.

The CNB was founded in March 1992. In order to promote bioethics, the newly formed organization set as its first objective to offer seminars in universities, governmental institutions, and physicians' associations. To that end, eight seminars were held from June to November 1992.

In September 1993, the *First National Symposium in Medical Ethics* for the Dominican Medical Association was organized, and in October 1998, the CNB was included in UNESCO's International Directory of Bioethics Organizations. In July 1999, the CNB subscribed to the Panama Declaration, in adherence to the principles of the International Federation of Global Bioethics created by V. R. Potter.

Peralta, A. E. (2011) described the *Beginnings and Development of Bioethics in Dominican Republic* at a conference presented at the VII Congress of the Latin American and Caribbean Federation of Bioethics Institutions (FELAIBE) at Viñas del Mar, Chile, in June 2011.

Major Actors in the Development of Bioethics

The attendance and participation of members and directors of the CNB in activities and events in the field of bioethics held by international organizations, especially in Latin America and the Caribbean, significantly contributed to the development of bioethics in the country. Four organizations have played a fundamental role in that process.

The Regional Program in Bioethics of the Pan-American Health Organization (PAHO/WHO) is among the regional entities that contributed greatly to that development, especially in the sphere of undergraduate and postgraduate education.

Directors of the CNB participated in the seminar/workshop *Bioethics in Latin America and the Caribbean*, held in the University of Santiago de Chile in November 1994 and in 1995 in the workshop for Central America and the Caribbean *Analysis of the Bioethical Aspects of Health Research* at the Victoria de Girón Basic and Pre-Clinical Sciences Institute in Havana, Cuba, both organized by the Regional Bioethics Program of PAHO/WHO.

In July 1997 CNB, with help from the Regional Bioethics Program of PAHO/WHO and with accreditation by the Universidad Nacional Pedro Henriquez Ureña, organized the seminar *Foundation of Bioethics*, taught by Dr. Juan Carlos Tealdi, director of the Latin-American School of Bioethics in Argentina. In February 2000, the workshop for the *Guidance for the Teaching of Bioethics* was held with the sponsorship of the Regional Bioethics Program of PAHO/WHO and the Instituto Tecnológico de Santo Domingo (INTEC), with the attendance of 30 professors from 10 different Dominican universities.

In August 1999, the NBC backed the application of INTEC University to become the site of the Master's Program in Bioethics of the Regional Bioethics Program of PAHO/WHO, which was started in 2001.

The Latin American Federation of Bioethics Institutions (FELAIBE) has been another one of the organizations that contributed to the development of bioethics in the country. Directors of the NBC participated in the *First Congress of Bioethics in Latin America and the Caribbean* and in the *Fifth FELAIBE Meeting* in Sao Paulo, Brazil, in 1995. During the latter, the CNB became an institutional member of FELAIBE.

Members of the CNB have participated and given talks in the congresses of FELAIBE in Brazil, Ecuador, Colombia, Panama, and Chile.

The Latin American Forum of Health Research Ethics Committees (FLACEIS) was founded in Mexico City in October 2000. In the founding assembly, the president of the CNB was elected vice-president of FLACEIS.

In March 2002, the commission organized the course/workshop Interpretation and Implementation of the Helsinki Declaration at the Universidad Católica de Santo Domingo, under the auspices of FLACEIS. The Ministry of Public Health and Social Assistance and its National Commission of Bioethics in Health (CONABIOS), the Executive Commission for Health Sector Reform (CERSS), and the Pan-American Health Organization (PAHO/WHO) participated in this event that brought together both governmental and private sector Health Research Ethics Committees, as well as hospitals' committees of healthcare ethics,

universities' health sciences faculties, and researchers from Mexico, Uruguay, Cuba, Haiti, Puerto Rico, and the Dominican Republic. At the closing of the event, the Dominican chapter of FLACEIS was formed.

UNESCO's Latin America and the Caribbean Bioethics Network

Since its inception up until today, this organization has contributed to the advance of bioethics in Dominican Republic.

In September 2004, the president of the CNB was elected member of the board of directors of RedBioetica during its second Workshop of Bioethics for Latin America and the Caribbean in Havana, Cuba. In October of the same year, he participated in the regional seminar on bioethics titled *An International Challenge*: *Towards a Universal Declaration of Bioethical Norms*, organized by RedBioetica, which took place in the Ministry of Justice and Human Rights in Buenos Aires, Argentina. During this last event, the Letter of Buenos Aires was signed, in which the countries of Latin America stated their position concerning the inclusion of social bioethics topics in the *Universal Declaration on Bioethics and Human Rights of UNESCO* (Peralta 2004).

Since 2004, members of the CNB have participated and presented works in seminars organized by Redbioética in Cuba, Uruguay, Argentina, Colombia, and Trinidad and Tobago.

In September 2007, within the activities to promote principles and postulates of UNESCO's Universal Declaration on Bioethics and Human Rights, with the collaboration of the CNB and on the initiative of the Dominican ambassador to UNESCO, the international seminar *Towards a Sub-Regional Convention of Bioethics* was organized, with the participation of bioethics organizations from Costa Rica, Cuba, El Salvador, Guatemala, Honduras, Nicaragua, Panama, Brazil, Argentina, Chile, Uruguay, Bolivia, Colombia, Haiti, and Dominican Republic.

At the end of the seminar, the representatives of Central America and the Caribbean signed the Declaration of Santo Domingo, in which they committed to promote in their respective countries the implementation of the postulates of the Universal Declaration on Bioethics and Human Rights of UNESCO (National Commission of Bioethics of Dominican Republic [CNB], 2011).

Major Concerns Over Time

The National Commission of Bioethics (CNB) is a not-for-profit, nongovernmental, and autonomous organization with 45 members since 1999. Members include journalists, linguists, lawyers, physicists, environmentalists, psychologists, forest engineers, ecologists, architects, nurses, bioanalysts, physicians, sexologists, biomedical researchers, oncologists, and bioethicists.

On April 24, 1997, by executive decree, the government recognized the National Bioethics Commission as an "autonomous organization and advisor of the

executive branch in ethical matters, as a way of preserving and promoting the ethical values that influence the attainment of a dignified life with quality, equity, justice and liberty, by every inhabitant of the Dominican Republic" (CNB, 2011).

The Dominican Bioethics Consulting Council UNESCO (CCDBU) was created in July 29, 2009, allied to the Dominican National Commission to UNESCO with a 15-member board of directors. A work project has been designed along four areas: bioethics education, bioethics and health, bioethics and media, and bioethics and politics.

In October 2009, the CCDBU held a first seminar on *Bioethics Legislation* for the nation's congress with the participation of the Latin America and the Caribbean Bioethics Network of UNESCO (RedBioetica). In February 2010, the executive council started a program of teleconferences aimed at university students. Among the topics addressed were Informed Consent in Healthcare, Reach of the Universal Declaration on Bioethics and Human Rights UNESCO, and Role of Ethics in Health Research (Dominican Bioethics Consulting Council UNESCO [CCDBU], 2009).

Competence Building in Bioethics

In order to train its members and with the collaboration of the Regional Bioethics Program of the PAHO/WHO, the National Bioethics Commission (CNB) organized in July 1997 the seminar Foundations of Bioethics at the Universidad Nacional Pedro Henriquez Ureña. It was attended by 20 professionals in diverse areas of expertise.

Competence building has continued with congresses, seminars, workshops, and conferences with presentations by members of the CNB. In February 2006, with the collaboration of the National Commission for State Reform (CONARE), Adela Cortina and Jesús Conill, two distinguished Spanish bioethics professors, were invited to give a series of talks on the topics: Ethics and Enterprise, Ethics in Economy, Ethics and the Law, Participative Democracy, Bioethical Aspects of Assisted Reproduction, Ethics and Politics, Ethics and Citizenship, Relationship between State and Civil Society, and Humanization of Health Services.

In September 2000, the course *Ethics in Research*: *The View From the South* was offered at the Center for Maternal-Infant Research (CENISMI) taught by Dr. Olga Rodriguez of the National Center of Clinical Studies in Cuba.

The seminar *Bioethics and Genetically Modified Organisms* was held in February 2001 at the Universidad Católica de Santo Domingo.

Diffusion of Bioethics

The CNB has struggled to spread the principles of bioethics among wide sectors of the education community, professional societies, and scientific, business, and governmental organizations. More than 90 talks have been given throughout the country in congresses, seminars, workshops, courses, and presentations to the media.

From its inception, the CNB was structured as a nongovernmental and autonomous organization without ties to academic institutions or professional organizations. This has allowed it to act independently and to maintain an open and frank dialogue with respect among its participants. Work meetings are promoted in universities, healthcare centers, biomedical research centers, governmental and nongovernmental organizations, academy of sciences, environmental organizations, and medical associations to which its members belong, always maintaining freedom of opinion.

The CNB subcommissions have made significant progress in the areas of education in bioethics, the environment, biomedical research, and the promotion of the creation of bioethics committees in hospitals. Some advances were also made in human rights and behavioral science (CNB, 2011).

Relationships with International Organizations and Institutions

In June 1993, the National Commission of Bioethics was affiliated with the Latin American and Caribbean Federation of Bioethics Institutions (FELAIBE), and on November 1994, it was included in the Directory of Bioethics Centers and Institutions of the Regional Bioethics Program of PAHO/WHO.

In addition, the CNB maintains collaborative relationships with bioethics centers and institutions in Latin America. In December 1995, the CNB created, together with bioethics centers from Cuba and Puerto Rico, the Caribbean Confederation of Bioethics. This confederation elaborated an *Agenda for Bioethics in the Caribbean*, giving priority to fields of work such as bioethics foundation, research in bioethics, human resources formation in bioethics, biomedical research, clinical bioethics, and hospital bioethics committees.

Members of the CNB have participated over the last 20 years as exponents in 34 congresses, 20 workshops, 9 lectures, 8 seminars, 5 symposia, and 5 panels, giving a total of 190 talks in international bioethics organizations in 18 different countries.

In July 2001, Van Rensselaer Potter proposed the creation of a Global Bioethics Network with a group of 10 professors from the USA, Canada, Italy, and Japan as members of the Global Bioethics Core Group. In Potter's opinion, this was necessary because of the strong convictions about what this concept really means, without being obligated to support the evolution of the points of view of the original proponent.

In addition to this group, several scholars from Latin America and other 26 countries who had actively supported the perspective of the original bioethics and the idea of an *International Council on Global Bioethics* were included in the Global Bioethics Network. Some of them have developed educational programs; others are editors, founders, presidents, or authors in the field. Among those scholars, Potter included two members of the National Bioethics Commission of the Dominican Republic.

In April 2005, the then president of the CNB was invited to speak at the Extraordinary Meeting of the International Committee of Bioethics UNESCO

held in Paris, France, where he presented the talk entitled *Towards a Universal Bioethics Norms Declaration*. In March 2006, the president of the CNB was invited by the director general of UNESCO to join that organization as a member, and he will remain a member until December 2013 (CNB, 2011).

Human Resources for Bioethics Teaching

At the start of activities by the CNB in 1992, the country had no professionals with a formal background in bioethics. In 1999, one of the founding members received the title of *Master of Bioethics* in the course Regional Program of Bioethics of the PAHO/WHO that was taught in the Universidad de Santiago de Chile with the collaboration of the Universidad Complutense de Madrid. Another member obtained the title of *Diplomate in Bioethics* at the Lateranense University in Rome. A third one participated in the course of Specialization in Bioethics for university teachers at the Bioethics Summer Institute financed by the National Endowment for the Humanities and held at the Center for Humanistic Studies and Bioethics of the University of Puerto Rico in 1998, 1999, and 2000. In 1997, the CNB held a survey about the teaching of Medical Ethics at the university level in 24 centers of high education. Only eight of the universities returned the survey stating that they taught ethics at the professional level in all of them and at the technical level in one of them, under the names Professional Ethics, Medical Ethics, Ethics of Values and Norms, and Moral Systems.

Faced with that fact, in July 1999, the Workgroup on Education of the CNB organized the workshop *Curricular Structure for the Teaching of Bioethics* at the Universidad Nacional Pedro Henriquez Ureña, which was attended by 20 professionals of 10 national universities. The workshop was taught by Dr. Elena Lugo, of the Mayaguez Campus of the University of Puerto Rico, and members of the CNB.

In February 2000, the workshop Didactics in Bioethics was organized with the backing of the Regional Bioethics Program of the PAHO/WHO at INTEC, which was attended by 30 professors from 10 Dominican universities.

In August 1999, the CNB supported the petition to the Regional Bioethics Program of the PAHO/WHO, which proposed INTEC University as the candidate site for the Master's Program in Bioethics to start in 2001. The university continued the negotiations and INTEC was awarded the site.

During 2000 and 2001, INTEC taught the master's course with the academic validation of the Universidad Complutense de Madrid, Spain, under the directorship of Dr. Diego Gracia. Twenty-eight (28) professionals from several Latin American countries, including seven from the Dominican Republic, completed the course.

In 2003, INTEC started its own Master's Program in Bioethics of 2-year duration, attended by several professionals from the fields of health, psychology, and law. To date, it has graduated 110 masters, 30 % of them Dominican.

In 2000, the Instituto Tecnológico de Santo Domingo (INTEC) created the first University Center of Bioethics with undergraduate and postgraduate academic programs in Clinical Bioethics and Social Ethics. It is important to mention the INTEC Forums of Bioethics, organized and developed by the undergraduate students of the school of medicine. To date, they have held 31 such forums.

Other universities have created bioethics committees in their faculties of health sciences and jurisprudence science.

In 2004, the Universidad Autónoma de Santo Domingo (UASD) and in 2009 the Universidad Católica Nordestana (UCND) started to implement programs Diplomate and Specialization in Bioethics, which have not continued in a regular manner.

A survey done in 2010 for a master's thesis in bioethics in INTEC analyzed the curricular content of the programs in bioethics of 10 Dominican schools of medicine. The survey showed that, with the exception of one sole program, the topics included did not follow a logical sequence of the ethical dilemmas that arise during the life cycle of human beings from conception to death. The study showed that in seven of the ten schools, the class is called bioethics; in one it is called medical ethics and in another one deontology and bioethics (CNB, 2011).

Collaboration with Governmental, Legislative, and Educational Organizations

The promotion of the CNB of the implementation of the principles of bioethics has yielded recommendations to universities and public and private institutions.

The Dominican Medical College, with the counsel of the CNB, updated its ethical code in 1993. Other professional associations have designed codes of ethics with the assistance of the CNB, such as the Dominican College of Psychologists and the Dominican College of Engineers, Architects and Surveyors (CODIA).

In 2001 the Universidad Tecnológica de Santiago (UTESA) created the *Master Lecture in Bioethics Andres Peralta Cornielle*, in honor of the then president of the CNB. Yearly until 2005, a guest lecturer from a roster of Latin American and Dominican professors was invited to teach this master class. With the accreditation of the CNB, each guest lecturer would give conferences in bioethics in each of the campuses of UTESA throughout the country, in other national universities, and in the Dominican Medical College.

In 2008, there was an environmental crisis in the country caused by the clandestine importation of rock ash refuse. The Environmental Subcommission of the CNB oriented the community concerning the negative health effects caused by rock ash refuse. Later, the Environmental Subcommission organized the conference *Environmental Ethics* with the participation of over a hundred citizens and community leaders from different parts of the country.

Also in 2008, the CNB and INTEC University signed a contract with the Metropolitan Transportation Authority of Santo Domingo to teach civil ethics to 50 traffic agents during a 16-h-long workshop and course.

In May 2008, the aspects concerning research on human subjects of Article 33 of the General Law in Health (No 42–01) were debated at the Dominican Academy of Medicine (CNB, 2011).

Commission on Public Ethics

In the master's program developed at the INTEC University, professionals from different areas have been trained to serve as consultants and advisors in bioethics, including public ethics. INTEC, in its center of bioethics and in collaboration with the CNB, wrote a project proposal aimed at the ethical duties of civil servants. To that end, in November 2004, a public ethics workshop was offered, which included talks on the historical/philosophical framework of ethics, its relationship with public and private places, and the development of an ethically responsible citizenry. Several lines of action have been proposed to promote ethics, education in values, ethics in public administration, and creation of public ethics committees. Promotion, education, and prevention were assumed as the main tasks.

In FELAIBE's congress in Puerto Rico, in September 2003, a member and ex-president of the CNB gave the talk *Ethics and Civil Society in Dominican Republic* (Suazo, 2004).

Collaboration with Professional Organizations in Latin America

In October 1999, bibliographical references requested by the College of Physicians and Surgeons of Costa Rica were submitted. To disseminate the principles and postulates of bioethics in Haiti, in 1999 the president of the CNB gave the talk *Anthropological Foundation of Medical Bioethics* at the Haitian Society of Oncology, in Port-au-Prince.

The Haitian Bioethics Society was later founded, and its representatives have participated in activities of the CNB and have applied for membership in Latin American and Caribbean bioethics organizations.

In 2007, the CNB participated in the creation of the National Committee of Bioethics in El Salvador. The president of the CNB gave the talks *Evolution of Legislation to Regulate Clinical Research in Latin America* and *Philosophical Context of the Universal Declaration on Bioethics and Human Rights UNESCO*.

Members of the CNB participated as speakers in bioethics events in Cuba, Argentina, Puerto Rico, México, Haiti, Panama, South Africa, Brazil, Costa Rica, Nicaragua, France, Colombia, Ecuador, Canada, Trinidad and Tobago, El Salvador, and Chile.

At present, a distinguished member and ex-president of the CNB with a Masters in Bioethics is part of the faculty of the Certificate in Bioethics of the Hostosian

Institute of Bioethics of the University of Puerto Rico since 2009. He has also been invited to bring bioethics workshops to the Salvadorian Institute of Social Security and been guest faculty for the Law Doctorate at the Catholic University of Panama.

Congresses and Conferences

Since its foundation, the CNB has organized 3 congresses, 103 conferences, 9 workshops and seminars, and 5 panel discussions in the country. The first meeting of the commission with the scientific and academic community was held at the Universidad Nacional Pedro Henriquez Ureña (UNPHU) in March 1992, during the workshop/seminar *Ethics in Health and Quality of Life*, in which relevant aspects of clinical and environmental ethics were debated.

In its first congress, held at the Pontificia Universidad Católica Madre y Maestra (PUCMM) in November 1994, titled *Bioethics*: *Science of Survival*, participants analyzed the foundations of bioethics.

Its second congress, at the Universidad Nacional Pedro Henriquez Ureña in November 1997, was built around the topic Education in Bioethics. During this congress, the basis and strategies to promote the formation of Dominican university professors in the discipline were defined.

The third congress, with the topic *Bioethics, Poverty and Human Rights*, took place February 24–26 in 2000, jointly with the Third Congress of the Caribbean Federation of Bioethics, at INTEC, with the participation of speakers from Cuba, Puerto Rico, and Venezuela (CNB, 2011).

Resources Developed

Societies

The Puerto Rican Federation of Bioethics, the Cuban Commission of Bioethics, and the National Bioethics Commission of Dominican Republic created the Caribbean Federation of Bioethics in December 1995. In September 2002, the 41-member Dominican chapter of FLACEIS was created.

In October 2011, a member of the CNB participated in an event in Havana, Cuba, where the first steps were taken for the creation of Central American and Spanish-speaking Caribbean Bioethics Network, with help from the Latin America and the Caribbean Bioethics Network of UNESCO.

Books and Journal Publications

The following is a selective list of books published by members of the CNB nationally and internationally:

Rodríguez, J.E.:*Living in Society*. 1997.

Pichardo, A.: *Civic and Penal Responsibilities of the Physician*. 1999.

Pichardo, A., Reynoso, J.: *Organ Donation and Transplantation: Ethical and Legal Considerations*. 1999.
Pichardo, A. *Forensic Medicine*. 1999.
Suazo, M.: *Bioethics for the New Ones*. 2002
Pichardo, A.: *Euthanasia: Ethic-Legal Viewpoint*. 2002.
Pichardo, A.: *Bioethics*. 2002.
Silié, J.A." *Ethics of University Faculty*. 2003.

Internet

In March 2000, the UNPHU University webpage was set up at http://unphu.edu.do. The page has a section on bioethics that can be used freely to search or publish information on bioethics by contacting the address egarcia@unphu.edu.do.

Teleconferences

Throughout 2010, the Dominican Bioethics Consulting Council (CCDBU) organized a series of teleconferences on diverse topics from the field of bioethics, aimed at university students.

Media Publications

An ex-president of the CNB wrote for several years a section on bioethics for the national newspaper *Hoy*. In addition, he published articles on bioethics for the monthlies *Revista Ahora*, *Amigo del Hogar*, *Respuesta*, *FUNGLODE*, *Revista UNESCO*, *Acta Bioetica/OPS*, and *Revista Voces*. The National Council on State Reform (CONARE) publishes the latter, which includes articles such as *Bioethical Aspects of the New Social Security Laws* and *Why We Must Study Bioethics*.

Another ex-president of the CNB published articles in the regional newspaper *La Informacion*, among them *Bioethical Aspects of Cloning*, *Ethical Aspects of Culturing Human Embryonic Cells*.

Bulletin

The first issue of the Informational Bulletin of the CNB was published in June 1994, and it continued a biannual run until 2001 (CNB, 2011).

Current Bioethics Infrastructure

To accelerate its programs, in 1996, the CNB created several working subcommissions in the areas of education in bioethics, social bioethics, hospital ethics

committees, research ethics committees, bioethics and religion, medical ethics, bioethics and the environment, bioethics and human rights, bioethics and mental health, and bioethics and the media.

Subcommission for Research Ethics

In September 1992, the subcommission organized the seminar/workshop *Ethics and Health Research* at the Universidad Central del Este.

Because there were no official organizations to regulate biomedical research – with the exception of the Maternal-Infant Research Center of the Health Ministry, which only evaluated protocols from governmental health institutions – and in the interest of promoting the establishment of ethical norms for said research, the CNB decided in 1995 to create inside its own infrastructure the Research Ethics Subcommission. Over the period of 5 years, it evaluated 15 research protocols for their design, methodology, and ethical implications. From July 1994 to December 1999, the Research Subcommission of the CNB received, reviewed, and decided about 15 research protocols.

In January 2000, on the suggestion and efforts of the CNB, in order to regulate biomedical research, the Ministry of Health created the National Council of Bioethics in Health (CONABIOS), which initiated its activities with the conference *Importance of the Research on Human Subjects Ethics Committees*.

In July 1998, several members of CNB participated as speakers in the Second Caribbean Bioethics Congress, held in the Mayaguez campus of the University of Puerto Rico, on the topic *Research in Health*.

At present, there are 10 research ethics committees in the country, with members graduated from the Master's Program in Bioethics. The CNB has actively collaborated to create some of these committees.

Subcommission for Hospital Ethics Committees

In 1995, a workshop was held concerning the importance of hospital ethics committees, together with INTEC University, one of the most recognized and solid higher education institutions in the country.

In 1998, workshops were brought to hospital in the northern region of the country, with the collaboration of the Mayaguez campus of the University of Puerto Rico and UTESA University. Similar workshops were held at the Health Plaza General Hospital, the main public hospital in the country's capital, in 1999, and eventually successfully established their first hospital ethics committee.

In June 1999, the CNB developed guidelines for the implementation of hospital ethics committees in the Dominican public health system. Once the Ministry of Health approved the project, 25 hospitals were selected, most in the capital and 3 in other regional hospitals.

Since 1997, members of the CNB have served as advisors for the creation of hospital ethics committees in several public and private institutions.

Subcommission for Environmental Ethics

The radio programs *No More Violence*: *Respect for Human life and Dignity* were begun in April 1997. In July 1999, the monographic symposium *Bioethics and Biodiversity* was published. In October 1999, a talk was given for employees of the natural reserve Parque Mirador del Norte. In 2000, Nasseb Dajani, a representative of the Swiss organization Global Harmony Foundation, taught the course *Community, Environment and Lifestyle for the 21st Century*. In November 2000, at the UTESA University School of Medicine, the talk *Global Bioethics* was given, and the Code of Ethics of the Explosives Chapter of the Dominican College of Engineers and Surveyors was evaluated.

Bioethics Committees and Centers

Presently there are two university centers of bioethics, one in INTEC led by an ex-president of the CNB and the other at the Universidad Católica Nordestana led by the current president of the CNB. The CNB also participated in the creation of the ethics committee of the Faculty of Judicial and Political Sciences of the Universidad Autónoma de Santo Domingo (UASD) in March 2001.

Policies and Legislation

By decree number 751–03, dated August 12, 2003, the president of the Dominican Republic officially named the CNB as an advisory organization to the executive in bioethics matters. This decree widened the future field of action of the commission since it offered a legal framework for its intervention in the analysis of specific ethical problems submitted to the executive branch of government and/or public institutions, which would facilitate the goal of safeguarding the values that influence the attainment of a dignified life with freedom and justice for the citizens.

In October 2003, the Environment Subcommission of the CNB referred its response to the request of the directorate of wildlife and environment to put into effect the Project of Development of a National Framework for Biosecurity in Dominican Republic. The project's objective was to establish the guidelines to guarantee the safe use of biotechnology and genetically modified organisms in our country.

In October 2009, the Dominican Bioethics Consulting Council UNESCO (CCDBU) organized a seminar on *Legislation on Bioethics in the National Legislature*, with the participation of the Latin America and the Caribbean Bioethics Network UNESCO and exponents from Argentina, Uruguay, and the Dominican Republic. Among other topics presented to the congressmen were the legislative perspective and judicial precedents relating to the strategic importance of bioethics and the creation, by law, of a National Council or Committee of Bioethics in the Dominican Republic.

In September 2011, the Consulting Council of Bioethics UNESCO sent their response to the request made by the Ministry of Health to analyze the proposed law on sanitary career before submitting it to congress.

Public Debate Activities

Public debates have been held in congresses, seminars, workshops, and in the activities of the subcommissions (CNB, 2011).

Major Bioethics Issues and Discussions

By initiative from the National Commission of Bioethics (CNB), over the last 20 years, most ethical dilemmas that present throughout the life cycle of human beings, the practice of medicine, and the protection of the environment were analyzed in congresses, seminars, and workshops.

1. Beginning of Life
   Since 1992, topics such as Abortion, Cloning, In Vitro Fertilization, and the Use of Stem Cells have been discussed. Every program of Medical Ethics and Bioethics of university medical schools includes topics concerning ethical issues of the beginning of life.
2. End of Life
   The topics of Euthanasia and Assisted Suicide were debated in workshops and talks organized by the CNB and with the participation of its members. Publications in books and journals by members of the CNB approach such subjects as the terminal patient, pain and human suffering, palliative medicine, euthanasia, and assisted suicide.
3. Health and Disease
   In congresses, workshops, and roundtable discussions organized by different specialized medical professional associations, it is more and more frequent to invite members of the CNB and the Dominican Consulting Council of Experts in Bioethics UNESCO to discuss bioethics topics related to the ethics of medical practice, patient's rights, and the promotion and defense of the postulates and principles of bioethics.
4. Healthcare System and Access to Healthcare
   In the Third Congress of Bioethics of the CNB and Third Congress of the Caribbean Confederation of Bioethics, in February 2000, the central topic chosen was Bioethics, Poverty and Human Rights. The topics Bioethics and Healthcare in the Dominican Republic, Bioethics in the Context of Poverty and Human Rights, How Philosophical is Bioethics?, Efficiency Without Justice?, Ethics and the Care of Humans, and Bioethical Implications of Economic Globalization were discussed in other conferences.

   In September 1999, during the workshop Consultation of Inter-Institutional Governmental Commission on Public Sector Hospital Reform, the CNB stated its position in promoting efficiency in healthcare.

In April 2000, representatives of the CNB were invited by the Minister of Health to participate as speakers in the First National Forum on Quality of Healthcare.

5. Genetics
   Ethical issues related to genetics have been discussed in conferences given in national universities and the Dominican Medical College. For example, in March 1995, at the Pontificia Universidad Católica Madre y Maestra (PUCMM), a conference was taught on Ethical Challenges of Advances in Human Genetics, and in March 1997, the symposium Ethical Aspects of Cloning and Organ Transplantation at the Dominican Medical College.
6. Reproductive Medicine
   Topics concerning the ethics of reproductive medicine were analyzed in conferences held at the APEC Institute of Sexual Education (INSAPEC), during the seminar Ethics and Sexuality and Ethics and AIDS. In the seminar organized in March 2001 as part of the Fourth Forum of the Center of Bioethics of INTEC University, the Bioethical Implications of In Vitro Fertilization was presented.
7. Medical Research
   Various activities related to the ethical aspects of research on human beings have been promoted by the CNB in congresses, seminars, and workshops nationally and internationally. Among the topics covered in several conferences by members of the CNB are Current State of Biomedical Research in the Dominican Republic, Ethics in Biomedical Research, Implementation of Standardized Operational Procedures in the Ethical Review of Health Research, Implementation of the WHO Operating Guidelines, Structure for Ethical Evaluation of Research in Health in Dominican Republic, Interpretation and Implementation of the Helsinki Declaration, Challenges of Ethical Evaluation in Health Research, Principles and Criteria of Ethics in Health Research, Structure and Functions of Health Research Ethics Committees, Balance and Perspectives of Ethical Evaluation of Health Research in Latin America and the Caribbean, Theoretical Framework of Research on Human Beings, Capacity Creation and Ethical Evaluation of Research on Human Beings, Reach of the International Conference on Harmonization of Health Research, Ethics of Investigations on Human Beings: A Global Perspective, Ethical Analysis of AIDS Research Protocols, Role and Perspective of Health Regulatory Agencies at the National and Regional Level, Consent and Clinical Research in Latin America and the Caribbean, Informed Consent in Clinical Research Studies, Ethics of Biomedical Research in the Context of the Universal Declaration on Bioethics and Human Rights, Limits Among Clinical Practice and Clinical Research, and Importance of Programs of Continuing Education for Members of Research Ethics Committees.
8. Public Health
   The Environment Subcommission organized the seminar Ethics and Environment at the Universidad Nacional Pedro Henriquez Ureña in October 1992 and, in September 1994, the project Green Belt for the North Zone of Santo

Domingo, to improve the environmental conditions with an educational program and ethical orientations to the community. In March 1995, a meeting was held with community concerning air quality for a healthy colonial city.

A past president of the CNB was invited to give the conference Research Ethics and Human Rights: International Legal Framework, presented in the Caribbean Conference on Bioethics, hosted by the Trinidad and Tobago National Commission for UNESCO, and organized by the RedBioética UNESCO, in Port of Spain, Trinidad and Tobago, in 2006, and the lecture Overview of the Regulation Research Review in Latin America: a Comparative International Workshop for the Regulation Research Review, hosted by the faculty of law, Toronto University, Canada, in 2005.

9. Infectious Diseases
   Members of the CNB gave talks in the conference Bio-Psycho-Social Aspects of Sexually Transmitted Diseases and AIDS, organized by Dominican Foundation for Health (FDS), in July 1992 and in February 2000 in the conference Human Rights of Immigrants with AIDS in Dominican Bateyes.
10. Transplantation Medicine and Organ Donation
    In September 1999, the conference Current State of Liver Transplants was presented, given by Dr. Juan Madarriaga, professor of the University of Pittsburg Transplant Institute. The conference was organized by the CNB and the Universidad Católica de Santo Domingo.

    An ex-president of the CNB gave the conference Ethical Aspects of Organ Donation and Transplants at the Dominican Medical College and the speech Therapeutic Equivalences: Immune-suppressors in Organ Transplantation, at the National University of Costa Rica in 2008.
11. Emerging Technologies
    In October 1992, the seminar Ethics in Health and Technological Novelties was held at the Dominican Institute of Industrial Technology (INDOTEC), and in July 1994, Father Alfonso Llano Escobar, from Javeriana University in Colombia, gave the talk Bioethics for a Technological Culture.

    In February 2000, the CNB organized the conference Biotechnologies and Power in the Third Millennium given by Dr. Jose Acosta Sariego from Cuba. An ex-president of the CNB gave the talk Role of Bioethics in Scientific Development at the Santo Tomas de Aquino Major Seminary, in 2002, in Santo Domingo.
12. Palliative Care
    In April 2002, an ex-president of the CNB gave the Master Class Pain and Cancer: Bioethical Considerations, at the First Dominican Congress on Pain.
13. Care of the Elderly
    Members of the CNB gave talks in national congresses of the Dominican Geriatrics Society, on care of the elderly, and also held national seminars with the topics Growing Old and Bioethics: The View from Clinical Practice, Ethical Principles for Clinical and Epidemiological research on the Elderly, Bioethical Aspects of Oncology in the Elderly, and Bioethical Considerations in the Elderly Patient.

14. Chronic Diseases
    Topics related to chronic diseases presented in seminars, and roundtable discussions by members of the CNB have focused mostly on the oncologic patient.
15. Psychiatric Care
    The CNB participated in the seminar/workshop Duties, Human Rights and Ethics in Mental Health in August 1992 at the Dominican Medical College.

    In October 2000, during the Second Northern Regional Psychology Congress, a member of the CNB presented the conference Humanity: From Suffering to Hope.
16. Pediatric Care
    The symposium Research in Children: Some Ethical Questions, organized by the National Commission of Bioethics (CNB) and the National Maternal-Infant Research Center (CENISMI), took place in July 1995. Members of the CNB also participated as speakers in courses organized by CENISMI.
17. Emergency Care
    In October 2000, an ex-president of the CNB gave the talk Principles of Bioethics in the Practice of Surgery to the surgery residents of the Cabral y Baez Hospital.
18. General Practice
    The CNB has organized several events directed at general practice in medicine, promoting the creation of hospital ethics committees and organizing seminars, workshops, and conferences with the purpose of contributing to the modernization and humanization of healthcare at different levels through the creation of ethics committees in public and private health institutions. The First National Symposium of Medical Ethics was held in September 1993, in collaboration with the Dominican Medical Association.
19. Health Promotion and Education
    In the area of health promotion and education, the members of the CNB have spoken on several topics in congresses and seminars in the country and internationally: Bioethics and Communication in Health, Education in Bioethics, Universal Ethical Values vs. Cultural Relativism in Global Bioethics, Bioethics and Medical Deontology: Present and Future, Anthropological Fundamentals of Medical Bioethics, Values in the Formation of Health Personnel, Role of the University in Education Health Personnel, Why Teach Bioethics?, and Universal Declaration of Bioethics Norms and Human Rights UNESCO.
20. Scientific and Professional Integrity
    Members of the CNB in conferences given in the country and internationally have discussed the concepts of personal integrity, conflict of interest, and corruption.

    An ex-president of the CNB was invited by the World Medical Association to give the conference Examining Conflicts of Interest and Research Incentives, at the University of Pretoria, South Africa.

21. Relations with Industry and Donors/Sponsors
    So far, the relationship with industry and promoters of multicenter research on human beings has been infrequent and limited. Some conferences and workshops developed in the country have been financed by the pharmaceutical industry (CNB, 2011).

Future Challenges

There is no legislation to regulate research on human beings in the Dominican Republic. The National Council on Health Bioethics (CONABIOS) of the Ministry of Health only has an administrative order to supervise biomedical research. There is also no actualized registry of research studies on human beings taking place in the country. Legislative and administrative directives to regulate, monitor, supervise, and accredit research ethics committees and hospital ethics committees are also nonexistent.

The Ministry of Education, to date, lacks projects or programs to promote education in bioethics in primary, intermediate, or high school levels. The Ministry of Higher Education, Science and Technology has not elaborated programs to promote education in bioethics in any university departments. There is no governmental or private organization in the country dedicated to a thorough analysis of the bioethical aspects of new biomedical technologies. Recently, a stem-cell bank was established in the Dominican Republic, although the Ministry of Health has no legal or administrative regulation of such installations. Foreign companies, staffed by foreign professionals, with the assistance of Dominican physicians, have been performing treatments with stem cells for years, in the absence of any type of governmental regulation. These companies advertise on the Internet and offer "health packages" that include airfare, hotel lodging, and performance of the treatment procedures in private medical institutions.

There is an urgent need for performing studies to diagnose the state of knowledge of the principles and postulates of bioethics by professors at all levels of education in the country. Based on the results of such studies, strategies and programs may be designed to further the knowledge and promote the principles of bioethics.

Conclusion

Bioethics in the Dominican Republic is still in development. Despite the country having signed the Universal Declaration on Bioethics and Human Rights UNESCO, there still has not been a concrete governmental initiative to promote the implementation of its principles and postulates.

There also is no governmental support for bioethics organizations, like the National Commission of Bioethics (CNB), which for two decades has been dedicated to promoting bioethics in different fields in the country, despite the existence of an executive decree from April 1997 designating the CNB as an autonomous advising organization to the executive branch of government in matters relating to ethics.

The Ministries of Education, Higher Education, Science and Technology, Environment, and Public Health should promote programs and processes to implement the principles and postulates of the Universal Declaration on Bioethics and Human Rights UNESCO, with counseling from the two organizations with experts in bioethics in the country: the Consulting Council of Experts in Bioethics of the Dominican National Commission in UNESCO and the National Commission of Bioethics.

It is worrisome that despite the diffusion of bioethics having started in the Dominican Republic in 1988 and after two decades of activities promoted by the two organizations mentioned above, the Dominican legislature still has not generated a law promoting the principles of discipline in the health, education, research, or environmental sectors.

Bioethics Development

When and How Bioethics Started?

The Beginning of Bioethics in Egypt: Moral and ethical codes have a long history and they were dealt with in several philosophical and medical traditions. In all cultures, from the inception of humanity, medical practice was regulated by codes of ethics. Medical practice in both developing and developed countries is shaped by the level of growth in general and that of science and technology in particular.

H.A.M.J. ten Have, B. Gordijn (eds.), *Handbook of Global Bioethics*,
DOI 10.1007/978-94-007-2512-6_18,

Spectacular advances in medicine have increased patient expectations and put pressure on medical society (Serour, 1994).

The beginning of Egyptian bioethics dated back to the times of the Pharaohs, where there are many historical evidences that ethical and moral codes were proposed and instructions were given to respect them in the well-known Papyrus documents. Among the first principles of what is now called bioethics were those conceived in Pharaonic Egypt the Goddess MAAT, which represents the concept of truth, justice, righteousness, balance, and order, dates back to 4000–3500 BC. It calls for individual responsibility for the community – including health, no fear of death, and for those who are wealthy and powerful to use these advantages not to exploit those less fortunate but rather to help them (Karenga, 2003).

Known collectively as the Coffin Texts, the spells contain the earliest known body of Egyptian teaching on ethics.

The Coffin Texts are well-known literature for death. They were given to the dead to take along on their trip into the underworld. The earlier but better-known Pyramid Texts, which were written on the monumental tombs built for pharaohs in the latter part of the Old Kingdom (2980–2275 BC), contain the first known written record that man believed in a life after death. The Coffin Texts, which were composed for the tombs of noblemen rather than kings, express a more complicated insight: that man in the next world will be rewarded for his good acts and punished for evil ones.

Smith Papyrus (1,700 years BC, third dynasty Egypt) shows the first medical ethics guidelines (1,300 years before Hippocrates: Have an expectant attitude and trust nature's healing. Be observant of the patient's condition (Sleem, Elkamary & Silverman, 2008).

However, more constructed guidelines were developed later, history tells that different oaths were proposed for treating physicians, among them are (Source: Serour & Omran, 1992).

Moses Maimonides Oath

Moses Maimonides, who was an Egyptian Jewish scholar, and the private physician to Salah El Din the Great (AD 1135–1204) developed an oath and prayers. His oath clearly stated the two principles of beneficence and non-maleficence: "I shall use my professional skills to help in achieving the objectives of all living creatures to live in peace and him to perfect his ego. I swear to fight through my work so as to reduce danger, noise, attempts at impairment of purity of earth, air, and water pollution and fight destruction of natural beauty, mineral elements and wildlife" (Serour & Omran, 1992: 53). The oath extended the two principles of beneficence and non-maleficence to the environment and did not restrict it to human beings.

Abil Hassan Ibn Radwan Oath

Abil Hassan Ibn Radwan who was an Egyptian scientist and a doctor more than 500 years ago, advised that a physician should distinguish himself with seven virtues:

1. Be impeccable in behavior, physically fit, intelligent, good looking, appreciative, studious, and cal.
2. Be well dressed, good smelling, clean in hands, and clothing.
3. Be secure on patient secrets, and never to divulge anything pertaining to their disease.
4. His drive to cure his patient should be stronger than his desire to obtain payment. His desire to treat the poor should be greater than his desire to treat the rich.
5. Be keen on learning and on rendering help to people.
6. Be good hearted, endowed with chastity, and honest in his speech. Whatever he sees, women and riches, while visiting homes of his patients, he should hold in respect and refrain from taking advantage of them.
7. Be trustful, and never to prescribe a deadly medicine or to inform others about it or to prescribe a drug which aborts a fetus. He should treat his enemy with good intention just as he would do with a friend (Serour & Omran, 1992: 54).

Cairo Medical School Oath

The medical oath which was adopted on the occasion of the opening the medical school in Cairo during the reign of the founder of the Modern Egypt, Mohamed Aly Pasha (AD 1806–1848) included the three principles of beneficence, non-maleficence, and justice.

It stated that:

1. The physician should be keen to preserve the conditions of honor, help and doing good in his practice (Beneficence).
2. The physician should serve the poor free of charge and should not overcharge his patients (Justice).
3. The physician should not use his profession in doing harm, should never prescribe a poison, a harmful or an abortion-inducing drug to a pregnant woman (Non-maleficence).

The Egyptian Medical Oath

The Egyptian Medical Syndicate for example developed an oath, which the physicians swear before they start their medical practice (the seventh year). The oath observes three ethical principles: justice, beneficence, and non-maleficence. It states that the physician will protect human life in all its stages and in all conditions and circumstances. He will do his utmost to rescue it from death, disease, pain, and anxiety (beneficence). He will strive in the pursuit of knowledge and harness it for the benefit of mankind and not for his/her harm (non-maleficence). He will extend his medical care to the near and the far, to the virtuous and the sinner and to friend and enemy (justice).

The Oath of the Muslim Doctor (1981)

Adopted by the first International Conference on Islamic Medicine held in Kuwait in 1981 and published by the Islamic Organization of Medical Sciences, Kuwait, in 1982, then adopted by the current Egyptian medical syndicate, it included the main four ethical principles.

It stated that the physician will respect people's dignity and their privacy, and will not disclose their secrets (autonomy). It also indicated beneficence, non-maleficence, and justice as the other oaths.

Formal Bioethics Development

With the increasing demand for observing ethical values and with the observed increasing trend of violation of ethical values by researchers conducted in Egypt, a grant was made available by the Ford Foundation (FF) to the International Islamic Center for Population Studies and Research, Al-Azhar University to fund a working group of medical, legal, and religious scholars to develop a code of bioethics for reproductive health research in Egypt and to support a conference to discuss and ratify the code and plan for its implementation at the beginning of 1 January 1991. The working group met bimonthly during the first 6 months of the grant, then monthly for 3 months preceding the conference. The conference was conducted during the period 11–13th of December 1991. The date was chosen to coincide with the yearly meeting of the Ethics Committee of the International Federation of Gynecology and Obstetrics (FIGO) which was held in Cairo during this period. By choosing that date, the members of FIGO who are internationally recognized scholars in reproductive bioethics were able to participate in the conference. The conference was held under the patronage of the highest religious authority in Egypt, the Grand Sheikh of Al-Azhar and attended by the most eminent scholars and experts from Egypt and abroad. As a result of the conference, the first committee of bioethics ever formed was approved by the Rector of Al-Azhar University. This was the seed for a long way to disseminate widely the concept of bioethics, the proceeding and the guidelines for ethical research were published and due to the high demand for it, it was published repeatedly for several times (Ragab, 2009).

The bioethics curriculum was developed in early 2000 to be introduced to the faculty of medicine, Al-Azhar University. The curriculum was developed and tested and it is currently being taught to the medical students of the fourth year. Eventually with the progress in the field, this curriculum needs to be, continuously updated. In the year 2012, the updating process has started and is expected to be finalized soon.

Who Have Been the Major Actors/Forces?

The International Islamic Centre for Population Studies and Research, Al-Azhar University has a long history of introducing ethics into the Muslim countries. The first initiative in this regard was an international conference on "Bioethics in Human Reproduction Research in the Muslim World," which was organized by the Center in Cairo, December 1991 as mentioned above. From there, bioethics became institutionalized in the center's activities and in cooperation with other funders, conferences and workshops were organized and books on bioethics published.

Maryland University (USA) in collaboration with Ain-Shams University promoted Bioethics Education and Research Ethical Committees in Egypt since the last decade.

UNESCO and ISESCO supported many bioethics activities in Egypt as in many places of the world. The Ford Foundation contributed to building capacities, for example, supporting individuals to participate in the European Master of Bioethics program.

What Have Been the Major Concerns over Time?

In the 1990s, Sandra Lane, a program officer of the Ford Foundation at that time, observed major violations of bioethics in some studies that include giving children fatal experimental drugs, while safe drugs were available in addition to administration of intravenous fluids to premature infants in a manner that diverted greatly from generally accepted guidelines for parenteral therapy and endangered their lives. In fact, many of the observers commented on that and highlighted the need for establishing research committees (Lane, 1994).

In a study of Wazaify, Khalil, and Silverman (2009) the therapeutic misconception was analyzed. The majority of research participants expressed inaccurate beliefs regarding the degree with which individualized care will be maintained in the research setting.

Khalil, Silverman, Rafaat, El-Kamary, and El-Setouhy (2007) examined the attitude, understanding, and concerns regarding medical research among Egyptians through a qualitative study. The study participants recognized the value of medical research and have a great deal of trust regarding medical research and their participation in research. There were, however, concerns with the level of research risks associated with several types of medical research. Many of the participants demonstrated confusion in regard to research methodologies. The publication recommended enhancing educational efforts regarding general research concepts to enhance the validity of informed consent.

While efforts to establish research ethics committees (RECs) in countries of the Middle East, including Egypt, have recently increased, the quality and consistency of ethical review remain unclear (Sleem, El-Kamary, & Silverman, 2010). In general, commentators have voiced concerns that RECs might not be able to promote high standards of human subject protection due to inadequate financial and material resources, lack of adequately trained REC members, insufficient diversity of membership, lack of REC independence and inability to monitor approved protocols. In order to overcome the problem of the little data that are available regarding processes of ethics review, member composition, training members, workload and resource needs of RECs, and challenges that RECs encounter in the region, Sleem et al. (2010) designed a study that revealed variability among respondent RECs in many of the structural and operating processes, including member composition, existence of written standards of practice and conflict of interest policies, access to adequate financial and material resources, and protocol review.

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

The International Islamic Center for Population Studies and Research, Al-Azhar University published several books:

- The proceedings of the first international conference on "Bioethics in Human Reproduction Research in the Muslim World." Due to the increasing demand on this particular book, it was reprinted for the second time (in the year 2008).
- The Ethical Guidelines for Human Reproduction Research in the Muslim World, 1992.
- The proceedings of a workshop in collaboration with ISESCO on "Ethical Implication of Assisted Use Reproductive Technology for the Treatment of Human Infertility," Cairo, 1997.
- The proceedings of a workshop in collaboration with ISESCO on "Ethical Implication of Assisted Use Reproductive Technology for the Treatment of Infertility. Update," Cairo, 2000.
- The proceedings of a conference, in collaboration with the Ford Foundation on "Ethics of Medical Information and Medical Advertisement," Cairo, 2003.

All these activities created awareness of medical ethics in Egypt and paved the way for acceptance of the need to introduce bioethics in the medical curriculum and to establish Ethics Committees.

The Regional Resource Center for Bioethics that was established in the year 2010 with the support of UNESCO started some activities and collaborated with other bodies. Another body was formed with the assistance of UNESCO, is the Arab Network of Women's Health in 2011. The Regional Resource Center and the Arab Network of Women Health organized a regional conference in Cairo, 7–8 December 2011 to examine bioethical aspects of women's health. It was a good opportunity to network between experts.

Current Bioethics Infrastructure

(a) Teaching of bioethics at university and other levels: A master program had been started in the USA that includes 12 months of courses at Maryland Baltimore Campus and another year for a research project in Egypt. Opportunities for PhD are available, but outside Egypt. Members of research committees had the chance to participate in other certificate programs that are available for the Egyptians through the program with Maryland University, however, this program, as all donor's dependent programs, is lacking sustainability.

On the undergraduate level, bioethics, for a long time has been a part of Forensic Medicine teaching, it is only recently introduced as a separate subject, but to the undergraduate students only. Al-Azhar University is the only one that has produced a curriculum of Bioethics. The curriculum links between basic

ethics and Islamic teachings. It affirms that all the ethical principles have roots in Islam texts.

It should be stated here that there is no separate department for Bioethical Studies and there are no PhD studies in the discipline in Egypt. However, with the growing number of bioethics Master holders, it is expected that separate bioethics programs will be established in the near future.

(b) Bioethics committees: Al-Azhar University Bioethics Committee was the first committee to be established in the year 1992. The national bioethics committee started in 1996 by a Ministerial decree of the Ministry of Higher Education and Scientific Research. Starting from the year 2002, many ethical committees have been established in response to the funding agencies' requirements. Currently, there are 13 ethical research committees federally approved to review researches funded by USA. However, not much have been done regarding hospital ethics committees, what routinely done is review of some cases during different departments, meeting. There is an obvious need to promote hospital ethics committees.

The first meeting for the Egyptian Ethics committees was held in Ain Sokhna, a beautiful sea side city in Egypt during 16–18 October 2008. Since then many activities were carried, among them, forming a network and developing guidelines. Till now, there are no National Guidelines developed.

(c) Expert bodies/centers: The International Islamic Center for population studies and research was the first and it took about three decades to have more centers, currently the main universities in Egypt (Cairo, Ain-Shams, Alexandria, Assiut, and Mansoura) have expert bodies. A resource center was needed and with support of UNESCO, the center is now established at the Egyptian Academy of Sciences.

(d) Relevant legislation: The first national committee for reviewing researches was developed after a Ministerial Decree of Higher Education and Scientific Research in 1996. However, Al-Azhar University had established its committee before that date (1992). The Medical Syndicate has its own legalization and committee that examine the misconduct of the medical doctors after a complaint of a patient or a referral from the court.

(e) Public debate activities: The public is concerned with the increase of medical misconduct either technically or in behavior. Recently, media reported on many of the mistakes and misconduct of some medical doctors, although few, but this has percussion on the public. Some incidents of harassment of clients and recording video tapes secretly without consent were discovered.

Public debate was raised, and still, on issues concerning organ donation and the definition of death since there is a close link. This debate has been influenced much by theological perspectives. Theologians needed a clear medical opinion on these issues from trusted medical experts, which was lacking as the medical experts were in conflict regarding the definition of death.

Another debate, which is peculiar of Egypt and some parts of Africa, is the medicalization of female genital cutting/mutilation (FGC/M). Nearly 75 % of the practice, which is a traditional one that involves cutting some of the external

genitalia of girls (clitoris and labia minora), is conducted by medical doctors. Although the practice is criminalized by a recent law in Egypt, still many of the FGC/M practices are conducted as many believe wrongly that it is required by Islam (Fahmy et al., 2010).

(f) Other: Recently, with the increasing of the influence of Islamists in the educational system and other governmental bodies, it is expected to have more debates on gender issues, human rights, reproductive and sexual health. Consequently, bioethics scholars and activists should be ready to clarify the ethical and moral aspects of such issues.

Major Bioethics Issues and Discussions

(a) Beginning of life: at what stage during the pregnancy does the fetus become a human being? Answering this question is central to the debate. Some believe that it is after 120 days, others believe that it is 42 days, depending on the Quran and the traditions and sayings of the prophet Mohammed (peace be upon him). However, there is an emergent medical opinion which is accepted by the theologians that the crucial point is at 14 days from conception. Any of these definitions allow embryo and stem cell research and allow for early abortion, provided that there is a medically justified cause, however, it should never exceed 120 days of pregnancy.

(b) End of life: The common belief among the public and the theologians is that the end of life is a divine decision and should not be taken by humans. Consequently, there is no much debate about the issue currently.

(c) Health and disease: The fatalistic attitude of the majority of the public shapes the perception of health and diseases that they are from GOD. However, seeking treatment is a following of Islamic Teachings, according to the Prophet (PBUH): "God did not create a disease without creating its treatment; some knew it and some do not." In this regard, Muslim Scholars believe HIV/AIDS have treatment, but no one know it, currently.

(d) Health care system, access to health care
In Egypt, where resources are limited and a major part of the national budget goes to the military, available basic health service is well below accepted standards in the public sector. Urban bias exists, since big and well equipped health facilities are there, while in rural areas even basic services either do not exist or lack the necessary equipment and/or personnel. Health insurance for all is a promise of all governments of Egypt, but never fulfilled. In the private sector, very expensive centers that are well equipped and having the best staff do exist. However, the expensive centers would only be able to offer service to a relatively small sector of the society. This should not be at the expenses of providing basic health care service to the major sector of their population.

(e) Traditional medicine: Traditional medicine does exist side by side with the modern medicine; however, there are major concerns about it, as there is no body that controls its use. Advertisements that give wrong information and

magnify the impact of certain herbal extracts abound on different private satellite channels. It should be mentioned here, that most of these products are advertised as aphrodisiacs.

(f) Genetics: Genetic engineering and gene therapy were discussed widely among Muslim scholars. Hathout (2006) argued that genetic engineering involving the introduction of the genes of one species to another is not permissible except as a means of treating illness and alleviating suffering. Nontherapeutic manipulations are controversial and the majority of scholars are cautious regarding its implications on the society level and the universe as whole (Bayaumi & Ali, 2001). Gad El-Hak (1992) argued that human gene therapy should be restricted only to therapeutic indications. Somatic cell gene therapy is encouraged as it involves remedy and alleviation of human suffering. However, enhancement genetic engineering or eugenic genetic engineering would involve change of Allah's creation which may lead to imbalance of the whole universe and should be prohibited. Gene therapy to manipulate hereditary traits such as stature, beauty, intelligence is a serious attempt as it might imbalance the life of man (Serour, 2001).

Hathout (2006) and many other scholars, are of the opinion that, stem cell research on the preimplantation embryo may be justified if the aim is to save actual patients suffering from serious illness, on the basis of the juridical rule of choice of the lesser of two evils. Stem cells derived from adults gain acceptance of the vast majority of Muslim scholars.

Islamic scholars differentiate between PGD for medical purposes which is currently a routine practice offered to high-risk parents, to help them having healthy children, and the controversial preimplantation genetic manipulation which is aiming at enhancement. As a result of PGD, gender selection whether for medical or social purposes has been debated and there are conflicting views. While the vast majority of Islamic scholars approve gender selection for therapeutic purposes or in selected cases for social reasons, where there is a need for a fetus of the selected gender (Serour, 2001). The minority approves gender selection for social reasons without any restrictions.

(g) Reproductive medicine: Regarding human cloning a distinction must be made between reproductive cloning aimed at the birth of identical individuals and nonreproductive cloning limited to the in vitro phase. Hathout (2006) argued that cloning is outside the bounds of religious permission if used for production. Its use for purely research purposes may be permissible during the very early stages before body systems are formed (Hathout, 2006; Serour, 1995).

Regarding assisted reproductive techniques, adoption is not allowed in Islam, however, there are many verses in Quran that indicate that sponsoring orphans is encouraged and rewarded. In this regard, treating infertility and assisted reproductive techniques are welcomed and encouraged by Muslim religious leaders. From the early days on, scholars supported assisted reproductive techniques, using different modalities, provided that there is no third party like surrogacy, egg or semen donation, and the technique should be

carried out during the validity of marriage contract, not for divorced women or a widow (Gad El-Hak, 1992; Serour, 1995).

(h) Medical research: medical research was discussed extensively by participants of the International Conference of Bioethics in 1991. The participants came to consensus on the following:
   1. Evidence should be available to indicate that the proposed therapy or procedure can be superior to currently available alternatives.
   2. Adequate data must be available from animal studies and from studies on a small number of human subjects to confirm safety and to suggest effectiveness. The ethically acceptable practice is to do clinical trials in three successive phases, I, II, and III, and only to move to the next phase after the successful completion of the previous phase.
   3. It is unjustifiable to do clinical trials with drugs that are unlikely to become available to people in the country or community. For example, drugs that are likely to be non-affordable or non-marketable should not be tested in a given population. This applies in particular to industrial and international research.
   4. Research should only be done by investigators who are fully aware of the scientific literature on the subject, who are well qualified and who have the necessary facilities.
   5. The research should not conflict with the society's cultural, moral, religious and legal values.

(i) Public health: Although preventive medicine is at the heart of public health, lacking health education is affecting it negatively. Bilharzia is an endemic disease that is transmitted through Nile water, which is essential for the farmers for irrigation and they cannot stop using it. However, with health education, these risks can be minimized. Also anemia is a problem for women in reproductive age and can be corrected with proper health knowledge. Health, especially reproductive and sexual health, are lacking and affecting much the public health.

(j) Infectious diseases: The ministry of health has strong and up to date standards and protocols for infection control; they are not applied in many settings. There are concerns of lack of infection control in health delivery points in villages and in remote and slum areas.

(k) Transplantation medicine and organ donation: The Sharia allows organ donation from a healthy person to another sick person to save his/her life provided that the donor is not seriously harmed from this donation and the involved benefits exceed or overweight the potential risks. Organs may be transplanted according to medical norms provided the donor does not need the organ he/she gives or will be harmed by this donation. The free informed consent must be obtained without pressure, coercion or exploitation (Serour, 1994).

Information emerged recently through media about gangs that target street children and the poor to buy their kidneys. The operations are usually done in poor settings with many complications.

(l) Emerging technologies (nanotechnology, information technology): Since Egypt is a developing country with limited health resources, expensive nanotechnology and new technology do not exist and they are not welcomed by the ethics community as they believe that, resources should be properly allocated with ultimate justice.
(m) Intensive care: Intensive care units are available, but they are not sufficient to accommodate the increasing demand. However, for the public, the fatalistic attitude prevents many of using it. It is not surprising, that many persons who need to be admitted do not do that because of the rejection of their families.
(n) Palliative care: Palliative care is accepted and welcomed by the public and by the providers; however, it is a private practice mainly. Only few public clinics do exist and mostly exist within cancer treating centers.
(o) Care for the elderly: The tradition in Egypt is that families are responsible of taking care of the elderly. However with the decline of the extended families, the growth of the aging population as a result of improving health, and the emerging trend of small nuclear families as a result of the family planning program, family support is lacking. This compounded by the limited number of elderly homes, the available homes are expensive. Consequently, unless the government of Egypt takes action, the problem, that care for the elderly is increasingly inadequate, will continue to exist.
(p) Chronic diseases: Diabetes and hypertension are increasing in the country, while some educational programs exist but they do not reach the public. Leprosy patients usually are isolated in certain camps. The HIV/AIDS incidence is very low; people living with HIV/AIDS used to be isolated in fever hospitals, however, currently, only those who develop symptoms are isolated. Stigma, expelling from work, divorce are facing people living with HIV/AIDS.
(q) Psychiatric care: For a long time, chronic mentally ill patients were isolated in specialized hospitals, might be for life. However, currently, there is a trend to treat them in public hospitals.
(r) Pediatric care: Because children are valued parents seek care as early as possible even in the private sector. However, in certain parts of the country, the preference for male children is so clear that, when a son becomes ill, the parents seek care immediately, while for a girl, they may seek advice from a neighbor or a pharmacist.
(s) Emergency care: It is a complex issue, as the decision to seek care is in the hands of the head of the family, and if the decision would be taken, the traffic jam in Cairo or the lack of transport in rural areas, or the lack of personnel and equipment in the health facility to deal with the emergency will be obstacles.
(t) General practice: The Ministry of Health is promoting family health doctors and health insurance for all; however, due to economic constraints and political instability, these efforts did not succeed.
(u) Health promotion and education: The country lacks health promotion and education, especially in his field of reproductive/sexual health. However, there are many attempts to deal with the issue.

(v) Scientific and professional integrity, conflict of interest, corruption: The scientific and professional integrity is promoted widely by different Universities and the National Research Academy; however, still, there are many incidents where false results of research were presented and copying other researchers' work without acknowledging.
(w) Relations with industry and donors/sponsors: Before the start of the efforts to promote bioethics in the country, Egypt was the place of many research projects sponsored by the industry; many drugs were tested without informed consent.

Future Challenges

(a) In the field of bioethics infrastructures.
There is a need for national guidelines and there is need for more ethics committees. The ethics committees should be independent and protected. Legalization should be proposed to organize the ethical committees work and to empower them.
(b) In the field of new and emerging issues.
The new emerging issues are always discussed at large by the concerned experts and theologians who usually come to an opinion that takes into consideration the teaching of Islam and the needs and welfare of the people. However, with increasing number and influence of conservative Islamists after 25 of January revolution, there are greater risks of more conservative attitudes toward issues like organ transplantation, contraception, young age at marriage, and female genital mutilation.
(c) After the revolutionary events of 25 January 2011, conservative Islamists became a powerful force in the country. However Islamists are not unified. While the majority is moderate, there are some fundamentalists that have a great number of followers and have a strong voice. Any ethical debate should take into consideration the Islamic point of view.

Summary Conclusion

The current study dealt with the development of bioethics to date, the current bioethics infrastructure, the major bioethics issues and discussions at the moment and the challenges for the years to come.

It is hard to identify the beginning of bioethics in Egypt as the recorded history is full what are considered to be ethical guidelines. Different oaths were recorded that contain what are now called ethics principles. Islam is the religion of the vast majority of the population. Consequently bioethics guidelines were driven from its teachings.

The first Biomedical Research Committee was established at Al-Azhar University and the first National Committee was established in the year 1996. About the year 2002, many bioethics committees were established in nearly all 17 University

in the country and a network was established and coordination strengthened but, till now, although there are some attempts, no approved national guidelines were promoted.

After the 25 January 2011 revolution, the country is polarized into two positions: the majority are Islamists and they are obeying the teaching of Islam, which in its ideal level is consistent with ethical and moral values; the minority is more liberal and views human rights as the central issue that should not be bounded by any constraints. This could be one of the challenges, as the Islamists are not unified and there are a growing number of conservatives that might harm efforts to promote bioethics.

The debate on ethical issues, so far, is driven by Islamic teachings which are rich and full of supporting evidence on all issues that needs ethical reflection. Providing the theologians with the medical facts will be necessary so that they will come with the ethical guidelines concerning relevant issues.

Thus, bioethics activists should work hard to promote the discipline and to work on developing National Guidelines and to network, not only among themselves, but also with different stakeholders, mainly religious leaders, legislators, and health policy makers.

Bioethics Development in Ethiopia

The development of bioethics in Ethiopia can be traced back to around the introduction of biomedicine in to Ethiopia. Hence, it becomes relevant to discuss the development of biomedical science and modern medicine and health care in the country.

Country Background

Ethiopia is located in the eastern part of Africa, often called the "Horn of Africa." It is the second most populous country in sub-Saharan Africa, with increasingly promising economic development. The oldest human fossils in human history so far are found in Ethiopia, and hence, it is considered as "Cradle of Mankind." Unique to other African countries, Ethiopia is the oldest independent nation in the continent and an icon of freedom as it has never been colonized, with the exception of a short-lived Italian occupation from 1936 to 1941 which was accompanied by continued freedom fighting. Ethiopia is the tenth largest country in Africa with great geographical diversity with a variety of contrasts ranging from high peaks of 4,550 m above sea level to very low depression of 110 m below sea level. Ethiopia is a home to mosaic nations, nationalities, and peoples with more than 80 different spoken languages. The country is among the least-urbanized countries in the world with more than 80 % living in rural areas. And its population is predominantly a young population.

The major health problems of the country remain largely preventable communicable diseases and nutritional disorders. Despite major recent progresses, the country still faces a high rate of morbidity and mortality and a low health status with life expectancy of 54 years (53.4 years for male and 55.4 for female), infant mortality rate of 77/1,000, under-five mortality rate of 101/1,000, and maternal mortality ratio of 590/100,000 (CSA, 2012). In addition to relatively inadequate availability of services, cultural norms and societal emotional support bestowed to mothers, distance to functioning health centers, and financial barrier were found to be the major determinant factors.

Ethiopia is a Federal Democratic Republic, composed of nine regional states, having their own regional governments and two city administrations including the capital Addis Ababa. The country's economy is mainly dependent on agriculture. The regular droughts combined with poor cultivation practices make Ethiopia's economy vulnerable to climatic changes, and the country has suffered from various natural calamities until the recent past. Despite being one of the poorest economies in the world, there are very impressive and obvious changes and economic progress in the past decade to the level of meeting the Millennium Development Goal targets in certain areas such as education and health care.

The Federal Ministry of Health of Ethiopia takes the main responsibility for medical services in Ethiopia. The private medical service is emerging and mainly urban centered. The Ethiopian health policy of 1993 is focused more on public health interventions and primary health care. The ministry has formulated and implemented a number of policies and strategies that afforded an effective framework for improving health in the country. The main objective of Ethiopia's health services policy is to provide a comprehensive and integrated primary health care in health institutions at the community level.

History of Modern Medicine in Ethiopia

The Ethiopian health system has been in constant change corresponding to the socioeconomic and political changes that took place during the last century. There have been rapid developments in the last two decades in terms of new health policies and programs and growth of the private sector in the context of the global paradigm of health sector reform. Even though modern medicine began to be practiced in Ethiopia only at the beginning of the twentieth century, its introduction and utilization date back to the start of the sixteenth century.

Western modern medicine was introduced to the country by foreigners such as religious and diplomatic missions to travelers, traders, invaders, and warriors. Further progress in the development of modern medicine was made during the reign of Emperor Menelik II (1889–1913). The Russian mission established the first hospital in the country (the Russian Red Cross Hospital) in 1897 and subsequently few Ethiopians were sent abroad for medical training.

As signatory to the 1978 Alma Ata charter, Ethiopia has adopted the 1979 declaration of "Health For All by the year 2000" using the PHC strategy and it is one of the pioneering countries in implementing the basic health services approach with its "Health Center Team Training Program," launched in 1954 with new cadre of health professionals (health officers, community nurses, and sanitarians) assigned to render services at the district level to perform mainly community-oriented health activities. The main strategic and policy focus of the national health program is on preventive and promotive aspects. Since 2002, the country has launched a massive community-based health program "The Health Extension Service" with more than 30,000 community-based health extension workers (Haile Mariam & Kloos, 2005).

Ethiopia has a long tradition of indigenous medical practice, which deserves an important place in the country's social and cultural history as Ethiopians have been familiar with a wide range of diseases and medical complaints for which they had long-established names, both in their ancient classical language, *Ge'ez*, and in other indigenous tongues of the country (Pankhurst, 1990).

History of Health Research and Research Ethics in Ethiopia

Health Research in Ethiopia is more than a century old. The first publication was on "Abyssinia in Its Sanitary and Medical Aspects" in *The Lancet* (1868). Abyssinia is the old name for Ethiopia. However, output in terms of quality and quantity remains low as the total number of publications is still fewer in number. In Ethiopia, the agenda of health research ethics is a recent phenomenon. Despite the attention given to the issue, the knowledge and practice of standardized regulations and follow-ups remain shallow. The health department

of the then Ethiopian Science and Technology Commission in collaboration with the National Health Science and Technology Council embarked to address health research ethics issues in the country. Accordingly, in 1994, the commission officially launched the National Health Science and Technology Policy and established a broad-based body at a level of a council with a function to advise the federal government on health science and technology issues in general and research and development in particular. One of the standing committees of the council was the National Health Research Ethics Review Committee which is given the responsibility to review health research ethics issues, fundamental principles of health research ethics, and their applications in the Ethiopian context. The first health research ethics guideline was developed by the commission in 1995 and has been revised twice, in 1997 and 2004 (ESTC, 2005). With the expansion of postgraduate programs in Addis Ababa University and other immerging universities and with the availability of funding related to HIV/AIDS and other diseases of public health importance, the number of research projects with human subjects on yearly basis is progressively increasing. This clearly puts demand on the current system to be more effective and efficient.

Health research ethics review committees have been established at three levels: national, regional, and institutional. The National Research Ethics Committee is responsible for the final approval of all clinical trials, research on very sensitive issues, multicentered and collaborative research projects, research financed or carried out by external donors, research to be conducted in more than one region of the country, and projects that require sample transfer (ESTC, 2005). Regional ethics review committee is responsible for the ethical review of projects involving more than one institution in the region and can review projects other than those mentioned under the mandate of National Research Ethics Committee. Institutional ethics review committees review all health research proposals of an institute and are responsible for reviewing and deciding upon all proposals of the institute which do not come under the mandates of either the national or regional committees. Accreditation and recognition of ethics committees are mainly done by National Research Ethics Committee. All regional and institutional committees need to be registered at the secretariat of National Research Ethics Committee, to be renewed every 2 years.

Major Actors of Bioethics in Ethiopia

The major actors for bioethics (for both medical ethics and research ethics) in Ethiopia include academic institutions, hospitals, government offices, and professional associations. Below are some of the prominent actors. These entities have played major roles in the initiation and development of a system for ethics in biomedical research and medical issues in Ethiopia. The contributions of each could vary but all have put significant contributions and remain to be both potential and major stakeholders.

Addis Ababa University

Established in 1950, Addis Ababa University (http://www.aau.edu.et/) is the oldest and largest higher education institution in Ethiopia, which has made a remarkable contribution to the country through provision of trained manpower, research, and community services.

One of its main campuses is the College of Health Sciences, which for many years used to be the Medical Faculty having the country's oldest and biggest specialized teaching hospital, the Tikur Anbessa [in Amharic Black Lion] Specialized Hospital. The college incorporates School of Public Health, School of Medicine, School of Pharmacy, School of Allied Health Sciences, and the teaching hospital integrated to form one administration center which envisions to be the center of excellence in health-related issues.

The university has contributed as spearhead in higher education and research in Ethiopia and beyond. It has helped a lot in the establishment of national system for biomedical research ethical review under the Ministry of Science and Technology. Most of the national steering and standing committee members were and are from the Medical Faculty of Addis Ababa University. The then Faculty of Medicine and current College of Health Sciences run an IRB, which is the first African IRB to receive Strategic Initiative for Developing Capacity in Ethical Review (http://www.sidcer.org) recognition from WHO. The IRB serves in capacity building for the national research ethics review in collaboration with partners, i.e., professional associations and donors. In addition to research ethics, the university is expected to lead in the development of bioethics in Ethiopia. There have been efforts to establish Medical Ethics committees in the university's teaching hospital, i.e., Tikur Anbessa Hospital. Yet, the progress so far is nor remarkable.

Armauer Hansen Research Institute (AHRI)

Armauer Hansen's Research Institute (http://www. eaccr.org/sites/ahri/) is a biomedical research and capacity-building and training institute in Ethiopia. It is involved in conducting research with relevance to disease control, particularly in tuberculosis, leprosy, leishmaniasis, and other diseases of public health importance including malaria and HIV. The institute was founded in 1969 through the initiative of the Norwegian and Swedish Save the Children organizations seconded by the Ministry of Health of Ethiopia. More than 350 papers in peer-reviewed journals have been published from AHRI and it has produced a substantial number of theses and dissertations from international and Ethiopian scholars in biomedical research. It has played a key role in institutionalizing Bioethics and is the home office for Pan-African Bioethics Initiative (PABIN). Its ongoing projects, among others, include Establishing an African Coordinating Office for Ethics through PABIN (EDCTP) and Ethics Review Committee Establishment in the Universities in Ethiopia (with ETBIN).

Ethiopian Health and Nutrition Research Institute (EHNRI)

Ethiopian Health and Nutrition Research Institute is the result of the merger of three institutes: National Research Institute of Health, Ethiopian Nutrition Institute, and

Departments of Traditional Medicine, under the Federal Ministry of Health of Ethiopia (http://www.fmoh.gov.et). The main objectives of the institute are to: contribute to the development of health science and technology; provide referral medical laboratory services relating to the causes, prevention and diagnosis of major diseases of public health importance; and establish and support National Laboratory Quality Assurance Programs and systems.

Being a national research institute on public health and biomedical science, EHNRI has contributed a lot on the development of health research ethics in the country. The institute is one of the network members of the Ethiopian Bioethics Initiative and continues to help in capacity-building and ethical trainings. The institute owns its own IRB and its staff serve in various national ethics committees. The institute also runs capacity-building trainings and seminars on research ethics for medical researchers.

Ethiopian Medical Association (EMA)

The Ethiopian Medical Association was founded in 1961 under the patronage of the then Emperor of Ethiopia (http://www.emaethiopia.org/). The association exists to promote professional excellence of Ethiopian medics in both preventive and curative medicine through medical research, annual and special conferences, and publications. It provides professional and technical advice to the Ministry of Health and other concerned organizations and the exchange of clinical knowledge and research information at the local and international levels. EMA runs continuing medical education sessions on ethics. It also runs various trainings on ethics for medical doctors, researchers, and editors. It has developed and published a guideline on "professional code of practice for physicians in Ethiopia." EMA is one of the standing members of the Health Professional Ethics Committee at EFMHACA. These values allowed EMA to maintain a standard of behavior that is always humane and rational, for dealing with lives of people.

Ethiopian Public Health Association (EPHA)

Ethiopian Public Health Association (http://www.etpha.org/) is an association of public health professionals of varying categories and levels of training which envisions the attainment of an optimal standard of health for the people of Ethiopia, through promotion and advocacy for better health services and high professional standards, professional competence, relevant policies, and effective networking. The association stands for professional development of its members without prejudice as regards gender, religious, or ethnic affiliation. Like the Ethiopian Medical Association, it also serves as member of the national networks in medical ethics and runs various capacity-building sessions through continuing medical educations and trainings. It also runs regular trainings on "Research Methods and Ethics" for its members in different locations in the country. In addition, it owns an independent IRB which reviews proposals on health research. EPHA also contributes to the national dialogues in ethics.

Food, Medicine and Health Care Administration and Control Authority (FMHACA)

Food, Medicine and Health Care Administration and Control Authority (http://www.fmhaca.gov.et/) is one of the wings under the Federal Ministry of health. Like the Federal Food and Drug Administration in the USA, it is responsible for the accessibility of quality health service to all citizens throughout the country. Accordingly, health and health-related services and products quality regulation core process are redesigned in the purpose of protecting the public from any emerging health risks. One of its major objectives is to standardize health services and protect the public from unqualified and unethical professionals and substandard health institutions. The authority is responsible for ensuring professional ethics. Its Professional Ethics Committee looks into medicolegal issues and does case-based deliberations and advises the legislative body on medical malpractice. In addition, all drug clinical trials need to be further registered, approved, and regulated by FMHACA. For this, a guideline had been developed incorporating Good Clinical Practice and made publicly available.

Ministry of Science and Technology (MOST)

Ministry of Science and Technology (http://www.most.gov.et), which used to be Ethiopian Science and Technology Commission (ESTC), is a governmental institution established with the mission to create a technology transfer framework that enables the building of national capacities in technological learning, adaptation, and utilization through searching, selecting, and importing effective foreign technologies in manufacturing and service-providing enterprises. The ministry has the powers and duties to forward recommendations based on studies for adopting and revising polices, strategies, laws, and directives on the development of science, technology, and innovation activities that support the realization of the country's socioeconomic development objectives. As is mentioned under the section "development of research ethics in Ethiopia," the then commission in collaboration with the National Health Science and Technology Council (NHSTC) embarked the first organized national initiative to address health research ethics issues in the country. The National Health Research Ethics Review Committee under the ministry is endowed with the responsibility of reviewing health research ethics issues at a national level and setting principles and standards on health research ethics and their applications in the Ethiopian context. ESTC launched three versions and revisions of the national research ethics guideline (1995, 1997, and 2004) (ESTC, 2005). The ministry is responsible for licensing and regulation of Research Ethics Committees at national, regional, and institutions levels. Its National Committee is composed of various independent stakeholder members responsible for reviewing proposals that need to be reviewed at national level.

Ethiopian Bioethics Initiative (ETBIN)

The Ethiopian Bioethics Initiative is a country chapter of the Pan-African Bioethics Initiative (PABIN) which aims to build capacity in ethical clearance of health research in the country. Established in 2002, its secretariat is based at AHRI,

which is a founding member institution and itself important stakeholder in bioethics in Ethiopia. ETBIN hosted the Third PABIN Conference in Addis Ababa in 2006. ETBIN helped in implementing the initiation of capacity-building program that aimed at supporting other institutions establish Ethics Review Committees and to strengthen existing committees. The national network provides a forum for regular meeting and discussion on bioethics in Ethiopia in order to preserve and promote Ethiopian traditions in ethics and bioethics. It also aims to improve communication among ethics committees in reviewing biomedical research (health, behavioral, and social science) in Ethiopia. It assists in fostering education in bioethics and the trainings, promoting and assisting the development of ethical committees, acting as an Ethiopian collaborating center for fostering ethical review, organizing national meetings and symposia, and assisting with the implementation of standard operating procedures for ethical review in the country. ETBIN is in the UNESCO Bioethics databases and receives project support from EDCTP (European and Developing Countries Clinical Trials Partnership).

Resources Available and Steps Taken for Bioethics in Ethiopia

There are some regulations and guidelines in Ethiopia made available to provide guidance on the ethical conduct of health professionals. These guidelines are developed by the government and by professional associations.

The revised 2005 version of Criminal Code of the country (Proclamation 414/2004), which is based on the country's Constitution, has addressed issues in the medical practice. Article "271 of the penal code" states as follows:

> (1) Whoever, in the circumstances defined above [i.e., in time of war, armed conflict or occupation . . . and in violation of the rules of public international law and of international humanitarian conventions] organizes, orders or engages in: . . .(c) compelling persons engaged in medical . . . activities to perform acts or to carry out work contrary to or to refrain from acts required by their . . . professional rules and ethics or other rules designed for the benefit of the wounded, sick or civilian population, is punishable in accordance with [rigorous imprisonment from five years to twenty-five years, or, in more serious cases, with life imprisonment or death]. (FDRE, 2004, Ethiopian Criminal code - FDRE, the Criminal Code of Ethiopia; Proclamation No. 404/2003).

There are also a number of professional codes of conduct by respective professional associations. "Medical Ethics for Physicians in Ethiopia" has been published by the Ethiopian Medical Association twice so far (EMA, 2010). Other resources include an introductory text on Professional Nursing and Ethics, which is a textbook and reference material for mainly nursing professionals (Cherie, Mekonen, & Shimelse, 2005); "Professional Code of Ethics and Conduct for Midwives" by the Ethiopian Midwives Association (EMWA, 2011); and Code of Ethics For Medical Laboratory Technologists Practicing In Ethiopia by the Ethiopian Medical Laboratory Association (EMLA, 2008). The federal ministry of health has developed a module for health extension workers on health management, ethics, and research, as a blended learning module for the Health Extension Program, for health

extension workers, and as a guidance for research in primary health care (FMOH, 2011). The Ethiopian Society of Obstetricians and Gynecologists (http://www.esog.org.et) also has developed Sexual and Reproductive Health Ethical Guidelines for Ethiopia, which is available on the web. There are also curricula on general ethics for undergraduate students. However, the courses are more on civics than bioethics. There are very few or less available resources in Public Health Ethics and much is integrated to the public health systems and ethics is not treated separate such as tobacco proclamation and guideline.

Several guidelines on research ethics exist in Ethiopia. The Ministry of Science Technology (MOST) has training modules on research ethics for the Ethiopian context and National Research Ethics Guideline on how the national research ethics review system should work at the national level which are made available (http://www.most.gov.et/). The Ethiopian Public Health Association (EPHA) has also developed a course on Research Methods and Ethics for its members and other public health professionals (http://www.etpha.org). EFMHACA has guidelines available on the web on the applications of Good Clinical Practice (http://www.fmhaca.gov.et/). In addition, most IRBs (such as Addis Ababa University) have their own SOPs and guidelines published in book formats available for applicants, reviewers, and IRB members.

Current Bioethics Infrastructure

As explained under the section "Research Ethics System in Ethiopia," there is a very good structure available for research ethics review. The public media also frequently hosts and broadcasts public debates and panel discussions on various topics on Bioethics.

Teaching of Bioethics at University and Other Levels

Regarding training in bioethics, for very long, there have not been medical ethics courses in the medical curriculum. Recently, medical ethics is included as a course in undergraduate medical trainings in the medical school. The course is given for other health professionals such as nursing and medical laboratory technology. So far, there are no independent academic courses in research ethics. This is addressed under research methods trainings for postgraduate students. Professional associations such as EMA and other partners give various trainings on "research ethics." But these are not very structured as such. Still, there are no full-blown graduating programs in bioethics.

Bioethics Committees

Even though there are no bioethics committees in the hospitals, almost throughout the country, there are functional research ethics committees both at national,

regional, and institutional levels. These are generally research ethics committees, but not bioethics committees dealing with clinical ethics and case deliberations. Tikur Anbessa Specialized Teaching Hospital is the first one to have a bioethics committee which is functioning below its capacity. The main reasons for the retarded progress in the clinical aspect of bioethics have to do with less awareness, less expertise, and existence of few ethical dilemmas, compared to much advanced countries.

Legislations

The main legislation guiding medical ethics in Ethiopia is the Ethiopian Civil Code; there is a Professional Ethics Proclamation under review and a number of national guidelines available (see section on resources and guidelines above).

Public Debate Activities

Media and panel discussions have taken place mainly in the areas of medical professional ethics organized by media groups, professional associations and agencies such as Ethics and Anticorruption Commission.

Major Bioethics Issues and Discussions

Contemporary major bioethics issues in the Ethiopian context are dictated by the current socioeconomic and medical developments in the country and the sociocultural context. Below are issues pertinent to the Ethiopian context. The list is not exhaustive by any standard but demonstrates some of the major highlights.

End of Life

There are few places which provide modern palliative care in Ethiopia. Many persons with terminal illness are treated in general wards or even at home. According to the Ethiopian code of medical ethics, physicians are not permitted to advocate or practice euthanasia (Nwafor, 2010; EMA website). There is no published data regarding public opinion about issues of end of life in Ethiopia.

Autonomy and Disclosure

Decision-making in medical care and health research at an individual level is determined by ethno-cultural factors existent in the country. These factors vary

according to the specific location and tribe. As in many other traditional societies, individual autonomy is not absolute in the Ethiopian context. In the Ethiopian society, individual decisions are not made on an autonomous basis; consensus from the public and the community elders is unusually sought in major community undertakings such as community-based interventions and research undertakings. The extended family is the most important institution. In the medical practice, direct and frank disclosure of certain medical information such as diagnoses and prognoses of grave illness or death of a family member is considered as inappropriate and insensitive. Therefore, in these conditions, doctors would communicate little information to patients and usually tell the bad news to a family member first. During illness and crisis, Ethiopians rely heavily on family members to help them cope. In the Ethiopian culture, the patient-healer relationship is paternalistic and protective, and trust is a major component of this relationship. Physicians and nurses therefore need to take time to understand and pay attention to such paradigms which could take different shape across ethnic differences in this multicultural country (Beyene, 1992). Confidentiality (keeping medical secrets) is more one sided with a patient telling his medical secret to a doctor in confidence. Sharing something in confidence would mean the issues to remain only between a certain group of individuals and not to be shared outside those boundaries. The more traditional the culture, there is less truth telling regarding the patient's condition. (Blackhall et al. 1995; honesty is the most highly valued character trait in the Ethiopian culture and truth is socially defined. However, confidentiality is not very well maintained in medical care practice in Ethiopia). Existing national medical codes and guidelines affirm the importance of this principle; however, its application needs to be carefully laid out (EMA, 2010).

Health-Care System and Access to Health Care

The Ethiopian health-care system is mainly a public health system. However, there are discrepancies between and within societies, regarding responsibility, decision-making, risk sharing, and fair distribution of resources. For instance, urban-rural discrepancies are documented in various surveys (CSA, 2012) as there appears an urban bias in the distribution of health facilities even though great majority of the country's population resides in the rural areas. Current estimates put the coverage by the modern health system at about 50 %, which is merely geographic coverage of health services, disregarding actual utilization of services. Many residing in the catchment area of health facilities may not be utilizing any of the services for reasons of lack of awareness, cultural barriers, economic problems, and difficulty of physical access. Thus, the proportion of the population benefiting from the modern health sector is much less than the one calculated based on the geographic coverage. Furthermore, resources required for health care are very scarce. Compared with other policy sectors, the health sector has not been given due priority as evidenced by the very low MOH expenditure per capita per annum (Haile Mariam & Kloos, 2005).

Reproductive Health

According to the Ethiopian Society of Gynecologists and Obstetricians, there are a number of considerations for Ethiopia in relation to reproductive health. Reproductive health workers are expected to be instrumental in addressing ethical issues in gender and reproductive health. Gender inequality is a long-standing problem in Ethiopia, which is demonstrated via access to basic medical and social services, such as education and job opportunities. Traditional reproductive health practices such as female genital mutilation are common. Gender-based violence is a common phenomenon. Modern advancements in infertility treatment such as artificial reproductive technologies are still not well developed as average options for Ethiopians, and the ethical dilemmas associated with them are rare at this stage. Sexuality is a socially defined issue in Ethiopian society, which is considered very conservative compared to other countries even in Africa. Sex before marriage and abortion are taboo but the study indicates it is becoming common for minors and unmarried women (Alemu, 2010). A big area of debate is abortion, which will be discussed further later.

Traditional Medicine

Another area of moral dilemma in the medical practice in Ethiopia is traditional medicine. For modern health professionals, traditional medical practices are considered wrong and inappropriate, while most Ethiopians do visit traditional practitioners, and there are at times conflicts between the two areas. Traditional Ethiopian practitioners possessed a wide variety of cures. Many of these came from medicinal plants. Much knowledge about traditional Ethiopian medicine is preserved in the folk memory of Ethiopians in many parts of the country.

There are a number of traditional medicinal practices that reflect the diversity of Ethiopian cultures which are concerned not only with the curing of diseases but also with the protection and promotion of human physical, spiritual, social, mental, and material well-being. The health and drug policies of the Ethiopian Ministry of Health recognize the important role traditional health systems play in health care. However, little has been done to enhance and develop the beneficial aspects of traditional medicine including its possible integration into modern medicine (Kassaye et al., 2006). In some cases, traditional medicine is generally prescribed for mental illnesses and chronic conditions as the modern medical care is believed to not to help (Birhan, Giday, & Teklehaimanot, 2011). As there are beneficial practices, there also are a number of traditional medical practices which are harmful and are associated with immediate and long-term complications. False health beliefs and ineffective treatment caused delays in the treatment at modern health services of infectious and noninfectious diseases (Kloos & Kaba, 2005).

There is always the possibility that traditional Ethiopian medicine possesses valuable ingredients for use in modern medicine. Most patients do visit traditional practitioners and continue to do so together with seeking modern health care. It is

always good to explore and address such issues and use them positively and provide comprehensive awareness (Pankhurst, 1990).

Cultural Issues in Medical Research

Especially in the rural areas, there is little understanding of research, which is often misinterpreted as treatment. The concept and even the terminology of research are nonexistent in most of the local languages. This therapeutic misconception is a challenge for proper consent processes in biomedical research. In addition, consent and decision-making mechanism are influenced by a number of cultural and social issues such as stigma and discrimination. Rural patients are afraid of participation in a genetic study, fearing that the study might aggravate stigmatization by publicizing the familial nature of the disease. That genetic study should be approved at family level before prospective participants are approached for consent (Tekola et al., 2009a). Like in other developing and traditional countries, there is increasing recognition of the need for research in developing countries where the burden of disease is high. Understanding the role of local factors is important for undertaking ethical research in developing countries. It is recommended that researchers should evaluate the effectiveness of consent processes in providing appropriate information in a comprehensible manner and in supporting voluntary decision-making on a study-by-study basis (Tekola et al., 2009b).

Disclosure and Data Ownership Issues in Public Health

There are circumstances when the public health system has been very protective of public health data. Good communication policy and strategy are equally important in guiding response and creating a responsibly and trustworthy atmosphere. Ethiopia is one of the signatories of the new revised International Health Regulation (IHR) (WHO, 2008), which was ratified in the World Health Assembly (WHA) in 2005 and fully enforced starting from 2007 and has clearly established the importance of national and international responsibilities in epidemics by stating codes of conduct in reporting and notification. Irrespective of the impacts it might have, it is an ethical mandate of the public health system to be just and transparent in providing early notification to the country's public and also to the international community in cases of travel-related risks and cross-border phenomenon. To this effect it is high time to reconsider the policy of nondisclosure of such outbreaks to the public and beyond. The moral laws of autonomy and justice would otherwise be violated (Addissie, 2009). It is to be understood that a country needs to have its own policies on how data should be shared and utilized, but this should not impede and get in conflict with the international regulations and agreed up on treaties like IHR (WHO, 2008). Recently, there are very useful movements implementing a data-sharing policy in major research centers, for example, in EHNRI and the AAU Butajira Health Project.

Medical Issues in Ethiopian Black Jews

The Black Jews who lived for centuries in Ethiopia, as part of the exodus of Jews, are resettling back to Israel. Though the origins of the Ethiopian, Jews are obscure; they traditionally relate to the lost tribe of Dan. These Black Jews have faced different levels of stigma and discrimination in various forms including discarding blood donated for transfusion and involuntary forced contraceptive administration. In 1996, the Israeli government dumped hundreds of units of blood with the reason that the Ethiopian Jews could have HIV/AIDS. This instigated a fierce reaction from the public and from the Ethiopian Jews themselves (Weinstein, 1996). In addition, recent news in Israeli and other international media revealed the administration of involuntary contraceptives to the settlers by health professionals (Nesher, 2013).

Malpractice: Medical Professional Ethics

Professional ethics among medical practitioners is a growing concern of the Ethiopian public and the media and panel discussions mention a lot about it. The medicolegal discipline is not developed in Ethiopia and currently falls under the digression of courts and the media. Medical malpractice is becoming a public concern and there is not a clear system. Yet, codes of practice exist. A study done by the School of Law (Simachew, 2011) revealed that medical malpractice claims in Ethiopia fall within the general ambit of private law. Medical malpractice claims might be raised based on the law of contract or extra-contractual liability. Generally, a claim for medical malpractice in Ethiopia is adjudicated based on the determination of fault which caused the injury.

Ethics of Public Health and Medical Emergencies

Ethiopia is known to be affected by repeated public health disasters. Thus, dilemmas arise about how to respond to such emergencies. Public Health Emergency Management (PHEM) is a directorate under the FMOH, mandated to respond to public health emergencies and health-related disasters at national and regional levels. The PHEM guideline mentions of standard procedures to follow during such events but the ethical issues are not well explored (PHEM, 2012). Issues often raised include the need of ethical approval of such investigations and the consent from individuals as well as the ethical mandates of response. Even though it is taken for granted that there is no need for ethical appraisal of such investigations, there is no clear guideline available. The same analogy applies to clinical emergency care in Ethiopia. Issues arise concerning consent and mandates to responding to medical emergencies in the clinical setting. Emergency medicine is yet undergoing developments and there is a need to address the associated ethical issues (Germa, 2011). Another issue is the availability of resources and the dilemma of discontinuing some supportive interventions such as artificial ventilation.

Abortion

Another very controversial issue in Ethiopia is abortion and termination of pregnancy. Abortion has been illegal until 2004 when the Ethiopian Parliament voted to approve a new, progressive law. Though the new Criminal Code of the Federal Republic of Ethiopia (2005) maintains the legal prohibition of abortion, it stipulates that abortion is allowed by law in the following conditions: when the pregnancy results from rape or incest, when continuation of the pregnancy endangers the health or life of the woman or the fetus, in cases of fetal abnormalities, for women with physical or mental disabilities, for minors who are physically or psychologically unprepared to raise a child, and in the case of grave and imminent danger that can be averted only through immediate pregnancy termination.

The revised law establishes that poverty and other social factors may be grounds for reducing the criminal penalty for abortion, and that in cases of rape or incest, no proof is required beyond the woman's statement that it has occurred. However, the law does not allow abortion for economic and social indications and abortion is not available just on request (Wada, 2008). By allowing abortion for minors who are unprepared to raise a child, the law also marks a significant change for Ethiopia, where adolescents make up more than 45 % of those seeking abortions.

In contemporary Ethiopia, abortion decision-making is a challenging process involving moral and religious dilemmas, as well as considerations of health and safety. Amidst widespread condemnation of female premarital sex and clear moral sanction against induced abortion, young Ethiopian women are nevertheless sexually active, and induced abortions are still sought and performed, with the potential for grave physical harm and social stigmatization (Kebede, Hilden, & Middelthon, 2012). The Ethiopian public is predominantly conservative and religious, and this makes it difficult to implement the law in uniformity. While there are health-care providers whose personal values do not conform to the new law. Others rather might abuse the system.

The majority of unwanted pregnancies of minors are ended in abortion, which are undertaken without medical professional intervention (self-induced or with traditional medication and in illegal places). Most girls who undertook abortion feel ashamed and guilty of committed sin and crime; hence, they have no internal peace. Minors who are from relatively lower income families mostly go to traditional abortionists. The major religious institutions in Ethiopia have no official stand on the use of contraceptives by married women and leave the choice to individuals. However, the institutions highly condemn sex before marriage (Alemu, 2010).

HIV and AIDS

Being located the sub-Saharan region, Ethiopia is one of the countries affected by HIV/AIDS. Currently, the burden and rate of infection is said to be decreasing. However, there are a number of moral dilemmas associated with HIV and AIDS.

Examples include disclosure of HIV testing information to partners when the client is not ready to disclose, religion and condom issues, when to disclose serostatus for children, and treatment adherence issues. Another criticism is about the rationing of treatments: ART treatment guidelines developed using methods that do not fully satisfy the requirements of fair processes (Johansson et al., 2008).

Medical Tourism

Due to the lack of medical advancement in Ethiopia, it has now become a common trend to refer patients for unavailable medical services to foreign countries. The list of countries where patients often visit includes Kenya, South Africa, Thailand, and India, while some patients travel to Europe and the USA. Especially the Thai and Indian markets are very appealing to most Ethiopian patients. The major reasons for such medical trips are malignancies, cardiac surgeries, and transplants. Reports have indicated that nearly 95 % of African citizens are travelling to countries like Thailand, Singapore, South Korea, and India for better treatment in orthopedics, cardiology, pediatrics, and internal medicine. Patients need an official referral from the government. Important issues concern the costs. But there are also brokers and agents who claim to facilitate. The question is whether they are genuine or looking for business. In general, post-trip follow-up is not often available in the country and one would ask the ultimate benefits of the clients.

Psychiatric Care

Two major ethical issues exist within the psychiatric care system in Ethiopia. The first issue is the lack of resources for psychiatric care including infrastructure, trained manpower, and availability of effective psychotropic medications (WHO, 2006). For many years, modern psychiatric care was only available at a few centers located in the Capital, Addis Ababa (Alem, 2001). Among persons with severe mental illness living in rural Ethiopia, only less than 10 % had visited modern psychiatric care (Negash et al., 2005). Most families take their sick relatives to traditional treatment places (Girma and Tesfaye, 2011) and the treatments are applied against the patients' will that are often shackled (Alem, 2000). In those treatment centers, there are no checks for the rights of patients. Many families keep their sick relatives restrained at home until they are no more violent (Alem, 2000). It is not uncommon to see patients presenting to psychiatric facilities with wounds from tight chains around their arms and legs. The second issue is the fact that there is no mental health legislation in Ethiopia (Girma and Tesfaye, 2011; WHO, 2006). It means that mental health professionals rely on the general ethical codes. In practice, clinicians only need informed consent of persons who escorted the patients for involuntary admission and treatment (Alem, 2001). It has been found that mental health professionals in Ethiopia are more likely to recommend involuntary hospitalization, inform the spouse against the patient's wishes, and apply restraints

compared to professionals in other countries. Also, there is a tendency to withhold information about side effects of medications when professionals thought that the patient might refuse to take the prescribed medications (Alem et al., 2002). The problems in the breach of ethics and patients' rights in the context of psychiatric care in Ethiopia could be much worse as the reports might be affected by social desirability bias. In addition, Ethiopia does not have separate human rights body with authority to oversee mental health institutions and to ensure rights of patients (WHO, 2006). Consequently, none of the mental health institutions and residential facilities have been inspected or reviewed by an independent human rights body in the past (WHO, 2006).

Brain Drain

Ethiopia has an inadequate number of health professionals of all categories. On top of this, many doctors migrate to the USA, Europe, Middle East, and Southern Africa for greener pastures. The Ethiopian government is determined to fight against brain drain and the quest for skilled nationals should be armed with enthusiasm. Others regard this as a positive phenomenon since doctors in the Diaspora continue to contribute to the country directly and indirectly. The American Health Professionals Association (ENAHPA) is making extreme efforts to the realization contributing back to the country and people by the Ethiopian medics practicing currently in North America. Ethiopia should do all it can to mitigate brain drain and make a maximum use of its skilled manpower in the Diaspora. Others argue that the disadvantages of brain drain are more significant than the advantages in the case of Ethiopia where manpower training is markedly under-subscribed. The country should formulate a government policy sooner than later to facilitate retention of skilled manpower and to serve as a springboard for moving forward in the development endeavor and catch up with the tempo of the rest of the world (Mengesha & Kebede, 2005). In response, Ethiopia is now planning for a flood of medical doctors within "three to four years," an influx meant to save a public health system that has been losing doctors and specialists to internal and external migration. Some argue the quality of training is compromised with a rapid intake of medical students; for others, quality is relative and the number of professionals reflects also quality.

Summary and Future Challenges

Ethiopia being a country with diverse social and cultural identities, the issue of bioethics is also diverse and dictated by context-specific realities. The country has tried to address bioethics issues in different ways; however, this is yet to be strengthened. There are a number of issues related to building bioethics capacity in the country using more indigenous and local experts and resources in the area.

Having a supporting infrastructure and system is vital for the development of bioethics in Ethiopia. One of the challenges is the enforcement of existing laws and legislations. More attention needs to be paid to this issue. At times, there is confusion regarding the standard operating procedures for the implementation of the existing procedures. The same is true for the existing policies. Due to the lack of national standards, the governance of professional and research ethics is not very well defined by decree and a research act does not exist. Legislation needs to be in place to address emerging issues such as artificial reproductive technologies and genetic research.

Bioethics Development

When and How Has Bioethics Started?

Bioethics in Iceland started in relation to the teaching of ethics to students of the health professions, especially nursing in the late 1970s. The Centre for Ethics at the University of Iceland, which has been the main forum for research and publications in the field, was founded in 1988.

Who Have Been the Major Actors/Forces?

A pioneer in bioethics teaching in Iceland was Arnór Hannibalsson, professor of philosophy at the University of Iceland, who prepared some teaching material in courses he taught at a private continuing education nursing school during the 1970s. He later taught an introductory course in philosophy for nurses at the University of Iceland in the early 1980s where he introduced topics in health care ethics. Another pioneer in this field is Örn Bjarnason, MD, who initiated discussion about issues in medical ethics in medical circles, not least through his position as editor of *The Icelandic Medical Journal* in the 1970s. Dr. Bjarnason also taught some medical ethics to medical students at the University of Iceland. A third pioneer in bioethics in Iceland, Dr. Björn Björnsson, professor of social ethics at the Faculty of Theology (1969–2002), developed a course on topics in medical ethics from a Christian perspective and advised students who wrote their thesis in theology on bioethical themes.

A major actor in the field since the late 1980s is Vilhjálmur Árnason, professor of philosophy and chair of the board of the Centre for Ethics at the University of Iceland. Árnason wrote the first comprehensive monograph in Icelandic on ethical issues in medicine and health care. Since then he has been an active participant in the field of bioethics through teaching, research, public lecturing, writing, and international cooperation.

What Have Been the Major Concerns Over Time?

In the early days, the main concerns were issues at the beginning and the end of life, such as questions related to euthanasia, abortion, and IVF, occasioned both by new technology and by increasing demands for self-determination in the population. Attention was also paid to analysis of the codes of ethics for the health professions and the patient-professional relationship. In recent years, the focus has been more on issues in research ethics, particularly genetic research and population databases. A primary reason for this is that one of the major genetic research companies in the world, deCODE genetics, is located in Iceland (Árnason, 2010a). The company went through financial difficulties, but is presently fully financed and its research is thriving.

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

In relation to his teaching, Prof. Hannibalsson (1982) produced a collection of chapters on major themes in ethics of the health professions which was the first writing in Icelandic where the classical big issues of bioethics, such as euthanasia, abortion, and justice, in health care were discussed in one place. This material was only used for teaching and not published.

In 1991, Dr. Bjarnason published a book on some themes in the ethics of medicine (*Siðfræði og siðamál lækna*). The largest part of the book is a collection of ethical codes for the profession both in English and in Icelandic translation by Dr. Bjarnason who also writes an introduction (Bjarnason, 1991). Much of this material had previously appeared in *The Icelandic Medical Journal*. Two other books about philosophy of medicine in Bjarnason's translation accompanied his book: *Philosophy of Medicine* by Henrik Wulff, Stig Andur Pedersen, and Raben Rosenberg and *Rational diagnosis and treatment* by Henrik Wulff.

Among the first publications of the Centre for Ethics was a book on ethical codes for the professions (Kristinsson, 1991). In 1933, Vilhjálmur Árnason published a book, *Siðfræði lífs og dauða* (Árnason, 1993). *Erfiðar ákvarðanir í heilbrigðisþjónustu* (*Ethics of Life and Death, Difficult Decisions in Health Care*), which had grown out of his teaching for nursing students and active involvement in professional ethics and biomedical issues generally (Árnason, 2011). The book deals with all the major topics in bioethics, but the main emphasis is on various issues concerning the everyday interaction of patients and professionals. It is the main textbook in bioethical education in the country, has been used widely by health care professionals, and was also well received by the general public. The book has been reprinted several times and appeared in a new and revised Icelandic edition (2003). The second edition was translated into German as *Dialog und Menschenwürde. Ethik im Gesundheitswesen* (Árnason, 2005).

In the last decade, three books about genetics from the viewpoints of science criticism (Erlingsson, 2002), biology (Eggertsson, 2005), and anthropology (Pálsson, 2007) have been published by Icelandic scholars. All these authors discuss topics relevant to bioethics and also partly address explicitly bioethical questions.

Icelandic readings in bioethics consist otherwise of single articles and book chapters by various authors in the fields of medicine, philosophy, law, nursing, and theology. In the last 2 years, two medical doctors who have education in philosophy, Ástríður Stefánsdóttir and Stefán Hjörleifsson, have edited a regular ethics section in *The Icelandic Medical Journal*. In this section, cases are briefly presented and analyzed from an ethical perspective.

No society or networks for bioethics have been created in Iceland. The Centre for Ethics has been part of a Nordic Network for Philosophy of Medicine and Medical Ethics, funded by NordForsk, which is a venue for cooperation between Nordic and Baltic scholars in the field of bioethics. No Icelandic media resource or specific programs on bioethics have been made. The Centre for Ethics has led

international research networks, most notably ELSAGEN, funded by the EC 2002–2004 (Häyry, Chadwick, Árnason, & Árnason, 2007).

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

Bioethics has been taught in several departments of the University of Iceland, usually at the initiative of the professors of philosophy (Árnason, 2002). Among the first Icelandic articles in the field were written by professors of philosophy, Páll Skúlason ("Medicine and the Moral Sciences," 1977) and Thorsteinn Gylfason ("On Euthanasia," 1981). Since the University of Iceland was founded in 1911, most students have been expected to take an introductory course about the philosophical foundations of the sciences or "philosophicum." The main objective of the philosophicum is to motivate students to think critically about science in general and about their particular field of study. Since the early 1980s, the course has been optional and designed for each department. This provided a good opportunity to introduce bioethical issues to the students of the health sciences.

Since the philosophicum became optional in the early 1980s, it has not been taught for medical students at the University of Iceland. However, since 2004, a course in ethics for first- and second-year medical students has been developed, dealing mainly with topics related to the doctor-patient relationship but also with issues such as prioritization and end of life questions. In the fourth year, an effort is made to improve and consolidate the ethical education provided in clinical courses in cooperation with senior clinicians in different specialities. Medical ethics is also taught as part of an extensive program in medical communication and clinical skills, medical professionalism, and confidentiality.

In the program of public health, there is an introductory course where a philosopher has given three lectures on the ethical issues in public health.

Students in the Department of Physical Therapy take a course in their third year of study which has a considerable emphasis on various themes in health care ethics, such as the patient-professional interaction and just health care. Graduate students of physical therapy also attend a half-day seminar on research ethics with medical students.

Since nursing became a university discipline in the late 1970s, there has been a heavy emphasis on the philosophicum oriented toward the ethics of nursing, medicine, and health care. The specific objective of this course is to enable students to perceive and tackle the ethical problems that arise in the nursing profession. Within the Department of Nursing, there is a special program of midwifery, where ethical issues related to the discipline are discussed.

Students of dentistry have been obliged to take a small philosophicum course in the spring semester of their second year of study, emphasizing issues in health care ethics.

Within the Faculty of Theology, students have had the option to take a course on ethical issues that may arise at the beginning and at the end of life. In cooperation

with the Centre for Ethics, the faculty has run a continuing education MA program in pastoral care with considerable emphasis on ethics at the end of life.

Selected bioethical themes are dealt with by professors of law, for example, abortion, euthanasia, and privacy. Occasionally, students take interest in these issues, and then they are able to write their thesis under the supervision of these professors.

Some teaching on the topics of bioethics has been taken up as small parts of other courses in the Department of Biology, but not regularly except in a course on human genetics where a discussion about the ethical implications of human genetics is included at the end of the course.

Until recently, there was no systematic teaching of bioethics within the Department of Philosophy. Occasional seminars were taught on issues in applied ethics with emphasis on bioethics, and special seminars have been devoted to the ethics of the life sciences and genetics. These seminars were mostly attended by students of philosophy but also from other departments, such as biology, medicine, and theology.

In 2002, a 1-year program in professional and practical ethics started within the Department of Philosophy in cooperation with the Centre for Ethics. This program has now been developed into a full master study of applied ethics where students can choose a program in bioethics. A doctoral study in applied ethics has recently been established at the Department of Philosophy.

The Department of Philosophy also offers a course in English for graduate students in all fields of study on the ethics of science and research.

In the School of Education, an ethics course has been designed for social educators which largely includes bioethical themes. In particular, the course deals with ethical issues relating to disability, such as prenatal diagnosis, the rights of the disabled, and professional ethics.

At the University of Akureyri, a one-semester ethics course is taught in the fall in the Department of Nursing and Occupational Therapy. Approximately half of this course is devoted to bioethics.

For several years, an introductory course on ethics was taught to lab technicians and X-ray technicians at the College of Technology. Special emphasis was placed on research ethics and on some aspects of the professional-patient relationship.

Ármúli High School has a special health line where students who intend to work as assistant nurses, medical secretaries, dental assistants, pharmacy technicians, and masseurs are expected to take a course in ethics with an emphasis on the issues concerning the patient-professional relationship. Although Ármúli High School is the best example, bioethics is taught as a part of health education in other Icelandic high schools around the country.

The Institute of Continuing Education at the University of Iceland offers a variety of courses in the area of health care, some of which have bioethical themes. A recurring course has been held for administrators in health care institutions where professional duties and patient's rights have, for example, been discussed. Special courses have been held on bioethical topics such as genetics, ethics of life and death, just health care, and autonomy of the elderly.

There is no systematic teaching of bioethics or medical ethics at the National Hospital, but in the 1990s, short courses for health professionals devoted to some special topics within health care ethics and a postgraduate course in medical ethics for young doctors were offered at the hospital.

The individual health care professions sometimes sponsor their own special lectures or even seminars on bioethical issues. There has been especially strong emphasis on continuing education for nurses, partly because nursing has only been a university subject since the late 1970s and those with older education needed to upgrade it. Health care ethics seminars have also been offered for physical therapists and occupational therapists.

Bioethics Committees

The Icelandic National Bioethics Committee was founded in 1997 as part of the law on the rights of patients. The main objective of the committee is to evaluate applications for research proposals on health-related issues involving human subjects. Such proposals include genetic research on human diseases, drug trials, or experimental treatment aiming to alleviate pain and cure diseases, as well as studies involving the collection and interpretation of health-related information or data provided through questionnaires by participants themselves. The members of the National Bioethics Committee were initially nominated by professional organizations and academic institutes. In the summer of 1999, in the midst of the heated debate about a Central Health Sector Database, the Minister of Health ousted the National Bioethics Committee (Abbot, 1999; Árnason, 2004). For a few years, the committee members were nominated exclusively by the government. The nomination has now been changed again; four members are appointed by ministries, two by the Directorate of Health, and one by the Centre for Ethics at the University of Iceland.

Expert Bodies/Centers

The main expert body for bioethics is the Centre for Ethics at the University of Iceland. The center was founded in 1988 and started as a joint project of the University of Iceland and the Icelandic Church. Since 1998, there has been no official relation to the church although the church council still appoints one member to a board of five. The other members are appointed by the Department of Philosophy (chair), the Department of Theology, the School of Education, and the University Council. Until 2008, the center was among few other interdisciplinary centers directly under the university council but is now formally a part of the Institute for Humanities.

The center is a forum for research, education, and service, and its main tasks are (1) to strengthen research in ethics at the university; (2) to cooperate with other universities in the field of ethics; (3) to publish books, educational material, and

research results; (4) to give information and council about matters of ethics; (5) to coordinate interdisciplinary education in ethics; and (6) to hold courses and public lectures about ethics.

The Centre for Ethics has hosted several workshops, seminars, and conferences. In 2004, the center hosted in cooperation with the European Society for Philosophy of Medicine and Health Care an international conference on genetics and health care (Árnason, Nordal, & Árnason, 2004).

Prof. Páll Skúlason was the founder and the first chairman of the Centre for Ethics at the University of Iceland. The current chairman since 1997 is Prof. Vilhjálmur Árnason, and Salvör Nordal, MPhil, is the director of the center since 2001.

Relevant Legislation

The relevant legislation is mentioned in discussion of the main topics as appropriate. See http://eng.velferdarraduneyti.is/legislation/.

Public Debate Activities

Although it is officially among the roles of the National Bioethics Committee to participate in public debate about bioethics and publish recommendations about matters in its sphere of activity, it has in practice limited its role mostly to research review. Unlike in other Nordic countries, there is no national ethical council in Iceland which has the main task of raising public debate about bioethical developments and policy like, for example, the Danish Ethics Council or the Norwegian Biotechnology Advisory Board. For many years, there was an Ethical Council of the National Directorate of Health which functioned both as a review and policy committee. After the National Bioethics Committee was founded in 1997, the Directorate Council focused on issues of policy and social debate. It was active in both the initiation of the act on the rights of patients and of the act on biobanks and worked on guidelines for informed consent in medicine. In 2000, the Directorate of Health could no longer finance the council and started working on the idea of establishing a national ethical council. It soon became clear, however, that the political environment was not fertile for this idea, and it was aborted.

In the absence of a national ethical council, there is no structure to the public debate activities on bioethical issues in Iceland. To take one example, the societal debate on stem cell research in Iceland was exclusively initiated and sponsored by independent professional societies and research centers, such as the Icelandic Association of Health Care Professionals, the National Bioethics Committee in cooperation with the Icelandic society of biologists, and the Centre for Ethics at the University of Iceland in cooperation with the National Director of Health (NordForsk, 2007). The Icelandic Research Foundation facilitated a dialogue between a geneticist and a moral philosopher as part of its popular series “Science Café” in 2005.

Although the Centre for Ethics or professional organizations try to put bioethical issues on the agenda, they do not have legal mandate to facilitate public dialogue with the aim of informing the legislator about public concerns and principled positions.

Major Bioethics Issues and Discussions

Beginning of Life

Ethical issues at the beginning of life were among the first discussed in this field when the abortion debate entered the national scene in the early 1970s. The discussion of abortion was closely related to the battle of women for increased self-determination and focused on the legal right to have abortion. The first scholarly article on the topic appeared in 1974 in *The Lawyers' Journal* (*Tímarit lögfræðinga*) by a young lawyer who had also studied philosophy of law at Oxford.

Abortion has been legal for both social and medical reasons in Iceland since 1975. The abortion should preferably take place before the 12th week, and after the 16th week, abortion is not legal unless there are strong medical reasons for it. A special committee must permit such exceptions. In all cases, a woman who requests an abortion must go through counseling.

Although abortion has not been discussed much in the last two decades, it has been indirectly on the agenda through an ongoing debate about prenatal screening. The debate on this issue in Iceland started in the mid-1980s, but ultrasound examination around 18–19 weeks of pregnancy became a standard procedure in antenatal care in 1984–1986 (Gottfreðsdóttir & Árnason, 2011). In 1991, nuchal translucency screening was introduced for women over 35 years of age in order to reduce the use of amniocentesis. Since 2005, nuchal translucency screening for Down's syndrome and other trisomies during the first trimester of pregnancy has been a routine part of antenatal care in Iceland. In the capital area, where screening is easily accessible, 84 % of pregnant women opted for screening in 2005 (Gottfredsdóttir, Sandall, & Björnsdóttir, 2008).

The Icelandic Medical Journal in 2001 devoted a special issue to this topic: "Systematic search for genetic defects in early pregnancy. Scientific knowledge and humane positions." The guest editor was Jóhann Ágúst Sigurðsson, professor of family medicine at the University of Iceland, and the contributors are from the fields of medicine, ethics, nursing, disability studies and organizations, midwifery, theology, and literature (Sigurðsson, 2000). The debate has mainly been about the decision-making process; the policy is justified by reference to autonomy and responsibility of the expecting parents, while the complexity and uncertainty of the information makes it hard for people to make an informed decision. It is also debated whether it is justifiable to offer this kind of screening to all pregnant women since the benefits do not clearly outweigh the risk of harm. Moreover, the issue

of genetic discrimination has been discussed. Statistics for 2004 and 2005, for example, show that all fetuses identified with Down's syndrome following screening were aborted (Gottfreðsdóttir, 2009). This has raised questions of eugenics, and the history of eugenic practices in Iceland in the 1920s and 1930s has been brought to the fore.

End of Life

Issues at the end of life were also among the first discussed in Icelandic medical ethics discourse. Again, one of the first scholarly publications appeared in a journal of the students of law in 1976 where the topic of euthanasia was discussed from the perspectives of law, Christian ethics, and medicine. In 1989, *The Icelandic Medical Journal* published the Appleton Consensus, international guidelines for decisions to forgo medical treatment at the end of life followed by a round-table discussion on the ethical questions involved with participants from medicine, theology, and philosophy.

In 1987, the Icelandic Cancer Society initiated hospice service for terminally ill patients, and in relation to that, an advisory interdisciplinary group was set up. Ethics was among the expertise represented in this group which organized well-attended conferences on ethical questions at the end of life. *On Death and Dying* by Elisabeth Kübler-Ross in Icelandic translation was published in 1983.

End of life issues have never been hotly debated in Iceland. Spokesmen for active euthanasia have been few, and they have not gained ground in the discussion. At regular intervals, there has been public discussion about care at the end of life and death with dignity. Two documents have been issued on these topics by the National Directorate on Health in Iceland. First, in 1996 the Directorate Council of Ethics issued "Guidelines for limiting treatment at the end of life." It is emphasized in these guidelines that health care professionals should preferably discuss with their patients, and their relatives if the patient so wishes, the options that may arise in the terminal phase of their treatment. The options are divided into (1) full treatment, (2) full treatment up to resuscitation, and (3) palliative care only. The Directorate Council of Ethics based these guidelines on older guidelines initiated by Pálmi Jónsson, MD, Chief of Geriatrics. Landspitali University Hospital (Jónsson, 1989). In 2005, the Directorate issued a living will or advance directives for treatment at the end of life. In this directive, it is also possible to declare a willingness to donate an organ.

In 1995, a medical student presented a questionnaire about limiting treatment at the end of life for physicians and nurses working in Iceland. The general result was that these health care professionals found it important to respect patients' wishes to deny life-prolonging measures. Under certain conditions, 5 % of the physicians and 11 % of the nurses found it justifiable to perform euthanasia. Another medical student repeated this study in 2010. The results now showed that 18 % of physicians and 20 % of nurses found euthanasia justifiable, while only 3 % were willing to comply with such a wish of a patient.

Health and Disease

There has not been much bioethical discussion of health and disease in Iceland. In 1982, however, the society of psychology students at the University of Iceland published proceedings from a conference on the concept of disease, its meaning, use, and limitations in psychiatry and psychology (Hjaltason, Wiedman, & Sturluson, 1982). Specialists from philosophy, sociology, law, and psychology contributed, and the position of the psychiatrist T. S. Szasz is summarized. One of the most controversial parts of Árnason's book (1993) was his argument against a wide definition of health involving a social dimension. Árnason's argument is that a clear distinction needs to be made between the concept of health on the one hand and the determinants of health and recovery on the other hand where the social dimension is crucial.

The phenomenon of medicalization has received some attention. In a report on the future prospects of the health care system published in 1987, a chapter was devoted to the criticism of the prevailing paradigm in medicine by Ivan Illich, Ian Kennedy, and Thomas McKeown. In 2004, The Centre for Ethics at the University of Iceland published a collection of articles on medicalization (Jónsson & Jónsdóttir, 2004). Among the authors in that book is Sigurðsson, professor of family medicine, who has been a critic of overtreatment in medicine, particularly in the form of overuse of SSRI drugs for anxiety, depression, and related disorders. The use of these kinds of drugs is pervasive in Iceland and much more than in the neighbor countries. Prof. Sigurðsson has been part of a Nordic research group that has written about medicalization in many forms, such as pregnancy, population screening, and treatment of coronary disease and hypertension (Getz, Kirkengen, Hetlevik, Romundstad, & Sigurdsson, 2004). Another author, Stefán Hjörleifsson, has written widely about medicalization (Hjörleifsson, 2008), largely in the spirit of Illich, and its kinship with the processes of geneticization (Árnason & Hjörleifsson, 2007).

Related to this critique of medicine, an interdisciplinary group of Nordic scholars focusing on the conditions for a more humanistic medicine was formed at a meeting in Skálholt, Iceland, in May 2001. In the following years, this group held several seminars in Rosendal, Norway, stimulating reflection on themes such as moral responsibility in medicine and the nature of the biomedical paradigm in medicine and its limitations (Getz, 2009). The Rosendal group, as it came to be called, has had considerable impact in medical circles, particularly in family medicine in Norway (Trondheim and Bergen) but also in Iceland.

Health Care System, Access to Health Care

In 1996, the Icelandic Minister of Health set up a working group which had the task to formulate guidelines for prioritization in health care. Two members of this working group had education in bioethics. The group took into account similar reports that had been published in other Nordic countries, the Netherlands, New Zealand, and the state of Oregon, USA. The working group agreed that the

main objectives should be the following: (1) The health service shall be fair, based on a mutual responsibility shared by all citizens and mainly financed by public funds; (2) access to health care shall be easy and as equal as possible for everyone; and (3) those in greatest need of health care shall be given priority (Ministry of Health, 1998; Árnason, 2009a). The recent economic collapse in Iceland has made the issue of prioritization in health care even more pressing than before and will present challenges in the future.

Traditional Medicine

Traditional medicine has not entered the discourse on bioethics in Iceland. Icelanders have an interesting history of widespread interest in spiritual healing. A recent study shows that Icelanders use complementary and alternative medicine to a considerable degree and increasingly in recent years. Most users of this type of treatments seem to use them as a supplement to the care received in the general health care system (Helgadóttir, Vilhjálmsson, & Gunnarsdóttir, 2009).

Genetics

A plan to construct a central databank of the population's medical records came as a bomb on the Icelandic bioethical scene in 1998. This plan was part of a larger project by deCODE genetics, a private company, for human population genetics research (Rose, 2001). The act from 1998 has the following definition: "Health sector database [HSD]: A collection of data containing information on health and other related information, recorded in a standardized fashion on a single centralized database, intended for processing and as a source of information." These data were to be extracted from medical records of those Icelandic citizens who did not explicitly opt out. In order to opt out, people were to notify the Directorate of Health that data on them should not be transferred into the HSD. The act also authorizes the licensee to connect data from the HSD to data from two other databases: a database with genealogical information that have been processed from public genealogical records and a database of genetic information that is processed from biological samples obtained with explicit consent for research by physicians cooperating with deCODE genetics.

The debate about the HSD centered largely about the issues of consent and privacy (Árnason, 2004). In the first bill, consent was not even mentioned, and only after fierce protests was an opt-out clause put in. To many, this was far from meeting the moral requirements of consent to participation in research of the kind planned by deCODE genetics. Some argued for an informed consent for each research project, while others argued for a more general authorization for conditions of use that would be more appropriate for population database research where secondary uses of samples are unforeseeable at the time of collection. Defenders of the presumed consent policy argued that explicit consent would obstruct the

gathering of information and the scientific utility of the database would be diminished. The personally nonidentifiable data would mainly be used for epidemiological research and statistical analysis useful for public health policy. They also pointed to overwhelming support for the project shown in opinion polls (Gulcher & Stefánsson, 2000).

Critics responded that it was highly controversial whether the data are personally identifiable or not, and it should not be used as an argument for waiving consent. When health care data are connected to genealogical and to genetic information, there is a considerable risk in a small society that individuals can be identified, even though the data obtainable for research and inquiries from the HSD were only to be in statistical form and never about fewer than a group of ten (Árnason, E., 2002). While an opting-out policy might be suited for competent informed adults, it neglected the interests of vulnerable groups who need special protection. They also pointed out that the overwhelming public support could be used as an argument for obtaining explicit consent. Polls indicated that people were ill informed about the project. A group of scientists, doctors, and concerned citizens was formed – Mannvernd, Association for Ethics in Science and Medicine in Iceland – and its members actively opposed to the HSD project. They argued that the bill violated internationally sanctioned norms of biomedical practice and encouraged citizens to opt out of the database (Sigurdsson, 2003).

A young woman who had opted out of the database brought the privacy issue to court. Data about her deceased father were in the database, and she argued that the combination of medical and lifestyle, genealogical and genetic information could be used to identify her and thus pose a violation to her privacy. The Icelandic high court agreed. Three things stand out in the high court ruling no. 151/2003: first, that it was not unreasonable to expect that the woman could be indirectly identified by the information about her deceased father; second, that the access to information to the database was open to many others than health care professionals without explicit consent of the individual concerned; and third, that the stipulations concerning privacy are not clear in the law but are left to the regulatory agencies. Consequently, the court argued, constitutional right to privacy is not sufficiently protected in the HSD law.

The high court ruling implies that the policy of presumed consent requires stricter privacy protection than a policy of presumed nonconsent, especially when parties outside of the health care setting can have access to the information. This had been a major argument of the Icelandic Medical Association. As guardians of information that had been collected in confidential interaction with patients, physicians reacted strongly to a policy which required them to hand over medical records to third parties, not involved in the patients' care, without their patients' explicit consent.

It is implicit in the high court ruling, as well as in the position of the Icelandic Medical Association, that the situation would have been quite different had HSD been within the public domain of the Icelandic national health care system. In that case, a policy of presumed consent could have been substantiated by an appeal to

reciprocity and common benefit. However, when the information has become a commodity of a for-profit commercial firm, it is in a very different ethos. But this has not been particularly disturbing to the majority of the Icelandic public who decided to trust the company, although it may have been a major reason why over 20.000 people, approximately 7 % of the population, decided to opt out of the HSD.

As a consequence of the high court ruling and some other factors, the HSD project was aborted (Helgason & Gibbons, 2008). Nevertheless, deCODE genetics has been a thriving research company which has built up large population databases as a resource for its research. This has come about in an ongoing large-scale research of many diseases, frequently in cooperation with physicians working at the National Hospital. Participants provide a blood sample, and an interview is taken about their medical history. They can also allow physicians to provide information from their medical records. The company performs a genealogical analysis of the list of participants which provides a basis for exploring interactions between genes, genealogy, lifestyle, environmental factors, and health/diseases.

It has been argued that with the exception of the HSD case, human genetic research and its potential effect on health and society has not been much discussed. The author is especially critical of the Icelandic media coverage which has left highly relevant questions unattended (Hjörleifsson, 2008). The study demonstrates that news briefs from deCODE about their successes are uncritically taken up by the media which even leaves out the company's own reservations. In this way, the scientific and health care benefits of the research are treated as being beyond reasonable doubt, while uncertainty about financial issues is predominant (Hjörleifsson, Árnason, & Schei, 2008).

This media study squares well with the main features of the public debate around HSD. The discussion was very polarized and often personalized, and in so far as it was about ethical issues, it was narrowly framed. The focus was on legal and technical problems, such as legal technicality about identifiability and coding techniques, while larger societal issues, such as the geneticization of health care, were neglected. Besides, both the parliamentary debate and the public debate in the Icelandic society suffered from the fact that public and private interests were mixed throughout the process (Árnason & Árnason, 2004). The Icelandic government has been very favorable to the company, probably in the belief that it would bring great benefits to the Icelandic economy. Similar attitudes have been reflected in the media discussion.

The pervasive genetic research in Iceland has presented some challenging tasks for the regulatory agencies. The National Bioethics Committee has developed guidelines for consent for participation in database research involving biosamples. Participants are given options to sign one of three consent forms with more or less restricted consent. For samples stored in biobank with wider consent, NBC decides in each case whether new consent shall be obtained for further use and cross-matching of samples for additional research.

Reproductive Medicine

When the Act on Artificial Fertilisation was in the works in 1996, the most debated issue was about the right of the individual, who is conceived by ART with a donor sperm, to know about his or her origin (Árnason, 2005). The act prioritizes the right of donor to anonymity and leaves it to him to decide whether it should be lifted or not. Only when the donor has not requested anonymity can the individual at 18 years of age get information about identity of the donor or the other biological parent. A committee that was asked by the parliament to review the law in 1998 recommended that the individual at 18 years of age should have a right to have access to genetic information about the donor because of relevance for susceptibility to genetic diseases. This was not observed.

In the 1996 act, only a woman in marriage, in civil partnership, or who had been living together with her partner for 3 years or longer could have access to the services. In 2006, a few articles in the law were changed to make it clear that the partner of a woman could be another woman. Very little public debate took place around this change of access to ART which came as a part of major changes in the legal status of homosexuals in Iceland. The current act also permits single women to access ART, and as a consequence, this act conflicts with an article in the law on the rights of children to have paternity (Nordal, 2010).

The ART act prohibits surrogacy, and this issue had hardly been discussed at all in Iceland until an interview appeared in 2007 in one of the newspapers with a couple who is unable to have a child unless by the help of a surrogate mother. Another case in the media was about a couple who had a child with help of a surrogate mother in India. This has stirred a debate in the media, where some insisted on the right of people to have children and the corresponding duty to provide the help needed, while others focus on the interests of the child and the surrogate mother. A bill has been introduced in the parliament where it is proposed that altruistic surrogacy be legalized in Iceland. Almost all professional organizations that have commented on the bill have been opposed to it. A committee, consisting of two lawyers and a moral philosopher, has now been appointed to work on a proposal on the legal text on this matter.

The surrogacy issue demonstrates very clearly how much the national debate suffers from the lack of a National Ethics Council responsible for facilitating public debate and informed policy making. This also partly accounts for the unusually liberal ART legislation which can probably also be explained by the fact that the population is relatively homogenous, pronatalist, and with little diversity in religious views. Also, there is wide trust in science in the population which has never encountered any scientific scandal or serious misconduct in its history.

In the act from 1996, research on embryos was prohibited unless it was part of an in vitro fertilization treatment or intended to advance such treatment (Ministry of Health, 2008). The new Act, however, allows stem cell nuclear transfer technology (SCNT) to create human stem cell lines for medical purposes if the same objectives cannot be reached by research on adult stem cells or stem cells procured from surplus embryos. It is emphasized that while an "ordinary embryo" has genetic material from

two parents like human beings, the cloned blastocyst has genetic material only from one human being. The Icelandic term for embryo, "fósturvísir," implies that the human fetus is about to be formed and is not used for the cloned blastocyst. The act does not allow creation of "ordinary embryos" for the sole purpose of using them for the procurement of stem cells. This is regarded as a much larger and more debatable step to take, because it implies that human embryos would be produced merely as a resource to exploit even though it would be for beneficial purpose.

In 2003, a paper reporting a survey of the views of medical doctors, Lutheran ministers, and lawyers on the use of human embryos for clinical medicine was published (Óskarsson, Guðmundsson, Sigurðsson, Getz, & Árnason, 2003). The results showed quite liberal views among these professions, which seems also to be the case among the general public.

Medical Research

Considerable attention has been paid to ethics of medical research in Icelandic bioethics. Árnason (1993/2003) includes a chapter on the topic, and a special handbook on the methodology of research in the health sciences has been published by the University of Akureyri (Kristinsson, 2003) with chapters on the ethics of research. The main international ethical guidelines for medical and nursing research have been published in professional journals.

The regulation of medical research in Iceland is mainly in the hands of two agencies: the National Bioethics Committee (NBC) and the Data Protection Agency (DPA). NBC is responsible for the evaluation of applications for research proposals which concern health issues and involve participation of human subjects, such as genetic research, drug trials, and studies comprising the collection and/or interpretation of health-related information (www.visindasidanefnd.is). The role of DPA is the protection of individuals with regard to the processing of personal data and the free movement of such data (www.personuvernd.is). In Icelandic law and regulations on scientific research, there is considerable leeway for these agencies to interpret the general letter of the law, without these agencies being furnished with clear and lawful parameters on which to base their evaluations. This has often created tension between researchers and the regulatory agencies and feelings of frustration in the scientific community.

The Centre for Ethics at the University of Iceland conducted research with focus groups of stakeholder representatives discussing these issues and how they can be improved. In 2008, the center sponsored a meeting between the Ministry of Health, the National Directorate of Health, members of NBC and DPA, and representatives from the scientific community, for example, from deCODE genetics, the Cancer Registry, and the Icelandic Heart Association. The unanimous conclusion of the meeting was that there was an urgent need to set up a working group to prepare a new bill on scientific research. The main aim of this new law would be to differentiate more clearly what is done in the current legislation between various types of research, for example, clinical research and database research where the

nature of participation is very different. Also, the aim is to state clearly in the law the parameters on which regulatory agencies are to base their evaluations. In 2009, the Ministry of Health set up a working group which is still working on a comprehensive bill regarding research in medicine and health care. The working group has had close and extensive consultation with the main stakeholders in the field.

Among the changes of ethical relevance in the new bill is that a wide consent can be obtained from participants in database research. In that case, the participants must be enabled to follow the course of the research and have the possibility to opt out of particular research projects. It will be an interesting challenge to create a framework for implementing this practice which moves away from an exclusive emphasis on the initial consent to a more dynamic process which is intended to keep alive the option of withdrawing data from research. This is regarded as preserving the ethos of voluntariness without insisting on informed consent for each particular research project. An argument has also been put forth that this will contribute to more active citizenship by raising awareness in society about population database research (Árnason, 2009b). Sigurður Kristinsson (2007) has argued that the prevailing association of informed consent and individual autonomy is mistaken and the argument for informed consent should rather be based on respect for persons in the Kantian sense.

Public Health

Awareness about public health has been on the increase in Iceland since the Public Health Institute was established in 2003. The institute merged with the National Directorate of Health in 2011. The issue of public health has not entered much into the bioethical discussion. In 2005, the 8th Nordic Public Health Conference was held in Iceland and the opening lecture was given by a philosopher on ethical issues in public health. In 2010, the Nordic Bioethics Committee held a 2-day conference in Reykjavík on ethical issues in public health (Soini, 2011). Some philosophical discussion has taken place about addiction and the right to restrict individual liberty, both in *The Icelandic Medical Journal* and in handbooks for students and parents about prevention of addiction.

Another topic that has received some attention in the bioethical discourse on public health is obesity. Ástríður Stefánsdóttir (2011), physician and associate professor of ethics at the School of Education at the University of Iceland, has argued that it is largely mistaken to conceive of obesity primarily as a medical problem which concerns the obese individual and the health care professional. This conception, she argues, identifies the problem in a wrong way and leads us to respond to it by ineffective means. She suggests that obesity should primarily be seen as a social problem since its main reasons lie in the fact that people are living in an environment which makes difficult for them to lead healthy lives. By regarding obesity as a social and even as a political issue, the primary responsibility is put on politicians and others who have the power to shape society and not the individuals concerned.

This emphasis on the collective responsibility for obesity is indicative of a trend in Icelandic bioethics in recent years to intertwine bioethics and biopolitics.

Árnason and Hjörleifsson have argued that bioethics can take on a legitimating role by focusing too narrowly on particular ethical questions at the neglect of the larger social implications (Árnason & Hjörleifsson, 2007). Bioethical analyses tend to focus on questions concerning a particular set of issues relating to basic human interests, such as privacy and consent and risk of harm or discrimination. If there are good reasons to believe that these interests can be protected, a particular bioethical technology could legitimately be introduced. For example, the introduction of genetic testing could be discussed primarily in terms of whether the practice would duly meet the requirements for informed consent of patients undergoing the tests; whether the test would put the person at considerable risk, for example, relating to knowledge of nontreatable disease; and whether privacy of information would be protected so that the patient would not be in danger of being discriminated against on the basis of his genetic susceptibility for certain diseases. The question concerning the effects of introducing pervasive genetic testing upon health care services, public health, and the practice of medicine might not, however, be taken into account. Such a narrow ethical discourse is ideological in the sense that it implicitly covers up important moral aspects of the effects of biotechnology while claiming to analyze its main ethical implications. This is a major reason why increasing attention needs to be paid to social and political issues and bioethics must not be distinguished sharply from biopolitics (Árnason, 2008).

Infectious Diseases

Stefánsdóttir (2006) has discussed ethical issues relating to infectious diseases in an article about health services for immigrants in Iceland.

Transplantation Medicine and Organ Donation

In 1991, two important bills for this discussion were passed in the Icelandic parliament. The first was a bill about determination of death and the second a bill about removal of organs and autopsy. In 1989, the general assembly of Icelandic Lutheran Church decided to commission a report from the Centre for Ethics at the University of Iceland about the moral questions raised by these two bills. The Centre for Ethics set up an interdisciplinary working group consisting of two philosophers, a theologian and a medical doctor. The working group produced a report or position paper on the definition of death and the removal of organs which was published as a pamphlet (Árnason, Ásmundsson, Björnsson, & Karlsson, 1990). The working group supported the brain death criteria introduced in the first bill and the policy of presumed nonconsent for removal of organs. This policy has worked without complications in Iceland, but recently, voices have been raised to the effect that the policy for organ retrieval from dead donors should be changed from presumed nonconsent to presumed consent.

Emerging Technologies (Nanotechnology, Information Technology, etc.)

In the beginning, the main arguments used by the spokesmen of deCODE genetics for compiling a comprehensive collection of population data were that it would enable researchers to identify key genes linked to common diseases and to the regulation of drug response. The argument was that this could play a crucial role in delivering personalized medicine (Hákonarson, Gulcher, & Stefánsson, 2003). In 2007, deCODE genetics launched an online direct to consumer service, deCODEme, which offers a comprehensive genome scan and online analysis of individuals' DNA profile by scanning one million variants in their genome. Users are to learn how scientific knowledge about ancestry, disease risk, and the inheritance of physical traits applies to them. This has generated some bioethical debate in *The Icelandic Medical Journal* and in the media. There has also been a discussion in the Icelandic parliament about the need for regulation of this kind of service.

The ethics council of the Icelandic Medical Association has discussed the matter and written a quite critical evaluation report. It is argued that because of the nature of the service, it should be categorized as health care, but then it would have to meet several conditions that it presently fails to meet, such as the following: (1) Because no professional agent acts as an intermediary between the company and the individual, there is no way to know whether the sample which is sent to the company comes from the individual who sent it or not. (2) For the same reason, there is no one to help the individual to interpret and analyze the information she receives from the company and to give appropriate genetic counseling. The statistical information about susceptibility to several diseases can be quite difficult to interpret. (3) The information is also inaccurate, especially because the relationship between the statistical results about risk for diseases and their clinical penetration is not well substantiated. (4) If this information is regarded as health care information, the company is violating important articles in the Icelandic physicians' Code of Ethics, such as articles about providing patients with accurate information and avoiding giving information which can create unnecessary fear for the patient. (5) This unmediated online service can create unintended burdens for the public health care system since people are likely to bring their genome scan analysis to their family doctor for interpretation. This would increase the cost of public health care for services that are not likely to have beneficial consequences for public health (Stefánsdóttir, 2010).

The spokesmen of deCODEme have argued that the information is not to be regarded as health care information which is seen by critics as strategically motivated to avoid regulatory action. The company's CEO has defined the service as "health promotion," and the information should be understood as "my map to better understanding of my future health" (Stefánsson, 2007). The main moral justification for this is to enhance peoples' self-knowledge and individual autonomy. The accusation of incurring unnecessary anxiety is seen as paternalistic.

In a recent ethics seminar of the Icelandic Medical Association, it was argued that Icelanders might become the first nation where whole-genome sequencing could be used to predict susceptibility for diseases in an entire population. It is

a major challenge to translate the research findings by scientists at deCODE genetics into more targeted therapeutic and preventive strategies for genetically defined groups and individuals based on predictions of genetic susceptibility to diseases. Such a project would raise major challenges for bioethics in Iceland, not only concerning the effects that introduction of genetic testing may have on individuals, but also on health services and society at large (Árnason, 2012).

Intensive Care

Intensive care has only entered the bioethical discussion insofar as it relates to treatment at the end of life.

Palliative Care

See discussion above about issues at the end of life and on chronic diseases below.

Care for the Elderly

In 1995, three people working in bioethics formed a research group about self-determination of the elderly in Iceland. With funding from the Icelandic Elderly Council, a questionnaire was formed and inhabitants of five nursing homes in Iceland participated in a study where they were asked about their everyday life. A book with the results was published in 2004 with a philosophical discussion of autonomy and the elderly and critical analysis of the law on the elderly. The book stirred much discussion and controversy about the elderly in nursing homes (Stefánsdóttir & Árnason, 2004). Based on the empirical study, the authors demonstrated how the self-determination of the elderly in nursing homes concerning their daily life was radically restricted. This restriction comes about by a combination of factors, such as the routine of the service provided, the frailty of the people concerned, and their own attitudes toward self-determination once they have moved to nursing homes. The authors argue that the official vision of nursing home as a home rather than an institution does not stand to scrutiny. The authors held several meetings with nursing home staff and professional organizations to discuss their findings. The media showed unusually much interest in the study which is the clearest example of empirical bioethics done in Iceland.

Chronic Diseases

The Icelandic association for the study of pain has held a couple of meetings where philosophical and ethical issues of living with pain and the treatment of chronic pain have been discussed. But no specific attention has been given to chronic diseases from a moral point of view.

Psychiatric Care

The little discussion that has taken place in Iceland about ethics in relation to psychiatric care has centered around involuntary institutionalization. A study conducted in 1989 of the feelings and attitudes of patients admitted against their will to the Department of Psychiatry of the National University Hospital, Reykjavik, Iceland, concluded that involuntary admissions should be prepared more thoroughly in cooperation with the patient and more emphasis should be placed on giving the patient clear information about his/her legal rights (Guðmundsson & Stefánsson, 1989).

In the wake of the collapse of the Icelandic banks in 2008 (Árnason, 2010b), some discussion has taken place in *The Icelandic Medical Journal* and the media about psychopaths in corporations and their impact in the financial sector which has created fertile soil for ruthless, risk-seeking individuals (Briem, 2010).

Pediatric Care

As in many Western countries, complex ethical questions arose when new technology enabled health care professionals in neonatal care to save the lives of children with serious conditions which in earlier time would have resulted in early death. Some meetings were held in the 1990s where these issues were discussed among health care professionals and moral philosophers. Árnason (1993, 2003) has a chapter on ethical issues in neonatal care and argues for a "best interests of the child" approach to selective nontreatment in the spirit of Weir (1984).

Emergency Care

No particular publication has been produced on this topic in the Icelandic bioethical literature.

General Practice

No particular publication has been produced on this topic in the Icelandic bioethical literature, but members of the above mentioned Rosendal group come from general practice (Getz, 2009).

Health Promotion and Education

Considerable interests in and discussion about this topic has taken place on Iceland, especially among nurses, but it has not entered the bioethical discourse.

Scientific and Professional Integrity, Conflict of Interest, Corruption

Icelandic universities have ethical guidelines concerning good practices in research and education. Since 2010, the Icelandic Research Council has been working on comprehensive guidelines about good scientific practice and research integrity for the Icelandic scientific community. Two philosophers working in bioethics have been part of an interdisciplinary team drafting these guidelines which are modeled by the guidelines of the national advisory board of ethics in Finland. A committee will be established to oversee that good practices are observed. One of the tasks of that committee will be to formulate guidelines about conflict of interests.

Relations with Industry and Donors/Sponsors

Along with increasing and closer relationship between industry and research and education, the issue of conflict of interest has been raised. This issue has been discussed at seminars within the University of Iceland and has been one of the topics addressed in the ethics section in *The Icelandic Medical Journal*. It still remains a challenge for the scientific and research community in Iceland to adopt a strong policy on the conflicts of interests. This is one of many issues that have been increasingly on the agenda in the wake of the collapse of the Icelandic banks. A working group on ethics that was part of a parliamentary commission looking into the cause of the collapse of the Icelandic banks pointed out that the relationship between the academic community and the financial sector was too close.

Future Challenges

In the Field of Bioethics Infrastructures (Need for Legislation, Ethics Committees, Ethics Education, etc.)?

There is a need for a National Ethics Council in Iceland, a body that would have a role similar to that of the Danish Ethics Council to facilitate public debate about bioethical issues and help to prepare responsible public policy on these issues. The Centre for Ethics at the University of Iceland has proposed to the Icelandic parliament to establish such a committee, and the issue is being discussed in the parliament. A bill has been introduced in the parliament to increase education in ethics and critical thinking in the Icelandic school system, and the University of Iceland has introduced a new policy with increased emphasis on teaching of ethics.

In the Field of New and Emerging Issues?

The genetic research that is being carried out at deCODE genetics will present complex ethical issues relating to whole-genome sequencing and personalized

medicine. Discussions are already taking place between the National University Hospital and deCODE genetics about how results from genome-wide association studies can be translated into medical practice. These plans will not only raise particular ethical questions of consent, privacy, and risk of harm but also about the effects upon our health services and society. These developments are likely to provide future challenges for bioethics in Iceland.

Summary Conclusion

Bioethics in Iceland is in many ways typical in the sense that it has dealt with the major questions thrust upon us by new technology and changed mentality in the last decades. One distinguishing characteristic comes from the fact that in such a small nation, the contribution of very few individuals, such as that of the present author, becomes relatively large. Another distinctive characteristic is the pervasive influence that deCODE genetics, one of the major research companies in the world, has upon the bioethical discourse. In all likelihood, that influence will continue since there are major challenges ahead concerning how to translate the genetic knowledge that is the fruit of the research into therapeutic and preventive benefits.

Introduction

Almost a population of 1.2 billion substantively permeated with an inbuilt ethical consciousness traditionally inherited from almost the dawn of the human civilization but poorly professionalized at the applied level; this formulation might absorb the paradoxical reality of the Indian bioethical scenario. The following comment by Chattopadhyay, barring its extreme tone, is a rather realistic representation of bioethics in India: "Bioethics in India is, to say the least, a complex and difficult terrain where even angels may fear to tread. Any discussion of US-born-Western-bioethics-headquartered-at-Paris in the Indian scenario may open up a 'Pandora's box' of intricate issues – some of which remain unresolved, others inadequately addressed, and a few even untouched. Worse, attempts to address these issues run the risk of generating more heat than light" (Chattopadhyay, 2011, p. 20).

Bioethics in its modern Western sense made its presence in India in the 1980s. It is still to take a definite structure and shape at the theoretical and infrastructural levels. Perhaps, this is due to historical reasons linked to the age-old ethical consciousness of the country. Not that India did not encounter bioethical issues in modern times, rather, given the deeply inbuilt ethical and spiritual consciousness of the country, many of the active problems in bioethics in the Western world tended to be pseudo-problems for India. For instance, many in the country still consider it an anathema to hold public debate on euthanasia since there are foregone conclusions for the Indian mind-set in such regards.

India is the world's second most populated country with an estimated population of 1.2 billion. India is a union of 28 states and 7 union territories. India is a nation that is characterized in its constitution as a sovereign socialist secular democratic republic. Like the United States, India has had a federal form of government. However, the central government in India has greater power in relation to its states, and its central government is patterned after the British parliamentary system. India is the world's largest democracy in terms of citizenry. The president of India is the head of the state, and the prime minister of India is the head of the government. Executive power is exercised by the president and is independent of the legislature. Legislative power is vested in both the government and the two chambers of the parliament of India, the Lok Sabha and the Rajya Sabha. Federal and state elections generally take place within a multiparty system. The judiciary is independent of the executive and the legislature, the highest national court being the Supreme Court of India.

Under the constitution, parliament has the power to make laws for the whole of or any part of the territory of India. The state legislatures have the power to make laws for the states. Parliament has the exclusive right to legislate in respect of items such as defense, foreign affairs, currency, income tax, excise duty, railways, shipping, and posts and telegraphs. state legislatures have the exclusive power to make laws in relation to items such as public order, police, public health, communications, agriculture, lotteries, taxes on entertainment and wealth, and sales tax. Both parliament and the state legislatures have the power to legislate in items

appearing in the "concurrent list." This list includes items like electricity, newspapers, criminal law, marriage and divorce, stamp duties, trade unions, and price controls. Health care in India is mostly a concern of the state governments. Public health pertains to the "state list" of items upon which the state governments have the exclusive powers to make legislation.

India inhabits enormous cultural, linguistic, and genetic diversity. A journey across this nation will enable one to encounter almost a series of "countries" with different cultures, life-styles, and habits in every 300 mile utmost, typically underscoring the catchword of the Indian nation, unity in diversity. As per the 2011 census, the country is home to 1.2 billion people with diverse languages, groups, religious faiths, and cultures. India has been the cradle of contrasting diversities, varying from the highest forms of the mystical traditions through the atheistic and materialistic traditions of *Charvaka* to the nonviolent political ideology of Mahatma Gandhi in recent times. Though India habitats the largest religious festival, the *Kumbh Mela*, it is not ironical that it was in Kerala, the southern state of India, that the communist-Marxist party was voted to power through democratic means for the first time in the world. India also holds the paradoxical record of the growing number of millionaires and the largest number of poor people in the world. While a significant percentage of the population has access only to the primary health centers, medical tourism even from Europe and America has been gaining momentum in the country for over a decade. The paradoxical setting of bioethics in the Indian context has to be understood within this paradoxical social and economic reality in which the nation is placed at large.

This chapter attempts to give a bird's-eye view of the bioethics activities in India, at various levels. Starting with the history of bioethics, it dwells on the current issues, legislations, and future challenges pertinent to bioethics in India. Some directions for the future course of developments for bioethics in India in particular are made, and some areas of engagement between the Indian and the Western bioethics in general are also proposed.

Bioethics in India: Development and Current Infrastructure

The origin and development of bioethics in India has been closely associated with the Indian Council for Medical Research (ICMR), "the apex body in India for the formulation, coordination, and promotion of biomedical research" (http://icmr.nic.in/human_ethics.htm). It has been assigned with the additional task of formulating ethical guidelines for biomedical research, bioethics training, providing ethics consultation, as well as maintaining a database and coordinating international collaboration on bioethics. As stated on the website, the mission of ICMR is "...building capacity in bioethics which is relevant to Indian ethos, with special emphasis on research ethics related to genetics, drug development (including traditional medicine), public health ethics and social sciences, and international research ethics" (http://icmr.nic.in/human_ethics.htm).

Indian Council of Medical Research (ICMR) Ethical Guidelines

In 1980, ICMR drafted its ethical guidelines concerning ethics committees; informed consent; clinical trials; and clinical and medical practices involving the vulnerable sections of the society like children, the mentally disadvantaged, and those with diminished autonomy. The revised guidelines incorporating the modern challenges were formulated in 2000. However, a serious loophole with the Indian bioethics system is that the ethical guidelines are not adequately imposed by corresponding legislation or it has been weakened by delayed legislation. However, some of these guidelines were effectively incorporated in the amendments to the *Medical Council of India Act, 1956* of 11 March 2002 and the *Drugs and Cosmetics Act*, *1940* on 20 February 2005 (Kumar, 2006).

The revised ICMR guidelines also serve as a sort of template for guidelines on stem cell research, on radiopharmaceuticals, or on bioterrorism as it carries 12 general principles. There are also specific principles articulated on issues pertaining to clinical research on human genetics and organ transplantation, including fetal tissue transplantation, and stem cell research including embryonic tissue, epidemiology, and assisted reproductive technology. A draft of the guidelines for the *ethical issues surrounding genetically modified food* and *stem cell research and therapy* is jointly formulated by ICMR and the Department of Biotechnology, a government funding agency for biotechnology. This draft was originally prepared in 2006 and revised in 2008. The lack of consensus among political parties and policy makers has delayed its introduction in the parliament as a bill, though the recent controversy in the country over the Bt-brinjal has revived the discussions on the same. ICMR has a bioethics page on its website, which includes the institutional ethics committee survey questionnaire, a model format for submission of applications by principal investigators to the ethics committee, and a format for reviewers on what points they look for in approving a proposal. It also gives guidelines for preparing standard operating procedures for ethics committees.

The policy statement of the ICMR *ethical guidelines for biomedical research on human participants* was submitted to the Ministry of Health and Family Welfare for empowerment with legislation in 2006 (Ministry of Health & Family Welfare, 2011).

Bioethics Training Programs

ICMR hosts a studentship program, the appeal of which is doubling every year. ICMR has found it an imperative to offer courses and training programs in bioethics in the country. Though with no concordance, some universities in India offer bioethics courses. There is a clear instruction from the Medical Council of India to make bioethics as part of its general syllabus in the various medical colleges across the country. St. John's Medical College in Bangalore tops the list of the institutions with a strong ethical sensitivity in its medical curriculum with a legacy of over 45 years of teaching ethics. Though the instruction of the Medical Council is not binding on the medical colleges, many universities and medical colleges are

making genuine efforts to introduce medical ethics in the curriculum. Rajiv Gandhi University in Karnataka, MGR University in Tamil Nadu, Maharashtra Medical University in Maharashtra, and Father Muller Medical College in Mangalore are some other front runners in this regard. As of now, the nation does not have a uniform curriculum for training in biomedical ethics though many health institutions have launched their own programs. ICMR has also initiated measures to rectify this issue by drafting a uniform core curriculum. This process is still on and expected to be completed by the beginning of 2013. Subsequently, there is the possibility of Medical Council of India adopting this syllabus. If Medical Council of India makes medical ethics a separate subject in its syllabus, all the medical colleges and universities in the country will implement it. There is a strong call from bioethicists in the country to make medical ethics a compulsory course with requisite attendance for the award of medical degrees. Making ethics an optional course in medical colleges does not serve its purpose In India.

The training program of the ICMR has a three-pronged strategy. The first, the sensitization program, covers the undergraduate, postgraduate medical students, nonmedical students, institution ethics committee members, researchers, and faculty members. The first of its international workshops was held on 6–10 February 2006. An informal teaching module via distance education is planned with the help of the Indira Gandhi National Open University. The short-term training for the trainers forms the second component, targeting the faculty and researchers. In the long-term course which constitutes the third component, the trainees undergo training at various places and institutions. ICMR hosts joint workshops with the World Health Organization in alternative years where a common module is designed and used at health science universities and institutions in a number of states. This helps the medical and nonmedical participants to be introduced to the essential principles and practices of ethics in biomedical research. It is lamented that even those universities, which included medical ethics in their syllabus, have not made it mandatory to be part of the syllabus for examination (Kumar, 2006).

The document on "Ethical Policies on the Human Genome, Genetic Research and Services," (Tandon, 2005) issued by the National Bioethics Committee, established by the Department of Biotechnology, Govt. of India, was a follow-up to the recommendations of the "International Bioethics Symposium on Human Genome Research: Emerging Ethical, Legal Social and Economic Issues" organized by the National Academy of Sciences in India in 1998. However, these initiatives do not offer an adequate platform for the rapid progress of the ethics projects in the country (Eubios Ethics Institute 1998).

Ethics Committees

The overall state of affairs with the IECs in India is disheartening. A survey by ICMR in 2000 disclosed the surprising facts that many important institutions in the country are unaware of the ICMR guidelines. Still worse, there was no legal expert in most of the committees. "Appointment procedures were unethical and there was

lobbying for appointment as members. Decision-making was either by consensus or by majority opinion. The number of proposals reviewed varied from 2 to 60 in a meeting. The institution which had 60 at that time now has more than 100 and they are reviewed in half a day!" (Kumar, 2006, p. 62). The survey also showed that the prevalence of ethical committees is relatively better in the states of Maharashtra in central India, Andhra Pradesh in the southeast, and Karnataka in the southwest. This factor is at their lowest ebb in the northeastern states like Sikkim and Tripura. Set up in 2000, the Forum for Ethical Review Committees in Asia and the Western Pacific (FERCAP) had a joint workshop with ICMR in 2002 for developing standard operating procedures for institutional ethics committees. The chapter for India was launched in 2002 in FERCAP.

Clinical Trials Registry

Yet another creative and important initiative taken by ICMR is the clinical trial registry. This was conceived in the context of the outsourcing of the clinical trials to the country. The regulatory bodies had no adequate mechanism to handle this situation as the multinational agencies and clinical research organizations flooded into India. ICMR organized a number of workshops where multiple stakeholders were involved and the result was the planning of the clinical trials registry.

ICMR also networks with the World Health Organization, National Institutes of Health, the Wellcome Trust, the Bill and Melinda Gates Foundation, and the Ford Foundation in its bioethics campaign. On the whole, though ICMR has made a significant impact upon the bioethics map of India, it still has a long way to go by developing more sensitization programs and seeking international collaboration for capacity building.

A major milestone in the progressive bioethics campaign in the country is the launching of the South India Unit of UNESCO Chair in Bioethics at Father Muller Medical College in Mangalore in the southern state of Karnataka in January 2012. The UNESCO Chair in Bioethics, established at the University of Haifa in Israel, inaugurated a unit at Father Muller Medical College. This unit runs parallel to similar units in Malaysia, Singapore, Indonesia, Pakistan, Sri Lanka, and Japan as part of the Asia Pacific Network to address the issues in bioethics education in medical and allied health care education and research in South India and the Asia Pacific region. The unit aims at achieving excellence in health care through bioethical principles.

The objectives of the unit include imparting and empowering health care professionals in Father Muller Medical College with bioethical principles, collaborating with medical schools across South India and Asia Pacific Network in promoting bioethical concepts, and acting in concert with the Chair of the Asia Pacific Network and the UNESCO Bioethics Chair in Haifa in implementing relevant and appropriate projects and programs. In achieving its mission and objectives, the unit has designed a three-pronged activity framework consisting of an information bank, education and training programs, and research. The unit also envisages

networking with human rights infrastructure in the country and seeks to take the lead role in representing bioethics and human rights at the governmental and nongovernmental levels in South India.

With no financial commitment, the UNESCO Chair in Israel provides the technical know-how, online books, and online curriculum template to this unit and facilitates contacts with other units. So far, the unit has created ethical awareness and sensitization among nurses and doctors at the said medical college through public lectures. They have also been organizing regular training programs for their future faculty in teaching ethics with expertise by the bioethics professionals from the various parts of the country and abroad. The unit has also initiated the measures toward establishing a master's level medical ethics course at the Father Muller Medical College.

Traditional Indian Medical Ethics

Bioethical discussions in India inevitably find themselves within the conceptual and philosophical matrix of the Indian philosophy and spirituality in general. Unlike the philosophical frameworks of the Western ethical discussion, Indian ethical deliberations cannot delink themselves from the perennial perspectives of India on life, humans, cosmos, and God. Hence, a short recourse to the general ethical framework of India is necessary at this point.

There are very strong theoretical principles incorporated from science, ethics, and philosophy in Indian medical ethics which act effectively in solving practical ethical issues. Many Indian doctors practicing in foreign countries have reported that they are intuitively helped by their tradition and upbringing when faced with ethical dilemmas. Traditional Hindu medical ethics uses the theoretical principles such as the sanctity of all life, nonviolence (*ahimsa*), transmigration (cycle of death and rebirth), and a willingness to accept life situations as defined by one's *karma* (actions in life). There is a holistic unity and interconnectedness to realities of universe and life therein. The foundation of ethics is the unity of existence, not merely of human being alone, but extending to all other beings. Hinduism emphasizes the relative nature of dharma (moral righteousness) and does not recognize absolute good or evil; evil may be described as what is less good. One cannot stipulate what is absolutely good or evil for all men at all times.

What India can boast of in biomedical forums is its historicity pertinent to medicine and medical ethics dating back to several centuries before Christ. Unlike the Western system, in India, bioethics has not emerged itself as an independent branch of ethics though the mainstream ethical thinking in India and the ancient literature on Indian medical tradition are rich with bioethical principles and practices.

Dhanvantari is the father of the traditional Indian medicine of *ayurveda*. He looms in immemorial past. Indian historians claim that Dhanvantari's descendants, Charaka and Sushruta, lived prior to Hippocrates (460–370 BC). *Charaka Samhita*, the ancient treatise on medicine formulated by sage Charaka, defines *ayurveda* as

follows: "That is named *Ayurveda* wherein is laid down the good and bad life, happy and unhappy life, and what is wholesome and what is unwholesome in relation to life and also the span of life" *(Charaka Samhitha – Sutra Sthana, 1:41)*. The *Siddha Vaidya* branch of Indian medicine, which deals with pharmaceutical chemistry, is an independent branch, and later, it was incorporated into *ayurveda*.

Charaka advocated a departure from faith-based approach to medicine and emphasized a reason-based approach. Charaka seems to criticize fatalism and passivity that is pervasive among millions of people even today and asserts the procedural nature of a good life. "Good conduct, in his view, implied the avoidance of the overuse, underuse and misuse of the senses and the mind" (Valiathan, 2003, p. 178.). By emphasizing reason-based approach to medicine, Charaka has placed the responsibility of creating optimal conditions for a good life squarely on the individual and the community. The ethical outlook advocated by *ayurveda*, as it is explicated in various ayurvedic texts, is based on the conception of a comprehensive philosophy of life. Ancient Indian medical manuals have prescribed strict ethical codes for discouraging and penalizing medical malpractices and unethical procedures. There are ample references in the Indian epics such as the *Mahabharata* (Hopkins, 1993) and secular texts like the *Arthashastra* (Kangle, 2006) of Kautilya about the desired conduct of physicians. This shows the importance of public accountability of the medical professionals. Charaka, for instance, asserts that a physician should invariably seek the happiness of all beings. He ought to heal the sick with his whole heart and should not do it for money alone (Sen, 1917). Indian medical tradition stresses certain characteristics for the patient too. According to Charaka, good memory, willingness to follow the instructions of the physician, fearlessness, and not hiding any relevant information about his symptoms and disease are the four qualities of a good patient.

In India, medical practice has been traditionally paternalistic. The doctor-patient relationship is paternalistic in *ayurveda* also. In the medical practice of *ayurveda*, such a transition from paternalism to informed consent is least noticeable as paternalism or ethics of trust still holds good here. Sushruta holds that a physician must not reveal the secrets of the household or the patient nor spread broadcast the demerits of the family. He must therefore never expose the patient and must honor the confidence the patient has in him.

Major Bioethics Issues

Beginning of Life

Hindus have clear prohibition for abortion except to save the life of the mother. It is considered as against the universal order and a sinful act against the moral law of *dharma* fraught with karmic repercussion. Hindu ethics does not justify abortion because of the actual or potential deformity or mental retardation as each birth has a divine purpose.

Medical Termination of Pregnancy (MTP)

MTP is a legalized procedure in India and is widely practiced. The Medical Termination of Pregnancy Act was enacted by the Indian parliament in 1971 and was brought into force from 01 April 1972. The MTP act was revised in 1975 and further in 2002. Despite the clear prohibition of abortion in traditional Hinduism, the Indian MTP act is very liberal in itself.

One of the reasons for this liberal approach could be the strong requirement of the country to address the issue of the growing population. The liberal policy of the country favoring abortion to address the specific interest of the growing population and not addressing the life-long mental stress of the women conceding to abortion is a major ethical dilemma that is conveniently neglected.

The liberal attitude toward the medical termination of pregnancy has not alleviated India's woes with newborn and maternal deaths. India records 26 million births every year which is 54 % of the total births worldwide. 23 % of the babies born have low weight (below 2.5 kg), and India is among the world's five countries that account for more than half the world's 3.3 million newborn deaths. Almost 45 in every 1,000 births are born to mothers aged between 15 and 19. As regards maternal deaths, India sees the highest number of women dying during childbirth. In India, one woman dies every 8 min due to pregnancy-related complications.

Female Feticide

Many abortions in the Indian context are done as female feticide. India has a skewed sex ratio in favor of males. In 2011, indicating a continuing preference for boys in society, the child sex ratio in India has dropped to 914 females against 1,000 males. The ICMR guidelines have very specifically put forward that prenatal diagnosis (PND) should be limited to detect the fetal abnormalities or genetic disorders as per PND technique and not for sex determination of the fetus. In 1994, India banned the use of technology to determine the sex of fetuses and abortion on the basis of gender, but still sex determination is commonly practiced. The country has made it mandatory that all ultrasonography centers should be registered to get the license and should explicitly mention the fact that no ultrasonography will be done for sex determination. The law was implemented in 1994, but still the sex ratio is not in favor for girls.

The Women's Code 2011

The Commission on Rights and Welfare of Women and Children in the Kerala state in its proposed Women's Code Bill 2011 recommended that a fine of Rs. 10,000 or 3 months simple imprisonment deserves to be slapped on the expectant father of a third child. The proposed bill maintains that violation of family norms will be deemed a legal disqualification and parents will not be eligible to receive any benefits from government. It insists on that religious and political outfits should not be allowed to discourage population planning and no person or institution shall use religion, region, sect, cast, cult, or other ulterior inducements for the bearing of more children. Medically safe contraceptives and instructive literature are suggested to be made available free at the time of marriage. Safe abortion should

be made free and through hospitals and health care centers in both private and government sector. These recommendations have already sparked off much hue and cry in the state.

End of Life Issues

In India, especially in the Hindu tradition, people generally wish to embrace a natural death. Unnatural hastening or delaying is not appreciated in the country. In circumstances where treatment cannot assure the patient a certain quality of life, it is considered better to forego treatment beyond palliative measures. Given the belief in the predetermined timing of death, Hindus do not strain to gain a few months. For some traditional sects, sustaining life on life support machine is tantamount to torturing the soul. Hindu scriptures do discuss nourishment related to life support and allow the termination of food and water at the request of the terminally ill. Hindu philosophy does not support assisted suicide leading to the death of a patient at the patient's own request. In the Hindu worldview, such measures only reinforce the *karma* (cycle of death-rebirth) which one wishes to escape.

In India, in general, the life-shortening actions near the end of life like withholding treatment, stopping treatment, treatment of symptoms accompanied by shortening of life, and actions terminating life - in the strict sense, administering lethal drugs - is not practiced in general. Euthanasia was neither practiced nor legalized in the country till recently. In modern times, all available aggressive treatments are carried out to the end of life. Such a support is a natural expectation from the patients and the relatives, though the physician may not share this view as it is medically futile to treat the condition. The concept of medical futility does not seem to be appealing to the general public. The medical practice in India when it concerns end of life is very much culturally conditioned (Puri, 2005).

Passive Euthanasia

However, a landmark ruling by the Supreme Court of India on March 7, 2011, changed forever India's approach to the contentious issue of euthanasia. The court ruled for the first time that life support can be removed for some terminally ill patients in "exceptional circumstances" – for example, when a patient is kept alive purely mechanically and when he or she is only able to sustain involuntary functioning through advanced medical technology. All mercy killing pleas should be heard by a two-member bench of the appropriate High Court, and decisions may be taken only after seeking medical opinion from three empanelled doctors, who must examine the patient, his or her medical records, and also get the views of the hospital staff. Decisions will be case-by-case and made by high courts after hearing the opinion of the family and a medical panel. The ruling came in the petition for Ms. Aruna Shanbaug, a former nurse, who has been lying in a vegetative state for 37 years following a sexual attack. However, the same ruling declined euthanasia for Ms. Aruna given her medical conditions. And till parliament introduces new laws on euthanasia, it is Ms. Shanbaug's case that is to be used as a point of reference by other courts.

Advance Directive

An advance directive is the formulation of a competent patient's moral and legal right to refuse treatment in the post competent period based on the principle of respect for autonomy and individual self-determination. In India, the practice of advance directives hardly exists. There is no indication in the bioethics literature that this aspect has trickled down to ethical discussions on end of life issues. The nonexistence of an advance directive in India is possibly the result of specific cultural values and age-old social and religious philosophies.

Hospital-Patient Protection Law

In 1992, India expanded the purview of the Consumer Protection Act of 1986 to cover the paid medical service against medical malpractice. The greed of the medical establishments in the country to some extent has disfigured the pristine values of the medical profession in the country, which has resulted in instances where people attack hospitals, doctors, etc., a negative trend which has been on the rise in the nation for over a decade. It has forced a number of state governments to draft doctor-patient protection act. Such laws are already enacted by the states of Andhra Pradesh and Karnataka. The Kerala Health Services Persons and Healthcare Service Institutions (Prevention of Violence and Damage to Property) Ordinance issued by the state government, which also includes provisions to ensure patients' rights, proposes that all violent acts committed against a hospital and its staff be made a cognizable and non-bailable offense. It also proposes that the rights of patients to receive complete information about the medical treatment received at the respective hospitals be ensured and that the patients' right to redress of any grievances regarding any lapse in medical treatment or service provided by a hospital be ensured.

Drug Development Ethics

India produces synthetic, genomic, and plant-based drugs with investment from the public and private sectors. Although genomic drugs are well regulated in the country by regulatory committees, such regulation is not adequate in the field of plant-based and synthetic drugs. The guidelines followed in this regard are the ICMR ethical guidelines and the Indian good clinical practice guidelines. The 1982 amendment of the *Drugs and Cosmetics Act*, *1940* now covers the traditional medicine too with independent clauses (Section 33-C) for *ayurveda*, *siddha*, and *unani* medicines with recommendations for quality control of the formulations, the appointment of a drug technical advisory board and a drug consultative committee, provision for government inspectors and analysts, etc. The amendments of January 2006 of the same act imposed mandatory compliance with good manufacturing practice and mandatory testing for heavy metals in export formulations. When it concerns drug trial approval, it is mandatory in India that the chairman of the institution ethics committee is from outside the institution. Biotech recombinant

products have to get the approval from three bodies at the federal level, that is, Biosafety Committee, the Review Committee for Genetic Modification, and the Genetic Engineering Approval Committee, though efforts are on now to promulgate a single window for clearance.

Health and Disease

The Indian mind-set has a philosophical way of looking at health and disease, traditionally conceived from the ancient Indian medical legacy of ayurveda. Ayurveda, the science of positive health, has three goals: achievement of positive health for the individual, protection of health of the masses, and obtaining ultimate liberation. Health is defined as the inseparable combination of the body, sense organs, mind, and soul. As such, the emphasis on wholeness in the WHO definition of health is inbuilt in the Indian view with more spiritual and metaphysical grounding. The body is the synchronized conglomeration of the five great elements (*pancha mahabhutas*), namely, earth, water, fire, air, and space. Two types of substances are essential for creation – material and immaterial. There must be an immaterial essence and material form in every living organism. When the variations and combinations of *pancha mahabhutas* are well balanced, the body is intact. Therefore, health is the harmony of the body within itself and with the cosmos and the divine. This also tells what disease is. Bharadwaj, an ayurvedic physician in 600 BCE, had stated that the root cause of all illness is the loss of faith in the divine. It suffices to state that in ancient India, physical and mental health were never considered separate from sane living.

The impact of the traditional belief system of the concept of rebirth is still evident in modern times too where some people are inclined to look at disease as the result of one's wrong actions in the previous birth. In the traditional Hindu belief, development of disease is not considered to be caused by external agents or injury but a result of the *karma*, the fruit of the past actions of the individuals in his/her past life. These belief systems need to be critically redressed for a relevant and practical ethical discussion. Fatalism, the view that one's life is predetermined by fate, is still dormant and operative in the minds of many when it concerns disease and sickness. However, the modern Western scientific and rational approach toward health and disease is permeating the Indian mind-set in general in modern times.

The traditional medicine of *ayurveda* and the *unani* medicine from Persia also form part of the medical system in India. Another traditional system, *siddha*, has its roots in India centuries ago. These classical traditional systems are still recognized by the government though there have been some moves toward disapproving some of the alternative medicines in recent years.

Health Care

Health in India is mostly a subject of state governments. According to the Medical Council of India, the allopathic doctor-population ratio works out to 1:1722,

in May 2007. The patient-nurse ratio depends on various factors like type of patient care provided and nature of specialization and varies from 5:1 to 19:1. India had been somewhat successful in meeting health parameters since independence in 1947, such as increase in life expectancy and eradication of some endemic diseases. In 2009, India has 271 medical colleges throughout the country out of which about 31,000 medical students graduate every year. According to estimates by the Planning Commission, India is short of 600,000 doctors and one million nurses. The low doctor-patient ratio does not make medical care affordable. This shortage is all the more pronounced in India's rural communities as the majority of the doctors live and practice in cities. The 11th five-year plan, therefore, aims at establishing 60 medical colleges and 225 new nursing and other colleges in deficit states. India needs many more doctors and many more medical institutions. Augmentation of medical institutions in the country is one of the important first steps to overcome shortages. The public sector spending on health accounts for 25 % of aggregate expenditure. The balance 75 % is the expenditure incurred by patients to private practitioners of various hues. Public spending on health in India has itself declined after economic liberalization in 1990s from 1.3 % of GDP in 1990 to 0.9 % in 1999. Central budget allocations for health have stagnated at 1.3% to total central budget. In the states, it has declined from 7.0 % to 5.5 % of state health budget (Srinivisan, 2011).

Genetics

Though in its infancy, India is venturing into the relatively new field of genetics research. As research in this area invades into the previously untouched concerns of ethics and morality, the Department of Biotechnology of the Government of India has set up a National Bioethics Committee to prepare guidelines for research in genomics, as part of its new human genome initiative. The committee has been set up to fulfill obligations under the UNESCO Declaration on the Human Genome and Human Rights, to which India is a signatory. Ethical Review Committee set up by the Indian Council of Medical Research (ICMR) has finalized a comprehensive set of ethical guidelines to regulate biomedical research involving human participants. There are no specific laws governing the processes of human genetic modification at any stage. Human cloning is prohibited by the ethical guidelines. Respect for embryos in the context of genetic research, by ethically regulating conditions of research and safeguarding the commercialization of embryos, is upheld. It also prohibits the generation of embryos for the sole purpose of obtaining stem cells and gene therapy for enhancement of genetic characteristics and eugenic genetic engineering.

The leading centers for genetic research in the country are the Genetics Unit, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi; the Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGI), Department of Medical Genetics, Lucknow, which offers a Medical Genetics course; Genetics Cell, Sri Ramachandra Medical College (SRMC) Porur, Chennai; and Surendra Genetics Laboratory, Royapettah, Chennai, India.

Genetic research initiatives in India need to make genetic tests feasible to the common man in India, especially of the genetic diseases common to the general Indian population. Lack of accessibility and exposure to the genetic knowledge and lack of well-equipped lab infrastructure are the challenges that India faces today. Social disparity of the poor and the rich plays a major role in accessing knowledge and treatment of genetic disorders. One important field with great potential in the Indian genetic context is the genetic exploration of the causes of the diversity of the Indian populace. Governmental initiatives are minimal in the genetic field in India.

Reproductive Medicine

India has been considered a highly fertile country. Therefore, governmental initiatives started with the issue of contraception and fertility control. India's engagement with contraceptive medicines started as early as in the late 1950s (Unnithan, 2010). This, in fact, did not give justice to the numerous problems related to fertility, sexually transmitted diseases, and the particular Indian social context and poor quality of health care provisions during pregnancy, delivery, and post pregnancy. Popular reproductive techniques in India include the different variants of IVF, intrauterine insemination, intracytoplasmic sperm injection, and surrogate motherhood. Surrogate motherhood is more of an arrangement than a technique. In India, the first baby conceived through in vitro fertilization (IVF) techniques, Harsha, was born in 1986. Surrogacy became popular in India after the 1990s. Commercial surrogacy is legal in India as it is recognized by the Supreme Court of India in the year 2002. The Assisted Reproductive Technologies Regulation Bill of 2010 puts up some important guidelines in the Indian context. This draft bill highlights the regulations for the clinics performing ARTs and the rights and duties of patients, donors, surrogates, and children and the punishable offenses in this regard (Ministry of Health and Family Welfare, 2010).

What India needs today is a contextually based ethics which goes beyond the biomedical framework in the case of ARTs. Context plays an important role in the ethically important concepts like choice, consent, and assent. In India, infertility is ritually highly stigmatizing, and often, women are held responsible for not having children. With the ARTs, there are growing tendencies of commodification by compromising the health, well-being, and personhood of women. Over 13–15 million couples were estimated as being infertile in India in 2005, and a majority are women who suffer from secondary sterility. There is also a higher rate of exploitation of poor and rural Indian women. Low success rates of technological interventions are yet another concern.

Medical Research

Medical research in India is a very well-established field with its cheap cost of medical trials, trained staff, and well-equipped lab settings. Besides, India is a hub

of infectious diseases specific to the Indian general public. The Indian Council of Medical Research is the highest body in India to conduct, regulate, and promote biomedical research. ICMR undertakes and supports basic, applied, epidemiological, and operational research in the area of public health. It lobbies for certain methodologies which need to be used to carry out high-quality research. In 2006, ICMR issued the *ethical guidelines for biomedical research on human participants*. Medical research and trials are governed by the Drugs and Cosmetics Act of 1940 and the ethical guidelines provided by the Indian Council of Medical Research (Indian Council of Medical Research 1980, 2000). The last amendment to this act was in the year 2010. Besides these, the Drugs Controller General of India and the Medical Council of India are the major surveillance bodies for conducting medical research and clinical trials of drugs in India.

Sponsors of clinical research in the first world move clinical trials to less costly countries, and India is one of the hotspots for such trials (Glickman et al. 2009). Therefore, most of the trials conducted in India are solutions to the health problems of the affluent countries, and remedies specific to the Indian medical scenario are not aptly sponsored and researched. Lack of stringent laws monitoring medical research in which people are participants and lack of clarity with regard to the guidelines for research related to genetics and the inefficacy of already existing regulatory bodies vouch for the unethical practices and corruption in India in the area of medical research. The president of the Medical Council of India and some colleagues were arrested by the Central Bureau of Investigation in India for their alleged roles in a 440,000 dollars bribery case, in April 2010. The practice of illegal payment to medical practitioners, wherein a certain percentage of salary in cash could be given to them without having to remit income tax on the said portion, is a common practice. Moreover, disparities with regard to wealth, education, gender, and class in India do endanger the interests of the research participants (Thatte & Bavdekar, 2008).

Public Health

The Constitution of India makes it mandatory for the government to ensure fulfillment of the right to health for all without any discrimination under Articles 14, 15, and 21 (rights to life, equality, and nondiscrimination). Health constitutionally is an issue of the state (The National Health Bill, 2009). The central government can interfere to assist the state governments in issues related to public health. Being densely populated, India is highly vulnerable to public health issues. For instance, India was plague free from 1966 to 1994. But, in 1994, a total of 693 suspected bubonic or pneumonic plague cases were reported to WHO by Government of India, a grave stigma on the public health map of India. Water and land sanitation, pollution, poverty, class and gender disparities, environmental problems and overpopulation are major concerns of the public health department. The Indian Government has taken major initiatives in eradicating or containing some of the endemics like kala-azar, malaria, filariasis, polio, tuberculosis, cancer, and

HIV/AIDS. The National Rural Health Mission established in 2005 assists in marginally bringing down the public health issues.

Union Health Minister Ghulam Nabi Azad announced on February 25, 2012, during the inaugural session of the two-day Polio Summit, that India is finally off World Health Organization's list of polio endemic countries. This means that no new polio case has come up in the country in the last one year and also all laboratory samples collected during this period have tested negative for the virus. According to the emergency preparedness and response plan put in place for polio, any new case will now be declared as a public health emergency. If India remains free of any new polio cases over the next two years, it would finally be declared polio free in 2014.

India is easily susceptible to zoonoses (diseases transmitted from animals to humans) due to the close contact with animals especially in the rural areas. Many diseases, which authorities claimed to have been eradicated, reemerge after a period of quiescence. The administrative responsibility of public health care is shared by central and state governments. Spread of major infectious diseases like HIV/AIDS, polio, and leprosy is monitored and controlled by central government. From the late 1990s, the Indian Council of Medical Research has stepped up its funding in the field of research on infectious diseases, especially the emerging diseases (Kant, 2008). The Government of India uses two-pronged action strategies in combating infectious diseases. It uses special programs for monitoring and controlling selected infectious diseases. The National Tuberculosis Control Programme, the National AIDS Control Programme, and the National Leprosy Eradication Programme are some of the examples. It also helps state governments upon demand for the control and eradication of regionally significant infectious diseases (John et al., 2011). India has a Public Health Act (1897), and most of the programs for the control and eradication of infectious diseases are funded by the WHO.

Public health issues are not easily addressed in India. Poor pandemic management and geographical inaccessibility are some of the hurdles that India faces in the public health management. Pollution of food, water, land, and air; changing life-styles; and poverty are the main causes of poor public health status of India. Inadequate public health centers and lack of facilities and human resources worsen the public health situation in India. The growing scale of chronic diseases is a clear indicator of the public health situation of India. Creating of public health cadres to work for prevention of disease, ensuring that every village has access to safe drinking water, and accelerating efforts to providing hassle-free and cashless outpatient care in the public hospitals are some of the recommendations of the high-level expert group setup by the Planning Commission on Universal Health Coverage.

Transplantation Medicine and Organ Donation

Organ donation and transplantation in India today transcend mere medico-pharmaceutical needs. In India, organ transplantation is regulated by the Transplantation of Human Organs (THO) Act of 1994, which has legalized the concept of brain death. The first successful cadaver kidney transplantation was done in KEM

Hospital, Mumbai, in I967. The first successful heart transplant was done at AIIMS, New Delhi, in 1994, and the first successful multiorgan transplant was done at Apollo Hospital, Chennai, in 1995. Today, many hospitals have set up the Organ Donation Registry with the purpose of encouraging organ donations.

In India, only a very few patients can really afford transplantation of human organs. Lack of proper awareness among the common public, the shortage of related organ donors, and the failure in collecting cadaver organs lead to illegal organ trafficking in India. Statistics show that annually for over 100,000 patients with end-stage renal disease, only 3,000 receive kidneys in India. In India, the number of actual organ donors per million is 0.08, and it does not account even for the 10 % of the demand. There is also the middle man between the potential donor and the patient who earns heavily from the deal (Prakash, 2008). Besides, religious and cultural background of India with belief in rebirth also restricts the possibility of cadaver organ donation and transplantation. Poverty and illiteracy also come into play in organ transplantation and donation. There have been numerous instances of medical practitioners fraudulently removing kidneys of poor people during a surgery.

Intensive Care

Intensive care in India is only on its way to a full-fledged medical service. Critical care initiatives began in the Indian medical context in the early half of 1970. The Indian Society of Critical Care Medicine was formed in the year 1992. Community hospitals which are run by government, private hospitals, and nursing homes are the major sectors, through which intensive care is provided in India (Prayag, 2002). The number of ICU beds available is disproportionately low both in private as well as public sector hospitals in India. Many hospitals in India are not adequately equipped and duly staffed with regard to intensive care. Intensive care units in the private sector are very expensive. Therefore, the majority of Indians cannot afford this service. Future challenges in critical care include the development of guidelines, the consolidation of training activities, and research on the outcome of critical tropical problems which are peculiar to India.

Palliative Care

India, a nation known for its virtues, has got a very ancient history of administering to the needs of the dying. It is said that Emperor Ashoka (304–232 BCE) established a *mukthi bhavan* (salvation home) on the banks of river Ganges for the people to take refuge during their last days. However, palliative care, as a branch of medicine, traces back to the 1980s in India. Most of the legal pronouncements in this regard, whether constitutional or judiciary, refers to the cure of the patient, and very less is referred to the concept of alleviating the pain of the suffering. The Delhi High Court in 1998 ruled that patients who suffer moderate and severe pain have the right to be administered medicines that can assuage their pain (Amon, 2009). Indian palliative

care facilities do not suffice to the demand of the number of patients with incurable diseases. There is a very serious dearth of palliative care units. Only less than 10 % of patients with incurable diseases receive palliative care in India. The delayed access to the palliative care units due to sparse distribution of such units at the national level is yet another problem in India.

Care for the Elderly

With its rich cultural heritage, Indian younger generation has been showing respect and care for the elderly. Elderly people were in general looked after in a homely ambience and died in the presence of the near and dear ones. However, cultural variations like industrialization, urbanization, modernization, and the changing understanding of family and relationship affected very critically the way Indians look at the elderly. In India, the Ministry of Social Justice and Empowerment looks after the welfare of the aged. This ministry is ably assisted by the National Council for Older Persons for the execution of policies related to the well-being of the elderly. The Indian government had issued a National Policy on Older Persons in the year 1999, which provides the framework for the social, economic, and constitutional security for the elderly citizens of the country. Old-age pension, widow pension, and income tax rebate for the elderly are some of the benefits that the Government of India provides for its senior citizens. State and central governments give concessions to senior citizens for conveyance by bus, train, and planes. The older population of India, which was 56.7 million in 1991, is 72 million in 2001 and is expected to grow to 137 million by 2021. The Indian Gerontological Association (www.gerontologyindia.com) was established in the year 1968 which is devoted to the well-being of the aged and promotes research on aging.

Economic issues, cultural diversity, changing definitions of family and relationship, and changing views of suffering and life after death critically altered the way young Indian generation look at the elderly today. With the predominance of nuclear families, senior citizens do not get their due with regard to respect and care from their own families. Therefore, the number of the elderly left to themselves is increasing day by day. However, the number of old-age homes does not reciprocate the number of senior citizens left alone by family members. One statistics has it that there are only a little over 700 age-old homes in India, out of which 125 are in the southern state of Kerala. Many of the Indian old-age homes do no admit senior citizens with dementia. The problems of elderly widows are still more complex. Besides, disputes about the property and poor economic conditions of the elderly are stresses that the senior citizens of India are subjected to.

Chronic Diseases

India has been known for its serene life-style, closeness to environment, and a majority of people with vegetarian food habits. However, with changes in culture

and life-style, India is becoming easily vulnerable to a variety of chronic diseases. There are governmental and nongovernmental agencies formed for control and awareness programs. The Centre for Chronic Disease Control based in New Delhi is a nonprofit research organization for the control, generation, and transmission of knowledge of chronic diseases which now accounts for 53 % of deaths in India. The major chronic diseases that India faces today are diabetics, cancer, stroke, heart, and respiratory diseases. India has the dubious first in terms of losing potential productive years due to cardiovascular diseases.

According to a recent joint study by WHO and World Economic Forum, India will lose a whooping US $ 235 billion by the year 2015 because of the occurrence of the chronic diseases among the working class. Awareness programs on healthy diet and life-style have to be conducted all throughout the country. Trained and qualified counselors for stress and depression management are to be deployed nationwide. India also lacks a governmental policy development with regard to the control of the spread of the chronic diseases.

Psychiatric Care

Indian culture has always looked at the holistic well-being of the person. Traditional Indian medical systems like *ayurveda*, *unani*, and *siddha* give illustrations of psychiatric disorders and its remedies. Mandu Hospital opened by Mahmood Khilji (1436–1469) at Dhar in the present state of Madhya Pradesh was the first Indian mental asylum. Bombay asylum was the first lunatic asylum in modern India, and it was built approximately 1750 AD. The famous central mental hospital, Yerwada, Pune, was opened in 1889. The first asylum for insane soldiers was established at Monghyr, Bihar, in the year 1975. The Bhore All India Institute of Mental Health was set up at Bangalore, in the year 1954, which later came to be known as National Institute of Mental Health and Neurosciences. The National Mental Health Programme was initiated in the year 1982 for earmarking vulnerable populations, causes, and the effects of the mental disorders in various regions of the country (Parker et al., 2001). The Government of India has passed the Mental Health Act in the year 1987.

The situation of mental health in India is very complex. Changing patterns of life-styles, family setup, work stress, competition, and relationship affect the psychological health of the Indian population. Scarcities of trained and qualified psychological counselors and failure of governmental initiatives to reach the rural areas are some of the major problems in solving the problems of mental disorders. Social stigma and alienation add to the agony of the patients and their families. Treatment of mental illness does need a multidisciplinary approach which combines clinical psychological treatments, counseling, spirituality, and sociology. This kind of holistic approach to mental health in India is rare. Preservation of the basic human rights of the mentally sick person is another challenge that India faces today. Many patients live in subhuman conditions.

Emergency Care

Emergency care in India is gaining significance due to the amount of road accidents, natural disasters, and the outbreak of infectious diseases. Every year, nearly a million deaths occur due to road traffic injuries, falls, burns, poisoning, drowning, suicide, work place/occupational injuries, disasters, and violence. In a significant ruling in 2007, the Supreme Court has ruled that all injured persons especially in the case of road traffic accidents, and assaults when brought to a hospital/medical center, have to be offered first aid, stabilized, and shifted to a higher center/government center if required. It is only after this that the hospital can demand payment or complete police formalities. Failure to administer emergency care in the wake of an accident or disaster amounts to the violation of the constitutional "right to life." Emergency care in the military with well-equipped staff has been functioning in India since the 1960s. The first emergency department at the private sector, modeled after the American system of emergency medical care, was established in Chennai at Sundaram Medical in the 1990s. In the year 2009, the Medical Council of India recognized emergency medicine as the 30th specialty of medical curriculum.

Emergency care and the trauma relief system in India are very sparse, and sometimes, it is totally absent in the rural areas. The ignorance of common people to administer first aid in case of emergency in India is another problem that has to be immediately sorted out. Emergency services in India are not systematically networked, and therefore, a lot valuable time is lost before the patient has being admitted to the best suitable place. Emergency care coupled with better rehabilitation programs for the injured is the need of the time in India. Trained professionals, better equipments, and creating mass awareness can produce better care during emergency cases. A policy-based injury control and trauma relief system would do great help for the proper functioning of the emergency care in India (Subhan & Jain, 2010).

General Practice

In the past, the upper and the rich class of Indian society had access to *vaidyas* (physicians), and the people who belonged to the lowest rung of the society depended mainly on household remedies. India did not have a well-established public health system before the arrival of the British. They established medical colleges and hospitals mainly centered in cities. This pattern led to a hospital-centered urban medical care for the patients contrary to the context of India. The 1930s witnessed the arrival of general practice in India in Mumbai (Pingle, 2002). General practitioners had a cordial relationship with the patients and were generally humane in their approach. Changing cultural patterns, greed for money, competition, breakage of traditional familial concepts, and the trend of specialization led to alterations in the general practice and more importantly changed the way a patient related with the doctor.

Prevalence of unethical practices is common in general practice today. India is known for general practitioners who are inexperienced or even unqualified.

Commercialization of medical care is another factor that affects Indian general practitioners. Malnutrition, illiteracy, and poverty are some other factors that challenge the general medical situation. Pregnancy-related deaths are very common in rural India. Another area of concern of the general practitioners in India is the medical condition of the tribal population. Modern medicine is very technical in its approach, and this is contrary to the traditional Indian medical context. Generally, the traditional Indian medical context is communitarian, holistic, and eco-friendly. General practitioners today have the Herculean task of coupling effectively Indian traditional value-based medical ethos with modern medicine for the holistic well-being of the patients.

Nanotechnology and Information Technology

India is slowly catching up to the immense possibilities that nanotechnology offers in the field of medicine. In India, the Department of Science and Technology of the central government is overseeing the development and promotion of nanotechnology. The Nano Mission Council, the highest advisorial policy-making body for nanotechnology in India, is under this department; it also includes two other advisory groups, namely, Nano Applications and Technology Advisory Group and the Nano Science and Advisory Group. The main nanotechnological research bodies in India in the field of medicine are the Indian Council of Medical Research, the Council for Scientific and Industrial Research, and Indian National Science Academy. The Department of Science and Technology and the University Grants Commission (UGC) now fund nanotechnological research initiatives in India.

Today, information technology in India is making revolutionary inroads in all aspects of life. With its rich and large pool of IT professionals and English-speaking young generation, India is fast becoming the hot spot for the IT revolution. For the first world countries, India is one of the favorites for outsourcing because of its cheap but efficient labor. The Information Technology (IT) Act was passed in the year 2000 and invited major amendments in the form of the Information Technology Amendment Act of 2008. The Information Technology Action Plan of 1998 and recommendations of the National Association of Software and Service Companies (NASSCOM) help the Department of Telecommunications to draw out policies which will safeguard the security of the nation and the rights and duties of its citizens in the cyber world.

Infrastructural and knowledge constraints limit the growth of nanotechnology in India. The problem of the absence of a clear-cut patent policy is another drawback. Nanotechnological initiatives could go any farther ethically by invading the private space of an individual with "nano-implants." In this regard, who manages it would be a very important question. It could be manipulative in the hands of the powerful; this is very true in the context of Indian social setup. In India it can lead to uneven distribution of knowledge, power and wealth as there is the extreme inequality in all aspects of life (Sharma & Noopur).

Anonymity, the issue of intellectual piracy in the form of documents and software cracks, are already posing threats to the security of the nation. Erosion of the cultural values is one of the issues that India faces today in the field of Information Technology. Health related problems and emotional insecurities plague the young Indian generation who work in the IT field. Information technology has brought in a sort of colonization whereby the talents of the young generation are tapped without adequate remuneration and other work related rights of the professionals. Information technology coupled with nanotechnology can raise unprecedented ethical problems in the context of India. The power generated by knowledge can easily be manipulative in the social setup of India as many live in subhuman situations with evils like social inequalities, gender disparities, and poverty. The plight of the best talents in the country to the IT sector adversely affects the fundamental research in other branches of science.

Emerging Contexts and Future Directions

This section discusses some of the active bioethical issues in the country and the possible challenges that India will have to address in the near future and suggests some directions for the future course of bioethics in India.

Conflict of Interests

India, especially the southern state of Kerala, seems to be at the epicenter of the world's endosulfan debate in recent times. India is the largest manufacturer and exporter of the pesticide and its second largest user. As the debate on endosulfan has been gaining momentum in the Stockholm Convention in Geneva, Kasargod, a district in the state of Kerala, has been highlighted as a classical case of the nightmare with a certain population of brutal victims attributed to the misuse of this pesticide, with the aerial spraying of the same by plantation corporations. Even when most other countries are supporting a ban on endosulfan, the Government of India is opposing a ban against the persistent pressure from the state of Kerala. Settling this open debate in the country will have wider ramifications for the bioethical concerns in the country.

Labeling Laws

The absence of labeling laws in India has been exposed by the hot public debates in recent months on the release of Bt-brinjal, the genetically modified form of the vegetable, in India. The Genetic Engineering Approval Committee is the recommendatory body for clearance of such crops. Though cleared by the GEAC, a series of public consultations organized by the Ministry of Environment led to a moratorium on commercial cultivation of Bt-brinjal.

Toward Justice

A contextual challenge to the bioethicists in India is posed by the inefficient and unjust health care delivery system because of which the benefits are not available to all sections of society. It is unto the bioethical theorists in India to sensitize the Indian doctors to the national efforts to provide quality health care to all, especially in the rural areas.

The Interdisciplinary Pursuit and Networking

The networking between the governmental bodies of the Indian Council of Philosophical Research (ICPR) and ICMR can accelerate the promotion of bioethics in India. Teaching ethics is strong in the faculties of philosophy in the various universities in India but with inadequate integration of the bioethical discussions. Interdisciplinary attention to be paid to the development of the bioethics is all the more crucial in the diverse and polyvalent context of bioethics in India. The current bioethical theorists and champions are not adequately equipped to promote this interdisciplinary exercise. Hence, a serious engagement between the various stakeholders in related fields is important for the effective promotion of bioethics in India.

Engaging the West

The dream project of ICMR like the development of a uniform curriculum for bioethics blending the Western philosophical and theological streams with the noble Indian conceptual and religious traditions which sensitizes the Indian context and Indian reality, if duly materialized, will be a significant contribution to the international project of bioethics with the rare addition of local sensitivity and global responsiveness, a mandate for the international community of bioethics at large. Those engaged in bioethics in India seem to be placed at the polar ends of the uncritical accommodation or blind negation of the Western bioethics in India. Indian thinkers need to learn to engage the West in a more constructive and informed manner.

Legal Enactment

Ethical guidelines in the country often lack the teeth with no legal promulgation. India is a country with poor law enforcement, and the soft-pedaling on ethical guidelines results in almost defeating the very goal. For instance, in the recent ruling on euthanasia, the Supreme Court of India has called for the parliament to build the principles outlined in its ruling into humane legislation.

The Holistic Matrix

The dormant principles in the Indian paradigm of bioethics disclose the cultural, social, religious, and existential embeddedness of the ethical issues. The model of India might call for the deeper issues at stake in an effort to resolve it. The Indian model postulates the wider philosophical and spiritual horizons of decision-making in bioethical issues.

Infrastructure

The bioethical activities in India may be coordinated under a single umbrella by erecting a National Bioethics Commission which addresses ethical problems pertaining to science and society, engages in deliberations, and advises the government and the public.

Conclusion

This chapter discussed firstly the bioethics infrastructure in India elucidating the role of the Indian Council of Medical Research in promoting bioethics in India through workshops, networking with international bodies, establishing ethics committees, formulating guidelines, training programs, and developing a curriculum. Next, the roots of the biomedical ethics in India are explored in reference to the traditional Indian medical system of *ayurveda*. The subsequent part dwells on the bioethics issues and discussions related to beginning of life, end of life, health and disease, health care system, genetics, reproductive medicine, medical research, public health, information technology, and nanotechnology. The current state of affairs with each of these issues in the country at the applied, legislative, academic, and social level was presented, and the concerns about them were expressed. The common strand of perception emerging from these discussions was that though ethical sensitivity is present in all these issues, the need for systematization and infrastructure development with definite shape and mandate are imperatives for the development of bioethics in India. It has also been noted that a systematic and standard approach and an organized way of dealing with ethical issues are missing in the Indian medical setting. Some suggestions for the development of bioethics in India in order to address the future challenges from emerging context are also made.

Challenges, Changes, Concepts for Future Generations

Soenarto Sastrowijoto, S. Yati Soenarto, Nur Azid Mahardinata, and Wika Hartanti

Introduction

Values and ethics in medicine have been discussed since ancient times: in Chinese medicine (2838–2698 BCE), in Babylonia (the Code of Hammurabi, 1780 BCE), in Sanskrit documents in India (1500 BCE), and in Greece (the Hippocratic Oath/Corpus, 430–330 BCE). In the following centuries, the teaching of ethics was found in the curriculum in China (AD 618–906), Rome (Galen, AD 700), and

DOI 10.1007/978-94-007-2512-6_28,

Arabia (al-Ruhani and Ibn Sina, Canon of Medicine, AD 900–1200). During the seventeenth century, the teaching of ethics was included in the curriculum in European medical education (Paris, Padua, Vienna, Leiden), and in the following centuries, America lead the way in medical education (Calman, 2007).

Since the 1960s, the emergence of the field of bioethics has been closely related to rapid progress in science and technology in the biological and biomedical sciences. The term *bioethics* was first used by Aldo Leopold (1949), a land ethicist and conservationist, and by Van Rensselaer Potter (1970), a cancer specialist. Bioethics can represent a radical transformation of ancient and traditional medical ethics (Callahan, 1995; Widdows, 2011).

Medical and health education in Indonesia was begun by the Dutch government in 1894 in Batavia/ Jakarta and Surabaya, 1913. After Indonesian independence in 1945, the Faculty of Medicine at Universitas Gadjah Mada (UGM) Yogyakarta was established by the government of the Republic of Indonesia as a public university. In 2012, there were 72 medical schools in Indonesia, located in various provinces. Ethics education for medical students in Indonesia has been improving, particularly since in 2000, when each school of medicine developed a unit or team of Ethics or Bioethics and Medical Humanities. The term *bioethics* was first formally used in Indonesia at the School of Medicine UGM (1997) in developing the Bioethics and Medical Humanities Team, chaired by Prof. S. Yati Soenarto, Ph.D. After a conference titled, "The Bioethics 2000: An International Exchange," organized by the School of Medicine UGM in collaboration with the Harvard School of Medicine, each medical institution developed a unit or team of Ethics or Bioethics, appropriate to their own situation or condition.

Here, the development of ethics, bioethics, and global bioethics, particularly in schools of medicine in Indonesia, will be clarified and discussed as it relates to education, research, health and medical care. Nationally and internationally, networking, partnerships, and collaboration among health and medical institutions and professional organizations will be briefly reported.

Organizational Development of Bioethics in Indonesia

The term *bioethics* was used at the national level in developing the Indonesian National Bioethics Commission, or Komisi Bioetika Nasional (KBN, 2004).[3] Before the KBN, the term *bioethics* was used at the School of Medicine UGM in developing the Bioethics and Medical Humanities Team (1997) and in a scientific meeting, "Bioethics 2000: An International Exchange." This successful scientific meeting was carried out at the School of Medicine UGM in partnership with Harvard Medical School and was followed by the development of the Indonesian Health Bioethics and Humanities Network, or Jaringan Bioetika dan Humaniora Kesehatan Indonesia, and their first national conference (JBHKI, 2000).[4] JBHKI holds periodical bi-annual meetings and the School of Medicine UGM is the permanent secretariat office. These meetings have been held in Yogyakarta (2000), Bandung (2002), Jakarta (2004),

Surabaya (2006), Medan (2009), and Semarang (2011); in 2013 the meeting will be held in Padang. Most schools of medicine in Indonesia has developed a team, unit, division, center, or department of Bioethics and Medical Humanities.

Ethical commissions related to medical and health research have been established, such as the "Komisi Nasional Etika Penelitian Kesehatan" (KNEPK, 2005), or the National Commission of Health Research Ethics, to develop various national guidelines of ethics in medical and health research. At the institutional level (schools of medicine or hospitals), there is the "Komisi Etik Penelitian Kesehatan Institusi" (KEPKI), or Institutional Review Board (IRB). At the national level of the Indonesian Medical Association there are committees related to ethical, disciplinary, and legal issues in the practice of medicine. Ethics committees related to education, particularly at the higher education institutions, have been developed and are quickly growing. At the schools of medicine, these committees for medical students, faculty members, and nonacademic or support staff have been established in some universities.

Internationally, Indonesia, in partnership with the other countries (Taiwan, NTU and TMU; Malaysia, USM; USA, University of Washington at Seattle, Harvard; The Netherlands, AMC; and Australia, Monash University), developed "UBHEN" (University Bioethics and Humanities Education Network). This network plans partnerships in teaching bioethics, particularly in master's programs in bioethics, collaborative research or studies, and conferences in bioethics.

Bioethics in Medical Health Education

The teaching of bioethics is still developing in Indonesia, especially in the face of global progress in science and technology. The medical curriculum developed in the first generation was science based, and in the second generation it was problem based, focusing on innovation and values; the third generation (system based) includes leadership (Frenk et al., 2010). Bioethics/values and innovation was implemented in Indonesia in 1997, and the Indonesian Medical Council approved national standards in basic medical education and postgraduate medical education, particularly in specialty training. Currently, medical education in Indonesia uses competence-based curriculum (CBC) to produce professional medical doctors, meaning that medical students must be trained and pass examinations in knowledge, skills, and behavioral competencies (WFME, 2003; KKI, 2004). Among 72 schools of medicine, if we ask who teach bioethics the responses of each school are various. This is our challenge, and it might also be the case in the other countries.

Teaching Bioethics in CBC Medical Education

Based on the International Standards in Medical Education (WFME, 2003), medical education as a continuum of education consists of basic medical education

(undergraduate and graduate) standards, postgraduate medical education (master's and doctoral degree programs and specialist–subspecialist training programs) standards, and standards of continuing professional development (CPD) program. All of these programs should be carried out through CBC, consisting of cognitive, psychomotor, and affective domains competencies. The teaching and learning process should be carried out in the school setting, clinical setting (primary, secondary, and tertiary care), community setting, laboratory setting, and any other setting in the practice of medicine. The methods of education should be innovative and include problem-based and integrated teaching and case discussion.

The teaching of bioethics should be integrated into all activities of medical students (lectures, tutorials, laboratory practice in biomedical sciences, clinical, bioethics/humanities, community, etc.) (Boelen, 1999; Cruess, Cruess, & Streinsert, 2009; Frenk et al., 2010; WFME, 2003). There is a clear relationship between the development of moral ethics, biomedical ethics, bioethics, and global bioethics and a new sense of medical professionalism in practice. These issues may be linked with medical education to avoid a misalignment between the health care system and the medical education system (Castellani & Hafferty, 2010; Frenk et al., 2010; Van Lyuk, 2005; Passi et al., 2010). In developing medical professionalism for future doctors, some issues should be seriously considered, such as curriculum design, student selection, teaching and learning methods, role modeling, and assessment methods (Passi et al., 2010).

There is agreement in Indonesia that teaching bioethics and medical professionalism should be carried out via a continuum process and program, in a conventional or innovative curriculum (Fig. 67.1).

The implementation of the teaching and learning of bioethics and medical professionalism is integrated into all student activities: lectures; tutorials; laboratory practices in biomedical sciences, bioethics and humanities; clinical skills, community health; and interprofessional skills. All activities in undergraduate and clinical rotation, in postgraduate programs (master's degree, doctorate, specialist, subspecialist) and in CPD are carried out in a continuum process.

Student assessment in the CBC program is based on students' competencies in the cognitive (C), psychomotor (P), and affective (A) domains (Fig. 67.2):

All schools of medicine in Indonesia are implementing this national guideline model of teaching bioethics, appropriate with the conditions of each institution. Examples include the following:

1. The Universitas Jendral Soedirman (Purwokerto) adapted the CBC and PBL. Teaching bioethics for medical students in the school of medicine is coordinated by the bioethics team. In 2007, a bioethics subdepartment was established under the Department of Public Health and Community Medicine. Teaching bioethics in a Block of Bioethics and Health Law (BHL) was organized by the subdepartment of Bioethics with five academic staff (two full-time and three part-time). In early 2012, the School of Medicine developed the Department of Bioethics, with seven staff (three full-time and four part-time from the other department's faculties). Bioethics teaching is now organized by the Department

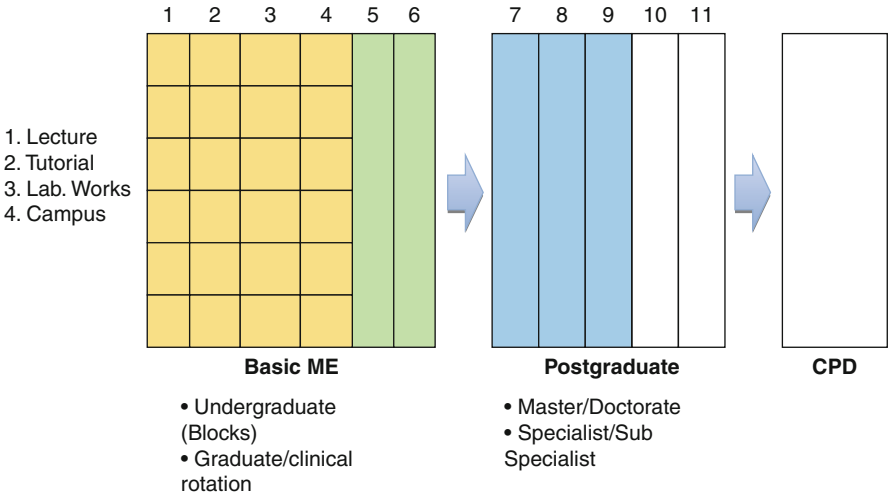

Fig. 67.1 A continuum process of bioethics teaching in medical education (basic, postgraduate, continuing professional development) (Sastrowijoto, 2006)

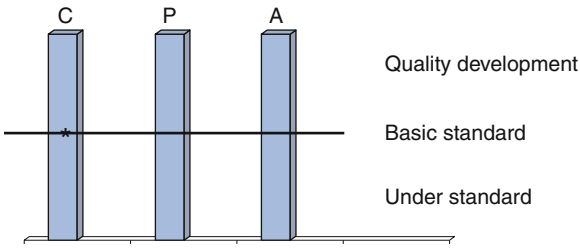

Fig. 67.2 Competence – based – curriculum examination (pass and failure). Minimal standards score of student should be achieved before graduation in all C, P and A competencies (Sastrowijoto, 2006)

of Bioethics, which collaborates with the Bioethics Team from the Faculty of Biology and with the Medical Education Unit.

2. At the Universitas Padjajaran (UNPAD, Bandung), the School of Medicine established the Bioethics and Medical Humanities Unit in 2001 to manage the teaching of bioethics for undergraduate medical students. This unit is supported by faculties from various departments, including obstetrics and gynecology, surgery, psychiatry, forensics, neurology, pediatrics, anesthesiology, internal medicine, and public health. Bioethics teaching is integrated into lecture themes, tutorial case scenarios, and other activities. The UNESCO core curriculum, developed in 2008, influenced the curriculum significantly. The school has used a fully student-centered approach since 2000. Each clinical department develops bioethics teaching related to their field of study and has the responsibility in teaching bioethics in the clinical rotation/clerkship and residential training.

3. At the Universitas Muhamadiyah Jakarta (UMJ), the Team of Bioethics, Medico Legal and Human Rights was established in 2007, and in 2011, related to teaching bioethics to undergraduate medical students, a new team was approved by the dean of the school, the Team of Bioethics–HELP (Humanity, Ethical, Legal and Professionalism). The team is chaired by Dr. dr. H. Anwar Wardy, Neurology and Forensic Medicine, and the secretary of the team is dr. H. Amir Syafruddin. Teaching of bioethics in integrated in various medical student activities in the CBC implementation.
4. At the Universitas Pembangunan Nasional "Veteran" (UPN) Jakarta, bioethics teaching is organized by the Medical Education Unit, in a continuum process for undergraduate medical students, with teaching and learning processes through various student activities such as lectures, card games, mini-seminars, role play, debates (devil's advocate), and workshops. Bioethics and medical humanities modules were developed to support the program, and all are organized by a program coordinator.
5. At the School of Medicine Gadjah Mada (UGM), teaching bioethics formally started in the competence-based curriculum (2002–2007), in a special block of bioethics at the end of first-year undergraduate education, Block VI. After a 5-year program evaluation, the result was that the student perception of this block of bioethics was that of lectures in theory and understanding of bioethics and medical humanities. Students have no experience with the internalization process, implementation in case discussion, or real cases in practice of medicine (the clinical setting); the program had little opportunity for students to mature in their character. With the new CBC (2007–2012), the teaching/learning process was integrated in varies activities of students, such as lectures, tutorials, laboratory practice in the new bioethics and humanities lab, clinical skills lab, community or public health lab, and on campus or in the teaching hospital (inter-professional training). In clinical rotation or clerkship and residential training, teaching bioethics was organized by each clinical department. On the other hand, faculty members (clinicians) should be trained in mentoring students, integrated with the apprenticeship concept, and the positive feedback is very important.

In teaching bioethics, particularly global bioethics in the era of globalization (liberal and free market), the appropriateness to local and national wisdom should be carefully considered, analyzed, and discussed. The concepts of local and national wisdom, tradition, culture, religion, and pluralism should be included in the teaching of bioethics, through small group and panel discussion, stimulated with cases (real or theoretically developed, simulation, etc.). The new sense of global bioethics is the concept of bioethics involving national ideology, philosophy, and wisdom, cultures, traditions, religions, and pluralism. These wisdoms, such as Pancasila (Indonesia), Rukun Negara (Malaysia) Semaul Udong (Korea), Confucianism (China), Hinduism (India), and Buddhism (Thailand), should be implemented to balance the liberal and free market concept of bioethics. In the long run, the balance of Western bioethics and Eastern (Asia) bioethics could minimize or eliminate

global injustice and inequities, particularly for disadvantaged populations worldwide, for the happiness and harmony of individuals, families, and communities in the future (Sastrowijoto, 2010).

Graduate Certificate, Graduate Diploma, and Master's Program in Biomedical Ethics

In responding the needs and demands of bioethics teachers, the development of graduate certificates, graduate diplomas, and master's programs in bioethics should be a priority not only in Indonesia but also in all Asian and Asian Pacific countries. The importance of the program is related to the moral obligation and responsibility of the university to their social mission (Horton, 2010). With the advance of science and technology, social justice needs to be rediscovered; a "remoralization" of health professional education is needed (Frenk et al., 2010) and international standards in medical education (WFME, 2003).

Nationally, graduate certificate, graduate diploma, and master's programs in bioethics have been carried out at the UGM and could be developed at the other universities (e.g., University of Indonesia, University of Airlangga, and University of Padjajaran). Internationally, these four universities have collaborated with University of Washington in Seattle. UGM is also developing partnerships with TMU in Taiwan, USM in Malaysia, and Monash in Australia to have an international master's and PhD program in bioethics and medical humanities, in collaboration with Harvard, UW Seattle, and AMC Amsterdam. The road map of the curriculum could inform the development of the curriculum at USM, TMU, NTU, and Monash, and vice versa.

The road map of the curriculum of the Graduate Diploma and Master Program in Bioethics and Medical Humanities consists of eleven blocks and includes international graduate certificate, diploma, master's, and PhD programs in bioethics and medical humanities. It is a collaboration between UGM, TMU, USM, NTU, and Monash, in partnership with HMS, UW/ Seattle, and AMC (2013) (Table 67.1).

The objective of this master's program in bioethics is:

- To educate the participants with important issues related to bioethics (Humanity, Ethical, Legal, and Professional Behavior aspects, HELP) of local, national, regional, and international health care, research, and education.
- To pay specific attention to the Asian–Asian Pacific national and regional wisdoms, traditions, cultures, and religions, as a pluralism.
- To promote the debate and exchange of experiences and ideas among participants and staff, and the possibilities of developing collaboration or partnership.
- To prepare participants in teaching and training in bioethics at their own institutions, applying bioethical concepts in health care, research, and education.
- To promote the participants in exploring their national wisdom to support the continuing development of the new concept of global bioethics for the future generation to eliminate the global inequities and injustice

Table 67.1 The road map of the curriculum (UGM, 2013)

Out put	Blocks		Contents	Credits
Graduate CERTIFICATE 33 credits	Core	I	Bioethics, General Theory and Methods	4
		II	Bioethics, the Development and Its Applications	3
		III	Bioethics, 'HELP' Aspect Approach (Humanities, Ethics, Legal, Policy/ Professionalism)	3
	Core Specific	IV	Bioethics in Medical – Health Care	5
		V	Bioethics in Medical – Health Research	5
		VI	Bioethics in Medical – Health Education	4
		VII	Bioethics in Global Health System	4
	Optional	VIII	Bioethics 'HELP' Aspect Approach, Case, Discussions and Lectures	5
Graduate DIPLOMA 37 credits	Core	IX	Writing – two case reports – one literature review Inter-university activities (Research, Symposium, Seminar, Video Conference, and Publication)	4
MASTER in Bioethics 45–50 credits		X	Research Methodology and Biostatistics	3
		XI	Thesis for Master in Bioethics	
			– By Course (Research Proposal)	5
			– By Research (Research)	5
				50

The implementation of this program:

- The type and timeline could be part time or full time. The first graduate in the graduate diploma at UGM was part time, due to the fact that most of the participants must follow the regulations of their institution as lecturers and even as managers related to their limited human resources.
- The format of program could be a joint, double, or dual program between UGM, TMU, USM, NTU and Monash.

Bioethics in Medical Health Research

Currently, research in School of Medicine UGM, institutionally, nationally, and internationally is coordinated by the dean's office in inter-country or inter-center collaborative studies. The rapid advanced of science and technology in medicine, clinical trials, and translational research encompasses a complexity of medical professionalism in the social complex system (Campbell, Chin, & Voo, 2010; Castellani & Hafferty, 2010; UNESCO, 2008). In comparing the capacity building of each medical institution, they must develop strong biomedical (biomolecular) studies, clinical studies, and public health studies and improve translational research collaborations and partnerships with various stakeholders. In this case, the A-B-C-F-G partnership – A (Academicians/University), B (Business),

C (Community), F (Funding Agencies/Foundation), and G (Government) – and the possibility of bioethical issues must be seriously considered (Sastrowijoto, 2011).

There are some issues that should be analyzed, clarified, and discussed to improve the quality standards of studies, scientifically and ethically:

1. The ethical and regulatory aspects of health research, e.g., (a) scandals and tragedies in health research, (b) guidelines in health research involving human and animal participants, (c) health research in certain populations (communities, pregnant women, children, captives, those with impairments, etc.).
2. Ethics imperialism, e.g., in international collaborative clinical trial/translational research, from developed to developing countries, usually engaging cross-cultural ethics. Are ethics local or global?
3. Issues of conflict of interest: in international or inter-center studies, before the study will be started, some kinds of agreements should be considered and agreed upon, e.g., material transfer agreement (MTA), the owner of the specimen, data, equipments, the right of researcher(s), sponsor(s), research participants, authorship, patency, product(s) marketing, etc., and all should be based on fair sharing benefit principles.
4. Scientific misconduct, informed consent, report writing, and publication should be seriously considered.
5. The needs of the DMC (Data Monitoring Committee), DSMB (Data and Safety Monitoring Boards), and CIC (Conflict of Interest Committee) should be considered and developed by sponsor(s) and author(s) if necessary.
6. How should the A-B-C-F-G partnership be managed to eliminate or minimize financial conflict of interest and other issues of interest among parties?

In clinical trials/translational research, the clinician is also a researcher, and also a guardian of the patient's health and welfare, including safeguarding the freedom and safety of the patient, who is also the research participant. In gaining informed consent, the following must be seriously considered: Who is to be served of his/her two masters? Indonesia is one of many countries that is a common site of clinical trials. In balancing global bioethics in a global era of corporatization of education, research, and health care, there is a new sense of global bioethics to minimize or eliminate global injustice and inequities, particularly for those who are relatively powerless and who suffer most from these inequities. It is our responsibility to sustain the planet for future generations. They should live in a happy and harmonious world (Campbell et al., 2010; Sastrowijoto, 2010, 2011; Widdows, 2011). See Fig. 67.3.

Activities Related to Bioethics

Some activities related to bioethics at the institutional, national, regional, and international level, such as conferences, symposiums, workshops, courses, and scientific oral or poster presentations, will be briefly reported. National conferences in bioethics have been carried out regularly by JBHKI, regionally by Asian Bioethics Conferences, internationally in IAB World Conference in Bioethics, and by the UNESCO Chair of Bioethics.

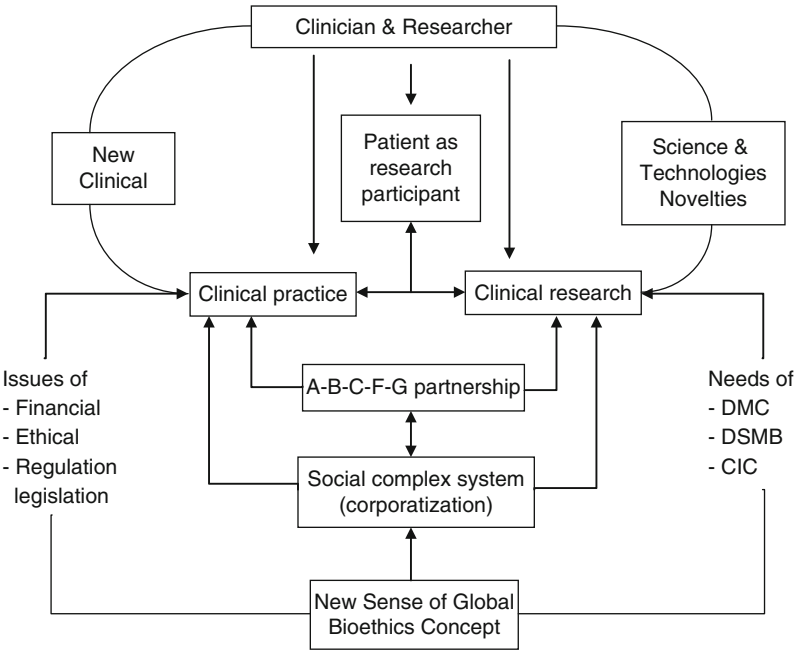

Fig. 67.3 The relationship of clinical trials and A-B-C-F-G partnership and the new sense of global bioethics

Examples from Some Schools of Medicine

1. Activities in Bioethics at the School of Medicine UPN "Veteran" Jakarta
   (a) "Teaching Bioethics and Medical Humanities at UPN "Veteran"." Oral presentation (2008)
   (b) "Role Play as the Instructional Media on Doctor's Professionalism in Teaching Bioethics, at UPN Veteran"
   (c) "Malpractice Victims Gathering as the Instructional Media on Doctor's Professionalism and Patient's Safety in Teaching Bioethics at UPN "Veteran"."
   (d) Fifth JBHKI conference (2009)
   (e) "Building Perspective Principle Based Ethics in Medical Student through Role Play Method." Oral presentation, 10th World Congress of Bioethics, Singapore (2010).
   (f) "Strategies and Instructional Media in Bioethics Teaching." Oral presentation, National Workshop USM (2011).
   (g) "Learning of Understanding in Culture through Game: A Study of Bioethics and Medical Humanities at UPN "Veteran"." Sixth JBHKI conference, Semarang.
   (h) "Devil's Advice as Learning Media on Bioethics and Medical Humanities at UPN "Veteran"." Oral presentation

(i) Poster presentation: "Field Study as a Mean of Developing Student's Responsibility for Their Professional Behavior."
(j) "Clinical Ethics Workshop to Review Medical Student (7th semester) at UPN "Veteran"."

2. School of Medicine UNSOED, Purwokerto
Beginning in 2008, research on "A comparative study on bioethics teaching between students from the previous curriculum (semester credits system) and the new curriculum (competence-based curriculum)." As of 2012, seven studies have been carried out; three have been analyzed and four are ongoing. More students have expressed interest in supporting bioethics studies.
3. School of Medicine UNPAD, Bandung
Some research, survey, and reviews articles, including the following:
(a) Multidisciplinary approach for bioethics education at UNPAD, from curriculum to online journal (2009–2012)
(b) Baby blues syndrome as an infanticide causal factor in the Conundrum of Indonesian justice system (2011)
(c) Implementation of bioethics education in residential trainee program (2011)
(d) Portfolio for assessing professional behavior (2010)
(e) Ethical issues in the case of high-cost public medical school in Indonesia (2010).
(f) The ethics and legal dilemma of clinical supervisory activities (2009)
(g) The Ethics-medico legal aspect of "forcep dismissal" of classical forensic in emergency unit (2009)
(h) Dilemma of the application of DNA paternity testing involving extra-marital children in Muslim society (2009)
(i) Social problem of disaster victim identification in tsunami Pangandaran (2009)
(j) Forensic aspects of the missing in post-conflict and post-disaster scenarios: Indonesian perspective (2007)
(k) Disaster victims identification in cultural and religions perspective (2005)
(l) Can DNA test for kinship determination could be accepted by Muslim law? (2004)

Future research, surveys, review topics may include:
(a) Indonesian perspective on various ethical issues and norm
(b) Education and assessment of professional behavior in residential trainee.

4. School of Medicine UGM, Yogyakarta.

Activities

A. Seminars, workshops, symposia
- 2000
  - Bioethics 2000: An International Exchange (Harvard Medical School – Gadjah Mada Medical School)
- 2007
  - Seminar and workshop: International Exchange on Teaching Bioethics for Medical Students.

- 2009
  - Seminar and workshop: Teaching Bioethics and Medical Humanities in Clinical Setting (AMC and GMC; TMU; USM; UW Seattle, UGM)
- 2010
  - Graduate courses in Bioethics and Medical Humanities (Grad. Certificate and Grad. Diploma) – (AMC, TMU, USM, UW, Harvard, UGM)
  - Will be continued to postgraduate program (master) for bioethics and medical humanities (BMH)
  - TMU suggested/ supported – Regional Master Program
- 2011
  - ABC meeting in Taiwan and visit/collaboration with TMU, NTU, NCKU, NCU, etc.
  - Developing "BEN" (Bioethics and Medical Humanities Education Network) – TMU, USM, AMC, UW, UGM. MEEN/ BMHEN?
    MEEN (Medical Ethics Education Network)
    BMHEN (Bioethics and Medical Humanities Education Network)
  - USM – Meeting: Seminar on Ethics Teaching Common Approaches for Regional Teaching: "Ensuring a Sustainable Tomorrow"
  - Bangkok meeting. Asian Pacific Bioethics/ UNESCO
- 2012
  - Symposium number 42 in 11th World Congress of Bioethics (Rotterdam, June 26– 29 2012) "Thinking Ahead: Bioethics for the future – challenges, changes, concepts"
  - Topic: The Graduate Diploma and Master Program in Bioethics and Medical Humanities: Partnership of UGM-TMU-USM and its Collaboration with UW-Seattle and AMC-Amsterdam.
    A New Sense of Global Bioethics for the future.
    Note: – Courses on Bioethics by WHO–SEARO (New Delhi),
  - UNESCO (Bangkok), NIH (India, Jakarta) etc. UI and UGM
  - UW at Seattle – UI, UNAIR, UNPAD, UGM

B. **Research Activities**

- 2000
  - Similarities and differences of the faculties' and students' perception on teaching bioethics, Harvard/ UGM – Fulbright
- 2003
  - End of life: medical care in Indonesia. Harvard/ UGM – Aminef/ Fulbright
- 2003–2008
  - Tobacco Cessation in Indonesia/ Quit tobacco – Arizona/ 2009–2014 UGM – NIH/ Fogarty
- 2003
  - Field testing "Teaching Guideline and Case Material" for SEARO countries – WHO.

- 2004–2006
  - Health system reform and ethics: Private Practitioners in 2006–2008 Poor Urban Neighborhoods in India, Indonesia & Thailand. DANIDA –Aarhus – AIIMS – DANISH – Naresuan – Gadjah Mada.
- 2005
  - Refinement and Dissemination of the Teaching Guideline and Modules for the Medical School in Indonesia – WHO
- 2006–2007
  - Supporting young children in disaster area/ Aceh. Bernard Van Leer – The Netherland.

Future Studies

1. Pro-life and pro-choice attitudes about **abortion** among religions, gynecologists, women, etc. in Yogyakarta.
2. **Euthanasia** – perception among practitioners, patients, and the family in Yogyakarta.
3. Medical **tourism**, medical practitioners, patients, national policy (authority) perception and action.
4. Exploring local/national wisdom, related to components of **professionalism** in Indonesia (*iman*: faith, belief, creed; *luhur*: noble, nobleness, budiluhur: noble-mind, beriman: faithful).

Other schools of medicine have experienced various degrees of progress depending on their situation and the condition of various available resources and their own school's programs. UI, UNAIR, UNHAS, and USU have various researchers and activities and will likely develop graduate diploma and master programs.

Bioethics in Medical-Health Care

All Indonesian medical and health care institutions, public and private, must appropriately implement in their activities according to the regulations and guidelines developed by the Indonesian Medical Association (Code of Ethics Conduct) and regulations from the central and local government. The Medical Practice Act (2004) requires each medical-health care institution to develop its own local and institutional standard operational procedure (SOP) based on the available resources of human expertise, buildings, laboratories, medical-health equipment, and so on.

Because Indonesia is a large country, a main issue is the allocation of scarce resources. In discussing medical-health care issues, Indonesia is faced with conflicting problems in the health care system. First, health care and the education system must respond to the increasing needs and demands of health care with the highest medical and health technology (e.g., genetic diagnosis and treatment, organ transplantation, etc.). Second, for some rural areas of Indonesian people, even basic health care services is not yet well distributed.

In developing national regulations and guidelines and the institutional SOP, we adapted various available scientific resources, such as the "Clinical Ethics for the Medical House Officer, General Principles and Cases" (Forrow, Zand, & Baden, 1999), "Clinical Ethics" (Jonsen, Siegler, & Winslade, 2010), and "Medical Ethics and Law: The Core Curriculum" (Hope, Savulescu, & Hendrick, 2009), as appropriate with Indonesian national wisdom, cultures, traditions, religions and pluralism.

Global Bioethics Challenges, Changes, and Concepts for the Future

At the beginning of the twenty-first century, we must consider the effects of two different and conflicting processes. First, rapid progress in medical science and technology has made available new and more effective diagnosis and treatment of diseases that were once considered incurable. Second is the global health condition marked by injustice and inequities due to the poverty and the seriously lack of access to health care (UNESCO – IBC, 2009; UNESCO Report, 2010; Frenk et al., 2010). Another condition is the concept of the free market idea in the era of globalization, which is closely related to freedom, liberty, autonomy, individualism, liberalism, capitalism, colonialism, imperialism, and **corporatization** or **commercialization** of health care. Other issues are the implications of the new ways of corporatization, colonialization, capitalization, and imperialization from developed to the developing and from advantaged to disadvantaged groups of populations in a country and among countries; all are emerging challenges to bioethics and must be responded to by changes in the global mindset, developing a new concept of global bioethics in the local and global context.

Bioethics is considered a systematic multi-disciplinary field of study that is closely linked to various science and technological developments and is strongly related to a wide range of issues: politics, economics, humanities, education, environment, tradition, cultures, religions, pluralism, and globalization (Nasim, -). The economic and political positions of developed countries and advantaged population groups are growing stronger. They are exploring natural resources (forestry, mining, etc.) and developing big companies and factories with large capital investments (Ronald Cohan, 2012), employing the disadvantaged group of population without sharing benefits appropriately and sometimes inhumanly. Global warming and climate change may present further natural, political, economic, psychological/mentally, ethical, legal, and human disasters and crises (Nasim, -; UNESCO – IBC, 2009; UGM, 2010).

A global mindset is the ability to perceive, analyze, and decode behaviors and situations in multicultural contexts and to use those insights to build productive relationships and organizations across cultural boundaries.

Why this new concept of bioethics for the future development? First, the rapid progress of science and technology, including biomedical or molecular studies, began in the 1960s and 1970s, followed by the overexploitation of natural resources (oil and wood), which has lead to economic growth. On the other hand, global

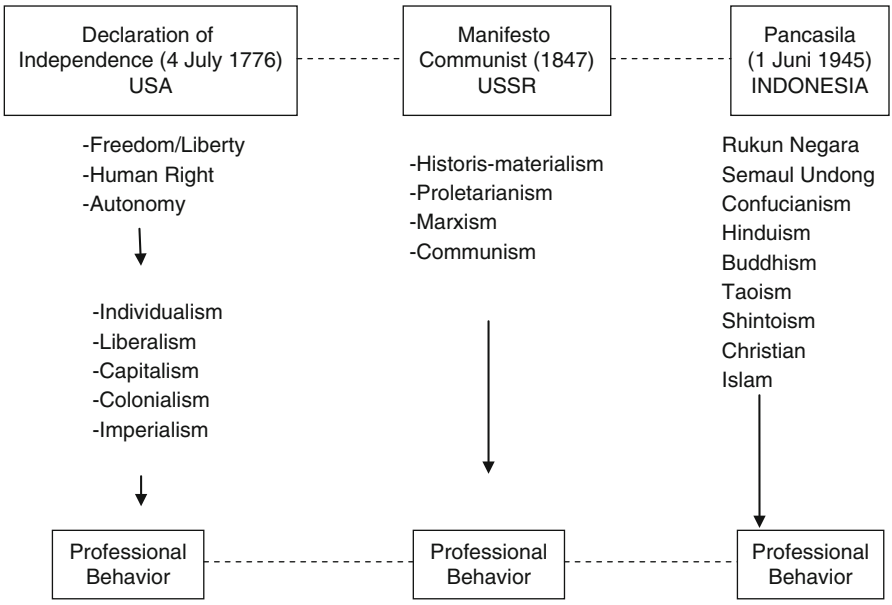

Fig. 67.4 The development of professional behavior based on their own local/national wisdoms. Contribution in social complex system and global professional behavior

climate change and various disasters also resulted. The other result of the overexploitation of natural resources is the fragility of "our one and the only world." We must also consider our moral responsibility for future generations. Another issue is the commitment of universities to the health of the disadvantaged and other underserved people. Have some universities come to do research "on people" rather than "for people"? The goal of the UN in this decade is for better education and health for all, adequate shelter, respect for human rights, rational use of resources, a culture of peace and nonviolence, and international solidarity (Blumental and Boelen, 2001).

The Universal Declaration on Bioethics and Human Rights stresses the need to reinforce international cooperation in the field of bioethics, taking into account, in particular, the special needs of developing countries, indigenous communities, and vulnerable populations.

How should we respond? Serious discussion should involve local or national wisdoms, ideologies, philosophies, cultures, traditions, and religions to develop a new concept of global bioethics. In developing a new concept of global bioethics, one starting point might be to discuss and analyze the differences and similarities between three basic national philosophies: the Declaration of Independence (USA, 1776), the Communist Manifesto (USSR, 1847), and Pancasila (Indonesia, 1945) (Fig. 67.4.). The Declaration of Independence is based on the philosophy of freedom (liberty, human rights, and autonomy); the Communist Manifesto is based on histories of materialism, proletarianism, and communism.

Pancasila, the state ideology of Indonesia, is based on the following five principles:

1. Ketuhanan Yang MahaEsa (Value of divinity or diety or faith)
2. Kemanusiaan yang adildanberadab (Value of humanity)
3. Persatuan Indonesia (Value of unity)
4. Kerakyatan yang dipimpin oleh hikmat kebijaksanaan dalam permusyawaratan perwakilan (Value of deliberated democracy)
5. Keadilan sosial bagi seluruh rakyat Indonesia (Value of social justice for all)

The ideology of *Rukun Negara* (Malaysia) consists of:

1. Kepercayaan kepada Tuhan (Belief in God)
2. Kesetiaan kepada Raja dan Negara (Loyalty or allegiance to king and country)
3. Keluhuran perlembagaan (Grandeur or lofty or uprightness of the institution)
4. Kedaulatan undang-undang (Act's sovereignty)
5. Kesopanan dan Kesusilaan (Good manner and morality)

Semaul Undong (Korea) is the spirit of the Korean people:

1. Change of Korean people's mindset
2. Innovation in every activity
3. Hardworking behavior
4. Honesty
5. Collective spirit

Confucianism (Boyle & Theol, 2004), the origin of morality in China, values: Traditional Chinese thought directed to social, political, educational and moral action – as the ancient Chinese medical ethics. The origin of morality in China are REN, YI, LI, and ZHI.

The contemporary China in facing modern bioethics debate such as moral status of the fetus, abortion, healthy birth and eugenics, physician – patient relationship, death and euthanasia, reproductive technology and genetics, basically the same with the original morality in China (REN, Humaneness, YI- Righteousness, LI-Propriety and ZHI –wisdom) – a virtuous person.

1. REN (humaness: love, humanity)
2. YI (righteousness: rightness, wise, justice)
3. LI (propriety)
4. ZHI (wisdom)

The ideology of *Taoism* (Hsin, Hsin Chen, & Macer, 2004) includes:

1. The importance of "quality of life and quality of death"
2. Letting life and death follow its natural course
3. Seeing death as a return to the nature

The people of Taiwan may adapt ancient the Chinese philosophy of Confucianism, Buddhism, and Taoism as their value system.

Hinduism:

1. Nature as the teacher, enriching human's wisdom.
2. A diverse body of religion, philosophy, and cultural practice native to and predominant in India, characterized by a belief in reincarnation and supreme being many forums and nature, by the view that opposing theories are aspects of one eternal truth, and by a desire for liberation from earthly evil.

Buddhism:
Vertical philosophy of nature:
1. Arupadhatu (wisdom)
2. Rupadhatu (enlightenment, free from carnal desire)
3. Kamadhatu (carnal desire)

Japan:
Shintoism and Buddhism:
1. Meiji government, with the slogan of "a rich country and strong army and navy"
2. Western trades – Christianity (The Netherlands, Russia, England, France, America), in equal treaties.

Christianity:
1. All of the God's creations provide comparable values.
2. The moral excellence or virtue of theology of faith, hope and love or affection.
3. The virtue of Christianity are prudence, justice, temperance, fortitude and excellence.
4. There are Beato and Santo related to miracle of healing.

Islam:
1. Human beings are the crowning creation, as a God's agents are endowed with responsibility in the care and stewardship of others (humans, animals, plants, microbes, and the environment)

These national wisdoms could be globally organized to develop new principles based on **social investment**, called "A New Sense of Global Bioethics." This new concept would balance the old sense of global bioethics, which is based on **capital investment** and the liberal free market.

Professional practitioners must develop clinical and ethical decisions that are scientifically, ethically, legally, and humanly based (Sastrowijoto, 2005). Currently, the ways of practicing medical professionalism have developed into various competing types or clusters and might be influenced by the concept of neo-materialism, neo-individualism, and neo-liberalism in the globalization era through corporatization and commercialization of health care, research, and education (Castellani & Hafferty, 2010). The type of medical practice that could be observed or studied in Indonesia could be predicted to be not much different than what had been studied by Castellani and Hafferty in the US.

The contribution of local and national wisdoms and collaboration could serve as a strong foundation for a new sense of global professional behavior and a new concept of global bioethics in a challenging era in the twenty-first century (Fig. 67.5.).

Discussion

Teaching bioethics and professional behavior should be in a continuum process for the medical profession, using "heart," "head," and "hand," thought and feeling. When students and residents were asked about the teaching of professionalism, they said, "We are being asked to be professional in an unprofessional environment. Faculty should be subjected to the same criteria for assessment as students and

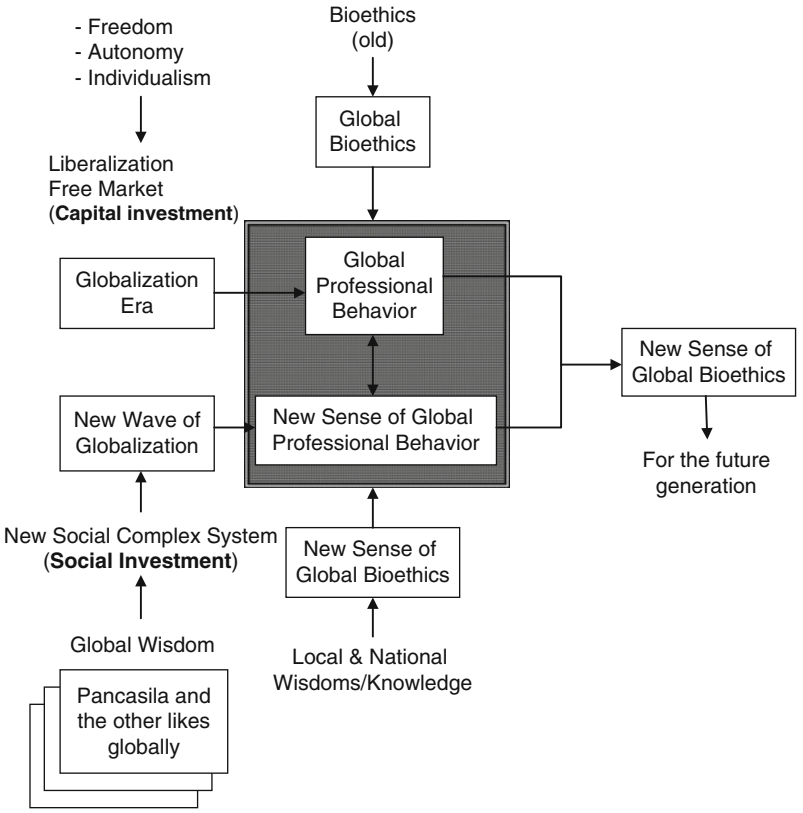

Fig. 67.5 Development of new sense of global bioethics, based on local/national wisdoms from around the world

residents" (Hundert et al., 1996; Hafferty et al., 1994; Sterm, 1998). Related to this issue, discussion of training cases should be carried out not only by the students and residents but also by all faculty members and nonacademic staff. The main goal is to improve institutional professionalism.

Basic concepts of moral/ethical principles (respect for person/autonomy, beneficence and non-maleficence, and justice) are influenced by globalization. One of definition of global bioethics is the ethics or the voice for those who are relatively powerless and who suffer most from global injustice, the poor and vulnerable (Widdows, 2011).

Students had the following views (Stigler et al., 2010) on professionalism in the twenty-first century: (1) students agreed on knowledge, skills, and attitude to be achieved by all doctors before graduation; (2) students should be involved in the entire process; (3) students from low income countries should have the benefit from such an initiative; (4) interprofessional forums should include medicine, nursing, pharmacy, and allied health professionals together; (5) students from all professions

and all countries should be involved in a joint planning mechanism. These students' views are worth including in developing medical professionalism in future doctors. A systematic review is provided by Passi et al. (2010). The development of medical professionalism might include (1) student selection, (2) curriculum design, (3) teaching and learning methods, (4) role modeling, and (5) assessment methods.

The Belmont Report (1979) lists the following basic moral principle of ethics: (1) Respect for person, (2) Beneficence, and (3) Justice. The following concepts (Beachamp TL and Childrens JT, 1979/ 1983/ 1989/ 1994/ 2002) have been put forward as the basic moral principles of biomedical ethics: (1) respect for autonomy, (2) non-maleficence, (3) beneficence, and (4) justice. A concept of biomedical ethics as an abstract "mantra" is empty of normal ingredients of moral concern without grounding in dominant ways of people in their day-to-day lives.

The term *biomedical ethics* developed into *bioethics* (Khushf, 2004). In the global era, *bioethics* became *global bioethics*, with various meanings, perceptions, and perspectives. It is different between West and East, and also between the advantaged and disadvantaged population groups. Today, challenges and changes should be responded to with a new concept, especially for the future generation. The basic moral principles in the twenty-first century may consist of (1) belief in God or faith, (2) respect for others (human, animal, plant, microbes, and environment/nature), (3) beneficence, (4) non-maleficence, and (5) social justice.

Conclusion/Summary

In Indonesia, the development of ethics, biomedical ethics, bioethics, and global bioethics has proactively engaged by the School of Medicine UGM in partnership with others in the face of challenges, changes, and concepts for the future generation.

Global injustice and inequities should be minimized or eliminated through the development of a new sense of global bioethics, involving local and national wisdom, traditions, cultures, religions, and pluralism. This new concept is an appropriate approach to responding the need and demand for qualified teachers, not only in Indonesia but also for other parts of the world.

Iran, Islamic Republic of

68

Alireza Bagheri

Introduction and Historical Background

The Islamic Republic of Iran is in the Middle East region, with a land area of 1,648,000 km^2 and a total population of 74 million. The per capita gross domestic product (GDP) was about 4,540 USD in 2009 (World Bank, 2009), with health expenditures at 5.5 % of GDP (WHO, 2009) and literacy rate at 76 % in 2002 (National Literacy Policies, 2002).

Like many other countries, there is increasing interest in bioethical issues in Iran. These issues have attracted scholars from different backgrounds, including medicine, biology, law, philosophy, and religion, however, physicians are the leading

figures in bioethics. Mostly, topics in medical ethics have been discussed in recent years. Based on the importance of Islamic opinions on different bioethical issues, Islamic scholars are involved in the discussion of issues such as abortion, artificial reproductive technologies, brain death, and organ transplantation. They have been called upon in early discussions by specialist physicians who seek their official *fatwa* on the issues. Given the fact that Iran is becoming a leading country in terms of overall growth of science and technology in the region, attention has been called by scientists to the ethical issues posed by recent scientific developments, and ethics experts urge policy makers to seek the necessary infrastructure to address related ethical issues.

This chapter provides a map of bioethics in Iran, including current developments, infrastructure, special issues, and future challenges. Before Islam (625 AD), Iranians were Zoroastrian, and religious teaching emphasized the behavior and character of medical doctors. For example, in a section of *Avesta*, the holy book of the Zoroastrians, entitled "Vendidad," there are explanations about the character of physicians and some ethical issues in medicine (Larijani & Zahedi, 2006). An analysis of the qualities of the ideal physician in the sixth century AD can be found in the Sassanian Persian's encyclopedia, *The Dinkard* (Najmabadi, 1987). After the introduction of Islam, based on moral Islamic teachings that govern all aspects of society, Muslim physicians inspired by religious encouragement put more emphasis on ethical values in their medical practice. The prophet of Islam, *Mohammad* (PUH), announced the perfection of morals as the aim of his appointment. He said, "I have been appointed as the prophet for the completion and perfection of morals" (Al-Mustadrak, Vol. 2, 1002 CE). Going back to the flourishing time of Iranian (Irani) medicine in medieval times, there was great attention paid to the ethical issues in medicine by the Iranian physicians such as Razes (865–925 AD) and Avicenna (Ibn Sina) (980–1038) in their books, teachings and medical practices. For centuries, their medical ethics instructions were dominant in the teaching and practice in medicine, and they were followed by other prominent Muslim physicians. A review of contemporary bioethics in Iran shows that the first academic book on medical ethics was authored by a physician at Tehran Medical School in 1963, *Medical Ethics and Customs*. In this book, Dr. Etemadian discusses ethical issues in medicine such as abortion, privacy, the doctor-patient relationship, confidentiality, and the moral character of physicians (Etemadian, 1963).

Development of Bioethics

Bioethics Activity: Medical ethics, led by physicians and health authorities was the main force behind the bioethical activity in the country. In the 1990s, ethical questions were raised by the application of assisted reproductive technologies (ARTs) and organ transplantation. Hence, the need to address related ethical issues became an emerging issue for the health authority. Therefore, some bioethics initiatives were the starting point to create the necessary infrastructure in biomedical ethics in the country. To this aim, the Center for Study and Research on

Medical Ethics was established by the Ministry of Health in 1993. The center was the first official organization working on ethical issues in medicine. However, it should be noted that the word *bioethics* and its translation into Persian as "Akhlaghe Zisti" appeared in scientific articles in late 1990. With the increasing interest in medical research in 1990s, the National Ethical Codes in Biomedical Research were compiled in 1997 (Farhadi et al., 2000).

In 1998, the National Research Ethics Committee to review research protocols was established by the Ministry of Health, and in the same year via an administrative order, all universities and research centers were instructed to establish an ethics committee for research. Currently, the National Research Ethics Committee is undergoing a major revision in terms of its structure, membership, and working methods. The development of national ethical codes in biomedical research and the establishment of research ethics committees across the country are two important tasks of the Center for Study and Research on Medical Ethics. The first international congress of medical ethics in Iran was held in 1994 and was a step forward towards promoting ethical discussions at the national level. The participation of physicians, lawyers, philosophers, religious scholars, and health policy makers created a platform for a multidisciplinary discussion on various bioethical issues and raised national awareness of bioethical issues.

In 2004, the Research Center for Medical Ethics and History of Medicine was formed by Tehran University of Medical Sciences. This center has played a great role in bioethics education and research. The center developed the national medical ethics strategic plan and bioethics network in the country, with participation of religious scholars, physicians, philosophers, legal experts, and sociologists. The center holds national seminars, workshops, and courses on different bioethical topics. It also has offered a Master of Public Health (MPH) course with a major in medical ethics since 2004, which has been a successful course for mid-career physicians. A PhD course on medical ethics designed for physicians, dentists, and pharmacists was developed by the Ministry of Health in 2008. Currently, there are three universities offering a PhD in medical ethics. The Second International Congress of Medical Ethics in 2008, organized by this center, provided a platform to introduce what had been achieved so far in the country and to promote ethical discussions and awareness. It paved the way for future developments. The establishment of the departments of medical ethics in the universities, national and regional research ethics committees, courses, book publications, and related bioethics associations and committees at university and national level are among the steps that have helped to promote medical ethics in Iran.

Currently, there are 47 public medical schools across the country that offer a two-unit compulsory course on medical ethics for undergraduate students (Ministry of Health, 2011). However, there is no compulsory bioethics education and nursing ethics for nursing students. Currently, the nursing curriculum is under review by the Ministry of Health and Medical Education. One issue is the consideration to add nursing ethics as a compulsory course for students in the faculty of nursing. The Specific National Ethical Guidelines for Biomedical Research were compiled in 2005. They include Ethical Guidelines for Clinical Trial, Ethical Guidelines for

Research on Minors, Ethical Guidelines for Genetic Research, Ethical Guidelines for Gamete and Embryo Research, Ethical Guidelines for Transplantation Research, and Ethical Guidelines for Research on Animals. Along with these initiatives, some other universities, such as Shahid Beheshti Medical University in Tehran, Shiraz Medical University in Shiraz, and Tabriz Medical University, have established a dedicated center working on ethical, legal, and philosophical issues in biomedicine in their universities. Following the UNESCO recommendation to member states, a National Bioethics Committee was established under the UNESCO national commission in 2001 (Zali et al., 2002; National Commission of UNESCO, 2010). In the past few years, the number of institutes and research centers focusing on medical ethics has increased followed by a growing number of academic journals of bioethics. For instance, the *Iranian Journal of Medical Ethics and History of Medicine*, as the first professional journal in medical ethics in Iran, was published in spring 2008. This is an online, bilingual (Farsi and English) journal. There are several scientific journals, including *Hakim*, *Journal of Medical Law*, and *Iranian Journal of Ethics in Science and Technology*, publishing peer-reviewed articles on bioethical issues in Persian. Recently, some active bioethical groups have been organized, including the Iranian Association of Ethics in Science and Technology (http://iranethics.irost.org/) and the Iranian Association for Medical Ethics. The Avicenna Prize for Ethics in Science is an initiative by the Islamic Republic of Iran to acknowledge the importance of ethics in science and technology and to become involved in the international bioethical discussion. The prize consists of a gold medal of Avicenna along with a certificate, the sum of $10,000, and a 1-week academic visit to Iran, which includes the delivery of speeches in the relevant academic gatherings. The prize is awarded every 2 years. It is intended to reward the activities of individuals and groups in the field of ethics in science. The prize owes its name to the renowned eleventh-century Iranian physician and philosopher of medieval Islam Ibn Sina (980–1038), known in Europe as Avicenna. A healer and a humanist, Avicenna developed an exemplary holistic approach that captures the essence of ethics in science (UNESCO, 2011).

Bioethics Infrastructure

In Iran, like many other countries, ethical dilemmas in health care were a starting point for bioethical discussions. However, unlike many other countries, the leading figures were medical doctors and not philosophers, lawyers, or sociologists. This is the reason why, in comparison to other disciplines in bioethics such as environmental ethics, only issues in medical ethics have been discussed in depth, and the infrastructures have been established in medical schools. The dependency of medical ethics on socio-cultural and religious issues has urged policy makers in Iran to take these issues into account and to utilize the rich Iranian-Islamic culture in addressing ethical issues raised in biomedicine.

Bioethics Organizations: In the last two decades, the number of research centers, institutes, and committees dedicated to bioethics has increased dramatically. As mentioned earlier, in the 1990s there was only one research center at the

Ministry of Health focusing on ethical issues in medicine. Now there are several bioethics or medical ethics centers and institutes across the country, and all major universities and research centers have established research ethics committees and/or hospital ethics committees. Therefore, due to the establishment of research ethics committees in all universities and research institutes, there is good coverage of ethical issues in biomedical research. However, when it comes to clinical bioethics there is a lack of infrastructure and programs to address ethical issues at the bedside such as ethics consultation.

Regarding bioethics education, the number of programs has increased and, currently, there is a PhD course on medical ethics at the medical universities of Shiraz, Tehran, and Shaheed Beheshti; a 1-year fellowship program designed for university medical specialists at the Shaheed Beheshti medical university; a master of public health (MPH) with a major in bioethics at the Tehran medical university; and several specialized courses and seminars providing post-graduate training. It should be noted that the two-unit course on medical ethics for undergraduate medical students has recently been revised (Bagheri et al., 2009).

There are several initiatives to translate critical bioethics reference books into Persian to allow more people to use these resources. It should be noted that, although the importance of ethical issues in regard to the environment has been discussed recently, compared with the issues in medical ethics, there is still less representation from environmental ethics in the country.

During the last decades, several initiatives by health authorities have helped the expansion of bioethics centers. For example, the Iranian Academy of Medical Sciences formed a new department of medical ethics in 2006. In 2011, the Ministry of Health established a new organization called the High Council of Medical Ethics in order to monitor medical ethics programs and coordinate bioethics activities with other governmental agencies and ministries as well as national policy making in the field of medical ethics. This council can issue national guidelines on different aspects of medical ethics and undertake the supervision of issues related to medical ethics in the country.

Based on the recommendation of the United Nations Educational, Scientific and Cultural Organization (UNESCO), the UNESCO National Commission in Iran has established a National Bioethics Committee with representation from different related organizations, such as the Ministry of Science, Research and Technology, the Ministry of Health and Medical Education, the Organization for the Protection of the Biological Environment, the Ministry of Agricultural Jihad, and the Legal Medicine Organization. The committee also includes some independent experts. The National Commission also established the National Ethics Committee on Science and Technology in 2003. However, recently, the National Commission has combined these two committees into one, the Iranian National Committee of Bioethics and Ethics in Science and Technology (National Commission of UNESCO, 2010).

Capacity to deal with new bioethical dilemmas: In Islamic jurisprudence, the issues and problems that come along with the progress of human knowledge and technology are considered as newly emerged problems. Islamic regulations are originally expressed as certain general principles and norms that are not expounded

in details. Therefore, for many bioethical issues raised along with new technologies there are no textual ordinances offering explicit guidance. It is a matter that falls within the domain of legal discretion (*ijtihad*). In Iran, in order to deal with newly emerged issues in medicine, scholars of religion and jurists work in collaboration with medical specialists in order to find a solution for such complex questions. For example, the medical specialists first explain the problem of brain death and the patient's state and conditions to a *faqih*. The *faqih* then utilizes authentic sources and documents that include God's Holy Book (the Qur'an), tradition (*Sunnah*), consensus (*Ijma*), and reason to extract the ordinances of the Islamic law. When such a rule is expressed by *faqih*, it is called a "legal opinion" or *fatwa*. Muslim physicians perform their therapeutic duties according to such legal opinions and recommendations. It should be noted that in Islamic law controversy exists not only among different schools of thought such as Shi'at and Sunni but also within each one of these schools. For instance, different ruling *fatwas* on the application of assisted reproductive technologies and also abortion can be seen among Shi'ee scholars and Sunni scholars (Bagheri & Afshar, 2011).

Legislation in the area of bioethics: In the area of bioethics there are several bills that have been passed into law by the parliament. The first was the Brain Death and Organ Transplantation Act (2000), which authorizes organ removal for transplantation from a brain-dead patient. The Act has expanded the donor pool and has increased the number of organs available for transplantation. In 2003, based on the religious approval for embryo donation, the Iranian Parliament ratified the "Act of Embryo Donation to Infertile Spouses." This Act regulates embryo donation to infertile couples under certain conditions. In 2005, the parliament regulated abortion by ratifying the Act on Therapeutic Abortion. According to this Act, a pregnancy can be terminated within the first 4 months of pregnancy if the fetus suffers a congenital abnormality, mentally or physically, or when the mother's life is in danger. It is noteworthy that there are several techniques and methods, especially in the area of ARTs such as surrogate motherhood and sperm donation for which there is religious permission (*fatwa*). However, there is no law or regulation in this area. This poses ethical challenges for healthcare institutions. Thus, more attention and efforts need to be paid in order to regulate these reproductive techniques.

Major Bioethical Issues

Looking back to what has been common practice in dealing with bioethical issues in Iran, one may find that, in many cases, following the emergence of an ethical dilemma raised by the application of a new technology (e.g., ARTs), the responsible authority has formed a panel of experts in order to deal with the issue and provide an ethical guidance for the health system. However, by establishing different ethical bodies, the health authority is trying to deal with these issues in a more structured form. Some of the bioethical issues that have emerged in biomedicine and the responses to the ethical challenges posed by these issues are discussed below.

National Priorities in Medical Ethics

A national survey has recently identified the top ten priorities in medical ethics across the country (Bagheri, 2011). In this survey, scholars who are involved in bioethical discussion, teaching, research, and policy making from different fields have been asked to choose ten priorities among 20 topics in a questionnaire about medical ethics. The issue of patient rights has been chosen as the first priority, followed by doctor-patient relationship, just resource allocation, autonomy and informed consent, fee splitting, hospital ethics committee, public health ethics, capacity building in medical ethics, ethics in medical education, and finally the issue of ethics in research.

Patient Rights

As mentioned above, the issue of patient rights is the top priority in the national survey. Recently, special attention has been given to patient rights by the Ministry of Health and Medical Education. The Iranian patient rights charter was compiled with a novel and comprehensive approach in 2009 and has been adopted by the Ministry of Health. This charter aims to elucidate the rights of recipients of health services as well as to observe ethical standard in medicine. The charter has 5 chapters and 37 articles, including a vision and an explanatory note. The charter's five chapters are (1) the right to receive suitable services, (2) the right to access to desirable and adequate information, (3) the right to choose and to decide freely about receiving health care, (4) the right to privacy and confidentiality, and (5) the right to access an efficient system of dealing with complaints (Parsapoor, Bagheri, & Larijani, 2010). It must be noted that, although adopting the patient rights charter was a step forward to ensuring patient rights, a serious challenge is faced in implementing the charter and bringing it into medical practice within the healthcare system in Iran.

Brain Death and Organ Transplantation

In Iran, the Organ Transplant Act, 2000, allows organ removal from persons declared dead, based on brain function. The significant value placed on saving a life in Islam provided the foundation for this ruling, and religious teachings encourage people to donate their organs for transplantation to save human lives. The living unrelated (LUR) kidney donation program was started in 1997 based on the idea of "rewarded gifting" in which organs are not bought, but rather donors receive a "reward" for the gifted organ. As a result of kidney procurement from LUR donors, the waiting list for kidney transplantation in Iran was eliminated in 1999 (Ghods, 2002). The so-called "sacrifice gift" is given as a reward from the society to compensate the donor's altruistic donation. The acceptance and regulation of LUR kidney donation in 1988 provided the foundation for this initiative.

According to this program, after organ donation, the donor submits several documents, including a certificate from the hospital certifying that the procurement was performed, to a NGO called the Charity Foundation for Special Diseases. The NGO then pays the donor a fixed amount of ten million Rials ($1,000) as the sacrifice gift (Zargooshi, 2001). However, it should be noted that, since the start of this program, the number of living related organ donation has decreased dramatically. A study shows that the living unrelated donor program had an adverse effect on the number of living related donors. In this study, 81 % of the kidney recipients from living unrelated donors had a potential living related donor. In those cases, family members were reluctant to donate because of the availability of living unrelated donors for transplantation (Ghods, Savaj, & Khosravani, 2000).

It was hoped that a LUR kidney transplant program would decrease the waiting list mortality and improve quality of life for patients undergoing dialysis. Before the implementation of LUR donation, only 30 % of patients on the waiting list for transplantation would receive a kidney from a living (related) donor.

However, the program has been criticized because it facilitates the possibility of a private transaction between an organ donor and a recipient because they can get to know each other under the program. The program does not eliminate the possibility of individual kidney sales, and in some cases it may encourage people to offer their kidneys for sale through a private transaction rather than a donation (Bagheri, 2006). In reality, the program is not well designed to prevent donor-recipient monetary relationships. If donors and recipients are known to each other, it is easy for them draw up a contract together for a private transaction. In fact, the program in Iran lacks secure measures to prevent the risk of a direct monetary relationship between donors and recipients, and this is the main ethical problem and loophole of the procurement system in Iran. However, preventing any direct monetary relationship between donors and recipients through a "nondirected living donation" policy can be instrumental in overcoming this ethical problem (Bagheri, 2006).

Assisted Reproductive Technologies

In Iran, on average 10–15 % of couples are infertile and many of them seek assisted reproductive technologies to have their own baby. The first infertility center was established in Yazd Province in the central part of Iran in 1986. Since 1990, when the first test tube baby was born in Iran, there have been major technological achievements in the area of infertility treatment. Currently, infertile couples do not have any legal barriers to taking advantage of these technologies (Abbasi-Shavaz et al., 2006). There are 50 IVF clinics across the country, among the highest numbers in the Middle East. Assisted reproductive technologies have been in practice since 1989 based on the religious authority permission (*fatwa*), and none of the techniques, such as eggs and gamete donation or surrogacy, have been governed by legislation. In the absence of a legal regulatory framework for assisted reproductive technology, however, infertility clinics have been able to practice all forms of gamete donation and surrogacy to benefit their infertile

married couples based on the existence of religious permission (*fatwa*). Although all assisted reproductive techniques such as IVF, surrogacy, and embryo and sperm donation are available in the county, only embryo donation has a legal basis in Iran.

The Act of Embryo Donation to Infertile Spouses was ratified by the parliament in 2003. It noteworthy that, among Islamic countries, Iran is the only one in which assisted reproductive technology using donor embryos is supported by legislation. The Act has five articles. Article 1 of the Act requires that the donors should be legal or canonical spouses. It also states that the donated embryo should be produced from the IVF procedure and written spousal consent is necessary. Article 2 details the prerequisites for receiving the embryo, and Article 3 is about duties and responsibilities of the spouses adopting the embryo. Article 4 mentions the role of the Family Courts and the legal process of embryo donation, and Article 5 obliges the Ministry of Health and the Ministry of Justice to provide a guideline or bylaw for embryo donation after 3 months (The Act, 2003). As a result, the executive bylaw of the Act was passed by the Cabinet Council in March 2005. However, the Act addresses only embryo donation, while there is a lack of legislation on the other forms of gamete donation or surrogacy. The Act of Embryo Donation to Infertile Spouses can be instrumental in helping infertile couples. However, the vagueness of the Act created more confusion and lack of clarity. The Act has been criticized for several reasons. First, it does not restrict the donated embryos to surplus embryos and is silent about the number of embryos that could be transferred. Also, the Act is silent on the issue of heritage, which can be a challenging issue under the anonymity policy in embryo donation (Afshar & Bagheri, 2012). Currently, there is no standard national protocol or guideline to evaluate the prerequisite conditions of the embryo recipients and supervision of the embryo donation. The same problem exists for the application of other assisted reproductive technologies in the country.

Abortion

As in other countries, abortion is a sensitive issue. However, in the conservative Islamic society the issue becomes critical. In Iran, as a Muslim country, the *Shari'a* law, based on Shiite school, is the basis of the ruling *fatwas* on abortion and it influences public attitudes and practice. Based on Islamic jurisprudence, ensoulment takes place at 120 days of pregnancy and after that time a fetus is considered a full human being; thus, abortion is not permitted after ensoulment. Against this backdrop, abortion is permitted before 120 days of pregnancy under very restricted conditions, for example, if the mother's life is endangered. In 2005, the Therapeutic Abortion Act was passed by the parliament and approved by the Guardian Council (which is the responsible body to check all laws passed by the parliament to avoid any contradiction with Islamic *Shari'a*).

The Act reads as follows: "Therapeutic Abortion is permissible with definite diagnosis of three specialist physicians and approval of Legal Medicine Organization for cases in which fetus suffers from congenital anomaly or retardations and causes hardship to mother and also for cases in which mother suffers from a life

threatening disease, before ensoulment (4 months of pregnancy) with consent of mother and there is no penalty for consulting physician. Violators of this act would be punished based on Islamic punishment act" (Therapeutic Abortion Act, 2005). However, critics believe that the Act provides a wide range of maternal as well as fetal indications for abortion that are subject to misuse. The condition of "hardship" as referred by the Act is a vague concept and subject to interpretation (Bagheri & Afshar, 2011).

Stem Cell Research

Ethics in biomedical research was one of the first bioethics issues that attracted the attention of researchers and health policy makers in Iran. As a result, national ethical codes in biomedical research were compiled in 1997. However, stem cell research was not a popular topic at that time. Therefore, the national ethical codes lack any specific reference to stem cell research. In Iran, there is an increasing interest in research on stem cells and, in a recent initiative, a draft of ethical guidelines in stem cell research is under review by the Ministry of Health. These include general ethical guidelines and specific guidelines explaining ethical issues in research on stem cells; a second part deals with ethical issues in stem cell therapy (Nejad Sarvari et al., 2010).

Environmental Ethics

As mentioned earlier, bioethical discussion began with exploring ethical issues in medicine, however, some issues such as environmental ethics are receiving more attention. Nonetheless, public awareness has increased due to air pollution in big cities, and academic discussions on global warming and climate change have caused experts in the field and policy makers to pay more attention to environmental ethics. Many believe that the world faces an environmental crisis and a solution for this crisis can be found by returning to religious tradition (Mohaghegh-Damad, 2000).

Islamic teachings urge Muslims to take care of the environment and animals as Almighty God's creatures. Although, from the religious perspective, the particular attributes of human beings give mankind on a special status compared with other creatures, but at the same time it gives them responsibility toward nature and the environment. Such responsibility demands that the possible consequences for other living organisms not be ignored in decision making regarding the environment (Abedi-Sarvestani & Shahvali, 2008).

In fact, both religion and religious leaders have the potential to encourage people, based on religious teachings, to care more about their surrounding environments. However, this has not been fully exercised in Iran.

There are several universities in Iran that offer undergraduate and post-graduate studies in environmental sciences. Recently, courses in environmental ethics have gained more attention. For instance, environmental engineering programs at the

graduate level have been developed since 1990. However, there is not an environmental ethics course in this program. The addition of several courses to the curriculum of all environmental engineering programs in Iran has been suggested, such as environmental law, environmental economics, and environmental ethics and philosophy (Alavi Moghaddam, Maknoun, & Tahershamsi, 2008). It is noteworthy that the number of NGOs dedicated to preserving the environment is increasing. However, due to the lack of public awareness, except for air pollution, other environmental issues have not yet become topics of public discourse.

Physician-Patient Relationship

The physician-patient relationship in Iran does not operate on a patient-centered model of decision making, as one might find in Western countries. Looking at the four prominent models of physician-patient relationship (paternalistic, collaborative, informative, and technician models), one can find that, currently, the dominant physician-patient relationship in Iran is not a purely paternalistic model, nor is it one of the other models. Two decades ago, the medical system was based on a purely paternalistic model, but due to social changes, public awareness, and changes in medical education, the relationship between physicians and their patients is now in a transitional phase. It is hard to predict which model will become the predominant model of relationship between physicians and patients. More time is needed before the result of these changes can be seen.

Several factors have been claimed as a major force in changing the physician-patient relationship model, including fee splitting, sharing medical fees with professional colleagues for patient referrals (Parsa & Larijani, 2009), as well as direct monetary relationship between physicians and their patients (Bagheri, 2011). Traditionally, there is a relatively high level of trust between patients and their physicians. However, this tradition is threatened by the recent expansion of the practice of fee splitting and under-the-table payment due to unrealistic fee-for-service payments set by the health authority, especially in the private sector. The trust between the medical profession and society is fragile and is in a critical stage. Without constructive intervention by the health authority as well as professional associations, the relationship between healthcare providers and patients will undoubtedly be damaged (Bagheri, 2011).

End-of-Life Decision Making

For many Muslims, religious beliefs are a fundamental part of both personal and social existence in their daily life and a major determinant for healthcare decision making, especially at the end of life. In Islamic teachings, the importance of inter-human as well as human-divine relations are emphasized. Muslims look to these teachings in shaping their relationships with others and with the Almighty God. In this section, some issues related to end-of-life decision making are discussed.

It should be noted that, although Iran has a relatively young population, because of the scarcity of health resources, end-of-life issues are among the important topics in bioethics.

Right to Die: According to the Qur'an, life is a divine trust and cannot be terminated by any form of human intervention. Its term has been fixed by the unalterable divine decree. The Holy Qu'ran reads, "God takes the souls at the time of their death" (Holy Qu'ran 39: 42). Since the decision to end a life is a divine decree, the Islamic *Shari'ah* refuses to recognize individual rights in that matter (Sachedina, 2005). Therefore, the current notion of the right to die is not recognized. Hence, the right to be assisted in dying, whether "passively" or "actively," is also ruled out. The juridical principle of non-maleficence, which states, "No harm shall be inflicted or reciprocated in Islam" (*la darar wa la dirar fi' l-islam*), provides the justification of this ruling. However, it recognizes the possibility of arriving at a collective decision by those involved in providing the health care, including the attending physician and the family to withhold or withdraw life support intervention deemed futile. Instead of contemplating ways to end one's life, either by refusal of life-support treatment or by requesting to die with active assistance, Muslims afflicted with illness are advised to ask God to forgive their sins and pray for an opportunity to have a fresh start with restored health.

When death approaches, close family and friends try to support and comfort the dying person through supplication as well as remembrance of Allah and His will. The purpose is to help the dying person to repeat their commitment to unity of God. The recently developed Iranian Charter of Patient's Rights emphasizes the special needs of a dying patient and urges healthcare providers to be sensitive to these issues (Parsapoor et al., 2010).

Surrogate Decision Making: End-of-life decision making arises precisely at the critical point when a person lacks the capacity for making a decision. What must be done at that point? What are the patient's wishes, and who knows them? In case of minors, one may face the same difficulties in decision making. In Islamic societies, the family has the right to decide on behalf of their loved ones based on his or her best interest, especially if the patient did not express their wishes. For minors, parents are surrogate decision makers for their children. In case of emergencies and unconsciousness, accompanying family members act as surrogates.

Disclosure to the patients/families: In medical practice in Iran, family authority is often more dominant than the patient's autonomy. Many physicians provide the facts to the family members but not to the terminally ill patient. If the family asks physicians not to tell the patient, many physicians will agree to this request, and many patients accept this as standard practice. Therefore, it can be claimed that decision making in healthcare is based on a family-centered model.

Futile Treatment: The end of life should be as calm as possible and any unnecessary intervention or care management that could bring additional suffering to the dying patient or his relatives should never be used. Withholding and withdrawing life support interventions deemed futile is a controversial issue in Iran. In general, life-support withdrawal should be discussed with the family. If the treating physician finds that a certain modality of treatment is useless or will

increase the suffering of the patient, that modality of treatment should not be enforced (Albar, 1999).

Suicide: The Qu'ran is very clear on the subject of suicide: "Do not kill yourselves as God has been to you very merciful" (Holy Qu'ran 4:29). Taking away life should be the domain of the One who gives life. There is pain and suffering at the terminal end of an illness, but, as Quran reminds, there is reward from God for those who patiently persevere in suffering (Holy Qu'ran 39:10 and 31:17).

Future Challenges

Bioethical Challenges

There are several major challenges in bioethics in Iran, which influence the approach taken when dealing with bioethical issues.

The relationship between ethics, law, and Islamic jurisprudence (*fiqh*) is an important challenge. In the scholarly literature there are different approaches toward multidisciplinary discussion in bioethics (Mohaghegh Damad, 2010). Being a religious country, it is important to define the position of Islamic *Shari'a* on the questions raised by an ethical dilemma. In practice, the priority of the religious position is evident by the fact that, in case of any question (permission or prohibition of an act) on the application of a new biotechnology, scientists and physicians are keen to explore what would be the opinion of Islamic scholars (*faqih*) on the issue.

In the last two decades, the approach to an ethical dilemma has been as follows: First, a physician or a group of physicians who face an ethical dilemma in their practice would explain the problem to a *faqih* or to a committee of Islamic scholars in order to obtain the religious opinion on that issue. After approval by the religious authority, the issue would be taken to the health authority for the development of national guidelines or to the parliament for policymaking, if needed. Then ethical deliberation and discussion to explore the ethical dimensions of that issue would begin. For instance, the religious authority first accepted the notion of brain death and organ removal for transplantation from brain-dead cases. Then, based on this acceptance, an act was passed to allow the use of brain-dead cases as a source of organs. When organ procurement became part of medical practice, the ethical issues such as organ sale were then discussed. The same pattern can be seen in the case of abortion. It is interesting to mention that, because of this trend, there are several practices such as sperm donation and surrogate motherhood that are permissible according to the ruling *fatwas*. However, the ethical issues have not been fully discussed and there is no law or regulation governing the procedures.

Another challenge is that, as an Islamic country, there is a great effort in Iran to define principles of biomedical ethics based on Islamic ethics. In an article by Larijani and his colleague, the following principles have been proposed for dealing

with ethical issues based on Islamic Ethics: the principle of "the public interest" (*Maslaha*), the principle of "do no harm" (*La Dharar wa la Dherar*), the principle of "necessity" (*Dharura*), and the principle of "no hardship" (*La Haradj*) (Larijani & Zahedi, 2008). However, there remains a need to initiate a multi-disciplinary project with the participation of all stakeholders, Islamic jurisprudence, ethics, philosophy, medicine, and law to develop Islamic principles of biomedical ethics which are acceptable for the key players in the field.

A third challenge is that existing institutes and research centers have mainly focused on ethical issues in medicine. As a result, there is less attention paid to other topics in bioethics such as environmental ethics. Therefore, capacity building and strengthening the necessary infrastructure to deal with other critical topics in bioethics remain a challenge for the future of bioethics.

The last serious challenge for the development of bioethics is a lack of public discourse about bioethical issues. Given the importance of public discussion in bioethics, especially in policy making as well as implementation, there is a need to enhance public discussion and involvement in bioethical discussions. This, in turn, will bring about better public awareness and participation.

Bioethics Development

Two main factors, from the second half of the 1970s, paved the way in Italy to the development and success of bioethics. The first was the debate about the value and

dignity of human life prompted in the first place, although not exclusively, by the strong political and cultural conflict on abortion. The law that allowed women to terminate a pregnancy was adopted in 1978, but the controversy continued. A proposal to repeal the law was submitted to a national referendum in 1981 and rejected by nearly 68 % of voters, notwithstanding the strong opposition of the Catholic Church. The focus on the beginning of life also encompassed other and new aspects related to scientific development. In 1984, the same year the *Report of the Committee of Inquiry into Human Fertilization and Embryology* was published in Great Britain, a commission (the "Santosuosso Commission" after its chairperson) was established, with the aim of preparing a bill on assisted reproduction. Although the confrontation over these issues did not necessarily imply the reference to "bioethics," the route was thus marked out. In effect, the first person to introduce the word in Italy had been Menico Torchio, a professor of Marine Biology, who had published *Rapporti uomo-natura secondo le principali metafisiche orientali, loro implicazioni bioetiche ed ecologiche* (*The relationships of humankind and nature following the main Oriental Metaphysics, with their bioethical and ecological implications*) in the journal "Natura" in 1973. He relied on the broad, ecological perspective sketched by Potter just 2 years before but had little success. This does not imply that the idea of a "bridge to the future" grounded on the respect for nature and the whole biosphere was simply dismissed, nor that the question of "animal rights" did not receive attention, but Italian bioethics, from its very first steps, gave priority rather to cutting-edge issues stemming from different evaluations of the rights to be recognized and the obligations to be performed when human life is on the threshold of its beginning and end.

The second decisive factor contributing to orientate fledgling bioethics towards the challenges of the biomedical sciences, as well as towards medical rather than environmental ethics, was the impact of new technologies on health care and clinical practice. This impact was strengthened by the shift from the old paternalistic to the new autonomy-centered paradigm of medicine. It was no longer simply about looking for the best "technical" method to apply a treatment or to decide when it had become futile and should therefore be suspended. It was about looking for the best way to involve the patients in this complex process of decision making, enabling them to make their own choice in terms of free and informed consent while ensuring at the same time the concrete availability of the appropriate treatment and a rational allocation of resources, in a context where access to quality health care is guaranteed to everyone as a fundamental constitutional right, regardless, among other things, of economic conditions.

As a consequence, many initiatives and committees were established in the 1980s, both within hospitals and research institutions and via academic bodies and other cultural organizations. For the former, initial experiences arose in Milan (Clinical Institutes for Specialisation, Hospital S. Raffaele with Paolo Cattorini, National Institute for Research and Treatment of Cancer), Genoa (National Institute for Research on Cancer), and Rome (Catholic University of the Sacred Heart). Two different clusters of responsibilities can be easily highlighted. On the one hand, there were the obligations of respect connected to

research on human subjects, starting with the application of the principles already made explicit in many international documents in the wake of the *Nuremberg Code*. On the other hand, it was also necessary to cope appropriately with those conditions of disease which entailed a great deal of suffering, no concrete hope of recovery, and, at the same time, the possibility of tapping more and more powerful means of treatment simply to prolong life. In some cases, the competence to assess the results of the application of the law on pregnancy termination was also explicitly foreseen.

The controversy over the right to life, in its various declinations, is indeed the Ariadne's thread of this first period, even though other issues were considered at the same time. Theologians and philosophers, as well as scientists and jurists, were involved. Relevant documents from the magisterium of the Catholic Church were published rapidly, one after the other. The oldest Italian philosophical journal, the "Rivista di filosofia," that had published an article by Maurizio Mori pointing at the rapid development of bioethics in 1980, devoted a special issue to this topic in 1983. The Catholic Church undoubtedly played a major role. The "Centre for Bioethics" at the Faculty of Medicine of the Catholic University of Rome, where Elio Sgreccia had begun teaching bioethics 2 years before, was inaugurated in 1985. With the support of the journal "Medicina e Morale" (founded in 1950) and one of the greatest specialized libraries, this center imposed itself as the benchmark of a bioethics strictly aligned with the teaching of the Church. Sgreccia himself, who was made cardinal by Pope Benedict XVI in 2010, is probably the most influential representative of this position. His *Manuale di bioetica* (*Handbook of Bioethics*) was printed in several editions and has been translated to many languages. The center, directed since 2006 by Adriano Pessina, is now at the service of the whole Catholic University and its main seat has shifted to Milan, whereas in Rome, the Institute of Bioethics, set up in 1992, continues its work. At the same time the "Lanza Foundation" was established in Padua. A crucial attention to bioethical issues and to the relationship between ethics and medicine – as we can read on the website of the foundation – was assumed as a part of its more encompassing mission to address the challenge "to respond to the compelling scientific and technological progress and massive changes in our economic and social system" on the basis of Christian ethical principles.

Many other initiatives were launched in the 1980s, independently of the Church and often openly opposing it. In 1987, Uberto Scarpelli published in "Biblioteca della libertà" a short essay entitled *La bioetica. Alla ricerca dei principi* (*Bioethics: in search of the principles*), pointing at new ways outside theology and at two fundamental principles: tolerance and dignity. The contribution of secular thought was decisive from the very beginning, as well as that of different interests and sensibilities. The "Centre for Bioethics" established in 1984 at the University of Genoa by Luisella Battaglia tried to renew a broader awareness of human responsibility for all life, with a special focus on the rights of animals as an issue of interspecific justice. The "Italian Society for Bioethics," linked to the Chair of Anthropology of the University of Florence (Brunetto Chiarelli), also aimed, relying on Potter's legacy, to connect the bioethics of medicine with the bioethics of environmental studies and biological sciences:

Potter himself came and gave a lecture in Italy at the invitation of Chiarelli in 1990. The Centre for Research and Education in Politics and Ethics "Politeia," established in Milan in 1983 and with a liberal background, started a section on bioethics, which contributed to boosting open, interdisciplinary debate in 1985. In 1990, Politeia promoted an important congress on *La bioetica: questioni morali e politiche per il futuro dell'uomo* (*Bioethics: moral and political questions for the future of humankind*), inaugurated just 1 day after the formal establishment of the National Bioethics Committee, through a decree signed on March 28 by the president of the Council of Ministers. In 1989, still in Milan, the neurologist Renato Boeri founded the "Council for Bioethics," with the aim of supporting a secular approach to biomedical issues. In Rome, the year before, the "Gramsci Institute" had started a project on life sciences: the congress on *Questioni di vita. Scienza*, *etica e diritto* (*Questions of life: Science*, *Ethics, Law*) was the first initiative of its Centre for Bioethics.

Most of these centers – as well as producing books and other research material – also founded journals, such as "Problemi di bioetica," later renamed "Global Bioethics" (Italian Society for Bioethics, until 2006), and "Bioetica. Rivista interdisciplinare" (Council for Bioethics), that has rapidly become one of the most important references for the debate in Italy. Among the journals published by these institutions devoting special attention to bioethics are "Kos" (San Raffaele Foundation), "Notizie di Politeia," and "Etica per le professioni" (founded in 1999 by the Lanza Foundation). By the beginning of the 1990s, the first pioneer period of bioethics in Italy was over and we entered a new phase of progressive widening and reinforcement that has continued uninterrupted to the present.

Current Bioethics Infrastructure

Academic teaching and research, institutional and other cultural and scientific sites for public debate, and legislation are the most telling indicators of the growing, pervasive relevance of bioethics in the last 20 years. Bioethics is now taught in most Italian universities: in the faculties of medicine, although it has not yet been included as an obligatory part of the curriculum but also in faculties and departments of law and philosophy. The traditional sectors that provided and continue to provide the greatest numbers of bioethicists are legal medicine and history of medicine, philosophy of law, and moral philosophy. As a consequence of these differentiated and interdisciplinary approaches, master's and PhD programs have come to take place within numerous institutional frameworks, often relying on and boosted by the specific competence and commitment of prominent scholars. Many centers for bioethics are either located within universities or promoted by university professors, and it is therefore quite obvious that research and teaching activities are placed side by side. Curricula in bioethics have been proposed at different levels in Turin, Genoa, Milan, Padua, Firenze, Siena, Rome (Catholic University, Lumsa, La Sapienza, Roma 3), Napoli, Bari, Lecce, Palermo, and Messina, among others. The Pontifical University Regina Apostolorum of Rome, which as such does not belong

to the Italian university system, unlike the University of the Sacred Heart and Lumsa (another Catholic university, where Francesco D'Agostino set up a Centre for Biojuridical Studies now directed by Laura Palazzani), has even established an autonomous Faculty of Bioethics, where a UNESCO Chair in Bioethics and Human Rights is also to be found. Other pontifical universities in Rome and many teaching and research institutions of the Catholic Church elsewhere have also started programs in bioethics.

Of course, not all of these initiatives have had the same impact and shown the same capacity to consolidate themselves. Expertise in bioethics is as flexible as it is uncertain in terms of immediate employability, although it still appears to be required in the first place to effectively address the new challenges arising in the domain of biomedical sciences. It was the "Istituto Superiore di Sanità" (National Institute of Health) that launched the SIBIL Project (Sistema Informativo per la Bioetica in linea/Online Bioethics Information System: www.iss.it/sibi) through its documentation service in 2001. The SIBIL Project is an integrated system aiming to provide as complete an overview of bioethics as documents, internet sites, university courses, congresses, and reports from the media (other portals for bioethics are www.biogea.org, established by the Basso Foundation, and www.portaledibioetica.it). As a part of the SIBIL Project, the Italian Bioethics Thesaurus was published in 2006, including over 1,000 terms related to bioethics. In the master's programs, which are often located within faculties of medicine or organized with their decisive contribution, this orientation is more explicit: teachings of moral philosophy, philosophical anthropology, and philosophy of law but also private and international law and sometimes management of health care systems are offered, with a background of genetics and genetic engineering, gynecology and obstetrics, endocrinology, anesthesiology, and epidemiology. The practice of medicine and medical research, as well as the need to regulate unprecedented possibilities and risks in this field, have been and are likely to be in the future the crux of Italian bioethics.

Apart from that within universities and teaching, the infrastructure of public debate, in Italy as in many other countries, is characterized by the presence of an institutional body flanking many initiatives whose number has been steadily increasing over the last decades. The National Bioethics Committee (Comitato Nazionale di Bioetica) is appointed by the president of the Council of Ministers, with the task "of expressing opinions, and also for the purpose of preparing legislative acts, to address the ethical and legal problems that may arise as a result of the progress in scientific research and technological applications on life" (quoted from the website of the committee: www.governo.it/bioetica). In 1992, a National Committee for Biosecurity, Biotechnology and Life Sciences (Comitato Nazionale per la Biosicurezza, le Biotecnologie e le Scienze per la Vita) was also established, with the more specific task of assessing the risks arising from the use of biological agents, developing criteria for the definition of safety standards, and cooperating in drafting regulations from European directives. A joint group of the two committees is entrusted with discussing those issues of shared interest and responsibility, such as, most recently, genetic tests and the collecting of biological samples according to the principle of consent.

The decision to appoint a *national* committee, which should be representative both of different methodological approaches and ethical perspectives and sensibilities, is rooted in an awareness of the special relevance of the problems that bioethics deals with. Constitutional essentials are at stake, starting with the right to life and the right to quality health care. Bioethical controversies may impinge deeply even on the idea of shared citizenship and therefore require the greatest effort to overcome or at least to contain the conflict as far as possible, especially when it comes to legislative action. The committee has been chaired by Adriano Bompiani, Adriano Ossicini, Giovanni Berlinguer, and twice by Francesco D'Agostino. The present president (until December 2012) is Francesco Paolo Casavola, former president of the Italian Constitutional Court.

Notwithstanding the role and important activity of the National Committee, the true "engine" of Italian bioethics is probably still to be found in the many centers and institutions disseminated throughout the territory. Among the initiatives established in the 1990s that make explicit reference to the Catholic tradition, the Sicilian Institute for Bioethics distinguished itself through a specific commitment to developing a Mediterranean bioethics. The institute that published the journal "Bioetica e cultura" and a *Dictionary of Bioethics* (1994) is now called "Istituto di Studi Bioetici Salvatore Privitera" (from the name of its founder), offers a master's degree in Mediterranean Bioethics and publishes the journal "Bioethos." Still in Sicilia, the Laboratory of Bioethics, set up in Messina in 1993, is now a center linked to the Salesian Pontifical University. The "Scienza e Vita" (Science and Life) Association, established in 2005, has undertaken the task of boosting awareness of the intrinsic dignity of every human being in every stage of his or her existence, especially at its beginning or end or when it is burdened with disease, fragility, or disability. The position of the Catholic Church, however, remains just one of the perspectives inspired by religious faith, even in Italy. The Union of the Methodist and Waldensian Churches, for example, established a working group (thereafter a commission) on bioethics in 1992 that has produced documents on pregnancy termination, euthanasia, assisted reproduction, secularism. These documents offer arguments and solutions inspired by a very different set of principles and therefore provide further evidence of the inadequacy of addressing Italian bioethics through the key of a conceptual *passe-partout*, according to which the supporters of the principle of the sanctity of life on the one hand and the supporters of the principles of quality of life and self-determination on the other hand simply clash one against the other.

Needless to say, one of the most urgent challenges remains that of providing conceptual tools and normative guidelines for the new responsibilities that the medical profession is called upon to deal with. The Jano Institute, directed by Sandro Spinsanti, is a telling example. Referring to a divinity endowed with rich symbolic meaning and orientated to the experience of transitions and changes that so deeply characterizes the time we are living in, the Institute aims to reconcile the traditional deontological dimension of medicine (the look at the past) with the unavoidable outcomes of innovation and increased technical power (the look at the future). "Janus" is the journal for this program of integrating knowledge stemming

from the sciences of nature with anthropological questions and social commitment in a more and more multiethnic and pluralistic environment.

In this perspective, the experience of the Ethics Committees established by hospitals or research structures, which had already played a major role in the pioneer phase of bioethics in Italy, is still decisive. They have the specific task, according to European directives and other long-established normative statements concerning research on human subjects, to assess pharmaceutical clinical trials, therefore verifying the relevance of the experimentation, the adequacy of the protocol, the competence and expertise of researchers, the respect of the principle of free and informed consent as well as of all other aspects that should be relevant in order to protect the rights, and the well-being and safety of every individual involved in the trial. According to the register of Ethics Committees, a section of the database of the National Monitoring Centre of Clinical Trials (*OsSC*), there are by now more than 250 Ethics Committees in Italy and their number has continued to increase after the last Ministerial Decree of 2006 that provided the minimum requirements for establishing such committees and the following transposition to regional laws. The composition of these committees guarantees a wide interdisciplinarity and article 3 of the decree explicitly mentions the possibility of also entrusting the committees with a consultative function over ethical questions linked to activities of assistance, quite apart from those of scientific interest. The committees are also entitled to propose initiatives for training and professional education in the field of bioethics. In this way, they are likely to become more and more indispensable when conceptual clarifications and legislative actions arise.

Major Bioethics Issues and Discussions

Looking at the opinions and motions of the National Bioethics Committee, two main features of bioethics in Italy stand out. The first one is the width of debate in the country. Most of the crucial ethical issues that developed societies have now to face as a consequence of a faster and faster scientific development have been addressed, either in connection with traditional arguments over the value and dignity of life or dealing with the many aspects that the respect for such value and dignity now entails, starting with the respect for everyone's autonomy and self-determination, *vis-à-vis* both the new technical possibilities that have been made available in the biomedical domain and the responsibility to allocate limited resources according to the fundamental principles of fairness and justice. The work carried out by the committee – to focus just on the most recent years and to mention just some of the opinions – is actually a reliable summary of the present agenda of bioethics in Italy, ranging from pivotal aspects of research and clinical ethics (conflict of interest in biomedical research and clinical practice, pharmacological and clinical trials, secrecy in drug regulatory system procedures, premature infants, conscious refusal and renunciation of health care in the patient-doctor relationship, criteria for the ascertainment of death, organ donation, use of placebo, conscientious objection) to new versions of the never-ending controversy on the

status of the embryo (the destiny of embryos resulting from medically assisted procreation; chimeras and hybrids, with specific attention to cytoplasmic hybrids) and the most advanced frontiers of research, including its economic fallout (pharmacogenetics and pharmacogenomics, genetic testing and insurance, health and new information technologies, biobanks and research on human biological material, nanosciences and nanotechnologies, neurosciences). The conceptual and normative span of bioethics is broadening, encompassing issues such as minor sexual differentiation disorders, biometrics, ethics, sport, and doping responsibilities toward animals. At the same time, the National Committee is contributing to fostering awareness of the idea that bioethics necessarily relies on and impinges upon a cultural, social, and political context, whose values, rights, and obligations and networks of solidarity are at stake. That is why bioethics must also cope with old and new risks of discrimination (women, elderly people, prisoners, developing countries) and be perceived as a challenge for education, possibly even in schools rather than just at university.

In many cases these opinions, which can also be found in English on the committee website, have been voted for by a large majority of the members. However – and this is the second feature of Italian bioethics that the experience of the committee helps enlighten – it remains true that whenever the discussion approaches the limits of self-determination as applied to the beginning and the end of human life, conflict breaks out once more. There seems to be very little room for consensus, and we are often left with an "on the one hand [. . .] on the other hand" argument. A telling example is to be found in the opinion concerning the conscious refusal and renunciation of health care of 2008: "On the one hand there's the position according to which human life constitutes a good that cannot be disposed of, which must be always protected and preserved, guaranteeing adequate medical care. On the other hand, the position that considers life as a good without question of primary importance and deserving of the outmost protection, but not for this subjugated to a system that totally forbids the disposition of it, having to take into account the value that the individual attributes to it, in light of the principles and of the moral choices that reflect the meaning each person gives to his/her own life" (§ 8).

The legislative actions that define and delimit the disposability of human life at its very beginning have prompted the hardest confrontation among bioethicists and in public opinion. The constitutional court itself, in many judgments, has implemented the "balancing of principles" as a tool to contain the consequences of a disagreement that directly impinges on the first of human rights and obligations, depending on the status that the embryo and fetus are recognized. This is the conceptual background of the law that introduced the right to terminate pregnancy in Italy. The State acknowledges, respects, and protects the self-determination of a woman and her interest in her own health and well-being but reaffirms at the same time the importance of respecting and protecting human life from the very moment of conception. In the unfortunate case of conflict between the two principles, prioritization is unavoidable. However, accepting that the principle "x" overrides the principle "y" in a given situation, where it is impossible to guarantee both of them, does not entail in any way the possibility of simply dismissing "y."

The criterion for prioritization was set by the court in February 1975, in a judgment which has become the cornerstone of all subsequent legislation and jurisprudence. A woman "is already a person." Therefore, her right to health and well-being has to take precedence over the respect even for the life itself of an embryo or a fetus, which are "not yet a person." The law 194/1978 draws on this assumption, aiming at balancing as far as possible this priority with the principle of respect for human life. In Italy, at least *de principio*, abortion is not simply free on request, and the State, although allowing it to be performed free-of-charge in public hospitals or private structures authorized by the regional health authorities, is not simply a spectator. Even during the first 90 days, some *indications* are to be considered and termination is permitted in circumstances that "would seriously endanger" women's physical or mental health, "in view of their state of health, their economic, social, or family circumstances, the circumstances in which conception occurred, or the probability that the child would be born with abnormalities or malformations." There are also *time limits* to be respected: after the first 90 days, voluntary termination of pregnancy may be performed only where the pregnancy or childbirth entails a serious threat to the woman's life or where serious abnormalities or malformations of the fetus, which could constitute a serious threat to the woman's physical or mental health, have been diagnosed. Eventually, where it is possible that the fetus may be viable, the physician may perform the termination only in case of immediate threat for the woman's life and undertaking every action to save the life of the fetus as well. Even though the actual application of the law has largely eluded the provisions made for the first 90 days and abortion is substantially free on request within such a limit, the idea of balance implies that the final goal of the law be that of preventing women from resorting to pregnancy termination, therefore supporting them in the attempt to remove the reasons of this choice. It is worth reminding that there had been two referendums against the law and carried out in 1981: the one promoted by the "pro life" supporters, which I have already mentioned, and another one aiming to eliminate all restrictions, which was rejected by an even larger majority of voters.

The law on assisted reproduction (40/2004) has also been discussed and harshly criticized in terms of balancing of principles. There was widespread agreement that new technologies should not simply be allowed to fulfill all kinds of wishes. However, the law passed by parliament was fiercely contested by the opposition, many experts, and associations because of what they considered a very limiting approach. The most controversial provisions of the law were the prohibition on creating more than three embryos at one time and the obligation to transfer all of them to the maternal womb in order to avoid embryo cryopreservation, the prohibition of using gametes from a third person outside the couple (heterologous fertilization), the prohibition on performing screening for genetic defects, and the prohibition on research on human embryos for purposes other than diagnosis and therapeutic treatment aiming at protecting the health and development of the embryo itself (with the subsequent strict ban on destroying embryos in order to obtain stem cells for the purpose of research). As in the case of abortion, a national referendum was promoted, with the aim of removing these restrictions.

The referendum was carried out in 2005 and did not achieve success due to the rules that regulate it in Italy. In order for a referendum to produce its repealing effects, it is required that more than 50 % of voters go to polls and the percentage of voters remained far below this threshold, although the great majority of those who went to polls expressed themselves against the restrictions.

However, the controversy continued in other forums. The constitutional court gave a judgment by which the prohibition of producing more than three embryos was overcome, together with that of cryopreservation. The argument, once again, pointed at a different balancing of principles, orientated more to the safeguarding of a woman's health than to that of the embryos. The prioritization of the former made it acceptable to resort to cryopreservation in order to avoid repeated cycles of ovarian hyperstimulation and reduce the risks of multiple pregnancies. The debate remains open, as does the confrontation on the use of embryonic stem cells for the purpose of research and experimentation.

Over the last years, end of life issues have also become a major subject of discussion. In this case, we draw on some shared premises. The criteria of death are no longer a matter of controversy, even though new scientific knowledge has triggered a reassessment of procedures (see the Decree of the Ministry of Health of 11 April 2008) in ascertaining "whole brain death," already acknowledged in a law of 1993 as fundamental neurological criterion. This is the assumption the 1999 law on organ transplantation is based on, in Italy as in most other countries. It can also be said that, at least so far, there are very few political actors and associations, as well as bioethicists insisting on the necessity of legitimizing the practice of "active" euthanasia, that is considered, according to article 579 of the Penal Code, a crime (murder at the request of the victim) punishable by imprisonment of between 6 and 15 years. Incitement to suicide and assisted suicide are also illegal, and it is worth underlining that "passive" nonassistance of a person in danger, when the one who omits is legally obliged to intervene, as it is normally the case for a physician, is made equal to an active behavior for penal consequences, according to article 40 of the same code.

Article 32 of the Constitution offers the key to address the fundamental point of confrontation with regard to end of life decisions: "The Republic safeguards health as a fundamental right of the individual and as a collective interest, and guarantees free medical care to the indigent. No one may be obliged to undergo any health treatment except under the provisions of the law. The law may not under any circumstances violate the limits imposed by respect for the human person." Apart from the recognition of access to health care as a fundamental "social" right of citizenship, pointed out as the goal and touchstone of a specific and ineludible political responsibility, the two principles to be balanced are still the protection of human life as "a collective interest" on the one hand and autonomy and self-determination of the individual, who cannot "be obliged to undergo any health treatment," on the other hand. There can be conflict when a patient refuses a treatment which is perfectly adequate and proportionate to the aim either of fully restoring him or her to health or to prolonging his or her life. Jurisprudence and clinical practice, according to the obligations deriving from the shift from the

ancient paradigm of paternalistic medicine to the new one of autonomy and those clearly stated in all relevant international documents about free and informed consent, have long since aligned in Italy with the recognition and acceptance of the patient's word as the last and decisive word to be said, even when such a decision implies, with full awareness, the consequence of renouncing life itself. This is obviously easier to make consistent with the collective interest of safeguarding every individual's health when the treatment which is refused (not even started) or renounced (the patient asks to stop the treatment at some point) could only prolong life in conditions of great suffering without any concrete hope of recovery, as may happen in the case of terminal illness. However, this is to accept in any case, notwithstanding the physician's obligation to advise patients of all the consequences of their decisions and to carry on the effort to persuade them not to give up too hastily, according to the idea of clinical practice as a "therapeutic alliance" between patient and physician.

Two cases have recently reignited the debate, with the consequence of reaffirming this conclusion and focusing on the issue of advanced directives, respectively. In the first, a man who was suffering from a progressive neurological disease and had been living for many years in enforced immobility and attached to a breathing machine asked for the machine to be switched off. This is the case the opinion of the National Committee on the conscious refusal and renunciation of health care that I have mentioned also referred to. In order for a patient to refuse a treatment or to renounce it when it is already in use, no "active" intervention is normally required by a third party: the physician ought simply to abstain, because the patient's will sets an insurmountable limit of privacy and respect in a context where a legal obligation to cure oneself is excluded, even with regard to the physician's general duty to intervene. Does it make a substantial difference if the decision to renounce, given the impossibility for the patient to switch a machine off by himself, requires for its fulfillment someone else's help? Whereas there have been different moral evaluations on this point, the judicial proceeding left no room for further uncertainties. The physician who made it possible for the patient to exercise his right to renounce the treatment was acquitted of any charge.

In the second case, the father of a woman in a vegetative state for many years asked to stop artificial nutrition and hydration and let his daughter die, asserting that she had expressed many times, before the accident that had determined such a condition, her firm will not to accept it. After many judicial rulings, accompanied by a fiery confrontation in public opinion, a court eventually allowed the interruption of the treatment and the woman died in a few days. In this case, however, the debate remained open on the necessity of adopting legislative measures on advanced directives (or statements, according to the title of the bill discussed in parliament for many years and strongly supported by the Catholic Church, which considers this kind of care an unconditional application of the principle of respect for human dignity). The point of immediate and hot disagreement concerned the possibility of stopping artificial nutrition and hydration, on the premise of an advanced directive, in an extreme condition such as a vegetative state that prolongs itself for many years. The more encompassing and difficult challenge that still

needs addressing is that of a fair balance between the collective interest to safeguard life as a good in itself and the right for everyone to maintain the control of his or her own body. The balance is more difficult, and the obligation of the physician to comply with the directives could be perhaps less strict or at least require some process of interpretation when the individual's will cannot be expressed "here and now" and had been anticipated in view of an imagined and not actually experienced condition.

I have mentioned many subjects that Italian bioethics is currently dealing with. This is likely to help reshape and possibly eventually to overcome a currently ongoing polarization. The contraposition between "Catholic" and "secular" bioethics is indeed key to understanding the general framework of debate in Italy. In the *Caritas in veritate*, the encyclical letter given in 2009 by Pope Benedict XVI, the statement is unequivocally made that bioethics is a "crucial battleground in today's cultural struggle between the supremacy of technology and human moral responsibility" and we are therefore presented with a clear *either/or* between two types of reasoning: "reason open to transcendence or reason closed within immanence" (§ 74). In vitro fertilization, embryo research, and the possibility of manufacturing clones and human hybrids are the new frontiers, while systematic eugenic programming of births adds new concerns about "the tragic and widespread scourge of abortion," and a pro-euthanasia mind moves forward.

On the other side, the features of a secular bioethics have been summarized by Giovanni Fornero as follows: humankind as the one and only source of moral values, refusal of a normative concept of "nature," autonomy, disposability of life, knowledge as an instrument of progress, refusal of suffering, different qualitative value of lives, the functionalistic concept of person, pluralism and liberalism, and an antiabsolutistic approach. This polarization, even though underscoring some relevant aspects of the bioethical debate, may result in putting worries of alignment before insight into the complexity and the often overlapping aspects of the questions addressed, especially when it comes to legislative action. It is therefore challenged by those who claim that it is not the religious or irreligious personal choice that can provide and actually provides bioethics with the decisive line of argument.

Future Challenges

The National Committee, in its 2010 opinion on bioethics and education in schools, launched the idea of a "bioethical citizenship," pointing out a double aim. On the one hand, evidence suggests that enhancement of this specific kind of ethical awareness relies on an enhancement of scientific education. Bioethical debates are triggered both by the increasing experience of pluralism of values and spurs stemming from the unprecedented pace of development of biomedical sciences and their applications. Therefore, scientific knowledge "not only *can*, but, in its essential data, *must* be acquired and shared by *all* moral subjects, in order to find an answer to the new ethical questions." On the other hand, communication is also

a decisive challenge. What is at stake is the "public good" of science and its applications. Therefore, public debate on these issues should be improved "regardless of sensationalism and ideological pressures." The possibilities opened up by scientific and technological progress impose choices which "must be the result of free and informed debate between *all* those involved" (§ 1): both active and responsible participation and mature awareness of the new rights and duties involved are required.

Looking at this idea of a bioethical citizenship, there are two challenges. The first is the necessity to strengthen not only scientific education in schools, including those aspects related to the environmental and social determinants which have a direct impact on life and its quality, but also the orientation and habit of recognizing and properly addressing the ethical issues and responsibilities arising thereby. In this perspective, the observation that bioethics has not yet been included as a fundamental teaching in all the curricula of those professionals whose activity is immediately related to life and its safeguard (starting of course with physicians and nursing personnel but also veterinarians) sets a priority that cannot be eluded any further. The second and probably even more relevant challenge, besides toning down the debate and freeing it from its most ideological component, is that of redefining and updating the agenda of bioethics.

This update will probably entail a broader sensibility towards the environment and all other living beings, which are objects of growing attention, partly as a consequence of the awareness of the global risks for humankind determined by unhinged exploitation of resources. Some legislative actions have been undertaken to enforce animal protection, in connection with compulsory European directives, but also beyond that. A new crime of failure to offer assistance to animals of affection or those belonging to protected species involved in accidents, for example, has been introduced in the Road Code and Italian legislation against abandonment and maltreatment of animals is among the most severe. This widening of interests is consistent with maintaining a focus on the bioethical debate which is more directly connected to human life. The confrontation over the concept of dignity of life and the rights and obligations to respect, protect, and fulfill where it begins and ends will carry on. Nonetheless, other issues also require more and more attention as we are at the crossroads of scientific development, economic interest and constraints, political responsibilities, juridical order as a premise, and the guarantee of technological order (D'Avack 2009). Nanotechnologies and genomics, for example, are two issues that the National Committee as well as other centers and institutions have already started dealing with extensively.

The broad "horizontal" impact where nanotechnologies meet bioethics contains some crucial points: consequences for the environment; specific problems of information stemming from the "invisible" nature of nanoparticles, with special regard to the toxicological hazard arising from exposure people could not be aware of; the combination of organic and inorganic molecules; the applications of nanomedicine as a new, powerful instrument of therapy but also of possible enhancement, together with the necessity to draw up guidelines for research and experimentation in this field; the so-called nanodivide, that is, the possible

deepening of faults of inequalities between the developed and the least developed countries. Research on the human genome and genomics was involved with the bioethical debate from the beginning. At first, it focused on differences when compared to other kinds of research on human subjects. There is a need to reconsider the modalities of consent, depending on the fact that research is carried out on a sample and not on an individual and that the consent of the person involved could easily become a sort of "blank check" (the definition was proposed in an opinion of the National Committee of 2006) in relation both to the time limitations for use and the possibility of other uses within projects completely unknown to the subject. Other important issues, also widely discussed at the international level, are the issue of secondary information and/or unexpected findings and that of so-called group consent, that is, the possibility that some individuals, including relatives, could be involved in the outcomes of research.

Nowadays, two other major challenges are imposing themselves with increasing urgency. One is the risk of possible discrimination and stigmatization. Decoding the genetic endowment of individuals implies the possibility that some specific "fragility" could be made accessible to third parties: insurance companies, employers, educational institutions, pharmaceutical companies, or even public systems providing health care. The fundamental question of privacy is manifestly at stake. On the other hand, there is also the new and promising scope of pharmacogenomics and personalized medicine, which is going to deeply reshape clinical practice itself and raises important questions in terms of access and affordability, especially in the framework of a public health care system like the Italian one.

It is exactly this overlap of bioethics with the more general issue of health care that is likely to become a greater priority. Italy is among the countries whose citizens can rely on a longer life expectancy: almost 79 years for the male population and over 84 for the female. However, the scheme of the National Health Plan for the biennium 2011–2013, coordinated by the Ministry of Health, already stresses the urgency of improving appropriate standards with regard both to the introduction and the use of new procedures, drugs, and medical devices. The task to fulfill remains that of marrying "quality" and "sustainability" of health care and also taking advantage of information and communication technology. Among the emerging problems, besides aging of population, there is exactly the problem of access to new technologies. The ministry points out the importance of both personalized medicine and medical genetics and can but acknowledge the existence of deep, growing asymmetries as to the distribution and availability of the most advanced technologies and therefore opportunities of diagnosis and treatment in the different regions of the country. It is from this perspective that the link between bioethics and social and political responsibility looks set to strengthen.

Summary and Conclusion

Bioethics deals essentially with a question of limits and a question of commitment: the question of the limits we ought to accept in the use of biosphere and in

developing our technological grip on the world, as well as those that are to be set as an insurmountable bulwark to protect the dignity of human life; the question of commitment to widening the room for a mutual exercise of freedom and rights and sharing the benefits of scientific progress, especially as far as health and health care are concerned, avoiding digging new faults of inequalities and deepening the old ones. In Italy, the debate over the most controversial issues related to the beginning and the end of human life has long taken priority, particularly in connection with important legislative actions such as those on abortion and assisted reproduction. The National Committee, many other centers for bioethics, and the ethical committees which operate within hospitals and research centers have long since contributed to addressing the relevant ethical issues arising in the biomedical field and the new responsibilities to be met in clinical practice, in a country that provides its citizens with a high standard of health care. The polarization between Catholic and secular bioethics has played and keeps playing a role in public debate, but the new challenges require a less ideological and far more articulated approach.

Bioethics Development

Bioethics in Kazakhstan began has developed recently, mainly in the last decade. Representatives of the medical community initiated the establishment of public bioethics committees to promote ethical principles in medicine. The Congress of Physicians in 2002 adopted an oath of a doctor of the Republic of Kazakhstan (thereafter adopted as a code) that contained core ethical principles for health workers' professional activity. An international conference on the topic of good ethical practice in biomedical research was held in the same year under the auspices of the FECCIS/WHO with the support of the Ministry of Health (MoH) of the Republic of Kazakhstan (RK) and several international organizations. This conference played a significant role in the development of ethics in biomedical research in the country. A network of ethics committees was established, proposals to the regulatory and legal framework were made, training was conducted, and international cooperation with international organizations such as WHO/SIDCER, UNESCO, OHRP/DHHS (USA), WMA, FIC (USA), COHRED, and the World Bank was developed. A working group on development of the new Code of People, Health, and the Healthcare System was established in 2006 and included experts in research ethics. A number of articles were included in this code concerning ethics committees' organization, conducting ethical reviews, and the ban on euthanasia, patients' rights in health care, the legal framework for reproductive technologies, organ transplantation, and medical and genetic counseling. The code was approved by decree of the president on September 18, 2009. The Central (National) Ethics Committee (NEC) of the Ministry of Health of the Republic of Kazakhstan was established, along with local committees at research institutes and centers and medical universities.

Bioethics was included in both undergraduate and master's programs in public health in medical universities as a compulsory component in 2009.

Major Actors and Forces

A nongovernmental organization, the Association of Physicians and Pharmacists of the RK (currently the National Medical Association), has played a leading role in the development of bioethics in the domain of health care in Kazakhstan. This organization initiated some of the above-mentioned initiatives, and today the National Medical Association continues to promote bioethics issues in health care through education, legislative initiatives, conferences, and seminars for doctors, lawyers, nurses, and other professionals.

Since the establishment of the NEC of the Ministry of Health, the committee has become a leader in the promotion of ethical principles during research involving human subjects. Significant work is in progress on improvement of the system of ethical review, as well as the methodological, coordinating, and educational role of the NEC Ministry of Health embedded in the Constitution of NEC.

Currently, the NEC Ministry of Health is involved in development of proposals to amend the existing law on science of the RK to extend the scope of application of bioethics general principles for research in biology, genetics, biotechnology, ecology, sociology, psychology, and other fields. The NEC Ministry of Health is a national partner of the National Commission of the RK for UNESCO, and a number of important activities were held under the UNESCO Participation Program with the support of the National Commission and UNESCO Cluster office for Central Asia in Almaty.

The Central Asian Bioethics Association (CABA) was established in 2008 and joined experts in bioethics from Kazakhstan and other Central Asian countries. The secretariat of this Association is located in Astana, Kazakhstan. CABA is one of the most active players in bioethical principals' promotion in the country ensuring international cooperation in this field.

Major Concerns

Priority areas for bioethics development at the initial stage were implementation of ethical principles in medical practice, especially the practice of obtaining informed consent (IC) prior to medical interventions. Currently, this practice is implemented everywhere, the list of medical interventions is defined where written patient consent is required, and forms of IC are approved by the Order of the MoH.

Issues that have been highlighted the last decade include patients' rights, justice, quality, access to health care, fair resource allocation in the healthcare system in a transition economy, and healthcare policy (discussion of reforms and programs to improve population health and public participation in health issues discussion).

Special attention was also paid to the implementation of ethical principles in such areas as mental health services, HIV/AIDS, assisted reproductive technologies in connection with IVF development, and stem cell research.

A working group on stem cells research of the Ministry of Health was established as a result of public discussions concerning the ethics of stem cells research in 2006. A specialist in bioethics was included in this working group.

The result of this commission was an order of the Ministry of Health calling for a temporary suspension of research with the use of embryonic and fetal cells prior to the development of regulations.

Remarkable results have been achieved in the field of assisted reproductive technologies (ART) during the past 15 years. All known ART are applied in Kazakhstan today, and there are 10 centers for IVF. Women have a right to fertility treatment according to the legislation of the Republic of Kazakhstan, including the use of modern assisted reproductive technologies that are permitted in the country: germ cell donation, artificial insemination, in vitro fertilization, and embryo implantation. Men and women of marriageable age have the right to bank germ cells. The law of the Republic of Kazakhstan declared that human cloning is prohibited in the country.

Surrogate motherhood is permitted for medical reasons in the Republic of Kazakhstan and assumes carrying of a pregnancy and childbirth by agreement between the surrogate mother and prospective parents with remuneration payment or without.

When using assisted reproductive methods and technologies, sex selection is not allowed except the in cases where there is possibility of inheritance of a sex-related disease.

The law of Kazakhstan states that a human embryo cannot be obtained for commercial (buy/sell), military, or industrial needs (Lokshin, 2012).

Another priority area is transplantation of organs and tissues. The basic framework for tissue and organ donation regulation has been defined, and the concept of consent presumption was enshrined by the law with respect to posthumous tissues and organs donation. A ban is imposed on buying or selling organs A pronouncement procedure of biological death or irreversible brain death has been established.

Resources

No professionals in Kazakhstan have been involved in bioethics on a permanent professional basis. Training is carried out mainly with books by Russian and foreign authors, and there is no textbook in Kazakh approved by the Ministry of Education and Science that has been adapted to the local cultural and religious conditions.

Training manuals on bioethics, medical ethics, and research ethics were developed and approved at the university level for students of medical universities.

Since 2001, Kazakhstan has actively participated in the SIDCER (Strategic Initiative for Development of Capacity for Ethical Review) initiative supported by WHO/TDR. Through the regional forums for ethics committees (FECCIS), many activities have been implemented to strengthen the capacity for ethical review of biomedical research. Participation in this network has been an important force behind research ethics development in Kazakhstan.

As a result of collaboration between SIDCER/FECCIS and Western Institutional Review Board (WIRB, Olympia, WA, USA), a participant from Kazakhstan took part in a 6-month course on bioethics and ethical review in 2005.

Measures Taken

A working group on development of the new Code of People Health and Healthcare System was established in 2006 and included experts in the bioethics of research. The code was approved by the decree of the president on September 18, 2009. The Central (National) Ethics Commission of the Ministry of Health of the Republic of Kazakhstan was established according to the code, along with local committees at research institutes and centers and medical universities. These committees mainly review biomedical research involving human subjects.

According to the code (Article # 181), the commission is an independent national body, the main objective of which is to protect rights, health, and well-being of research participants and patients and to guarantee their safety.

The commission carries out activity to enhance national legislation on the ethics of science and technology by developing appropriate proposals and recommendations. The commission is also provides an independent ethical and legal review of clinical research materials.

The commission also provides methodological assistance, consultation, education, and contacts to mass-media. The action plan of the commission also includes carrying out of international ethics conferences and publication of articles in the scientific magazines.

The commission was established on an interdisciplinary basis and consists of experts in the field of medicine, biology, pharmacology, law, religion, and representatives from state and public organizations. The commission fulfills a key role of developing guidelines to help frame the ethical protections of the interests of patients. These include:

- The Constitution of the Republic of Kazakhstan;
- The Code of People Health and Healthcare System;
- The Declaration of Helsinki;
- The Order of the Ministry of Health Rules for Carrying Out Clinical Research, Medical and Biological Experiments and Clinical Trials in the Republic of Kazakhstan;
- The Good Clinical Practice (GCP) standards of the Republic of Kazakhstan;
- The Commission Constitution and standard operational procedures.

To create favorable conditions for the development of similar structures in other ministries and agencies, the commission determined principal targets for the near future:

- Coordination of the activity of the local ethical committees in the country;
- Development of a unified approach to requirements and mechanisms of the ethical review process;
- Counseling help for other ethical structures and implementation of different models;
- Help in training of experts;

One directions for future activity is to develop international cooperation in the field of human rights protection while undergoing medical care, and within the framework of research with human subjects, exchange of experience, joint development of training materials and recommendations in ethics, and other projects in collaboration with international organizations (WHO, UNESCO) and other stakeholders.

In addition, public bioethical committees were established at the Academy of Science, at the National Coordinating Council for Healthcare of the Ministry of Health, and at other public organizations. These committees dedicate their activity to education, increasing public awareness, public discussions, and promoting legislative initiatives. A significant achievement was the inclusion of bioethics in educational programs at the undergraduate and postgraduate levels.

Due to new approaches to moral and ethical problems in medicine and science and the emergence of bioethics as a cross-sectoral discipline in recent decades, it is now necessary to review all levels of training programs. Although "bioethics" has not been included in the state standard of higher medical education, issues related to bioethics are included in other programs. For example, issues of biomedical ethics have been introducing within the framework of communication skills at the Department of Introduction to Medicine, General Medicine. A course on research ethics has been suggested as an elective for undergraduate students (General Medicine, Public Health). The issues of bioethics and law are included in the master of public health program (2 years), master's in medicine program (2 years) as a compulsory course, and for the doctorate in public health (3 years) as an elective course. Also, bioethics and legal aspects are offered to physicians doing post-graduate studies.

The Higher School of Public Health (MSPH) has included discussions on ethics of scientific research in health in its training programs since 2001. Starting in 2002, the HSPH participated, together with the Bangladesh Medical Research Council with financial and technical assistance from an international award, in bioethics training and career development at the International Fogarty Center (FIC) and the National Institutes of Health (NIH) in the United States.

Professor Harun Al-Rashid was the Director of the Program, Director of the Bangladesh Medical Research Council (BMRC), and am member and secretary of the Committee on Ethics of this council, which is considered to be the National Committee of the country.

The program consisted of two components: Kazakhstan and Bangladesh. The Kazakhstan consultant for the program is Professor M.K. Kulzhanov, the principal of the HSPH. The coordinator of the program is B.E. Sarymsakova, M.D., Academic Secretary of the HSPH.

The program consists of the following aspects:

1. Development of complete curriculum/program for a bioethics seminar;
2. Training of young scientists (having various areas of expertise) in bioethics of scientific research.

An intensive training seminar on the ethics of scientific research was developed by the Higher School of Public Health in 2002–2003. The program included a seminar, panel discussions, and meetings. About 20 specialists from various scientific and research institutions in the country participated in development of the seminar program. During preparation of the training program, the teaching staff conducted an intensive seminar on the ethics of scientific research in Kazakhstan. The seminar program was approved by a consulting committee that provided general management of the program, its monitoring, and evaluation. This program was translated into English and sent to international consultants for review and to offer any improvements. At the time, pass-fail forms for trainees and general evaluation of the seminar were also developed.

The Seminar is intended for young scientists doing research in various scientific areas. Fifty people total were trained during three seminars over the course of 5 days. The main purpose of the training in scientific research ethics is to improve ethical practice during scientific research, increase awareness of ethical issues

during scientific research involving humans, provide basic and applied knowledge of ethics with an emphasis on its international aspects, and to familiarize trainees with existing ethics guidelines.

Issues of ethics related to international scientific research in the area of health were specifically emphasized at the seminar. The seminar covered such subjects as historical perspective of ethics related to scientific research in health, international declarations and guidance on scientific research involving humans, informed consent, confidentiality, motivation, ethics of clinical studies, ethics of population and demographic research, ethical issues of scientific research on reproductive and children's health, functions of Committees on Ethics; ethical expertise guidelines, conduct of scientific research in developing countries, and religion and culture in ethics.

The teaching staff included key national experts with respective professional and educational experience in philosophy, legislation, public health, epidemiology, reproductive health, and genetics. Professor Harun Al-Rashid was one of the main professors with experience in conducting such seminars and he speaks Russian fluently. In total, 10 professors were invited to conduct this seminar.

Those doing research in biomedicine, clinics, and public health were invited to participate in the seminar. Notices were sent to all medical institutes, universities, state, and non-state medical organizations. Trainees were selected based on recommendations of the institutions themselves. Heads of the institutions selected a few candidates to take part in the seminar based on the selection criteria as set forth in the information letter. The candidates had to demonstrate their involvement in research and have a minimum of 3 years of research experience. This seminar was intended for young professionals under 35 years old. Criteria for selection were offered and approved during development of the training program. Candidates had to send all necessary documents, including references, of the head of their institution and to the Organizing Committee for the Seminar (OCS). Potential participants were selected on a competitive basis at the OCS meeting. The seminar was organized by the management of the Higher School of Public Health (HSPH) Almaty, Kazakhstan. Trainees received certificates signed by the Principal, Academic Secretary of the Public Health School, and the Director of the Program. A total of 50 young scientists from all regions of Kazakhstan were trained under the program.

Bioethics was included in undergraduate and master's programs in public health in medical universities as a compulsory component in 2009.

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

The basics of bioethics are included in educational programs for students of medical universities at the faculties of public health, nursing, pharmacy, and dentistry in the third course for 36–54 h. Bioethics issues are included under the subject of

"communication skills" at the Faculty of General Medicine in a volume of 36 h. Biomedical research ethics is offered as an elective course for third-year students in the general medicine specialty.

Bioethics as a compulsory component is included in master's programs in medicine and public health for 54 h; foundations of bioethics and biomedical research ethics are found as an elective course in doctoral programs in the specialty of public health.

Foundation courses in bioethics and health law and biomedical research ethics have been proposed for advanced professional training for healthcare providers, ethics committees members, researchers, and other professionals in the faculties of additional medical education.

Bioethics Committees

In Kazakhstan, the system of ethical review of research in the field of health care has only been recently introduced. The basic elements for the functioning of such a system are the legal framework, a network of the ethics committees (EC) at the national and institutional levels, and personnel training. Status and functions of the EC are approved by "The Code of Public Health and Healthcare System of the RK" (2009) and other regulations. Today the EC's work is under way, but in many cases there is a low degree of interaction with authorities and a lack of effective control over the research being conducted.

The system of ethics review of research in the healthcare sector consists of two stages: the Central Ethics Commission under the Ministry of Health of the RK and the Local ethics committees at the level of research institutes/centers of MOH RK. The commission was established as an independent body whose primary purpose is to protect the rights, health, and welfare of the subjects and researchers, and to create guarantees for their safety. The Central Commission for Ethics conducts an independent evaluation of studies at international and national levels.

The Ministry of Health, at a meeting of the Academic Council (2007), recommended establishment of the local ethics committees (LECs) in all research institutions and medical schools. The composition of the LECs and their regulation are approved by an order of the head of the healthcare organization under which the commission has been created. The LECs carry out an independent ethical review of clinical research performed in the establishment and guarantee the rights of patients participating in studies, as well as monitor and control of the interim study after granting permission to conduct.

The commission on ethics may include specialists in healthcare, science, art, and law, along with representatives from religious groups and public associations. The work of the commissions is guided by international instruments, national laws, regulations and statutes, and standard operating procedures (SOPs). SOPs define all of the ECs' activities: the creation and organization of the EC, its composition, procedure for considering an application, documentation, paperwork (application, decision, and report), archiving, and so on.

According to the regulations, ethical review is mandatory at the planning stage of research and is performed by the ethics committees under the research organizations of the Ministry of Health of the RK. In most cases, this work is carried out under the *local* ethics committees under the healthcare organizations accredited as clinical sites for clinical studies/trials (CT) and approved by the Order of the Ministry of Health of the RK.

Procedures for mandatory ethical review of clinical trials have been implemented since 2005, under the order of the Ministry of Health of the RK. This order laid the foundation for the process of accreditation of healthcare organizations for conducting clinical trials and training of professionals involved in clinical trials. An indispensable condition for obtaining the right to conduct clinical trials was the establishment of ethics commissions under the sites to be accredited, as well as availability of specialists with knowledge of the basics of good clinical practice (GCP).

Expert Bodies

The scheme of interaction between the Central and local ethics commissions in considering requests for clinical trials is as follows: application (sponsor-customer) → expert body (the Center for Medicinal Products Expertise under the Ministry of Health of the RK) → Central Commission for Ethics under the Ministry of Health of the RK → expert body → Committee for Medicinal Products Control of the Ministry of Health of the RK → Customer → clinical site (basic researcher) → local ethics commission → conduction of clinical trials.

Without the approval of the ethics commissions, documents on the clinical research or tests cannot be approved by the authorized body (the Ministry of Health of the RK), and the research itself cannot begin.

Relevant Legislation

The basis for legal regulation of biomedical research and its ethical review in the RK is formed by a series of international guidelines and recommendations on research ethics (WMA Declaration of Helsinki, Manual CIOMS, ICH-GCP, the WHO recommendations, etc.). With regard to the domestic system of legal regulation of biomedical research in the RK, it should be noted that detailed regulation exists for clinical studies and trials of medicinal products only.

"The Code on People's Health and the Healthcare System" (2009) regulates the conduct of biomedical experiments, pre-clinical (non-clinical) and clinical studies, use of new methods of diagnosis, treatment, and medical rehabilitation (provision 180).

The State Standard of the RK for "Good Clinical Practice" (65–119 GCP RK) was developed and approved in due course and came into effect in January 2008 (51). This document is a scientific and ethical standard for running clinical studies

and tests, the results of which are scheduled for submission to the authorized bodies. This standard is based on ICH-GCP-Guidelines for Good Clinical Practice of the International Conference on Harmonization.

The principles established in this standard can be applied to other clinical research and tests that may affect the safety and well-being of the subject.

In accordance with Provision 74 of the Code of RK the "Regulations for clinical researches and (or) pharmacological tests of medicinal products, medical devices and medical equipment" (2009) were approved. These regulations for clinical research and (or) pharmacological tests of medicinal products, medical devices, and medical equipment (hereafter, clinical research) in the Republic of Kazakhstan (hereinafter, the Regulations) define how to conduct clinical research in the Republic of Kazakhstan, providing protection of the rights, safety, and health of persons involved in the research, as well as accuracy and precision of information obtained during the clinical research.

Thus, the current system of legal regulation of biomedical research in the Republic of Kazakhstan ensures compliance with generally accepted ethical standards and requirements, especially in the field of clinical research. However, questions of ethical regulation of research not related to medicinal products testing (genetic, sociological, epidemiological, and other biomedical research involving human subjects) require additional legal regulation.

One of the basic problems that was revealed was the absence of unified approaches to the LECs' work organization. It is necessary to develop Unified National Ethic Guidelines on organization and conduct of biomedical research with due account to the international requirements. The most essential element of such guidelines should be a unit devoted to conduct of ethical examinations and organization and examinees' rights protection. In this case, it is necessary to standardize creation procedures and activity of ethic committees/commissions through distribution of standard operational procedures (SOP) approved by the Ministry of Healthcare and the Ministry of Education and Science.

Each LEC should create and follow its own SOP guidelines, whose application and field of influence reflects activity of the LEC and refers to national and international standards for ethic examination in biomedical research.

Future Challenges

In Kazakhstan, a system of ethical review of research in the healthcare sector has been created and in operation, which has a legal, regulatory, and institutional framework (the central and local ethics commissions).

It is worthwhile to develop and implement a clear scheme of cooperation for structural elements of the system and to divide their functions and authorities. This should result in increased efficiency and quality of examination of scientific research with human subjects.

Moreover, it is important to provide conditions for EC functioning (administrative, organizational, and financial support at the institutional level). A key problem

is training LEC members and providing methodological, informational, and resource support for the committees' activities. Creation of an Information and Resource (or Methodological) Center under the Central Committee on Ethics Issues Ministry of Health RK has been suggested. This center is supposed to carry out the following functions:

- Create and update the national database on EC, resources, results of completed ethic examinations within different healthcare organizations (clinical, scientific, training);
- Support permanent system of dialogue between the EC members (annual conference, foundation of the EC association/forum, creation of special website for opinion exchange between the ECs and the exchange framework within an organization, etc.);
- Implementation of the EC experience for teaching medical students, biologists, geneticists, and people in other related specialties.

It is necessary to include discussions of bioethics, research ethics, and ethical review of research projects in the system of continuing professional development of physicians and researchers, experts, and members of the ethics committees, which will increase the level and quality of scientific research in accordance with international standards. The concept of training expert members of the ethics committees has been suggested and included of basic and continuing education. It is crucial to include the subject of bioethics in the state educational standard for undergraduate and postgraduate education based on the UNESCO core curriculum on bioethics.

The system of the ethical review of research involving human subjects in the Republic of Kazakhstan has a legal (the legal framework) and an institutional (the ECs network) basis. The legislation regulates the ethics, mainly, in clinical research, and there is no regulation for other ethical principles of biomedical research involving human subjects.

Implementation of the system of ethical review of research in the Republic of Kazakhstan requires effective support from the government and research organizations: training professionals for the LECs, increasing interaction of local ethics committees, and improving the regulatory framework for biomedical research with regard to their ethical regulation.

According to self-assessment and expert review, the local ethics committees' activity in research institutions of the Ministry of Health of the Republic of Kazakhstan is not yet in line with international recommendations, especially with regard to management of ethics committees and the level of expert committee members' training.

Results of this study have formed the basis of recommendations for further improvement of the system of ethical review of research organizations of the Ministry of Health RK. There have been proposed measures to improve the regulatory framework of ethical review and improve training for the LEC members, providing institutional support to the LEC, and increasing interaction of ethical committees at various levels that will improve the quality of ethical review of research in the health sector, in line with international recommendations.

New and Emerging Issues

Strong measures for development of science and technology are under way in Kazakhstan. Government programs to support scientific and innovative development of the country have been approved, and new universities, research centers, and technology parks have been established. The HSTC (Higher Scientific and Technical Commission) defined national priorities for science development for 2011–2013, which were approved by the protocol resolution №20-55/372 dated April 21, 2011:

1. Energy industry (energy efficiency, ecological cleanness and environmental safety, alternative safety, renewable sources, nuclear and thermo-nuclear power);
2. Advanced processing of raw materials and products (refining of hydrocarbon and mineral raw materials, chemical and mining and smelting technologies, and agricultural products);
3. Information and telecommunication technologies;
4. Life sciences (medical and biomedical research, biotechnologies, ecology, anti-aging, pharmacy, agriculture);
5. State intellectual capacity (basic natural science and humanitarian international level research, exploratory research in promising directions).

The following priorities are defined in the field of medicine for 2011–2015:

1. Environment and health;
2. Active longevity (prolongation of life and rejuvenation);
3. Regenerative medicine (cell technology, artificial organs);
4. Child welfare and reproductive health technologies;
5. Technologies to prevent premature death and disability from disease and injuries;
6. Technologies to prevent and reduce the burden of communicable and socially significant diseases (tuberculosis, HIV/AIDS, viral hepatitis).

The new Nazarbayev University, named after the first president of the country, was opened in 2010 in Kazakhstan. Science and technologies schools and a Center for Life Sciences were opened at this university, where the main focuses are anti-aging, cell technologies, personalized medicine, and genetics research.

Transplantation is being actively developed in the country; a National Coordinating Center for Transplantation was established in 2012, which should develop an organizational, legal, and methodological basis for this service development in the country.

There are some unresolved issues, however, such as lack of donor organs and ethical and legal basis for organs removal. The key issue – the consent for organ and tissue removal – is not regulated and did not accurately determine the presence of intra-vitam refusal from the deceased patient for posthumous tissues and organs donation and did not establish a mechanism for access to the deceased patient's relatives for such a data request or for their opinions. In addition, the issue of brain death as the death criterion is not fully resolved. All this will serve as an impetus for the further bioethics development in the country.

Other Problems and Opportunities

Kazakhstan and other Central Asian countries (Kyrgyzstan, Tajikistan, and Uzbekistan) have well-established historical, social, and linguistic ties, having been part of a single country (the Soviet Union) for more than half a century. However, the region its own unique identity that is evolving and is influenced by the region's strong geopolitical location at the crossroads of two large regions, Asia and Europe. The need to recognize and cultivate a uniquely Central Asian identity has been the impetus for the creation of the Central Asian Bioethics Association (CABA). In Central Asia, this identity represents the convergence of many factors: for example, traditional and modern values, the increasing influence of Islam in many regions, rapid economic development in some sectors, and insufficient resources being dedicated to science and technology, education, and innovation. The region's diverse cultural and religious composition makes development of ties and sharing of information imperative with countries throughout Asia and the Middle East, as well as with the former Soviet bloc.

During the years after the break-up of the USSR, the system of science and education changed drastically, relations between scientists weakened, there was a substantial outflow of qualified specialists, the material and technical base deteriorated, and funding was reduced, etc.

At the same time, the role of scientists who are called on to control disease and improve health has become more important. This research often involves humans, which imposes a special responsibility on a researcher. The advancement of medical and biological research causes concern, as it makes it difficult to predict social and general biological consequences following from the latest scientific discoveries in genetics, stem cell therapy, and other areas. Bioethics, as an interdisciplinary scientific school of thought, tries to answer these challenges.

For Kazakhstan, increasing globalization of science and technology presents new opportunities to build quality and efficiency into research among all actors engaged in promoting best practices in the country: bioethics committees, researchers, research institutions, and universities, as well as those benefiting from scientific and technological achievements, including patients and consumers. Awareness in the country has already been raised regarding the importance of interdisciplinary cooperation in the field of bioethics.

In the course of socioeconomic transformation, there is a necessity for Kazakhstan to develop its science and technology sector and to invent new technologies in medicine and biology. In this regard, there is a growing attention to the importance of ethical principles in scientific and health research National, regional, and international guiding principles are imperative for the effective functioning of ethics expertise. However, international ethical standards are not sufficient to ensure ethical practices, for example, the protection of human research subjects, if information gathering, knowledge dissemination, and educational activities are conducted without systematic approaches at the national level. For Central Asia, the relatively small size of countries in the region means the number of specialists working on bioethics issues is quite small, only a few in each country. Because of this, a regional approach based

on national support mechanisms is necessary to comply with the highest ethical and scientific standards in research practice of the region.

CABA's advantage is its partnership approach and collaboration among experts from the leading institutions of the region and international organizations. This initiative will provide those in Kazakhstan with an opportunity to discuss bioethical problems raised by the application of biotechnology and research at the national, regional, and international level. It is also proposed to create allies with other organizations that are dealing with science, research, and ethics, including research institutes, health facilities, governments, and NGOs. CABA is supporting countries, institutions, and society by providing opportunities to develop ethics and science, contributing to an inclusive ethics-based decision-making process and creation of a legal framework that takes into account the interests of citizens in the region.

Conclusion

Bioethics has developed over the last 10 years in Kazakhstan. Public medical organizations, physicians, and researchers were at the origins of this process. This determined the main vector of bioethics development in the following years; the emphasis mainly was on medical ethics and medical research ethics.

Significant results have been achieved in this field today: legal basis, a network of ethics committees, and training in the basics of bioethics in medical universities. However, due to development of new scientific discoveries and technologies and international cooperation of scientists in the field of basic research, further bioethics development with the involvement of others from outside the medicine sectors is required. For this purpose, it is necessary to establish cross-sectoral structures interested in promotion of bioethics principles in various fields of science, education, and new technologies development. It is necessary to raise the awareness and involvement of the widest social strata in the discussion on urgent bioethics issues, to implement training in bioethics in school and university curricula, and to develop international cooperation.

Lithuania

71

Eimantas Peicius and Vilius Dranseika

Lithuania is a country situated at the northeast part of Europe along the east coast of the Baltic Sea. Currently, Lithuania is a civic democratic society governed by a freely elected parliament (Seimas) and a president, and has been a member of European Union since 2004. With more than three million inhabitants, the country has one of the lowest GDPs in the European Union, comparable to Latvia, Romania, and Bulgaria. In this chapter we are going to discuss development and the main characteristics of Bioethics in Lithuania.

Bioethics Development

The development of ethical norms related to the field of medicine in Lithuania can be divided into three historical periods: nineteenth to mid-twentieth century discussions on norms governing behavior of medical doctors, Soviet medical ethics, and bioethics since re-establishing the independence of Lithuania. The first two periods were mostly concerned with medical deontology, that is, the duties of medical professionals. The third period witnessed the expansion of the field in terms of establishing new academic and governmental institutions dealing with bioethics, as well as establishing international connections, cooperation, and engagement around a much broader thematic scope of issues.

The first fragmented ethical considerations related to medical activities can be found at the beginning of the nineteenth century in the Faculty of Medicine of Vilnius University, the oldest education center in Lithuania (established in 1579). The departments of hygiene and forensic medicine were established, and the course on social hygiene and forensic medicine was introduced at the Faculty of Medicine, Vilnius University. In the context of those activities, some historical sources indicate academic discussions over physicians' duties to patients in amputation, surgery, and other medical procedures. However, further developments were impeded by the suppression of academic activities in Lithuania by the Russian Tzarist rule. (Most of Lithuania was a part of the Russian Empire from 1795 until World War I). Between 1918 and 1940, Lithuania was an independent state until it became a part of the USSR during World War II. During the independence period, academic activities in the field of what now would be called bioethics were few and mostly concentrated on professional behavior and character traits of medical specialists. Perhaps the most notable example was "On Professional Ethics of Medical Doctors," a small booklet by Petras Avižonis published in 1929 (Avižonis, 1929), which addresses three issues: (a) moral, intellectual, and physical features of a good doctor; (b) duties of doctors towards their colleagues; and (c) their duties towards patients.

The second stage of bioethics development happened during the Soviet period while Lithuania was a part of the Soviet Union (USSR). In general, Soviet medical ethics, usually referred to as medical deontology, was a set of rules mainly based on the Hippocratic Oath. These rules were integrated into the Soviet ideological philosophical teachings based on dogmatic Marxism (e.g., Černeckis, 1971; Žemaitis, 1976). Without going too deep into the political and ideological conditions of Soviet totalitarianism, it would be sufficient to state that, arguably, the development of bioethics in the Soviet Union was nearly impossible and significantly differed from the historical and political circumstances prevalent in Western countries. In such a context, officially prescribed norms and principles that were imposed upon professional activities should rather be distinguished from the ethical norms and values actually accepted and practiced by health care professionals. Consequently, the narrow understanding of medical ethics of the former socialist countries of Eastern Europe and especially the former Soviet Union has usually been identified with the statements taken from "The Oath of Soviet

Physicians." This oath included, for instance, obligations to always take into account the interests of the society, to make sure that "the conduct of all my actions accord[s] to the principles of the Communist morality" (Gefenas, 2009b, p. 469), and to keep in mind the "high responsibility I have to my people and to the Soviet government" (ibid.).

Since the re-establishment of independence in 1990, bioethics has gradually developed both in academic and governmental activities. A number of academic departments conducting research and teaching medical humanities were established in educational institutions across the country. A system of ethical review of biomedical research was established, both in terms of institutions and legal regulations. A number of international collaborations were initiated, and the number of publications in the field of bioethics began increasing gradually.

Three major factors shaped the development of bioethics during the transitional period from a totalitarian to a democratic society. First, reforms in health care, social policy, and other realms of social life caused growing academic interest in the Western heritage in the fields of philosophy, ethics, sociology, psychology, and other disciplines in humanities and social sciences. The need to incorporate medical humanities into the medical students' curriculum was a part of this process. In the early 1990s, individual scholars started to introduce into the curriculum topics of human rights, personal autonomy, and social justice as well as more practical problems, like those of informed consent, abortion, or allocation of scarce health care resources. Second, changing realities of the healthcare system triggered new practical challenges. Health professionals have expressed a growing interest in medical humanities because of the changing needs and expectations of patients and the shift from a paternalistic approach to one rooted in patient autonomy. The need to join international biomedical research is another example of those changing realities. The system of ethical review of biomedical research began with initiatives of individual researchers in the late 1980s, and resulted in a quite comprehensive system a decade later. The third factor was a legal development related to Lithuania's integration into the international scene and European structures, most notably joining the European Union in 2004. This process of harmonization resulted in a number of legal instruments being implemented in the field of bioethics in Lithuania, including Directive 2001/20/EC of the European Parliament and of the Council on the Conduct of Clinical Trials on Medicinal Products for Human Use in 2004.

The two major actors during the third stage of the development of bioethics in Lithuania were the academic centers of medical humanities and the Lithuanian Bioethics Committee, an official governmental institution responsible for policy making in the field of bioethics as well as ethical review of biomedical research. These two factors have played and are still playing a crucial role in the development of bioethics in Lithuania. Educational activities and the system of ethical review of biomedical research more specifically require a more detailed discussion.

Currently, there are no bachelor's or master's level study programs in bioethics or medical ethics offered in Lithuanian educational institutions. However, courses in medical humanities are an integral part of medical professionals' education.

Courses in bioethics are taught to students in some other study programs as well, such as philosophy. A notable example of international cooperation in the field of bioethics education is a combined online-onsite study program, the "Advanced Certificate Program: Research Ethics in Central and Eastern Europe," offered by the Vilnius University Department of Medical History and Ethics in collaboration with the Bioethics Program at Union Graduate College – Mount Sinai School of Medicine (USA). The fourth cohort of students from Central and Eastern Europe have finished their studies in 2012. These studies are focused on research ethics and international bioethics and the goal is to prepare students to function as independent research ethicists in their home countries.

The development of the system of ethical review of biomedical research started in the late 1980s with the establishment of the first hospital-based research ethics committees. In 1994, the Law on the Health System was adopted, which led to the establishment of the Lithuanian Medical Ethics Committee (now called the Lithuanian Bioethics Committee) a year later. The committee functions as a national bioethics council and it also has a subcommittee for ethical review of biomedical research. In 2001, the Law on Ethics of Biomedical Research introduced a two-tier system of ethical review with one central committee (the Lithuanian Bioethics Committee) and two regional committees. One of these regional committees was established at Kaunas Medical University (now known as the Lithuanian University of Health Sciences) in 2001 and another one at Vilnius University in 2008. Regional committees are assigned geographically defined jurisdictions. The Lithuanian Bioethics Committee supervises the regional committees and reviews their decisions upon appeal. It also issues decisions on clinical drug trials and on biomedical research studies that take place in more than one region. A more detailed account of the system can be found in Dranseika et al. (2011).

Healthcare ethics committees have been also operating in Lithuanian healthcare institutions since the early 1990s. However, their efficiency in addressing ethical concerns in the healthcare setting remains questionable (see Gefenas, 2001 for an overview).

The main institutional developments during the last two decades can be summarized as follows. Several academic departments related to bioethics were established in the early 2000s, a system of ethical supervision of biomedical research was established, and hospital ethics committees have been functioning in most healthcare institutions since the 1990s. In relation to these activities, a number of textbooks on bioethics, especially on medical ethics were translated into Lithuanian, mostly from English. Several monographs and textbooks on medical ethics and nursing ethics were written by Lithuanian authors as well (e.g., Blaževičienė & Jakušovaitė, 2008; Liubarskienė, 2005; Liubarskienė, Peičius, Blaževičienė, & Urbonas, 2008; Širinskienė & Narbekovas, 2007).

The academic and institutional development of bioethics in Lithuania was followed by some difficulties. First, new democratic values such as respect for persons, freedom, and civic participation challenged the heritage of previously widespread cultural traditions and moral values (i.e., obedience and paternalism). Second, competition between egalitarian and libertarian principles in the domestic

health policy and health care provision has continued to exist. Despite the fact that equitable access has been declared as a priority in the official Lithuanian health policy documents, a scarcity of healthcare resources constantly pushes the system towards a libertarian type of health care. Third, the emergence of secular bioethics has been followed by religious perspective on bioethics. However, a fruitful dialogue between these two perspectives is often lacking in Lithuania.

Current Bioethics Infrastructure

This section contains information on the main features of the current bioethics infrastructure in Lithuania: academic departments, educational activities, the system of ethical review of biomedical research, and the main legal instruments pertaining to issues of bioethics.

Currently there are four academic departments in different educational institutions of Lithuania dealing with (among other issues) research and teaching in the field of bioethics:

- Department of Medical History and Ethics, Vilnius University
- Department of Social Sciences and Humanities, Lithuanian University of Health Sciences (Kaunas)
- Department of Biolaw, Mykolas Romeris University (Vilnius)
- Research Center on Marriage and Family, Vytautas Magnus University (Kaunas)

Another institution, the Regional Bioethics Information Centre at Vilnius University, is an information and documentation center taking active part in a number of European research and networking initiatives with a special emphasis on activities in Central and Eastern Europe.

Courses in bioethics and medical ethics are currently part of the curriculum of medical schools at the Faculty of Medicine at Vilnius University and the Lithuanian University of Health Sciences. Courses in bioethics are sometimes taught for non-medical students as well, for example, students of philosophy at Vilnius University or students of biolaw at Mykolas Romeris University.

The system of ethical review of biomedical research in Lithuania consists of two tiers. The Lithuanian Bioethics Committee (Lithuanian Committee for Medical Ethics before 2000), established in 1995, is the chief institution responsible for bioethics policy in Lithuania and it is also responsible for the ethical review of multi-site biomedical research projects. In addition to the Lithuanian Bioethics Committee, there are two regional research ethics committees responsible for ethical review of biomedical research conducted in particular regions of Lithuania. The Kaunas Regional Biomedical Research Ethics Committee was established at Kaunas University of Medicine (now Lithuanian University of Health Sciences) in 2001. The second regional committee was established at Vilnius University in 2008.

The development of legislation in the field of bioethics in Lithuania is closely related to the integration of Lithuania into different international and European structures. Such international bodies as the Council of Europe,

the European Commission, and UNESCO played an important role in this process. The most important international instruments in force in Lithuania are the European Convention on Human Rights and Biomedicine (ratified in 2002), regulating the protection of human rights in the field of biomedicine (together with its Additional Protocols on the Prohibition of Cloning Human Beings (ratified in 2002) and concerning Biomedical Research (signed in 2005)), and Directive 2001/20/EC of the European Parliament and of the Council on the Conduct of Clinical Trials on Medicinal Products for Human Use (implemented in Lithuania in 2004), which sets the framework for clinical drug trials. The most important national legal documents are the following: the Law on the Health System (1994), which, among other things, led to the establishment of the Lithuanian Bioethics Committee; the Laws on the Rights of Patients and Compensation of the Damage to their Health (1996) and on Legal Protection of Personal Data (1996), which together set the framework of patient rights and protection of health and other personal data; and the Law on Ethics of Biomedical Research (2000), which completed the establishment of the two-tier system of ethical oversight of human biomedical research. (For a list of all the relevant documents including ministerial decrees see the website of the Lithuanian Bioethics Committee (http://bioetika.sam.lt)).

Major Bioethics Issues and Discussions

The development of bioethics in Lithuania, as indicated previously, was strongly influenced by the political and cultural shifts during the last two decades. A number of debates related to specific bioethical problems have been initiated in political, academic, and public circles while trying to apply European democratic values in practice, especially in the healthcare sector. Lithuanian bioethicists analyzed general concepts like human dignity, health, illness, and personal autonomy when discussing and often justifying pluralistic and patient-centered medicine, which was replacing the tradition of paternalism in Lithuanian medicine (Jakusovaite & Peicius, 2003). Integration of the practice and culture of respect for personal autonomy into decision making in health care met significant difficulties, mainly because the values and principles of a free and democratic society had been suppressed during the decades of totalitarian regime, where personal autonomy was regarded as secondary to the "best interests of the society." Recent efforts aimed at replacing traditional paternalism should be seen not only as attempts at developing a safeguard against abuse of patients' rights but also as part of a wider social and political effort to develop broader understanding of respect for persons (Gefenas, 2009a). Much of the current activities of Lithuanian scholars, researchers, and the public that is focused on such issues as ethics in clinical care, research ethics, and social ethics regarding the organization of healthcare system can be seen as a reaction to this fundamental challenge.

The analysis of the shift from paternalism to autonomy in the health professional–patient relationship currently is one of the most actively addressed issues in the country. The discrepancies between officially declared principles of

patient autonomy, informed consent, and rights to healthcare access, inherent in the legal system, and their implementation in medical practice have been repeatedly reported. Accordingly, the need for more active patient participation in medical decision making is one of the most important challenges in the reorganization of health care in Lithuania. Attempts at the application of a partnership relationship in, for instance, the general practitioner–patient relationship in primary care reveal a number of questions: How well are patients informed about their rights? How much and what kind of medical information should be disclosed to the patient and on what conditions? How is such information perceived by different patient groups? How should it be managed? And to what extent should health professionals take patient opinions into consideration if these opinions contradict the benefit of patients themselves? (Grabauskas, Peičius, & Kaminskas, 2004).

Paradoxically, the legislation of patient rights and its adoption in practice as a reaction to the widespread paternalistic culture in health care has led to some misconceptions. First, the formal adoption of bioethical principles such as informed consent did not affect medical practice in the way it was intended to: the gap between declarations and daily practice was noted by the public and the media as well as by the scholars. Second, the practice of informed consent became too formalized and too demanding, both in terms of time and other resources. Straightforward application of the principle of informed consent basically boiled down to the requirement to obtain a written form of patient's consent in every step of the treatment. This caused many complaints and increased mistrust between health professionals and patients rather than striking the right balance between physician duties and patient rights. Active debates on the procedure of informed consent in clinical practice have led to the amendment of the Law on the Rights of Patients and Compensation of the Damage to Their Health in 2010. New provisions have been included in order to respond to the growing complaints of health professionals regarding the requirements to obtain formal informed consent from the patient at every step of healthcare service provision. For instance, in the context of voluntary admission to healthcare service, informal consent of the patient could be deemed sufficient for many medical procedures if adequate information is provided to the patient according to his or her demands. Consequently, written informed consent must be obtained only in the case of performing interventional, invasive, or surgical procedures or when the patient opts for another treatment than the one recommended by the physician. These amendments have initiated wide debates on the patient role and adequate sharing of responsibilities, for example, in primary care or preventive medicine and public health. Moreover, different interpretations have appeared regarding the application of informed consent in special conditions such as psychiatric or emergency care and concerning who can be the proxy decision makers when a patient has lost the capacity to consent or if the patient's will contradicts the will of the patient's relatives.

Another field of debate involved practical problems of biomedical research involving humans. Issues addressed by Lithuanian scholars included questions of implementing ethical requirements of biomedical research, identification of vulnerable persons, and protection of their interests in research as well as in the

practice of informed consent, protection of privacy and confidentiality, civil liability of the sponsor and principal investigator, insurance of research subjects, conflict of interests, and others (see Gefenas & Cekanauskaite, 2003 for an overview). The implementation of informed consent of the research participants and conditions of valid consent in research were among the most actively discussed issues. Despite the fact that the requirement of informed consent was introduced into the legislation more than 10 years ago, it was found that a rather significant proportion of research participants do not really understand the key elements of the information provided. The issues of readability of informed consent forms in biomedical research and the failure to understand the nature of medical procedures can be traced to insufficient knowledge and the widespread passive social role of research participants in the country (Čekanauskaitė & Gefenas, 2010; Lukauskaite, 2003). Additionally, the legal provision to the effect that research without informed consent is prohibited by law in the country has been continuously challenged by emergency medicine representatives. Exceptions to informed consent and critical analysis of a minimal risk standard of research on incompetent (e.g., seriously injured) persons in the context of emergency medicine, as well as global tendencies toward its liberalization, remain contested issues in Lithuania. By enforcing the statement that research is allowed only on the persons capable of consent and having one of the strictest laws on biomedical research in Europe, Lithuania faces a number of questions in the field of research ethics. For example, is it ethical to use and apply the results of scientific research that was prohibited by law in Lithuania, but allowed and conducted in other countries, having different legal and ethical standards on research involving vulnerable groups of research participants?

Regulations on informed consent in relation to the use of bodies of the deceased for scientific research and especially for educational purposes were discussed repeatedly by the public and by scientists. The consent is allowed by law only in the cases of the donation of bodies for educational purposes. However, controversies over how the will of the dead should be expressed, interpreted, and formalized as well as who (close relatives only or someone else) may adequately represent the will of the person are still under debate. The issue of the consent requirements applicable to the research on biological materials removed from the deceased, however, was also addressed by expert and public debates. So far, there is no consensus on how to legitimate informed consent regarding the use of such biological materials for research purposes. These questions are important in the context of Lithuania, since the discussion has just emerged and the attitudes and preferences of various interested parties are little studied.

Next, issues of social justice and solidarity have been and remain of high importance in Lithuania. The common problems of the distribution of limited resources and equal access to health care become especially pressing in the context of healthcare reforms. Liberalization of service provision in health care as well as insufficient economical capacity of the country to cover growing public needs of health services induced tension and confusion between different approaches to social justice on the level of health policy decision making. In attempting to increase the cost effectiveness of health services in Lithuania, contradictory

strategies have been employed to date. For example, decentralization and privatization have been implemented as part of health policy to achieve greater efficiency (at least in theory). However, in practice, the reform of decentralization of healthcare organizations resulted in the emergence of private health care, which, according to some accounts, reduced access to health services for the most vulnerable social groups (Bankauskaitė & Jakušovaitė, 2006).

Additionally, financial deficits in the hospital sector have resulted in the unofficial but widespread practice whereby patients are asked to pay for medicines and disposable goods. Some empirical surveys indicated that about 30 % of pharmaceuticals used in hospitals were in fact paid for by the patients, though officially they are to be provided free of charge. The practice of under-the-table payments, inherited from the Soviet period, has been reduced in the outpatient sector, but it may have increased in the inpatient sector. As many as 40 % of hospital inpatients reported having paid money for services that are officially free of charge (Cerniauskas & Murauskiene, 2000). Previous studies revealed that, in Lithuania, households in the top 10 % income bracket spend 20 times more on health care than the bottom 10 % of households. As indicated by Eugenijus Gefenas, "egalitarian principles are still not followed in the domestic health policy," and "the economic and political reality is that access to health care is very much a function of the ability to pay and therefore amounts to a libertarian type of health care, despite the fact that equitable access is still declared as a priority in the official health policy documents" (Gefenas, 2009b, p. 599).

Among the ethical problems related to the outcomes of healthcare reform in Lithuania, a number of others can be mentioned, in particular, in reproductive medicine and palliative care. During the last decade, different projects of the Law on Artificial Insemination have been widely debated in parliament and publicly, however, with little results as the bill has still not passed. Controversial opinions regarding the artificial insemination model in Lithuania have engaged different social actors in a general discussion on the concepts of person, family, disease, and social welfare. Furthermore, competition between more liberal and more conservative (led by the Roman Catholic church) approaches to in vitro fertilization (IVF) or change of sex has resulted in serious debates on the questions of the moral implications of infertility and the status of such conditions from the medical point of view. Regarding IVF, the moral and ontological status of the embryo as well as defining its normative position in a legal system and the procedures regarding the excess of already produced embryos seem to be the major problems standing in a way of achieving considerable consensus. Opinions regarding use, storage, and donation of frozen embryos and the treatment of infertility are still very much polarized in Lithuania. In contrast to Western European countries, issues of surrogacy, bio-banks, and commercialization of germ cells are lacking on the legislative agenda and are little discussed by the public in the country.

Recently, there has been growing interest in medical decisions at the end of life, and the topic is beginning to be more frequently addressed in academic, public, and political discourses. Previously, discussions on ethical issues concerning death and dying were very sensitive because of the influential Catholic Church's pro-life stance.

However, discussions on the issues around the right to die or withdrawal of life supporting treatment have emerged naturally as the result of social and political changes in the country. In particular, issues related to potential legislation of euthanasia occurred in the context of economic difficulties to cope with the imbalance between the needs of the growing number of geriatric and terminally ill (such as oncologic) patients and the lack of resources to cover these needs, for instance, in palliative care. Taking into account global trends in bioethics, ethical dilemmas of the end of human life will obviously be among the central issues in Lithuania in the near future.

Future Challenges

Both academic developments in the field of bioethics and institutional changes in research subject protection in Lithuania were unsurprisingly followed by some concerns and challenges. In general, official and formal adoption of previously mentioned international documents and legislation of widely accepted bioethical approaches affect medical practice to a lesser degree than expected. Despite the fact that patient rights were widely highlighted by newly established regulations, the gap between declarations on paper and implementation in practice seems to remain. Overcoming professional and public skepticism concerning moral requirements as well as widespread stereotypes in moral reasoning and daily activities is one of important future tasks for bioethics in Lithuania. In this respect, public education, for example, introducing the principles of modern moral reasoning and argumentation, as well as active public involvement in the discourses around important bioethical problems are imperative. It should also be noted that the various discourses on the negative image of health professionals as well as malpractice, negligence, or even discrimination in clinical units are continuously emphasized by the mass media, and these problems require further attention. Other important problems of inter-professional relationships in health care are still less debated: for example, high professional insecurity and a poor capacity for teamwork sometimes result in inappropriate management of healthcare services and decreasing public trust.

Additionally, bioethics as an academic discipline is not regarded as sufficiently serious both in terms of philosophical contributions and empirical scientific research. The common criticism of bioethics is imposed by biomedical professionals who would think of bioethics as an obstacle to the progress of biomedical science. On the other hand, philosophers sometimes assume bioethics as being a populist and simplistic application of normative ethics. Lawyers may be dissatisfied by the dilemmatic character of bioethical discourse not resulting in any clear policy or legal framework. This opinion is sometimes seconded by biomedical professionals as well. So there is a deep conflict between the goals and constraints of the public policy process and the aims of academic scholarly activity in the discourse around bioethics in Lithuania (Gefenas, 2002).

Another challenge to be met by bioethics in the educational process is the integration of new interdisciplinary subjects. Integration of such disciplines as medical anthropology, medical sociology, human ecology, bioethics, and literature into the teaching of

bioethics are still works in progress in Lithuania. Currently, the multidisciplinary nature of bioethics in the medical education curriculum is usually reduced to medical ethics, basically because of insufficient attention to humanitarian disciplines in national education policy, which leads to a situation where medical humanities are not sufficiently represented in the academic curricula of medical professions.

Moreover, collaboration between scholars of different disciplines, even in the context of medical humanities, is an exception rather than a rule, not to mention the lack of efficient cooperation between competing research centers. Thus, studies of the bioethical issues are not systematic. Research on the ethical problems is usually framed as a supplement or part of social politics or medical sociology. Also, simplistic methodologies might be employed, for example, when, in order to determine the perception of medical information among terminally ill patients, quantitative research methodology is used instead of qualitative.

Finally, as a consequence, the emergence of secular bioethics has been followed by a surge of the religious perspective on bioethics. This process has been particularly active in Roman Catholic–dominated Lithuania, where some universities and medical schools filled the vacuum in medical humanities with courses of Catholic bioethics and medical ethics. In addition, the remains of post-Soviet thinking, ethical skepticism, and the lack of professional training result in a situation where bioethics is still at the crossroads in finding its place in Lithuania (Gefenas, 2009b). Establishing meaningful dialogue between different professional groups, for example, academics and policy makers or between groups holding different worldviews, is one of the foremost challenges in relation to the future of bioethics in Lithuania.

Conclusion

The development of bioethics in Lithuania during recent decades occurred mainly within the framework of medical education and ethical review of biomedical research. Scholarly interest in bioethical issues has significantly increased since the collapse of the totalitarian Soviet model of society, which brought enormous changes in political and social conditions in Central and Eastern Europe, including Lithuania. Additional input was provided by the processes of integration of Lithuania into European and international structures. A key event in the institutionalization of bioethics in Lithuania was the establishment of the Lithuanian Bioethics Committee in 1995. It played an important role in increasing the activities related to the development of research ethics and other bioethics issues in Lithuania.

Medical humanities were gradually encompassed into the education of healthcare professionals by including courses on medical ethics in the curricula of medical schools and establishing bioethics-oriented departments in a number of Lithuanian universities. The issues of patient rights shifting from paternalism to personal autonomy and implications of informed consent in therapeutic and research activities were the most frequently addressed in the studies and reviews, both academically and practically. Issues of social justice and resource allocation in health care as well as issues regarding the beginning and end of life are perhaps the

most actively debated issues in bioethics among public and experts in Lithuania. One of the foremost challenges is thinking ahead about future development of bioethics in Lithuania, as well as the more collaborative dialogue between different professional groups, between academics and policy makers, or even between parties with different world views.

Bioethics Development

The history of bioethics in Malawi is closely linked with the University of Malawi, College of Medicine. It is at the College of Medicine where bioethics started. Today, the University of Malawi, College of Medicine, is one of the very few

medical colleges in Africa that considers the subject of bioethics and research ethics as necessary and indispensable. It is one of the few medical schools in Africa that introduced a compulsory biomedical ethics curriculum, which covers all 5 years of medical training. All the initiatives in the areas of bioethics and research ethics at the college and in Malawi are spearheaded by CEBESA.

CEBESA was established in 2001 and falls under the Department of Community Health at the College of Medicine. The Center is committed to helping healthcare professionals, researchers, students, and policymakers in addressing ethical issues in Malawi. CEBESA seeks to promote the ethical practice of medicine and the ethical conduct of biomedical research in Malawi. The Center also seeks to reach out to various institutions, projects, researchers, and communities, using various means. It also provides training to ethics committee members and researchers on research ethics, clinical trial monitoring, and good clinical practice. In addition, it provides advice to various stakeholders including government, health practitioners, research ethics committees, hospitals, members of the public, and others on issues related to bioethics, research ethics, and good clinical practice (GCP). The major concerns so far are in the areas of funding for research and trainings.

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

CEBESA has established a related human rights initiative called the Medical Rights Watch (MRW). The MRW was born in a bioethics class and it is taking bioethics to the grassroots and making people aware of their rights and responsibilities. The primary objective of the organization is to bring basic ethical values to the attention of all key health decision makers at all levels, with the goal of transforming the health system into one that effectively applies justice, beneficence, and autonomy. MRW is achieving this through making basic bioethics knowledge available to all these decision makers and giving them guidance on how to resolve ethical dilemmas, so as to achieve ethical decision making. The goal of MRW is to promote and protect the rights and responsibilities of patients, research participants, and health practitioners in Malawi. As the first and so far the only health rights organization in Malawi, MRW is fighting for safe, accountable health care that does not compromise the rights of patients. This work is extending to all parts of the Malawian healthcare system, including research and training institutions throughout the country.

CEBESA is also championing the African moral theory of ubuntu/uMunthu, (which will be explained later in this Chapter) and urging medical students to apply it in their medical practice. The Center also has a newsletter which covers issues of bioethics and research ethics in Malawi. Members of CEBESA have published in the field of research ethics, bioethics, and human rights in local and international journals and book publications.

CEBEASs publications focus on applying ethical theories to ethical challenges and moral dilemmas that emerge in the context of research in Malawi, and by

extension, Africa. The aim of our publications is to provoke new ways of thinking. Key issues addressed in our publications apply ethical principles like informed consent, confidentiality, justice, beneficence and nonmaleficence to research. Of late, the central thrust underpinning our work is the promotion of African ethics and values in bioethics in the context of globalization. It is within this context that we hope to contribute to the African and global discourse of ethics by championing the ethic of uMunthu and Ubunthu.

What Have Been the Steps/Measures Taken (Policies, Legislation, Infrastructures, Teaching Programs, Committees, etc)?

In order to achieve its goals, CEBESA has two main components, which include research and training. Below are some of the major activities carried out by CEBESA: teaching of bioethics to undergraduate students in all programs in the College from the 1st year up to the 5th year.

- Teaching of bioethics and research ethics to postgraduate students in the Master of Public Health Degree (MPH) and Master of Medicine (MMED)
- Training Fogarty Fellows from Eastern and Southern Africa in international research ethics, as part of the University of Malawi College of Medicine and Michigan State University Fogarty Training Program
- Providing training to ethics committee members and researchers on research ethics, good clinical practice, and research methodology
- Conducting research on various topics in the area of bioethics and research ethics
- Advising various stakeholders including government, research ethics committees (RECs), hospitals, researchers, healthcare practitioners, students, members of the public, and others on issues related to bioethics, research ethics, and good clinical practice

Currently, CEBESA is running three projects funded by the Wellcome Trust Bioethics Research Project, the Fogarty International Research Ethics Training Program for Eastern and Southern Africa, and the European Union and Developing Countries Clinical Trials Partnership (EDCTP) projects on building and strengthening national capacities in ethical review and clinical trial monitoring in Malawi. Bioethics is thus being championed by at the University of Malawi, College of Medicine, with financial investments from the United States, the United Kingdom, and the European Union.

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

As stated above, bioethics is being taught to undergraduate students from 1st to 5th year of medical training. Medical students are introduced to both bioethics and research ethics and understand theories and principles of bioethics and research

ethics. Bioethics is also taught to postgraduate students in the Master of Public Health and the Master of Medicine programs. Bioethics training is also offered to researchers and health workers. Other institutions involved in the training of health workers such as Kamuzu College of Nursing and School of health sciences also have medical ethics integrated into their curriculum.

Bioethics Committees

There are only two government approved research ethics committees in Malawi. They are the National Health Sciences Research Committee (NHSRC) and the University of Malawi, College of Medicine Research and Ethics Committee (COMREC). The NHSRC was established in 1988 as a Research Unit in the Ministry of Health, and in 1993 became incorporated as a committee in the National Research Council of Malawi (NRCM). A detailed description of the role of the NRCM is provided below. COMREC was established in 1996. The NHSRC is the technical committee of the National Commission for Science and Technology (NCST). The Ministry of Health (MoH), through its Research Unit, is the designated secretariat of the NHSRC. COMREC is the Independent Review Board (IRB) for the University of Malawi, College of Medicine. The Research Support Center at the College of Medicine provides administrative support to the secretariat of COMREC. Members of CEBESA are involved in running the Secretariat of the College of Medicine Research and Ethics Committee (COMREC), and they are also members of both the COMREC and the National Health Sciences Research Committee (NHSRC). The Director of CEBESA has also been appointed as the Chairman of the National Committee for Bioethics (NACOB) in Malawi. The IRB Administrator is also a member of the NACOB. Briefly put, NACOB is a committee which is located within the NCST that was set up to focus on advising government and policy makers on ethical issues that affect the country.

COMREC's mandate is territorial and jurisdictional in the sense that the IRB reviews research proposals from members of the University of Malawi's College of Medicine (COM) and Kamuzu College of Nursing (KCN) and their research affiliates, Blantyre Malaria Project (BMP), Centre for Reproductive Health (CRH), Malaria Alert Centre (MAC), Malawi-Liverpool Wellcome Trust (MLW), and Johns Hopkins University-Project (JHU-P). The committee's review is also limited to studies deemed to be of national interest, which are referred to the NHSRC. National interest studies include: vaccine trials, stem cell research, cloning research, genetic studies, national health surveys, and drug and medical device trials where patent issues are involved and where safety issues remain fully unknown. Thus, by way of deduction, the NHSRC reviews all research proposals from outside of COMREC's mandate and all studies deemed to be of national interest.

The achievements of both research ethics committees include the development of guidelines for the conduct of health-related research in Malawi, and Standard Operating Procedures (SOPs). These guidelines are within the parameters of national policy and sensitive international ethical guidelines on research. These

include the Declaration of Helsinki (WMA), the International Ethical Guidelines for Biomedical Research Involving Human Subjects (CIOMS/WHO), and Guidelines for Good Clinical Practice (ICH-GCP).

Relevant Legislation

Relevant legislation that supports bioethics and research ethics activities, especially in the field of health research in Malawi, is available. The National Research Council of Malawi (NRCM) was established on 30 March 1974 with a *co-ordinatory and advisory* function (Malawi Government Gazette, 11 June 1976, General Notice No. 398). Since 1974, NRCM was mandated to:

- Coordinate all research activities conducted in this country.
- Ensure that any research project proposed for execution was geared toward achieving national development needs and goals.
- Approve the establishment of sectoral research co-coordinating committees (REC/IRB) where it is necessary and justified.
- Approve procedures and guidelines of RECs/IRBs (NRCM procedures, 2002, p. 5).
- Accredit, register, and audit RECs/IRB.
- Establish and review national minimum standards or code of conduct to guide the operations of RECs/IRBs and any other stakeholders.
- Establishment of Research Review Committees.

The NRCM established the National Health Sciences Research Committee (NHSRC) and the College of Medicine Research Ethics Committee (COMREC) in exercising functional authority from central government, using executive powers of government.

In addition, The Pharmacy, Medicines and Poisons Board (PMPB) was established in 1988 with the main mandate to regulate the pharmacy industry in Malawi and to complement the role of ethics committees [Section 42(1) of PMPB Act, 2003 Supplement]. PMPB also issues product licenses for clinical trial–related products.

Since 2008, joint review of vaccine and drug development clinical trials is done by NHSRC and PMPB. However, PMPB Act only recognizes "*medical practitioner and dentist*" as only a cadre of investigators who can administer or under whose supervision administration of a trial medicinal product can be done and only to "*his patients*" (PMPB Act, 2003 Supplement).

The National Commission for Science and Technology (NCST) was established by a Science and Technology Act No. 16 of 2003 effectively which became effective from July, 2009. The Commission is now a body *responsible for all functions* which were being performed by NRCM. The NCST's Mandate is to advise government and other stakeholders on *ALL* matters of research, science, and technology in Malawi. Functions of the NCST include:

- Chart out national direction and establish national priorities in research, science, and technology development in relation to socioeconomic development needs.

- Promote the formulation and revision of policies, strategies, laws, and regulations for research, science, and technology.
- Coordinate all research, science, and technology-related issues in the country.

Thus, the NCST is an overall body that regulates all forms of research, science, and technology initiatives in Malawi. Health Research issues are co-coordinated by the Division of Health, Social Sciences and Humanities. The Division is supported by committees at national and institutional level with *legislative anchorage (Section 11) as outlined below:*

- National Committee on Bioethics (Advisory and policy making).
- National Health Sciences Research Committee.
- *College of Medicine Research and Ethics Committee*.
- The Drug Regulatory Authority (PMPB) continues to certify and offer joint authorization of vaccine and drug trials.
- Research Support Centre at College of Medicine spearheading research support and oversight services at college level.

Malawi just like any other African country is vulnerable to unscrupulous researchers. Therefore, collective responsibility in protecting human research participants is always critical. This calls for fair and objective policies and regulations that aim at promoting research and development while at the same time not compromising the protection of research participants.

Public Ethics Debate Activities

Members of the CEBESA are often invited to participate in public debates and discussions hosted by various organizations and institutions. For example, members of Centre have participated in 2 science cafes hosted by the Malawi-Liverpool Wellcome Trust on the following themes: "Should people participate in clinical trials" and "Why we participate in medical research as a community." The science cafes aim to engage the lay community on the ethical imperatives of research. Our participation in these debates is twofold: firstly, to provide ethical insights into some of the ethical requirements for research and to assure the community on how ethics committees ensure that human subjects are protected in research.

In Malawi, there are currently interesting public debates in the media and among the general population regarding different ethical issues. These debates include topics such as medical strike, equitable access to education and healthcare, homosexuality, abortion, mandatory HIV testing of pregnant women, research misconduct, and misconduct of medical professionals.

The country has recently experienced an increasing number of medical strikes. These strikes are due to a variety of reasons among which include issues related to dissatisfaction of medical workers with their work conditions, remunerations, and allowances (Ponje, 2012). Consequently, these strikes have contributed to the neglect and deaths of some patients. This has caused great concern, anger, and debate on the media and among the general public on whether or not medical professionals are justified to go on strikes.

The Government of Malawi is committed to achieving universal education and healthcare coverage. However, despite the intense government efforts and the positive developments in the education and health sectors in Malawi, equitable access to education and healthcare still remains a challenge and subjects of continued debate in the media and among the general population in Malawi. The education and healthcare systems in Malawi favor the rich and those in the urban areas (National Statistical Office, 2011). In rural areas, schools and hospitals continue to face various challenges such as shortage of qualified personnel, inadequate infrastructure, and poor transportation among others, which continue to undermine full realization of quality of education and health care service delivery. What this means is that poor students who are largely residing in rural areas do not have a good chance at furthering their education at the University of Malawi, because the selection process tends to favour those who attend schools in the cities.

Furthermore, the recent propositions to legalize homosexuality and abortion by the international bodies and local activists in Malawi have attracted uptight debates in the social media and among the general population. This is partly due to the fact that the majority of Malawians are religious people who regard homosexuality and abortion as sinful acts, and therefore do not support the proposals to legalize these practices.

The Malawi is proposing a contentious bill for mandatory HIV testing of pregnant women (PlusNews, 2012). This bill is aimed at promoting HIV testing and prevention of mother to child transmission. The current policy in Malawi obliges every pregnant woman to undergo routine HIV testing during antenatal visit. This practice and the proposed bill has raised debate on media and among the general public on whether it is ethical to subject pregnant women to obligatory HIV testing. In addition, issues regarding research misconduct and misconduct of medical professionals have also been areas of continued public debate in Malawi.

Major Bioethics Issues and Discussions

End of Life

Decisions concerning end-of-life issues and end-of-life care in Malawi are rather difficult for medical practitioners to tackle head on. This is because of "our Malawian culture of secrecy on issues of death and dying" (Chunda and Lavy, 2005, p. 552). In spite of this, the principles guiding healthcare practitioners in Malawi include the principle of respect for persons/autonomy, beneficence/maleficence, and justice. In Malawi, active or passive euthanasia or mercy killing is illegal and, therefore, withholding or withdrawing treatment would be tantamount to committing a crime. The most preferred option in circumstances where treatment offers no hope of improving the patient qualitatively or quantitatively, a gradual shift from restorative to palliative care is raised either by the family or healthcare practitioner.

There is no discussion, debate, or guidance on how to proceed with medical cases that can be declared futile to treat. Medical futility is defined and understood as "the inappropriate application of medical intervention that is unlikely to produce

any significant benefit for the patient" (Bagheri, 2008, pp. 45–53). In Malawi's context, HIV, AIDS, and cancer are common fatal diseases that present medical doctors with challenges, given the costs of treatment, lack of human resource and facilities, for example, bed space in often overcrowded hospital wards. These challenges also introduce moral and ethical dilemmas on whether or not to withdraw or withhold treatment. Often these dilemmas are resolved by quickly discharging patients that are terminally ill. As Chunda and Lavy explain, "In many developing countries, Malawi included, the existing health infrastructures are inadequate to provide in-hospital care for AIDS patients, and thus there is great pressure on hospital personnel to discharge AIDS patients quickly, with little or no treatment" (Chunda and Lavy, 2005, pp. 51–52). This is because in Malawi, active or passive euthanasia or mercy killing is illegal and, therefore, withholding or withdrawing treatment would be tantamount to committing a crime. The most preferred option in circumstances where treatment offers no hope of improving the patient qualitatively or quantitatively, a gradual shift from restorative to palliative care is raised either by the family or healthcare practitioner.

This is because, in the Malawian context, bioethics is seen as a relationship of a human being with himself/herself, with nature, and with other human beings. This relationship is based on cooperation and fairness, and it is rooted in the African moral thinking of umunthu/ubuntu, as it is commonly known in many Southern African countries (Mfutso-Bengo and Masiye, 2011, p. 155). Simply put, *ubuntu/umunthu* means being humane. Mfutso-Bengo and Masiye explain the theory of *ubuntu/umunthu* like this:

> It is a moral reflection or study of African humanism and moral systems. Malawian (African) bioethicists consider *ubuntuology/uMunthology* as the main theory of African Bantu bioethics. The *ubuntuology/uMunthology* theory starts with defining what African humanism is, and how one can become human. The theory presupposes that not every human being is human. One becomes human through positive relationships and encounters that are based on beneficence, respect, trust, hope, and justice (Mfutso-Bengo and Masiye, 2011, p. 155).

John Mbiti's popular quote reveals this. Only in terms of other people does the individual become conscious of his [sic] own being, his own duties, his privileges and responsibilities toward himself and toward other people. When he suffers, he does not suffer alone but with his corporate group: When he rejoices, he rejoices not alone but with his kinsmen, his neighbors, and his relatives, whether dead or living. Whatever happens to the individual happens to the whole group, and whatever happens to the whole group happens to the individual. The individual can only say, "I am, because we are; and since we are, therefore, I am" (Mbiti, 1970, p. 141). A person is thus defined in relational terms – "as a being whose nature is determined by its relationship to the community" (Sebidi, 1998, p. 66). The Zulu have a saying, "*Umuntu ngumuntu ngabantu*" (a person is a person through others), captures this. *Ubuntu/uMunthu* is an ethic that reinforces the idea of corporate existence. *Ubuntu/uMunthu* is human centered and concerned with the interests and welfare of humankind. The ethic of *ubuntu/uMunthu* is also expressed as an ethic of solidarity. Solidarity, as defined by Ezra Chitando, implies "standing for, and standing with

'the other" (Chitando, 2008, p. 156). According to African bioethics, "to be human is to be in relation, and to become human is to be constantly in right relation" (Mfutso-Bengo and Masiye, 2011). "Being in relation is an essential part of being human" (Kasanene, 2000). In short, the ethic of *ubuntu*/*uMunthu* and the ethic of solidarity provide a framework for putting into action values such as compassion, kindness, care, justice, and respect.

To clearly appreciate the application of *ubuntu*/*uMunthu* in the practice of medicine in end-of-life decisions in Malawi, one only needs to understand the role of culture in African societies which also shapes medical policy and law in Malawi. When one understands the role of culture, one also appreciates why palliative care is the most preferred option when dealing with medical cases in which no amount of medical treatment will improve the physical condition of the patient.

Health Care System; Access to Health Care

Access to health care is considered a human right in Malawi. The United Nations Universal Declaration of Human Rights affirms that "everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food, clothing, housing and medical care" (Universal Declaration of Human Rights). The constitution of Malawi recognizes the right to health under section 13(c) and affirms that the state shall "provide adequate health care, commensurate with the health needs of Malawian society and international standards of health care" (The Constitution of the Republic of Malawi, 1994). Healthcare services in Malawi are provided by three main agencies, namely, government, private sector, and Christian Association of Malawi (CHAM). CHAM health facilities are nonprofit religious organizations, but they charge a small amount of user fees.

Although the government provides free healthcare services to all Malawian citizens, the health indicators for Malawi have generally remained poor. The average life expectancy at birth is estimated at 49 years (World Health Organization, 2008). The HIV/AIDS pandemic has significantly contributed to the country's low life expectancy. Malawi has one of the highest HIV prevalence in both African region and globally. About 11 % of Malawians aged 15–49 years are living with HIV/AIDS (National Statistical Office, 2011). The maternal mortality ratio in Malawi still remains high at 675 deaths per 100,000 live births. This rate is five times higher than the MDG target of 155 deaths per 100,000 live births, and it is highly unlikely that Malawi will meet this goal (Malawi Millennium Development Goals, 2010). The under-five mortality rate in Malawi is also high at 112 deaths per 1,000 births, while infant mortality rate is 66 deaths per 1,000 live births (National Statistical Office, 2011). Besides having poor health indicators, Malawi continues to experience higher levels of poverty. About 39 % of the population is living below poverty line, i.e., less than $1 per day (NSO, 2012), and the vast majority (86 %) of the population resides in the rural areas (WHO, 2008).

In order to address these challenges, the Ministry of Health in Malawi and its collaborating partners developed the Essential Health Package (EHP) and other

interventions aimed at improving the healthcare delivery system. The EHP refers to a prioritized but limited set of basic healthcare services that focus on the major causes of morbidity and mortality, particularly those affecting the vulnerable population (Ministry of Health, 2011). The Malawian EHP has 13 components including maternal and child health services. Its objectives include promoting equitable access to healthcare services and ensuring universal healthcare coverage. However, evidence shows that the delivery of EHP is constrained due to different challenges currently confronting the public health sector in Malawi. Prominent among these challenges are the shortage of health workers, inadequate infrastructures/services, insufficient health funding, and lack of essential drugs and other medical supplies (Mueller et al. 2011). The existence of high disease burden in Malawi also places demand on the available scarce resources for the effective delivery of EHP services.

Access to health services in Malawi remains a challenge, more especially for the vulnerable populations such as women, children, and the poor people. Different studies conducted in Malawi have documented inequalities in health status and access to health services among different population groups. For instance, the Malawi Demographic and Health Survey (MDHS) reports higher levels of morbidity and mortality among the poor, rural residents, women, and children (National Statistical Office, 2011) In addition, a study conducted by Mangham in 2006, revealed that women, children, and the rich people consume more public health care services than men and the poor (Mangham, 2006). The study findings further revealed that more urban population (38 %) than rural population (29 %) utilize public health facilities.

Documentation further shows that even though EHP services are provided free of charge, household out-of-pocket payments have increased during the implementation of EHP services (Mueller et al. 2011). In many cases, when patients visit public health facilities, they are often referred to private hospitals to access health services or to private pharmacies to buy medicine, using their own money. This becomes a huge problem and a burden especially on the poor people who cannot afford to pay the high cost often charged by private hospitals or pharmacies. As a result, out-of pocket payments act as a barrier to healthcare access for the poor people.

The Government of Malawi recognizes the importance of achieving fair and equitable distribution of wealth and health as crucial to the achievement of development, as outlined in the Vision 2020 plan (Malawi Vision 2020). The concept of health equity is an ethical value that is inherently normative, grounded in the ethical principle of distributive social justice or fairness and core human rights principles (Braveman and Gruskin, 2002). Pursuing health equity strategies entails promoting access to health services to vulnerable populations, thereby improving population health. In Malawi, there is a need for health systems strengthening to promote achievement of a greater coverage for and access to effective health interventions, without compromising efforts to ensure quality of healthcare and safety of patients. Promoting the right to access health care services in Malawi will help to ensure that people are not discriminated against for being sick or based on their social attributes. It will also promote economic productivity and ensure that Malawians live healthier and longer.

Levels of Healthcare in Malawi

The healthcare system in Malawi is designed in a three-tiered network of interlocking medical facilities. The bottom tier consists of a large network of rural hospitals and health centers throughout the country. Often, they serve as the first port of call for many people who reside in the rural areas of Malawi. "Their services are free and they are often the only medical facility that many village people will see in their lifetimes" (The Malawi Project). The rural hospitals and health centers serve around 30,000 Malawians covering 50 villages. Though the centers are deprived of doctors, nurses and clinicians substitute them. These rural health centers offer treatments for fractures, malaria, abrasions, and postnatal and prenatal care (Malawi Health). The middle tier consists of district hospitals and according to the government's healthcare plan when a medical case is deemed too difficult and critical for the rural hospital or health center to handle, the system calls for the person to be transferred to the district hospital. These facilities are centrally located in each of the 27 districts in Malawi. The district hospitals are better equipped in offering medical treatment to the people. Apart from having good doctors, these hospitals are equipped with x-ray machines, laboratories, and various other modern equipments. Surgical treatment is also available to the patients. The top tier hospitals are located in the major urban centers (Queen Elizabeth Central Hospital in Blantyre, Zomba Central Hospital in Zomba, Kamuzu Central Hospital in Lilongwe and Mzuzu Central Hospital in Mzuzu). They are bigger and designed to have more advanced technology, resources, medicines, and medical personnel in order to handle the more complicated cases that cannot be handled at district level. Patients are referred to such facilities when medical "problems cannot be resolved at either of the two levels" (The Malawi Project). To top it off, there are some expensive clinics and hospitals situated in the cities of Malawi that are quite inaccessible to the ordinary Malawians. Usually, these are fee-paying facilities that are linked to medical aid service providers.

Medical Research

Medical research in Malawi and in Africa has witnessed a tremendous growth in the past decade and yet to date. The great demand for clinical research in Africa is creating many challenges with respect to research ethics. For the past 50 years, ethical issues in biomedical research have received increasing attention. However, of late, focus has been on the ethical implications of carrying out biomedical research in low socioeconomic settings such as Malawi. This is especially so because of the increasing number of multinational biomedical research institutions working in developing countries. A key principle that informs and grounds all major ethical guidelines in research is the principle of informed consent. There is a general consensus among researchers and ethicists that acquiring an effective informed consent from research participants is a prerequisite to the conduct of an ethically sound study. Although it has been noted that getting genuine informed

consent in practice tends to be difficult, it is believed that problems of getting quality informed consent are even greater in settings with low social-economic settings. This is partly due to undue inducements to research participants in low socioeconomic settings.

CEBESA conducted a study which aimed at improving understanding of individuals and communities cultural attitudes, beliefs, and perceptions on research, community consent, and the informed consent process in urban and rural settings. The study sought to assess the validity of Western concepts of autonomy and informed consent in an African cultural and social context so as to provide a base for informing, reforming, and improving informed consent policy and practice. The study was conducted in Bangwe, an urban community, and Mpemba and Madziabango which are rural communities surrounding Blantyre.

The study yielded some very interesting results. The findings of the study revealed that the majority of participants chose to participate in biomedical research as a way of accessing better quality medical care and getting incentives. In a situation of poor service delivery as is the case in Malawi, medical care in a research setting is described in favorable terms and it is not surprising. In Malawi, medical care in Government facilities is free and yet, the quality of care is very low and characterized by overcrowding and scarcity of basic medicines. In this study, participants joined biomedical research in order to obtain health benefits. While the participants in the study differentiated biomedical research from normal health care, when they accepted to participate, they knew very well that they were participating in biomedical research. It thus became apparent in this study that people participating in biomedical research was not as a result of therapeutic misconception, but simply because of the desire to access better and faster medical attention. This finding thus prompts the question: Does biomedical research in limited resource settings constitute an undue inducement? Is it reasonable, ethically justifiable, and acceptable to take part in biomedical research with better quality medical care as a reason for participation within the Malawian context? If people are induced by better quality medical care, is it logical to conclude that they are unduly induced to participate in biomedical research? Similarly, participants in the various studies were given better and excellent treatment than the other patients in the same hospital. Findings suggest that people made their decisions autonomously but that they were motivated by better and excellent medical care. Their willingness to join the study on these grounds, therefore, is not unethical and does not constitute an undue inducement. This is echoed by Ezekiel Emmanuel when he notes, “it is not an ethical worry” (Emmanuel, 2004). In a context like the Malawian setting where access to good medical care is difficult, it can be argued that it is reasonable for one to make a decision to save his/her own life as failure to take the offer to participate in such a biomedical research is tantamount to one harming his/her child. This is further supported by African notions of morality, which do not allow and yet African morality does not allow a person to harm himself/herself. In other words, it is ethical for people to choose to participate in clinical research in pursuit of better medical care.

Unethical Aspects of Tobacco Control

This section discusses the unethical aspects of antitobacco lobby using three ethical principles of beneficence, respect, and justice. In principle, it is affirmed that smoking is a health hazard, and ought to be discouraged. However, in practice, Malawi is faced with an ethical dilemma. That is to encourage tobacco production for export – for external consumption on the one hand, and discourage internal consumption on the other. This is because tobacco is the biggest foreign exchange earner for Malawi. Malawi gets 75 % of its foreign exchange revenue from tobacco, and about 40 % of government tax revenue comes from tobacco. More than half of Malawian work force has to do with tobacco or related activities.

According to the principle of beneficence, there is a need to maximize what is good and minimize the cost and harm. There is no doubt that smoking is a big health risk. However, if a benefit and risk/cost assessment is calculated regarding the cultivation of tobacco in Malawi, it is apparent that the benefit of cultivating tobacco for Malawi far outweighs the health risk and economic cost of not cultivating it. Without tobacco, the Malawian health sector will collapse.

Smoking is not a big problem in Malawi, because many Malawians are nonsmokers, and tobacco industry is geared at export and not at the local market. However, this is not guarantee that this situation will remain the same. Unlike UK where tobacco revenue is only 3 % of GDP and their economic cost of smoking far outweighs tobacco revenue, in Malawi, about 40 % of government tax revenue comes from tobacco. Tobacco is the biggest foreign exchange earner for Malawi. And this is why, it is not to the best interest of Malawi to join tobacco control lobby. The antismoking lobby and tobacco control measures in the West have been triggered more by the rising economic cost of smoking and not primarily by the desire to improve global healthy. According to healthy indicators of Malawi, smoking is not national healthy problem number one and yet the hard currency obtained from selling tobacco is crucial in funding social services such as hospitals, schools, and in buying drugs.

The global campaign to control tobacco spearheaded by mainly USA and supported by WHO appears well intended but in fact might have unethical motivation because at its roots it is less motivated by the need to promote global healthy than to control the soaring economical cost of smoking, mainly in the Western countries. This campaign seems to neglect the interests of very poor countries like Malawi who are dependent on single export product such as tobacco for their survival. If the powerful nations have national interests and protect them, why should the poor and vulnerable nations not protect their national interest and autonomy or sacrifice the same for international concerns? Tobacco growing is of great national interest. One does not clearly know the criteria of firstly focusing on tobacco, and not, for instance, at arms trade and unfair trade. In Malawi, there is a growing increase of pollution from cars. The healthy hazards caused by polluted air in Malawi are bigger than the ones caused by smoking at present. In USA and Republic of South Africa, tobacco contributes a very small part of their huge economies and car industries are among the backbone of the western economy such as German, France,

USA, and Japan. Arms trade is a big business in Europe and USA, and yet little is being done to control the proliferation of small and big guns. It seems that the prioritization and selection of agendas at international forums is being dictated and dominated by the interests of Western powers with little consideration of interests of the least developed countries like Malawi. To the contrary, ethically, the least developed countries economies are the most vulnerable; hence, they need more protection and much needed attention.

The antitobacco lobby touches at the very existence of Malawi's economy. To impose it on Malawi without finding and funding the equivalent and alternative economic activities is unjust. Some may suggest that Malawi diversify to other more acceptable traded goods and products. Who defines what is acceptable traded product or goods? Diversification is a very attractive policy; however, on the ground, it is difficult to implement it. As of now, the manufacturing sector in Malawi is shrinking instead of increasing. Diversification will need very large capital input. It is in the best interest of Malawi, first to implement diversification, and then tobacco control, and not vice versa. However, diversification requires massive investments and capital input. Without fair trade, the least developed countries like Malawi have less chance to have successful diversification process. There is a need to handle the unfair trade issues with urgency. To tell Malawi to diversify its economy from tobacco to something else without guaranteeing this poor country a fair access to the most protected Western agricultural market is selfishness. The slashing of huge EU agricultural subsidy by half can fight food shortages in Africa by half, in doing so making African agricultural products more competitive, and in the process encouraging more investments in food production. There are many more global issues, which need more sense of urgency than this, such as unfair trade, environmental issues, and arms trade.

It is argued that tobacco control is unethical because it fails to understand and consider the negative social, economical, and healthy impact it has on the least developed countries like Malawi. Tobacco control predicates its argument on the principle of beneficence: to do good and avoid harm. One cannot avoid harm by avoiding justice. One cannot talk of health benefits of tobacco control without knowing exactly who is benefiting and how the benefits are distributed? In case of poor Malawi, it will benefit far much less from tobacco control than for instance UK. Tobacco control in the West is motivated more by economic interest than global healthy interests. In the West, the economic cost of smoking far outweighs the economic gains of tobacco production; that is why they are keen to control tobacco and not arms production, which is killing more people away from their countries.

The moral dilemma that is discouraging smoking in Malawi, and yet encouraging the farmers to produce more tobacco for export will continue as long as funding for diversification is not forthcoming. This contradiction can still be maintained without being unethical, as long as the world trade structures do not allow a fair trade and fair play in agricultural industry, which encourages cash crop production at expense of food production. It is noted that tobacco control is not only a health issue, but involves and impacts in other areas such as economics, politics, behavior,

and culture. All these aspects ought not to be forgotten if one wants to register success in tobacco control at global level. Those involved in global tobacco control ought to be aware that its endeavor to control tobacco should above all consider those vulnerable and poor countries, whose economies and healthy infrastructures are dependent on and sustained by tobacco production. Secondly, the question and the cost of diversification should be addressed honestly, if one wishes to control tobacco production worldwide. And thirdly, the question of unfair trade should be confronted honestly and fair solution ought to be sought as soon as possible.

As a conclusion, the basis of the argument on this dilemma in Malawi is between promoting tobacco growing and discouraging tobacco smoking, as guided by public health ethics principles of necessity and proportionality. The principle of necessity can be clarified from the perspective that Malawi's economy is largely dependent on tobacco; hence, banning its production without immediate alternative will endanger public health programs which are largely funded from funds generated from selling tobacco. On the other hand, the principle of proportionality can be viewed from a perspective that the burden of diseases caused by tobacco smoking is negligible, about less that 1 %, in Malawi. Therefore, there are more benefits in tobacco selling in Malawi than harm.

Conclusion

This chapter has provided an overview of the strides made in the area of bioethics in Malawi. In particular, it has provided information on how bioethics has developed; current bioethics infrastructure and major bioethical issues and discussions within the country. Malawi is one of the few countries in Africa that has made significant strides in promoting bioethical teaching, discourse, and practice. However, despite making significance progress, there are some challenges affecting bioethics and research ethics which include lack of funding for research and trainings. This chapter has also provided a discussion on the role of ubuntuology/uMunthology in the practice of medicine and ethical decision making in Malawi, as well as the one only needs to the role of culture in shaping medical policy and law in Malawi. Lastly, the chapter has also provided an interesting discussion and debate on unethical aspects of tobacco control in Malawi.

Pierre Mallia

Introduction

Officially, bioethics in Malta can be said to have started immediately after the 1987 general elections when, following 16 years of socialist administration, a more conservative Nationalist Party administration was elected. Setting up a "National Dialogue on Bioethics" was described by the then Minister of Social Policy, Dr. L. Galea, as one of his Ministry's "keynote acts." This was followed by a public conference to which Professor Laurence J. O'Connell from St. Louis University was invited. These two facts already quite simply dictate the path that bioethics was to take: the taking on of bioethical issues by a conservative government concerned

with traditional moral values, which the country embraced as they were felt to have been abandoned over the past years (Galea, 1989), and the invitation of a professor from a Catholic university in the United States.

The proceedings from that meeting (Cortis, 1989) remain a historical document, having laid the scene for the next years. In this book, the important role that the Church was to play was confirmed in various papers and reflected upon in one of the talks (Grima, 1989). An issue which was discussed by the Prime Minister was "Bioethics and Future Generations" (Fenech Adami, 1989). Following the recent contribution Malta had made at the United Nations in the context of proposals of a new Law of the Sea, and general rules governing "common heritage," the Prime Minister spoke about the relevance of genetics and its impact on future generations. At the time, the University of Malta also had a "Future Generations Programme" which dealt not only with bioethical issues but which also took a broader view upon future generations. Several years later, an international meeting on genetics was hosted by this program, the proceedings of which were published by Kluwer (Agius & Busuttil, 1998). Genetics however never really took on major debate in Malta, probably because there was never a successful attempt at genetic technology.

Many of the papers of the above public meeting however focused on reproductive technology, in particular, in vitro fertilization. This was already being practiced, and indeed people were starting to question not only the morality of the technology but also the lack of a legal framework within it was working (Grech, 1989). Grech pointed out that the Catholic Church sympathizes with couples who cannot conceive but that its position was that getting children is not a right. It can be said that this debate continues to this very day within the context of assisted procreation. The main question posed is that if we say that childless couples have a right to have children, it would be conveying a message of children being a property or a commodity. The Catholic Church has held this position in *Donum Vitae* (Ratzinger, 1987). Obviously in this context other issues, such as the respect for the embryo, embryo freezing and when human life begins, were brought up as well (Grech, 1989; Tabone, 1989).

The major concerns over time have been various but central to all these remained the issue of in vitro fertilization, with the government at times feeling paralyzed to move forward. A key contention was how to go about not freezing embryos while not putting the mother through undue and unnecessary procedures. With the recent developments of cryopreservation of ova, this seems to have been solved, but many remain skeptical as to whether this can be used for the masses (Mallia, 2010). Perhaps what kept legislation back was the lack of initiative of the relevant committees to start with agreeing on principles within the conflicts that existed. Clearly, there were conflicts of value about whether IVF should be used at all. An agreement to move forward on agreed principles between the government and the Church would probably have saved a considerable amount of time. At one point when all seemed to be ready for legislation, Archbishop Mercieca made a statement that IVF remained illicit and that it involved the killing of human life. Following this, then President of the Republic, Dr. Fenech Adami, stated that he will not give his signature of approval on any legislation put forward by parliament unless the Church is in agreement (Mallia, 2010b).

It is pertinent here to point out that Malta is a southern European and Mediterranean country and as such influenced by the deontological approach to bioethics in these areas (Gracia, 1993). Malta has always been under European influence, with the exception of a several hundred years in the first millennium, after the fall of the Roman Empire. During that time, it was under Arab rule, which in turn influenced the language. This Maltese has a Semitic background, although it is Latin in writing and influence.

Other than that, Malta has always been European and thus besides Mediterranean, southern European. It was part of the Kingdom of the Two Sicilies, during which period it was transferred from one nobility to another during the fiefdom period, until it was finally given to the Knights of St. John, from whence they obtained the name of the Sovereign Military Order of Malta. During this time, the Catholic Church was always very influential, and more recently the book by Montserrat, *The Kapillan of Malta*, clearly shows the social role priests play on the island. In bioethical debate, most Maltese people look to the Church for advice. This is not necessarily a disadvantage as the population has strategically placed individuals who are also easily accessible to guide them on what largely remain Catholic normative values.

Resources

Legislation in bioethics continues to be evasive. Malta is close to legislating on reproductive technology, but some issues with cryopreservation remain. Other legislation which challenged normative values, such as that of the introduction of divorce, and the periodic sermons by bishops which attack assisted procreation creating wide media response may have played a role in setting back legislation. The issue of IVF therefore was sidetracked a number of times (Op. Cit. Mallia, 2010b) due to the other consequential questions it raises: to whom to offer it (legally married couples, cohabiting couples, single parents, same sex couples, etc.), issues with freezing of embryos, and, when the issue became hot on a European level, what to do with frozen embryos and stem cell research. Conversely, there is general agreement about abortion (even the Green party, Alternattiva Demokratika, has taken a stand against it), that embryos have a right to life and not to remain frozen, and that IVF should be offered only to heterosexual couples who can offer a traditional family environment.

While legislation remains elusive, however, there are at the country's disposal a number of structures which have been set up. The main platform is the Bioethics Consultative Committee. Also, teaching programs within various degree courses at the University of Malta have been set up. The media plays a major role as many bioethical issues create a lot of sensation. This was seen especially with regard to IVF, stem cell research, and cases of removal of nutrition and hydration of people in a persistent vegetative state (namely, the Terri Schiavo and the Eluana Englaro cases). Moreover, some scholars commit themselves to public education on bioethical issues on newspaper columns and radio programs. These scholars and commentators are frequently invited on the more popular television debate programs. There is

therefore a considerable amount of public debate, which unfortunately, on a small island, can even taint the reputation of some who take more liberal stands, and abuse verging on subtle defamation has not been absent.

Infrastructure

Teaching of Bioethics

The main teaching of bioethics occurs under the aegis of the University of Malta. Both Faculties of Theology and of Medicine and Surgery have their own programs. Recently, the Faculty of Theology has started a Master's program in Bioethics. This will be followed shortly by a Master's program in *Clinical Ethics and Law* in the Faculty of Medicine and Surgery, within its Bioethics Research Program. This second degree is necessary because it is felt that while the MA degree offered by the Faculty of Theology offers a substantial humanities approach to bioethical issues, it does not prepare students for professional carriers such as clinical ethicists.

The Faculty of Medicine and Surgery's Bioethics Research Program falls directly under the Dean of the Medical School. This program is intended to be a platform for research in ethics by encouraging students to choose bioethical topics for their theses and by participating in local and international research projects, especially those related to the European Community Framework Program. In addition, it promotes the understanding of bioethical issues by the general public through media such as daily newspapers and television and radio program. The author, who is the coordinator of the program, has a regular column on *The Malta Independent* on Wednesdays and is a weekly guest on the morning program *Bongu* (meaning "good morning"), for example. These media are used to speak mostly about current affairs in bioethics when they arise and also to promote understanding of mainstream areas of bioethics including patients' rights issues.

The author occupies the only academic post in bioethics (with a special focus on patients' rights) in Faculty of Medicine and Surgery but has an agreement with the university administration to teach in the Faculties of Laws, Sciences, Health Sciences (including nursing school, laboratory technicians, and nursing Master's programs such as Mental Health), Education (in conjunction with Sciences), and Dentistry. He also participates in the Master's degree offered by the Faculty of Theology.

Bioethics Consultative Committee

This committee is non-statutory; members are not paid and are self-selected by the Minister of Health. It is a consultatory committee, as the name suggests, to the minister of health. In the past, it has also been under the Ministry for Social Policy. Thus, it has oscillated between these two ministries. It has taken on

a quasi-official role as being the "national" bioethics committee, and therefore it is members from this committee who participate in the CDBI meetings of the Council of Europe. For several years, it has been organizing a yearly seminar on a topic which is relevant to the country at the time. In the past, proceedings of these conferences were published along with any document the committee may have released. Such was the case when the committee worked on the Reproductive Technology Document and the Organ Transplantation Document (Cauchi, 2000).

As stated above, the members of this committee are selected by the minister. This has not always been ideal as it very much depends on the importance that the minister gives to the committee. Thus, although members from various sectors which are deemed to have a stake in bioethics are chosen, such as clergy, media, and lay representation, many members are also political appointments. In 1999, the committee contained no less than 50 % of its members who had contested the general elections for the same party. However, these situations were rare. But it has to be mentioned that the chair of this committee has been for several years a member of parliament who remains a politician. Nevertheless, he has a strong interest in bioethics, but one can argue that the opinion of the chair may be biased.

Health Ethics Committee

"Following EU Accession, Malta has to adopt EU Directives as part of its own legislation. Three such directives concern the conduct of clinical trials in European countries – 2001/20/EC, 2003/94/EC and 2005/28/EC. These directives, and the respective guidelines explaining their implementation, have considerably changed the way clinical trials are conducted."

Maltese researchers and hospital consultants have long participated in international trials, especially at phase three levels. It is envisaged that with the forthcoming construction of a science park near the University of Malta, which in turn has the Medical School at Mater Dei Hospital on adjacent grounds, phase 1 and phase 2 trials may also be feasible, where before they were not because there was no appropriate setup. At first, the introduction of the HEC was frowned upon as something interfering and impeding progress in research, but time has convinced researchers that it is indeed in their interest and protection that such a committee exists. According to protocol, the HEC must give an answer to an application within a stipulated time frame of 2 months. If that time is exceeded, it can legitimately be taken that the research has been accepted. On average, the HEC handles about five to ten international research applications annually (usually from local consultant who have been asked by drug companies to participate in a phase three trial). There is a separate scientific committee at the Medicines Authority. The HEC has to give its ethics approval. This usually concerns issues such as informed consent processes and data protection. There is still some concern on the informed consent process as the application forms do not address this appropriately.

The HEC follows guidelines which were transposed into Maltese legislation (Clinical Trials Regulations, 2004 (LN490 of 2004); Cauchi, Aquilina, & Ellul, 2006) from the relevant EU directives (above). The Medicines Authority and the HEC have not stipulated any further requirements than what is laid by the directives. The HEC has, however, to take into consideration all kinds of research, even research carried out by private family doctors in small private clinics. These would usually be questionnaires and may not pose large problems as clinical trials. However, there have been instances where family doctors were recruited by drug companies to participate in phase three or four trials.

Other Research Ethics Committees

There are several research ethics committees, all at the University of Malta. Both the Faculties of Medicine and Surgery and that of Health Sciences have their own REC for research done by students, graduates, and health professionals working in the NHS hospitals. The latter, being teaching hospitals, have at their disposal the service of these committees, which are chaired by professionals working within the same structure.

The RECs look into scientific validity and methodology of the study and ethical issues relating to informed consent, safety, and data protection. They are composed of professionals, ethicists, and lay representation.

The University of Malta also has a central REC – the University Research Ethics Committee (UREC) – which overlooks also research done in the humanities, especially psychology, which involves human interviews or studies, and animal research done in the Faculty of Science. It also overlooks the other two RECs mentioned above. Relating to research on animals, there have been ongoing tensions, as Malta has yet to implement EU directives with regard to research on animals, which is mostly done on mice in the department of neuropharmacology. The UREC therefore has to deal with this research, and it is being considered to establish a subcommittee to deal with animal welfare.

Research and Public Debate

Research in bioethics takes the form of theses and of participation in local and EU-funded projects. As stated above, the *Bioethics Research Program* has been developed specifically to aid such initiatives. The program has as yet no funds but has already conducted research in areas of palliative care (Abela & Mallia, 2010) and participated in several FP-EU-funded projects. The coordinator of the program (author) is also the ethics advisor to the Medical Council of Malta, the chair of the above-mentioned Health Ethics Committee, the Dean's delegate for ethical, social and public relations to the faculty of Medicine and Surgery, and also holds the academic post of the above-mentioned patients' rights and bioethics.

Public debate has been mentioned already, but only in the context of public seminars. It is important to note however that the media plays an important role in bioethical debate, with popular prime-time evening programs which choose different topics each week giving a major contribution. Cases which create sensation are usually debated and offer an opportunity not only for academicians and stakeholders to either explain the background and theory or to have their position stated but give a significant opportunity for the general public to participate. Issues which were significantly discussed were the reproductive rights, including the right to IVF, abortion, status of the embryo, and right to life, as well as the Elauna Englaro and Terri Schiavo cases, in which issues of hydration and nutrition and the meaning of a "natural death" were widely debated. Another significant case was the Maltese Siamese Twins debate, which followed the case of the separation of "Mary and Jody" in the children's hospital of Manchester which was resolved in the UK Courts of Justice (Kaveny, 2002).

Legislation

Although as discussed there is no specific legislation in bioethics, there are other laws which are worth mentioning that govern bioethical issues. Reference here is made to Cauchi et al. (2006).

Human dignity, rights, and freedoms are protected under the *Press Act*, the *Code of Organization and Civil Procedure*, and the *Criminal Code* which address the dignity of the victim. The *Commissioner for Children Act* set up a commissioner to oversee the dignity, respect, and fairness in the treatment of children. Also, the *Constitution of Malta* guarantees against discrimination and protects rights and freedoms.

Furthermore, especially in relation to bioethics, the *Data Protection Act* protects privacy and has generated considerable consideration in the area especially with regard to research. The *Criminal Code* distinguishes between intimate and non-intimate samples taken from a person (Cauchi et al. (2006)). Article 350 defines intimate samples as blood samples, semen or any other tissue fluid, pubic hair, and any swab taken from any orifice of the body other than the mouth. Non-intimate are defined as a sample of hair (other than pubic hair), samples of nail or from under the nail, swabs taken from mouth or other areas of body excluding other body orifices, urine, saliva, footprint, or other impression other than a part of hand. Magistrates are given the authority to authorize the taking of samples from intimate areas or to take intimate photographs.

The *Civil Code* describes the procedure for informed consent and where this is not valid (e.g., where it has been given by error or extorted by violence or fraud. Conversely, the *Prevention of Disease* ordinance requests doctors to notify the health authorities of communicable diseases, which are listed in the ordinance. The *Health Care Professions Act* regulates the medical professions and includes section on *ethical Codes of Conduct*. The Medical Council of Malta has requested from its ethics advisor a suggestion for an update on this part of the law. Suggestions have been made with regard to (1) obtaining consent, (2) research on human subjects,

(3) confidentiality, (4) dual responsibilities of doctors, and (5) advertisements. To date, these recommendations have not yet been entrenched into the law. They adapt the UK General Medical Council guidelines for the local scenario.

Malta also respects directives issued by the European Union. To date it has not signed or ratified the *Council of Europe's Convention on Human Rights and Biomedicine* due to some controversial areas of bioethics, such as abortion, which are still being studied, but it is expected to do so.

Finally, there is a *Mental Health Act*, which has recently been updated and which describes the rights of the mentally ill and the procedures necessary to admit patients into psychiatric wards without their consent. The law does *not* refer to research on mentally ill patients. Although this can easily fall under the general rules of research, the fact that mental patients as a vulnerable group had not been discussed with bioethicists during the drafting of the law shows the insufficient awareness of the field of clinical and bioethics when it comes to legislation.

Major Bioethics Issues and Discussions

Malta is largely a conservative society which is highly influenced by tradition, culture, and religion. This is slowly changing and more liberal ideas than those proposed by Catholic tradition are influencing secular society. The latter may defend issues like abortion and euthanasia, but by and large this does not mean that Maltese society has made substantial shifts to decrease ecclesiastical influence on legislation. For the purposes of this chapter, three selected areas, which have given rise to public debate, are discussed.

In Vitro Fertilization

Malta has been trying to regulate the use of in vitro fertilization since the beginning of bioethics debate on the island. In vitro fertilization poses problems in several areas. First of all, according to the Catholic Church, it does not follow natural law, as interpreted through divine law. The Catholic document *Donum Vitae* (literal translation: the gift of life) categorically states that IVF is "illicit" because it bypasses the conjugal act. Many often think that the Catholic Church has reservations on IVF merely because it results in the freezing of embryos. While this is also true, the whole nature of the matter, and therefore the debate, has been on whether IVF is licit or not. Although many priests in pastoral care have encouraged married couples to use the technology, once the issue came into public debate it was quite clear that the Church had the final say which halted the whole process (Mallia, 2010a). Part of the problem was that the true conflict – the nature of IVF itself – apart from other consequential issues like protection of the embryo and the family unit had not been discussed at high levels of government and curia. Had agreement on this been reached, then it would have been difficult for the curia to issue statements at the eleventh hour.

The debate continues to move forward, and the Prime Minister recently made a statement that all problems seemed to have been resolved with the possibility of cryopreservation of ova. A proposal was made by a parliamentary committee that the government should consider the possibility of a limited amount of embryo freezing, however, with the possibility of donating these embryos should the parents, for some reason or other, not use them within a stipulated time. But many remained uncomfortable with freezing and also with donating embryos. Certainly legislation would have to be put in place for the government to be able to take custody of these embryos, something which would need considerable legislative thought.

The issue of IVF brought on a persistent debate about the freezing of embryos. One possibility was to freeze an egg which has been fertilized before the two pronuclei have met – as is done in Germany. Again there was some debate on whether life should be considered to begin when fertilization is complete or when fertilization begins. Part of the problem was that debates went directly into the public realm, and there was no serious academic effort to provide proper information to the government and educate the public at the same time. Therefore, issues such as differentiating between a zygote and an embryo were very difficult to discuss on the media which continuously insisted with academics invited to participate on programs to speak in language which everybody can understand. Although the media contributed considerably to the debate, one cannot resolve the issues here. Although many priests did take part in the discussion, the Curia avoided debate completely and even when invited to comment on a report issued by the Bioethics Consultative Committee as early as 2000, it simply said that the priests that were on the committee were sufficient. And yet, when the bioethics committee held its annual seminar on the topic and the media reported on the issue, an angry archbishop called the minister who in turn called the then secretary of the committee for an explanation (Mallia, 2002).

The issue, according to many, has changed with the introduction of divorce, many feeling that the Church has lost its power. In this author's opinion this is not correct, losing on an issue (and divorce has been considered as a civil right in the mind of many) does not mean that the Church still does not enjoy ecclesiastical authority in matters of morality.

The government is committed, however, to move forward on legislation. This has been stated by the Minister of Health and the Prime Minister on several occasions. While it is recognized that the Church sees IVF as illicit, it is also recognized that the responsibility of the state is to legislate within good standards and that state law cannot be according to canon law. There is general agreement that there should be protection of embryos and of family values. However, an ongoing debate had been whether to offer IVF only to married couples or also to cohabiting couples. If the former, it meant that since most legally married couples marry within the Church, paradoxically, IVF will be offered only to these couples (Mallia, 2002). There were, however, strong arguments also to offer the service to cohabiting couples. Certainly since until this year divorce was not possible, people from broken marriages (legal separations) would have settled with another partner, and

some of these would invariably be infertile. Since they could not legally marry again, the argument was whether it would be an insult to the institution of the family if they were offered IVF. One compromise was to offer it to those people who had separated at an early stage and were awaiting annulment. In fact, it was often said that the problem with divorce took on a lot of force because of the considerable number of separated couples who either waited too long (sometimes up to 8 years or more) for a church annulment, or those who lost hope in ever obtaining such an annulment. State annulments took much less, on average 2 years, and this raises the issue whether it is licit. However, many young people still feel that the church annulment is the proper annulment to take. This raised the question that if the Church was more efficient, the question of divorce may not have gained momentum.

Divorce now will make IVF possible to many more couples and resolved the issue of offering the service to legally married couples. Naturally, for the Church, it is presumed that only the first marriage counts, but this does not seem to be an issue which impedes IVF; the stronger issue is the problem of freezing of embryos. Here, the government seems reluctant even to follow the advice of the parliamentary committee for social affairs which made a recommendation for a limited amount of freezing – as it is quite impossible to impose the technical fertilization of one ovum at a time. It is not clear whether the advent of cryopreservation of ova resolves this issue. In practice, one still has to see as this method was not introduced in any way to treat whole populations. Although it was a method for those who had problems with freezing of embryos, one has to ask whether it will be feasible for whole populations. Certainly one would need to employ an embryologist as freezing of ova is not without its problems. In the first instance, you lose much more ova than you lose embryos when you thaw them. Moreover, due to changes that occur in the outer lining of the ovum, one would have to use intracytoplasmic injection of sperm (ICSI) to fertilize eggs on each occasion. This method is more expensive and requires more time than current practices.

While with the freezing of ova one presumably needs less hormonal stimulation of women to obtain such embryos, one still has to use hormonal stimulation to emulate a pregnancy when introducing fertilized eggs. Again, a pertinent question remained: How many fertilized eggs are you going to introduce in one attempt? If you introduce more than one then you will still have to go through the process of ICSI several times. Practically, it is difficult to imagine embryologists working on populations fertilizing only one egg at a time, without risking waiting list and mistakes, such as (albeit on rare occasions) mixing accidentally ova and sperm of different people. The government has not yet tackled the numbers: up till now, only those who could afford went for IVF; once everyone would be entitled on the National Health Service (and therefore free of charge), it remains to be seen whether one would be able to cope with the demand. Certainly this mistake was done in the construction of the new main hospital. Besides, for some unknown reason, having fewer beds available, the planning team did not envisage that many would now want to go to the state-of-the-art hospital, whose hotel services were even better than those offered by private hospitals. The result was a considerable rise in waiting lists. Can infertile couples afford to wait

weeks or months before the embryologist/s have time to fertilize another ovum and have it introduced in the uterus due to the larger demand?

Another problem is that many seem to think that there is no moral weight with ova. Indeed, throwing away an ovum is not as problematic as discarding an embryo. But gametes do have moral weight attached to them for the simple reason that they are gametes. Unlike males, females have a limited amount of ova. Many may be uncomfortable with having them thrown away once they have conceived. Property rights have not yet been considered in this regard. What if someone refuses to have her ova discarded? Can she legitimately ask the court that they be preserved? In such an event, can she legally be made to pay for their preservation? What if she cannot afford this?

In the meantime, the issue of legislating IVF continues to elude at the time of writing of this chapter.

Hydration and Nutrition

The problem with hydration and nutrition was put in evidence following the Terri Schiavo case (in the USA) and later the Elauna Englaro case (in Italy) which were portrayed as euthanasia by conservative Catholics.

It was quite clear from the onset of the debate of Terry Schiavo that the moral theologians and ethicists in Malta were of the opinion that extraordinary treatment need not be given. When the case of Eluana Englaro surfaced a few years later, however, the public outcry in Italy (Italy being very close to Malta) and the fact that a bishop spoke to Prime Minister Silvio Berlusconi to prevent the removal of artificial feeding and nutrition created a situation where many erroneously believed, or started to believe, that removal of water and nutrition is always passive euthanasia. This was reinforced by the allocution of Pope John Paul II (2004) who had said that they should always be considered basic care.

Yet several statements were made on the media by ethicists at the time. The allocution of Pope Pius XII (1957a) that doctors cannot treat (even force-feed) without the consent of the patient was referred to. For all intents and purposes, this still holds. Secondly, patients need not accept extraordinary treatment but are morally obliged to accept ordinary treatment. What many people, including health-care professionals, often do not understand is that *it is the patient* who decides what is ordinary and extraordinary for himself. The allocution clearly states that extraordinary has nothing do to with the state-of-the-art of the treatment or care being provided. Rather it has to do with disproportionate care, with discomfort, and with respecting that people do die and that this is in itself not a bad thing.

Pius XII (1957b) also had explained the concept of double effect in the provision of pain relief – that death brought about unintended while giving pain relief, even if foreseen, is allowable. Standards of care have to be followed, but since a considerable amount of health-care provision in Malta is given at home, for many GPs who have to use limited resources, following specific protocols is not always feasible. Indeed, it would be extraordinary care to bring all resources

available in hospital to the bedside at home as this would require a disproportionate expense on the part of the patient. Doctors therefore can use their clinical training as a means of titrating proper doses of pain relief. A study done recently (Abela & Mallia, 2010) shows that GPs appreciate vocational training in this regard, for example, on the use of syringe drivers and other therapeutic issues in giving palliative care at home.

The point which was shown to the public was that not all that seems like euthanasia is indeed euthanasia and the frustration was that many Catholics seemed to believe so. The problem is made more complex by some theologians who seem to have a definition of artificial nutrition and hydration as being *always* ordinary treatment and who also seem to omit what the Catholic Church says also in regard to burden on the family (and not only therefore on the patient). Admittedly, the allocution of John Paul II on hydration make things more difficult to explain to the public especially in cases of persistent vegetative state which has lasted several years.

People in Malta often go to bishops to inquire about end-of-life issues when a relative is on life support. Bishops always explain that allowing nature to take its course is an option, which means that if there is no reasonable hope, then people, even if not brain-dead, can be removed from advanced life support as it is extraordinary. One had to extrapolate this argument to show that if this is allowable in people on advanced life support who are *not* brain-dead, then it should be allowable also to people in PVS. PVS is a state which is brought about by modern medicine, and when speaking on disproportionate efforts to keep people alive, Pope Paul VI made the point that it was immoral to push people into PVS. PVS was described in the early 1970s as something brought about by advanced care and in a letter to the International Federation of Catholic Doctors, Cardinal Villot, on behalf of Pope Paul VI, stated that it would be a useless torture to impose a "vegetative reanimation" (Petrini, 2011). So once this vegetative state occurs, the question is why cannot one alleviate any perceived suffering and terminate artificial means of keeping the person alive?

Moreover, it often has to be explained that hydration and nutrition in PVS is not ordinary feeding. In the first instance, it requires expertise to maintain the tubes and to provide the physiological solutions. Secondly, when infections do arise they are often treated and that therefore it is doubtful how only nutrition and hydration is being provided. Thirdly, people are not getting any sensation of feeding – a former relative explained on the media how his mother would crave for some tea when in hospital even though the nurse would have just poured the tea through her naso-gastric tube. There was no sensation of "drinking" tea. Fourth and most important, but one which people tend to comprehend least, is the fact that in a true PVS, only the brain stem is alive. This is a transition zone between the upper brain (basal ganglia and cortex), which gives experience and consciousness, and the spinal cord. Even dead people continue to have reflexes of the spinal cord for some time. Therefore, it is understandable that the brain stem may continue to function. This does not mean that the person is experiencing anything. Therefore, it does not make sense to "starve" a PVS patient, as starvation is a sensation. Nevertheless, the facial reflexes and the continued beating heart and respiration can often deceive people

that there is conscious life. But is this situation not the same one we declare people on life support brain-dead but whose relatives, seeing a body which is still warm and monitors showing a beating heart, refuse to accept that the person has died? Are not these advanced life support taking the place of the brain stem?

PVS creates an illusion of the possibility of conscious life. While there certainly is life, one has to return to the basics of whether basic ANH is ordinary or extraordinary. What is more, health-care professionals should accept that it is not their choice but that of the patient, and when the patient cannot make that choice, the family's wish should be taken into consideration. One has to accept that many will say that they opt to remain in that state if they ever find themselves in that position; others will not. Also many families can accept their loved ones in that state; others may want them to die peacefully. This is certainly an area where greater Catholic dialogue would illuminate Catholic countries like Malta.

Abortion

One would think that in a country where most people are against abortion and all political parties have declared themselves to be pro-life as well, that abortion would not be an issue of debate. Yet debate occurred on several instances. Three will be mentioned here: in the instance of emergency contraception, in the instance of the Dutch ship which visits countries providing abortion (Women on Waves), and in the instance of the Constitution of Malta.

Emergency contraception and some other contraceptive measures such as the coil have been known to provide a risk of aborting a fertilized egg. Traditionally, therefore, they have never been allowed into Maltese health care. It was only for a short while during a socialist administration and until awareness was raised that insertion of the coil was allowed in government health services. Coil insertion is still, however, done privately. Moreover, abortion is a criminal act, and so is assisting an abortion in any way. Legally, a pregnancy is defined as "woman carrying child." Yet it is clearly evident that in a Catholic country, to "carry" does not mean implantation – as decided by the UK courts of law in the case of the Society for the Protection of the Unborn Child (SPUC) challenging the provision of the morning-after pill (Levonelle) through pharmacies across the UK, claiming that these were abortifacient and therefore a criminal offense. Mr. Justice Munby held that since a woman is not yet carrying a baby, she cannot be said to miscarry. Maltese morality follows the Catholic teaching that life has to be protected from conception.

This is not to say that there are no advocates of abortion. Yearly data are published of Maltese women who have gone to the UK for an abortion. Although abortion is illegal in the UK, it is provided for health reasons (health being defined in the broader term of including not only biological reasons, as in Ireland where they provide abortion for *medical* reasons but also psychological and social).

Emergency contraception falls therefore in an area of difficulty. The Catholic tradition speaks of emergency contraception in instances of rape – it cannot allow

EC in marriage and for extramarital sexual activity. It is clear, following the British Episcopal Conference statement that a girl who is raped has a right to defend herself from pregnancy. She can only do so, however, if she is not ovulating. Therefore, ovulation tests may be used. There is an element of coercion here as the woman will not be provided with EC unless she accepts this test. There is ongoing debate in this area in which the author is involved, and hopefully it will be resolved in the future. There has been an argument (Mallia, 2005) to show that it can fall under double effect. Moreover, recently Sulmacy (2006) argues that testing for pregnancy should be morally equivalent to testing for ovulation, which of course is more acceptable – the test is more directly implying a pregnancy or not.

Women on Waves (WOW) had created some public debate with advocates of abortion coming forward in the media. In general, they are still small in numbers. It is interesting to note however that democracy can tie or untie moral values. Although morality is never a statistic, as one experienced with the divorce debate, numbers do count. It may be the case that some politicians will privately speak in favor of abortion, but they and their parties will know that this will be a cause for condemnation by the religious community and can thus cause a loss of votes. WOW also sends abortifacient medication to women by post. There are no statistics to show whether this service is being used and how many women use it. There do not seem to be any restrictions by the post either as when one sends for medicine, one only has to state that they are not for commercial use.

However, the visit by WOW and the ensuing debate created a movement of people to protect the unborn child and which even advocated, at one stage, that there should be a law which not only prohibits women to travel abroad for an abortion and that the partner may actually impede a pregnant woman from traveling as well if he suspects her intent. Moreover, they argued that the state should protect the unborn child also from women who abuse alcohol, drugs, etc. Of course these proposals did not find any support as they were largely based on emotion and ignorance. Although good in intent, they ignored the freedom of the woman and basic human rights that a pregnant woman should enjoy other than prohibiting direct abortion. This triggered discussion on whether we should have a "protection of the embryo act."

This "embryology act" was proposed in 2005 by the Vice Prime Minister following pressure from pro-life groups to prevent abortion, freezing of embryos, and the use of embryos for research. It made considerable debate at the time but never actually reached implementation as existent law already prohibits abortion and that any new reproductive technology law will legislate against freezing irresponsibly anyway.

This was followed by a push to insert an antiabortion law into the Maltese constitution. This move was motivated primarily to make a statement, especially in view of Malta's entry into the European Union. Amendment to the constitution requires a two-third majority in parliament and not a simple majority vote which can be passed by a presiding party. The idea was to protect that law and enshrine it into the constitution. The Church even invited speakers to encourage this move. Although there would not have been anything wrong with this, it was not really

necessary as abortion is not seen as a problem in Malta: it is already illegal, and all political parties have stated they will never legalize abortion. The idea was therefore shelved as it is understandable that with so much work facing parliament, one cannot use up valuable time to pass unnecessary laws.

Conclusion

This overview has shown that Malta remains largely a country with Catholic normative values, but social change is occurring over time and people are challenged to object to some of the Church's teaching when it comes to medical treatment. Although there are no great debates on abortion and euthanasia, when it comes to reproductive technology and end-of-life issues, legislation is showing a change in trend of these normative values. However, people often find solace in seeking advice from Catholic authorities.

This is not to say that there are disadvantages to this. Many priests in pastoral care would not hesitate to help people to make an ethical choice to have IVF. Moreover, the application of natural law also means application of allowing a natural death, which in turn translates into helping people and families with loved ones at the end of life, not to feel pressured to allow extraordinary measures to be taken. Conversely controversy at the beginning of life is more difficult to tackle as it challenges the very concept of when life begins and the protection of that life from the beginning. This does not mean that dialogue in areas such as emergency contraception and IVF is still not possible. Recent developments of Trinitarian ontology within the Catholic Church and how this may be applied to social problems such as bioethics provide a hopeful window for a better understanding while maintaining one's fundamental position in favor of life.

Gerrit K. Kimsma and Evert van Leeuwen

Introduction

Bioethics has become "of age" in the Netherlands slowly after the 1960s, with a slow recognition of its value and significance for clinical academic medicine. Technological developments, educational renewal, and societal demands for more transparency in medicine and medical decisions have strengthened the importance

of ethical expertise, in addition to political and judicial pressures in the areas of the beginning and end of life. Since the eighties the input of ethics has been stimulated both at the level of complex patient care and the level of future developments of affordable care at the national level. Institutional and national committees have inspired the development of a vast group of academically trained group of professional bioethicists, without whom the field of health care is unthinkable.

Bioethics Development

The field of ethical reflection on medicine and health care in the Netherlands became robust in a relatively short period in the late sixties and seventies of the previous century. Not only because of the increasing need for ethical reflection because of the growth of medical technology but no less also because of important changes in Dutch society that together had profound effects on the nature and scope of the ethical debates and the infrastructure of bioethics.

These changes can be observed in the succeeding descriptions of the field. As in other countries, the term "medical ethics" is gradually being replaced by "ethics of health care" and then "bioethics." This change is indicative of a massive shift in focus and social weight of the field. "Medical ethics" traditionally focused on the professional activities and behavior of physicians, as "ethics *in* medicine." "Ethics *of* health care" refers to a broader field, of the implications of the health-care system on both individuals and society, while "bioethics" again covers a much larger field with a focus on the effects of the biological sciences and biotechnology for the future of mankind, guided by a sense of urgency, based on the realization of the need to focus on the survival of the human race and life on planet Earth.

The subjects of "old medical ethics," viewed from the present perspective in the twenty-first century, were confined to the practice of medicine, with a guiding concept on combatting disease from the point of view of physicians. Ethics was based on self-evident convictions that medicine was the prerogative of physicians, assigned to and best managed by the profession. The outcome of this conception can be observed in the topics in one of the few books on medical ethics in the early sixties, by *Gerrit Arie Lindeboom (1905–1986)*, professor in internal medicine, the history, and encyclopedia of medicine: the doctor-patient relationship, professional secrecy, the beginning of life, abortion, and the end of life, with a focus on dealing with incurable and terminal patients (Lindeboom, 1960).

This narrow conception of medical ethics received new broader orientations, as the maintenance of health rather than curing disease, due to developments both in medical science and society.

Of essential importance for Dutch medical ethics, in hindsight, is the publication in 1969 of a small, prophetic booklet by psychiatrist *J.H. van den Berg* (1946–2012), a prolific author on psychiatric, medical historical, and cultural subjects, with his *Medische Macht en Medische Ethiek*, (Medical Power and Medical Ethics) (Van den Berg, 1969). In it he argues, with examples of extremely problematic "heroic"

life-saving cases, the need for a *new ethics*. This ethics should not be based on the premise to save biological life at all costs through medical technology, *but to save, protect, and prolong life only in so far as life will be meaningful*. At the time this new conception of medical morality seemed a quaint voice, but its prophetic significance has become "normal medical practice" in daily nontreatment decisions and patient choices in modern medicine.

These changes are reflected in the topics of the "first" textbook on *Ethics and Health Care* by *Paul Sporken, a Roman Catholic theologian* and the first appointed professor of medical ethics in 1974 at the Medical University of Maastricht.

Besides traditional subjects, a different broad line of issues is the focus of "health-care ethics" (Sporken, 1974). Ethics is introduced as a philosophical science; social aspects of the health-care system are included, such as the relationships between individuals, society and the system of health care, and the structure of health care as a societal system based on financial regulations. Chapters on scientific progress are discussed, such as eugenics/genetics, artificial procreation, organ transplants, and resuscitation. And the "new position" of patient rights is dealt with in chapters on abortion, euthanasia, gender transformation, and sterilization.

This further expansion of the field of health-care ethics in the Netherlands is best illustrated by the publication in 1988 of the *Handboek Gezondheidsethiek (Manual of Health Care Ethics)* edited by *theologians* Heleen Dupuis and Inez de Beaufort, collecting 40 authors with more than 600 pages in 53 chapters on "old" but also on many more "new subjects," such as the relationship between health-care ethics and health law, quality of life, health-care costs, patients' rights, neonatology, anencephalics as organ donors, genetic screening for hereditary diseases, ethical aspects of AIDS, and many others (De Beaufort & Dupuis, 1988).

The newly professed concept of maintenance of health as opposed to curing disease not only presented a whole new set of ethical issues but also resulted in an expansion of recognized participants in the system of health care other than physicians: these workers demanded a voice in the search for the correct medical procedures and decisions. This development was exacerbated by scientific progress, creating new dilemmas that forced other than physicians alone to deal responsibly with the issues at the level of direct care and the procedures of health-care decisions. But progress in medicine also created an awareness of the dangers of scientific applications and questions that arose on quality issues, forcing reflections on the ever-expanding medicalization of society.

Social Developments

In a fairly limited number of years in the early seventies, Dutch society and its social institutions underwent fundamental changes with profound effects on the system and perception of health care, designated by terms as paternalism versus self-determination, individualism, hierarchical views versus loss of traditional systems of morality in society, and consensus on shared values. Dutch society became secularized in a relatively short period of time.

Social values changed from churchgoing community values to neoliberal and social democratic values. One of the legacies of World War II time was a certain benign neglect of church authorities in medical ethical issues. But in the fifties and sixties, progressive Dutch theologians participated in ethical debates and often supported their philosophical views with ideas from French existentialism (Sartre, De Beauvoir, Camus) with its focus on authentic realization of individual existence and the demand for uncompromised freedom to act for individuals. Other factors in the national debates were the effect of the coming to age of the postwar "baby-boom generation," intending to fulfill the hopes of the wartime generation. When this "baby-boom generation" from 1945 and on entered the workplace or went to college and university, students and workers successfully demanded the right to participate in managing workplaces and teaching programs at universities.

They also demanded the right to exercise their newly found freedom with the use of soft drugs and to experience sexual liberties that became available through the rapid introduction of female contraceptives by the Dutch pharmaceutical company Organon. These developments caused the end of traditional hierarchies, shifting from a religion-organized society with separate religious-oriented health-care institutions to "neutral" social institutions. The emergence of movements of emancipation to end paternalistic relations, both within the religious and other societal systems, leads amongst others to the emancipation of the profession of nursing but also in society in general in developing patients' rights.

Changes in the Health-Care System

Not only technological changes but also changes within the distribution of social power enhanced the rise of bioethics. Steep increases in health-care costs forced a confrontation of the issue of "medical scarcity" and the potential injustice of inequality in rights and access to health-care provisions. In 1974 the *Secretary of Health Hendriks* introduced the *Structuurnota Gezondheidszorg*, the *Structure Policy Health Care Paper*, as a first attempt to regulate and limit health-care expenses by focusing on the cost impact of primary health-care facilities and regional health-care insurers. This move however caused unintended mergers of insurers in the field without accountable effects on the actual cost developments.

The conclusion that rising costs would exceed the possibility to pay health care within 30 years was however not disputed. Changes and choices had to be made. In the early nineties, a governmental commission, called after its chair *Dunning*, presented a model to make those choices transparent. Efficacy, need, efficiency, and accountability were to be the four criteria of the health-care delivery process that should produce sustainable and affordable care within a collective system of health insurance for every citizen, with free access for all. Politicians struggled for several years with this concept, trying to evade the financial consequences and

the realization that different innovations should be imposed to curb an ever-expanding medical need. A new system was developed more than a decade later, *forcing basic health insurance as an obligation on every citizen* in order to be able to continue the maintenance of the ideals of solidarity and justice. It was decided also to open up the health-care institutions and services for economic competition through the "laws of the market." Following neoliberal beliefs it was expected that "the invisible hand" would eventually be effective to curb costs through competition. The new system started in 2006. Since then costs however have increased even steeper, driven by a combination of growing demand and "medical" willingness to supply. Hence, the system is again under review with the same ethical questions as in 1974: Should distributive justice govern the health-care system? What treatments should be included in the basic insurance and should accessibility be limited? The area of health care as a basic social institution becomes a field of conflicting moral values between medicine and economics.

Moments of Crisis

Looking back at the start of what is called bioethics today leads to the inevitable conclusion that its development resulted from many different factors, mostly the same as in other developed Western countries: the growth of technology in the post-World War II period and changes in societal perceptions of promise and risk of this technology in an ever-expanding system of health care.

There are also a few "moments of crisis" that put the spotlight on distinct dangers of unforeseen effects of medical technology itself. The first one has become known as "the Softenon affair." The term refers to the sudden appearance, between 1957 and 1961, of babies born without arms and/or legs from mothers who during pregnancy had taken the drug thalidomide. This resulted in the existence in many European countries of more than 10,000 babies with *phocomelia*, as the medical diagnosis became known. Since the drug was not marketed in the USA, the "disease" did not appear on the North American continent. The scandal brought on by an apparently "innocent" drug shocked not only the medical and pharmaceutical world but society as a whole and resulted in a decrease of trust in technology and an increase in societal demands for involvement and more careful research practices ever since.

Another "scandal" became known as "the DES daughters," daughters of women who had been treated in case of earlier miscarriages with diethylstilbestrol. The period ranges from 1946 to 1977 when the drug was taken off the market because of the unforeseen effects on daughters and sons. In the Netherlands the estimate is anywhere between 189.000 and 378.000 cases. The female offspring showed rare forms of the so-called clear cell vaginal cancer, including a risk of infertility and anatomical disfigurations in the male offspring's genital organs. The affected women also had a risk of twice the normal figure for breast cancer.

Also, mostly unknown outside of the Netherlands, the Dutch public was confronted with the so-called Planta affair in 1960. Thousands of citizens suddenly came up with skin "rashes" that were caused by a new chemical in a popular margarine. It was immediately withdrawn from the market but nevertheless started a public and political awareness of the dangers of technology and meant the beginning of the field of modern toxicology.

End-of-Life Issues

In hindsight there seems to be one area of attention that has dominated the ethical debates throughout the past 50 years. That is, the subject of dealing with death and dying patients. Even though there has not been a distinct "death awareness movement" in the Netherlands, the subject of dying and "medical death" has dominated and inspired ethical debates ever since the sixties of the past century.

The line of thinking on the "end of life" expressed itself in several areas or subjects with a more or less specific Dutch trait. Successively we will deal with the areas of truth at the bedside, euthanasia, palliative care, hospice movement, and termination of life of severely incurable neonates.

Truth Telling

Contrary to medical custom to hide a diagnosis of malignant diseases for patients, more and more it became an obligation to tell the truth about possible effects of therapies and prognoses for the future, even in cases with an extremely short life expectancy. Books and articles from nonphysicians, mostly pastors and theologians, set the tone. The name of the "American" psychiatrist *Kübler-Ross* must be mentioned, because her ideas have, and still do, motivated many in and outside the field of health care in the Netherlands. Her ideas on the stages she developed of the psychological process to accept death have shaped that field until today. Even earlier in the sixties, a shift occurs from doctor-centered towards patient-centered conceptions and policies. "Terminal sickbeds" seem to be a central place for truth telling, of which the Protestant minister Buskes in his *Waarheid en Leugen aan het Ziekbed*, (Truth and Lies at the Sickbed), from 1964, with many reprints, is a good example (Buskes, 1964). His book is also an example of the influence of continental existential philosophy in theology, especially French philosophy from Camus (The Plague) and De Beauvoir (A Very Easy Death), with an appeal to sincerity in matters of life and death, without evading the tragic moments of life.

Justifications of "respect for patients as persons" were augmented with more general ideas on the "rights of patients" for a death with dignity. These ideas were

generated in a period of deep social changes in Dutch society in the early seventies, with a focus on authenticity, self-determination, autonomy, and individualism. And "a right to die with dignity" is seen as the utmost and most genuine expression of that position. The intention is to confront death and dying in adult ways rather than focus on health care as an institution with a nonrealistic ideal to be able to prolong life indeterminately.

Euthanasia

The subject of euthanasia is dealt with in extenso because of the leading position of the Netherlands from a "historical" perspective. Several developments should be kept in mind before the history of euthanasia is described in more detail. In the first place, euthanasia as a practice emerges from public pressure, medical cases, and jurisprudence rather than from legislation. Secondly, the Dutch medical profession, organized into the *KNMG*, discussed the issue since 1968 in generally affirmative terms. Thirdly, the supporting legal decisions in subsequent court cases from 1974 onward with their focus on medical science and medical ethics instead of criminal law resulted in, especially after 1984, a lasting cooperation between the medical profession and the Departments of Justice and Health Care in developing guidelines, regulations, and evaluation procedures. For a comprehensive evaluation of Dutch "euthanasia," see Youngner and Kimsma (2012).

Legal Development Through Jurisprudence

Ideas and convictions on the right to death with dignity and one's own choice became hotly debated public issues with the "first" euthanasia case in the Netherlands that went to court in 1971 and ended with a "light" conviction in 1974. The case concerned family physician Mrs. Postma-van Boven, in the province of Friesland in the northern part of the country, who ended the life of her paralyzed and incontinent mother, whose senses were compromised severely, at her repeated request, with an intravenous injection of 200 mg morphine. When her action became known in the nursing home where she stayed, she was arrested. The surprising angle of the Regional (Lower) Court in Leeuwarden was not on ending the life of the patient from a criminal point of view, but the Court rather focused on how physicians deal with seriously ill patients and what is to be considered normal medical care, even if life of a requesting, suffering patient is shortened by intravenous increasing doses of morphine, with the intention to alleviate suffering and accept a shortening of life. Mrs. Postma was found guilty because she did not follow the medical standard of increasing doses of morphine(!), but injected 200 mg at once. She, however, received a light suspended sentence of 1 week in jail. Also the Leeuwarden Court stipulated that helping someone to die should not be limited to terminal patients, but could apply to persons with for them serious physical

or mental suffering, but with the possibility of a longer life expectancy. This ruling was generally experienced as a landmark case that opened to the door for "acceptable euthanasia." For several years the case fuelled the debate on euthanasia and physician-assisted suicide in the Netherlands. A conference on euthanasia was attended by an unusual large number of more than 2,000 participants, with a large share of nurses. Mrs. Postma became one of the founders of the *Netherlands Voluntary Euthanasia Society* that quickly counted a membership of thousands and today is the largest euthanasia society in the world.

This focus on "medical science and medical ethics" has been consistently maintained by the *Dutch Supreme Court (the "Hoge Raad," literally: the High Council)* cases. The important issues have always been two items: a voluntary request of a legally competent person and what constitutes "unbearable and hopeless suffering" in justifiable ending of life. There were a large number of "euthanasia cases" during these years; the cases from the Dutch Supreme Court are described here.

From a legal point of view, in the important *Schoonheim case* (1984), named after the defendant physician, the Supreme Court for the first time defines the judicial acceptance of ending life after a request by ruling that in case of a conflict of duties, namely, the duty to protect life versus the duty to alleviate suffering, ending a life could be excused. Unbearable suffering in this case was described as the presence of ailments and defects that were unbearable for the 94-year-old patient and would only increase in severity and further loss, denying her a death with dignity, without options to alleviate that suffering.

In the *Chabot case* (1994), also named after the accused physician, the Supreme Court rules that not the cause of suffering was fundamental, but the nature of suffering, in case of ending a life of a person whose suffering had no somatic origin, but the person suffered mentally and psychically, without a psychiatric disorder with additional incompetence. This ruling seemed to "open the door" for allowing to pass almost any type of personal suffering or anguish as a justification for euthanasia. However, the *Brongersma Supreme Court case*, from 2002, named after the patient, the Supreme Court finds physician-assisted death in this case not justified because the unbearable suffering of a person must be based on or rooted in a "medical classifiable disease or affliction."

In one other case before the Supreme Court, the *Van Oijen case* from 2004, the physician was found guilty of ending the life of a patient because of the absence of a request, while a claim of compassion was deemed to be insufficient justification.

Politics and Euthanasia

Compared to the practice of a permissive policy based on actual cases after 1974, jurisprudence and regulations worked out between the Department of Justice and the KNMG, the final acceptance of a "Euthanasia Law" has been long in formation. Lines of division between the political parties ran between the opposing Christian

Table 74.1 Percentage of medical decisions at the end of life

% of all deaths	1990	1995	2001	2005	2010
Euthanasia	1,7	2,4	2,6	1,7	2,8
PAS	0,2	0,2	0,2	0,1	0,1
LAWER	0,8	0,7	0,7	0,4	0,2
APS	19	19	21	25	36
NTD	18	20	20	16	18
Palliat. sedation			5,6	7,1	11,1
Reporting	18	41	54	80	77

PAS Physician-assisted suicide, *LAWER* Life-ending without explicit request, *APS* Alleviating pain and suffering, *NTD* Nontreatment decisions

parties and the supporting liberals, with a hesitant position of the socialist parties. Even within the group of proponents, opinions differed with respect to the urgency to realize legalization or whether a responsible euthanasia practice could be realized within the context of existing laws. The period 1984–1986 proved to be crucial. A liberal party (Democrats '66) introduced a law proposal, known by the name of the member of the Parliament that took the initiative, *Wessel-Tuinstra*, the *medical profession* came out in favor of euthanasia; the *Supreme Court* published a lenient decision, and a *State Committee on Euthanasia* published its report in 1985 with a positive advice on accepting the option of medical ending of life, even though a minority report against euthanasia reflected sharp dissension on the subject. Because the Netherlands has a democratic multiparty system, with shifting coalitions depending on election results, opposing positions along the religious-secular divide are pacified through complex rules of the "political game," intending to reach consensus in the end. This is to be observed in both the areas of abortion and euthanasia. The liberal D'66 Wessel-Tuinstra initiative forced the then coalition government to reach a decision. In the Netherlands the "solution" of politically dividing issues often is delayed by the political parties' elites, by putting off decisions through delegation to a committee for further study in depth. The effect of this procedure leads to a certain de-politization of the issue by focusing on the facts. In the case of the problem of euthanasia, the Government inaugurated the *Research Committee Medical Practice on Euthanasia* that became known under the name of its chairman, the *Remmelink Committee*, of 1991. This committee carried out a national survey on end-of-life decisions in the Netherlands and produced representative data for all medical decisions at the end of life, death after nontreatment decisions (NTDs), in the course of alleviation of pain and suffering (APS), voluntary active euthanasia, and physician-assisted suicide (PAS), and collected also data about life-ending actions without explicit request (LAWER). This national investigation, producing data that were representative of all medical decisions on patients who died in the entire country of the Netherlands, was repeated in 1995, 2001, 2005, and again in 2010. The massive amount of data shows that the percentage of voluntary active euthanasia cases varies between 1,7 % (1990) and 2,8 % (2010) (Table 74.1).

Reporting, now mandatory under the present law, increased from 18 % (1990) to 41 % (1995) and 54 % (2001) to 80 % (2005). 2010, the last year investigated, shows a rate of reporting of 77 %.

Legally Regulated Ending of Life

Around the turn of the century, a government formed by liberals and socialists, supporting the realization of a "Euthanasia Law," was in power. In 2002 that *Law on Termination of Life on Request and Physician-Assisted Suicide* was activated. The Law maintains the criminal nature of euthanasia in general but defines the *conditions under which physicians shall not be prosecuted*. These "due care criteria" are – the attending physician must:

(a) Be satisfied that the patient has made a voluntary and carefully considered request
(b) Be satisfied that the patient's suffering was unbearable and that there was no prospect for improvement
(c) Have informed the patient about his situation and his prospects
(d) Have come to the conclusion, together with the patient, that there is no reasonable alternative in the light of the patient's situation
(e) Have consulted at least one other, independent physician, who must have seen the patient and given a written opinion on the due care criteria referred to in a. to d. above
(f) Have terminated the patient's life or provided assistance with suicide with due medical care and attention

Significant is the provision in section 2, article 2, stating that an attending physician may comply with a written declaration of a patient age 16 or older, no longer capable of expressing his will, while the above stated due care criteria apply mutatis mutandis (italics in the legal text).

The Medical Profession: KNMG

Of undeniable importance during all these years, from 1970 on, has been the position and policy of the medical professional organization, the *Koninklijke Maatschappij ter bevordering van Geneeskunst (KNMG)*, the *Royal Dutch Medical Association or RDMA*. The KNMG discussed "euthanasia" in publications from 1968 to 1977, tending to come out in favor of it, but as a profession remained divided. In 1984 the *KNMG Board* came out with prudential policy in favor of active ending of life, justifying and attempting to regulate an already existing practice of euthanasia, wishing to end the legal uncertainty for physicians and inequality for patients, with guidelines following the lenient jurisprudence. The policy's focus is on accepting conscientious objection of opponents, stressing a choice for physician-assisted suicide rather than euthanasia, defining the conditions, underwriting the position that *assisting in ending life should only be possible for physicians within*

the doctor-patient relationship, and pointing out the need for prior consultations, from both nearby colleagues and of a colleague independent of a case.

The Board's recommendations became a guiding force, in spite of minority objections of members of the dissenting Dutch Doctor's Association, and formed the basis for future discussions with the Departments of Justice and Health Care and political parties preparing legislation. In fact, one observer concluded that "the rules and procedures that govern euthanasia were largely worked out within the medical profession before being adopted in the case law and in (proposed) legislation" (Griffiths, 2000).

In 1985 the KNMG appointed the *CAL*, the *Commissie Aanvaardbaarheid Levensbeëindigend handelen*, (Commission on the Acceptability of Medical Behavior that Shortens Life (MBSL) that subsequently published four reports on medical interventions in general, with neonates, with comatose, and with psychiatric patients. These reports, though without a clear legal position, nevertheless contained the outlines for future legal procedures in cases of incompetent patients.

The affirmative position of the KNMG has been consistently maintained with follow-up policy papers in 1995, in 2003, after the Law of 2002 regulating euthanasia became in force, in 2006, and in 2011.

In essence the RDMA cooperated with the state in defining justifiable ending of life or the state allowed the profession to self-regulate end-of-life decision making. One example of this cooperation is the *KNMG Richtlijn Euthanasie bij een verlaagd bewustzijn* (*2010*), (*KNMG Guideline Euthanasia in case of lowered consciousness*) formulated at the request of the Department of Justice. Other relevant policy papers are the *KNMG Richtlijn Palliatieve Sedatie, (KNMG Guideline 'Palliative Sedation)* (*2009*) and the last policy paper so far, *De rol van de arts bij het zelfgekozen levenseinde, (On the role of a physician involved in a self chosen end of life)* (*2012*), in which not only the options and limits of a physician's role in case of euthanasia and physician-assisted suicide are treated but also additionally in cases of intentionally choosing suicide by stopping with food and liquids and when patients choose to die through the ingestion of overdoses of medication.

Checks for a Careful Procedure: Consultants Before and Euthanasia Review Committees (ERC's) After the Act of Euthanasia

One of the early recommendations of the KNMG proposals from 1984 was the inauguration of the function of consultants before euthanasia could take place. This idea was realized in 1997 when the KNMG, in cooperation with the *Amsterdam General Physicians Society*, developed a training program for independent euthanasia consultants for the Amsterdam area, later to be expanded over the country and to be known under the acronym *SCEN: Steun en Consultatie Euthanasie Nederland, (SCEN: Support and Consultation Euthanasia Netherlands)*. This was the beginning of a national, efficiently functioning network of consultants for medical assessment of the conditions for a prudent practice, set up with continued financial support of the government, that today counts more than 500 physicians. Consultants

are available 7 days a week for information, support, and consultation, can be reached through a central phone number to assure independence, and can conclude a visit at the patient's site and write up a report, if necessary at the same day of a request. The system has been successful and appreciated by the medical profession, the government, and the *Euthanasia Review Committees*; the second function to assure the goals of the euthanasia procedures of *transparence, carefulness, and reluctance* to have "the law" dominates discussions between patients and physicians on how and when to die.

Before the inauguration of the five Euthanasia Review Committees, mandatory reporting by physicians, with an estimated low yield of 18 % of calculated euthanasia cases in 1991, leads to criminal proceedings of local prosecutors, with a final decision whether or not to prosecute taken at the Department of Justice by its Secretary.

In 1998 this system was replaced by a review of the *ERC's*, consisting of a legal expert, a physician, and an ethicist. This semilegal committee, putting "the law at some distance," evaluates whether each reported case has been within the limits of a prudent euthanasia practice, as set forth in the jurisprudence, with the expectation of an increase of reporting by including nonlegal experts. Reporting has increased from 18 % in 1999 to 80 % in the 2005 national survey and 77 % in 2010. The ERC's have been incorporated into the "Euthanasia Law" of 2002, while their area of authority has been expanded. They now have the final authority of assessment on all reported cases, including incompetents, such as comatose, psychiatric, and Alzheimer's patients.

When an ERC concludes that a case of physician-assisted dying has not been within the limits of the law, it refers the case to the legal authorities. However, of the 38 "not careful" cases out of a total number of 20,623 reported cases between 1998 and 2008, none have led to criminal proceedings. A 2005 evaluation of the ERC's and SCEN consultations shows adherence to the norms and intentions of the Law of 2002, while the SCEN reports excel in substantial information to complete the evaluation of the ERC's.

Neonatal Care

The debates on and legal developments in euthanasia, with regulations for persons over 16 years of age, were not without consequences for end-of-life decisions in pediatrics and neonatal care. Decisions to continue intensive care in cases of newborns with limited chances of survival and/or a prospect of severe impairment of the quality of life already were discussed in 1992 by the *Dutch Society of Pediatrics* in a report *Doen of Laten* (Acting or Letting Go). In the aftermath of criminal charges in one neonatal case, neonatologist and lawyer *Verhagen of the Groningen Medical Center* developed a protocol to regulate decisions to terminate the life of severely suffering neonates without prospect for survival. This protocol was accepted by the Society of Pediatrics in 2004 (Verhagen & Sauer, 2005). It caused intense national and international debates on the morality of ending life

of neonates but nevertheless received a legal status in 2007. Consequently every case of ending the life of a neonate as well as cases of abortion after 24 weeks of gestation, since 2007, needs to be formally reported to a state review committee (*the Central Expertcommittee on late terminations of pregnancy and life-ending of neonates*) that judges the carefulness of each case on the same conditions as the "Euthanasia Law" for adults. In case of interventions "without due care," physicians can be prosecuted for murder. This committee reviews only a few cases each year and far less than expected. One of the explanations is the use of ultrasound imaging after the 18th week of gestation that has increased abortions before 22 weeks, the time line for "legal abortions." However, in cases of newborns with none or a very limited prospect in life, the protocol seems to function well as a public review of medical decisions of ending or not supporting the life of some newborns.

Palliative Medicine

The development of palliative medicine in the Netherlands is thoroughly colored by the polarized national and international debates on euthanasia. That is an undeniable factor in both the debates and the actual growth of the field. Opponents of euthanasia in the eighties and nineties, both in- and outside of the Netherlands, claimed a lack of palliative options in the Netherlands that, if they had been in place, might have resulted in less requests for euthanasia. Proponents of euthanasia claimed a disrespect of opponents for the requests of autonomous patients, to fulfill their vision on the end of their life. Both claims have no scientific empirical foundation but nevertheless dominated the debate about the adequacy of palliative care in the Netherlands.

There is no denying that palliative medicine in this country was developed late in comparison to other European nations, especially to the "founding nation" Great Britain. But then again, the Netherlands was not the only country trailing in this development. However, given the international ambivalence towards the euthanasia policies in the Netherlands, palliative medicine and care have developed in relative isolation.

Early Initiatives

Early publicly funded initiatives to promote and improve palliative care, usually described as terminal care, are from 1975, with the establishment of a separate unit at the "Antonius IJsselmonde" nursing home near Rotterdam, aimed at a broad program of medical, nursing, psychological, and spiritual support. The seventies in general were a period of more public and private initiatives to improve care for terminal patients, with intensive contacts with St. Christopher's and St.Lukes hospices in London. The Dutch initiatives for similar hospices were inspired by religious convictions and privately financed. In 1988 the Protestant "Johannes Hospice" opened its doors in Vleuten, followed by "Hospice Rozenheuvel" in

1994 in the city of Arnhem and funded by Roman Catholic supporters and the Salvation Army. Many other initiatives followed, with a multidisciplinary care focus, supported and also staffed by volunteers. In 1996 practitioners of palliative care organized themselves into the *Dutch Association of Palliative Care*. The proliferation of both institutions and practitioners, with in addition the interest of members of parliament, forced the government to develop policies to guide and regulate the area of palliative care. The formation of policies, also with hopes of public funding, took place in an atmosphere of opposition to euthanasia. Views differed widely on the quality of expertise in existing institutions, such as nursing homes and hospitals, in comparison with the newly founded private hospices. Especially physicians in nursing homes were biased towards independent hospices, which they experienced as an intrusion into their field of expertise, with for them questionable justifications.

So the development of palliative care in the Netherlands has been distinguished by opposing views on the most desirable location of palliative care: inside nursing homes with special units or outside existing institutions in small-scale hospices. Even the terminology of "bijna thuis huizen," meaning "nearly/almost? home house" for hospices, reflects a bias against formal institutions, underscored by a claim of care in surroundings where patients can take along their personal furniture and be supported by family and friends. The ideal remains to provide for patients in need of palliative care in their own homes, cared for by a general practitioner and supported by a multidisciplinary team, on a daily basis. Institutionalization only is an option if the home-care delivery becomes problematic or insufficient.

Fact remains that the Dutch government and especially its liberal Secretary of Health Care Els Borst (Democrats '66), after promoting legal options for euthanasia, in 1996 took national initiatives to promote palliative care with funding for beds, institutional support, and research, both at the level of care and the ethics of palliative medicine. Much funding went to six academic centers where "*Centres for the Development of Palliative Care*" *(COPZs)* are established for both research and integration of palliative expertise into the curricula. Programs are coordinated with regional cancer centers; care teams put into practice the results from research and "disseminate their expertise through consultations in the context of primary, secondary, and tertiary care settings" (Ten Have & Janssens, 2001).

In addition, invaluable input has been received from the European Commission through the international *Pallium Project*, enabling research into the organizational aspects of palliative care, concepts, ethical debates, and development of the field. Two journals appear: *Pallium, Tijdschift over Palliatieve Zorg* (Pallium, Journal on Palliative Care) and the *Nederlands-Vlaams Tijdschrift voor Palliatieve Zorg* (the Dutch-Flemish Journal for Palliative Care).

Where in most countries palliative medicine is seen as an alternative to euthanasia, in the Netherlands (and Belgium) the dominant view has become that euthanasia is an option at the end of life after all palliative interventions have been exhausted or found insufficiently effective by terminal patients. This claim implies an adequate level of palliative care services, and this position is underpinned in the report *Ranking of Palliative Care Development in the*

European Union. Proposal by the European Association of Palliative Care from 2007. Based on the indicators: hospital units, support teams, home care teams, specialized beds, and full-time physicians, the report situates the Netherlands in a fourth position of the 27 European Community countries, after the UK, Ireland, and Sweden. With respect to the issue of legalized euthanasia as a substitute, or even an obstruction for palliative care, it appears that such a statement has no empirical foundation. On the contrary, this statement is substantiated by a *Report for the Commission on Assisted Dying Briefing Papers from October 2011 of the European Association for Palliative Care*, called *Palliative Care Development in Countries with a Euthanasia Law*. Its conclusion is that "palliative care is well developed in countries with legalized euthanasia/assisted suicide or at least no less well developed as in other European countries. Though international comparison is difficult given the differences in organization and structure of palliative care provision, these countries (Belgium, the Netherlands, Luxemburg, and Switzerland) rank high in Europe for most structural or national indicators."

Abortion

The area of abortion shows shifts in moral and legal appreciation in the Netherlands over the past 200 years. In 1811 it became criminalized in the Netherlands and to be regulated by the state. In the early 1900s abortion became an offense as part of the *Zedelijkheidswetgeving*, the *Morality Acts* from 1911, together with the display and advertising of contraceptives, pornography, brothels, pimping, and homosexual acts (Outshoorn, 2000). Abortion is only allowed in case a woman's life is in danger, even though until World War II, a more liberal practice could be observed with a focus on the woman's life, not only physically but also in case of mental stress. A change from illegal to legal abortion takes place in the Netherlands in the early sixties of the past century, initiated also by the abovementioned thalidomide disaster of severely deformed babies. A group of physicians identified with women with unwanted pregnancies. Physicians and a progressive part of the public realized that the old restrictions could no longer be maintained. This is the period when oral contraceptives become widely available, provided through "Organon," an established Dutch company. However, the medical profession as a whole remained divided on the issue of liberalization of abortion. After a permissive report of the *KNMG and the RDMA*, a conservative faction left to form its own *Nederlands Artsen Verbond*, the *Dutch Association of Doctors*. This polarization occurred also within politics and society as a whole. The professional organization of the Royal Dutch Medical Association comes out in support of careful procedures within a clinical environment, and feminist movements support the position of *Baas in Eigen Buik*, meaning the "self-control of women over their own bellies." Specialized "abortion clinics" in the sixties, run by doctors, defy attempts by the government to close them down, forcing parliament to regulate the issue, with supporting positions of the socialist and liberal parties and opposition from the Christian parties. Parliamentary debates on abortion discuss the principles of protection of

unborn life and the autonomy of the pregnant women. They end up focusing on defining the authentic interest of the state in this area of regulating public and individual morality. And the debates lead to a conclusion that in the end the state should adopt a neutral position as opposed to religion-based "paternalism."

The present *Law Terminating Pregnancies* (*Wet Afbreking Zwangerschap*) from 1981 aims to guarantee the protection of unborn life to the 22nd week of gestation, the right of women to gain aid to end unwanted pregnancies, and to assure careful procedures to end these. The Law however did not change the permissive practice and abortion is still easily available, also for non-Dutch inhabitants from countries where it is still prohibited.

The combined options between abortion and contraception have resulted in one of the lowest abortion rates in the world. In recent years there has been a slight increase due to the sexual mores and lesser use of effective means of contraception of women originally from non-Western, mostly Islamic cultures, where premarital sex is not officially accepted. The combined abortion rate then adds up to 8,6 in 1,000 women between the ages of 15 and 45, according to accumulated figures from 2001 through 2005 (Wijsen, Van Lee, & Koolstra, 2007). The use of contraceptives by women in these age brackets, oral contraceptives, IUDs, and sterilization, in about 60 % undoubtedly explains the low figures.

Early Activities and Early Centers

Ethics in the Netherlands as a separate scientific discipline becomes a serious academic activity in the seventies of the previous century. In these years medical ethics also becomes a distinct academic discipline, at first more often practiced by theologians and philosophers than physicians, even though the latest appointments are again of physicians with or without a philosophical education.

Medical ethics as a separate academic discipline takes off with the appointment of the progressive priest *Paul Sporken* in 1974 in the medical school at the newly founded public University of Maastricht, followed by philosopher *Jan Broekman* in 1980 in a part-time appointment at the Dutch-Reformed Protestant Vrije Universiteit, both at the medical and philosophical faculties, and was succeeded by *Evert van Leeuwen* in 1994. In 1986 the Leiden University Medical Faculty followed by elevating *Heleen Dupuis*, a graduate in law and theology and associate for many years, to the Chair of Medical Ethics. In 1991 the Roman Catholic Radboud University at Nijmegen appointed *Henk ten Have*, physician and philosopher, at the newly founded Department for Ethics, Philosophy, and History of Medicine. In 1992 the public Erasmus University followed by appointing theologian *Inez de Beaufort* to teach medical ethics, while in 1996 philosopher *Guy Widdershoven* became the Chair at the Maastricht University. The other universities followed suit in this century, starting with philosopher *Marian Verkerk* at the public University of Groningen in 2001, *Hans van Delden* in 2003 at the public University of Utrecht, and *Dick Willems* in that same year at the public University of Amsterdam, at its Academic Medical Center.

In 1984 the *Institute for the Ethics of Health Care* was founded as a publicly funded multidisciplinary research institute to act as a scientific "service center" to promote quality in health care through research in the ethical aspects of the ever-expanding fields of research, genetics, chronic and psychiatric care, issues of equality and fairness, and the end of life. Its first director was the Belgian philosopher *Maurice de Wachter*. The institute published a newsletter called *IGE Nieuws*, literally in Dutch "News from the Institute of Health Care," and a book series focusing on the relevant issues of the time: quality of life, medical confidentiality, medical scarcity, genetics, AIDS, and end-of-life issues. It also published funded research and policy papers, such as "drugs in sports."

In 2001 this institute was absorbed into the Medical School of the Maastricht University, while *Ruud ter Meulen* was its chair.

In 1987 the *Lindeboom Institute* in Ede in the Netherlands was founded, named after the well-known general internist and historian of medicine Gerrit Arie Lindeboom (1905–1986). The foundation of this privately financed Christian institute was motivated by a rejection of ethical developments of the day against the absolute protection of life, understood as the guiding Hippocratic inspiration for medicine, both at the beginning and end of life, as seen in abortion and euthanasia. *Henk Jochemsen*, its director, became an extraordinary professor of medical ethics at the Faculty of Medicine of the Protestant Dutch-Reformed Vrije Universiteit in 1988.

In 1988 the *Center for Bioethics and Health Law* was founded at the Utrecht University Faculty of Theology by theological ethicist *Egbert Schroten*, intended as an interfacultary institute. In 2003 this center changes its name to *Ethics Institute* and becomes located at the Faculty of Philosophy of the University of Utrecht.

In 1989 the *Interfacultary* I*nstitute for* E*thics* is founded at the Vrije Universiteit (IEVU) by theological ethicists.

In the early years from 1970 on, several professional organizations were established. The ethicists, mainly from a theological background, founded the *Vereniging van Ethici in Nederland*, the "Society of Ethicists in the Netherlands."

In 1981 the *Vereniging voor Filosofie en Geneeskunde*, the "Society for Philosophy and Medicine," was established by academic philosophers at medical faculties and medical practitioners as a forum for both internal and public debate. It published the journal *Scripta Medico-Philosophica* for several years and still organizes yearly meetings intended for interested professionals from all areas related to health care. This society appealed to a relatively small group of mainly philosophically interested members. In 1993 it associated itself with the already existent *Tijdschrift voor Geneeskunde en Ethiek*, "Journal of Medicine and Ethics," that became its official professional outlet. This journal has a history that is symbolic of social developments in Dutch society. As in many other areas of Dutch society before the seventies, reflective journals on the ethics and philosophy of medicine were divided along lines of religious affiliation: a Catholic, Protestant, and liberal a-religious orientation. Starting out as *Katholiek Artsenblad*, the "Catholic Physicians' Paper," it changed its name to the more neutral *Metamedica*, "Metamedicine," and then to the *Tijdschrift voor Geneeskunde en Ethiek*.

In 1993 a Nederlandse *Vereniging voor Bio-Ethiek*, "Dutch Society for Bio-Ethics," was founded on the initiative of Egbert Schroten of the Utrecht "Institute for Ethics," as a society with an open admission and with a broad focus on bioethical issues in the original biological sense, ranging from issues in health care to agriculture, ecology, and animals. This society, with a large membership, publishes a newsletter four times a year and a substantial "pre-advice" on relevant issues for its yearly meeting.

International Orientation

After the seventies of the previous century, a significant change in focus occurs with a shifting orientation from an internal national towards an external international orientation. Not only did Dutch ethicist broaden their perspective early on by active participation in the European *Societas Ethica*, established in 1964, but in later years they were also more or less forced to publish in international journals by their professional peer groups that had decisive roles in dividing government furnished research grants, holding international publications as a condition for continued financing. This international focus became relevant also for philosophers and ethicists in medicine and health care. Was the early postwar interest in the Netherlands directed towards the German intellectual sphere; since the seventies this position more and more is taken over by the English-speaking countries and especially the leading role of developments in the USA. Personal contacts, especially with philosopher David Thomasma from Loyola University in Chicago and the publication of his book on "The Philosophical Basis of Medical Practice," together with Ed Pellegrino, made a significant contribution towards establishing ethics of health care as a recognized independent scientific field.

Following the example of the then called *American Society for Health and Human Values*, Henk ten Have and Gerrit Kimsma in 1987 took the initiative to establish the *European Society for Philosophy of Medicine and Health Care (ESPMH)*, with a founding meeting in Maastricht, the Netherlands, on *The Growth of Medical Knowledge*. This society with a major European membership and also with many international members from other continents meets yearly for a conference, with invited presentations on a specific topic of interest. In 1994 the ESPMH organized the *First World Conference on Medicine and Philosophy* in Paris, in association with the French *Association Descartes* and *UNESCO* at the Sorbonne, followed by the *Second World Conference* on this subject in 2000 in Cracow, Poland, together with the *Central and Eastern European Association for Bioethics* and the *Jagiellonian University* of Cracow.

In 1998 the *European Society* started with the publication of the three-monthly *Medicine, Health Care and Philosophy. A European Journal*, edited by Henk ten Have and presently also coedited with Bert Gordijn. A guiding idea of this journal is to be a platform for European philosophers, physicians, and bioethicists with the intention to focus on European philosophical sources and traditions in confrontation with modern-day medical and health-care problems.

Dutch ethicists also have been active in helping realize the *International Association of Bioethics (IAB)* of which the founding meeting in 1992 took place in Amsterdam and then again a meeting was organized in 2012 in Rotterdam.

Government Interventions

The nature of government interventions with ethical issues in the Netherlands has not been in reaction to crises or undesirable events. Technological progress forced the state to react. This reaction has the nature of a response but at the same time also caused a process of reflection on its own tasks and the division of responsibilities in the area of ethics between the state, the relevant organizations, such as the universities, and the workers in the field. In a general sense, the state considers its interventions from three different perspectives. The first one is *to create order* between public pressures, initiatives, and the actual legal system. The second one is *to protect citizens* in their encounters with the system of health care, and the third motive is the *promotion of equal access* to a system of health care of adequate capacity and quality (Struijs & de Beaufort, 2010).

The actions of the state expressed itself in two broad areas: research and policies. Initial activities of the government in the area of ethics from 1989 on focused on the promotion of quality research by inaugurating "schools for research" and "work groups" in theology and philosophy, intending to subsidize peer group-evaluated projects. In this period the field of theological and philosophical ethics shifted from theoretical towards more practical and applied ethics, and the ethicists organized themselves in 1994 into the *Onderzoekschool Ethiek*, the "Research School of Ethics." The *Nederlandse Organisatie voor Wetenschappelijk Onderzoek* (NOW), literally the Dutch Organization for Scientific Research, became the dispensary of state funding in cooperation with established leaders in the various scientific fields, organized into the Koninklijke Nederlandse Academie voor Wetenschappen (KNAW), the "Royal Dutch Academy for the Sciences." From 1996 on the government stimulated programs as part of its *Ethiek met Beleid*, "Ethics with Management" program. Especially the condition of interdisciplinary research between ethicists and researchers in other fields of health care, biology, and technology resulted in quality research and significant progress that led to a continuation of further funding from 2003 onwards.

The second area of ethical initiatives of the Dutch government also came in reaction to technological developments, such as the possibility of cloning. The state realized that it should respond to these developments together with the workers in the fields. From that time on, ethics was placed on the agenda of the various advisory organs of the state such as the *Raad voor de Volksgezondheid en Zorg (RVZ)*, the "Council for Public Health and Care," a more regulatory institution for public health and health insurance, and the *Gezondheidsraad*, the "Health Council," an advisory organ for the government itself. The state established the *Centrum voor Ethiek en Gezondheid*, the "Center for Ethics and Health," a cooperation between the aforementioned councils, with the assignment not only to advise the government but also to be an information

center for the general public and function as an intermediate for all possible and potential parties with interests in ethical issues in health care. Essentially, the Center is an institution for anticipatory detection of potentially "ethically loaded" issues.

In its existence since 2003, it has published opinions on many issues. The growth of the state's participation in ethical debates is undeniable, but the nature of its involvement is also subject to substantial change. As said before, this development also meant a reflection on its own role in shaping morality in issues of health care and other areas of public life. Several shifts may be concluded (Struijs & de Beaufort, 2010). In the first place, a shift in policy is seen in the area of moral paternalism towards a more neutral liberal conception of its role. Instead of setting a norm, the focus shifts towards stressing procedures. The government's angle shifts from reacting on events and developments towards proactive or more anticipatory developing of policy. The state's focus also changes from orientation at the level of individuals to the meso and macro level of ethical issues, as becomes apparent in areas of medical treatments, issues of science and technology, and scarcity issues in the system of health care. Councils and centers function as both signaling new developments and providing policy choices in their advisory capacity.

Bioethics as a Discipline

The intense involvement after the seventies of ethicists in areas of health care, technology, agriculture, and the environment automatically led to reflections on the nature and the value of ethics, its methodology, its claims, and its conceptions of ethics as a science. Both in the international arena and in the Netherlands, the need for conceptualizing the "new ethics" as opposed to the old "Hippocratic" variety led to lively debates. In the Netherlands the ethicists from theology and philosophy carried on a debate characterized as a conflict between paradigms, between the "universalists" and the "contextualists." The question concerned the possibility of a universal morality in order to analyze particular moral traditions, the nature and value of ethical theories, and the nature of moral argumentation (Musschenga, 2010). The universalists tended to agree on the option of a "narrow morality" versus a "broad morality," and their ideas on consensus fitted the concept of consensus on a basic social morality, as the basis for a democratic society. In a pluralistic society, the dominant political morality is the liberal approach that prescribes the limits of interactions between the states and individuals. The conception of a "narrow morality" also influenced debates about the relationship between political morality and broader life- and worldviews on the "good life," in this case a broader vision than in medical practice itself. The difference between "narrow" and "broad" conceptions becomes visible also in visions on the relationship between "theory and practice," with pragmatic positions on a minimally necessary shared political views threat to function as opposed to a view that foresees the loss of philosophical foundation and content for ethical analysis. The latter approach aims to regain ethics as a science to "uncover" and articulate the meaning of moral experience behind or in actual moral behavior, the so-called hermeneutical approach. This debate continued when

ethicists were confronted with questions of empirical research in institutions and actual policies of health care. This debate of the ethicists took place in a context where physicians more and more felt threatened in the control of traditional and inherent morality in medical practice, as if medicine in itself did not express adequate morality and was in need of extern expertise. *Widdershoven* can be seen a leader in the "hermeneutical" movement to analyze the internal morality of medical practice in a dialogue with practitioners, patients, and ethicists, describing various justified approaches, depending on the issues: principled, phenomenological, narrative, hermeneutical, discursive, and care ethics, depending also on the level of health-care problem (Widdershoven, 2000).

This change in perspectives for physicians was in detail described by Ten Have, already in 1989, in an analysis and confrontation with the international, primarily the American, developments, of applied ethics, clinical ethics, and the ethics of interpretation. His conclusion is that the position of ethics needs to prevent the approach of "moral engineering" of applying outside ethical principles on individual cases in the practice of medicine. Instead a "prudent" approach is most effective in recognizing the inherent moral components in medical practice, to make the implicit explicit. This approach should function both at the level of medical ethics committees for patient care within a cultural setting and in comparing medical practices between cultures. Only then the critical function of the ethicist will come to full force and possibly have a material addition also in medical training (Ten Have, 1990).

Other Issues and Discussions

Research Ethics and Institutional Research Boards

The need for regulation of medical experiments on animals and human beings has increasingly been felt in the post-World War II period. Not only the Nazi experiments during the war, leading to the *Neuremberg Code* in 1947, but also the reality of unacceptable experiments in the USA after the war underscored the need for regulation of the research activities in Europe, also the Netherlands. At least one unauthorized experiment on radiological experiments, with institutionalized mentally handicapped, became known in the seventies, and in general the conclusion was that several researchers did not live up to the necessary standards. Even though the urgency of the matter was clear, the legal regulation of animal experiments crystallized in 1977 before the inauguration of a law on experiments with human beings in 1999. Before 1999 medical research involving human subjects was *regulated by the medical profession itself* through adopting international codes, such as the mentioned *Neuremberg Code* from 1947 and since 1964 the *Declaration of Helsinki* of the *World Medical Association* followed by its successive later revisions, and the World Health Organization (WHO) together with the *Council for International Organizations of Medical Sciences (CIOMS)* from 1982. The first *Hospital Research Ethics Committees* were established already in 1965, at the

University of Leiden by pharmacologist Noach and at the Vrije Universiteit in Amsterdam by general internist Van der Meer, followed by most hospitals. These hospitals, with a decisive role for academic medical centers, founded the *Nederlandse Vereniging voor Medisch-Ethische Toetsings Commissies (NVMETC)*, the *Dutch Society for Medical-Ethics Review Committees*.

Government advisory organs and hospital associations in 1984 developed a system of norms and licenses in the spirit of these codes, delegating responsibilities for good clinical practice in research to hospital management. Much energy is devoted to issues of defining the various experimental designs and the inherent ethical differences. Distinctions between therapeutic and nontherapeutic experiments, patients and non-patient volunteers, and the competent and the incompetent, such as minors and mentally handicapped, psychiatric patients, prisoners, and military personnel, are discussed in detail and prudent procedures for each category are established. The intense discussions and regulations over the years resulted in the parliamentary acceptance of the *Wet Medisch-Wetenschappelijk Onderzoek met mensen (WMO)*, the *Medical Research Involving Human Subjects Act* in 1998. The law covers the protection of research subjects, of minors and incompetent subjects, protocol requirements, patient information, the consent form, outside consultation of an independent physician not connected with the research in question, and the insurance for research subjects. Hospital review committees, as a result of this law, became legally required, independent local advisory organs for hospital management.

A national committee, the *Centrale Commissie Medisch-Wetenschappelijk Onderzoek (CCMO)* with its bureau becomes responsible for establishing a system of licensing local review boards, but also for review in specific complex areas such as gene therapy, xenotransplantation, embryo research, nontherapeutic interventional studies in minors, and observational research of psychological behavioral interventions. The CCMO as an agency has overall responsibility for the administration of all ongoing research protocols; it functions as arbiter in conflicts between Review Boards and researchers and its bureau serves as an information center for the medical field and the public.

Institutional Ethics Committees

The development of Institutional Ethics Committees in the Netherlands has been profoundly inspired by the history of the American Committees. The original so-called God Committees in case of a morally acceptable practice to share kidneys when transplants became possible cleared a conception of medical decision making involving "the public" in final choices. This development enhanced a publicly shared conviction that others than the medical profession needed to be involved in final choices about acceptable moral choices in health care, especially where it concerned a scarcity of organs and also of a balanced choice between possible medical progress and risks of new research projects. A publication of the Dutch Society of Bioethics on *Ethiek in Commissies*, "Ethics in Committees," in 1999 is

representative of this development and the institutionalization of these Committees. An important theme is the broadening of the basis of committees with outside expertise other than the professionals, both in case of animal experimentation and experiments with human beings. In the late eighties most institutions, either academic hospitals, general hospitals, psychiatric institutions, and nursing home facilities, possess an "ethics committee," in accordance with a concept text of a law on medical experiments from 1987 that became finalized in 1999 but nevertheless had influence on shaping the practice of committees. After that period the potential of ethics committees for both research and individual case analysis leads to a diffusion of this instrument throughout the health-care system, realizing goals of consultation in individual cases, developing protocols for care and treatments, realizing educational objectives, and more generally in activities of reflecting on debates in society and health care (Verweij, Brom, & Huibers, 1999).

Introduction: Bioethics Development in New Zealand

The growth of bioethics in New Zealand really began in 1988 with the Cartwright Report in which the treatment provided for women in National Women's Hospital was found to have been distorted by the theoretical commitments of a senior medical figure, Professor Green. Over more than a decade, he had pursued a study of cervical cancer based on the presupposition that early changes in the cervix were not precancerous, were being far too aggressively treated, and could be observed rather than excised when first detected. This put him at odds with orthodox medical approaches, but he pursued his convictions in the treatment

regimens he offered as standard treatment for women presenting for state-funded treatment. The Cartwright Inquiry was convened to examine the discrepancies between practice at National Women's Hospital and international opinion.

The treatment was, in the inquiry, seen to be closely linked to ongoing research and close scrutiny of the events revealed that ethical standards had been deficient both in terms of patient autonomy and their protection in clinical practice and medical research. It also led to an upsurge in public and professional interest in bioethics.

The Cartwright Report

The events at National Women's Hospital became known as "The unfortunate experiment" and their exposure caused an upheaval in New Zealand medicine (Coney, 1988). The idea that senior medical figures might have acted unethically toward their patients was, at the time, almost unthinkable, but the Cartwright Inquiry (1988) and its conclusions overturned that belief. They instituted a social change in ethical review of research and clinical practice and a major change in bioethics education. The Cartwright Report is, however, critiqued in a controversial recent history (Bryder, 2009) claiming that doctors were unfairly victimized by the inquiry and that the post-Cartwright reforms have not only been to the detriment of a healthy professional-public relationship but also caused a breakdown in the ethos of medicine.

This debate is very important to the ethics of health care throughout Australasia, in which the New Zealand model has been influential (McNeill, 1993). However, that critique of the Cartwright Report and its effects has itself been called into question (Manning, 2009). The author is, for instance, accused of distorting medical history in that she "relies on selective evidence, misreads sources, and makes no attempt to weigh the quality of the sources" (Brookes, 2009, p. 101) suggesting that the author "ran with one side." And the principal epidemiologist advising the Cartwright Report speaks of a "misrepresentation of the medical context" that "should be of serious concern to the profession in New Zealand" (Paul, 2009, p. 138). The observations of a medical student during the contested events will be used to reexamine "the internal morality of medicine" (Paul, 2000; Veatch, 2001) that prevailed before the Cartwright reforms.

"Internal morality" is an ethos, focused on the good of patients, that should guide professionals and protect patients against harm, but the alternative focus on patients' rights led to a radical interrogation and reform of NZ health care that introduced an "external morality" into health governance. Independent ethics committees and patient advocates, nonaligned with medical professional interests, were intended to counterbalance the paternalism thought to dominate existing clinical contexts and professional surveillance mechanisms. The relative disempowerment of patients was depicted as a moral crisis needing to be addressed so that abuses of power in health care could be overcome. The relative disempowerment of patients and the ways in which it led to clinical abuses are evident in the lived and transformative experiences of a medical student of that time (Gillett, 2011).

The relevant experiences cast a revealing "light from within" on a proud and highly principled profession as it existed in New Zealand in the 1970s. Take the example of a patient with metastatic breast cancer encountered during a surgical attachment. The students were told to examine her axilla for "shotty lymph nodes," and then, as the group left the bedside to discuss findings with the surgeon, the patient spoke up; "Excuse me but could you tell me what is wrong with me?" The surgeon's dismissive and breezy reply conveyed no reassurance at all, no indication that he would return to discuss her condition with her, and irritation at her interruption. As the group continued out the door, she screamed "Please, won't you tell me what is wrong with me!" One feels compelled to ask: Why didn't the students say something?

Another example was student puzzlement during apparently contradictory and clearly charged lectures about gynecological cancer and its management and of clinical tutors who acknowledged the problem and tried to help. Increasingly, desperate measures were taken to indicate the sinister implications of cytological findings and the necessity of follow-up in line with international practice. This acrimonious dispute exposed a political schism at the heart of medicine and its science. It would have taken a great deal of personal courage and confidence for any student to form an opinion and speak out in that climate. One woman student did so and was dismissed from an ob-gyn theatre during a session on per vaginal examination with a patient under anesthetic; her sin was speaking up to say that the patient, under anesthetic and about to be examined by half dozen or so medical students, had said that she would be willing to be examined by the student she had met but not by a group of anonymous others. The professor ordered the student from the theatre and refused to allow her to participate any further teaching from him. What should her classmates have done?

The medical profession was, and is, a club that medical students want to join; they are being socialized into the junior role, learning their place. They do not fully understand the ethos of bullying and intimidation (even in some enlightened medical settings). To be sure, there are mentors who take a personal interest, make themselves available to speak frankly, and discuss students' worries, but the "internal morality" sometimes has little to do with collegiality, core purposes, and "morality of the practice of medicine" (Veatch, 2001, p. 622). Internal morality exists at two levels: one deeply humane, caring, and engaged and the other political and riddled with power. There are some traditional doctors perhaps a little anachronistic but with a twinkle in their eyes who do not quite fit the establishment line. These are often memorable characters who embodied an unspoken criticism of some features of the health-care establishment. Other good, solid, and caring doctors, a little apart from the internecine tensions around them, also embody traditional values. Thus the internal morality of medicine (which Pellegrino [2001] derives from the art of medicine and its aims and purpose) was not a uniform concretion of virtue but, in fact, a complex and disrupted reality. It is often effaced by institutions and discourses that embody privilege, power, and positioning and that "qualify, measure, appraise and hierarchize" (Foucault, 1984, p. 266). In fact, students enter medicine asking

a question that also worries many patients entering health care: "What is it OK to do around here?" The answer is conveyed implicitly rather than explicitly and the values conveyed within that milieu inscribe themselves to form clinical "souls." "This real, non-corporeal soul is not a substance; it is the element in which are articulated the effects of a certain type of power and the reference of a certain type of knowledge" (Foucault, 1984, p. 177).

Senior medical figures sometimes use clinical discourse to achieve their ends, often driven by their own convictions about the best way to do good for patients; their lives are a crusade, fuelled by dedication to their work. Such was Herbert Green, a man appalled by the disfiguring and distressing surgery done in the attempt to eradicate gynecological cancer. He was convinced that there had to be a way to spare women the evils caused by the collateral damage of the battle against cancer. Unfortunately, there was a disconnect such that his enthusiasm led to outcomes antithetic to the ethos that should sustain caring clinical medicine (Cartwright, 1988):

> Peer review is almost non-existent ... The lack of systematic seeking of consent to inclusion in research or treatment (except for operative procedures) and the inadequate procedures for approval and surveillance of research and treatment pose a serious risk to patient's rights. (212)
>
> Patients have not always been properly informed of the treatment and options available to them. (215)
>
> Relationships have been poor in the past and from time to time have contributed to the failure to put patient's health and welfare first. (216)

But the proper ethos of caring professionalism and "those values, norms and rules that are intrinsic to the practice of medicine ... brought the problem to light and limited the harm to patients" (Paul, 2000, p. 499). Policymakers reacting to events that had attracted intense public interest imposed an "external morality" – a set of societal and quasi-legal regulations that constrain the powerful players. This "external morality" and the effect of the moral crisis on the profession led to a more concerned, extensive, and inclusive response that has subsequently proved transformative to clinical and research practice, to professional regulation, and to medical education.

Partnership, as promulgated by the medical profession in the last decade (BMJ, 1999), is a change that fosters the well-being not only of patients but of the health-care professionals who care for them: "Partnership means that patients and doctors must change, sharing responsibilities as well as information and decision making. It takes two to tango"(BMJ, 1999, p. 719).

The Cartwright Report has helped create a reflective understanding essential in a profession that has been and is, increasingly worthy of the aspirations of some of our finest young people and of the trust of the public. It already had stability and an established, older, assured, set of mores and mentors able to guide those who joined it toward a liveable character and professional integrity but to that was added the wisdom of being able to listen and respond with understanding. The chance to reflect on the lessons emerging from moral crises and the experiences of those caught up in them is often denied. Such anomalies (the Alder Hey scandal,

inadequacies of consent and sensitivity associated with postmortem practice, scientific corruption – often inadvertent – in medical publishing and regulation, and the destruction or undermining of social roles and responsibilities intrinsic to professional practice) repeatedly threaten the internal morality of medicine. The Hippocratics saw the problem that can alienate doctors from patients and our need to respond to it:

> Physicians come to a case in full health of body and mind. They compare the present symptoms of the patient with similar cases they have seen in the past, so that they can say how cures were effected then. But consider the view of the patients. They do not know what they are suffering from, nor why they are suffering from it, nor what will succeed their present symptoms. Nor have they experience of the course of similar cases. (Lloyd, 1978, p. 142)

They also devised their code to try and entrench an internal morality, but when looking back at the Cartwright Report, it is clear that some doctors saw the code as recommending unstinting and sacrificial dedication rather than a genuine openness to the needs of patients and an understanding of the contributions they had to make to their own regimens of care. The women of New Zealand were seen as attacking the profession, but one could, with profit, reflect on *The Medea* by Euripides where a woman finds that certain promises are undermined by one she trusted. Her fury knew no bounds, and, in a similar way, strident advocates for women in New Zealand turned on the medical profession as an enclave of privilege. They spoke for the powerless demanding remediation, a restoration of balance, and a new mode of interaction that was sounder and less naïve. Many lament the "golden weather" of late twentieth century medicine and its harvest of wonderful technologies and remedies for the ills of the body but can forget that these were devised within an atmosphere somewhat like that of *noblesse oblige*. That time is past. The events of the moral crisis that was the Cartwright Report exposed internal morality and made New Zealanders rethink it.

The Sequelae of Cartwright: Bioethics Infrastructure in New Zealand

The post-Cartwright changes have also affected other areas of the New Zealand health-care environment.'

Patients in Research

The various government level initiatives which have waxed and waned over the last few years include the Health Research Council Ethics Committee and its partners including the Genetics committee, the Independent Biotechnology Advisory Committee, the Bioethics Council, National Advisory Committee on Health and Disability Services Ethics, National Ethics Advisory Committee, and the Ethics Advisory Panel of The Environmental Risk management Authority. The trend

recently has been to reduce public attention to ethical issues, knowledge among ethics committees, and the protection of patients. Changes were made in the ethical review of clinical research applications after the Gisborne hearings report in 2004 (McMillan, 2011), and recently, more changes [based on poor or no audit-based evidence (Cranleigh, 2011; HSC, 2011)] have also threatened to compromise the interests of research participants in New Zealand.

The Cranleigh Health Report and the Health Select Committee Report on the system of ethical review of clinical research in New Zealand, together with the government's response, convey an impression that ethical review of research in New Zealand is in a bad state. But there have been no formal audits of the work of the Multi-region Ethics Committee from 2006 to 2011, so it is unclear that any evidence shows that ethics committees have contributed to the loss of income in clinical trials in New Zealand over the last 10 years.

The Cranleigh Report claims that the clinical trial industry in New Zealand currently earns much less than half the NZ$100 M. p.a. it earned 10 years ago, a time span that is helpful in the analysis of the role of ethics committees in the decline. A thorough audit of the multicenter ethical review system (in 2002, its third year of operation) was undertaken by the Health Research Council Ethics Committee when similar accusations were being made (Evans, 2002). It showed that the views fuelling the current ferment concerning the committees are unfounded.

First, it is not true that clinical research is half what it was 10 years ago. In fact, there has been an increase of more than 320 % in the annual applications for ethics review during that time, and health research is alive and well in New Zealand. What has declined is the amount of money earned from abroad in conducting it. The reports suggest that this is related to a lack of timeliness in ethical review but, tucked away in the Cranleigh Report, is the interesting fact that NZ is among most expensive group of 15 % of 50 countries undertaking clinical research. Other developed countries are very much aware of the threat of developing countries in capturing research funding. India, where the cost of conducting a clinical trial per patient is only 10 % of that in many developed countries, has allegedly had a large increase in research income of this sort. In many of these destinations, there is not the same robust system of ethical review that was in place in NZ research but, surely, to reduce the protections to research participants, hard won following the Cartwright Report is detrimental to the maintenance of a fine system of ethical review in the country.

The issue of outsourcing medical research from New Zealand is also raised in the report, and much of the media discussion following its publication concerned New Zealand companies sending their research elsewhere. Fisher & Paykel Healthcare were mentioned as, by a long way, the most successful biotechnology company in the country for whom "clinical trials are a pivotal activity in the process of generating value in New Zealand's biotechnology sector" (Cranleigh, 2011, p. 29). The report claimed that the company is moving research overseas as a response to problems with ethical review but omitted to mention that the company not only expressed satisfaction with the service provided by New Zealand ethics

committees but gratitude for those committees making special efforts to review applications at short notice and at difficult times in the calendar of ethical review (Graydon, 2011, Letter to D Evans, personal communication). The overseas research being commissioned by F&P Healthcare, in fact, has been contracted abroad to develop products specific for countries like France and Germany which represent important markets. This positive feedback sits uncomfortably with the opinions quoted in the report, but complaints by biomedical industry are a worldwide phenomenon putting pressure on the ethical and scientific governance of research (Elliot, 2010).

It is possible that poorer countries, looking to become favored research sites, will be pressured into making ethical compromises to attract health research money, a problem that arose some years ago when the Health Research Council of New Zealand refused approval to a clinical trial being outsourced to the Cook Islands. Any research sponsored from a country should satisfy ethical standards both of that country and the setting in which it is to be performed (as in the Universal Declaration on Bioethics and Human Rights Article 8, UNESCO, 2005) and that such ethical requirements should not be able to be evaded by sponsoring companies in order to "get over" the "red tape" of a country's ethical review system.

The report based dissatisfaction on evidence that was hard to find in that it does not seem that there was widespread dissatisfaction with ethical review; in fact, only two second opinions on ethical decisions were sought during this period and only one resulted in a change, an excellent record by any standard. The evidence never appears in the discussions.

The Cranleigh Report measures ethical efficiency by using "turnaround time" – the time between the receipt and approval of applications. A 2002 audit, however, found that a major cause of extended times resulted from poorly prepared applications in terms of incorrect or incomplete applications, lack of Maori consultation (either by design or by oversight), or lack of adequate distribution to relevant ethics committees. In fact sometimes it took three months from initial receipt to the preparation of an adequate proposal, delays that were all included in "turnaround times" (though they were not the fault of ethics committees). When the times were analyzed, a different picture emerged: 18–21 % of the "turnaround time" was caused by the committee and 79–82 % by researchers (often reminders were sent from the committees). In some cases, it emerged that researchers were unwilling to amend protocols to comply with ethical standards. Thus the "turnaround time" used was a clumsy measure and should have been replaced by an index calculating the time between the receipt of the complete application (including all documentation) and the date of approval *minus* the time taken by researchers to respond to requests to clarify or amend protocols. This is a clear example of the way that interested parties or lobby groups within a government, who are focused on collaboration with the medical research industry, even in a health-care setting with high ethical standards, can manipulate political decision-making. Given that the Cranleigh Health did not have access to any proper audit of ethics committee function, it could not base its conclusions on sound evidence and implies that the ready

acceptance of its findings as authoritative almost certainly reflected a preconceived agenda rather than a genuine desire for improvement of the research review system. The example therefore highlights the potential for unfortunate developments at the interface between ethics and politics.

All parties in this episode emphasized the importance of maintaining robust ethical review, but the subsequent recommendations and policy proposals do not reflect that intent. Similar difficulties were encountered by analysts of proposed reforms to ethical review procedures in the United Kingdom (which mirrors almost exactly some of the proposals in New Zealand).

In the literature detailing complaints from the research community, issues of delay and bureaucracy feature strongly, and the insistence by ethics committees on real safeguards for participant well-being is disproportionately balanced with the value of medical science. "Ethics committees were perceived as getting in the way of valuable research. It created a danger that the UK would not be seen as a viable site for for lucrative international research. What resulted was pressure, particularly from industry to refine the remit and freedom of research ethics committees in the interests of facilitating research" (Cave & Holm, 2002).

Article 5 of the Declaration of Helsinki clearly declares that "In medical research on human subjects, considerations related to the wellbeing of the human subject should take precedence over the interests of science and society." Thus changes, for illusory economic gain, that compromise the independence and thoroughness of ethical review, should be resisted. The curtailments of ethics committee activity and excellence in New Zealand are exactly the kind of development the declaration warns us about.

The ethics system in New Zealand was reorganized in 2004, largely stimulated by researcher pressure: the number of ethics committees were reduced; the review of all multicenter studies were allocated to a new committee; "observational studies" were excluded from full ethics committee review (on the basis that no serious harms were possible in such research). This kind of measure has theoretical appeal but, in the event, proved no more cost effective than the old multicenter review system at great ethical cost in terms of thoroughness and skill creation in research ethics. The lesson therefore has global significance.

For many New Zealand studies, ethical review is carried out a long way (250–500 km) from the site of research resulting in some important losses (that are further intensified by recent changes).

First, the relationship between clinical researchers and ethics committees is weakened as researchers cannot attend meetings at which their applications are being discussed. Thus the gains arising from face to face discussion are lost, together with any sense of collaboration between researchers and ethics committees in a worthwhile activity.

Second, the voice of many research participant communities becomes muted. The population of New Zealand is heterogeneous, and specific community features may give rise to specific issues of which a local committee is more aware (such as

cultural restrictions on certain interventions in women). In this way, New Zealand can be very different from other countries of a similar size (e.g., Denmark with its relatively homogeneous population). The Minister of Health recognized that local assessment is important in ethical review and that this task went beyond the concerns of health-care providers, but, in that some research communities might be situated more than a 1,000 km from the committee assessing their study, further reductions of the number of ethics committees make proper locally informed ethical assessment impossible. The number of ethics committees in New Zealand should not be based on a per capita calculation but on the needs of diverse research populations. Thus a small country with a geographically scattered population like New Zealand may need more committees per capita than a densely populated country like the United Kingdom.

Third, compliance with ethical aspects of protocols is better addressed when research participants are closer to their ethics committees. No country has a good means of policing the compliance of researchers once an ethics committee has signed off the research protocol. New Zealand, largely because of its size, has done this more successfully than most largely through informal means (the committee keeping its ear to the ground and gathering information about local research activities). One committee, for instance, halted a study until compliance was achieved and ethical approval was withdrawn from another study because of the failure of the researcher to adhere strictly to the approved protocol. Geographical distance and lack of local networks undermine the possibility of "scrutiny" of that type for most approved protocols and even more streamlined measures would only worsen that situation.

The quality of any ethical review depends on the range of skill sets of the committees doing it. Under the old multicenter system, every committee in areas where research was to be carried out looked at the proposal so that many more non-lay (i.e., health-care professional) members, from different disciplines, examined the proposals together with a wide range of lay members. If only one set of professionals see the protocol (assuming a full attendance at the relevant ethics committee meeting), review cannot possible be as well informed or "robust." What is more, removing some "observational studies" from full committee review means that professionals alert to subtle (e.g., psychological) dangers may never see the proposals concerned. The "low risk" to participants justifying this decision is, however, often relativized to biomedical assessments only, and cultural and other concerns may highlight risks that many researchers would ignore and that are only likely to be picked up by locally knowledgeable ethics committees making informed judgments. The gap between well-intentioned researchers and research participants was highlighted by the Cartwright Report in relation to the unfortunate experiment, but we seem to be losing sight of that in the rush toward the industry-driven standards that have led to recent scandals in developed countries. What constitutes an unacceptable risk may mean that questions in observational studies may be very distressing when asked by the wrong person and yet may be judged to be low risk. Neither researchers nor selected subcommittees who may not have the

spread of relevant expertise to form a good judgment should be left to decide whether this is so or not in any given case.

The Health and Disability Commissioner

The establishment of the post of the Health and Disability Commissioner (HDC) and the appointment of patient's advocates was a further innovation that resulted from the Cartwright Report to empower patients who had difficulties with or complaints about their health care. Professor Peter Skegg (a leading medicolegal academic) in "A fortunate experiment? New Zealand's experience with a legislated code of patients' rights" (Skegg, 2011) points out that the HDC legislation creates a "middle road" between regulation and tort. It effectively creates patients' rights to respect, fair treatment, dignity and independence, appropriate standards of care, adequate communication about illness, informed choice and consent, support (including culturally appropriate support), a clear understanding of their role in teaching and research, and an open and transparent mechanism for the investigation and resolution of complaints (Skegg, 2011, p. 236). The code applies to both public and private health-care providers and practitioners and to both orthodox and complimentary health-care services.

The HDC allows for discussion and resolution as an alternative to a hearing leading to a censure (or other adverse finding) against a practitioner. Complaints can reach the HDC from a variety of sources: consumers/patients, other professionals, "whistle-blowers," and health care or patient organizations. Skegg concludes "The provision of a legislated Code of Rights has transformed New Zealand's medico-legal environment … [and] warrants its characterisation as a fortunate experiment" (Skegg, 2011, p. 266). We can therefore say that the enactment of legislation giving effect to bioethical principles in New Zealand has been a very positive move for all parties involved in health care.

Major Bioethics Issues and Discussions in New Zealand

Informed Consent and Patient Autonomy

Informed consent has evolved, or perhaps, based on the Hippocratic advice quoted above, gone back to the future. Current medical decision-making allows the patient to participate in and therefore take part ownership of medical treatment. Patient autonomy is a flagship issue for the post-Cartwright reforms and the mutual growth of medical law and health-care ethics in company with one another. Many doctors have been shaken by moving from the *Bolam* (1957) standard (the health-care professional view or a reasonable practitioner test) to a derivative of the *Sidaway* (1985) standard (reasonable practice plus truthful response to patient inquiries). But, in Australasia following Cartwright, a *Rogers and Whitaker* standard (1992), which is sometimes seen as a subjective patient test, has become the ethical norm. This has caused dismay in some reactionary quarters of the profession provoked but has been a welcome shift for many patient groups. In fact, autonomy is sometimes

said to be in full cry in New Zealand medicine to the point of entrenching a new hegemony as dangerous as unbridled medical paternalism, and some would say that moderating balance needs to be restored.

Informed consent should enable the patient to make a reasoned decision in the light of an adequate understanding of the facts about an illness. The information given to the patient, as determined in a recent New Zealand Health and Disability Commissioner (HDC) decision, should also cover the options open to the patient including nonintervention (HDC, 2004). The patient can then evaluate a health-care professional's recommendation (not prescription) and take a proper part in the decision-making. Clinical research and innovative treatment are bound by the same principles so that it is mandatory to disclose the fact that certain interventions are part of a research trial, unproven, or innovative in some way and therefore that they depart from standard clinical practice. Generally, a fairly comprehensive written information sheet about the nature of the research or innovation is required with, where practical, the usual reassurances about withdrawal. Any health-care professional who follows these guidelines should not have any serious worries about the adequacy of her or his practice in the area of informed consent and patient empowerment. But there are difficulties.

First, when the natural history and the odds of intervention are not clearly framed and the patient makes a decision on less than transparent information. Second, where informed consent is misconstrued on the basis of an ethical and legal separation (or even opposition) between the patient and health-care provider and in particular where the criteria of "disclosure" and "voluntariness" are interpreted in ways that negate the *duty of care* of the health professional. Therefore, proper attitude to informed consent is based on recognizing that the patient is on a journey and has lost the way in the badlands of illness and disease. Health-care professionals are the patient's guides in this strange and threatening place and therefore must be trustworthy as the illness journey is traced out. A health-care professional draws on experience to anticipate the patient's fears and uncertainties and should reach across the divide of professional distance (that prevents over-involvement or boundary violations between health professional and patient). The patient needs companions and an idea of what happens in *The land of Clinicum* (Gillett, 2004) and health-care professionals must meet that need. The patient is then part of the team that can bring the illness journey to the best possible conclusion. Thus informed consent should not be medicolegal standard that restricts the health-care provider's role and can be used as a defense but should indicate a duty to provide the relevant information, to ensure that it is understood, and to help the patient to make a good decision. Clinical care is a problem-solving exercise and when this partnership functions properly, informed consent enables good therapy in that intervention is attuned to the real needs of the patient. In New Zealand, as everywhere else, the reality is complex.

A key question within this partnership is the information that should be disclosed to the patient by the professional so that the patient to make an adequately informed decision. The legal "goalposts" in Australasia, as we have noted, have moved as

a result of some key court decisions but the difference between *spontaneous* and *responsive* disclosure is sometimes not reflected in ethical or legal discussions of the practice of consent.

Spontaneous disclosure concerns the information given in spoken, written, or video form. It should tell patients about their problem, its natural history, the aims of treatment, and the risks. The legal test is still *material risk* or *material relevance*, i.e., a risk that would be taken into account by a reasonable person making the decision in question. In effect, it means that serious but low probability risks, e.g., quadriplegia or incontinence, or less serious but more probable risks, such as wound infection or bone-graft pain would all be mentioned. A reasonable rather than an individual patient (with, perhaps, idiosyncratic concerns) makes this an *objective* rather than *subjective* patient standard and allows informative material to be devised and standardized.

Responsive disclosure comprises the information given in response to questions, and here *Sidaway* (1985) is still pivotal; in that the information given should satisfy the patient's needs. In practice, the requirement presupposes the partnership model requiring the health-care professional to enter into and appreciate the patient's perspective, as that unfolds over a normal conversation about the treatment regimen. Spontaneous and responsive disclosure occur within an ongoing and open-ended relationship and when teaching about informed consent in New Zealand, it is common for educators to detail criteria such as "disclosure," "understanding," "competence," and "voluntariness" (Beauchamp & Childress, 2009, pp. 120–141). Although that is useful in teaching informed consent, it can create the impression that informed consent is a series of tasks to be "checked off" by the health-care professional.

Reflective physicians following the partnership model are quickly alert to this problem and may regard the legal and ethical requirements as "out of touch" with "real" clinical practice but that rests on a mistaken view of the law (as something definitively expressed in legal writings) and of ethical norms. Both law and ethics should be informed by an understanding of the health-care partnership, and in New Zealand, the post-Cartwright climate tries to foster that understanding. That can be disconcerting to those who have not learnt skilled communication and sensitivity to the relevant cues from a patient (rather than just medical facts) as part of their training. Some health-care professionals are good at it and others have difficulty, but, in general, the health-care professional must make the relationship work and deal with the problems arising from the fact that one partner necessarily wields more power. The need for an active contribution by the patient must be made clear to both partners even though the power dynamics in the physician-patient relationship may mean that, despite patients believing their consent to be valid, they may not have been sufficiently empowered to make good decisions that are right for them. When the relevant events are examined retrospectively and critically, that may be apparent to the unbiased eye and then in New Zealand, the health-care professional will be held not to have met the required standard of care.

Because physicians generally know much more about the medical facts, patients must trust them to share the information needed to engage with the real clinical issues;

thus, despite a health-care professional thinking that a clinical encounter was adequately informative, it may not have been. This problem can only be overcome when, as a trusted guide in the illness journey, the physician justifies the patient's confidence in helping with the problem-solving that the illness occasions. Patients need accessible information in which they can take an intelligent interest, and they also need to see the difficulties and uncertainties involved in medical diagnosis and treatment. They should feel free to inquire about their tests and the rationale for medical decisions by being "given permission" to cross the patient-professional divide in terms of the clinical discussion. When that happens, the patients find, often to their surprise, that they can understand what is going on, claim genuine (part) ownership of the decision being made, and, as a result, share the burden of decision-making and relieve some of the moral burden on the clinician in any regimen of care.

A clinical interview should also decrease rather than increase the stress on patients.

Drawing the patient into the appreciation of tests and the planning of interventions empowers her not just to consent (in a way that is informed and voluntary) but to be part of the problem-solving therapeutic alliance whereby decisions are made in a collaborative way, uncertainties shared, and clearly understood recommendations followed, even if the outcome or process may not be exactly as initially envisaged (Gillett, 2004).

We should not, however, assume that a good relationship will compensate for neglect of the objective basics of consent, as a recent HDC decision demonstrated (2009). In the case in question, a bariatric surgeon became aware that the risks of surgery were significantly higher than what had been communicated. He arrived in the operating room to find the patient anesthetized and, believing that he could decide because he and the patient had a good relationship, proceeded with the operation. He was held to have breached the standards for informed consent in not ensuring that the patient had understood the real risks of the procedure prior to making the decision for surgery. Despite the surgeon's belief that he acted in the best interests of his patient, the objective standard was deemed not to be able to be set aside on the basis of an assumption about a doctor-patient relationship.

The decision in the New Zealand bariatric case revealed ethical and legal limits to a relationship-based approach and means that the patient should become an educated and intelligent co-traveller on the medical journey. That is reflected in our teaching on this subject. Even if an experienced clinician believes that only harm and neither benefit nor cure will result from using the latest medical technology, many cases are not clear-cut, and there are contested margins of information disclosure in relation to these. In every case, our skills and the relevant uncertainties must be communicated so that the patient has a realistic view of the issues. The patient should not be treated like an outsider offered a tiny peep into a complex situation interpreted in terms of current medical assumptions but should rather be treated as part of the team trying to solve a health problem in the face of uncertainty.

"Consent" can be a fairly shallow gloss on a forced choice made against a background of facts largely unknown to the patient, on "unfamiliar turf" according to a timescale fixed by somebody else (Gillett, 2004). Autonomy ought

to be part of a free, responsive, and rational cooperation and enables a patient to contribute to a management plan leading to an outcome he or she can accept as worthwhile, rather than a kind of pseudo-autonomy.

The ethico-legal evolution of informed consent has empowered patients and forced health-care professionals to relinquish a degree of control, even if gracious and kind, of the clinical relationship. That makes clinical life a much more cooperative and ultimately satisfying, adventure albeit with fearful risks. As such, it is healthier, not only for those who are cared for but also for those who care.

Future Challenges: Education and the Climate of Health Care

Bioethics Education

Prior to the Cartwright Report, individual academics and concerned professionals were interested in the issues raised by medicine and its technological advances in such areas as the determination of death, embryo research, and the patient as a person, but the Cartwright Report suggested the creation of explicit teaching and research programs in bioethics. That suggestion was taken up especially by the Otago University Medical School which introduced ethics components throughout the undergraduate and clinical medical curricula. These elements focused on the ethical aspects of decisions about treatment including informed consent, considerations of benefit, and harm from the patient's perspective, justice and resource allocation decisions, and the dignity of the patient. The initiative has continued and been strengthened with the expansion of the Otago Bioethics Centre and the postgraduate courses it offers for professionals and others. The academic staff of the Bioethics Centre produces a wealth of teaching material for pharmacy, dentistry, and physiotherapy courses all of which cover basic ethical issues like consent, confidentiality, the assessment of harm and benefit, research and patient participation in research, as well as legal and professional aspects of clinical practice. A growing set of Medical Humanities lectures on topics such as "consciousness, value, and the brain," and the history and philosophy of medical science are also part of the curriculum. Sessions on alternative medicine, the placebo response, and the political context of contemporary medicine jostle for space with related areas like communication skills, holistic clinical care, the biomedical paradigm, and the bio-psycho-social model of medicine. Some students find these sessions quite challenging as they are not used to the types of thinking involved, and it is hard to evaluate this educational input as the changes in the curriculum are ongoing.

A steady stream of students pursuing dedicated bioethics research and higher degrees in biomedical ethics is further evidence of a positive influence and certain practices, such as the unthinking application of intensive end-of-life interventions in service of a misconceived sanctity of life imperative have been brought under increasing ethical and clinical scrutiny recently. The climate of ethical reflection in New Zealand medicine has definitely been enriched as is evident from the topics

covered in academic meetings, continuing professional education, and health-care conferences. The Otago Bioethics Centre has played a key role in these developments.

A Bioethics Research Centre

The Otago Bioethics Centre (established in 1990) has a comprehensive program in teaching, professional education, and research. It has nine academic and two administrative staff and a growing body of graduate students making it a desirable setting for international academics wanting to work in a wide range of bioethical inquiry. As a center, it developed the *New Zealand Bioethics Report* (and then *The New Zealand Bioethics Journal*) which has become an international publication (the *Journal of Bioethical Inquiry*) that includes and encourages bioethics scholarship that arises from both Anglo American Analytic and Continental Philosophy and a range of disciplines within the social sciences and humanities. The Bioethics Centre embraces a similar range of topics through PhD and Masters programs covering standard bioethical issues like abortion, euthanasia, informed consent, and genetics and more specialized areas such as the philosophy of psychiatry, Neuroethics, and post-modern approaches to bioethics.

Some of its alumni have become distinguished contributors to the field, Tom Douglas, John McMillan, and Josie Johnston, to name but three. It has particular research strengths not only in Neuroethics and the philosophy of Psychiatry but also in the philosophy of medical science, end-of-life ethics, ethics in sports medicine informed consent, and the doctor-patient relationship.

Economic Versus Health Benefits

The Cranleigh Report, produced by a group of analysts from a merchant bank, reflects economic- and business-oriented attitudes rather than developed ethical thinking and reflects the mind-set of those who commissioned it. It is allied to a refusal to fund District Health Boards (DHBs) to undertake clinical research because that may distract them from the improvement, promotion, and protection of the health of people and communities; the reduction of health disparities; and the promotion of care and support for people with disabilities. Health-care research does, however, play a role in achieving these goals particularly when it is alert to clinical epidemiological concerns rather than the self-promotion of interested parties (whether political, professional, or commercial) and is aware of the conflicts that arise from externally commissioned and funded research that is not necessarily guided by well-informed ethical opinion and where ethical scrutiny has been "streamlined."

Evidence from clinical trials is a fundamental driver of innovation, patient safety, and improved care. In general, it is at least as safe and beneficial for patients to receive care in a clinical trial as it is outside a clinical trial, because care in such trials is more systematically planned, delivered, monitored, and followed up. Clinical trials can

bring treatments to the clinic before they would otherwise be introduced. Additionally, health-care organizations that are active in clinical research generally practice excellent patient care and have high retention of key clinical staff (NEAC, 2005).

Despite the possible link between clinical trials and patient welfare such that patients in clinical trials may receive better care (even when in the non-treatment group) than those receiving standard clinical care, ethics committees have the responsibility to ensure that standards of equipoise, for instance, are properly met and patients in trials are, in fact, adequately protected. While it is correct that evidence from clinical trials is a fundamental driver of innovation, patient safety, and improved care, those trials must not compromise care to research participants in doing so, for instance, by using a washout phase of significant psychotropic drugs with the risk of a deterioration in a serious mental disorder (Healey & Aldred, 2005). Patients *may* receive better care in clinical trials than elsewhere, but clinical trials test research hypotheses, and there have been instances where the research aim has damaged patients through unforeseen risks (Graham et al., 2006). All health-care research involves potential additional risks above and beyond standard care, and this can only be kept to a minimum when the safety of the research patient is ensured by adequate ethical review. The additional care in clinical trials may be beneficial but only if protections from unknown contingencies, not present outside the context of the clinical trial, are carefully built in.

Current changes to the ethical review of research in New Zealand are based on a poorly researched assessment of Ethics Committee function. The real reasons for some of the problems with review are not known but may have included poor ethical education of researchers and insufficient training of ethical committee members, activity which has been systematically squeezed out of health-care budgets. Adequate resources exist in New Zealand to remedy the situation, but no initiatives are in place to preserve New Zealand's international reputation for effective and well-informed ethical governance of clinical research. The report of the Cartwright Inquiry recommended a comprehensive system of research review involving the Health Research Council Ethics Committee and Regional Health Ethics Committees sufficient in number for a small and scattered population. These committees were resourced (never generously); they networked effectively and created a milieu where they educated and trained themselves for their work. In addition, a National Bioethics Council was created to safeguard ethical, cultural, and spiritual values in health-care and related areas (Good practice, 2013). Sadly, this set of measures has been extensively reduced for economic reasons resulting in a trade-off between the protection of New Zealand patient research participants and the cost and convenience of the ethical review or research. That is lamentable in a nation that has always prided itself on valuing what is truly valuable for its citizens.

Conclusion

Bioethics in New Zealand has a major public scandal – the Cartwright Report – as its effective defining moment and has developed in the basis of that scandal and the

issues that came to light. The scandal concerned treatment, research, and teaching in a major academic hospital, and it led to a reform of the attitude of the profession to clinical and research ethics in particular and bioethics in general. The scandal left a precious legacy in terms of the importance of patients, their stories, their integrity, and their value in health care and health-care research. Some believe that legacy to be under threat under the drivers of current health-care initiatives but it is hoped that the tangible structures and initiatives produced since the Cartwright Report stand us in good stead to resist those tendencies and political agenda that promote them.

Jan Helge Solbakk

Introduction

The history of bioethics in Norway is a narrative about the formative role of physicians in establishing bioethics as an academic field. At the same time, it represents an account of how bioethics slowly grew into an interdisciplinary field attracting individuals from other branches of academia such as engineering, law, philosophy, theology, nursing science, and social sciences. A third characteristic of this history is the paramount role played by the institutionalization of research ethics in the country, something which makes it reasonable to raise the question

whether Norway has reached a level of *ethicization* that may not only generate better research conduct and transparency but also lead to adverse effects of a kind that may hamper a genuine promotion of ethical reflection and bioethical discourse. Fourth and last but not the least, it is a narrative about lost opportunities and about recent regulations and legislations pertaining to bioethics moving in a direction not in compliance with international human rights law and commitments.

Bioethics Development

When and How Has Bioethics Started?

The story of bioethics in Norway may be dated back to 1935, when Ragnar Vogt, a professor of psychiatry at the University in Oslo, published the book, *Etiske problemer* (Ethical problems). His focus was the ethics of the medical profession and the need for reassessing it in the light of scientific, technological, and social changes. He was concerned about the academic neglect of ethics among his philosophical colleagues, and he pointed to the need for implementing systematic ethics teaching at the university, as only students in theology received some sort of moral guidance and training. In 1952, another psychiatrist, Trygve Braatøy, published the book, *Pasienten og lægen* (The patient and the physician), emphasizing the need for protecting the art part of medicine against the dehumanizing implications of specialization. From the 1950s, ethics became a part of the curriculum in social medicine at the Faculty of Medicine in Oslo. In his textbook on social medicine from 1963, *Legeetikk. Lærebok i sosialmedisin* (Physician ethics. Textbook in social medicine), Professor Axel Strøm included a chapter on ethics. In 1976, he published a new book, entitled *Legen, pasienten og samfunnet: problemer i legeetikk* (The physician, the patient, and the society: problems in physician ethics), a book which also reflected his experience as the first chair of the Norwegian Medical Association's Council of Physician Ethics. Also, research ethics had an early academic blooming in Norway, as its story may be dated back to 1966, when a young Norwegian physician, Erik Enger, was awarded his Ph.D. in medicine on a dissertation dealing with medical, ethical, and legal aspects of randomized clinical trials (Enger, 1966). The empirical part of his dissertation consisted of two huge randomized clinical trials, one dealing with patients having suffered a brain stroke and a second study dealing with heart infarction patients. The studies had been performed in the late 1950s and early 1960s, that is, before the first *Declaration of Helsinki* had been adopted in 1964. In contrast to the *Nuremberg Code*, the *Declaration of Helsinki* did not only deal with medical experiments on healthy subjects but also contained ethical guidelines for clinical research involving *sick* people. The patients participating in the studies had been informed about the purpose and scope of the studies, but no information had been given to them about the randomization procedures or about the use of placebo nor had formal consent from each patient been procured. The Helsinki guidelines challenged the young physician to include in his dissertation an ethical analysis of

this type of research design. Dr. Enger's doctoral dissertation represents one of the very first academic treatises in modern medical ethics – in Europe as well as worldwide. His dissertation was published the year Henry K. Beecher's famous article "Ethics and Clinical Research" sent shock waves through the American medical research establishment (Beecher 1966). In the two decades following his Ph.D. dissertation, Enger played a key role in the further development of medical ethics and research ethics in Norway. Besides forming a part of the small Nordic committee preparing the important 1975 revision of the Declaration of Helsinki requiring the assessment of all medical research protocols by an independent research ethics committee, as chair of the Council of Physician Ethics of the Norwegian Medical Association he was also a central figure behind the process of establishing research ethics committees. Although it took almost 10 years from the original proposal in 1975 of establishing such committees, the process witnessed that slowly medical research ethics had become an area involving many more stakeholders than physicians. For this reason, when the committees finally were established in 1984, they were given a broad, interdisciplinary composition, including ethicists, lawyers, and lay people and, notably, with medical and healthcare researchers in a minority position.

Who Have Been the Major Actors/Forces?

The *medical* part of the story of bioethics in Norway illustrates two features which could be said to be "pathognomonic" of the emergence of academic medical ethics and bioethics in Norway. First, it illustrates the role of physicians as academic initiators of the field. Nurses, theologians, philosophers, and lawyers entered the academic field of bioethics later. Other physicians who played a seminal role in making medical ethics an academic discipline in Norway were Professor Jarle Ofstad, the first chair of the National Committee for Medical and Health Related Research and chair of the Research Council of Norway's (RCN) program of medical ethics (for more about this, see Bioethics Committees and Expert Bodies/ Centres), Professor Astrid Nøklebye Heiberg, Professor Christian Fredrik Borchgrevink, and Professor Petter Andreas Steen. To this adds, Reidar Krumradt Lie, a M.D. also trained as a philosopher and with a Ph.D. in philosophy of medicine, who in 1992 became the first professor of medical ethics in Norway and the first Head of Center for Medical Ethics (CME) (for more about CME, see Expert Bodies/ Centres). Second, it draws attention to medical research as the original object of bioethical concern, besides physician ethics and codes of good medical conduct. The medical branch of bioethics would, however, not have become a visible academic discipline in Norway in the late 1980s without the enormous amount of preparatory work and diplomatic negotiations with medical academia undertaken by Knut Erik Tranøy, a professor of moral philosophy and founding father of science ethics. Already in the late 1960s, Tranøy started to give classes in medical ethics and philosophy of medicine for dentistry students and medical students at the University of

Bergen. Before retiring as a professor of moral philosophy at the University Oslo, he also served for 3 years as senior researcher at the Faculty of Medicine with the mandate of developing and implementing a teaching program in medical ethics for the faculty's students in medicine. Another key figure in the academic institutionalization of medical ethics was a professor in systematic theology, Inge Lønning, who served as rector at the University of Oslo in the most formative years of medical ethics in Norway, that is, the period of 1989–1995.

What Have Been the Major Concerns Over Time?

The main concerns underlying and driving forces behind the institutionalization of medical ethics and bioethics in Norway have been the perceived need for establishing systematic teaching in medical ethics for medical students, something which already in the 1930s came to expression as a request for physician ethics and training in codes of good medical conduct, coupled with the 1975 revision of the Declaration of Helsinki and the concomitant establishment of independent research ethics committees.

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

The first systematic textbook in medical ethics that came into use at the time all four medical schools in Norway had implemented a formal teaching program in medical ethics (early 1990s) was Knut Erik Tranøy's, *Medisinsk etikk i vår tid* (Medical Ethics in our time, 1991). Thirteen years prior to this event, another important publication from his hand saw the day, *Fra filosofi til fysiologi: filosofi, naturvitenskap og biomedisinsk etikk* (*From philosophy to physiology*: philosophy, natural sciences, and biomedical ethics, 1978), a book containing seminal historical texts in medical ethics and philosophy of medicine with introductions written by Tranøy. This publication proved to have profound influence on the way bioethics was conceived and implemented at the University of Bergen, first at the Faculty of Medicine and later at the Centre for the Study of the Sciences and the Humanities (SVT), as the interrelation between *medical epistemology* (or more broadly speaking – *philosophy of medicine*) and medical ethics here became a focal point of reference. At the University of Oslo, on the other hand, the philosophy of medicine approach to medical ethics adopted in Bergen was not implemented. Instead, Tranøy's second seminal book from 1991 became the master plan according to which the teaching program at the Faculty of Medicine in Oslo was designed. The approach in this book was strongly influenced by Beauchamp and Childress principle-based approach to biomedical ethics. Accordingly, medical ethics became to be conceived of as a form of applied ethics within the domain of medicine and with an ethics curriculum organized around teaching sessions with participation of clinicians in addition to an ethicist. In 1996, the Faculty of Medicine introduced a problem-based teaching curriculum.

One implication of this reform was that the number of ordinary amphitheater lectures was reduced to a minimum, in favor of the system with PBL-groups. Among many teachers in medicine, this reform was denounced as representing a fundamental threat to possibilities of providing the students with sufficient theoretical medical knowledge. This is not a view shared by the ethics teaching staff at the Faculty of Medicine in Oslo, as the system with PBL-groups may be viewed as representing a return to – and imitation of – the intimate format and moral space originally depicted by Plato in his dialogues. Consequently, the ethics teacher's primarily role is not perceived as a provider of theoretical and practical knowledge but as a discussion partner and helpful knower as well as an example of lived morality to be observed, be it good or bad. An additional reason for this preference is that within the moral space provided by a PBL-group medical students are not only made aware of but hopefully also become used to a shared form of "solving" or "resolving" ethical problems. This seems to be particularly suitable in view of the interdisciplinary nature and relational structure of today's medical practice. In a textbook in medical ethics designed to comply with the PBL 1996 reform at the Faculty of Medicine in Oslo, this issue is explicitly addressed (Ruyter, Førde, & Solbakk, 2007). Seven different theoretical positions in medical ethics are presented and discussed – a doctor's ethics approach, principle-based ethics, utility-based ethics, duty ethics, casuistry, virtue ethics, and last, but not least, a common morality approach to medical ethics. The presentation is structured as follows: After a short description of the position in question comes the confrontation with an authentic case, aimed at testing each position's resolution capacity. As the same test case is used in relation to all positions presented, the students are given the possibility of assessing the relative as well as the "absolute" strengths and weaknesses of each position. In the presentation, the authors try to demonstrate how each position can be used to defend diametrically opposed solutions. The intention behind this is partly to show that in moral decision-making ethical theories can be used to reach theoretically consistent and coherent solutions. More important, however, is the intention to demonstrate that an ethical theory is only an instrument and that depending on who is using the instrument – and the way it is used – the result might also differ. During the last 20 years also, a whole range of other bioethics textbooks have been published (Fjelland and Gjengedal, 1990; Nortvedt and Vetlesen, 1996; Nortvedt and Grimen, 2004; Brinchmann, 2005; Slettebø and Nortvedt, 2006; Slettebø, 2009; and Nortvedt, 2012).

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

Today, medical ethics is an integral part of the medical curricula (undergraduate and postgraduate level) at all four medical schools. In addition, other health professions and academic disciplines have established systematic training of undergraduate and Ph.D. students in the ethics of professions and in research ethics and science ethics.

Bioethics Committees

The first committee in Norway was set up by the Norwegian Medical Research Council (MRC) in 1978. Since the establishment of the system of *Regional Ethics Review Committees* in 1984, the MRC's Committee acted as a coordinating and advisory body in medical research ethics. A working committee consisting of one member from each of the RECs and headed by the chair of the MRC's Ethics Committee used to meet three to four times a year. In June 1989, the Norwegian Parliament (Stortinget) endorsed the recommendation of a 1988 White Paper from the Ministry of Education and Research for the establishment of national research ethics committees within the following three subject areas of research and development:

- Medicine in a broad sense ("health and life sciences")
- The social and behavioral sciences and the humanities, including law and theology
- Natural science/technology including those parts of biotechnology and genetic technology that do not fall under medicine

Great importance was placed on securing representation in the national committees from the fields of ethics and law, as well as on the adequate membership of lay persons. The members of the three national committees of research ethics are appointed by the Ministry of Education and Research on recommendations from the National Research Council (in 1993 the five existing discipline-specific research councils were merged into one council and named the Research Council of Norway, RCN). The secretariats of the national committees are administered by the Norwegian Research Council. It should be noted that the directors of the secretariats are required to have background training in ethics and in the first formative years of the committees they were also given the right to dedicate half of their time do their own research in ethics in addition to their administrative responsibilities. Lately, this right has been deleted from their job descriptions. For the subject area of medicine, the government in 1990 gave the Norwegian MRC's Committee for Medical Research Ethics the status of the *National Committee for Medical and Health Research Ethics*. The committee has 14 members with different professional backgrounds, including ethics and law. Besides, there are lay representatives in the committee. Traditionally, the committee has been chaired by a physician, but it has also been chaired by an individual with background training in theology. The members of the Committee are appointed for terms of 4 years, and no member may sit on the Committee for more than two terms. The Committee meets 5–6 times a year. According to the mandate laid down by the Ministry of Education and Research, the main assignments of the National Committee for Medical and Health Research Ethics are the following:

- To keep itself continually informed of current and potential questions of research ethics in the field of medicine
- To act as a coordinating and advisory body for the RECs
- To inform researchers, the administration, and the public of current and potential questions of research ethics in the field of medicine

- To submit reports on matters of principle relating to medical research ethics and comment on specific matters of special significance relating to research ethics
- To report on its activities at an open meeting at least once a year and in whatever ways it finds suitable promote informed discussion in society of ethical questions relating to medical science and knowledge
- To keep other national and international research ethics committees informed of its activities and in cooperation with them seek to establish a platform of principles of research ethics which extends beyond the boundaries of the respective research subjects

Similar charges are given in the mandates of the two national research ethics committees.

Since 2008, the National Committee for Medical and Health Research Ethics has also functioned as an appeal body for the seven regional committees for medical research ethics. These committees evaluate all individual medical research projects, while the National Committee for Medical and Health Research Ethics gives its opinion on issues that are more a matter of principle. Biannual meetings attended by the chairs and secretaries of all the councils deal with issues on which the committees need to collaborate. Furthermore, all members of the National Committee and the regional committees attend a two-day joint meeting in the autumn, for professional replenishment and discussion (http://www.etikkom.no/en/In-English/Committee-for-Medical-and-Health-Research/). During the parliamentary debate discussing the proposal of establishing the system of three national research ethics committees, a group of MPs from the opposition parties proposed in addition the establishment of a *The Norwegian Biotechnology Advisory Board*. This proposal was also endorsed by the Parliament. The Norwegian Biotechnology Advisory Board is an independent body consisting of 21 members appointed by the Norwegian government. Each member has a relevant background and/or education to competently discuss questions regarding modern biotechnology. Eight members of the Board represent different public organizations. The main task of the Norwegian Biotechnology Advisory Board is to evaluate the social and ethical consequences of modern biotechnology and to discuss usage which promotes sustainable development. The Board has approximately ten regular board meetings and organizes two to three public meetings annually. The Board publishes the free, quarterly journal "Genialt" in Norwegian. In addition, it makes information pamphlets on various topics regarding modern biotechnology (http://www.bion.no/index_eng.shtml).

During the last 13 years, there has been a further growth in the number of national bodies dealing with the ethics of scientific research and development, through the establishment of four additional institutions: the *Norwegian Board of Technology* (1999), the *Norwegian Advisory Board on Ethical Aspects of Patenting* (2004), the *National Commission for the Investigation of Scientific Misconduct* (2007), and the *National Committee for Research Ethics on Human Remains* (2008). The *Norwegian Board of Technology* works in the interface of science and technology. It aims to assess impacts and options of technology in all areas of society, to stimulate public debate on technology, and to support the political decision-making process and shaping of technological change. The Board

furthermore monitors international technological trends and methods for technology assessment. The results of its activities are communicated to the Parliament, governmental bodies, and the public at large. The Norwegian Board of Technology has 14 members appointed by the government. The members have a broad insight in different areas of technology, innovation, and societal issues. The secretariat is situated close to the parliament building and government offices in Oslo, colocated with the National Committees for Research Ethics. The work is organized in projects, and the Board sets its own agenda. The secretariat manages the projects and reports to the Board. The Norwegian Research Council acts as the supervising authority (http://www.teknologiradet.no/FullStory.aspx?m=5). The *Norwegian Advisory Board on Ethical Aspects of Patenting* was established by parliamentary decree and appointed in Royal Council ("Statsråd") in 2004, basically as a reaction to the need to adapt to the European Patent Directive. The Board is to be advisory for the Norwegian Industrial Property Office. Till date, the advice of the Board has only once been required. This was the case of a patent on a genetically modified salmon in which growth was enhanced. After in-depth discussions within the Board, it was concluded to advise negatively because of presumed sufferings of the animal and negative environmental effects. The Norwegian Industrial Property Office did not follow this advice, even though it first modified some of the patent claims on the basis of animal welfare issues. However, when the company claimed that no such negative effects where observed, the patent was eventually granted. In view of the paucity of cases sent to the Board, the Board wrote a report on the ethics of patenting (2008), where it suggested that the mandate of the Board be changed so that it could take a more proactive role and include a closer collaboration with the Norwegian Industrial Property Office, as well as a role in public debate. In light of this report, efforts are currently underway to improve the modus operandi of the Board (http://www.etikkom.no/en/In-English/Patent-Board/). *The National Commission for the Investigation of Research Misconduct* is responsible for assessing allegations of serious research misconduct and issuing a statement on whether any scientific misconduct has occurred or not. Ironically speaking, the establishment of this Commission was greatly facilitated by the publication of two spectacular research scandals in 2006 involving internationally acclaimed researchers. The first scandal involved two of the leading stem cell researchers worldwide, W.S. Hwang from *Seoul National University* in South Korea and G.P. Schatten from the University of Pittsburgh in the USA. The mastermind behind the second scandal was Jon Sudbø, a young Norwegian physician, dentist, and cancer researcher working at the most prestigious university hospital in Norway, the Rikshospitalet-Radiumhospitalet in Oslo. In both cases, the investigating committees found strong indications of deliberate fabrication and falsification of data on the part of the main researchers, Dr. Hwang and Dr. Sudbø. The report on J. Sudbø and coauthors was published on June 30, 2006 (report from the Investigation Commission appointed by Rikshospitalet-Radiumhospitalet MC and the University of Oslo). The committee's verdict was that 13 out of 48 papers published in the period of 1993–2005 had to be retracted, including three of six articles in his Ph.D. dissertation. Consequently, in December 2006, Sudbø was

stripped of his Ph.D. and his professional license in medicine. He was, however, allowed to continue to work as a dentist. Sudbø's coauthors, on the other hand, were acquitted of the charge of having participated in the fabrication and falsification of data, but they were criticized for not having paid sufficient attention to the rules of coauthorship. The National Commission for the Investigation of Scientific Misconduct covers all research fields and deals with research carried out by Norwegian research institutions private or public. It can also investigate cases abroad, if the research has been carried out by researchers employed by a Norwegian institution or if a substantial part of the funding stems from Norway. The commission is composed of seven members and four substitutes who all are nominated for a period of 4 years (renewable not more than once). The members cover different fields of research. The commission is independent but the members are appointed by the Ministry of Education and Research following the proposition of the Norwegian Research Council. The commission is expected to give advice to individuals and/or research institutes and to be a kind of knowledge base for questions and experience concerning research misconduct in Norway and other countries. The commission is cooperating with similar organizations abroad (http://www.etikkom.no/en/In-English/Scientific-Misconduct/). *The National Committee for Research Ethics on Human Remains* was established in 2008 by the Norwegian Ministry of Education and Research. The Committee consists of ten members: two lay representatives and members with different professional backgrounds. The committee evaluates the ethical aspects of research where the source material consists of human remains which are in public museums and collections, or which will be found in future archeological and other surveys (i.e., complete skeletons, parts of skeletons, and other human remains). These are often human bones found in archeological excavations, but may also include human remains which have never been in the ground, for example, parts of bodies used in artifacts, bodies contained in coffins, and sarcophagi (http://www.etikkom.no/en/In-English/Human-Remains/).

Expert Bodies/Centers

University of Oslo

Center for Medical Ethics (CME). CME is a national, interdisciplinary unit for research, teaching, and information in medical ethics at the Institute of Health and Society, Faculty of Medicine, University of Oslo. It was established in 1989 as the first of its kind in Norway and was during its first 5 years organized as a research program outside the university structure. During this period, the Center was governed by its own Board of Directors, which included representatives from the University of Oslo, the Norwegian Nursing Association, the Norwegian Medical Association, the (then named) Medical Research Council, and one representative from the Pharmaceutical Industry. The composition of the Center's first Board reflects its initial funding. Since 1995, CME has been located within the organizational structure of the Faculty of Medicine and with basic funding from the

University of Oslo. In 1990, CME was granted a five-year research program in medical ethics from the Medical Research Council of Norway (approximately 16 million NOK for the period of 1990–1995). Since the merging of the different research councils in the 1990s, MRC has been a part of the Research Council of Norway (RCN) and forms at present a part of its Division of Society and Health. In the first years of recruiting Ph.D. and postdoctoral research fellows, priority was given to applications within three areas:

1. Questions related to the normative basis of medicine
2. Research ethics, including normative as well as historical studies
3. Health policy, planning, and resource allocation

Since 1995, priority has also been given to *clinical medical ethics*, a field of research that has been undergoing rapid growth at CME during the last years. At present, the Center has five permanent full-time academic positions and two adjunct chairs. The interdisciplinary nature of CME is reflected in the professional background of permanent academic staff, covering fields such as history of ideas, medicine, nursing science, philosophy, theology, and engineering. At present, CME has two postdoctoral researchers and eight Ph.D. fellows. Till date, 17 doctoral fellows have defended their Ph.D.s. Since 2002, CME has been responsible for the coordination of the system of clinical ethics committees (CEC) in Norway. An important part of CME's responsibility as a coordinator is to evaluate the activity of CECs and conduct research on different ethical challenges pertaining to CECs. The activity of CEC is of great value for the prosperity of CME, in particular, the input it gives to the education of medical students, doctors, and other healthcare personnel in Norway. CME receives an annual amount of 2.25 million NOK from the Ministry of Health and Care Services to coordinate the committees, conduct research, and facilitate competency building for committee members. In 2008, CME was also given a national role in the strengthening of medical ethics at all levels in Norwegian community health care. CME has been granted an annual amount of two million NOK for this capacity-building activity and is now in the process of building up a research group in this field as well. Since the inception of the first research project in 1990, the academic staff at CME has given priority to international research collaboration, something which throughout the years have resulted in partnership in 7 EU-funded research projects, coordination of 3 RCN-funded projects with international collaboration, and partnership in two other international research projects funded by the RCN. In addition, CME is coordinating a research and capacity-building project with partners at University of Dar es Salaam, Tanzania. Through the work of the clinical ethics unit at the Center, CME has developed international cooperation through a European network for clinical ethics (ECEN) and also cooperation with researchers in the USA. In addition, CME has research collaboration with colleagues in Argentina, Brazil, and Colombia. At the national level, CME has a long-lasting research collaboration with colleagues at the *Centre for the Study of the Sciences and the Humanities* at the University of Bergen and with colleagues at the *Programme of Applied Ethics* at the Norwegian University of Science and Technology in Trondheim (http://www.med.uio.no/helsam/english/).

The ethics program. In 1991, the Norwegian Humanities Research Council (now an integral part of the Research Council of Norway) started a ten-year ethics program. The principal aim of this program, led by Dagfinn Føllesdal, Clarence Irving Lewis professor of philosophy at Stanford University and professor of philosophy at the University of Oslo, was to support foundational ethics research and area-specific ethics research within all academic disciplines. The University of Oslo was offered to host the program, something which gave this institution a unique opportunity to boost its development of ethics research. At its inception, there were relatively few individuals in Norway with scholarly competence in ethics, and with the exception of medical ethics (which since 1990 had had its own research program, see CME, above) and the traditional shareholders of ethics research, that is, the faculties of theology and the departments of philosophy, there were few sustainable ethics research ambiences in Norway. The recruitment of candidates was based on three pillars. First, a strong formative background within one's own academic field (preferably at Ph.D. level). Second, one year of pre-qualification courses in ethics, taught by the foremost experts in the field (Sam Scheffler, Robert Nozick, Martha Nussbaum, Alan Gibbard, and many others). These courses should provide potential Ph.D. candidates with sufficient knowledge about ethical theories and methods to carry out foundational and/or disciplinary ethics research within own academic disciplines. And third, interdisciplinary research collaboration. Only candidates with proven ability during the qualification period in addressing ethical issues in a competent way (through the writing of mandatory essays) were then offered the possibility of opting for a 3 years Ph.D. research scholarship. For these reasons, "double competency" also became a defining hallmark of the program. About 40 participants received their Ph.D. in ethics through the program. In 2002, when the program came to the end of its ten-year period, the activities were continued along the same lines by ethics centers at the various Norwegian universities. The University of Oslo started its Ethics Programme as one of the University of Oslo's three prioritized research areas in the program period (2002–2011). Its overriding aim was to promote and support ethics research and normative reflection at the University of Oslo. The Ethics Programme continued the interdisciplinary research school and provided stimulation funds for ethics research and teaching at the University. In addition, the Program coordinated a series of national research courses through the Norwegian Ethics Network, ran the site www.etikk.no, and hosted the fortnightly Ethics Seminar at the University of Oslo and the annual Oslo Lecture in Moral Philosophy. Throughout its last 10 years of existence, 36 Ph.D. research fellows and 17 postdoctoral research fellows have been part of the Ethics Programme. When the University of Oslo in 2002 decided to continue the successful Ethics Programme of the Research Council of Norway, and notably with substantial funding from the Council to coordinate a national network for ethics research training, an interdisciplinary research group at the university suggested the establishment of a permanent Center for Ethics Research. Since then, similar proposals from other relevant stakeholders have been forwarded to the university leadership, but to no avail. And in spite of the fact that the University of Oslo throughout the period of

1990–2011 had become the "owner" of an ethics research ambience at the international forefront, the University Board in 2011 decided to close down its program. "Audacity" is definitely not the wording best covering this situation; "loss of a great opportunity," on the other hand, is an expression easily coming to mind.

Centre for the Study of Mind in Nature (CSMN). Another research ambience at the UiO carrying out research with fruitful and interesting implications for bioethics is CSMN, a Norwegian Center of Excellence, funded by the Norwegian Research Council and the University of Oslo for the period 2007–2017. The goal of the Center, as stated on its website: "is to understand the *characteristic features of human minds and their place in nature*. On the one hand, human beings are natural, biological beings, subject to laws of nature. On the other hand, they are capable of acting rationally, morally and of using language to communicate and think. In its attempt to understand the mind and its place in nature, CSMN is focusing on central mental capacities as expressed in (1) rational, (2) linguistic and (3) moral actions. Rational, linguistic and moral agency are all forms of *rule-governed activities*. Rules and norms differ from natural laws in that they can be violated, but nevertheless give rise to obligations. Human beings naturally care deeply about these prescriptive or *normative* features of human agency. But as science reveals more and more about our physical nature it becomes pressing to show how they can be squared with a view of human beings inspired by the natural sciences. Understanding human normativity is therefore crucial to understanding the human mind as a *natural phenomenon*" (http://www.csmn.uio.no/).

University of Bergen

The Centre for the Study of the Sciences and the Humanities (SVT) was established in 1987 as a permanent interfaculty institution at the University of Bergen, Norway. The field of study, *Theory of Science*, was defined as research in the fields of philosophy, history, and social sciences focusing on the roles these different sciences play in society; in addition, it was defined as research into the theoretical and ethical aspects and uses of such scientific research. Bioethics, both in its narrow and broad sense, has throughout the years been important fields of teaching, public engagement, and research at the Center. The bioethics practiced at SVT has been influenced by its particular theory of science approach, in which the normative and the epistemological tasks are not severed from each other but seen as influencing each other. Thus, while bioethics sometimes (rightly) has been criticized for taking epistemological and political assumptions merely as givens, the theory of science approach has, to an important degree, been critical. In recent years, SVT has played an active and critical role in the national and international ethics debates on biobanking, biotechnology, clinical care, climate change and environmental ethics, global health, GMOs, nanotechnology, reproduction technologies, scientific integrity, xenotransplantation and systems biology, and synthetic biology. At present, the Center is coordinating several international research projects funded by the Research Council of Norway and the European Commission: *Reflexive Systems Biology*: explores ethical and social issues of systems and synthetic biology; *Value Isobars*: when new technologies enter into the public cross fire, important societal

values are at stake. Do we know what we are talking about?; *Technolife*: public imaginaries and ethical concerns with emerging technologies; *SEAT*: Sustaining Ethical Aquaculture Trade. Buying seafood from Asian aqua farms – what do we know about the sustainability and the ethics?; *PEGASUS*: genetically modified animals will soon be used in the food and pharmaceutical industries. Will we accept this (http://www.uib.no/svt/en)?

Global Health: Ethics, Economics, and Culture. This research group is organized under the Department of Public Health and Primary Health Care at the Faculty of Medicine, University of Bergen. It is closely linked to Centre for International Health (CIH), but the studies taking place under this department are distinctly focused on the thematic areas ethics, economics, and culture. The professional staff consists of four professors (two employed by the Department of Public Health and Primary Health Care, and two employed by CIH) and two associate professors. In 2011, 19 Ph.D. students were registered, coming from Norway, but also from Tanzania, Zambia, Ethiopia, and Sudan, with bachelor degrees in medicine, ethics, economics, anthropology, political science, history, nursing, and sociology. The research activities are concentrated into two main areas: (1) justice and priority setting in health and (2) health systems and patients' experience. Some projects are focused on specific problems and countries and are performed in Tanzania, Sudan, Ethiopia, and Uganda, while others embrace general research areas, such as *Gender in poverty reduction*, *The right to health through litigation*, and *Setting equitable priorities in health and health care: from theory to practice*. The group has been involved in developing more than 30 guidance documents for how to prioritize among patients seeking specialized care for cardiovascular diseases. The group collaborates with WHO in providing guidance on how to set health priorities directed at decision-makers from low and middle income countries. They are further involved in collaborations with the aim to develop guidance documents on equity concerns relevant for setting health priorities. The group has also done important research and developed a guidance tool to be used during counseling of HIV-positive women with infants. These guidelines were developed for Tanzania, but have received attention also from the WHO in developing guidelines for HIV-positive women in general (source: Evaluation of biology, medicine and health research in Norway, RNC, 2011).

Norwegian University of Science and Technology (NTNU)

Bioethics research and teaching at NTNU takes place within several organizational units (the *Institute of Community Medicine*, the Faculty of Medicine; the *Programme of Applied Ethics*, Department of Philosophy; and the *Institute of Social Work and Health Sciences*). The main areas of research are assisted reproduction, biobanking, genetically modified organisms (GMOs), issues pertaining to death and dying, prenatal medicine, and nanotechnology. At the Institute of Community Medicine, the professional ethics staff consists of one professor, one adjunct associate professor, two postdoctoral research fellows, and one Ph.D. student. This group is in charge of the ethics teaching for medical students at the faculty, following an "integrated" model, in the sense that the ethics teaching is integrated with the topical teaching the

students receive and with the aim of covering the majority of "classical" bioethics topics. The professional staff at the Programme of Applied Ethics consists of three professors, one associate professor, and one postdoctoral research fellow, while Institute of Social Work and Health Science has one associate professor and one postdoctoral researcher involved in bioethics-related research and training. The Nordic Journal of Applied Ethics, an open-access journal dating from 2007, originates from the bioethics and applied ethics ambiences at NTNU.

University of Tromsø

At the Faculty of Health Sciences, bioethics makes part of the *Health Services Research Group* at the Institute of Community Medicine (with one full-time permanent position). The group's research interests and activities include epidemiology, mental health, health technology assessment, health economics, medical ethics broadly defined, medical sociology, primary care, and complementary and alternative medicine (CAM). Bioethics is an integrated part of several curricula, for example, medicine, dentistry, and public health.

Relevant Legislation

Of particular relevance for the subject field of bioethics are the *Act relating to the application of biotechnology in medicine* (1994) 2003, the *Act on clinical biobanking* (2003, 2008), the *Act on medical and health research* (2008), and the *Act on patient rights* (1999). Norway was one of the first countries in the world establishing all-encompassing laws covering the fields of biotechnology and biobanking. The original Act on Biotechnology pertaining to medicine contained a total ban on research on fertilized eggs and human embryos. The Act also had a prohibition on egg donation and preimplantation diagnosis (PGD) except for in situations where the woman is a carrier of a serious sex-linked hereditary disease. Likewise, the Act banned sex selection except for in cases of incurable sex-linked hereditary disease. To this adds a total ban on reproductive cloning, inserted in the Act shortly after the publication of the first successful example of reproductive cloning in mammals, that is, of Dolly the sheep. In 2004, however, the restrictive stance on preimplantation diagnosis was lifted so as to allow for PGD not only for X-linked diseases but also for serious, hereditary diseases with high probability of being transferred to a future child. Additionally, the law opened for PGD in combination with HLA-typing and IVF so as to safeguard that the future child is an HLA match with an already sick sibling. This child could then potentially become a stem cell donor for its sick sibling, either by umbilical cord stem cell donation by birth or by bone marrow transplantation at a later stage. In 2007 also, the total ban on human embryonic research was lifted, so as to permit research on spare embryos from IVF younger than 14 days. In December 2011, the Norwegian Biotechnology Advisory Board presented its assessment to the Ministry of Health and Care Services of a report of evaluation of the Biotechnology Act prepared by the Norwegian Directorate for Health and Social Affairs. A small majority of the Advisory Board suggests a lifting of a total ban on egg donation so as to permit donation of

eggs to an infertile women and also of donation of spare embryos for others in need of IVF. In connection with the implementation of the Act on medical and health research in 2009, the original Biobanks Act from 2003, covering also research biobanks, changed its name to the *Act on clinical biobanking*, and the section on collection, storage, processing, and destruction of human biological material and data for research purposes was repealed from the Act. The alleged intention behind transferring the regulatory issues pertaining to research on human biological material and health and personal data derived from such material to the Act on medical and health research was pragmatic; that is, to gather the majority of legal requirements pertaining to medical- and health-related research under the jurisdiction of *one* law. Retrospectively, it has, however, become clear that this transfer did not only represent a contextual shift of certain legal paragraphs related to biobank research; it also implied a dilution of the original requirements pertaining to such research. First, in the original section on consent in the Biobanks Act, it was stated that in case of changed, expanded, or new use of material from a donor, deviation from the basic requirement of explicit, informed consent can only be justified in situation where it is "very difficult or impossible" to seek new consent. On the other hand, in the Act on medical and health research the paragraph pertaining to new or changed use of collected human biological material or personal health data (§ 15), this expression has been reworded to "difficult." To this weakening of the original wording has been added: "This may only be applied if the research in question is of significant interest to society and the participants' welfare and integrity are ensured." Second, also with regard to the paragraph pertaining to withdrawal of consent, the original requirements have been watered down so as to allow deviation from the rule not only in situations where the material or data have been anonymized, the material has been processed and has become part of another biological product, or the data have been included in scientific publications, but also: "If particularly strong social or research considerations so warrant, the regional committee for medical and health research ethics may allow continued research on the material and defer destruction, deletion or surrender until the research project is concluded" (Act on medical and health research, § 16). In paragraph 5, *On responsible* conduct, of the Act on medical and health research, it is stated: "Research must be based on respect for the research participants' human rights and dignity. The participants' welfare and integrity shall have priority over scientific and social interests." At first glance, this may seem to be a phrasing in compliance with Article 3 on *Human dignity and human rights* in the Universal Declaration on bioethics and human rights. This is, however, not the case, as the Declaration's wording is "the interests and welfare of the individual. . ." and not the participants' welfare and *integrity*. What is evident here, is that the considerations about the individual in the Act of medical and health research has been reduced to encompass only two interests, that is, welfare and integrity. To this adds that also in relation to Article 27 of the Declaration, *Limitations on the application of the principles*, the Act on medical and health research permits deviations from the requirement of explicit informed consent and the right to withdraw from research that are clearly at odds with the limitations specified in this article: "If the application of the principles of this

Declaration is to be limited, it should be by law, including laws in the interests of public safety, for the investigation, detection and prosecution of criminal offences, for the protection of public health or for the protection of the rights and freedoms of others." In Article 27, there is no mentioning of "research of significant interest to society" as a possible legitimate justification for a deviation from the rule of the primacy of the individual and his/her welfare and interests. Finally, in a report from 2008 on Article 6 of the Universal Declaration on bioethics and human rights, issued by the International Committee on Bioethics (IBC), blank and open consent procedures are deemed inacceptable while the Norwegian Act on medical and health research contains a paragraph (§ 14) explicitly allowing for the use of broad consent procedures in research pertaining to the use of human biological material and personal health data. In 1999, the *Law on patient rights* was enacted, based on the principles of autonomy, beneficence, nonmaleficence, and justice and guaranteeing patients certain inviolable rights to health care. Although this Act evidently represents an important part of the current bioethical framework in Norway, it still contains reminiscences of paternalism as the medical doctors have the ultimate responsibility for making decisions on behalf of noncompetent persons and as advanced directives and decisions based on proxies have no legally binding status.

Public Debate Activities

Since their creation, the three national research ethics committees and in particular the Norwegian Biotechnology Advisory Board and the Norwegian Board of Technology have organized open meetings, public hearings and consultations, educational campaigns, workshops, and consensus conferences on new emerging and potentially controversial issues. Examples of topics that have been addressed are aging and new technology, biobanks, biofuel, bioterrorism and biological weapons, climate change, DNA vaccines and gene therapy pertaining to animals, DNA registries for whole populations, egg donation, fertility tourism, genetic resources and rights, genetically modified plants and food, genmodified plants and sustainable development, globalization, health research and privacy, nanotechnology, the Norwegian gene pool, preimplantation diagnosis, sperm donation to single women and lesbians, religion and biotechnology, research on human embryos, sustainable fish farming, stem cell research, synthetic biology, the carbon footprint of food, the use of internet and mobile phones among young people, early ultrasound screening of pregnant women, vaccines, and whole-genome sequencing.

Major Bioethics Issues and Discussions

In this section, two major issues pertaining to beginning of life and to access to health care will be dealt with in more detail, *preimplantation diagnosis* and *access to health care*.

Preimplantation diagnosis. In Norway, PGD became the subject of a hot political and public debate in 2003 in connection with the case of Mehmet Yildiz, a Norwegian-Turkish boy who suffers from beta-thalassemia major. The only existing curative treatment for this disease is stem cell transplantation (bone marrow transplantation) from a genetically related, tissue-compatible living donor. The success rate with such treatment is well beyond 90 %. In Mehmet's family, no compatible donor was found. The only alternative source for the stem cells Mehmet was in need of was umbilical cord blood (eventually in combination with bone marrow) from a newborn, tissue-matching sibling. The alternative of undergoing a succession of pregnancies in combination with prenatal diagnosis and selective abortion until a matching fetus was traced was never an option for the Muslim couple. On the other hand, PGD and discard of affected and/or tissue-incompatible fertilized eggs prior to implantation, the couple considered morally acceptable. Although Mehmet's parents wanted to have a new child that was unaffected by thalassemia, they wanted as well to be sure that the child was tissue compatible with Mehmet. Therefore, they started to pursue the possibility of having access to PGD of thalassemia in combination with HLA-typing and IVF. The lack of this kind of *explorative* treatment in Norway, combined with the strict legal situation, compelled the parents to privately seek access to such treatment abroad. In December 2003, they were offered treatment in Turkey. At that time, the case was still unknown to the news media in Norway as well as to Norwegian politicians and the public. Unfortunately, the treatment was unsuccessful, as the mother had an early miscarriage due to extrauterine pregnancy. On January 1, 2004, the newly revised Act on Biotechnology came into force and notably with a ban on PGD except for in situations of serious, X-linked disease with no possibilities of treatment. On February 28 and 29, the story of Mehmet's sickness was broken by one of the main TV channels in Norway. The core message broadcasted was that Mehmet would soon risk dying if he was not offered stem cell transplantation. Besides interviews with Mehmet's physician and a specialist on IVF who had helped the family to trace treatment contacts abroad, the leader of the Parliament's Social Affairs Committee, a prominent representative from the progressive party, was interviewed. His message was clear: "The law must be changed immediately so that Mehmet's life can be saved. Mercy should prevail over the law." A few days later the progressive party proposed a Bill to change the paragraph on PGD in the Act on Biotechnology to enable Mehmet and/or children with other forms of *serious* diseases (genetic as well as nongenetic diseases) in need of stem cell transplantation to have access to this kind of explorative treatment. In the following days and weeks, a stream of newspaper articles, interviews, and debates about the case involving politicians, health professionals, patient representatives, and ethicists were published and/or broadcasted. The Minister of Health strongly defended the strict regulation of PGD, and he deemed it to be irresponsible if the Parliament decided to change the law just a few months after the revision of the Act on Biotechnology had taken place. With explicit reference to an expert report on thalassemia, PGD, HLA-typing, and IVF delivered by the Directorate of Health and Social Affairs just 2 weeks after the story of Mehmet had been broken, the

Minister of Health characterized the treatment Mehmet's family was requesting as *experimental research* and stated that the boy received the best *established* treatment currently available. The socialist leftist party that had sided with the parties forming the government coalition in the course of the parliamentary debate on the revised Bill on Biotechnology came under heavy pressure to change their newly adopted stance on PGD. Approximately 1 week after the Directorate of Health and Social Affairs had delivered their report, the party gave a press conference to inform that they had changed their mind on PGD as well as on PGD and HLA-typing in combination with IVF. The core element in the party's new stance was that the current ban on PGD except in situations of serious X-linked diseases without treatment possibilities should not be formally lifted. Instead, the paragraph in the Act on Biotechnology dealing with PGD should be supplemented with new subsections to make possible an *exemption* from the ban if and when "particular considerations" speak in favor of a case. By "particular considerations" were meant the presence – or the risk – of *serious, genetic disease without treatment possibilities*. An *independent* medical ethics committee enforced to grant exemption from the main rule on PGD should be set up and given the charge to evaluate individual applications. On May 11, 2004, the progressive party's Bill as well as the Bill proposed by the socialist leftist party were debated in the Parliament. After 3 hours of fierce and heated debate, the first Bill was thrown out while the second Bill won a majority vote against the three parties forming the government coalition in 2004. The mandate of the already existing Norwegian Governmental Appeal Board regarding medical treatment abroad was broadened to include also the responsibility for assessing applications of PGD to be carried out abroad. In 2008, the PGD part of the Appeal Board's responsibility was transferred to a separate Preimplantation Diagnosis Board. A study from 2010 evaluating the experiences with PGD in Norway so far revealed that the lack of a systematic report and evaluation system for PGD couples in Norway creates problems at several levels: It precludes the Preimplantation Diagnosis Board to know hardly anything about the outcome of the applications it is approving, a knowledge evidently of relevance for the Board in its assessment of future applications. Besides, it greatly hampers the possibility of evaluating the experiences with the current practice, something which is not in compliance with the Norwegian Parliament's stance on PGD. Furthermore, the lack of a systematic report and evaluation system implies that healthcare professionals in Norway in charge of advising couples in need of PGD lack vital information for undertaking such a service in a sustainable way. Finally, the lack of such a system makes it very difficult to undertake reliable cost-benefit analyses of this practice.

Healthcare system, access to health care. Norway was the first country worldwide that put priority in health care at the political agenda through the appointment in 1985 of an interdisciplinary working party with the mandate to look into the processes underlying [actual] prioritizations as well as assess and suggest different criteria and guidelines on which [future] prioritizations should be based. The working party was chaired by Professor Inge Lønning. The model of prioritization presented to the government in 1987 differentiates between five priority levels of healthcare services:

- *First* priority: emergency services of vital importance to individual patients, patient groups, or the society as a whole
- *Second priority*: *necessary* services, that is, services that if not offered will have disastrous or very serious long-term consequences for individual patients, patient groups, or the society as a whole
- *Third priority*: services with documented effect but with less negative consequences if not offered than services under first and second priority
- *Fourth priority*: requested services with perceived positive consequences for health and life quality but with less negative consequences if not offered than services belonging to higher priority levels
- *Zero priority*: requested services which are not necessary and without clearly documented utility

The two main criteria for prioritization underlying this model were *seriousness* and *cost*-effectiveness. In addition, *age* and *unhealthy lifestyle* was explicitly rejected as acceptable criteria for prioritization (but the latter with some minor qualifications). In addition, *unhealthy lifestyle* was explicitly rejected as an acceptable criterion for prioritization. Although the model suggested was unanimously adopted by the Norwegian Parliament, its impact on actual prioritizations was spare. For example, although highlighted in the report as areas in urgent need of more resources, that is, psychiatry, (re)habilitation, and care services, in the decade following the publication of the report, the distance between healthcare needs and factual capacity increased within these areas. The report came, however, to play an important *pedagogical* role, in the sense that it triggered a broad public debate pertaining to healthcare priorities. In 1995, a new working party was set up by the government, again chaired by Mr. Inge Lønning, with the mandate to propose a model for prioritization easier to implement in the Norwegian healthcare system. While the original model from 1987 was a *top-down* oriented model focusing on administrative and policy decisions at the macrolevel, the orientation in the new report was bottom-up, in the sense that it included a suggestion to establish representative groups of healthcare professionals with the mandate to classify and range services in terms of priorities within the context of the new model of prioritization proposed in the report and within their own areas of responsibility. Three criteria of prioritization were proposed – *seriousness*, *utility*, and *cost-effectiveness* – but with main emphasis on the two last criteria. Instead of differentiating between five different levels of prioritization, the new report suggested a distinction between four *priority groups* and with a substantiation of these four groups according to (medical) *conditions* and required *services*:

I. *Shall*-services, that is, basic healthcare services
II. *Ought*-services, that is, supplementary healthcare services
III. *Can*-services, that is, healthcare services with low priority
IV. Services outside the publicly funded healthcare system

In addition, the establishment of an *independent* and *interdisciplinary* National Council on Priority Setting was suggested. On the website of the Council, at present named the *Norwegian Council for Quality Improvement and Priority Setting in Health Care*, it is stated:

Assessments of patient benefit, cost-effectiveness and total costs will provide an important foundation for the Council's evaluations. The Council will handle complex and demanding issues, and their assessments will be based upon the best available evidence. In addition, dilemmas and elements of uncertainty also have to be highlighted for every each case. The Council's members will independently take initiatives they believe are necessary vis-à-vis follow-up, based on their positions of responsibility across the health services (http://www.kvalitetog-prioritering.no/R%C3%A5det/About+us).

While in its first years of existence the Council may be said to have been organized and functioning as an independent and interdisciplinary body with the mandate to advice health authorities and health policymakers with regard to priority setting, this can no longer be said to be the case, as today most members of the Council themselves hold top administrative positions within the Norwegian healthcare system. In addition, the Council is chaired and cochaired by the directors of, respectively, the Norwegian Directorate for Health and Social Affairs and of the Norwegian Institute of Public Health, that is, the two principal public institutions mandated to implement Norwegian health policy. The main argument for this "recompositioning" of the Council was to increase its impact on healthcare prioritizations. This may well have come at a loss of procedural independency and transparency.

Future Challenges

The abundant growth of national bodies dealing with the ethics of scientific research and development during the last 20 years makes it reasonable to ask whether Norway – in terms of research and technological development – has reached a level of *ethicization* that may not only generate better research conduct and transparency but also lead to adverse effects of a kind that may hamper a genuine promotion of ethical reflection and bioethical discourse. Several such effects can be identified: First, the existence of eight different bodies at the national level involved in assessing the ethical dimensions of scientific research and development may generate a perception among politicians and the public that scientific research is such a potentially dangerous and dubious enterprise that it needs to be constantly controlled and monitored. Second, the existence of eight such bodies at the national level may generate a normative landscape that is perceived as almost impenetrable by researchers and the public. Third, it may generate conflicts and power struggle between the different ethics bodies with regard to division of labor and division of responsibilities. This is already evident in the field of biobank research and genomic research. For these reasons, it may be due time for relevant ministerial authorities in Norway, in consultation with representatives from the ethics boards and committees themselves and the community of researchers, to discuss ways of making the Norwegian ethics bureaucracy a simpler and more transparent one, so that it does not lose its credibility but continues to promote ethical reflection and bioethical discourse within academia as well as in the society at large.

A second challenge relates to taking the necessary steps to secure that present and future regulations and legislations pertaining to bioethics are revised and shaped in compliance with international human rights law and commitments.

Summary Conclusion

Audacity and lost opportunities. The Norwegian history of bioethics is a narrative located in the interphase between these two opposing conceptions. In addition, it is a narrative about the formative role of physicians in establishing bioethics as an academic field as well as an account of how bioethics slowly grew into an interdisciplinary field attracting individuals from other branches of academia. The paramount role played by the institutionalization of research ethics in the country needs also to be acknowledged, both its role in turning bioethics into a sustainable academic field and a field of public discourse, but also its role in moving recent bio- and life sciences regulations and legislations in a direction not in compliance with international human rights law and commitments.

Oceania

77

Darryl Macer

Introduction

The Pacific encompasses thousands of islands and communities across the Pacific Ocean. The most populated countries are Australia, New Zealand (called Aotearoa by the Maori indigenous population), and Papua New Guinea. Although there are also a number of large island nations in the West Pacific such as the Philippines and Japan, these are commonly considered part of Asia, though some of the indigenous communities of Asia share much in common with those of the Pacific. While some of the inhabitants of those communities also identify themselves as Pacific people, this chapter's scope will focus on Oceania. Because other chapters in the compendium review bioethics in Australia and New Zealand, this chapter will focus on the other countries of the Pacific.

H.A.M.J. ten Have, B. Gordijn (eds.), *Handbook of Global Bioethics*,
DOI 10.1007/978-94-007-2512-6_86,

The term "Pacific peoples" is an umbrella term, as is "Pacific ethics," that in no way should diminish the richness of variety of Pacific Island nations and communities who are linguistically, culturally, and geographically distinctive from each other, while at the same time sharing some common situations and approaches to bioethics. Further scholarship is required to fully describe the diversity of approaches to bioethics in each community, but this review includes some general trends and a few specific examples, from regions of Melanesia, Micronesia, and Polynesia.

There are 22 Pacific Island countries and territories with great diversity in terms of their geography, populations, cultures, economies, and politics. Based on their ethnic, linguistic, and cultural differences, these countries and territories can be categorized under three Pacific subregions:

Melanesia

Papua New Guinea (PNG), Fiji, Solomon Islands, Vanuatu, and New Caledonia (territory of France)

Polynesia

Samoa, Tonga, Cook Islands, Tuvalu, Niue, Tokelau, *American Samoa* (territory of the USA), *Wallis and Futuna* (territory of France), *French Polynesia* (territory of France), and *Pitcairn* (territory of the UK)

Micronesia

Federated States of Micronesia, Kiribati, Marshall Islands, Palau, Nauru, *Guam* (territory of the USA), and *Northern Marianas Islands* (*territory (Commonwealth) of the USA*)

The 15 independent countries cover an ocean area of nearly 5 million square kilometers, have over 1,500 separate languages, and vary in population from just over 1,000 persons to over 6 million. They are all undergoing an epidemiologic transition in health terms from mainly infectious diseases to mainly noncommunicable diseases (NCDs). All face demographic transitions with gradually aging populations despite the presence of many young persons because of high reproductive rates and significant emigration of young persons to Australia, New Zealand, the USA, and other countries. Because they are small populations, they are particularly vulnerable to outward migration, and transitions in values are rapid with introduction of global media and communications.

The grouping together of peoples who have richly diverse sets of languages, customs, cultures, and homelands involves many tensions. Some of the peoples are grouped as nations, but in some modern nations, there are hundreds of communities and language groups (e.g., Vanuatu) or thousands (e.g., Papua New Guinea). Political power has also promoted the use of the term Pacific, to quote Tongan writer Epeli Hau'ofa, "We are the ocean, we must wake up to this ancient truth and together use it to overturn all hegemonic views that aim ultimately to confine us physically and psychologically in tiny spaces which we have resisted and from which we recently liberated ourselves" (Hau'ofa cited by Thaman, 2002, p. 8).

Bioethics Development

When and How Has Bioethics Started?

Bioethics is both a word and a concept. Bioethics in the Pacific is identified closely with a broad concept of love binding all of life together, and the terms and values used to translate English words of bioethical principles in Pacific languages have deep historical roots. Although there were a wide variety of concepts prior to European colonization of the Pacific, the modern Pacific is predominantly Christian in faith, with a blend of indigenous culture and a theocentric approach to life ethics. Thus, although the actual word "bioethics" comes to us only from a German paper of 1927 (Jahr, 1927), amplified by Potter (1970) in English, the concept comes from human heritage thousands of years old (Macer, 1994), and there has been rejection of attempts to introduce the term "bioethics" when it is associated with universal ethical principles.

The concept of love as a binding force resonates well with the modern Christian approaches of Pacific culture. This includes more than humans, however, with strong love of animals which live in the land and water and a love of nature. In Maori the word *aroha* is used to denote something broader than love but including a oneness with nature and animals. Bioethics has origins in exploring human relationships with animals and with nature (ocean and land) and spirituality.

Love continues to be taught to children from a young age as a noble ethical character. In Tonga, *ofa*, which means all forms of love, and *fe'ofo'ofani*, caring love as a family, are some of the basic values taught to children from a young age which influence their behavior. These concepts are expressed in the way that Pacific Islanders care for the sick, often with practical expressions that family members will accompany the sick person to the hospital and a relative will always stay with the person day and night in the hospital (Mafi, 1998).

Stories explaining the deeds of past generations and the symbolic nature of the landscape can be found in songs, laws, history instruction, and social systems (Fairbairn-Dunlop, 2009). It is not possible to trace the origin of bioethics back to their beginning, as the relationships between human beings within their society, within the biological community, and with nature and God are formed at an earlier stage than history provides (Macer, 1998). Love is recognized as both the biological heritage given to humankind by genes and a social heritage, as the society tries to pursue harmony between individuals and communities.

Because Pacific values and beliefs are transmitted orally, many have incorrectly assumed that bioethics were effectively nonexistent before the expansion of modern bioethics in the 1990s (Macer, 1998). Ethics has a central place in the Pacific's indigenous knowledge systems and processes. "Each daily life event is seen through a lens of ethical values, mores, and codes of conduct developed over years. Indigenous ethical systems incorporate technical insights and wisdom-based observations of natural, social, and spiritual phenomena which, in turn, validate place and identity, as well as the survival of Pacific nations in our increasingly globalized societies" (Fairbairn-Dunlop, 2009).

Ethical values and principles have developed in the context of epistemological systems and are central to how knowledge is gained and organized, how knowledge is used, and who has access to it. In the development of ethical principles for medical research, the Pacific Health Research Council in New Zealand wrote:

> Every Pacific society has a framework of knowledge that is systematically gathered and formulated within a paradigm of general truths and principles. Knowledge gathering and systems of validating knowledge and legitimizing information are processes that are often determined and regulated (but not exclusively) by a select group within the traditional hierarchy of knowledge with the aim of protecting the quality and wellbeing of people (Health Research Council [HRC], 2004, p. 10).

Tui Atua Tupua Tamasese Ta'isi Efi (2009) described the importance of the Samoan concepts of *tapu* (the sacred) and *tofa sa'ili* (the search for wisdom) in identifying ethical practices for application in research. He argued that it is possible to find a middle ground between ideas and practices grounded in religion, the spiritual, the sacred, and science. Against the background of an exploration of different facets of the Samoan concept of *tapu*, which encompasses the sacredness of the origins of all things as well as the affinity between people, the cosmos, and animate and inanimate earthly phenomena, he envisages a Pacific bioethics that reaches out for wisdom. Such activity and the search for knowledge would be grounded in a sense of connectedness to all things, the awareness of people's responsibilities as protectors of the earth, attention to the sacred essence of all things, and a desire for increased understanding without ever presuming to know God.

Who Have Been the Major Actors/Forces?

Colonization has been a major force to articulate bioethical value systems that were previously implicit in the relationships of people and nature. Along with colonization came waves of Christian missionaries, and the Christian faith was readily adopted in a "Pacific" form. Anthropologists also described a number of traditions, although some "sacred" knowledge is preserved among chiefs and only informed to those they decide to entrust such wisdom to. As more persons left the shores of the islands to study, they started to document more of these traditions, and in turn, these values in a more articulated form were discussed among many of the communities.

There has been funded medical research throughout much of the twentieth century. From New Zealand, the first research was funded in 1946 (Rankin, 1997). Pacific people are shifting from historically being the subjects of research to becoming active agents of research, but still some are concerned that they are over-researched. "Although there have been positive outcomes, there have also been instances where research has resulted in Pacific peoples being presented inaccurately, or in a negative light. There is also a history where the benefits of research have not been shared with the research subject population" (HRC, 2004).

Researchers have also played important roles in recent decades as they attempted to articulate Pacific values into Western social science models. Theoretical frameworks include the "Metaphor of Kakala" (Helu-Thaman, Tonga),

the "Faafaletui Model" (Tamasese, Peteru, and Waldegrave, Samoa), and the "Tivaevae" (Maua-Hodges, Cook Islands). These are frameworks that are based on Pacific values and necessitate the use of research methods that are most appropriate for Pacific peoples. The recognition of the need to govern research in the Pacific in a way consistent with historical Pacific values was behind the development of the "Guidelines for Pacific Health Research in New Zealand" (HRC, 2004). Those guidelines describe 11 principles that can be found to some degree in a number of international texts but are well accepted because of the consultation process associated with the document. They are centered on relationships as the overarching principle that binds each of the following ethical research principles: Respect, Cultural Competency, Meaningful Engagement, Reciprocity, Utility, Rights, Balance, and Protection. These have been identified as the guiding principles for conducting ethical relationships for research. These values are a summary of many of the values found around the Pacific, and further examples of values will be discussed when reviewing specific cases.

To develop, cultivate, and maintain principled relationships between persons and communities is integral to all ethical practice in the Pacific, more than individual rights. Each person is a member of the whole, and the whole includes the parts. Therefore, the bioethic is centered on building and maintaining ethical relationships. For example, the term *Va Fealoaloa'i* refers to the various spaces and places within which Samoan people interact in a meaningful and non-coincidental way and makes people sacred.

The research should enhance relationships, and an action may be deemed unethical if it harms relationships not only between people but also with nature. The relationship between the researcher and the research participant is based on respect for the inherent value of each human being and on each being, whether they be a dog or a tree. Rather than promoting a universalistic worldview, to practice in a culturally competent manner, the researcher must have an awareness of their own cultural beliefs, values, and practices and an understanding of how these impact upon their interaction with others. The beliefs, knowledge, and experience of the research participant are true to themselves, and the researcher must respect this even if it is different from their own beliefs, knowledge, and experience. Researchers are encouraged to build their cultural knowledge of the Pacific communities they work with. Researchers are encouraged to create safe and enabling research environments that support culturally competent practice, to seek ethnic-specific and context-specific advice on culturally competent practice, and to understand the importance of communicating appropriately translated information to Pacific people.

What Have Been the Major Concerns Over Time?

One of the principle concerns that people have had is the lack of engagement and miscommunication. As the HRC (2004) document states, "4.1 To conduct ethical research with Pacific peoples there must be meaningful engagement."

Effective "face-to-face" consultation is critical to establishing meaningful relationships with people in most societies, and this may take longer time in many Pacific communities.

Because relationships between patient and health-care professional are very important, reciprocity should be a guiding principle for research relationships. This has often been neglected in the Pacific Islands where there are significant social hierarchies.

Each individual, group, or community has the right and freedom to make an informed choice as to whether to participate or not, in any research. However, there have been abuses of people who have not been informed about the medical procedures. In the case of research, any risks inherent in a particular type of research must be made clear to the research participant, and they must feel completely free as to their decision to participate or not (HRC, 2004). There are a number of structural societal inequalities in most countries, so care must always be taken to protect those less powerful.

Reciprocity in research also requires that knowledge gained through research will be used to benefit research participants and (where relevant) other people. If knowledge acquired from research generates significant financial returns, then the people from where the original knowledge should share in the financial rewards generated by the research. However, there have been disputes about patenting of traditional medical compounds, and products of other wisdom, that was not compensated to the communities they came from. Any research partnerships formed with Pacific peoples should be equitable and fair for both parties, engendering symmetry in the balance of power.

One of the significant events was the controversies associated with intellectual property rights (IPR) and the attempts to patent DNA in the 1990s and research to explore human genetics associated with particular diseases. These concerns led to particular statements such as the Mataatua Declaration (1993) as well as responses from UNESCO (Chee et al., 1995). The Mataatua Declaration on Cultural and Intellectual Property Rights of Indigenous Peoples of June 1993 includes several recommendations to member states of the United Nations. Recommendation 2.7 states that "commercialisation of any traditional plants and medicines of Indigenous Peoples must be managed by the indigenous peoples who have inherited such knowledge," while Recommendation 2.8 demands that "a moratorium on any further commercialisation of indigenous medicinal plants and human genetic materials must be declared until indigenous communities have developed appropriate protection mechanisms."

The declaration also indicates the concern for increasing capacity for research in the Pacific, with the promotion of a "co-operative rather than competitive framework," and an "increase in the involvement of indigenous communities" in "research and training as well as education" that would make them participants in the process of development of industrial goods from human genome research and beneficiaries of possible commercial profits rather than being simply suppliers of samples that may eventually lead to significant therapeutic discoveries.

There are differences in the views towards use of genetically modified organisms (GMOs) between the South Pacific which tends to be negative and the Northern

Pacific which has a more positive attitude in line with the US agricultural policy that finds some genetically modified papaya and other crops being grown. Another significant activity in environmental ethics was the eventual abolition of nuclear weapons testing in the Pacific Islands, though there are still a number of islands off limits because of residual radioactive contamination.

Overall considering the directions of cross-cultural bioethics across the globe and the unanimous agreement with the Universal Declaration on Bioethics and Human Rights (UDBHR, UNESCO, 2005) by nation states, there is support for the approach linking the Pacific values of love of life with international ethical principles. However, Pacific communities insist that there are many forms of wisdom, each found in different countries and communities. The Western construction of knowledge has been questioned in a postcolonial Pacific, as many communities of persons start to think more widely and rediscover their indigenous roots and traditions. This led to some questioning of the Universal Declaration on Bioethics and Human Rights.

The UNESCO Ethics of Knowledge Production Conference in Dunedin in February 2006 considered a number of issues in ethics in the Pacific including that document, and the outcomes formed the basis of a further conference, Pacific Regional Ethics of Knowledge Production Workshop, held at the Tofamamao Centre, Apia, Samoa, on 13–15 November 2007. Understanding ourselves and others and understanding place and position all contribute towards fuller understandings of Pacific ethics, knowledge, and values. UNESCO also held national workshops in Apia, Samoa, and Suva, Fiji, in September 2006 to explore the concerns on so-called universal ethics. References to Christian values were made by Pacific speakers and workshop participants, noting that the UDBHR seems to have no spiritual grounding, as they would have liked a more Christian basis. This may appear ironic, since the spread of Christianity in the Pacific was associated with colonization; however, it reflects the strong theocentric mentality of understanding life ethics in modern Pacific culture.

Ethics systems and processes are central to every aspect of the life of Pacific indigenous communities. Although not well documented, and long disregarded in the privileging of Western ideas about ethical practice, Pacific ethics processes integrate epistemological, pedagogical, and methodological considerations. For Pacific people, each daily life event is seen through a lens of ethical values, mores, and codes of conduct that have developed over many years, while remaining responsive to changing times (Du Plessis & Fairbairn-Dunlop, 2009).

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

There are a few papers on Pacific ethics, emerging from the conferences described above, and networks in Asia-Pacific region include the UNESCO Asia-Pacific School of Ethics and the Asian Bioethics Association. Some are referenced in the chapter here, but there are still relatively few compared to the diversity of values that exist (Du Plessis & Fairbairn-Dunlop, 2009). The Asia-Pacific Science,

Technology and Society Network has held several conferences on indigenous bioethics issues, and the papers have been published (Hutchings, 2012; Yamaguchi, Cronin, & Macer, 2012).

What Have Been the Steps/Measures Taken (Policies, Legislation, Infrastructures, Teaching Programs, Committees, etc.)?

The conclusion of the 2007 UNESCO **Pacific Regional Ethics of Knowledge Production Workshop** was summarized in the **Tofamamao Statement**, which reads,

That we Pacific peoples, local and global, genealogically, spiritually and culturally connected to the lands, the skies and seas of the Pacific region:

i. Undertake to lead, support and promote the development of Pacific indigenous ethical guidelines and protocols governing contemporary Pacific research implementation; with the respective aim of protecting, upholding and vitalising Pacific indigenous knowledge;
ii. That such ethical guidelines and protocols take into consideration our unique ancestral legacies governing traditional inquiry processes; and reflect a common epistemic heritage which upholds the mana of all things, sentient and insentient, and is cognisant of tapu and sacred relations between and among all things;
iii. That we undertake these responsibilities through our institutional, cultural, religious, global, regional, national, provincial, local, governmental and non-governmental organizations, groups, agencies/agents, families and communities; for Pacific generations, past, present and future.
iv. That the Tofamamao working Party and other interested persons and parties, including UNESCO, should work collaboratively to advance focused activities in this area.

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

There are few courses related to bioethics in universities in the Pacific, except for the well-developed programs in Australia and New Zealand universities. Among these, the Otago Bioethics Centre, University of Otago Medical School, has had significant numbers of students looking at Pacific ethics, though the focus has been more on Maori values.

Bioethics Committees

There is a national bioethics committee in Fiji linked to Fiji School of Medicine. Pryor, Morse, Prasad, Koloi, and Kennedy (2007) found that

PNG, Fiji, Solomon Islands, Vanuatu, Samoa, Tonga, and Palau all have a functional structure and processes in place for the technical and ethical review of health research proposals. The other countries undertake an ad hoc process as needed, although they did not find a process or structure for this in Niue and Nauru. There is variability in the degree to which the existing ethical review structures utilize standard operating procedures and forms to help guide the review process. Some of these processes for ethical review were through National Research Committees, such as the Cook Islands. The research committees consider ethical issues in addition to scientific aspects, and with small populations, the case could be made for inclusion of ethical review duties in the total review of the application, rather than by a separate committee.

The Vanuatu National Cultural Council is responsible for research (see Chap. 186, 6(2) of the Laws of the Republic of Vanuatu). The Vanuatu Cultural Centre is the executing arm of the National Cultural Council and responsible for implementing the policy. The guidelines identify priority research topics, charge fees for applications for research, consider traditional copyright, and request Vanuatu participation in research and training.

Expert Bodies/Centers

There are no bioethics centers in Oceania, except for those in Australia and New Zealand. In Oceania, the University of the South Pacific (head office, Nandi, Fiji) is the main research university in the Pacific, and some researchers have explored bioethical topics. Because the academics are spread out over many small campuses in different islands, they often take the role of generalists and may also play important roles in community decision making. Informal decision making by elders and those considered "wise" plays a role that at times substitutes for formal ethics committees.

Relevant Legislation

While Pacific research continues to emphasize the endurance of customary ways, there is also a growing recognition of the role of universal rights and principles. For example, the recent public monarchy confrontations in Tonga (2005) began on a platform of poverty-related grievances, but they moved quite quickly to impassioned appeals for rights and democratic principles. Sovereignty issues are also gaining prominence in Pacific Small Island Developing States (SIDS) – including the emergence of more critical appraisal of the relevance of global conventions to the Pacific and the "right" of external agencies to set those agendas.

Case law in most countries upholds the principle of informed consent.

Fiji in its 1997 modification to its Constitution applied a number of ethical principles of the 2005 UDBHR for medical research, for example, some excerpts:

> Chapter 4, Section 22, Life: "Every person has the right to life. A person must not be arbitrarily deprived of life."
>
> Section 23, Personal liberty: (1) A person must not be deprived of personal liberty except: . . . (g) for the purpose of preventing the spread of an infectious or contagious disease; (h) for the purpose of the person's care or treatment or for the protection of the community if he or she is, or is reasonably suspected to be, of unsound mind, addicted to drugs or alcohol or a vagrant; or . . .
>
> Section 25, Freedom from cruel or degrading treatment: (1) Every person has the right to freedom from torture of any kind, whether physical, mental or emotional, and from cruel, inhumane, degrading or disproportionately severe treatment or punishment. (2) Every person has the right to freedom from scientific or medical treatment or procedures without his or her informed consent or, if he or she is incapable of giving informed consent, without the informed consent of a lawful guardian.
>
> Section 37, Privacy: (1) Every person has the right to personal privacy, including the right to privacy of personal communications.
>
> Section 42, Human Rights Commission: (1) This section establishes a Human Rights Commission.
>
> Section 38, Equality: (1) Every person has the right to equality before the law. (2) A person must not be unfairly discriminated against, directly or indirectly, on the ground of his or her: (a) actual or supposed personal characteristics or circumstances, including race, ethnic origin, colour, place of origin, gender, sexual orientation, birth, primary language, economic status, age or disability; or (b) opinions or beliefs, except to the extent that those opinions or beliefs involve harm to others or the diminution of the rights or freedoms of others; or on any other ground prohibited by this Constitution. (3) Accordingly, neither a law nor an administrative action taken under a law may directly or indirectly impose a disability or restriction on any person on a prohibited ground. (4) Every person has the right of access, without discrimination on a prohibited ground, to shops, hotels, lodging-houses, public restaurants, places of public entertainment, public transport services, taxis and public places. . . .

Public Debate Activities

There have been public debates over the use of genes from living organisms found in the Pacific for development, especially when attempts to patent these genes have been made (Mead & Ratuva, 2007; Ratuva, 2009). One of the famous cases is the Hagahai patent from a PNG tribe. In March 1995, the United States government issued a patent on a human cell line from an indigenous Hagahai man from the rain forests of Papua New Guinea. The US National Institutes of Health (NIH) were issued patent No. 5,397,696 by the Patent and Trademark Office (PTO), the first time that an indigenous person's cells have been patented, and there was much debate until its eventual reversal (Robie, 1997).

Other

A substantial proportion of Pacific persons live in Australia and New Zealand (Dunsford et al., 2011). Some of the traditional ethics influence the actual bioethics that governs the interactions of citizens and health professionals in those countries, and readers should refer to the chapters on those countries.

Major Bioethics Issues and Discussions

Beginning of Life

Most Pacific countries have Christian faith. However, abortion is available with various criteria considering the health of the mother and fetus. Let us explore in detail a Samoan analysis of Tui Atua Tupua Tamasese Efi (2009). The Samoan term *faatosaga* literally means "planting and growing the seed," which advocates a particular model for encouraging successful fertilization where the techniques of *fofo* (massage) and a strict regimen of physical health and diet are prescribed. According to the traditional midwives, *faatosaga*, the main objective of the massage is to place the fallopian tubes in the best possible position to the ovaries. This is to help ensure the ease of passage for male sperm. The main objective of healthy eating and exercise is to ensure that the body and mind of the potential mother are in synchrony. Harmony of the mind and body allows for easier (and more enjoyable) sexual activity, which is considered a necessary precursor to successful conception.

From the moment the egg is fertilized and the mother experiences the symptoms of conception, a human life is said to exist. Here, the fetus is recognized as a person. As a person, the fetus gains a sacred essence. It becomes tapu. When the fetus is deliberately terminated by abortion, a breach of tapu has occurred. Pardon must be sought for this breach. Throughout the process from conception to birth, the main job of the faatosaga is to steer the mother using massage and good advice towards a successful birth. The regimen of massage and counseling is holistic. The relationship between the mother and the unborn child is sacred. In ancient Samoa, once conception was established, there was a ritual celebration. This was known as afuafua (literally, meaning beginning). The prayers, chants, and rituals of the afuafua are today replaced by Christian prayers and special food, in the few families which still practice it.

End of Life

Traditional medicinal remedies are still widely used, and some of these offer pain-killing properties. Although active euthanasia is rejected, there is a recognition of the limits of Western medicine as well as limited intensive care facilities in most islands. Rather than sending elderly relatives to distant hospitals on other islands for intensive therapy, palliative care among family may be preferred.

Health and Disease

Diabetes is a major health issue with Western diets, leading to significant obesity, with its associated morbidity and mortality. Tropical diseases are a significant issue in some islands, such as Papua New Guinea. Some parts of the disease require storage of samples in a refrigerator.

Health-Care System: Access to Health Care

Pryor et al. (2007) studied the health-care systems in 15 Pacific countries and described wide diversity in the governance and management of the health-care systems. Palau was an exception, having the highest per capita GDP and highest Human Development Index, with substantive overseas health research partnerships, associated with its close association to the USA. The Melanesian and larger Polynesian countries generally have a more developed national health research and health-care structure and management processes than the smaller Polynesian and Micronesian countries.

The fundamental belief is that family communal systems ensure the spiritual, economic, and social security of family members, and they set the standards for all behavior. This knowledge has been passed on by word of mouth, from generation to generation (Fairbairn-Dunlop, 2009).

Traditional Medicine

Traditional practices and holistic approaches to health are common. For example, see the Samoan example of birth, described above. Traditional medical knowledge is extensive, and medical wisdom is one of the sacred knowledges associated with traditional healers.

Genetics

Access to genetic testing services follows the general trends for the health-care systems, which can be difficult on dispersed small islands. There will be significant improvements in access as genetic testing kits become cheaper and require less technical support.

There was some debate over a possible tendency for increased violent tendencies in those children exposed to childhood abuse who were born with higher monoamine oxidase A (MAOA) levels, in what was commonly termed a "warrior gene." Gillett and Tamatea (2012) urged persons to focus on the main causative elements of family cycles of abuse, rather than complex genetic possibilities.

Reproductive Medicine

Life is to be promoted, and having birth using assisted reproductive technologies can be supported, with the right attitudes. Extended family systems have also allowed adoptions of children into nuclear families that do not have a child.

The use of a dead fetus for research is a breach of *tapu*. To tamper with the body of a dead fetus is to show disrespect for the sacred. The dead body returns to its Creator after death without having been tampered with. It is to return by the very route of its birth back to the earth. This principle of respecting the origins of human genealogical links with the earth is implicit in ancient Samoan practices of ritually burying the placenta and umbilical cords in the earth. Regarding the tapu on burying the placenta and umbilical cord, the cultural claim to any land or earthly inheritance is premised on a genealogical connection with the earth. The sacred aspects of rituals are commemorated in a belief held among most faatosaga that omitting to bury the placenta and cord in the earth can materially affect people. The faatosaga suggests that a dead body, born or unborn, belongs at death to none other than God, the Creator Progenitor, and so should be returned to Him without being tampered with. This, too, has significant implications on research using cadavers.

Medical Research

Pryor et al. (2007) found in a survey that few countries had a clearly articulated policy on health research. Among 15 countries, only 4 have invested in dedicated personnel and/or a dedicated unit responsible for development in the area of health research and evidence-based policy and practice (PNG, Fiji, the Solomon Islands, and Tonga). Only PNG had specific legislation on health research pursuant to establishing the PNG Institute of Medical Research (PNG-IMR).

Papua New Guinea (PNG) with its great diversity of population groups has a history of exploitative anthropological research, and some controversies regarding HIV testing and vaccine trials, because of the high HIV rate. One of the challenges for new drug development is that the population sizes are low which means that there are few persons available for any one clinical trial. This has also led to a phenomenon of persons being "over-researched," with some resentment of researchers if there is no expected benefit.

The rights framework used in modern medical research guidelines is considered to be based on individualized understandings of ethical practice and Western notions of autonomy, individual responsibilities, and freedoms. This contrasts with Pacific notions of interrelationship, responsibility to others, and decisions made with due consideration of the consequences for all (whom one is connected to). The issue of a collective – as opposed to an individualized – understanding of rights goes beyond the issue of consent. Pacific people are advocating for the validation of alternative

ways of viewing and approaching rights (New Zealand, 2007). For example, collectivist understandings of rights can be described in the following ways:

There are situations where the "I" (or individuals) do not have the right or authority to give consent for something that is communally owned.

- Rights are inseparably bound to responsibility.
- Rights only occur within the context of relationships.
- A collective rights framework is based on an understanding of humanity that is relational, collective, and concerned with others, as well as the individual.
- The concept of the individual is not negated, but instead they are viewed as contributors to collective and communal development.

Individuals are primarily seen as agents who contribute to collective and communal development with specialist skills, knowledge, and talents. Some of these features are seen in the New Zealand Health Research Council (HRC, 2004) Guidelines for Pacific communities discussed above.

If research targets the Pacific population, Pacific peoples should participate at all levels of that research project. Participation of Pacific peoples in a research project is encouraged on a number of levels, e.g., investigators, advisors, students, and interviewers, and can provide support for Pacific members of the research team. This concern has also been raised regarding the level of participation in discussions of bioethics.

Public Health

The Secretariat of the Pacific Community (SPC) has a public health program that supports Pacific Island communities. There is substantial funding also from Australia, New Zealand, WHO, and the USA to supporting these programs. The stated goals on the website are "The SPC Public Health Division (PHD) is dedicated to improving the health, and therefore the future, of all Pacific Islanders. PHD strives to promote and protect the health of Pacific Island peoples. It advocates a holistic approach to health, supports sustainable capacity development, and facilitates and promotes collaboration with partners."

At the 2011 Pacific Islands Forum leaders meeting in Auckland, the political leaders recognized the seriousness of the threat that noncommunicable diseases (NCDs) pose and declared the "Pacific is in an NCD Crisis." The leaders expressed their deep concern that NCDs have reached epidemic proportions and have become a "human, social, and economic crisis" requiring an urgent and comprehensive response. There is an SPC campaign for a healthy Pacific lifestyle, with focuses to promote physical activity and healthy nutrition and to combat alcoholism and smoking.

Infectious Diseases

The Samoan pandemic influenza case in 1918 clouded relations with New Zealand when a ship with many patients was allowed to dock leading to many deaths among the

resident population. There are laws regulating infectious disease control, and/or public health, in many countries. In the Constitution of Kiribati 1979, for example, it reads:

> Chapter II, Section 5, Protection of right to personal liberty: (1) No person shall be deprived of his personal liberty save as may be authorised by law in any of the following cases, that is to say - . . . (h) for the purpose of preventing the spread of an infectious or contagious disease; (i) in the case of a person who is, or is reasonably suspected to be, of unsound mind, addicted to drugs or alcohol, or a vagrant for the purpose of his care or treatment or the protection of the community.

The Secretariat of the Pacific Community (SPC) has been engaged in issues relating to HIV and other sexually transmitted infections (STIs) for the past 15 years. Its position has evolved according to the needs of the Pacific Island countries and territories (PICTs) and in response to emerging trends in HIV and related issues. The Pacific Regional Strategy on HIV and other STIs 2009–2013 as well as the Pacific Regional Strategy Implementation Plan II (PRSIP) are available online (SPC, 2013) (http://www.spc.int/hiv/index.php?option=com_contentandtask=blogsectionandid=12andItemid=123). In addition to HIV and STIs, there are efforts to combat tuberculosis among other diseases.

Transplantation Medicine and Organ Donation

Full range or organ transplantation services are offered in Australia and New Zealand, though patients have to wait for organs, which can be limited. However, patients in many islands have limited services because of shortage of clinical services as well as donors and may have to be shipped and flown to facilities in Australia, New Zealand, or Hawaii that offer transplants. In some cultures, there is a taboo against cutting up the dead body; however, the predominantly Christian religion has been used to promote the concept of the gift of life that organ donation can provide.

Emerging Technologies (Nanotechnology, Information Technology, etc.)

To some extent, there are two conflicting views of knowledge, that is, "sacred versus open." One perspective is that all knowledge should be openly and freely accessible to all. This is linked with the sense that people have a "right" to know things – i.e., what is known and what is not known about a subject. Thus, notions of privacy are complex and require specific knowledge of the community, and family, to know what should be provided.

Another perspective is that some knowledge is considered sacred, and it is not advantageous for this knowledge to be in the public domain. To be fair, all societies deem that some knowledge is best kept confidential or "sensitive" and is therefore not available in the public domain. In these cases, only the "trusted" and "initiated" have access to this knowledge, and stewards of such knowledge actively protect it.

For emerging technologies that relate to the environment, environmental ethics is dominated by concepts of stewardship and the interrelatedness of all parts of the

environment to God. The use of nanotechnology products in textile industry is being supported, although it does not reach to many islands who will continue to use traditional practices. There is little data processing ability to monitor what is actually happening.

Intensive Care

Critical care facilities exist in some islands, but ICUs are limited. There are ethical issues of rationing and providing access to the limited number of spaces for intensive care in small Island states. Most patients will be unable to be transported to ICUs in time, except for larger Island states.

Palliative Care

A time to go back to nature, and be with God, is recognized; thus, palliative care is accepted. The care will often be given in the family setting, rather than a clinic, event when there is an option of an ICU. The Christian faith helps a number of persons who cannot be treated to accept death. Traditional medical therapies are used to ease the pain of some diseases and are more accessible and affordable in most cases.

Care for the Elderly

There is care for the elderly in traditional community models which can have extensive and close family networks. There has been a challenge that many young persons have left the islands in search of employment, leaving older persons in the care of extended family.

In some communities, there is low life expectancy, but still when persons live longer, they will be taken care of by relatives. Emigration is challenging this when the elderly are left in the country, but relatives are often counted on to care for the elderly. Churches also provide broad support to the community.

Chronic Diseases

Chronic diseases like diabetes and cardiovascular disease are major sources of morbidity and mortality and targets under the public health campaigns.

Psychiatric Care

A holistic approach to health used in traditional practice includes counseling and emphasizes relationships among people rather than individual patients with

mental disease. There are also laws regulating the protection of patients with mental diseases in many countries. One of the ethical debates in these cases is whether the disease is due to the presence of evil spirits, or ancestors, in a sense similar to some types of belief in karma seen in Southeast Asia. In that sense, psychiatry is less recognized as a medical art but relates to the concerns that traditional healers use exorcism and other forms of spiritual "healing" to attempt to treat.

Pediatric Care

In some countries, there are good networks of pediatric care, and in critical cases the children may be sent to Australia or New Zealand to be with families there, in cities with modern health-care facilities (Dunsford et al., 2011). One concern has been the sensitive issue of child abuse by parents, which is a concern expressed by some, but also has been linked to calls of racial profiling in communities of Pacific Island peoples in Australia and New Zealand. However, there is no doubt that all peoples wish their children to be treated, but lack of knowledge of mental health issues may see reduced empathy in some circumstances. The statistics present a poorer record of child care in some communities, but the causative factors are not simple.

Emergency Care

Emergency care ranges between advanced in a few cities and local community measures in the islands that are very remote. For some islands, the only possibility of air emergency services would be helicopters if they are available, and at times cruise ships may provide emergency services for local communities. For example, Tokelau in 2012 decided not to build an airstrip on the precious land, rather renewing a ferry ship that requires a 2-day passage to Samoa.

General Practice

General practice is guided by the ethics of relationships and love. There is still a tendency towards maternalistic or paternalistic decision making in medical choices, although younger generations who return from more Western countries may expect greater communication, more shared decision making, and more informed consent. Officially the practice of informed consent is promoted in all countries; however, in practice the benevolent physician, midwife, or nurse may be more influential for decision making.

At the same time, there are laws specifically for health practitioners in Cook Islands, Fiji, Kiribati, Nauru, Solomon Islands, Tonga, Tuvalu, and Vanuatu. These laws focus more on professional conduct and generally do not enshrine detailed descriptions of informed consent, for example.

Health Promotion and Education

There are national campaigns for healthy lifestyles through schools, tribal chiefs, and community centers. Obesity and lack of activity are recognized as major health problems, and community bodies such as churches can also assist in promoting health. Obesity can be even more of a problem among Pacific persons living in Westernized environments in Australia, New Zealand, and the USA, with access to carbonated drinks and fast food, despite the health education in those countries.

Scientific and Professional Integrity, Conflict of Interest, and Corruption

There have been attempts to regulate scientific research and control corruption in all countries. The principle of trust is important among the relationships that people make. In particular areas, model legislation to govern the practice of researchers has been proposed, such as the draft *Model law for the protection of traditional knowledge and expressions of culture*, 2002 (the Model Law) which is an attempt by Pacific Island states to protect their traditional knowledge and expressions of culture. The draft Model Law was a result of a joint effort of Secretariat of the Pacific Community (SPC), Pacific Island Forum Secretariat, UNESCO, and the Council of Pacific Arts comprising the 27 countries and territories which participated in the Festival of Pacific Arts. It was endorsed by the First Conference of Ministers of Culture of the Pacific Region at SPC in 2002 [online] available from http://www.mabs.jp/countries/others/pdf/331e.pdf.

Relations with Industry and Donors/Sponsors

The traditional views on knowledge in Pacific societies is that it is collective and aimed at maintaining the relationships between people – past, present, and future generations – and the environment. While ownership of knowledge is familial and collective, differentiation can be made between knowledge that is protected and knowledge that is shared. In addition, because the focus is on maintaining relationships, knowledge sharing is an interactive and dynamic process.

It is not surprising therefore that there have been some controversial cases when pharmaceutical companies become involved in genetic prospecting. One case involved an agreement between the King of Tonga and a biotechnology company for human genetic sampling in the Tongan population, which, after controversial publicity and dissent, was terminated before sampling of the population was made. The King initially gave consent for the whole country to provide genetic samples to the company who could explore potential commercial uses of the genetic markers associated with diseases in some individuals in the community. It was ethically questioned whether any head of state could give consent on behalf of any ethnic group or country, and the decision was reversed after public outcry.

The question of who owns the primary knowledge that is derived from the experience and expertise of participants suggests that this knowledge indeed belongs to the research participants. The question as to who owns the combined outputs of the accumulated primary knowledge suggests that this belongs to the community of Pacific families and the community of researchers. Researchers should, where appropriate, protect indigenous Pacific knowledge and knowledge holders.

Future Challenges

In the Field of Bioethics Infrastructures (Need for Legislation, Ethics Committees, Ethics Education, etc.)

Capacity and capability building is a tangible example of reciprocity in action that is expected of any researchers who operate in the Pacific. It will demonstrate a commitment to the empowerment of the Pacific community. Participation is an important principle of Pacific research. Pacific research requires the active involvement of Pacific peoples (as researchers, advisors, and stakeholders), and Pacific people will no longer just accept to be the subjects of research. Where a research project targets Pacific populations, Pacific people should participate in the research team at all levels (e.g., interviewers, research assistants, investigators, and advisors). This ensures that the project is responsive and accountable to the research needs of the participant research population.

There is a core belief in many Pacific communities that knowledge should be used responsibly, and with wisdom, so as to not harm others. Pacific knowledge is tied to the collective good. To transmit knowledge to those who are not able to care for that knowledge, process it appropriately, or keep the meanings safe can however be seen as an irresponsible approach to knowledge. In the traditional Pacific context, a person earns the right to know through proving that they are worthy and ready for the information. This prevailing attitude may mean that some researchers face barriers that they might not experience if working with a different population.

In the Field of New and Emerging Issues

Although there have been several subregional bioethics meetings and UNESCO also organized workshops in Samoa and Fiji, there are still many communities in the Pacific who have not been involved in discussions of bioethics. Without considerably more expense, it will be difficult to describe the ethical worldviews and practices of all the diverse communities across the Pacific. Inclusiveness is important to Pacific values, and thus until describing more of the variety of ethical views scholars and policy makers have, we cannot adequately describe what is the representative regional ethics, as we will not have adequate participation to describe what is "Pacific bioethics." There is a continued need for more indigenous

research, including the mobilization of researchers and communities, healing, decolonization, and transformation (Smith, 1999).

An extension of love to other species and the concept of stewardship is one important lesson that could be applied to environmental ethics and ethics of climate change globally. Stewardship can apply to both the way people use other humans and the rest of nature. The concept has often been neglected but has a long history in many religions, being central to a Judeo-Christian doctrine of creation (Macer, 1998). Usually people prefer to ignore it and to think of dominion of humans over the earth, treating the earth with little value; however, this has caused many environmental problems. There are numerous pollution problems that affect humans and other species.

Any Other Problems and Opportunities for the Further Development of Bioethics in the Country?

Few would question the need for the Pacific to develop legislation and policies in bioethics that will guide national decision making and also protect Pacific communities from incidents such as external researchers carrying out research in the Pacific that would be prohibited in their home country and acts of biopiracy.

There is also a great opportunity for research and scholarship to document indigenous ideas and see how these are applied to contemporary challenges. There is a delve of research and, with proper partnerships, tremendous potential to rediscover many lost values and ideas.

Summary Conclusion

There is diversity of circumstances among the different Pacific countries and territories and diversity of language and worldview. However, some common principles of community involvement and participation emerge across all communities in the Pacific (Macer, 1994, 1998). The Pacific concept of *va* means the space between people – "the space that connects rather than separates" (Mila-Schaaf, 2009). By nurturing *va*, relationships among people and between them and everything else can be sustained. Pacific ethics is thus based on relationships between persons, organisms, and God, rather than rights.

Major Forces on the Development of Philippine Bioethics

Influence of Catholicism and Christianity

The development of bioethics in the Philippines cannot be divorced from the influence of Catholicism and Christianity on local culture. The strong influence of religion continues to prevail over many aspects of life and human relationships in

the country. Filipino values have long evolved against this backdrop. One should try to understand developments and prevailing attitudes relating to issues of bioethics with this backdrop in mind. There is a huge Catholic majority – exceeding 80 % – among the population, and the Catholic influence does not lie merely in numbers. The social dynamics reflect the way in which religion has been imbedded in ordinary life, and any serious account of Philippine bioethics cannot avoid being an effort to understand those social dynamics at the same time. Moreover, there are parallel political dynamics that need to be considered, these being closely intertwined with the former as well as with other factors bearing on bioethical developments and policy-related decision-making.

The Catholic Church in the Philippines has seen itself as a guardian of public values. This is how it positioned itself when the colonization of the Philippines by Spain started in the sixteenth century, and this is how the Catholic Church continues to position itself long after the colonial era. It is as if the Spanish colonizers installed a proxy to try to maintain their hold on the Filipino psyche and continue their subjugation of the locals. In this role, the hierarchy of the Catholic Church has chosen its battlefields, which are mainly to be found in the area of health care. Abortion and the broad family of reproductive health issues have provided one major battleground. Over the years, people identified with this religious sector have engaged in public debate with various protagonists regarding family planning and the promotion of contraceptive use. Lying at the foundation of this religious perspective is the idea that it is necessary to protect "the life of the unborn from the moment of conception" (the Constitution of the Republic of the Philippines). Given this fundamental position, it is no surprise that contraception is regarded as "intrinsically evil" with only "natural" family planning methods and abstinence being accepted as exceptions. In this area, we see how bioethics discourse almost inevitably takes on a religious dimension.

Notwithstanding its constant access to the ears of its followers, the voice of the Catholic Church has not gone unchallenged. It has been a magnet for strong organized resistance coming from groups advocating women's rights as well as from health-related nongovernmental organizations (NGOs). The participation of some of these groups in national debate may be seen to represent a kind of bioethical activism in that it goes beyond debate and public declarations. Wary of the dangers of leaving religious doctrine to define health-related policy, such groups have vigilantly contested the ultraconservative stance of the hierarchy of the Catholic Church on bioethics issues. They have also added an important dimension that helps to define Philippine bioethics discourse.

The proposed Reproductive Health Bill (RH Bill) has provided the most recent battlefield for heated exchanges between the Catholic Church and some of its opponents. Disagreements regarding the RH Bill have provided a venue for each side to unleash its brand of activism. The Catholic Church has expressed opposition to, among other things, what it takes to be the "non-consideration of moral principles"; "the antilife, anti-natal, and contraceptive mentality"; "the overall trajectory of the RH Bill toward population control"; "the use of public funds for contraceptives and sterilization"; and "the provision for compulsory sex education." Through a widely disseminated Pastoral Letter in 2011, the Catholic Bishops

Conference of the Philippines articulated its determination to "defend human life from the moment of conception or fertilization up to its natural end" and reiterated its belief in the responsible and natural regulation of births through Natural Family Planning. It also asserted that "conscience must not only be informed but most of all rightly guided through the teachings of one's faith." Thus, the Catholic hierarchy has referred the faithful back to fundamental Church dogma. Moreover, through the emphasis on being "rightly guided through the teachings of one's faith," the Pastoral Letter has the effect of negating an individual's freedom of choice as there is no escaping religious dictates in the end. Although there is an endorsement of "the freedom of religion and the right of conscientious objection," it is quite clear that these cannot be exercised to express sentiments regarding reproduction and conception that are contrary to what the Church sees as part of one's faith.

Supporters as well as opponents of the Bill have engaged in "activism," by encouraging or organizing mass action or by pursuing activities calculated to influence the outcome of the legislative procedures. The Catholic religious establishment itself has been engaged in its own kind of bioethical activism as described below. The weapons have included public demonstrations and vigorous lobbying, in addition to the sustained orchestrated preaching that has been its standard fare.

The activism that is referred to has the effect of intimidating people rather than merely presenting them with options backed up by convincing reasoning. With legislators as a target, the power to intimidate comes from a presumption of the intimidator's capability to influence the outcome of popular elections. In relation to the general public, intimidation hinges on the credibility of the threatened religious outcomes.

The dogmatic approach of the Church has been a target of criticism for those who support the passage of the Reproductive Health Bill. Supporters of the RH Bill have gained strength from among the ranks of nongovernmental organizations (NGOs). These NGOs have emerged as another notable locus of power in the country's bioethics scene. Many of them have carried their advocacies very forcefully. Those that see themselves as protectors of women's rights have battled with the Catholic Church and its allies in matters pertaining to reproductive health. Other NGOs have also been visible on the bioethics landscape in connection with their own specific advocacies. For instance, there are NGOs that have focused their energy in a campaign against the use of genetically modified organisms in agriculture and food development. There are others that have battled to keep pesticides out of agricultural farms. And there are those that have fought very hard for the enactment of laws and implementation of policies that are meant to provide broader access to effective health care and inexpensive medicines and treatment. They have sought to carve their respective niches in the bioethics spectrum.

On the other hand, the religious opposition continues to resist the RH Bill's role in family planning as a national mandated priority health program. It appears that religious influence is threatening to encroach on political decisions even at the level of local governments. This encroachment can be scary because of the way it threatens to erode the boundaries that separate Church from state. More and more, sympathy for religious authority is being translated into official actions upon the initiative of elective local authorities.

Decentralization and the Politicization of Health Services

The Congress of the Philippines enacted the Local Government Code of the Philippines in 1991, setting in motion the devolution of health-care services from the national government to local political authorities. The transfer of authority and responsibility aimed to increase the responsiveness and integration of government programs to local needs, thereby strengthening community ownership and accountability. The presumption was that local governments would have been in a better position to address health concerns within the context of their own developmental priorities. Local government units included the cities and municipalities within the 77 provinces of the Philippines.

While devolution was meant to improve the effectiveness and efficiency of health-care delivery and services, the Department of Health (DOH) was justifiably concerned about some troublesome issues. For one, the decentralization and devolution meant that the DOH assumed a diminished role in controlling and managing health-care funds that had to be given directly to local government units (LGUs). Because of the greater power thus given to local government units, the health policy agenda of the national government has been relegated to the background. Allocation decisions tend to be dependent on an elected leader, whose term of office is as short as 3 years, thus leading to variability (and possible long-term instability) in the position taken on some important health-care issues. Oftentimes, decisions made by elected leaders in the local government units have to reflect pragmatic and politically motivated considerations that could be highly incompatible with the crucial health-care requirements of the community. Unfortunately, the visibility of community projects has more immediate political value than long-term effectiveness and sustainability.

In consonance with the prescribed national system for allocating financial resources, funding for local governments has been dependent on the population and geographical size, and there are small local government units that suffer from a lack of resources to fully address local health-care needs. Taken together, the political exigencies and economic realities in vulnerable communities have resulted in a distorted sense of priorities that do not always depend on fair and equitable principles of allocating health-care resources. A truthful depiction of the bioethics situation in the country has to take this reality into account.

Maternal and reproductive health services have been greatly affected by devolution as these services are among those that were first discovered to be underfunded. This point is relevant to the understanding of bioethical developments since the current and highly controversial Reproductive Health Bill (like its precursors in previous congresses) has sought to address this finding. However, the progress of the Bill has been blocked because of very emotionally charged disagreements regarding ethical and religious implications.

To illustrate, finding sources of modern contraceptives became a problem when donations from a major foreign agency ran out some years ago. Local governments had to allocate money out of their limited funds or generate them from new donors in order to provide the needs of poor constituents. Executive officials of some local

government units were so heavily influenced by the official Catholic stance on modern contraceptives that they chose to promote only what they regarded as "natural" family planning methods. They decided to have nothing to do with more effective means that were opposed by the Catholic hierarchy.

One must understand the implications of such a policy in a context where health insurance coverage has been very limited and certainly does not extend to the reproductive health needs of women. Comprehensive health-care agreements existed that were intended to set priority health targets agreed upon by the DOH and the LGUs, but these were effectively set aside. These were not recognized as binding by the municipal governments that were dealing face to face with the public in the delivery of health services. If one imagines this experience repeated several times over in various parts of the country, one could see why the allocation of health services took place with suspect planning resulting in inefficiency and an overall system that often has been unresponsive to the needs of the population, especially the poor. There has been a lot of unfairness and inequity.

To be sure, experiences have not all been gloomy. Studies on maternal health and child welfare relating to reproductive health implementation have reflected stories both of success and suffering. But local leaders still have to show consistency of political commitment to actualize effective services to the citizenry and to forego political fears of losing the Catholic community's electoral support. They cannot surrender to political expediency when ethical responsibilities clearly point in the opposite direction. But such are the realities, and one could see in this area of health services an illustration of one of the major currents running through bioethical debate and dynamics in the country. As self-declared guardian of public morals, the Catholic hierarchy sees certain key issues as falling within its domain, and it has not been shy to assert its influence either on its members directly or on the political leaders who seem to get easily convinced that they need support from church leaders to further their electoral ambitions.

Major Concerns Over Time

Poverty

Bioethical issues in the Philippines must also be understood against a background of extreme poverty and vast disparities in wealth and power. The impact of poverty on people's lives has helped to characterize discourse and deliberation on matters of bioethical concern. The inability of government to deal successfully with poverty has also affected the manner in which authorities have responded to some of these issues. As in many other countries, economic barriers severely limit the options available to people when they have to make health and bioethical decisions. These barriers tie the hands of policy makers and hamper efforts to allocate resources in a fair and equitable way. In many cases, poverty-stricken individuals and families find themselves only with options they would ordinarily not be willing to take. This is not to say that poverty could make some decisions right that are otherwise wrong.

In this context though, issues of justice and access become more pronounced. When extreme poverty characterizes the context within which bioethical issues arise, realistic options tend to be diminished. Moreover, tensions among possibly conflicting ethical principles come to the fore and become very difficult to resolve.

Located in Southeast Asia, the Philippines is a developing country – an archipelago of 7,107 islands with an estimated population of 92 million people. It is a lower middle-income country with a wide chasm between the rich and the poor. In spite of the poor economic conditions, the country has a high literacy rate of 95 % for both men and women. Although many economic indicators have improved in the last two decades, the failure of wealth distribution has left millions of Filipinos mired in poverty. There was an increase of about 185,000 in the number of poor families – from 3.67 million in 2006 to 3.86 million in 2009. This meant an increase by almost 970,000 individual Filipinos from 22.2 million in 2006 to 23.1 in 2009.

If poverty were to be understood to include the impact of food sustenance and income on quality of life and human development, then the country has a long way to go before it can attain the United Nations' Millennium Development Goal of eradicating poverty. Poverty has become one of the important lenses for examining issues of bioethical significance. Its impact on the donation or selling of human body parts for transplantation has been documented. For many, it has been a big factor in deciding on end-of-life options, and we are familiar with economically informed dilemmas pertaining to the retention or withdrawal of life support systems among terminally ill patients. We also hear plenty of stories about difficulties in accessing health care because of the absence of comprehensive health insurance.

Migration of Health Professionals

The imbalance between the capacities of rich and poor countries to maintain a decent level of health-care services will continue to highlight the injustices that bioethics discourse has largely ignored. In the Philippines, the related issues have been openly debated. However, they are often looked upon with an economic rather than an ethical eye. Migration brings economic opportunities not only for the Filipino workers who move abroad but also for the rest of the country in terms of increased purchasing ability and its impact on local production and on related industries. A lot of people are thus satisfied with the economic outcomes of health manpower *outmigration* while they remain oblivious to its impact on local health-care delivery.

The situation with nurses has grabbed the attention of national health officials as well as the general public. The fact that the country spends a huge amount of its scarce educational resources to train nurses only to find those nurses serving foreigners abroad rather than Filipinos in their own country constitutes a glaring injustice in the eyes of many locals. Out of all nurses trained in the Philippines, only about 15 % remain in the country to serve local patients. The country has been the biggest source of nurses worldwide with up to 85 % of its nursing graduates going abroad to find jobs in the United States, the United Kingdom, Saudi Arabia, Libya,

United Arab Emirates, Ireland, Singapore, Kuwait, Qatar, and Brunei. During a critical period, the hemorrhage of nursing talent left many local hospitals severely understaffed, with 200 hospitals being forced to close between 2003 and 2005. A shortage of doctors and nurses also resulted in hundreds of hospitals having to stop operating some of their wards during the same period. The magnitude of the problem was also evident in the deterioration of the nurse to patient ratio to a level of one nurse to between 40 and 60 patients during the given period. This development has been thought to have resulted in other health-care anomalies: (up to 70 % of deaths between 2002 and 2003) taking place without the benefit of medical attention and the immunization rate among children going down to about 60 % in 2003.

In addition to nurses, physicians, physical therapists, occupational therapists, laboratory technicians, and other health-care professional have been joining the human resource migration bandwagon. At the turn of the millennium, Filipino nurses were in such demand in some developed countries that local medical doctors were enticed to switch careers in order to improve their chances of overseas employment. The effects of the health-care labor market have been truly unsettling for economic plans and, in many cases, for individual dreams. Health worker migration clearly points in the direction of unsettled bioethical issues that ought to be debated with sobriety even as the situation has given rise to impassioned calls for effective and immediate steps to stop the hemorrhage of health-care human resources.

The outward migration of health workers arises as a bioethical concern because justice demands that health-care services of sufficient quality and quantity be made available to Filipinos across different economic strata. The outflow of manpower has led to a lack of capacity to provide local health institutions with health-care manpower resources having the necessary skills and experience. When very new health-care workers are recruited to take over the work left by senior counterparts, overall quality is sacrificed and the cost of services even rises because there is limited supply relative to the demand. The Philippines (as well as other supplier countries) is left to provide stop-gap solutions, while the recipient countries receive a huge boost to their own capacity to provide skilled health care within their already thriving health infrastructures.

This draining of competent health-care workers has been blamed for an insufficient supply that has had a negative impact on the quality of health services, the morale of local nurses, the capacity of hospitals to cope with patient care demand, and the well-being of patients within the health-care system. However, the situation is complicated further by the active encouragement of migration coming from the national government as it takes into account the contribution of remittances from overseas workers to the economy. Clearly, economic considerations take top priority. The injustice is overlooked when the price is right.

One analysis of the situation tends to pin the blame on health workers themselves. The idea is that, having been subsidized greatly by the national educational system, health professionals ought to repay the cost of their training by rendering their services to the country. Another view finds blame in the national government

for neglecting to provide enough incentives to keep health-care workers at home and for promoting an outlook that sees health-care workers as assets who can bring economic resources to the country through their remittances. Then there is the view that focuses attention on the effects of international recruitment programs tempting developing country health-care workers with salary offers that are too good to refuse. These perspectives are tied to ascriptions of blame and responsibility that reflect dissatisfaction with migration trends. They also represent an ethical outlook that conflicts with a purely economic valuation of impact and outcomes. Each perspective correctly calls attention to an important facet of a nagging global phenomenon. However, one must also take into consideration the economic realities that various stakeholders have to contend with. There is an urgent need to discuss these outlooks openly but without presuming that the situation with regard to the movement of health-care professionals across national boundaries is a purely economic matter that can be resolved by determining how best to increase material wealth. It makes good ethical sense to undertake a broad assessment of where responsibilities lie. The possible causal factors for the problems that are being experienced are many, varied, and complicated. Some of these factors transcend national boundaries. It appears that assessment of responsibility should consider not so much who ought to be blamed but who could be in a good position to do something about the situation. Some kind of collective governance appears to be in order. The problems are global, and the root causes have global origins. Source countries and destination countries have their share in giving rise to these problems, and they must have their fair share in seeking to provide solutions not only for their respective concerns but also for other matters arising at either end of the migration process. This would entail fair and equitable bilateral and multilateral arrangements for recruitment and international deployment that acknowledge direct economic, social, and ethical responsibility on the part of destination countries for the effects of their recruitment on the source countries. A limited insular approach that only takes into account the interests of the parties separately will be not only ineffective but also unethical for failing to consider the full impact of prevailing policies on populations that inevitably have to suffer unpalatable consequences.

Bioethical Activism

Medical controversies often serve as catalysts for public debate on bioethics issues. The controversies catch public attention and engage people's imagination while also inviting media coverage. Bioethics discourse tends also to take the cue from exploding controversies However, the discourse often is associated with academic reasoning and medically related law as the venue is provided by academic institutions and publications. Still, it is important not to lose track of developments outside an academic context as these developments reflect a perspective that could be very different from realities portrayed by academics and expressed in academic verbiage. Bioethics discourse outside the academic community could be very lively and exciting. Using a language that perhaps lacks the clarity, consistency, and

sophistication of academic scholarship, it should not be discounted nevertheless, and its importance should not be diminished. Academics ought to try to understand popular bioethics discourse without having to reduce such discourse into academically precise formulation. While academic discourse is meant to appeal to academically established reasoning, lay discourse understandably appeals also to the feelings, emotions, and folk values that people have to deal with in their daily lives. Public discourse also tends to have a greater political impact that results in policy formulation.

It is important to make this clarification about varying bioethical perspectives (or various levels of bioethical discourse) if only to explain the phenomenon that is referred to here as bioethical activism. This phenomenon is explained in part by this distinction between levels of discourse but also by the intensity of people's commitment to competing bioethical values, beliefs, or principles. One aspect of this activism relates to the prominent role that nongovernmental organizations have assumed in society on matters having to do with health concerns that easily give rise to bioethical issues.

Bioethical activism has also been manifested in the efforts of local government officials to use their political power to propagate religious values. The Philippines is a constitutional democracy that recognizes the separation of church and state. Religious authorities are barred from holding positions in government or to run for elective posts. In the few instances when men of religion have pursued political positions during elections, they have had to give up their religious positions as a prior condition. However, this separation has tended to be challenged in relation to bioethical issues of reproductive health. The reference goes beyond conscientious refusals on the part of some government officials to engage personally in activities seeking to promote the use of contraceptive or similar devices that are regarded by the Catholic Church as contravening religious precepts. Behavior of this type is quite common and is to be expected. Government physicians have invoked conscientious objections in refusing to carry out tubal ligation or even some cases of abortion when mothers' lives were under severe threat.

Among other things, "bioethical activism" refers to efforts of government officials to impose their religious convictions on others by administrative or legislative fiat. The efforts go beyond merely trying to convince or influence and is more akin to coercion.

As mayor of the city of Manila in 2000, Joselito Atienza threatened to arrest government officials who introduced RU-486 (Mifepristone) to the city. He rationalized his order by citing a duty to enforce the provision of the constitution protecting the unborn from the moment of conception. Atienza issued an Executive Order entitled "Declaring Total Commitment and Support to the Responsible Parenthood Movement in the City of Manila and Enunciating Policy Declarations in Pursuit Thereof." City Health Department officials used the Order as basis for refusing the use of condoms, birth control pills, intrauterine devices, and surgical sterilization in the city's reproductive health initiatives.

The official stance was carried over to the next city administration. As a result, some residents decided to sue the city because of the practical impact of the policy.

The complainants decried the lack of birth control pills and other contraceptives at health centers. One mother said she already had six children because she could not afford to buy the pills on her own. According to the complainants, the policy prejudiced their right to health and well-being and resulted in deteriorating reproductive health outcomes – the policy deprived them of access to health care and health development and resulted in numerous pregnancies.

In other jurisdictions (and at about the same time that Mayor Atienza was in power), the governor of the province of Laguna and the mayor of the city of Puerto Princesa also initiated similar policies limiting support for family planning (FP) clinics providing only "natural" FP methods to their clients. Thus, some local government officials have engaged in their own brand of political activism. This kind of establishment-based activism should not be looked at in the same vein as activism on the part of nongovernmental organizations that are expected to support their advocacies in a way that does not depend on the use of government resources. When officials who have government resources at their command use those resources in a way that promotes advocacies based on their religious or ideological leanings, they betray the trust of the electorate by imposing, rather than democratically espousing, ideological perspectives. Thereby, they bring a disservice to the cause of democracy and fail to advance free and enlightened bioethical discussions. The practice does not necessarily help to cultivate an ideal context for bioethical maturation and advancement.

Through bioethical activism, individuals or groups try very hard to improve the situation and make things happen in accordance with their sense of what is right. This is potentially a very powerful tool for political involvement within a democratic society. However, society also has to ensure that activism takes place within a framework of objective, enlightened, and free deliberation and debate.

Measures and Resources Developed Over Time

Teaching of Bioethics at University and Other Levels

Formal teaching of bioethics and the corresponding offering of academic degrees have been going on in the country at the University of Santo Tomas (UST) and the University of the Philippines. The University of Santo Tomas (UST), the oldest Catholic university in Asia and a pontifical university that has roots deep within the Catholic tradition, was the first to offer academic degrees. The Department of Bioethics at UST has been part of the Faculty of Medicine and Surgery where it seeks "to stimulate future physicians to develop mature moral reasoning and to act in accordance with principled moral judgment thereby developing the attitude of a competent and compassionate Catholic physician." In addition to offering degrees, the Department of Bioethics seeks to educate medical students on bioethical issues in order to enable them to identify, define, and apply bioethical concepts and principles. Medical students go through a longitudinal bioethics program,

where they are taught basic bioethical principles, attitudes, and virtues in the first of a 4-year curriculum. Second-year medical students undergo a course on "Healing and Caring for Patients" that covers a broad range of topics including the beginning of life, death and dying, organ transplants and justice in the allocation of scarce resources, the human genome project, genetic manipulation, genetic engineering, prenatal testing, genetic counseling, and embryonic stem cell research. Third-year medical students are taught about the dynamics of the physician's relationship with the various stakeholders in a medical and hospital setting. Lessons also deal with the rights of patients, human rights, bioethics committees, and the role of physician in advocacy. Fourth-year students, referred to as medical clerks, present clinical cases and analyze them from a medical and ethical perspective with the assistance of the teaching staff and invited resource persons.

A Master of Science Program in Bioethics has been on offer at the University of the Philippines since 2006. The Program, jointly developed by two autonomous campuses of the national university, was set up with generous financial support coming from the United States National Institutes of Health – Fogarty International Center. It is a unique program in that graduates earn a dual degree that is granted both by the College of Medicine, which is based at the health sciences campus in Manila and the College of Social Sciences and Philosophy, which is based in a different autonomous campus in Quezon City. In addition to the Master of Science (Bioethics) degree program, the partnership of the two campuses has led to training programs in Bioethics and Research Ethics conducted throughout the country since 2001. These programs have been useful in educating members of ethics review committees, bioethics teachers, researchers, research administrators, and health-care professionals. Support from the Fogarty International Center has also enabled the training program to benefit professionals from other Southeast Asian countries.

Before the establishment of the Master of Science Program, a Diploma Program in Bioethics was offered as a 24-unit, postbaccalaureate degree in 2004. Many of the students had professional backgrounds and occupied key positions in the academe, health-care institutions, and government. Some of the graduates have gone on to serve on the Philippine Research Ethics Board, representing their professions and fields of expertise. Others have returned to their respective institutions to teach bioethics courses.

Other than the degree programs, short courses of various types have been offered by governmental and nongovernmental organizations, including the University of the Philippines Bioethics Training Program, the National Institute of Health, the Philippine Health Research Ethics Board, the Philippine Council for Health Research and Development, and the Bioethics Society of the Philippines. Collaborative initiatives among these institutions have also been quite common as they try to fill the bioethics training and educational needs that arise across the country. Courses on offer have been designed for the variable requirements of ethics review committees, researchers, research ethics monitors, and others involved in the ethics review chain throughout the country.

Collaboration between local and international institutions has also been a factor in enhancing bioethics capability in the Philippines. International conferences have

been organized with the support and participation of the United National Educational, Scientific and Cultural Organization (UNESCO), the World Health Organization (WHO), the European Union and the European Community, the Forum for Ethics Review Committees in Asia and the Pacific (FERCAP), the International Association of Bioethics (IAB), and the Asian Bioethics Association (ABA). Individuals and official representatives from the country have also participated in international activities organized abroad by the above-mentioned organizations. Some have taken on prominent leadership roles in the UNESCO International Bioethics Committee, the IAB, the ABA, and FERCAP.

Since nursing education is a very huge part of the health-care training burden in the country, it is worth noting that the Commission on Higher Education issued a memorandum in 2009 requiring bioethics to be part of the Bachelor of Science curriculum. To improve capability in this regard, the University of the Philippines has offered training programs for bioethics teachers in nursing schools.

Ethical, Legal, Social Issues (ELSI) Program, Philippine Genome Center

An Ethical, Legal, and Social Issues (ELSI) Program was established in 2011 in conjunction with the Philippine Genome Center. The ELSI Program was organized for the purpose of mapping a series of workshops for scientists, researchers, and legal scholars to identify and propose solutions to current ethical, legal, and social challenges for genomic research in the. The Program also has a mandate to take up governance, security, utilization, and sharing issues pertaining to genomic sample and data repositories, including those obtained from the newborn screening program. In addition, the Program could deal with issues of informed consent, privacy, confidentiality, public health concerns, and intellectual property. It is also expected to deal with the regulation of genetic tests and products directly marketed to the public, agricultural applications of genomics, the nonmedical use of genomic information (e.g., forensic, litigation, paternity, migration patterns), the practice of genetic counseling, and the conduct of public education.

Bioethics Committees

National Ethics Committees

Foremost among the bioethics bodies currently existing in the country is the Philippine Health Research Ethics Board (PHREB). This national body has been charged with the task of promoting the ethical conduct of biomedical and behavioral research. Having quasi-regulatory and monitoring functions, the body heads an ethics review infrastructure that also consists of regional ethics boards and institutional ethics review committees. With the Philippine Council for Health Research and Development providing its secretariat, PHREB lies at the core

of the Philippine National Health Research System as it undertakes its functions among researchers and research institutions working with the Department of Health, the Department of Science and Technology, the Department of Education, and the Commission on Higher Education. PHREB's guidelines are also observed in the conduct of health research by private individuals and institutions.

PHREB's functions were originally exercised by the National Ethics Committee, a body that was originally created in 1985 under the Philippine Council for Health Research and Development. After the research functions of the Department of Health and the Department of Science and Technology were integrated under the Philippine National Health Research system in 2003, it became necessary to set up a more broadly based body to take over the NEC's functions, with a supporting regional infrastructure. Shortly after taking over the ethics regulatory and monitoring functions, the PHREB conducted consultations leading to the revision of the National Guidelines for Biomedical and Behavioral Research in 2006. A training program for members of institutional ethics review committees was implemented nationally. In 2012, PHREB released the fourth edition of the national guidelines. This latest revision attests to the continuing effort of PHREB to keep up with rapidly changing health-care science and technology. In addition to general guidelines that offer heath research in general, the new guidelines have specific provisions regarding the most recent developments in biomedical research.

Not having a single national body to preside over matters of bioethics, the government's response to controversial developments in medicine and the biological sciences has been compartmentalized. There has been a National Transplant Ethics Committee (NTEC) for about a decade, with specific functions pertaining to the ethics regulation and monitoring of organ transplantation. It has been organized and reorganized several times in the past 10 years as authorities have struggled with effective remedies for dealing with problems such as organ selling, human trafficking, and various practices involving the coercion and deception of donors. Several reincarnations of the NTEC have failed to provide it with the autonomy fitting of a national body of such importance. The NTEC has a mandate to oversee the work of institutional transplant ethics committees on the basis of self-proposed national guidelines. However, its proposals are subject to the higher approval of the Philippine Board of Organ Donation and Transplantation (PBODT), thus preventing it from implementing its mandate independently, or without the interference of a higher body made up of members with conflicts of interest. It seems that in an effort to satisfy the desire of various stakeholders to be represented in the bodies that are being established to monitor and regulate the practice of organ transplantation, the government has inadvertently allowed conflicted interests to be entrenched and to put the integrity of transplant ethics under a cloud of doubt.

Relevant Legislation

The Philippines has been thin on legislation having significant impact on matters of bioethics. Perhaps because of the attention that the two houses of congress have had

to give to economic measures, they could not give much time to matters of bioethics. The most prominent that can be mentioned – and the one with the greatest impact – is the constitutional provision for protection of the unborn from the moment of conception. This provision was written into the basic law when it was rewritten in 1987, thus bolstering the basis for an old law that renders abortion as a criminal act.

Known as the "Generics Act of 1988," Republic Act No. 6675 was passed to promote, require, and ensure the production of an adequate supply, distribution, use, and acceptance of drugs and medicines identified by their generic names. As an item of social justice legislation, the Act meant to ensure the production of drugs with generic names at the lowest possible cost and endeavor to make them available free for indigent patients. It took 20 years before Republic Act 9052 or the Universally Accessible, Cheaper and Quality Medicines Act of 2008 was signed into law by the president. The latter Act sought to provide access to essential medicines through a combination of measures that were strongly opposed by the pharmaceutical industry for what its members characterized as restrictions on free enterprise.

Republic Act 9288 provides all Filipino newborns access to screening for congenital metabolic disorders. Known as the "Newborn Screening Act of 2004," the legislation mandated the National Institutes of Health to create the Newborn Screening Reference Center (NSRC), with the responsibility to be the repository of technical information relating to newborn screening.

The Philippine AIDS Prevention and Control Act was passed in 1998. It sought to protect infected individuals from discrimination and injustice in various ways. The Act prohibits compulsory HIV testing as a precondition for a broad range of rights and services including employment, admission to educational institutions, exercise of the freedom of abode, entry to or continued stay in the country, travel, or the provision of medical or any other kinds of service.

Republic Act No. 7170 Authorizing the Legacy or Donation of All or Part of a Human Body after Death for Specified Purposes provides the basic legal framework for the retrieval of organs for transplantation. It allows the declaration of death to be made on the basis of cardiac and respiratory functions or on the basis of brain functions.

Equal significance may be attached to unsuccessful attempts at legislation. Efforts to legislate a basis for advance directives illustrate the caution that has attended deliberations by lawmakers on Bills relating to bioethics. After the current constitution came into force in 1987, Bills seeking to provide a legal framework for advance directives have been filed every legislative cycle. None of these Bills have been passed. All efforts to enact a law defining and penalizing medical malpractice have also failed. When a malpractice Bill gained strong public support in the 1990s, it still ended up as a failure because of strong opposition by medical practitioners. The experience proved the dominant influence of the medical community and the power it wields on policy makers. It also showed that the medical community will do its best to prevent external review of decisions commonly made by medical practitioners.

In the 14th Congress, Senate Bill (SB) No. 812, "An Act Declaring the Rights and Obligations of Patients and Establishing a Grievance Mechanism for Violations Thereof and for Other Purposes," was also unsuccessful. Known as the "Magna Carta of Patient's Rights and Obligations," it sought to recognize the following as basic rights of patients: right to appropriate medical care and humane treatment, right to informed consent, right to privacy and confidentiality, right to information, right to choose health-care provider and facility, right to self-determination, right to religious belief, right to medical records, right to leave, right to refuse participation in medical research, right to correspondence and to receive visitors, right to express grievances, and right to be informed of his rights and obligations as a patient. Aside from the individual rights, the Bill also identified societal rights of patients: right to health, right to access to quality public health care, right to healthy and safe workplace, right to prevention and education programs, and right to participate in policy decisions.

Access to Cheaper Medicines

To make medicines affordable and accessible to the poor, the Philippine legislature passed the Generic Drugs Law in 1988 and the Universally Accessible Cheaper and Quality Medicines Act of 2008. The Generic Drugs Law requires the use of generic terminology in the importation, manufacture, distribution, marketing, advertising and promotion, prescription, and dispensing of drugs. Pharmaceutical companies operating in the Philippines have been required to produce, distribute, and sell generic counterparts for medicines they produce while all medical, dental, and veterinary practitioners have been required to use the drugs' generic names in writing prescriptions. Pharmaceutical companies have also been mandated to indicate generic names prominently in their products. Nevertheless, the generics initiative has had, on its own, very little success in making essential drugs widely available to the population. Before the passage of the Cheaper Medicines Act of 2008, as many as 7 out of every 10 Filipinos were thought to have no regular access to lifesaving drugs. Moreover, the country ranked second only to Japan in the cost of critical medicines. Relative to economically comparable India and Pakistan, some drugs are priced 5–45 times higher in the Philippines. Thus, we see why there is no regular access to drugs. The situation has made it quite easy to provide ethical justification for taking unusual legislative and regulatory steps to make lifesaving drugs available to those in need.

The Universally Accessible Cheaper and Quality Medicines Act of 2008 has put together several remedies to deal with the access and cost issues. The Act (a) provides for the parallel importation of patented medicines from foreign markets where these are available at a lower cost; (b) prohibits the grant of new patents where these based only on newly discovered uses of an already known drug substance; (c) enables the testing, production, and registration of generic versions of patented drugs by local generics firms; and (d) allows government use of patented drugs when public interest is at stake. In addition, the Act gives the president the power to set price ceilings on essential drugs.

Multinational pharmaceutical companies lobbied very strongly against the passage of the Bill when it was still being debated. They invoked, among other things, the country's commitment to a free enterprise economy. On the other hand, government instrumentalities argued that this commitment was easily outweighed by the very persuasive medical reasons as well as by considerations of social justice.

Newborn Screening

Considering that the government has not been able to provide sufficient medical coverage to its citizens, it is quite surprising that the Philippines has put in place a national newborn genetic screening program that has been mandated by legislation. It is equally surprising that the legislative process leading to the enactment of the Newborn Screening Act occurred without inviting adverse publicity. The Law provides all Filipino newborns access to screening for congenital metabolic disorders. It has also provided for the creation of a Newborn Screening Reference Center (NSRC), with the responsibility to be the repository of technical information relating to newborn screening. Medical assistance is meant to be given to newborns detected with life-threatening congenital metabolic disorders before the onset of the clinical symptoms.

Under the Law, parents are required to present their children for newborn screening except when they have religious objections. And if they refuse, Article 3, Section 5 of the Act requires them to acknowledge in writing that their decision "places their newborn at risk for undiagnosed heritable conditions. . . ." This hardly leaves parents with a choice, although an alarming number of families are known not to be able to afford the cost of screening. Moreover, it is not clear that parents are properly educated about the procedure and its implications or that there are qualified counselors to give proper advice. Meanwhile, samples collected for screening have accumulated, thus presenting temptations for their use even before ethical guidelines could be clearly formulated.

Major Bioethics Issues and Discussions

Abortion

Notwithstanding the legal prohibition and the firm opposition coming from the Catholic Church, an increasing number of induced abortions are being close to half a million taking place each year, and about 800 women die annually from unsafe abortions. One out of every three women who unintentionally get pregnant seeks an abortion, most of them poor and reporting themselves to be Catholics. Many of them rely on nonmedical personnel for help in ending their pregnancy. Only about 30 % obtain an abortion from a medical doctor. Obviously, socioeconomic factors play the key role in the decision to abort.

The alarming experience with unintended pregnancies and induced abortions may partly be due to a failure to legislate and implement a good reproductive health program that makes options available to women and gives them reliable information regarding those options. The Reproductive Health Bill currently being debated in Congress seeks to enhance women's options, but it remains to be seen whether the Bill will generate sufficient support to stand up to the opposition presented by the Catholic Church. If it does, we can say that the country is truly on the way to the maturation of its collective bioethics sense.

Reproductive Health

The Philippines has had to deal with the economic impact of its huge population and robust population growth rate over several decades. It has gone through a series of population control programs but has never succeeded in lowering the rate at which its population has grown. Starting out as a poverty-alleviation strategy in the 1970s, the family planning program became part of a combined social welfare and health initiative in the late 1980s. Recently, it has emerged as a reproductive health program seeking to balance the population, the available resources, and the environment. Faced with a population growth rate of 2.5 % and an estimated current population of close to 100 million, the government has taken initiatives to address population management as a poverty-alleviation, health, and development strategy. Many people feel that the population figures reflect a sad state of reproductive health that is also characterized by a surprising number of unintended pregnancies, induced abortions, and maternal death.

The Local Government Code of 1991 empowered local governments to undertake initiatives in their specific jurisdictions to deal with critical health issues. As a result, ordinances relating to reproductive health have been passed in some municipalities in the Philippines, the most prominent of which have come as a response to church lobby. Obviously, the Catholic Church has been busy promoting adherence to its core principles relating to reproduction: (1) The use of "artificial obstacles" to prevent the formation and birth contradicts the idea that "human life is the most sacred physical gift" from God, and (2) Parents have the "primary inalienable right and responsibility" to care for, nurture, and educate their kids.

In Quezon City, the response went against the expectations of the Catholic Church. While the ordinance reiterated the prohibition on abortion, it sought to make access to reproductive health information and services available to all, which included even the "nonnatural" means that the Church opposed. The ordinance also allocated funding for basic services that included adolescent health education beyond the confines of the family. The other ordinances in the city of Manila and the provinces of Palawan and Laguna supported only "natural" methods of birth control. The most controversial among the lot was an ordinance passed by the barangay council of a place called Ayala Alabang. The barangay is known to be a residential area for some of the country's rich and famous.

On January 3, 2011, Barangay Ayala Alabang passed an ordinance seeking to protect the unborn and the institutions of marriage and the family by penalizing any natural or juridical person who would advertise, endorse, prescribe, or distribute abortifacients where abortifacients were defined as "any device, medicine, substance, or practice which may damage, injure, interfere with the natural development, endanger or cause the expulsion or death of an unborn child." Abortifacients included intrauterine devices (IUDs) and hormonal contraceptives. The ordinance also required that contraceptives (including condoms) be sold only to consumers with a written prescription. This last provision easily caught public attention and resulted in a backlash that would have made the members of the barangay council regret their moment of legislative adventurism. The controversy that the ordinance generated showed that bioethical activism is alive and vibrant.

End-of-Life Issues

Advanced Directives

In November 3, 2010, Senate Bill 2573, the "Advanced Directives Education Act," was introduced by Senator Miriam Defensor Santiago that required the Secretary of Health to "develop and implement a national public education campaign on the importance of advance care planning and of an individual's right to direct and participate in his or her health care decisions" no later than January 2012. The Bill recognized the importance of having an advance directive that reflects the patient's values and wishes for care. It stated the right of the patient to direct and participate in his health-care decisions. It also spoke of the need for an ongoing dialogue among the family members, relatives, health-care proxies, and health-care providers to determine and be guided on how to come up with health-care decisions especially when the patients are already unable to express his/her wishes. The Bill calls on the Department of Health to employ the use of media materials and culturally and linguistically appropriate information to raise greater public awareness of advance care planning.

The passing of the Bill would have signified progress on the way to overcoming the paternalistic tendencies in Philippine hospital settings where many patients accept leave all decisions to doctors almost without regard for their own wishes and values. Thus, even if patients and families are instructed and encouraged in hospitals to assert their rights, further efforts need to be undertaken to truly enable them in this regard.

The filing of the above Bill acquires particular significance in view of the experience with proposed legislation seeking to provide a clear legal framework for implementing life or death decisions. In the meantime, medical doctors privately speak of cases where they allowed or advised relatives of patients to take matters into their own hands by pulling the plug themselves when they were convinced that further treatment was futile. Problems also arise when patients no longer could afford the cost of hospitalization and are forced to check out of the

facility even at the risk of death. Few hospitals have clearly laid out rules regarding the release of patients against medical advice although the practice goes on without much controversy. Even in situations when further treatment could still reverse the likelihood of a fatal outcome, economic factors dictate unpalatable decisions that hospital administrators have learned to recognize as part of everyday reality. In this kind of settings, futility could be seen in relation to economic rather than merely (or mainly) medical indications.

HIV/AIDS

The threat of HIV/AIDS gave rise to a legislative response in the 1990s that showed a highly mature bioethical sense. At the same time, the Department of Health thought it useful to draw attention to the problems the country was facing by engaging the help of a patient who was to go around the country and provide a "face" to the disease as authorities explained the imperative for cautious sexual behavior and for treating victims with care and compassion. For this purpose, the government selected a young female patient who had previously engaged in sexually promiscuous behavior. The young woman was to take on the task in the Philippines that a highly popular and successful basketball player had performed in the United States. While this gimmick succeeded in calling attention to the disease and the problems that came with it, the effect on the young woman herself was a tragedy. The public attention seemed too much for her to bear as continued to engage in unprotected sex with multiple partners. She finally settled down with an equally young partner with whom she bore a child, and their collective life story provided a touching and very educational illustration of the problems that HIV/AIDS victims faced.

Passed in 1998, the Philippine AIDS Prevention and Control Act sought to protect infected individuals from discrimination and injustice. The Act prohibits compulsory HIV testing as a precondition for employment, admission to educational institutions, exercise of the freedom of abode, entry to or continued stay in the country, travel, or the provision of medical or any other kind of service. It also protects the right of HIV/AIDS patients to seek an elective or appointive public office, to access credit and insurance, to receive health-care services without additional cost, and to decent burial services. There is also a clear commitment to privacy and confidentiality, as the Act requires HIV testing to ensure anonymity. Even though it provides for the mandatory reporting of HIV/AIDS cases to authorities, the Act provides for the "confidentiality of any medical record, personal data, file, including all data that may be accessed from various data banks or information systems." The use of information in data banks and information systems is limited to statistical and monitoring purposes.

Seeing the utmost regard to protect the rights of patients in the Act, it is quite ironic that this concern has not been reciprocated by countries with whom Filipinos have had to relate in their capacity as overseas workers. Filipinos who are seeking to find work in other countries have had to put up with the requirement for

HIV/AIDS testing as part of their application. It is also ironic that many reported HIV infections in the country have been imported from overseas by Filipino workers. As the country complies with international standards for the ethical management of HIV/AIDS, it finds its own citizens shortchanged when those standards are not maintained in countries served by Filipino workers.

Assisted Human Reproduction

Assisted human reproduction is a practice that has gone on mainly beyond public bioethical scrutiny. Local practitioners are mostly those who have established their practice in the country after having undergone training in fertility clinics abroad. They have brought with them not only the technology but also the ethical framework that provided the context for their practice abroad. As they operate on the basis of the same protocols that guided their training abroad, many of them may not be fully aware of the ethical implications of transporting a practice to a sociocultural environment that is not necessarily informed by the same values and traditions.

There has not been much awareness of the practice in the country, and this probably explains why there has not been much public discussion of ethical issues surrounding the practice in the local setting even as the first delivery of a child conceived through the use of either assisted insemination or in vitro fertilization (IVF) took place in 1996. The National Ethics Committee anticipated this development when it included in the 1995 edition of the National Guidelines for Biomedical/Behavioral Research provisions pertaining to the use of and research on embryos. In particular, the 1995 guidelines sought to prohibit the intentional creation of human zygotes, embryos, or fetuses for study, research and experimentation, or for commercial and industrial purposes; to limit research on an embryo to procedures intended to improve its life and health; to prohibit the sale of human gametes or zygotes; to limit the application of assisted reproductive procedures to married couples; to direct medical practitioners to ensure the emotional stability and maturity of beneficiary couples; to uphold the dignity and anonymity of the couples involved; and to prohibit the selective reduction of embryos.

The guidelines issued by the Philippine Society of Reproductive Endocrinology and Infertility (PSREI) in 2006 allow the use of techniques that utilize preconception sex preselection but with a qualification that does not allow "embryonic gender identification for social reasons alone." Operationally, this means allowing preimplantation genetic diagnosis for embryonic gender identification only in cases where there is a strong family history of sex-linked genetically transmissible disease (hemophilia, muscular dystrophy, etc.).

An effort to satisfy the Catholic position is also evident as the guidelines mention that "the zygote, pre-embryo, or embryo, are already considered unique human beings and are therefore entitled to full moral support as that of an adult." Couples undergoing the procedure are expected to give prior agreement to cryopreservation of excess embryos, but it is not clear how this could be sustained over prolonged

periods. There is also an expectation of minimal stimulation of ovarian follicles so that all embryos formed are transferred during the fresh cycle in order to avoid fetal reduction.

While official Catholic thinking is reflected in the recognition that the zygote, pre-embryo, or embryo is a unique human being entitled to full moral support, the guidelines appear to get into some contradiction by accepting "pre- implantation Genetic Diagnosis, whether carried out on gametes or embryos. . .when carried out to identify specific genetically transmissible abnormalities to help couples avoid the possibility of having abnormal children." One also wonders what could be meant operationally by the provision in the same section that "the disposition of the genetically abnormal embryos shall be the responsibility of the couple and shall be ascertained before the evaluation is done." These provisions of Section 24 appear to open the door for exceptions to a traditional interpretation of Catholic doctrine. It seems that specific guidance pertaining to the implementation of the guidelines under certain conditions is necessary.

Organ Transplantation

Organ transplantation is one of the areas of health care that have drawn the attention of lawmakers in the country. The story of bioethics pertaining to this field has unfolded in various stages corresponding to headline-worthy controversies. During the early period of its introduction into the country, organ transplantation elicited adverse publicity as it became known that prisoners were being recruited to serve as organ donors. Pioneer practitioners spoke of going to prisons to find donors unaware of the ethical considerations and the controversy that this could generate. Anecdotes of prisoners being given monetary compensation and material rewards for transplantable organs circulated. Nevertheless, authorities could not react readily in the absence of a clear and explicit ethical or legal framework that could be applied. Some reports were documented by foreign researchers.

The passage of Republic Act No. 7170 Authorizing the Legacy or Donation of All or Part of a Human Body after Death for Specified Purposes provided the initial legal framework for the retrieval of organs for transplantation by allowing the declaration of death to be made on the basis of cardiac and respiratory functions or on the basis of brain functions. A person could be declared dead in the absence of unaided cardiac and respiratory functions or in the event of the irreversible cessation of all functions of the entire brain, including the brain stem. The Law also gives heads of hospitals permission to authorize the retrieval of organs from brain-dead patients whose relatives could not be located after reasonable search.

The first case that brought the provisions of this Law into public attention arose after transplant physicians were sued for removing the kidneys, liver, and pancreas of a brain-dead accident victim. The relatives of the victim went to court as they failed to appreciate the legal implications of brain death. This happened after they discovered that the subject of a newspaper story about a successful multiple-organ transplant was actually the relative they were looking for. Surprised that the

transplant could take place without their consent or that of the donor, they accused the doctors of committing murder. For them, their relative was not "truly dead" when his organs were taken – he was only "brain-dead." It was one thing for a person to be dead in the eyes of the law and another thing to be dead in the eyes of loved ones, especially when taken in the context of organ retrieval for unconsented transplantation. The doctors were eventually acquitted but only after months of adverse publicity that effectively scared potential organ donors away as organ transplantation ground almost to a halt. More controversial developments were to follow.

The next controversy erupted when living donors grew quickly in number and filled the transplantation demand in a way that cadaveric organs could not. A massive trade in organs in various communities in Metropolitan Manila. The program host interviewed freshly scarred impoverished men from slum areas in Manila who had sold their kidneys. The donors jumped at the opportunity to make money in such amounts they had never seen previously in their entire lives. Some of the organ vendors were happy with the result, but most were not. Many soon realized that rather than monetary gain, they were left with debts still unpaid and an economic predicament no better than they were in prior to the organ sale. Many of them were also stigmatized, discriminated against in the search for jobs, and left to deal by themselves with the emotional and social scars resulting from their experience. People quickly realized that the poor were being exploited, the benefits went only the rich, and the rich were mostly foreigners who came with their valuable foreign currency.

Seeing the inevitability of the unfortunate outcome for paid organ donors, one easily understands why arguments supporting their right to receive payment could not be accepted. The poverty and ignorance of potential recruits clearly are being exploited, and available evidence strongly supports the need to protect them from unscrupulous agents.

Controversy also erupted when the demand for transplantable organs led to a proposal to offer sentence commutation to prisoners who were willing to donate. Because the actual use of prisoners as organ sources earlier had not been documented, the practice did not generate much public attention. The floated proposal did, mainly because proponents genuinely thought implementation could be workable, given the clamor among patients with end-stage renal disease. Much discussed was the example of a death convict who could be given a chance to have the punishment reduced to a life sentence in exchange for an organ to save another person's life. The proposal came from an interested party that stood to gain directly from its approval and implementation – the Kidney Patients Association of the Philippines. A highly placed leader of the Catholic Church expressed support, but no legislator was courageous enough to sponsor a Bill in Congress. The proposal made no further progress, and it appears unlikely now that it would be revived.

The use of support foundations to provide material and medical assistance to kidney donors has been a growing practice. These foundations have been known to ensure the delivery of pre- and post-transplant care to donors who are recruited under their auspices. These nongovernmental organizations are supposed to look

after the donors without situating the provision of assistance within a context of organ trade. However, it has not always been easy to ensure that the foundations have not merely been a cover (deliberate or inadvertent) for commercial transactions. The support given by these foundations includes monetary or other material assistance that could easily serve to incentivize the transactions for the vulnerable poor in a way that exploits their economic vulnerability.

Some of the experiences with these foundations are indicative of how they have been perceived. For example, there are many who have seen these establishments as commercial brokers. On many occasions, donors come to their offices indicating their willingness to make an organ available for a fee and inquiring about terms. Although these foundations insist that they have turned away individuals who have clearly wanted to sell organs, there is no denying the fact that their assistance packages have included money or material equivalents. It is not easy to explain why there is a substantive ethical difference between an outright sale and a donation made with a view to receiving an assistance package with such a material component.

After having donated organs in the past, some donors have been known to come back to ask if there is another organ that they could be asked to donate. Moreover, although donors are advised that they have to come back for follow-up medical examinations after the donation, not all of them actually do, partly because middlemen warn them that they have to make themselves scarce after the procedures to avoid having to answer questions pertaining to the donation that could be incriminating. And some of them are so poor that they would not be able to come back for medical checkups because of the cost involved. It could also be their ignorance of the health risks involved in organ removal that prevents them from coming back.

The latest official development regarding organ transplantation in the country is the release of Administrative Order No. 2008-0004-A by the Secretary of Health declaring the official policy that "foreigners are not eligible to receive organs from Filipino living non-related donors." The Order appears to have put a stop to the travel of foreigners to the country to be transplanted with local organs. However, the initial reaction to this announcement was a flurry of requests for exemption, confirming the extent to which medical tourism for the purpose of organ transplantation was being practiced.

Consistent with WHO guidelines on organ transplantation as well as with the Declaration of Istanbul on Organ Trafficking, current policy in the Philippines has been implemented successfully. In this respect, the country has been able to protect the vulnerable poor from transplant-related exploitation by foreigners. Nevertheless, the use of monetary incentives to recruit organ donors for transplant to local patients still prevails. This practice deserves to be given continuing attention by authorities.

Health Literacy

Article 2, Section 15 of the 1987 Constitution states that "the State shall protect and promote the right to the health of the people and to instill health consciousness among them." The Department of Health has the mandate of creating, regulating,

and promoting the health and health consciousness among the Filipinos through its health representatives in the municipalities.

The strategy of the Department of Health was to aggressively launch its campaigns during those periods when they are most timely. For example, in the rainy season, it will not be surprising to have commercials on *dengue prevention* (hemorrhagic fever) when mosquitoes are most prevalent and when many Filipinos suffer from floods and stagnant waters near their living areas. During the holidays of Christmas and New Year, gory images of amputated body parts caused by firecracker accidents are shown to raise caution on the hazards of their use. One of the most retentive campaigns was the one on the dangers of smoking where they used the catchy phrase "Yosi Kadiri" (roughly translated as "smoking is disgusting") together with its representative mascot. Nowadays, hospitals use the visual illustrations of a smoker's body to instigate a more fearful attitude for their body should they be firsthand or secondhand smokers.

Health literacy programs and awareness campaigns are helped spread by nongovernment organizations. The Likhaan Foundation, an NGO representing women's interests, made a documentary on the implications of the lack of support on modern contraceptives and failure of the government of Manila for a more responsive reproductive health agenda. They presented women who underwent illegal and unsafe abortions because of their unintended pregnancies. Notable also is the network on the Muntinlupa Youth Health Development program that primarily is targeted to improve health-care services and information to the urban poor youth of the municipality of Muntinlupa. The program involves cooperation with various stakeholders within the community including the teachers and the youths themselves.

Bioethics Development

In the last decade, bioethics has gained status and relevance in Portugal. Due to postgraduate teaching, a core of doctors, lawyers, nurses, and others have attained an excellent knowledge and a solid basis for teaching and research activities. Thus, the field is dominated by amateurs, albeit of good will, but rather by people who have acquired experience and skills. This is a novelty, as well as the emergence of academicians with Ph.D. degree in bioethics.

DOI 10.1007/978-94-007-2512-6_45,

When and How Has Bioethics Started

If the early phases of the development of bioethics are considered as a fast growing new area of science and morals, which independently of its American origins showed a marked tendency to expand in different continents, its beginnings were relatively late in Portugal. In fact, the first organized and structured group devoted to bioethical questions was established in Coimbra in 1988 as a nonprofit-making and independent organization (Centro de Estudos de Bioética) after the founding group had met informally for 2 years. Since then, however, there has been a remarkable evolution, a rapid expansion having occurred, with a relatively large number of graduates enrolling on Ph.D. and master courses. This has led to a considerable number of people of diverse backgrounds (doctors, nurses, philosophers, theologians, teachers, etc.), to acquire solid academic skills in the bioethical area.

Who Have Been the Major Actors/Forces

The main fora of bioethical debate are based in academic institutions and in societies which attract interested people. Curiously enough, universities generally were slow in recognizing the need for bioethical institutions to be created inside their own structures. The first institution responsible for acceptance and diffusion of bioethics in Portugal was undoubtedly the Centre of Bioethical Studies (Centro de Estudos de Bioética), which, since its foundation in Coimbra in 1988 in consequence of an informal think tank which had been working for 2 years, i.e., since 1986, has contributed enormously to the positive evolution of the area in this country. The CEB is an independent, non-confessional, nonprofit organization with a long roster of activities (see below).

The National Council for Ethics in Life Sciences (CNECV) is an advisory board dealing with all kinds of bioethical questions and giving opinions to the Government, National Parliament (Assembleia da República), and President. Founded in 1990, the CNECV has up to the present published 63 opinions on a variety of themes, ranging from medically assisted reproduction or the use of embryos for scientific experiments to obligatory testing for HIV-AIDS, from genetic data management to end-of-life questions, from drug abuse policy to death and transplantation, etc. It is a highly regarded organ and has exerted appreciable influence on the laws passed by the parliament. The chairperson was formerly nominated by the Prime Minister, while the other 20 members were nominated by 10 different entities (parliament and ministries, but also doctors', bar, and biologists' associations, the Academy of Science, and other academic bodies and/or citizens' organizations). Portugal was one of the first European countries to feel the need for a bioethics committee at the national level, established by Law No. 14/90, of 9 June 1990 (amended by Law n° 24/2009, of 29 May). On 29 May 2009, Law No. 24/2009 was enacted. In addition to other changes, the chairperson is currently elected by the members and modifications have also taken place with regard to the entities responsible for choosing the members.

The Centre for Biomedical Law (Centro de Direito Biomédico, CDB), an institute of Coimbra University Law School, has a relatively long history and since 1988 has reflected on problems arising from clashes of interest and the interpretation of deontological codes of the medical (and pharmaceutical) professions and their strict legal aspects and consequences.

The schools of medicine located at the universities of Lisbon, Coimbra, and Porto resorted to various means of teaching medical ethics, but it was only in 1996 that Porto University School of Medicine created a Department of Bioethics and Medical Ethics (Serviço de Bioética e Ética Médica, SBEM); thus for the first time the word bioethics appeared in the curriculum and organization of a medical school. In Lisbon, the School of Medicine was to follow suit, creating a Centre of Bioethics (Centro de Bioética) in 1998.

Nevertheless, the only university department dealing with bioethics in a wider sense, i.e., without conceptual and institutional links with medical teaching, is the Institute of Bioethics of the Portuguese Catholic University, which evolved in 2002 from a preexisting bioethical research group founded in 1995. This does not exclude other university departments from having contributed significantly to bioethical thought. In particular two philosophy departments should be mentioned, namely, that of the University of Azores (in Ponta Delgada) and the one in Braga (Faculdade de Filosofia da Universidade Católica Portuguesa). Both have a curriculum of postgraduate teaching of bioethics and have published books on relevant matters.

The Portuguese Association of Bioethics (Associação Portuguesa de Bioética) was formed at a relatively late stage (2003), the above-mentioned Department of Bioethics and Medical Ethics (University of Porto) maintaining very close personal and institutional links with this association.

Needless to say, all these institutions exert functions which are of relevance to the national evolution of bioethics. This will be summarized in the following sections.

What Have Been the Major Concerns Over Time

What Resources Have Been Developed

It is no surprise that the increase in bioethical activities and the considerable amount of research have resulted in a growing number of publications.

The "Revista Portuguesa de Bioética" (former Cadernos de Bioética), edited by the CEB, is the sole regular journal dedicated to bioethics. It has published quite an impressive array of articles in its 42 issues. Of course, a number of contributions dealing with bioethical questions are regularly published in medical journals, publications of doctors' and lawyers' associations, confessional journals, and cultural magazines. Popular and TV channels give (sometimes sensational) coverage to cases considered to be paradigmatic, such as the Schiavo case or the alleged cloning of human beings. Although people with bioethical knowledge are usually interviewed in this context, the majority of these reports are of poor quality.

Almost 80 books, strictly pertaining to bioethics, have been published in the last decade. These publications range from textbooks to more specialized books, dealing with various themes, like bioethics for nurses or for members of institutional review boards (the existence of which is obligatory in every hospital). Some of the themes addressed include ethics of genetics or of the initial stages of human life, cloning, common good and individual interest, clinical trials, eco-ethics, and assisted reproduction.

Two volumes with comments addressed the text of the European Convention of Human Rights and Biomedicine, as a result of the workshops organized by the Institute of Bioethics; they represent the interest of discussing legal documents (the convention was adopted by Portugal) with wide implications for care and cure. Lastly, collections of monographs, either of papers presented to congresses or representing the work of a sole author, complete the roster of these publications. In this area, the National Council of Ethics for the Life Sciences has launched an impressive series of 10 books with the contributions presented in the seminars which it organizes (besides 12 books containing the opinions presented by this body).

Current Bioethics Infrastructure

Public Debate Activities

Impossible as it is to refer to these in detail, within the remit of this short overview, the numerous activities undertaken by the above institutions will be summarized below.

Large meetings were organized by the Centre of Bioethical Studies (CEB) and the Institute of Bioethics to discuss questions of national relevance and themes with important implications for public policy in such a way that both members of the professional bodies and the general public were able and welcome to attend. Furthermore, in 1997 the CEB organized the European Congress of Medical Ethics Centres. At its Coimbra headquarters and branches in Lisbon, Porto, Azores, Évora, Madeira, and Braga, a number of regular meetings took place to deal with many important questions of bioethical interest. The annual seminaries organized by the National Council on Ethics for the Life Sciences (now in its 11th edition) represent important events and are usually attended by large audiences. The National Congress of Bioethics (now in its 12th edition) meets also annually; the last seven conferences have been organized by the Portuguese Association of Bioethics. There are still a large number of smaller meetings and workshops, often dealing with specialized areas (e.g., vulnerability at the beginning and end of life, teaching of bioethics in secondary schools, problems in the care of premature babies, terminal patients and palliative care, conservation of water resources) and attracting selected scholars. Moreover, scientific societies, lawyers' associations, and lay and confessional organizations often include in their conferences or meetings extra sessions dealing with bioethical questions of special interest to their members. Thus, there are actually several opportunities for either extending one's bioethical knowledge or interesting oneself in or acquainting oneself with the pertinent questions.

Teaching of Bioethics at University and Other Levels

As stated before, the university has been rather slow in recognizing its mission to teach and diffuse the knowledge of bioethics. In fact, only in 1986/1987 was the first postgraduate course on bioethics (dealing with the theme of medically assisted reproduction) launched (by the Faculty of Philosophy of the Catholic University, on its Braga campus). Since then, postgraduate and master courses of much larger scope, encompassing the whole gamut of bioethical issues, have been or are being organized by the above-mentioned universities where bioethics is a recognized constituent of the academic structure. Thus, the Institute of Bioethics of the Catholic University and the Department of Bioethics and Medical Ethics of the Medical School of Porto University each organized seven master courses, the Faculty of Philosophy of the Catholic University and the Centre of Ethics of the Medical School of Lisbon University being responsible for five courses each. As a result, approximately 100 students, after the successful completion of their master's dissertation, have so far been awarded a Master in Bioethics. More recently, the Institute of Bioethics initiated a Ph.D. program, approved by the Portuguese Accreditation Entity from the Ministry of Education, which is now in its second edition; about 10 students already obtained the Ph.D. degree.

At the graduate level, not only the medical schools but also a majority of law schools and nursing schools reserve a place in their curriculum for teaching bioethics. Surprisingly, faculties of biology and related sciences appear to include the teaching of bioethics only on some courses in their respective curricula.

A number of published studies have dealt with the need to teach an introduction to bioethical questions in secondary schools, and some concrete proposals are being tested in a research study organized by the Research Centre of the Institute of Bioethics. It is hoped that it will be recognized by the authorities that the implementation of a strategy offering young people first contact with the main questions of general bioethics would be worthwhile, for example, by choosing questions which can be discussed under the guidance of teachers of biology and philosophy. This innovative pedagogic approach has still a long way to go before being adopted.

Moreover, postgraduate students, albeit in small numbers, can make exchange visits to other foreign countries. São Paulo, Brasília, and Bahia in Brazil and Barcelona, Rome, Padova, and Paris in Europe have been cities at the hub of this international exchange.

Links to the United States, the UK, and other European countries also exist, kept alive by people who obtained their degrees in these countries or as a result of cooperation with foreign scientists on several research projects funded by the European Union. Portuguese scholars have been regularly appointed to the specialized bodies of the European Council, the European Union, and UNESCO, which deal with bioethical questions (respectively, Comité Directeur pour la Bioéthique, the European Group on Ethics of Science and New Technologies, the International Bioethics Committee).

Needless to say, a significant proportion of bioethicists from other countries have been invited to give conferences and seminars in Portugal and have contributed to the tutoring of postgraduate students preparing their dissertation.

Bioethics Committees

In Portugal, besides the National Council on Ethics for the Life Sciences (CNECV) and following the transposition of the European Directive 2001/90/CE, a National Committee for Clinical Research (CEIC) has been created in 2005; since then, all clinical trials must be approved by this committee.

Before the implementation of this new law, all the clinical trials were approved by the hospital ethics committees which by law are mandatory for all hospitals. After the implementation of the clinical trials directive, these committees are responsible for all research, apart from clinical trials, as well as for matters rising from the relationship of patients with health professionals and the institution itself.

Expert Bodies/Centers

The development of the master's dissertation involves a certain degree of research, and this has certainly been the case with the ones already approved. A much higher degree of quality research is undertaken by the school that offers a Ph.D. program. Apart from the individual research involved in the preparation of a master's dissertation or a doctoral thesis, research projects (both of a national and international cooperative nature) have and are being conducted by two institutions, namely, the Institute of Bioethics (Catholic University) and the Department of Bioethics and Medical Ethics (Porto University School of Medicine). For the time being, the only institute which may grant a Ph.D. degree in bioethics fully approved by the Portuguese accreditation agency is the Catholic University Institute of Bioethics, offering a program with classes in the 1st year followed by a structured program of research. Research, via the institute's research unit – the Bioethics Research Centre – has been another fundamental area for the building and credibility of the Institute of Bioethics. An international evaluation panel, mandated by the Foundation for Science and Technology from the Ministry of Science and Education, classified it as "very good," ensuring that the center's activities have been supported. The center also received funding from other institutions and recently a "trust" on bioethics has been established. The Bioethics Research Centre is currently focusing its activities on five research areas: medical ethics (with three research lines: (1) pediatric palliative care; (2) who cares for the carer, "burnout" in carers; and (3) ethics in public health) and ethics, science, and society (with two research lines: (1) teaching of bioethics in secondary schools and (2) using bioethics as strategy for teaching science to lay people).

Some examples of research lines from the Department of Bioethics and Medical Ethics (Porto University School of Medicine) include deaf-mute recuperation and ethical problems, xenotransplantation, and the ethics of allocation of means to health-care providers as well as living wills.

Thus, the outlook for the progressive involvement of Portuguese bioethicists, and especially of those of the younger generation, in research in fundamental and applied ethics appears to justify some optimism.

Relevant Legislation

It is understandable that all laws which in one way or another affect health and environment are of relevance to bioethics. Here, however, only those laws which appear to be of the utmost importance in the field and/or those which have been submitted to the CNECV for opinion (which is mandatory in the present legal framework) will be mentioned. Since the CNECV is an organ of a consultative nature, it follows that the law is not forced to follow the opinion and recommendations of the CNECV, but its statements clearly exert an influence on the legal text.

In Portugal abortion is a crime punishable by imprisonment (from 2 to 8 years), except under conditions such as danger of physical or mental harm to the pregnant woman, presence of severe and incurable disease in the fetus, and pregnancy after rape. In 2007 a referendum was conducted with the following question: do you agree with decriminalization of abortion, if done by women's option, in the first 10 weeks, in a legal authorized health service? Although there was a high proportion of abstentions, the result was favorable to the pro-choice current (59.25 % vs. 40.75 %). After the referendum a new point of exclusion has been included in the law, and since then, women may request an abortion till 10 weeks of pregnancy.

Following the law Lei n° 12/93, of April 22 (now amended by Law n° 22/2007 of June 29), transplantation is possible, the donors being dead (after diagnosis of brain death) or alive, subject to certain requirements; there is a registry of non-donors (people who declare that they do not allow their organs to be removed after death for transplantation purposes; all other people are presumed to agree with donation of their organs). Corpses may be used for teaching and research purposes under very limited conditions, prior informed consent of the person still living being mandatory.

Clinical trials are strictly regulated by the European Directive that has been adopted by the country (Law 46/2004 is a transcription of European Directive 2001/90/CE). Following that directive a National Commission (CEIC) has been established and is in charge of all clinical trials.

Medically assisted reproduction (MAR) has been regulated by a law in 2006, after decades of practice outside the legal framework. The present law restricts MAR to heterosexual couples (married or otherwise), but in exceptional cases allows heterologous fertilization and even surrogate motherhood. Surplus embryos may be used for research, and donation to other couples is also possible, with parental authorization and after a couple of years in a frozen state.

Finally, the incorporation into Portuguese Law of the European Convention of Human Rights and Biomedicine represents an important milestone along the path of bioethics in Portugal. With its insistence on informed consent, dignity of the human being, priority of individual interest over common interest, and prohibition of the production of human embryos for research purposes, it conveys an important array of bioethical notions which will strongly influence future legislation of bioethical significance.

Future Challenges

In the Field of Bioethics Infrastructures

Due to its characteristics, bioethics tends to be more international in its scope than many other areas of academic research. The goal, which many will call utopian, of reaching a universal bioethics consensus, which may guide attitudes and actions in vast areas of life sciences and preservation of the biosphere, is not attainable if people from different countries and continents do not exchange their views, discuss their cultural backgrounds, compare their basic tenets, and try to find some common ground. It is hardly surprising, in this context, that since the beginning of the "bioethical era" (which in Portugal really took place in the mid-1980s), Portuguese scholars have tried to establish and maintain links with colleagues and institutions in other countries. Due to language and cultural affinities, regular contacts were established with Brazil and other Latin countries (Spain and Italy). Portuguese and Brazilian scholars have held conferences and courses in each other's countries, and from this cooperation a Congress (Encontro Luso-Brasileiro de Bioética) has emerged (with its 7th edition in Lisbon in July 2012, following earlier conferences in Lisbon, Brasília, Ponta Delgada, São Paulo, Porto, Salvador da Bahia). This represents an important meeting opportunity, in which points of view are exchanged and approaches are discussed, with the bonus of common cultural and linguistic backgrounds being shared.

The UNESCO Portuguese Chair of Bioethics has been established at the Institute of Bioethics of the Portuguese Catholic University in 2007 and is held by Professor Walter Osswald. The project "UNESCO Portuguese Chair of Bioethics" focuses specially on development of bioethical training in Portuguese-speaking countries (apart from Portugal, Republic of Angola, Republic of Cabo Verde, Republic of Guinée-Bissau, Republic of Moçambique, Democratic Republic of S. Tomé e Príncipe). The main objective is the realization of a formation program of constitutive members of ethics committees. The unethical experiences, reported in several scientific publications, concerning research tests which are offensive to dignity and to the integrity of human persons in African countries that have no ethics committees (or in those which do not work), lead to the important collaboration with the local authorities, in order to form responsible and knowing elements able to integrate competent and active ethics committees.

A large community of Portuguese-speaking bioethicists can only gain from a cooperative effort to identify particular points of interest, approaches, and challenges in their respective countries and to foster collaboration between them in the capacity-building effort directed to students coming from Portuguese-speaking countries. This project can be subdivided in two main objectives: bioethics training program and strengthening and launching of ethics committees within African Portuguese-speaking countries.

Any Other Problems and Opportunities for the Further Development of Bioethics in the Country

A very important contribution to the international recognition of Portuguese work in this area depends on the publication in international journals of papers originating from this country. This is happening on a rather modest scale, and this type of activity needs to be encouraged and fostered. Portugal needs also to set up a local or national research ethics committee, ideally working in close cooperation with the main research funding agency, the Foundation of Science and Technology. A recent development consists in the creation of an ethics review structure in the frame of this institution, the ethical evaluation of all projects involving human beings and animals being thus warranted.

Calvin W. L. Ho, Jacqueline J. L. Chin, and Alastair V. Campbell

Introduction

Bioethics in Singapore is principally encapsulated in three main systems of values, practices, and concerns. The first to be formalized in regulatory and institutional structures relates to the practice of medicine and its allied disciplines. Naturally, this value system incorporates clinical ethics. The second is generally referred to as research ethics and applies to a broad range of biomedical research and clinical trials. The third is concerned with bioethics as an academic discipline and is

referred to as biomedical ethics. All three have been profoundly shaped by the healthcare infrastructure as well as the Singapore Government's Biomedical Sciences Initiative that was rolled out in June 2000 to establish the city state's biomedical and pharmaceutical capabilities as one of its key economic drivers.

This chapter provides an analytical overview of each of these systems, beginning with a brief description of the healthcare infrastructure. In the past decade or so, the Ministry of Health (MOH), the Bioethics Advisory Committee (BAC), and the Centre for Biomedical Ethics (CBmE, at the National University of Singapore) have been three important actors that shaped the ethical governance of medical practice and education, as well as biomedical research, in Singapore. MOH was responsible for establishing a system comprising hospital or clinical ethics committees to consider and address ethical issues in clinical practice. It has also implemented a variety of policies directed at meeting existing and emergent healthcare and public health needs and concerns. Some of the policies to be discussed in this chapter include those relating to reproductive medicine, infectious diseases, organ transplantation, palliative care, care for the elderly, and mental health. Working collaboratively with MOH, BAC has been instrumental in setting up a research ethics governance framework, primarily administered through institutional review boards (IRBs). It has also promulgated ethical guidelines for research relating to human pluripotent cells, genetics, human tissue, and personal information. Since its establishment, CBmE has supported both MOH and BAC by its research and expertise and has developed training programs for ethics committees and IRBs. Its scholarship has been important in establishing Singapore as a center for the ethical conduct of (bio-) medical practice and research. This chapter presents bioethics in Singapore as the outcome of the collaborative work of the MOH, BAC, and CBmE and concludes with a brief indication of some challenges in the foreseeable future.

Overview of the Healthcare Infrastructure

The healthcare infrastructure comprises different healthcare components, including primary, hospital, as well as intermediate and long-term care. In 2011, private practitioners provide 80 % of primary healthcare services, while 20 % is provided by government polyclinics. These proportions are reversed for tertiary care, where public hospitals account for 80 % of hospital care, whereas the remaining 20 % is met by private hospital care. There are seven public hospitals, comprising five general hospitals, a women's and children's hospital, and a psychiatric hospital. Inpatient and specialist outpatient services and a 24-h emergency assistance are provided in all general hospitals. In addition, there are six national specialty centers for cancer, heart, eye, skin, neuroscience, and dental care. As for long-term care, a range of resident and community-based healthcare services is available. They include community hospitals, chronic sick hospitals, nursing homes, sheltered homes for patients who have recovered from mental illnesses, inpatient hospice institutions, various home-based services, day rehabilitation centers, dementia day care centers, and psychiatric day care centers and rehabilitation homes.

There are a number of relatively distinctive characteristics of the system. First, it may be broadly described as "bifurcated" in that it comprises a large private general practice and specialist healthcare sector on the one hand and a network of government-subsidized polyclinics and "restructured" hospitals on the other. The two are not necessarily linked, as financially well-endowed patients can choose to seek treatment from specialists without requiring a referral from a polyclinic. Second, clinics in private general practice are responsible for both the examination and diagnosis of patients, as well as dispensing or prescribing drugs. Third, the healthcare infrastructure operates on mixed financing in three tiers: (a) government subsidy of up to 80 % of the total cost of treatment in acute public hospital wards; (b) a "co-pay" arrangement whereby a Singaporean can draw on funds from his or her Medisave, which is a compulsory individual medical savings account scheme that requires all working Singaporeans and their employers to contribute a part of the monthly wages into their accounts that are portable across jobs and into retirement; and (c) coverage under a low-cost catastrophic medical insurance scheme (or MediShield), which can be further enhanced (with integrated private insurance policies) for treatment in the private sector or supplemented (by obtaining additional coverage against severe disability, for instance). As an ultimate safety net, the government has established a medical endowment fund (known as Medifund) to meet the medical costs of Singaporeans who fall through the three levels of support. The supervening philosophy of this complex financing arrangement is to incentivize individual responsibility toward healthy living in a way that is calculated to keep the overall costs of healthcare down.

These structural features have contributed to a number of ethical challenges in all three domains of bioethics in Singapore. The ability of patients to decide on when and where they prefer to seek treatment could account for a general absence of long-term relationships of trust between doctors and their patients. The question of whether private clinics should be allowed to sell medicines has been an ongoing debate for some time now. More recently, the disciplinary proceeding against a surgeon for charging her patient (a member of the Brunei royal family) S$24.8 million for treatment over 7 months raised widespread debate as to whether a doctor in private practice should be free to operate on purely "market" principles (*Lim Mey Lee Susan* case, 2011). On the research front, a growing emphasis on industrial collaboration and commercialization has fueled concerns that research integrity and welfare of research subjects could be compromised. In the sections that follow, these and other issues, developments and discussions, are considered as concerns in clinical, research, and instructional ethics.

Clinical Ethics

Clinical ethics has been a concern of the MOH, which has overall supervisory jurisdiction over healthcare institutions and standards-setting professional bodies, including the Singapore Medical Council, the Singapore Nursing Board, and Singapore Pharmacy Council. In 2009, hospitals have been directed by the MOH

to set up Hospital Ethics Committees (HECs) to "encourage and promote the ethical care and treatment of patients within the hospital and to assist in resolving ethical problems involving their care and treatment" (Ministry of Health [MOH], 2009b: Section 3). To better enable the ethical provision of healthcare services, the functions of HECs include making recommendations to the hospitals concerned on the formulation of policies, fostering education and training, as well as reviewing and providing advice and recommendations on specific cases. The MOH is itself supported in its formulation of ethical policies and guidelines by its National Medical Ethics Committee (NMEC). Established in 1994, the NMEC assists the medical profession in addressing ethical issues in medical practice and to ensure a high standard of ethical practice. Since 1997, it has issued guidelines on a variety of ethical issues relating to medical practice, such as organ donation, end-of-life issues, apportionment of healthcare expenditure, and advance care planning.

From 1 January 2003, the SMC has been administering the continuing medical education (CME) program, which requires all medical practitioners to attain a level of medical training each year in order to maintain their registration status in order to practice medicine. The CME program includes ethical training to ensure that doctors keep abreast of ethical concerns and expectations. The profession has itself taken different initiatives to develop and promote clinical ethics. Annual scientific meetings of the two main hospital groups (referred to as "clusters") in Singapore include sessions on clinical ethics. Apart from these, the Singapore Medical Association (SMA) has been also been concerned with the development of clinical ethics. Formed in 1959 as a professional medical organization that represents the majority of medical practitioners in Singapore, the SMA has as an explicit goal the support of a higher standard of medical ethics and conduct. In addition, it emphasizes the need to recognize and remove barriers to good ethical medical practice, as well as to strengthen the culture of medical professionalism, through various means including promoting CME and personal professional development throughout a doctor's career. The Centre for Medical Ethics and Professionalism was established by the SMA to help doctors apply clinical ethics in daily clinical practice. The center's goal includes serving as a resource center on medical ethics and health law, developing and providing educational programs for doctors and allied health professionals, developing standards of ethical medical practice, and promoting public awareness of current medical and ethical issues in healthcare.

Research Ethics

Until 2000, engagement with biomedical research ethics has mainly occurred either within highly institutionalized and defined fields of practice, such as clinical trials, or on a "when necessary" basis, by an *ad hoc* IRB or similar body within academic and healthcare institutions. On the former, the term "clinical trials" has been defined by legislation to encompass all biomedical research that relates to the testing of a "medical product" or drug on a human subject. Detailed

provisions are set out under the *Medicines (Clinical Trials) Regulations*, which also incorporate and thereby confer regulatory effect on the *Singapore Good Clinical Practice Guidelines* (SGGCP) of 1998. The SGGCP in turn adapt the international standards prescribed by the guidelines of the International Conference on Harmonisation. Under this regulatory framework, a clinical trial may only be conducted after a clinical trial certificate has been obtained from the Health Sciences Authority (HSA). Initially, ethical approval from a HEC was a precondition to the application for a trial certificate. With the systematization of the ethics review process, this ethics review function has been assumed by an IRB and assessed independently of regulatory approval by the HSA. However, both regulatory and ethics approval will have to be obtained before a clinical trial may be commenced.

It is also a regulatory requirement for a locally registered doctor to obtain ethical and regulatory approval for a proposed clinical trial. In view of the fact that doctors are involved in clinical trials and other types of biomedical research, the NMEC has provided ethical guidance on research involving human subjects. It indicates that the Belmont principles of beneficence, justice, and autonomy upon which the guidelines are premised should be implemented by a research ethics committee (or IRB), to be established by each institution hosting or sponsoring the research (National Medical Ethics Committee, 1997: paragraphs 2.3, 3.1 and 3.2). A number of operational requirements, including the composition of a research ethics committee, have been detailed in the guidelines, along with considerations to be taken up in assessing the ethical acceptability of research proposals. Also important is an explicit indication for members of a research ethics committee to be indemnified (and explicitly indicated in their letters of appointment) by the institution concerned against "the cost of any legal representation and any compensation ultimately awarded to research subjects" (Biggs, 2010: 55–73; National Medical Ethics Committee, 1997: paragraph 3.3.4). The ethical guidelines of the NMEC apply only to hospitals and doctors licensed with the MOH and do not extend to researchers who are not so registered under this professional licensing scheme. However, a bill is currently being drafted, which, if enacted, would extend regulation across the whole field of biomedical research.

Effectively from 2002, an institutional framework on biomedical research ethics was put in place as a matter of national policy mainly through the efforts of the BAC and the MOH. The BAC was established in December 2000 by the Cabinet to provide the government with advice on ethical, legal, and social issues. Since 2002, the BAC has provided recommendations to the Steering Committee on Life Sciences, which was constituted by the Cabinet in June 2000 as the Life Sciences Ministerial Committee. The Steering Committee is responsible for advancing Singapore's biomedical research capability and establishing Singapore as a premier center for research and development activities. Between the years 2002 and 2010, seven sets of recommendations have been published by the BAC, and they relate broadly to the subjects of human embryonic stem cell research and cloning, human tissue, human subjects protection, and genetics. All the recommendations have been accepted by the government.

Although there is an overlap, the BAC's recommendations are directed at the biomedical research community in general, whereas the MOH is primarily concerned with research that either occurs within healthcare premises or conducted by healthcare professionals. This dual approach is due in part to historical factors, particularly since the medical profession and healthcare establishments have traditionally been closely regulated (Singapore Statutes, 2004a, 1999b), whereas researchers and research institutions have not (except for biosafety). In spite of these differences, a governance framework has emerged incrementally and through ever closer connections between the biomedical research and medical communities.

Ethics Review Infrastructure

In 2004, the BAC built on the guidelines of the NMEC and enlarged their application to all human biomedical research conducted in Singapore. Its report on research involving human subjects essentially formalized the requirement for all human biomedical research in Singapore, including research involving human tissue or medical information, to be subject to ethics review by IRBs (Bioethics Advisory Committee, 2004). The guidelines promulgated in the report built on the existing system of regulations for pharmaceutical trials and human biomedical research conducted by hospitals, private clinics, and other healthcare establishments under supervision of the MOH. They also set out the constitution, accreditation, and operation of IRBs, as well as their roles and responsibilities, in addition to those applicable to research institutions and individual researchers. In the main, the BAC regards high standards of ethical governance for the protection of life, health, privacy, and dignity of human subjects in biomedical research as vital to the progress of biomedical sciences in Singapore.

Concerned that there might not have been sufficient resources assigned to enable proper ethical review to be conducted, a number of measures were proposed, including reference to the institutional purveyor of ethical opinion on research projects as IRB rather than "research ethics committee." A major contribution to the entrenchment of this system of ethics review is the BAC's recommendations for institutions to ensure that "core members of the IRB … [have] sufficient and protected time commensurate with the workload of the IRB" and for the IRB to be supported by a permanent secretariat (Bioethics Advisory Committee, 2004: 51–52, paragraphs 7.6–7.8). It expresses a desire "to see institutional review boards established as full-time permanent supervisory bodies organised at and integral to the function of the highest administrative level in all institutions in which research is carried out" (Bioethics Advisory Committee, 2004: 28, paragraph 5.2). The fundamental responsibility of an IRB is set out as conducting ethics review with the "primary objectives of the protection and assurance of the safety, health, dignity, welfare and well-being of human research subjects" (Bioethics Advisory Committee, 2004: 41, paragraph 5.20). By this formulation, the ethical perimeter appears to be broader than the Belmont principles, although there is continued emphasis on free and informed consent, respect for privacy and confidentiality, and

respect for vulnerable persons. References to "dignity" and "welfare" further suggest a more deontological orientation, whereas the NMEC's guidelines could be viewed as consequentialist in its rather substantial discussion on risk and benefit analysis (National Medical Ethics Committee, 1997: paragraph 2.4). To be sure, the guidelines of both the NMEC and the BAC are ethically pluralistic and hence do not reflect a single philosophical ideology, even if one ethical position might be more pronounced than another on a particular subject matter. In the light of increasing research collaborations across institutional and geographical boundaries, more elaborate guidance has been provided by the BAC on ethics review of cross-institutional and cross-border research (Bioethics Advisory Committee, 2004: 36–38, paragraphs 5.42–5.57). Like the NMEC, the BAC similarly highlights the need for IRB members acting in good faith to be indemnified against any liability arising from their actions (Bioethics Advisory Committee, 2004: 54, paragraphs 7.20–7.21). Although the guidelines of the BAC do not have any direct regulatory authority, they have been accepted by the MOH (Ministry of Health, 2006a) and by the Agency for Science, Technology and Research (A*STAR), the principal public funder of biomedical research in Singapore. Consequently, the medical profession and biomedical researchers who are funded by A*STAR are required to observe these guidelines.

In 2007, the MOH issued supplementary guidelines on the day-to-day workings of an IRB, for which the BAC has set out the operating principles. These include guidelines on the composition of an IRB, a more elaborate discussion on the informed consent process, meeting requirements, and requirements relating to documentation (Ministry of Health, 2007b: 8–9, paragraphs 7.10.5, 7.12, Section 10). Interestingly, it did not adopt the BAC's broader formulation of ethical principles but reiterated the three "fundamental" ethical principles (earlier adopted by the NMEC) as respect for persons (encompassing autonomy), beneficence, and justice (Ministry of Health, 2007b: paragraph 3.1). A reason for this could be its primary focus on research involving patients (rather than healthy individuals) as research subjects. Indeed, the governance framework for research ethics in Singapore should not be confused with medical ethics (Ministry of Health, 2009a). The BAC does not address issues of medical ethics (whereas the NMEC does) although a number of its recommendations (particularly those relating to genetic testing and genetic information) could relate to both research and medical practice. As noted above, HECs, rather than IRBs, formulate policies, educate, review, and provide advice on ethical implications arising from the provision of healthcare services (Ministry of Health, 2006b: Section 2).

Research Integrity

The BAC-MOH framework does not explicitly address the requirement of research integrity, however. The NMEC recognizes that the research proposal must be scientifically valid and determined to be so by those with sufficient scientific expertise (National Medical Ethics Committee, 1997: paragraphs 2.4.1 and

3.2.4.1). The BAC goes further in its indication that "scientific review of research proposals does not lie with the IRB. It is for the researchers to satisfy the IRB that an objective review of scientific merit has been carried out and to make these findings (whether positive or negative) available to the IRB" (Bioethics Advisory Committee, 2004: 5, paragraph 24). However, the BAC discusses at some length the issue of conflicts of interest, which is recognized as research misconduct in the USA and the UK (Bioethics Advisory Committee, 2004: 35, paragraphs 5.36–5.41 (institutional conflicts of interest); 44 at paragraph 6.14 (on the part of the researcher); and 47–48, paragraph 6.36 (where the researcher is also the attending physician)). The MOH reiterated the BAC's position on conflicts of interest in its 2007 operational guidelines for institutional review boards (Ministry of Health, 2007b: 11 at paragraph 7.13). Even then, the discussion addresses conflicts of interest as an ethical concern, particularly where the well-being and interests of the research subject are compromised, rather than as a matter of proper research practice. At an institutional level, key research institutions such as A*STAR and the National University of Singapore (NUS) have policies on research integrity. They incorporate to varying degrees the key principles set out in the Singapore Statement on Research Integrity as honesty, accountability, professional courtesy and fairness, and good stewardship of research on behalf of others, while also defining irresponsible research conduct as essentially falsification, fabrication, and plagiarism (Kleinert, 2010).

Academic Biomedical Ethics

The work of the BAC comes within the genre of public bioethics, as it addresses ethical conundra arising from biomedical research by recommending policies that are intended to apply to all members of society (Evans, 2006; Hedgecoe, 2010). It is neither a body that debates foundational issues nor is it concerned with clinical ethics, although a number of its recommendations do affect clinical practice. Foundational bioethics and clinical ethics are addressed by other ethical bodies in Singapore. The former lies within the broad remit of the CBmE, which was established in 2006 at the Yong Loo Lin School of Medicine of NUS. The center operates under the direction of Alastair V. Campbell, who is the Chen Su Lan Centennial Professor of Medical Ethics, a position established in honor of one of the nation's best known philanthropists, the late Dr. Chen Su Lan. In December 2008, CBmE published the inaugural issue (and then subsequent issues) of the quarterly online journal *Asian Bioethics Review* in collaboration with the Hastings Center, which is one of the field's premier research bodies in the USA. CBmE undertakes a wide range of bioethics research, much of it in collaboration with overseas institutions. Current topics include ethics education, stem cell research and therapy, organ transplantation, human enhancement, medical jurisprudence and professionalism, clinical trials, equitable access to medications, and end-of-life issues (see http://cbme.nus.edu.sg/).

Medical Education and Instructional Ethics

The history of Yong Loo Lin School of Medicine (YLLSOM) of the NUS could be traced back to July 1905, when it commenced medical education. Since that time, YLLSOM has provided undergraduate medical training that has ensured a steady supply of doctors in Singapore (Law, 2012). The 5-year curriculum that leads to an undergraduate medical degree is broadly based on the British model of medical education. In 2005, a second medical school was jointly established by Duke University and NUS, as part of the Biomedical Sciences Initiative. Unlike YLLSOM, Duke-NUS Medical School is focused on training clinician-researchers at the postgraduate level, and its curriculum is patterned after that of the Duke University School of Medicine. In 2013, a third medical school jointly managed by Imperial College (London) and Nanyang Technological University (or NTU of Singapore) is expected to admit its first batch of students.

Ethics education is a component of the curricula of both YLLSOM and Duke-NUS Medical School, and it is likely to be included in the curriculum of Imperial College-NTU Medical School. This chapter focuses on ethics education implemented by the CBmE at YLLSOM. Designated as the Health Ethics, Law and Professionalism (HeLP) track in the medical curriculum, which arose out of a recognition by the medical profession here and abroad, knowledge of an ethical and legal basis of medicine is as relevant to clinical practice as knowledge of basic medical sciences (Stirrat, Johnston, Gillon, & Boyd, 2010: 55). This track is a longitudinal one in that it is fully integrated in such a way that pertinent issues in ethics, law, and professionalism are presented as an integral part of the five-year medical curriculum and clinical postings. It aims to develop in medical students ethical sensitivity, theoretical understanding, reflective and critical skills, and professional attitudes. The knowledge, skills, and attitudes acquired are continuously revisited and reinforced throughout medical education.

The five phases of the medical curriculum that the HeLP track follows through are introduction to health and disease and organ systems I (phase I), organ systems II (phase II), the core clinical practice phase (phase III), advanced clinical practice phase (phase IV), and the student internship program (phase V). In phases I and II, the HeLP track provides students with a basic grounding in medical ethics and law as well as an appreciation of medical professionalism. More specifically, it aims to provide an understanding of (1) ethical considerations and behavior that underlie and support good medical practice; (2) the legal and professional frameworks in Singapore, including the *Ethical Code and Ethical Guidelines* of the Singapore Medical Council; (3) the importance, scope, and implications of a doctor's duty of care; and (4) professional values and attitudes. A good grounding in professional values and attitudes will enable students to appreciate the practices, conflicts, and boundaries that they will encounter in the clinical environment. In particular, it highlights (a) the implications of practicing medicine in a multicultural, racial, and religious society; (b) the importance of trust, integrity, honesty, and good communication in all professional relationships; (c) the need to accept personal responsibility and be aware of limitations of your practical skills or knowledge and to know

how and where to seek appropriate help; and (d) the need to maintain professional boundaries with patients and to recognize and avoid all forms of unfair discrimination and areas of potential conflict of interest.

In phase III, the HeLP track provides the opportunity to apply and assimilate understanding gained in phases I and II as well as demonstrate (through reflective writing) the ability to (1) consider, apply, and reflect critically on ethical, legal, and professional aspects of clinical care in particular cases; (2) reflectively consider values of different people that are likely to be encountered in the course of medical practice; (3) respond appropriately to actual or potential clinical errors and adverse incidents; and (4) apply and reflect critically on ethical and legal responsibilities to patients. Finally, phases IV and V will prepare students for clinical competency and provide them with opportunities to explore ethical considerations and practices that underlie and support good medical practice. Students are expected to be able to apply their understanding, especially in the ability to integrate ethical and legal analysis of actual clinical encounters with clinical knowledge and skills, propose action or decision based on this synthesis, and display professional attitudes and behaviors consistent with the requirements of the medical profession.

In addition to the HeLP track, a number of complementary ethics programs are conducted by YLLSOM and supported by the Centre for Biomedical Ethics. In phase II and during clinical postings in phases III and IV, a number of medical specialties have related inputs on ethics that are directed at specific clinical concerns. For instance, there will be ethical components in the foundation courses on clinical skills and patient-based programs in phase II. The knowledge, skills, and attitudes that are developed in phases I and II will be revisited and reinforced in these clinical settings.

In devising modes of teaching and assessment, a key strategy in the HeLP track has been to relate specific learning outcomes with matching methods of assessment as progression through an ascending pyramid of knowledge-habituation-action that reflects knowledge, ethical sensitivity and reflection, and ability to act with clinical competence (Campbell, Chin, & Voo, 2009: 277–278). By this approach, teaching is most intensive in phases I and II, which is directed at raising the level of knowledge and understanding, and is mainly conducted by way of lectures and tutorials. In phase I, there are 12 h of lectures and 8 h of tutorials over a period of 34 weeks of instruction. In phase II, this is followed by 11.5 h of lectures and 3 h of tutorials over a period of 25 weeks of instruction. Some lectures are conducted with standardized patients in interactive sessions, where students are divided into smaller groups to increase the opportunity of engaging with these patients. Assessments are incorporated into the continuous and year-end assessments of the YLLSOM, so that modified essay questions in ethics will be included in selected continuous assessments and the final examination.

In phase III, students are required to complete a short reflective essay on professionalism after their clinical posting. This exercise is intended to encourage application and assimilation of knowledge and understanding from phases I and II through habituation, especially in critical thinking, ethical awareness, and empathy. For phases IV and V, lectures on ethical issues in specific areas of medicine are

conducted as a part of the combined teaching sessions to enhance clinical ethical competency. Ethical issues addressed include bereavement and dying, iatrogenic injury, advanced medical directive and human organ transplantation, and relationship with the pharmaceutical industry.

While there is no single agreed best approach to teaching ethics and professionalism, the HeLP track reflects widely accepted view that "ethics education should be fully integrated both horizontally and vertically with the clinical curriculum so that students can experience and appreciate the centrality of ethics to clinical practice," in hope of producing doctors that are "reflective, responsive and self-regulating" (Campbell et al., 2009: 279).

Apart from the HeLP track, the CBmE manages a program directed at training HECs or clinical ethics committees (CECs), known as the Clinical Ethics Network for Training, Research and Support (or CENTRES). This program was initiated by the MOH in 2009 to facilitate dialogue among the different HECs or CECs and to develop their capacity in clinical ethics consultation. The CBmE was appointed to manage this initiative and to develop a one-stop online repository of resources (www.centres.sg) and an online forum to stimulate discussion and knowledge sharing. In the first two phases of this initiative (which was completed in March 2011), the CENTRES initiative has been successful in obtaining an understanding the needs and challenges that HECs or CECs have been confronted with through needs and operations analyses and a web survey. Regular workshops have also been organized to develop capacity in ethical decision-making on a range of issues in clinical ethics, and a quarterly newsletter has also been launched.

Stem Cell Research and the Beginning of Life

The first set of recommendations published by the BAC is on human stem cell research and reproductive and therapeutic cloning (Bioethics Advisory Committee, 2002a). These recommendations include proposals for stringent regulation of human embryonic stem cell research in Singapore and the legal prohibition of reproductive cloning, which was taken up by the legislature with the enactment of the *Human Cloning and Other Prohibited Practices Act* in 2004. As with other major scientific jurisdictions, the legislation imposes a 14-day limit so that research involving a human embryo is allowed up to that point in development. Embryology is relied upon as justification for this standard as public consultation showed that there was no consensus among the main religious groups in Singapore as to when "personhood" could be said to begin (Ho, Capps, & Voo, 2010). On this basis, one could perhaps conclude that at least in ethical policy, human life begins from 14 days of embryonic development or when the "primitive streak" becomes evident. From a legal standpoint however, it has been argued that the law is much slower in recognizing when life begins, since, for instance, a pregnant woman has the discretion to terminate her pregnancy up to 24 weeks from conception (Singapore Statutes, 1985b). Similarly, the common law relating to inheritance and the penal code attribute legal "personhood" at a much later stage of fetal development (Kaan, 2010).

Eggs, Tissues, and Human-Animal Combinations

Following the publication of these recommendations, scientific developments in relation to cloning and induced pluripotent stem cell technology necessitated continuing review of Singapore ethical policies on stem cell and cloning technology. A review of the recommendations published in 2002 was formally undertaken in 2007, with the focus on ethical, legal, and social issues arising from the procurement and use of human eggs for biomedical research and on research involving human-animal combinations. Apart from scientific developments, review of these areas was considered to be necessary following the scandal from the unethical procurement of eggs in South Korea and, more importantly, from revisions to ethical policies and guidelines in the United States, Australia, Canada, and a number of European countries such as the Britain and Denmark. Recommendations relating to the donation of human eggs for biomedical research were published by the BAC at the end of 2008 (Bioethics Advisory Committee, 2008), after public feedback was received on various issues presented in a consultation paper between 7 November 2007 and 7 January 2008 and at a public forum on 11 November 2007. Another consultation paper was distributed for public discussion and comment on research involving human-animal combinations between 8 January and 10 March 2008. In September 2010, the BAC published a set of recommendations that permit the creation and use of cytoplasmic hybrid embryos and animal chimeras in research on a strictly regulated basis. It further recommended that a single national body be established to review and monitor all stem cell research involving human pluripotent stem cells or human-animal combinations conducted in Singapore (Bioethics Advisory Committee, 2010).

The BAC was also responsible for a series of recommendations which served to systematize ethical governance of research using human tissue. The report on "Human Tissue Research" was published in November 2002 to provide a set of national ethical guidelines to be applied uniformly by all persons conducting human tissue banking and biomedical research using human tissue in Singapore (Bioethics Advisory Committee, 2002b). The ethical principles embodied in the guidelines include the primacy of the welfare of tissue donors, the need for informed consent and confidentiality, respect for the human body, and sensitivity toward the religious and cultural perspectives and traditions of tissue donors. Taken together with its report on egg donation, the BAC communicates a strong stance against commodification of the human body (or any part thereof).

Genetics and Reproductive Technologies

Ethical governance of genetic research was formulated at two different junctures: at the point where genetic information is derived through various means of testing and in the management and use of the information itself. The report on genetic testing and genetic research served to operationalize a number of internationally recognized ethical principles in the local context (Bioethics Advisory Committee, 2005).

These ethical principles relate to the voluntary and informed basis of genetic testing, special care and responsibility when vulnerable persons are tested, and ethical conduct of human genetic research, among others. Specific ethical considerations have also been set out by the BAC in relation to five types of genetic testing, many of which can have profound influence over reproductive choices and reproduction. Preimplantation genetic diagnosis and preimplantation tissue typing are reproductive technologies that can be ethically practiced in Singapore but on a regulated basis. As for prenatal genetic diagnosis, the BAC states that it should be limited to serious medical disorders and must not be applied for the selection of desired traits or gender. Due to safety concerns arising from germline genetic modification, the BAC did not think it should be clinically applied. The recommendations in this report and those in the report on egg donation, taken with a set of directives of the MOH on assisted reproduction (MOH, 2006b), constitute the governance framework for reproductive technologies in Singapore.

Given the difficulty in interpreting genetic test results correctly, there has been considerable emphasis on genetic counseling before and after testing. In addition, the BAC indicates that genetic testing should generally be conducted through a qualified healthcare professional and that predictive health information should not be offered directly to the public. The personal nature of genetic information was more fully deliberated on in a further report published by the BAC on informational use in biomedical research (Bioethics Advisory Committee, 2007). The report proposes legal protection of personal information in biomedical research and sets out a number of considerations that could better safeguard privacy and confidentiality concerns in biomedical research. Similar to developments in the UK, the BAC recommends that a moratorium on the use of predictive genetic information for insurance purposes to be introduced and for employer access to such information to be limited, unless it is appropriate to address imminent workplace health and safety concerns. The recommendation of the BAC to provide disease registries that employ personal information in public health research on firm legal footing was taken up in legislation with the enactment of the *National Registries of Diseases Act* later that year.

Infectious Diseases

The regulatory framework directed at preventing the introduction and spread of infectious diseases dates back to 1976, with the enactment of the *Infectious Diseases Act* (Singapore Statutes, 2003b). New provisions were added with the outbreak of severe acute respiratory syndrome (SARS) in 2003 and its aftermath. These provisions relate to quarantine imposition and administration (including the more efficient imposition of social distancing measures), compliance with disease control measures, and handling of deceased persons (Singapore Statutes, 2003a). In essence, they enable strong state interventions in response to potential and actual public health emergencies posed by serious infectious diseases, of which SARS, yellow fever, and the plague are so categorized. This regulatory framework

proved to be robust during the outbreak of influenza A (H1N1) in 2009, although the pandemic was mild compared with the pandemics of 1918 (Spanish flu) and 1957 (Asian flu) (Lim, 2010: 860–861).

Apart from the three serious infectious diseases, 30 other infectious diseases are listed as requiring the MOH to be notified by medical clinics, clinical laboratory, and healthcare professionals and establishments of any person suspected to be suffering from or is a carrier of any of these infectious diseases (Singapore Statute, 2003b: Section 6 and First Schedule). The regulatory framework further enables the implementation of public health surveillance programs as well as the imposition of medical examination and treatment, when necessary. In 2008, the legislation was amended to include specific provisions directed at controlling the spread of HIV (Singapore Statutes, 2008a). The number of residents in Singapore reported with HIV or AIDS steadily increased from 2 persons in 1985 to 4,845 persons in 2010, of which 2,319 persons are asymptomatic carriers, 1,137 have or have had AIDS related illnesses, and 1,389 have died (Ministry of Health, 2011a: paragraph 1 and Table 1).

As the transmission of HIV in Singapore was found to be mainly through unprotected sex with an HIV-infected person, this legislative change places a greater responsibility on individuals whose sexual behavior puts their spouses or partners at risk of contracting the disease. Under Section 23 of the legislation, a person who has reason to believe that he or she has been exposed to a significant risk of contracting the disease must undergo HIV testing to ascertain his or her health status before the sexual activity. Otherwise, his or her partner must be informed of the risk of contracting HIV. The rationale behind this requirement is to encourage communicative openness between partners, condom use, and regular HIV testing, although the efficacy of this policy has yet to be fully ascertained. Since the legislative amendment came into force, a number of HIV-positive individuals have been convicted for not obtaining prior voluntary agreement to accept the risk of contracting HIV (through informed consent), following complaints made by their partners with whom they have had unprotected sex. Broader systemic challenges to HIV testing remain, of which mandatory notification of HIV-positive status to health authorities, as well as social discrimination and high cost of medical interventions, is the most likely concern among at-risk individuals. The government has since introduced a number of measures to address these concerns, including the launch of public education initiatives, extending financial assistance (via Medifund) to needy citizens who require HIV treatment (including medications), and allowing the use of funds in the national medical savings account (i.e., Medisave) to purchase approved drugs for HIV/AIDS (Ministry of Health, 2010b, 2011b).

Public Health

A major public health initiative has been to limit the amount of tobacco use in Singapore. Legislation to control smoking of tobacco in public places was introduced in 1970, and a tobacco tax was imposed in 1972. Since that time, a series of

regulatory measures and social programs have been introduced (see www.hpb.gov.sg/smokefree/). More recent policy measures that have been implemented include requiring health warning labels to be affixed to the outer packaging of tobacco products and prohibiting tobacco advertising, promotion, and sponsorship, as well as future innovative tobacco products (Singapore Statutes, 2011). In addition, a number of "softer" approaches have been adopted. These include the establishment of a peer-led program, working with grassroot communities to identify and implement localized solutions; launch of an initiative to recognize active tobacco control advocates in the business community (such as operating smoke-free premises) and the launch of a mainstream campaign involving a supportive network across the island to encourage smokers to make a personal pledge to quit. Between 1992 and 2010, smoking rate has fallen from 18.3 % to 14.3 %, and the current aim is to reduce smoking prevalence to below 10 % by 2020 (Health Promotion Board, 2012).

Apart from tobacco control, the Health Promotion Board (HPB) has established a number of programs directed at increasing the quality and years of healthy life among Singaporean citizens. These include health and dental services for school children, promoting physical activity, childhood injury prevention, screening for breast and cervical cancer, myopia prevention, and workplace health promotion. Public education through various means has been directed at AIDS, mental health, nutrition, and osteoporosis, among others. The HPB was established as a statutory body in 2001 with the key responsibility of implementing national health promotion and disease prevention programs.

Transplantation Medicine and Organ Donation

Organ transplantation and donation are strictly regulated activities. Under the *Medical (Therapy, Education and Research) Act* (MTERA; Singapore Statutes, 1985a), a person with the requisite legal capacity may pledge to donate his or her organs upon death for therapy (including transplantation), education, or research. Where such a pledge has not been made prior to death, the relatives of a deceased person are empowered to make the donation. However, the removal of designated organs for the purposes of transplantation is primarily regulated under another statute, the *Human Organ Transplant Act* (HOTA; Singapore Statutes, 2005). It provides that a kidney, heart, liver, and cornea may be transplanted upon the death of a Singaporean citizen or permanent resident who is 21 years of age and above and of sound mind. Such a person may opt out of this regime by lodging an objection with the MOH, although he or she will lose priority as a potential organ recipient to another person who has not opted out of the system. There is no age limit to being an organ donor or recipient.

Under the HOTA regime, living donor organ transplantation is allowed, provided that the donor has provided legally effective consent and the specified organ is removed in a hospital with the written authorization of the transplant ethics committee (TEC) of the hospital. Under the guidelines of the MOH (2009c), a TEC

has the responsibility of evaluating applications for living donor organ transplantation. Generally speaking, a TEC must be reasonably certain that the proposed donation is altruistic and that consent has been obtained without any fraud, duress, or undue influence. The decision of the TEC must be unanimous, having also taken into account considerations of public interest and community values (Singapore Statutes, 2004c). In addition, paired matching is permitted under HOTA, whereby a donor can be paired with a compatible recipient in order for another recipient of the donor's choice to receive an organ from another living donor or have priority in selection. Training for TEC members is provided by the CBmE.

Commercial dealing in organs is strictly prohibited under HOTA, although reimbursement for costs and expenses reasonably incurred in the course, and as a result, of the donation is allowed. Such costs and expenses include cost of the medical procedure, domestic help or childcare, loss of earnings, and short- or long-term medical care as a consequence of the donation. The judiciary gave effect to this policy stance when it meted out deterrent sentence on a vendor who attempted to arrange the sale of a kidney by an Indonesian man to a local recipient. Justice of Appeal VK Rajah explains the policy rationale (Wang Chin Sing case: 871–872): "While these middlemen often claim to be providing a useful service to the desperately ill, the truth of the matter is that they are usually purely inspired by unbridled avarice to maximise their financial returns from each transaction. Left unchecked, these middlemen can cause immeasurable harm to the parties involved (particularly the donors) as well as indelibly tarnish the standing of the medical community, which may be (unwittingly) drawn into this intricate web of deceit . . . in Singapore as the law now stands, any middleman who seeks to secure for himself any form of commercial advantage has absolutely no legitimate role to play in the process of donor or organ matching and transfer."

Traditional Medicine

Traditional Chinese medicine (TCM) is the most common and well-accepted form of alternative medicine in Singapore. Since 2000, the TCM Practitioners Board has been established under the TCM Act (Singapore Statutes, 2001b) to register TCM practitioners, accredit TCM institutions, and ensure that an acceptable level of ethical standards is observed (Traditional Chinese Medicine Practitioners Board, 2006). Unlike "western" medical practitioners, it is not mandatory for a registered TCM practitioner to take up professional indemnity insurance, since most TCM practice is not particularly invasive. Even then, a significant number of complaints have been made against TCM practitioners, mainly relating to professional misconduct and negligence. One case is related to a colonic cleansing treatment that a TCM practitioner introduced to his patient (*Lim Poh Eng* case, 1999). Due to the improper administration of the treatment and to inappropriate follow-up by the TCM practitioner, the patient developed extensive gangrene of her anal canal, which left her with the permanent loss of her rectum and consequently having to wear a colostomy bag indefinitely. During the trial, the High Court held that

a practitioner of TCM would be held to the standard of a reasonable TCM practitioner, and not of a "western" practitioner, and that a common standard of negligence applied to both civil and criminal cases. On this basis, the TCM practitioner was found to be criminally negligent. In addition, the TCM Act, and the ethical and professional standards promulgated thereunder, has extraterritorial effect in that a registered practitioner can be prosecuted for professional misconduct committed overseas (*Huang Danmin* case 2010).

End-of-Life Care and Advance Care Planning

A general lack of discussion of prognosis and mortality between patients and their physicians concerning the treatment of advanced cancer has been observed in the USA, Japan, and a number of European countries (Harrington & Smith 2008). Perhaps attributable to varying degrees of this deficiency, patients have unrealistic expectations about treatments and treatment outcomes, particularly if they are never told or are not told accurately about their health condition. Even when told, they may not believe information about benefits and risks of treatment. A study by Jacinta Tan and Jacqueline Chin showed that some of the challenges that confront end-of-life care in Singapore do not differ significantly from other countries (Tan & Chin 2011). However, cultural understandings of the meaning of information for patients and families and decision-making patterns within different communities are critical forms of knowledge that inform the framing of practical guidance on what, how, to whom, and by whom information disclosures are to be undertaken in healthcare settings.

End-of-life care has been rendered more complicated by modern technology that can prolong life in the final stages of a terminal condition. If it is envisaged that extraordinary life-sustaining treatment may be required, any patient who is 21 years of age and above, with the requisite mental capacity, may create an advance medical directive (AMD) to refuse such treatment. As a legal document, the AMD becomes effective when the patient subsequently loses mental capacity to refuse treatment and death is imminent. To be effective, the AMD must be completed in the prescribed format and signed by the patient in the presence of two witnesses before it is lodged with the Registrar of AMDs. One of the two witnesses must be the patient's doctor, while the other witness must have attained at least 21 years of age. Both witnesses must not have any vested interests in the patient's death.

In practice, very few Singaporeans have created an AMD for a number of reasons. First, the AMD has a very restricted scope of application as "extraordinary life-sustaining treatment" has been narrowly defined as "any medical procedure or measure which, when administered to a terminally ill patient, will only prolong the process of dying when death is imminent, but excludes palliative care" (Singapore Statutes, 1997: Section 2). In other words, the AMD will typically only be of relevance at the very end of the treatment. By that time, both the medical team and the family members of the patient may decide to cease intrusive medical

interventions on the basis of medical futility. Second, it is often unclear if a patient has made an AMD, as it is an offense for any person who has or will be likely to have the medical care of the patient to ask or otherwise enquire of the patient as to whether an AMD has been made or otherwise of an intent to do so. In addition, it is an offense to require or prohibit the making of an AMD as a condition for being insured or for receiving medical or healthcare services. Of course, the medical team may seek guidance from the family members of the patient, but the latter may not know or remember if an AMD has been made. Even if there is such a directive, family members often do not know if the patient has revoked the AMD or otherwise changed his or her mind after the directive was made. Third, many Singaporeans consider it culturally inappropriate to discuss end-of-life matters with family members. Where the patient is an elderly person or a legal minor, it has often been difficult to discern the patient's true wishes. Medical decision-making for these groups of patients has often been made collectively by families and, sometimes, by family members on behalf of the patient (Tan & Chin 2011: 9–10). Tan and Chin explain that elderly patients, for instance, may regard this passive involvement as an expression of altruistic sacrifice, assessing other financial needs to be more pressing (Tan & Chin 2011: 14–6).

The limitations of AMDs contributed to a shift in emphasis from making advance directives to advance care planning (ACP). In a guidance issued by the NMEC, ACP has been defined as "a voluntary process of discussion about future care between an individual, their care providers (irrespective of discipline) and often those close to the individual, should the individual become seriously ill in the future and be unable to make decisions, and/or communicate their wishes to others. Even if the individual is still able to make his wishes clear at the point when he requires the care, ACP would facilitate the decision to be made. ACP may include clarifications on the individual's wishes and concerns, important values and personal goals of care" (NMEC, 2010: 2, paragraph 11). To better realize the ethical goal of patient autonomy, proper and adequate communication is given considerable emphasis in ACP. Unlike the AMD regime, ACP endeavors to provide a broader basis for medical decision-making, particularly in its recognition of the inevitability of family involvement. The guidance states: "With more parties involved, disagreement may occur. One reason may be that the decisions made by the individual do not adhere to dominant culture. Sufficient time should be provided for discussions between individuals and their family members to acknowledge and respect the goals, values and wishes that the individual chooses" (NMEC, 2010: 12, Annex B).

Mental Capacity and Mental Health

A similar philosophy is evident in the Mental Capacity Act (MCA; Singapore Statutes, 2010), which came into operation on 1 March 2010. This regime attempts to balance personal autonomy in decision-making with safeguarding the person's best interests in the event that he or she lacks mental capacity to decide. The

legislation makes clear that mental capacity (or the lack thereof) cannot be assumed only on the premise that a person has a particular medical condition but must be assessed on a case-by-case basis, applying five statutory principles (Singapore Statutes, 2010: Section 3). In general, a person lacks mental capacity to make a specific decision at the time it needs to be made when he or she is unable to understand, remember, or weigh information relating to decision-making or to communicate the decision. The legislation also creates a new statutory form of power of attorney known as the lasting power of attorney (LPA). This is a legal document that allows a person who has attained 21 years of age, with the requisite mental capacity, to appoint one or more persons (donee(s)) to act and make decisions on his or her behalf, including the provision or refusal of consent to continue healthcare treatment or participate in clinical trials (Singapore Statutes, 2010: Sections 22, 26 and 29). However, a donee is precluded from making certain decisions including treatment for sexual sterilization, abortion, organ removal, or the gifting of the body (or any part thereof). In addition, the donee does not have the power to make or revoke an AMD, or to refuse life-sustaining treatment or treatment required to prevent a serious deterioration in the patient's condition. In the absence of an AMD, the doctor must these medical decisions in the best interests of the patient (Office of Public Guardian, 2008: 33–44; Singapore Statutes, 2010: Section 6; Tan & Chin, 2011: 38–39).

Neither the AMD nor the MCA regimes apply to persons under the age of 21 years. Generally speaking, a person below the age of 21 years is regarded as a legal minor, although legislation may specify otherwise. For instance, the law recognizes certain contracts entered into by a person who has attained the age of 18 years to be legally binding (Singapore Statutes, 1999a: Section 35). In most cases however, the consent of a parent or guardian is required as they are primarily responsible for the care and welfare of their child or young person. Parental or guardianship authority is not absolute, as any action taken or decision made concerning a legal minor (including receiving medical treatment or participation in a clinical trial) should invariably be in his or her best interests (Singapore Statutes, 2001a: Section 3A). Failing which, state procedures may be invoked to protect the interests of the legal minor (Ministry of Community Development, Youth and Sports, 2005). Although it is not a settled law in Singapore as to whether a legal minor can provide legally valid consent if he or she has sufficient understanding and intelligence to comprehend the nature and consequences of receiving medical treatment, for instance, English common law (Gillick case) serves as persuasive authority to at least require the active participation of such a child or young person in the informed consent process.

Apart from the regulatory frameworks that are in place, the government has announced various measures to meet the challenges of a growing and aging population. Under the National Mental Health Blueprint that was implemented in 2007 (Chong, 2007; MOH 2010), core services for mental health conditions were strengthened to enhance early detection and treatment of children with mental health issues and to train school counselors to better manage these children. Community psychogeriatric programs have also been introduced to

provide home-based mental health services for the frail elderly. In 2012, the MOH announced the government's plan to develop a new community-based mental health plan to complement its hospital-based services (MOH, 2012b). A key initiative under the plan is to integrate specialist-led multidisciplinary teams with primary care services, with the goal of improving access to care for mental health patients. These teams will be supported by more specialized setups to focus specifically on dementia patients. Counseling and psychotherapy services will also be expanded in the community to increase the capability of general practitioners to assist patients with mild to moderate mental conditions such as anxiety and depression. Mental health services have also been made more accessible in terms of cost. Qualified individuals are entitled to subsidized treatment at community hospitals (or polyclinics) for schizophrenia, major depression, dementia, and bipolar disorder. The use of Medisave funds is now allowed for outpatient treatment of these conditions as well as for inpatient psychiatric treatment. Besides these initiatives, the HPB will continue with mental health education and promotion efforts, which are directed at unfair discrimination and stigmatization of people with mental health illnesses. Within the profession, clinical practices relating to schizophrenia, bipolar disorder, and depression have also been evaluated and systematized (MOH, 2007a, 2011c, 2011d, 2011e).

Palliative Care

Another area that policymakers have given much attention to is palliative care. In 2011, a national strategy, commissioned by the MOH, highlights a number of changes that are necessary to enhance the provision of palliative care needs in Singapore and provides recommendations to ensure the sustainability of service offerings and use of nonpalliative care specialists and physician substitutes (Lien Centre for Palliative Care, 2011). In particular, the strategy maps ten goals directed at areas of service development, training and research, and public education and awareness. The recommendations for the national strategy for palliative care have been accepted by the government, and a taskforce will be set up to study it in greater detail (Pang, 2012). Since then, several measures have also been announced to render intermediate and long-term care services more affordable, including financial assistance to better support care for the elderly at home and in the community (MOH, 2012b).

Future Challenges

The last decade witnessed considerable developments in all three domains of bioethics in Singapore. Many contentions and challenges that have surfaced will continue to demand ethical and regulatory attention in the foreseeable future. Already, policy orientation is beginning to shift in anticipation of the healthcare

needs that a silvering population will present. With a population that is more educated, affluent, and mobile, greater demands on the medical profession, public health initiatives, and healthcare delivery in general are expected. Certain services that have been on the periphery of healthcare are likely to become more commonplace and controversial. Take for instance plastic surgery or cosmetic medicine. In a recent incident, the death of a heavily sedated liposuction patient from asphyxia highlights ethical and regulatory conundra that are expected to grow over time (Lum, 2012). The issues of cost, necessity, and accessibility that such services present find no ready solution.

Significant investment in biomedical research has also been made in the past decade. One can perhaps deduce that new biomedical technologies and medicines, along with innovative interventions, will generate many ethical challenges. In addition, the growing emphasis on industrial collaboration, translational medicine, and other market-oriented research practices will exacerbate conflicts of interest (especially financial) concerns. Even if new guidelines are promulgated, it is questionable if such a measure is in itself capable of meeting this challenge (Campbell et al., 2010; Ho et al., 2010; Krimsky, 2006).

Conclusion

This chapter has considered the establishment of an elaborate ethics governance framework through the collaborative work of the MOH, the BAC, and CBmE. To be sure, the account provided is not exhaustive, as other agents (such as those concerned with research involving animals and environment protection) have also actively contributed to this framework. However, this chapter has focused on developments since the year 2000 that have shaped bioethics in medical practice and education as well as biomedical research. While there are still many challenges ahead, no society has had to work in isolation. Instructive experiences and resources have been generated across all domains of bioethics and jurisdictions. They suggest that clarity of ethical goals, open communication, and earnest engagement, along with reflective and socially responsible conduct, will offer a reliable way forward.

Introduction

Due to significant developments in biotechnologies, biomedical research, and medicine in general, the present world, especially Europe, is witnessing a huge increase in interest in bioethics. This, however, often brings about new questions and problems with regard to the differences in understanding and actual approaches, that is, values, principles, and norms of bioethics. Many of those problems, which have been the subject of polemics and arguments in the world for many years, are now, little by little, being discussed on a professional level also in Slovakia (and in Central Europe). In Slovakia, medical, political, and ideological approaches dominate in the discussions and polemics in question; the interest and involvement of philosophers and ethicists is not very significant.

However, the UNESCO Chair in Bioethics at the University of Prešov is trying to develop a platform for an exchange of opinions and become a coordinator of a number of activities for the professional community. That means providing opportunities for meetings of medical professionals, biologists, health-care professionals, and other natural scientists on the one hand and representatives of philosophy, ethics, theology, and other humanities on the other. This chapter on bioethics in Slovakia is one of the results of the UNESCO Chair in Bioethics and cooperation among different groups of Slovak bioethicists.

Bioethics Development

When and How Did Bioethics Start?

The birth of bioethics in Slovakia can only be dated as far back as 1989. Philosophers although were concerned of these issues before. All there was before was experiments in natural science, especially biology, stating that there are also ethical aspects to life. The isolation of Slovakia from the course of events in the scientific world was the reason why the emergence of bioethics was delayed. It was also caused by political and ideological barriers caused by dividing the world into two contradictory political and ideological camps, which prevented prompt responses to new trends in biomedical research, medical practice, health care, as well as philosophy and ethics. It was not until after 1989 that a free exchange of information started and scientists, as well as philosophers, ethicists, and theologians, could freely express their opinions on intellectual stimuli in the world and also reflect upon them in the Slovak environment.

Who Were the Major Instigators?

The Western (European as well as American) bioethical tradition had a significant influence on the forming of bioethics in Slovakia. At the very beginning, the establishment of bioethics in Slovakia was shaped by specialists in medical and

natural science, such as Jozef Glasa, Ladislav Šoltés, Marta Kollárová, Ľubica Lacinová, and Ján Ďačok. These were later joined by philosophers, ethicists, and theologians, such as Peter Sýkora, Vasil Gluchman, Mária Nemčeková, Eva Smolková, Peter Volek, Zuzana Kiczková, Daniela Kovaľová, Adela Lešková Blahová, Lenka Bohunická, Igor Kišš, and others, as well as the lawyers Branislav Fábry and Ivan Humeník, and specialists from other areas (Glasa et al., 1999; Kovaľová, 2004; Lešková Blahová, 2010).

What Have Been the Major Concerns Over Time?

Medicine and nursing (and, within their scopes, especially medical and nursing ethics) have received most attention. Problems in claiming human rights and values in health care in the form of respecting patients' rights (patients' informed consent, information confidentiality, patients' autonomy, physical and mental integrity, palliative care), the issues of euthanasia and dignified death, organ transplants, instrumentalization of man in medical research, the issue of conscience (in health-care staff), as well as evaluating the relationship between the doctor or the nurse – the patient – the patient's family members, activities of (bio)ethical committees, etc., are at the forefront (Bilasová et al., 2008; Nemčeková et al., 2008, 2004).

Another large subject area in bioethics is formed by issues of gene technology, biotechnology, reproductive and regenerative medicine, which, however, in the Slovak environment are reduced to an ethical and moral discussion on the matter of the beginning of human life, and related issues regarding determining the moral (and, consequently, legal) status of the human embryo, abortion, cloning, the moral aspects of eugenics in the form of preimplantation and prenatal genetic diagnostics or the gender selection in one's future baby, and also research on human embryos or human embryonic stem cells, among others (Hrkút, 2009; Jemelka, Gluchman, & Lešková Blahová, 2008; Sýkora, 2010; 2008). A fair amount of attention is paid to methodological and metaethical issues of bioethics (Gluchman, 2009, 2008a, 2008b, 2005a, 2005b; Sýkora, 2008; Smolková, 2006; Lešková Blahová 2010).

A special category of bioethics in Slovakia is made up by environmental ethics (as part of bioethics), dominated by the following philosophers: Eva Smolková, Zlata Androvičová, Eva Odlerová, Ľubov Stekauerová, Dušan Špirko, the culturologist Ivan Dubnička, and others, who actively applied environmental theories in Slovak circumstances (Jemelka & Lesňák, 2008; Jemelka et al., 2010).

What Resources Have Been Developed?

Several codes of ethics on a national level have been established, such as the deontological code of the Slovak Health Chamber (1992, 1993, 1996, 1998), codes of ethics for nurses and midwives (part of Act No. 311/2002 Coll., Enclosures No. 1 and 2), codes of ethics for doctors and dentists (Enclosure Act No. 219/2002), codes of ethics for health-care staff (part of Act No. 578/2004 on health-care providers,

Enclosure No. 4), Charter of patients' rights in the Slovak Republic (2001), codes of ethics for the pharmaceutical industry in Slovakia (2004, 2006, 2008) (Glasa, 2009).

Conferences and symposia focused on bioethics are more and more common. Scholarly journals, treatises, and university course books are being published. An increased interest in bioethics is equally obvious, especially in the area of reproduction rights, also in NGO–civic pro-life movements and associations supporting Christian values are being founded, such as Forum for Life (Fórum života), the Centre for Bioethical Reform (Centrum pre bioetickú reformu), Yes to Life (Áno pre život), Community of Life (Spoločenstvo života), etc., as well as nongovernmental nonprofit pro-choice organizations, such as the Slovak Family Planning Association (Spoločnosť pre plánované rodičovstvo) and Pro choice (Možnosť voľby).

What Steps Have Been Taken?

After 1989, the political approach to bioethical and medical issues was the first to change, resulting from development of bioethics in the world, which was also reflected in legislation (still in Czechoslovakia, or the Czechoslovak Federation, i.e., until the beginning of 1993, when the country was divided into two independent republics: the Czech Republic and the Slovak Republic) regarding health care, the option for churches to take part in pastoral care in hospitals, etc. Further steps followed relating to the foundation of the Central Bioethical Committee (1990) and other committees in health-care institutions. Following the experience of developed western countries, courses of bioethics, or medical ethics, started to be included in curricula at medical faculties. These were, however, often taught by people lacking the appropriate education in ethics, or bioethics, that is, medical doctors, priests, or even Christian laymen interested in ethics and bioethics. It was not until 1995 when a broader infrastructure started to be created and attention started to be paid to bioethics at more universities. The second half of the 1990s saw the first ethics teacher training courses at faculties of humanities as well as training of other specialists in ethics, including bioethics.

Current Bioethics Infrastructure

Teaching Bioethics at Universities

After 1989, and especially in the second half of the 1990s, the first specialized scientific research and educational departments were founded, as well as other university departments, where courses in bioethics are taught (be it a narrower or a broader conception of bioethics) at all levels of university education within various specializations and study programs. At the same time, these departments carry out research activities in this field. With regard to the above, the following departments should be mentioned: the Department of Ethics at the Faculty of Arts, University of Prešov; the Department of General and Applied Ethics at the Faculty of Arts, Constantine the Philosopher University in Nitra; the Department of Ethics

and Applied Ethics at the Faculty of Humanities, Matej Bel University in Banská Bystrica; the Department of Applied Ethics at the Faculty of Arts, Pavol Jozef Šafárik University in Košice; the Department of Ethics and Moral Philosophy at the Faculty of Arts, University of Trnava; the Department of Medical Ethics at the Medical Faculty, Slovak Medical University in Bratislava; and the Department of Bioethics and Pastoral Medicine at the Faculty of Health Care, Catholic University in Ružomberok. Bioethics is also taught at all medical and health-care faculties in Slovakia.

Bioethics Committees

Up until 1989, there were no ethical, or bioethical, committees in Slovakia, at least not in the modern conception of the term. The Central Ethics Committee founded at the Slovak Ministry of Health Care (since 2005 under the name the Ethical Committee of the Slovak Ministry of Health Care, operating as a national bioethical committee) was not established until 1990 (Glasa et al., 1999). The process of institutionalization of bioethics in Slovakia also leads to the foundation of the Slovak Board for Bioethics at the Slovak UNESCO Committee (2004), the Ethical Committee for the Pharmaceutical Industry in Slovakia (2004), as well as the formation and activities of (bio)ethical committees, boards, and councils on a regional and local level (at research and health-care institutions).

Expert Bodies/Centers

In 1992, the first specialized scientific research and educational department (focused on the development of medical ethics, bioethics, ethics of nursing, and ethics of public health care in Slovakia), the Institute of Medical Ethics and Bioethics, was founded as a joint department of the Slovak Health Care University and the Medical Faculty at Comenius University in Bratislava (with Jozef Glasa as the chair). The institute is also known for issuing the international bilingual (Slovak–English) scholarly journal Medical Ethics and Bioethics (Medicínska etika & Bioetika – 1994, editor in chief Jozef Glasa). The year 2002 saw the foundation of the Institute of Social Medicine and Medical Ethics at the Medical Faculty, Comenius University in Bratislava. Later on, in 2008, the Centre for Bioethics at the Department of Philosophy, Faculty of Arts, St. Cyril and Method University in Trnava (with Peter Sýkora as the chair) was established. Undoubtedly, the foundation of the UNESCO Chair in Bioethics at the Faculty of Arts, University in Prešov (Vasil Gluchman being the chair) in May 2010 was a significant event. Hereby, the Department of Ethics at the Faculty of Arts, University of Prešov, which is its center, now ranks among exclusive UNESCO Chairs worldwide, dealing with research and education in bioethics as the only department of its kind in Central Europe. Publishing the international journal *Ethics and Bioethics (in Central Europe)* (2011, editor in chief Vasil Gluchman) is among the activities of this department.

Relevant Legislation

In contrast to other European countries, Slovak legislation regulating moral and ethical issues in biomedicine, such as in reproductive and regenerative medicine, medical genetics, and biomedical and biological research, is fragmented in many cases. With regard to the given areas of biomedicine, there are no special laws, or a particular biomedical law, to regulate them. This area is partly contained in several national laws, or legislative rules and regulations, as well as in general legal enactments regulating the protection of person (such as the civil code). The Health Care and Services Act in particular could be mentioned, regarding their provision (Act No. 576/2004 Coll.), their providers (Act No. 578/2004 Coll.), and their extent and payment (Act No. 577/2004 Coll.). There is also the Nursing and Midwifery Act (No. 311/2002 Coll.), the Medical Profession Act (No. 219/2002), the Medicines and Medical Devices Act (No. 140/1998 Coll.), the Public Health Service Act (No. 126/2006 Coll.), etc. The issue of genetically modified organisms appears to be an exception from this area, which, in Slovak legislation, is embedded in a special act (No. 151/2002 Coll.), the act on the use of genetic technologies and genetically modified organisms (Glasa, 2009; Lešková Blahová, 2010). The above acts apply at present, as amended by rules and regulations made by the Slovak government, while certain legal acts are adopted from European associations and the European Union. In a great number of cases, nonbinding or advisory international acts on a worldwide or European level are respected (such as UN and UNESCO statutes and agreements). In general, the Slovak Republic is a country with conservative, or restrictive, biopolicy (Humeník, 2008; Lešková Blahová, 2010).

Public Debate

After 1989, the most prominent topics of discussion in Slovakia regarding bioethics were abortion and the rights of unborn children. It was especially the Christian Democratic Movement (Kresťansko-demokratické hnutie) and other Christian organizations or NGOs that tried to tighten the wording of the abortion act, which originated back in the 1960s. It was presented as a remnant of the totalitarian past. Despite the fact that a majority of the population of Slovakia adhere to Christianity, the efforts of Christian democrats gained sufficient support neither publicly nor in the parliament, which meant that Slovakia kept a relatively liberal abortion law. Another significant topic which dominated the first 5 years of this millennium was the issue of conscientious objection and its legislative embedding, which would, for instance, allow doctors to refuse to perform an abortion or in vitro fertilization, should they conscientiously object to it. It was not in this instance either for the present liberal legislative to be made stricter, in spite of the actions of the Christian democrats who, in protest, resigned from the government, which resulted in early parliamentary elections in 2006.

Major Bioethical Issues and Discussions

Beginning of Life

The issue of the beginning of human life is undoubtedly very prominent in Slovak bioethical discussions. One of the reasons is that it impacts a number of biomedical branches, such as medical and molecular genetics (and especially genetic testing and gene therapy as part of it), regenerative medicine (especially at the level of cell therapy), reproductive medicine (with regard to moral issues of abortion and assisted reproduction), and biomedical research (research using human embryos and embryonic stem cells). The problem of determining the beginning of human life (in connection with determining the ontological, or metaphysical, status of human beings) predominantly lies in whether it is possible to attribute to a human embryo the full moral status of a human person or whether it is supposed to be perceived as a "mere" stage in human development, which could be used for the moral "justification" of its instrumentalization in medicine or scientific research. These and related issues are, in Slovakia, usually considered through the eyes of theology, medicine, law, and, to a lesser extent, secular philosophy and ethics. It is due to the powerful Christian cultural background of the country that the moral theological and methodological perspective dominates among the professionals. Secondarily, it is also caused by a low level of interest among secular professionals (bioethicists) in speaking about moral issues of this kind. This is one of the reasons why Slovakia is a rather conservative country, bioethically (Lešková Blahová, 2010).

When determining the moral status of the human embryo, and the related issue of respecting the moral value of human life and human dignity, the principle of potentiality remains the predominant argument in theological ethics (especially for personalist theories). According to this principle, the human embryo is a potential human being/person, who, thanks to this argument, deserves respect and protection from the very beginning and, consequently, in all stages of its development, which means that any instrumentalization of man is refused. Secondarily, the above-mentioned principle also refers to the genetic and numerical continuity of the developmental stages of man (Balák, 2009; Glasa & Glasová, 2002; Volek, 2006, 2007, 2008). It, however, meets criticism from secular philosophers and ethicists, regarding the issue of the numerical identity of man, or a reexamination of the ontological status of the human embryo (a scholarly polemic between Peter Volek and Peter Sýkora).

Among the Slovak professionals, there is also a less prominent but more liberal bioethical approach to the presented issue, especially identified with the secular philosophical–ethical tradition, in the form of the argument of rationality concerning lack of rational abilities in case of human embryo. Still, one cannot speak of any extreme form of liberalism, allowing (and not judging as an immoral action) any, be it insufficiently justified, instrumentalization or willful destruction of the human embryo in (bio)medicine. This is more of a compromise position in solving the given issue. With regard to the moral status of man, a so-called gradualist position is mentioned, more precisely, a gradualness in respect for the dignity of human life.

In simple words, this means that the moral status of man increases gradually with the rational abilities of the human organism, which are a prerequisite for its moral competence. This allows the given principle to morally justify the instrumentalization of a human being (not a person) in medicine and science. For it to be marked as morally acceptable, adequate respect toward human dignity befitting the particular developmental stage of the human being in question and a sufficient relevance or justness of such actions have to be present (Gluchman, 2005b, 2008c; Kišš, 2004; Lešková Blahová, 2010; Sýkora, 2006, 2008). Consequently, the bioethical debate moves to the legal sphere, where the legal status of the embryo is considered, for example, by Branislav Fábry and Ivan Humeník (Fábry, 2007).

End of Life

Neither euthanasia nor patient-assisted suicide (PAS) is legal in Slovakia. Health-care professionals have to act in accordance with the code of ethics (Paragraph 80 1d, Act No. 578/ 2004 Coll.). Euthanasia is illegal and considered a criminal act. Likewise, PAS or any suggestion, information, or instruction given by a physician on how to commit suicide is considered a criminal act. This raises important ethical questions. Terminally ill patients often ask their physicians about other options, and sometimes, they decide for STED (stop eating and drinking). If the physician does not inform the patient on how to proceed, this procedure can be truly painful, uncomfortable, and filled with suffering. Moreover, the patient in question can be declared incompetent, and the relationship between the patient and the physician can worsen. However, with adequate care and advice from the physician, it can lead to a peaceful death where the patient's fundamental needs are fulfilled. The question remains as to how well Slovak physicians are trained in listening to their patients' wishes at the end of their lives, how "culturally competent" and how ethically sensitive they are. Unlike in many European countries, there is no public debate about euthanasia or PAS in Slovakia. A significant issue connected to the end of life is that of withholding and withdrawing treatment. Patients have the right to reject all lifesaving treatments, medicine, and interventions, provided they are legally responsible for all the consequences of such a decision. Thus, a physician acting in accordance with the patient's wishes cannot be legally prosecuted. How about those cases when the patient is no longer able to express his wishes or is declared incompetent to make such decisions? Mostly, physicians agree that futile treatment ought to be discontinued. However, who should decide when and whether the treatment is futile? What about such cases when the patient's wishes and the physician's decision are in conflict? It is important to respect the patients' desire and their right (also the right of their families) to decide on where they want to spend their last moments. The patient has the right to refuse certain treatments (such as surgery, drugs, and chemotherapy), if he feels it does not help him, but, instead, subjects him to unnecessary pain and suffering. There is also a major influence from the Catholic Church, which strongly refuses euthanasia as a solution to great suffering in the final phase of life.

Health and Disease

Slovak ethicists often reflect on the matter of health and disease as an issue of quality of life. This helps to understand the problem of health in its complexity, and at different stages, tendencies to define the concept of health and disease in the holistic and normative view are not direct but, still, obvious (Bilasová et al., 2008). Lately, an original Slovak ethical theory, the ethics of social consequences (ESC), has attempted to deal with bioethical issues. Lately, the original Slovak ethical theory, ethics of social consequences (ESC), tries to engage itself with bioethical issues. As one of the outcomes of this interest might be considered the concept of health in which ethics of social consequences inspires itself by the holistic theory of health of Lennart Nordenfelt. The initial understanding of health within ESC is that health is (a) something good and, in this way, a moral goal and (b) an instrument which helps other life goals to be reached. A more detailed analysis of the concept of health shows a parallel with the holistic theory of health in that they both consider health an ability to fulfill vital goals. ESC agrees that the ability to fulfill one's goals reflects the quality of life. What ESC adds to the discussion is the importance of understanding the ability to set these vital goals as a kind of moral skill that has to be developed by a moral agent.

Health-Care System

The health-care system stands for all interferences by society (government, community, institutions, and individual members of society) in the matter of health and disease. Public health and the health of all members of the society are its main value and aim. Health is in this matter defined as something beneficial to society and as one of the conditions in which society can work successfully and can actively develop itself. In Slovakia, main roles and characteristics of the health-care system are defined in legislation (Act 576/2004). From an ethical viewpoint, the goals of the Slovak health-care system are based on fundamental moral principles: reduction of suffering, respect for the dignity and rights of others, prevalence of good over bad (or minimization of malice if the action cannot guarantee an overall prevalence of good), and production of positive social consequences, based on principles of humanity and justice (Gluchman, 2003; Komenská, 2011). The health-care system in Slovakia is a social system charged with guaranteeing the health of its members and with increasing the quality of their lives. The health-care system is a complex system created not only by health-care professionals but also by a well-organized system of institutions, organizations, and individuals who cooperate to reach their common goal. However, some of the bioethical problems are ineffectiveness of the health-care system in Slovakia as well as its latent corruption especially within public hospitals.

Traditional Medicine

In the sixteenth century, one could find healing-oil makers in the mountainous parts of Slovakia who used the healing power of herbs. In 1771, Jan Barvírek-Tonsoris

wrote the first Slovak printed book *Sana Consilia Medica or Medical Health Advice* (*Sana Consilia Medica aneb zdravá rada lékařská*) on traditional healing. Ľudmila Thurzová was a traditional healer whose educational work culminated in 1963 in the publication of *The Mini Atlas of Healing Herbs* (*Malý atlas liečivých rastlín*). At present, there are approximately 2,000 traditional healers in Slovakia. The number is inaccurate, as healers do not need a license to provide health care. Psychotronicists, herbalists, and chirotherapists all declare to be traditional healers. Chirotherapy is a measure, which, in Slovakia, should only be performed by medical doctors. There is no legal adjustment in the Slovak Republic referring to the status of healers. A healer does not need to have any medical erudition and can practice without restriction. According to Act No. 578/2004 Coll., healers are not health-care workers. The 2006 Criminal Code classifies harm to one's health as a criminal act committed by an offender who, in spite of not having appropriate specialized health-care skills, pursues health care and causes harm to one's health by an unprofessional or careless act. The ethical conflict relates to the undefined legal and professional status of traditional healers in Slovakia. Traditional healers are not obliged to prove their education and are not legally obliged to maintain confidentiality. Act No. 578/2004 Coll. states that a health-care worker must not encourage any other person to perform such acts which are permitted to be carried out by health-care workers only. The law does not prevent a medical doctor to be a traditional healer at the same time. The activity of healers is not inspected. By course of the WHO and EU resolutions, the Slovak Medical University in Bratislava founded the Institute of Traditional Chinese Medicine (Ústav tradičnej čínskej medicíny – ÚTČM) in 2010 as its executive organ. The activities of ÚTČM are based on the philosophy of traditional Chinese medicine (TCM) and its components, that is, acupuncture, physiotherapy, kinesthetic therapy, massage, and diet therapy. By its existence, the institute validates the use of TCM and its theories in health care as well as research in Slovakia. Acupuncture is part of health care, and its content was defined and approved by the Slovak Ministry of Health Care in Act No. 576/2004. At present, there are approximately 600 trained doctors–acupuncturists in Slovakia. Its particular application in the area of diagnostics, treatment, and prevention as well as physiotherapy is, however, problematic, as the major aim is not only to suppress illnesses but also to strengthen one's health with the aim of rationalizing the overall treatment and preventative measures as well as effectively saving health-care costs. It is necessary to monitor the validity of some traditional techniques as well as to test and inspect physiotherapeutic products. Likewise, there is a need to systematically inform health-care workers and the public about TCM.

Genetics

Bioethical issues of genetics, especially on the level of molecular and medical genetics, are, in the Slovak environment, reduced to medical, philosophical–ethical, theological, or legal bioethical discussion on preimplantation and prenatal genetic diagnostics (regarding measures within assisted reproduction). To a lesser extent,

contemplations on the ethical and moral aspects of gene manipulations (gene engineering) with regard to man emerge, mostly with human sex cells or embryos and fetuses. In this matter, one can often encounter polemics on the morality of genetic improvement human beings in the form of genetic interference into the human genome (gene therapy) on both the level of the individual and the species or on the eugenic threats of genetics. All this reasoning is perceived in the context of philosophical–ethical or theological reflection on (non)crossing the borderline of naturalness (natural order of things), interfering in human nature, (dis)respecting the moral value of human life and dignity, determining the moral status of a human embryo, etc. In most cases, these are mere informative articles. There are only few authors who stand out, who try to form their own evaluative analytical outlook regarding selected methodological (philosophical–ethical) standpoints, such as Peter Volek, Igor Kišš, Peter Sýkora, Adela Lešková Blahová, and others (Kišš, 2006; Lešková Blahová, 2010; Sýkora, 2010, 2006, 2008; Volek, 2009). Since Slovakia is a country with conservative, or even restrictive, biopolicy, a dismissive approach toward controversial measures within medical, or molecular, genetics is not surprising.

Reproductive Medicine

Moral issues of reproductive medicine in Slovakia are restricted to a discussion on selected measures of assisted reproduction, possibly, stretching to reproduction rights of man (especially human reproduction autonomy). The most common reasoning is directed toward morally controversial consequences of artificial and so-called unnatural creation of human embryos for the purposes of assisted reproduction, and, consequently, the matter of their genetic testing and possible selection, such as the gender of the future baby (preimplantation genetic diagnostics and prenatal genetic diagnostics in later stages of prenatal development). Other polemics are carried out about treating so-called excess human embryos in the form of their further keeping (cryoconservation), liquidation or disposal (killing), and adoption or usage in biomedical research (with regard to the isolation of embryonic stem cells). The issue of multifetal pregnancy reduction (in cases of assisted reproduction) also emerges to a considerable extent and, by effect, a more notable matter of acceptability of abortion in general. Again, these measures are evaluated in the context of acting for/against (human) nature, or the natural order of things, (non)attributing a human embryo a moral status, and (dis)respecting moral values of human life and human dignity or thoughts on their (in)humanity. Assessing moral issues of reproductive medicine is primarily supported (if at all) by the methodology of moral theology and, to a lesser extent, secular philosophy and ethics. It must be stated that the discussion on practical moral issues of reproductive medicine is still carried out on a rather theoretical ethical level (reasoning on the beginning of human life) with low potential for moral application and, only to a minimum extent, on a specialized scholarly level. The moral applications can be found only in the works of Igor Kišš, Vasil Gluchman, and Ján Hrkút (Gluchman, 2005b, 2008c; Hrkút, 2006, 2007, 2009; Kišš, 2006, 2004).

Medical Research

Slovak professional bioethical community mostly regards the level of clarifying fundamental theoretical methodological, or metaethical, issues (also) related to (bio)medical research. Two areas of thought can be recognized. The first level of rather medical or legal reflections is concerned with the participation of human subjects in research (especially the issue of acquiring their voluntary and informed consent, acting for the benefit/good of participants in biomedical research and assessing the resulting risks, or protection of personal information). Many a time, it concerns the level of giving information on basic human rights in clinical research, reaching out to those carrying out the research. In a broader context, specialists (mainly in medicine, natural science, and law) speculate about the competences of ethical committees who evaluate the ethical and moral acceptability of such research (Humeník, 2008; Magulová, 2005). With regard to this, deeper ethical reflections on (non)respecting the moral value of human life and human dignity, physical and emotional integrity, and safety and justified interest of research participants or (in)human and (ir)responsible actions by scientists/doctors are virtually lacking. The other area of bioethical discussions concerns assessing research performed on human embryos. Research on human embryos and embryonic stem cells, or so-called lines of human embryonic stem cells, probably causes the greatest controversy, in spite of the fact that this type of biomedical research is illegal in Slovakia. It is often perceived in the context of the (im)morality of (therapeutic and reproductive) human cloning (Glasa & Glasová, 2001). Only a small number of views get to a deeper level of ethical reasoning on the instrumentalization of man and disputes about actions which do (not) maintain the moral value of human life and dignity and are (un)natural (artificial, antinatural) and (in) human. In relation to this, a compromise approach of certain authors, such as Igor Kišš, Peter Sýkora or Adela Lešková Blahová, and others, can be mentioned (Kišš, 2006; Lešková Blahová, 2010; Sýkora, 2010).

Public Health

The following five areas are a priority for Slovak public health care: chronic conditions (predominantly cardiovascular diseases, tumors, and obesity), infectious diseases, influence of the environment on health, smoking, and alcohol. PHA (Public Health Organisation) is in charge of coordinating activities on a national level in the area of public health care, which is a contributory organization of the Ministry of Health Care. PHA controls 36 regional institutes of public health care on a national level; it monitors infectious diseases and, if required, takes action in the protection of life and the improvement of health. In 1993, *health advisory clinics* were founded as an integral part of the *offices of public health care* with the aim of giving advice on risk factors, healthy diet, giving up smoking, physical activity, mental health, and managing stress. In order to increase awareness, a great number of conferences, seminars, courses, and educational workshops are

organized regarding health protection (such as World Health Day, World Environment Day, International Day against Drug Abuse, World Food Day, World No Tobacco Day, and World AIDS Day). *Offices of health care* monitor the living conditions of children and the young; they sustain health by means of programs promoting healthy lifestyle (focused on the issues of smoking, healthy diet, drugs, HIV/AIDS, and sex). Offices of public health care (in cooperation with the Ministry of Environment and other sectors) monitor risk factors in the area of environment and health care. Prevention and screening programs in Slovakia are covered by the SHI. The aim is to create a society-wide effective system of measures focused on reducing the incidence and prevalence of the most serious heart conditions and vascular risk factors, as well as on reducing morbidity and mortality rates of the most serious cardiovascular conditions – ischemic heart disease, chronic heart failure, and sudden cardiac death.

Infectious Diseases

The pivotal strategy in the prevention of infections in Slovakia is maintaining high levels of vaccination. Slovakia has had a vaccination program since 1986. It is focused on elimination of infections, predominantly in children. The Slovak national immunization program is realized in compliance with the WHO goals for all countries in the twenty-first century. Consistent administration of this program managed to significantly improve and maintain a low or zero incidence of diseases preceded by vaccination. In 2007, Slovakia reached vaccination levels between 98.1 % and 99.5 %. Vaccination is of primary importance in the care of pediatricians. In 2007, there was no incidence of infantile paralysis, diphtheria, or morbilli. The epidemiological situation with regard to the incidence of infectious diseases in 2010 can be evaluated as favorable. The situation was satisfactory especially with regard to diseases prevented by vaccination, with the exception of pertussis (whooping cough), the incidence of which significantly increased in 2009. In 2010, 1,929 cases of all types of viral hepatitis were registered in Slovakia, which was 1 % less than in 2009. VH-C dominated among the chronic forms – 221 cases, that is, 67.8 %. An increase (by a factor of 2.3) was only observed in the acute form of VH-C. After several years, 1 case of VH-E was documented, imported from Vietnam. In comparison to 2009, an increase (by a factor of 1.2) in diarrheal diseases with explained etiology was observed. Between January 1, 2010, and December 31, 2010, 125 cases of SARI (severe acute respiratory infection) were reported. From 125 reported cases of SARI, 27 (21.6 %) patients died. From the total number of deaths, the pandemic virus A (H1N1) was confirmed in 14 patients.

Transplantation Medicine and Organ Donation

In Slovakia, transplants are restricted to two types, kidney transplants and, to a lesser extent, heart transplants. Slovak specialists in the field of transplantation

medicine achieve great results in the above areas. Neither liver nor lung transplants are performed. A lack of organ donors is, however, a frequent problem, which is often connected to a conservative Christian viewpoint among the public concerning the dead body and the option to donate organs in order to save a life, or lives, of others. Christian Churches are not directly against organ donation; they, however, take a dismissive standpoint toward organ sale, as, in their opinions, the significant ethical and moral effect of altruistically helping a sick person is lost.

Emerging Technologies

In the past 20 years, the situation in Slovak health care has considerably improved, with regard to the newest lifesaving technology as well as technology enabling early diagnosis of life-threatening diseases. Slovak health care, however, suffers from a serious lack of finances provided from the state budget or public resources, which is why it significantly lags behind developed Western European countries in the area of new technologies. So far it has not been possible to pursue any reforming steps which would provide greater space for the introduction of private funds in hospitals. These are, to a large extent, at the hands of the state, or, in some cases, regulated by self-governing regions. They, however, do not have enough resources for their development, sufficient financial evaluation of the staff, etc. On the other hand, nontransparent public procurement for purchases of expensive medical equipment and technology is a serious ethical and moral problem. Thus, state financial resources are wasted or ineffectively handled, and health institutions are continuously in debt.

Intensive Care

In the past decades, scientific and medical findings on treating life-threatening diseases have substantially improved. At the same time, medical equipment and technology used for saving human lives has significantly improved; however, limited financial resources available in health care in Slovakia as well as in other Central and Eastern European countries are still a serious problem. This is true, to the same extent, for intensive care units, where doctors as well as other health-care workers have to solve moral dilemmas regarding effective use of drugs, medical technology, and other equipment in treating patients living risky lifestyles, such as alcoholics and drug addicts, and, on the other hand, when it is necessary to save lives of young people who have been in accidents, patients with chronic conditions, and so on. The situation in the Slovak health service, including intensive health care, at the end of 2011 is further complicated by doctors going on strike and handing in their notice in protest to the health-care reforms of Iveta Radičová's government regarding privatization of hospitals (in an effort to prevent hospitals from falling further into debt). Furthermore, doctors in hospitals have requested pay rises. Patients have, thus, come to be doctors' "hostages" in their effort to maintain the status quo or improve their own financial situation.

Palliative Care

The Slovak Ministry of Health defines the concept of palliative care in accordance with the WHO definition of palliative care (2002). This means that the concept of palliative care in Slovakia is focused on symptom management, pain, and suffering relief. The only legal option for terminally ill patients is the provision of opiates that neither prolong nor shorten their lives. Caring for patients is multidimensional (bio-psycho-social), and thus, the caring team consists of specialists from various fields. Moreover, palliative care not only involves care for the patient alone but also for the family members. The problem is that, in Slovak hospitals and health-care institutions, spiritual care is usually only provided by a clergyman. Therefore, many patients reject it merely because they are afraid of being forced to convert. This is why the lack of humanist workers and specialists trained in spiritual care represents an urgent problem which needs solving. Palliative care can be delivered in hospices (patients over 65 years of age), specialized wards in hospitals, or at home. The first palliative care ward in Slovakia was established at the National Institute of Oncology in 1995. *The Hospice of Mother Teresa* (*Hospic Matky Terezy*), the first hospice in Slovakia, was established in Bardejovská Nová Ves (Eastern Slovakia) in 2002. Nowadays, there are a few hospice services available in several towns in Slovakia. Nevertheless, hospice care is not financed by the government but by nongovernmental organizations. Apparently, this financial support is not sufficient, and people have to pay to stay in such institutions. Not all people can, however, afford to spend their last days in these institutions. The fact that supply and demand are not equal, as there are not enough palliative care establishments in Slovakia, is also a problem. Since 2006, palliative medicine has been officially recognized in Slovakia as a new field of medical study. This is considered a major success.

Care for the Elderly

In Slovakia, the population of elderly people with chronic conditions makes up a quarter of the overall population. Health care provided to patients older than 65 years of age is called geriatric care and is aimed at prevention, diagnosis, rehabilitation, and nursing of elderly patients. Care for the elderly is available in geriatric outpatient wards, geriatric hospital wards, and in long-term care wards. The insufficient number of beds for elderly patients is another pressing concern. On average, there are two beds per 10, 000 inhabitants and one geriatric outpatient ward per 10, 000 inhabitants over 65 years of age. Moreover, these are usually understaffed. From the above facts, it can be inferred that care for elderly patients is inadequate and the elderly are not sufficiently informed about their situation due to the unsatisfactory number of specialized geriatric clinics. Elderly people are not often adequately informed, and thus, their physicians cannot be aware of their wishes about possible future treatment, or where they would like to die, since the elderly do not always keep these matters in mind. Specialized physicians and those in homes for the elderly, geriatric hospital wards, and nursing homes should help

elderly patients think about their future and find out what their ideas about life and death are. However, as those are not always available, elderly people can end up in conditions they never wished for. Even if the specialized care giver and care are provided, the question should be asked whether physicians and nurses are adequately trained to care for the elderly and to provide them with the best possible care. The fact that the elderly usually only receive a small pension and that treatment is rather expensive, as is residential stay in a private home for the elderly, causes another problem. The Ministry of Health Care and the Ministry of Labour, Social Affairs and Family do not seem to be able to make a decision as to who should be responsible for the matters of the elderly. Therefore, a solution of these problems has been hindered. At the same time, the elderly usually enjoy contact with their GPs, and since, in Slovakia, patients do not pay any fee for visiting their GP, these visits are not controlled, and many patients think of GPs as a possibility for some social contact. Thus, GPs who are not specialists in geriatric care often have to surrogate the role of a psychologist or a social worker.

Chronic Diseases

In Slovak bioethical discourse, the issue of chronic diseases is mostly reflected in case studies of specific diseases, such as cancer and AIDS, or conditions like Down's syndrome or from a particular point of view (Nemčeková et al., 2004). Most theoretical aspects regarding specific characteristics of chronic diseases and conditions are not defined. Ethical and moral problems such as autonomy, freedom and its absence, decision-making capacity, and ability to fulfill one's social role and function are reflected in philosophical and ethical discussions; however, they are absent with regard to chronic diseases. The most prominent chronic health difficulties in Slovakia are an increasing incidence of cardiovascular conditions, tumors, respiratory diseases, allergies, and fatal accidents. From the total number of deaths, cardiac and vascular conditions and cerebral vascular diseases have for a long time been the most common. At present, more people are dying of circulatory system diseases than of all types of tumors. According to the 2005 WHO/EURO data, Slovakia is in the third (out of 34 European states) of those countries with the highest death rates. In general, between 1981 and 2005, Slovakia registered the lowest decrease in death rate due to circulatory diseases. In Slovakia, neither the number of new acute coronary incidences nor the number of strokes is decreasing. Diabetes mellitus, as one of the most significant risk factors, is associated with a two- to four-times higher mortality and morbidity with regard to cardiovascular conditions. A dramatic increase in cardiovascular complications in diabetics is partly due to insufficient regulation of glycemia but especially to coincidence of hypertension and dyslipidemia. Ischemic heart disease is a disabling and deadly disease, killing over 15, 000 people in Slovakia yearly. In the past 10 years, Slovakia has seen a minimum decrease in the most serious risk factors connected to cardiovascular conditions in the population. Such high prevalence in the Slovak population results from a very low level of their regulation. According to the overall

findings, as much as 68 % of women and 78.4 % of men are at risk. The incidence correlates highly with age, gender, the level of education, and the region of Slovakia, while the best results were found in the population of large towns and the worst in the regions of Southern and Eastern Slovakia. These findings also concern dietary habits. Ethical and moral issues concern especially unhealthy lifestyle of the Slovak population and lack of permanent public health-care information concerning reasons of chronic diseases as well as shortcomings in primary and secondary education about the harmfulness of smoking, using alcohol, and drugs.

Psychiatric Care

Specialized psychiatric outpatient departments, general hospitals with psychiatric departments, specialized hospitals (psychiatric hospitals, centers for treatment of drug addiction, psychiatric treatment institutions), psychiatric day-care centers, psychiatric treatment facilities, home care agencies, community-based psychiatric facilities, crisis centers with mobile team units, and so on are all examples of institutions in Slovakia providing services to people with mental disorders, with the main aim of providing necessary health care based on their specific needs. In 2004, the National Programme of Mental Health was approved by the Slovak government, with the following goals (for the period 2005–2015): reduction of the stigma associated with mental disorders, development of home care agencies, development of crisis intervention services, and development of mental health programs. In spite of these efforts, it is important to emphasize that psychiatric care in Slovakia is undervalued and does not meet the actual needs of society. For instance, insufficient capacity as well as poor material and technical facilities of particular psychiatric institutions could be mentioned. From the geographical viewpoint, an unevenly and insufficiently developed network of psychiatric care facilities represents another negative feature with regard to psychiatric care in Slovakia. Furthermore, patients with mental conditions sometimes become victims of discrimination based on the permanent stigma and prejudice present in society. They are seen as unpredictable, unreliable, or dangerous. The stigmatization of mental conditions often results in handicapped people not searching for help (from a psychologist or a psychiatrist) refusing help and advice from family members. Consequently, their health deteriorates and can lead to social seclusion. That is why it is necessary to uphold the dignity of these people and enhance the value of psychiatric care and services in this field. Such aspects as the stigmatization of mental conditions and its negative view in society can be defined as the main reasons for the slow development of psychiatric care in Slovakia (in comparison to countries in Western Europe).

Pediatric Care

Slovak pediatrics is of a very high standard; it has especially expanded in the past 30–40 years. Pediatricians achieve excellent results in the vaccination of children

against infectious diseases. Vaccination of children against these diseases exceeds 90 %, which means that the health situation of the youth in Slovakia with regard to the incidence of infectious diseases has improved in general. In the past, a considerable number of newborns, or children of preschool age, died of these diseases. On the other hand, parents' resistance to compulsory vaccinations is emerging, stating that, in a certain part of the child population, unwanted side effects to vaccination occur. Most doctors, however, caution that the health benefits of vaccination in the population outweigh possible unwanted side effects. Nevertheless, compulsory vaccination in children has come to be an area of ethically questionable lobbying by pharmaceutical companies toward pediatricians, which might be seen as a latent form of corruption. Dealers of pharmaceutical companies offer many benefits for medical doctors (including pediatricians) in order to prescribe their vaccines, for instance, they offer them free participation in medical conferences in tourist resort destinations, holidays, etc.

Emergency Care

The emergency service has a long-standing tradition in Slovak health care, although its technological level still lagged behind the world standards in the recent past. Lately, the situation has significantly improved, especially at the beginning of the twenty-first century, due to some reforms in the Slovak health-care system and investment by the government with regard to improving the standards and technological equipment in providing emergency care. A significant role was played by the introduction of private funds in the operation of emergency services and the fact that the state's, or public health-care institutions', monopoly in providing emergency service in various regions of Slovakia ended. Nevertheless, ethical, or moral, doubts arise regarding the transparency of the selection process of emergency service providers in individual parts of Slovakia, since, many a time, they change after the parliamentary elections and a change in the government.

General Practice

The standards of general practitioners in Slovakia are considerably high, which is related to the health-care system and the network of general care centers, established in the past 50–60 years in the entire Slovakia, in every village, and, naturally, in every town, where specialist doctors are available. A lack of general practitioners in economically poorer regions in Slovakia is an issue, and more difficult access to general practitioners in mountainous parts of Slovakia can also be considered a weakness. In the near future, a lack of dentists might be a serious problem in general, and especially in peripheral regions of Slovakia, which is related to high financial demands for the equipment of a dental clinic and the insufficient financial remuneration of their vocation. A certain ethical and moral problem regards latent corruption related to the prescription of more expensive

drugs produced by certain pharmaceutical companies, which, similarly, increases the operational expenses of Slovak health care and decreases its efficiency and, by effect, the quality of provided health care. Slovak health-care system lacks enough financial sources and majority of public hospitals are in permanent debt; however, due to strong pharmaceutical lobby, it is impossible to approve an efficient act concerning prescriptive policy in Slovakia. Slovak hospitals very often buy too much expensive medical drugs and units because a system of public procurement is ineffective.

Health Promotion and Education

Most vascular diseases can be prevented, and, according to the WHO background data, even a moderate decrease in blood pressure, obesity, level of cholesterol, and tobacco usage could decrease the incidence of cardiovascular diseases by more than a half. The goal of the European Heart Health Charter is to considerably lower the death rate to cardiovascular diseases in each European country. In 2006 and 2007, the government authorized two strategic documents: the National Alcohol Action Plan – regarding the problems of 2006–2010 and the National Tobacco Control Programme. The principles included in the World Health Declaration and the 2005 Luxembourg Declaration, also approved and signed by the Slovak Ministry of Health in 2007 in Bratislava, state that health is a fundamental human right. Everybody has the right to the highest standard of mental and physical health. Each country has the responsibility and the sovereign right to implement recommendations, while respecting differences among individual regions, ethical values, and culture and while taking internationally recognized human rights into consideration. The health-care system is no longer focused on treatment but rather prevention. This change results from the essential principles for health sustenance published in the Ottawa Charter (1986), as well as in the European Heart Health Charter (2007). The goal is to create a positive society-wide atmosphere for the intensive, efficient, and long-term education of population, as well as to enhance the education of medical doctors, with the aim of improving therapy especially in arterial hypertension and dyslipidemia. A solution to this joyless situation in Slovakia lies in a holistic understanding of health with a systemic approach based on prevention. Theoretical holistic models, as they are known in health care, offer philosophical and pragmatic solutions to health-care workers as well as the public. Research into the causes, pathogenesis, clinical manifestations, and complications of cardio- and cerebrovascular diseases is a fundamental priority in biomedical research.

Scientific and Professional Integrity

In Slovakia, medical doctors in general have a strong social status and respect given by their qualification and, in most cases, also by their great approach to their patients,

mainly perceived as suffering human beings. On the other hand, manifestations of paternalism are quite frequent, especially toward elderly patients or from elderly doctors. Corruption in health care seems latent in the cases of, for example, nontransparent public procurement and purchasing of medical and information technology and services and in prescribing more expensive drugs. The public steps doctors take at present (in 2011) directed against any reforms in Slovak health care (including privatization of state hospitals with the aim of preventing hospitals from falling further into debt) do not help their professional integrity nor do the efforts to have their pay increased, which is, from the viewpoint of the economic situation in Slovakia, seen as unfair by a considerable proportion of the public and media.

Relations with Industry and Donors

Another serious ethical and moral problem facing the Slovak health-care system is the pervasive influence of pharmaceutical companies and companies mediating the purchase of medical supplies and technology necessary for health-care operation, which is manifested by state hospitals consistently falling further in debt. Equally serious is the issue of the functioning of state hospitals, whose management changes after every parliamentary election, and governing political parties are rarely interested in their privatization. The medical trade union presents the same approach, which, by effect, preserves the existing condition and could lead to serious problems in the functioning of Slovak health care in the future. The ownership terms regarding many private health-care institutions, hospitals, or pharmacies are not clear either. On the other hand, private health-care institutions (including hospitals) often function better than state institutions.

Future Challenges

Bioethics Infrastructure

In Slovakia, important legislation in bioethics is often lacking. Therefore, attention should be paid to this area in the future, as well as to increasing the level of training of members of bioethical committees, especially in the knowledge of ethical and bioethical fundamentals. At the same time, attention should also be paid to providing education in bioethics at medical faculties and universities. It would be desirable to introduce lessons focused on basic information in bioethics at secondary schools. These would be taught by qualified specialists in bioethics (who would also be competent in the basics of ethics).

New and Emerging Issues

There is a great amount of work ahead in Slovakia in the area of public discussion on a number of ethical issues (e.g., abortion, euthanasia, embryo stem cell research,

therapeutical or reproductive cloning, and biobanks), which are being dealt in the world. However, specialized scholarly and academic debate is, in Slovakia, often absent or rather poor. It could be presumed that new specialist forums for discussions and presentations of opinions, such as the UNESCO Chair in Bioethics or the journal "Ethics and Bioethics," can significantly enhance an exchange of opinions and a search of optimum solutions to the above issues, which would be accepted by a considerable proportion of the specialist as well as lay public in Slovakia.

Opportunities

Another opportunity for further development of bioethics in Slovakia is cooperation with UNESCO (Bioethics Section, Social and Human Sciences Sector) in Paris and contacts with other UNESCO Chairs in Bioethics in the world, especially with the UNESCO Chair in Bioethics at the University of Haifa (Israel). Cooperation with other like-minded departments in Central European countries, especially in the Czech Republic, Poland, and Hungary, is equally significant. For the development of bioethics in Slovakia is very significant to create a platform for discussion among different approaches to bioethics (for instance, medical, legal, philosophical, ethical, sociological, and theological) and to start public discourse on the topical bioethical issues in contexts with discussions in the world. The next step is to improve bioethical education especially in medical faculties and universities as well as among medical doctors, nurses, and health-care workers.

Conclusion

In the past 20 years, Slovakia has made considerable progress in bioethics. Still, a great amount of work is ahead in the area of cooperation in creating policies, legislation, increasing the quality of bioethical committees' function, improving the situation in bioethics education, as well as discussing bioethical topics and contemporary issues with the scholarly and lay public. This requires greater openness and cooperation among medical doctors, health-care workers, scientists, philosophers, ethicists, theologians, lawyers, and other specialists dealing with bioethics in Slovakia. It is supported by the Slovak Research and Development Agency, contract No. APVV-0432-10.

Bioethics Development

When and How Has Bioethics Started?

Whereas medical ethics, in the guise of the Hippocratic tradition with its famous oath, is arguably one of the oldest disciplines in the Western intellectual tradition, bioethics, as we know and practice it today, has mostly been a product of the aftermath of World War II. In South Africa during the first half of the twentieth century, "discussions on medical ethics. . .largely took place within the framework of the authoritarian, paternalistic behavior expected of professionals supposedly

adhering to the Hippocratic Oath and similar codes" (Benatar, 2004, p. 564). In this respect, South Africa resembles most other Western countries, even though it is widely regarded as a developing country. South Africa is often referred to as a "microcosm" of the rest of the world in the sense that it has distinct similarities with both developed and developing countries. The first document on medical ethics in South Africa was written by Guy Elliot in 1954 and was based on his experience of deliberations on ethical matters by the Medical Association of South Africa (MASA). This document dealt mainly with ethical codes, professional secrecy, advertising, the conduct of consultations, fees, and financial matters and only very briefly with abortion, sterilization, and the ethics of investigative medicine (Elliot, 1954; Benatar, 2004, p. 564).

Bioethics was particularly stimulated in the course of the 1960s, internationally and also in South Africa. The rise of medical technology (such as the "Scribner shunt," i.e., the first instance of renal dialysis, accomplished in 1960 by Dr. Belding Scribner on his patient Clyde Shields – the ethical problem that this yielded had largely to do with the question as to which patients acquired preferential access to this technology) and the concomitant power over disease that it conferred upon doctors had much to do with this. More powerful technologies inevitably gave rise to questions about access; for the first time, people became really struck by the reality of "the doctor as judge of who shall live and who shall die" (title of a book by the German theologian Helmut Thielicke, 1976). An event in the South Africa of the 1960s, in turn, also generated new concerns of a bioethical nature, namely, the first heart transplant by Christiaan Barnard on Louis Washkansky on 3 December 1967 – an event that, apart from its overt significance in the history of medicine, was responsible for renewed reflection on the definition of death and the resultant emphasis on brain function, rather than cardiopulmonary function, as the significant and morally definitive indication of death. Following this event, a number of conferences, mainly organized by theologians, on medical ethical issues took place in South Africa in the 1960s and 1970s, but they led to very little public or professional debate in the country (Benatar, 2004, pp. 564–565).

At this time, bioethics was not yet regarded as a separate subject in the medical curriculum. To the extent that ethics received any attention in medical training, it was believed that it ought to be taught perfunctorily and informally "at the bedside."

Although the events just referred to no doubt also played a significant role in the rise of bioethics in South Africa, the struggle against apartheid and discrimination – respectively, the struggle for the acquisition of a culture of constitutionalism, human rights (enforced by law), and an open, democratic society – also played a pivotal role in the rise of bioethics, particularly in the 1970s and 1980s of the twentieth century. This will be dealt with in somewhat more detail in the next section.

Who Have Been the Major Actors/Forces?

As a discipline, bioethics was first systematically taught at the medical schools of the University of the Witwatersrand (Wits) and the University of Cape Town (UCT)

from the early 1980s onward. At Wits the teaching responsibility was mainly carried by a human geneticist, Prof. Trefor Jenkins. At UCT, the pioneer was Prof. Solomon R. Benatar, head of the Department of Medicine and a versatile physician with training in a number of medical specialties. To this prowess, he energetically added bioethics from the beginning of the 1980s and created a Bioethics Centre at UCT that became the vehicle of both the bioethics teaching program as well as a host of other activities that continue to this day. Benatar must be regarded as not only the true pioneer but the main driving force of bioethics in South Africa since the 1980s. Besides his numerous publications, Benatar was the first chairperson of the National Health Sciences Research Ethics Committee of South Africa (more about this below), and he is also a former president of the International Association of Bioethics. Bioethics teaching, let alone research, took a significantly lower profile at the other South African universities until the beginning of the 1990s.

Formal qualifications in bioethics in South Africa are mostly a product of initiatives of the 1990s. At Stellenbosch University, Prof. Anton van Niekerk (a philosopher, not a physician) created a Centre for Applied Ethics with a Unit for Bioethics in 1990 and designed a master's program in bioethics from 1996 onward (it is still offered and creates much interest). Many of the students that completed this program are today visibly active in bioethics research and training in South Africa and abroad. Prof. Willem Landman at the University of the Western Cape also developed an interest in bioethics in the course of the 1980s. He moved to the Department of Humanities at the Brody Medical School of East Carolina University in the USA in 1994 where he attained full tenure before returning to South Africa in 2000 to set up the Ethics Institute of South Africa, which will be discussed in the next section. The next section will also address the more concerted training programs in biomedical research ethics that came into being in the course of the first decade of the twenty-first century.

The first full-time position in the Wits faculty for teaching bioethics was created about 15 years ago, when Prof. Udo Schuklenk was appointed there. He took responsibility for undergraduate training and also created a postgraduate program that was offered online. He has since left South Africa and is currently teaching bioethics at the Philosophy Department of Queen's University in Canada. The teaching programs at Wits are continuing under the auspices of the Steve Biko Centre for Bioethics. During his stay in South Africa, Schuklenk also created the Blackwell-published journal for bioethical issues in the developing world, *Developing World Bioethics* that he has edited since 2001, initially with Willem Landman.

Bioethics, however, did not only gain interest because of the work of individuals. A train of events related to the death of Steve Biko, one of the best-known martyrs for freedom during the struggle against apartheid, also played a pivotal role in sensitizing people to bioethical issues in the course of the 1980s.

The Biko history can only be fully understood and its relevance for bioethics only adequately appreciated against the background of the reality of apartheid, South Africa's notorious system of racial discrimination and oppression that was

only overturned when the country became a democracy in 1994 under the leadership of Nelson Mandela. Apartheid, which blossomed between 1948 and 1994 when the National Party was in power in South Africa, was a political and sociocultural system that institutionalized racism and racial discrimination. Under apartheid, black people had no vote and were excluded from any significant political power. The races in South Africa were socially separated, and blacks were systematically discriminated against by means of the Population Registration Act (in terms of which whites and blacks were identified as such), the Group Areas Act (which enforced separate residential and business areas for the different races), and the Mixed Marriages Act as well as Article 16 of the Immorality Act, in terms of which marriages between black and white were prohibited and sexual intercourse between members of different races was criminalized. There was strict separation of schools, with blacks receiving patently inferior education, and in the labor market, they could at best operate in jobs that required little formal education. Blacks were expected to move to so-called ethnically based "homelands" where they could execute political rights, but these covered hardly 13 % of the landmass of South Africa and were utterly underdeveloped areas with little or no potential for agricultural, economic, or sociopolitical development. The "homelands" were also never recognized by the outside world as politically legitimate or sustainable entities.

Steve Biko was a medical student and a pivotal leader of the Black Consciousness Movement in the 1970s in South Africa – a movement that espoused the philosophy that black people should take pride in who and what they are, despite the dehumanization of apartheid to which they were daily exposed, and should take responsibility for their own liberation. He was taken into custody in Port Elizabeth because of his dissemination of these ideas. In the process, he was tortured and received patently inadequate medical care. He sustained a very serious head injury that was not diagnosed by the physicians who, in collusion with the apartheid authorities (notably the then South African Police), paid lip service to examining him. He consequently was thrown naked, with only a hard rug to lie on, into the back of a Land Rover and driven about 750 miles to Pretoria Central Prison, where he died unattended in his cell the next day, 12 September 1977. His death was immediately world news. The questions regarding how he died and the cause of death were deliberately ignored by the South African government, and the significance of his death was rudely downplayed, particularly by the then minister of justice, Mr. Jimmy Kruger, who, in a speech in parliament, made the notorious statement that "Biko leaves me cold."

What makes the Biko history particularly significant for the history of bioethics in South Africa has to do with the responses to the circumstances surrounding his death by the organized medical profession in South Africa. The South African Medical and Dental Council (SAMDC) – the body that at that time registered and disciplined all healthcare professionals – refused to act against the doctors (Lang and Tucker) who (mis-) treated Biko. This caused a national and international furore. Consequently, a small group of medical doctors, led by Prof. Frances Ames, Philip Tobias, and Trefor Jenkins (all from Wits University), took the

SAMDC to court for neglecting their duty in this regard, and this led to a supreme court injunction against the SAMDC, resulting in a reversal of its previous decisions and the imposition of disciplinary action against the guilty doctors.

In a recent publication, the significance of the Biko affair for the rise of and interest in bioethics in South Africa was formulated as follows by Van Niekerk and Benatar:

> [T]he Biko affair, and the way in which it highlighted the importance of a moral orientation in the practice of medicine, directly contributed to a re-organization of the institutionalized medical profession in South Africa. Greater attention to ethical responsibilities toward prisoners, detainees, and hunger strikers was another gratifying response to the Biko case (Jenkins, 1987, 1988; Benatar, 1988, 1990; Kalk and Veriava, 1991). The public confession of guilt by the district surgeon who bore major responsibility for Biko's medical care, emphasized the need to maintain professional independence in the face of state security and other coercive pressures. . .[T]ogether with an event such as the Soweto uprising of June 1976, Biko's death made it clear that all rhetoric from government leaders about the intended justice of the homeland system, and other alleged feats of apartheid, was bogus, that the system was morally corrupt, and that its demise was merely a matter of time. At the same time, it highlighted the depths to which a society can sink when gross violations of human rights occur and are tolerated. It is no exaggeration to claim that the Biko affair, together with other factors, played an important role in sensitizing the country at large about the dire need of a culture of human rights in South Africa. The Bill of Rights that today introduces the South African Constitution (finalized in 1996) is therefore, in a special way, a testimony to the important lessons learned in South Africa from the Biko affair, and from the canons of medical ethics. In this sense it can be argued that the Biko affair was also a very significant turning point in South African history, and an illustration of the social and political impact that a severe violation of medical morals had on South African society. (Van Niekerk & Benatar, 2011, pp. 138–139)

What Have Been the Major Concerns over Time?

In the previous section, mention was made of the fact that it was only in the 1980s that bioethics attained systematic and sustained attention from academicians in South Africa, followed by a flurry of activities and a growing range of outputs in the course of the 1990s and the first decade of the twenty-first century. In addition, there was a discussion regarding the way in which collusion with the apartheid regime by senior and authoritative members of the medical profession in the 1980s resulted in bioethics mainly focusing on the issue of medical professionalism and justice in the access to and administration of healthcare.

The *Proceedings of a UCT Faculty of Medicine Symposium*, held in July 1991 and published in 1992, give an indication of the kinds of issues and concerns at the forefront of bioethical reflection in South Africa up to that point. The main contributors to the published proceedings were philosophers. Allen Buchanan and Dennis Thompson were invited from abroad, whereas Willem Landman, André du Toit, and David Brooks made up the South African philosopher contingent. Other contributors were Solly Benatar, Cedric de Beer from Wits, the theologian Willem Saayman, and the medical sociologist Dingie van Rensburg. Most of the

contributions were on the issue of the alleged right to healthcare as well as the most advantageous health system for a South African society that, at that time, was in transition and would elect its first democratic government within 2 years of publication. Another theme that was addressed was the growing AIDS epidemic and its ethical ramifications, as well as isolated papers on hospital ethics and the issue of the withdrawal of life support from terminally ill patients.

In the first half of the 1990s, the newly created Unit for Bioethics, part of the Centre for Applied Ethics at Stellenbosch University, also organized a range of annual conferences on, at that time, topical issues in bioethics. These topics were the status of prenatal life, the moral problems provoked by the AIDS pandemic, genetic manipulation (as it was then called), and the issue of healthcare as human right. Four books were published as the outcome of these conferences (which were well attended). Contributors included philosophers (Anton van Niekerk, Willem Landman, and Johan Hattingh), physicians (Jacques Kriel and Pierre de Villiers), lawyers (Andreas van Wyk and Lourens du Plessis), sociologists (Dian Joubert), and theologians (Etienne de Villiers, Danie du Toit, and Daniel Louw). It is clear from these initial activities that bioethics was, from the beginning, approached in a multidisciplinary manner.

HIV/AIDS grew in prominence as a major issue in the course of the 1990s and the first decade of the twenty-first century, mainly because of the controversy surrounding the government's apparent inertia toward the problem and the way it seemed to spiral out of control. The issue of HIV/AIDS in South Africa will be more fully addressed later on in the section concerning "Infectious Diseases".

The 1990s also saw significant developments in connection with abortion and euthanasia as traditional bioethical issues. The year 1996 saw a new, revolutionary abortion law (the "Choice on Termination of Pregnancy Act"), which overturned South Africa's archaic statutory position on abortion into one of the most liberal dispensations available in the world. As regards euthanasia, a comprehensive investigation was undertaken by the Law Commission in the latter half of the 1990s and brought to completion by a comprehensive report and provocative recommendations. This report, which was tabled in parliament, has not succeeded in drawing any significant response from the government to this day. These two events shall be dealt with in more detail in section "Major Bioethics Issues and Discussions".

Topics that have come to dominate bioethical reflection in the course of the past decade have been again HIV/AIDS but also biomedical research ethics (including the issue of benefit sharing in research ethics in the developing world) as well as global health ethics.

What Resources Have Been Developed?

South Africa's Medical Research Council (MRC) set up an ethics committee that, since the late 1970s, formulated guidelines for medical research. This was in response to a need for guidelines in the South African context that would complement the adherence to universally authoritative, yet less specific guidelines such as

the Belmont Report, the Nuremberg Code, and the Declaration of Helsinki. The first two editions of these guidelines (1979 and 1987) were small, pocket-sized volumes. They were followed by a much more comprehensive revised edition in 1993 which was also, with permission, extensively based on reports from the Royal College of Physicians of London. Up to this point, the guidelines were contained in a single volume. The MRC ethics committee, under the leadership of Prof. Peter Cleaton-Jones of Wits, again oversaw a comprehensive revision of these guidelines, which resulted, shortly after the turn of the century, in the publication of five separate books of guidelines. They all have the overarching title of *Guidelines on Ethics for Medical Research*, and the five more specific themes are (1) general principles, (2) reproductive biology and genetic research, (3) the use of animals in research, (4) the use of biohazards and radiation, and (5) HIV vaccine trials. Some of South Africa's most eminent bioethicists and medical scientists and researchers contributed to this work.

Since the publication of these five volumes, the South African Health Professions Council (the follow-up of the former SAMDC referred to earlier in connection with the Biko incident) also published guidelines for good clinical practice.

A significant number of books in the field of bioethics have been published by South African bioethicists. A few of the more recent titles may briefly be mentioned. The first is Solly Benatar's most recent book *Global health and global health ethics*, a volume he edited with Gillian Brock and which was published by Cambridge University Press in 2011. This year (2011) also saw the publication of a comprehensive introduction to bioethics, titled *Medical Ethics, Law and Human Rights*, edited by Keymanthri Moodley and published by Van Schaik. Moodley and Sudeshni Naidoo also published a book *Ethics and the Dental Team* in 2010. Ames Dhai and David McQuoid-Mason of the Steve Biko Centre for Bioethics similarly edited a book with the title *Bioethics, Human Rights and Health Law: Principles and Practice*, published by Juta (2010). Anton van Niekerk and Loretta Kopelman edited a volume titled *Ethics and AIDS in Africa: The Challenge to our Thinking*, published by David Philip in South Africa and Left Coast Press in the USA in 2006. Mention must also be made of Solly Benatar's penetrating chapter titled "Ethical challenges for health care in South Africa" in HCJ van Rensburg's comprehensive volume *Health and Health Care in South Africa* (Van Schaik, 2004).

South African bioethicists publish in journals all over the world. A South African bioethics journal has recently been created and has the title *The South African Journal of Bioethics and Law*. It is edited by a team of no less than 12 people. *The South African Medical Journal*, however, also regularly publishes articles and letters of a bioethical nature. Mention has been made of the journal *Developing World Bioethics*, currently edited by Udo Schuklenk and Debora Diniz. Although published by Blackwell in Britain and not specifically South African, this journal has attained a certain popularity in South African bioethical circles and mostly addresses issues that are quite pertinent to the South African context.

The Internet nowadays offers a series of networks in which South African bioethicists often participate. A recent and quite active example of this is the Bioethics International Facebook Network.

No specific society for bioethics has been created in South Africa, although an ethics society was set up a number of years ago but was found to be unsustainable. South African bioethicists seemingly prefer to attend and contribute to international societies and conferences, notably those of the International Association of Bioethics. Solly Benatar (an ex-president) and Anton van Niekerk have served as board members of the latter international society.

What Have Been the Steps/Measures Taken?

Reference has been made to policies with bioethical ramifications that have been put into place (like the Abortion Act of 1996) and the Law Commission Report on the possibility of voluntary active euthanasia in 1998 – a report that has not yet been acted upon in South African legislation. A number of constitutional court cases related to end-of-life care as well as to justice in the distribution of healthcare have taken place, of which the best known is that of *Soobramoney versus the Minister of Health in Kwazulu-Natal* (1997), the first in which the court had to adjudicate on the universal constitutional right to medical treatment as against the problem of an underresourced healthcare system. Mr Soobramoney was a terminally ill patient who required access to renal dialysis but was refused access by Addington Hospital in Durban because he did not meet the eligibility criteria. The hospital argued that, in the light of the overwhelming demands on this treatment facility, the chances of less ill patients benefiting considerably more from the treatment than Mr Soobramoney were significantly better. The constitutional court ruled in favor of the hospital.

A measure of order and coherence among a disparate number of policy documents related to a variety of medical treatments and research was restored with the promulgation of the new National South African Health Act (No. 61 of 2003). This act is important for a wide variety of measures that it now regulates. For the field of bioethics, mention must particularly be made of its provisions for medical research as well as the creation and accreditation of research ethics committees via the National Healthcare Ethics Research Committee (NHERC). Both of these aspects will be dealt with in more detail later in this chapter. Ethics committees for both clinical overview and research review are currently quite pervasive in South Africa. Much has also been achieved in terms of setting up teaching programs in bioethics at most of the healthcare training facilities in South Africa, even though the outcome of these efforts is currently somewhat uneven. This will be discussed in more detail in the next section.

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

The teaching of bioethics in South Africa mainly occurs at two levels: that of tertiary education in the health and biological sciences and at the level of

continuous professional development of health workers registered at and accredited by the South African Health Professions Council (SAHPC). The second level will be discussed before moving to the first.

For more than the past decade, the SAHPC has required mandatory continuous professional development (CPD) for all health workers registered under its authority and auspices (medical doctors, dentists, psychologists, nurses, physiotherapists, and occupational therapists). Each health professional has to score a number of annual points for such CPD. For most of these professions, a tally of 10 CPD points for bioethics training needs to be scored by each individual annually. Separate sessions or seminars for ethics training are therefore set up regularly, whereas it has now also become customary to have a special plenary on ethics at every large healthcare conference that is organized in the country. The hope is that this CPD ethics training might to an extent compensate for the lack of sufficient ethics education characteristic of particularly an older generation of healthcare workers in South Africa. The author of this article has been involved in a wide variety of these activities over the past decade. Greater, though arguably not adequate, ethical sensitization has developed in healthcare circles because of these initiatives.

Whereas bioethics training at universities (particularly medical schools) was sparse in the 1980s, much progress has been made ever since. Bioethics has gradually been introduced into the undergraduate training of healthcare workers in the course of the 1990s, but full curricula have only been developed in the first decade of this century. No fully-fledged departments of bioethics or of medical humanities have been created in the medical schools in South Africa, and likewise, no fully-fledged chairs in bioethics have been established. What has rather occurred is that centers or units for applied ethics or bioethics have been established at universities such as UCT, Stellenbosch, Wits, and Kwazulu-Natal. These centers undertook ethics education as part of their brief, but they originally developed as centers for research and service delivery. Nowadays, particularly at the four mentioned institutions as well as the medical schools of the Universities of Pretoria and to a lesser extent the Free State, full curricula in bioethics have been developed and are being taught, mostly by staff in the medical school and often assisted by philosophers. The book edited by Keymanthri Moodley and mentioned earlier (*Medical Ethics, Law and Human Rights*) gives an adequate idea of the type of curriculum contents that, for example, is being taught at the medical school of a university such as Stellenbosch. The idea of bioethics as a fully-fledged subject with equal status to that of the other medical disciplines (as occurs, e.g., at some universities in the USA, such as East Carolina University) and taught in every year of medical training has not been seriously entertained in South Africa.

This also raises the question about who trains the trainers. Not all efforts at developing postgraduate training programs in bioethics in South Africa have been successful, though a number have been attempted. UCT created a master's in bioethics that was abandoned after a few years, because of other developments in research ethics training that we will deal with shortly. The same is the case for an online master's that was attempted at Wits. Wits Medical School currently offers a master's in medical sciences in bioethics. The best known and attended of these postgraduate

general programs in bioethics has, however, been the two-year master's in philosophy in bioethics that has been offered by Stellenbosch University's Philosophy Department and Centre for Applied Ethics since 1996, still continuing with ever-growing numbers. (The structure of the program is changing slightly from 2012 onward due to new directives about master's degrees by the South African Department of Higher Education.) A total of about 80 bioethicists have been trained through this program, and many of them occupy influential positions in healthcare faculties and other academic structures in South Africa and abroad. A small number (about 12) of the students who completed this program successfully have gone on to attain PhDs in bioethics, most of them at Stellenbosch University.

Thus far, we have predominantly addressed general bioethics training at under- and postgraduate level. Over the past decade, postgraduate training in specifically biomedical research ethics has become very important and prominent in South Africa. Van Niekerk and Benatar write in this respect:

> As in the rest of the world, clinical research has become a major enterprise (and an instance of big business) in South Africa, and, increasingly, in other parts of Africa. In their chapter on health research in South Africa in the 1999 edition of the *South African Health Review*, Mbewu and Mngomezulu write that, for many years prior to democracy, South Africa has been regarded as a "researcher's 'paradise' . . .because of its first world technology alongside a third world captive population, largely unprotected by codes of conduct and with extremely poor human rights protection" (Mbewu & Mngomezulu, 1999, p. 370). Consequently health research done in South Africa and other African countries was often not submitted to rigorous ethical scrutiny in a manner that would have been required in developed countries, and the benefits (if any) of which were often not made available to the populations amongst which the research was originally done. A lot of what is currently done in bioethics in South Africa deals with capacity building in research ethics, in particular capacity to participate in the ethical review of research protocols. Research – including the research initiated and executed by multi-national conglomerates in the developing world – prima facie always has a beneficial intent. Yet, these multi-national corporations at the same time have commercial, profit-seeking agendas that do not always operate with altruistic intent and to the demonstrable benefit of research subjects in these countries. Bioethics therefore faces a special responsibility not to be hi-jacked by those same agendas, and to exercise its morality-seeking responsibility with real integrity. (Van Niekerk & Benatar, 2011, p. 144)

In view of this need to thoroughly train actual and potential members of research ethics committees or institutional review boards for the informed execution of their responsibilities, two networks or initiatives were formed, namely, the International Research Ethics Network of Southern Africa (IRENSA), under the leadership of Prof. Solly Benatar in Cape Town, and the South African Research Ethics Training Initiative (SARETI) under the (eventual) leadership of Prof. Doug Wassenaar of the University of Kwazulu-Natal (in collaboration with colleagues at the University of Pretoria). Both these initiatives applied for grants by the Fogarty Foundation of the National Institutes of Health in the USA, and both applications were successful. In the IRENSA initiative, apart from the South African multidisciplinary contingent of faculty members, lecturers from abroad such as Peter A. Singer from Toronto and Len Doyle from London became actively involved in the teaching. IRENSA offered a postgraduate diploma in international research ethics, and SARETI a master's degree.

In the case of the IRENSA program (which ran for 8 years, from 2003 to 2010, with one renewal of the grant), a total of 244 students – many from African countries besides South Africa – applied for the program; 97 were admitted to the program and 79 completed the training. Generous bursaries were allotted to the successful applicants that enabled them to attend three annual lecture series. They were also expected to complete a practicum. There can be no doubt that the training done in this course will, in due course, have a very significant effect on the quality of work done by research ethics committees in South Africa and on the continent of Africa. A highly informative (though unpublished) *Impact Report* on the IRENSA program became available in the course of 2011. It contains information of the student intake and success as well as reports from the trainees, the countries, and the institutions involved and a range of reflections on their experience in the program by members of the faculty.

Recently, another application to the Fogarty Foundation for a similar program offered by the Centre for Medical Ethics and Law in the Health Sciences Faculty of Stellenbosch University has been successful. This initiative is called Advancing Research Ethics Training in Southern Africa (ARESA) and also takes the form of a one-year postgraduate diploma. The principal investigator is Prof. Keymanthri Moodley, director of the center, assisted by a co-PI, Dr. Stuart Rennie from the University of North Carolina (Chapel Hill), as well as a multidisciplinary team of lecturers. The first intake of students occurred in 2011.

Bioethics Committees

The original bioethics committees in South Africa are the ethics committees of the Medical Research Council and of Wits University, both of which were fully operational in the course of the 1980s. Mention has already been made of the series of *Guidelines for Medical Research* that were published over three decades by the MRC committee. In the course of the 1990s, research ethics committees that take the responsibility of an ethics review of all new research proposals that are undertaken by researchers of a particular institution have been created by all the universities that are engaged in healthcare research. The work of these institutional committees has progressively increased over the years, and there are currently serious concerns about their sustainability across the board (particularly at large institutions with high volumes of research) without due compensation to members or without significant additional investment in administrative support for the work done by members who are mostly ordinary academics burdened with many other responsibilities.

It has in South Africa, as elsewhere in the world, increasingly been accepted that any research involving human beings, even if the research is not strictly of a medical nature, requires ethical scrutiny, particularly in terms of issues such as confidentiality and the informed consent of research participants. The result is that we are also increasingly seeing research ethics committees making their appearance in faculties of humanities and social and economic and/or business

sciences as well as the faculty of education. The treatment of animals requires such committees in faculties of science, veterinary science, and agriculture, whereas the issue of the possible impact of research on the environment has also resulted in such committees being set up in faculties such as science and engineering.

Ethics committees also occur in institutions that are not strictly academic. The South African Medical Association has set up an ethics committee, and ethics committees are increasingly being created at a number of hospitals in South Africa, mainly for consultation regarding morally problematic clinical situations. A research body such as the Council for Scientific and Industrial Research (CSIR) currently has an ethics committee.

This proliferation of ethics committees raises the question as to the capacity for service on the committees. The relatively recently promulgated South African Health Act (2003), referred to earlier, has created an oversight body that is supposed to take care of this problem. In terms of this new act, this body is known as the National Health Sciences Research Council (NHSRC), which is strictly speaking not an ethics committee itself but a national policy-making body that is appointed by and reports to the Minister of Health. This council is expected to accredit and register all legitimate ethics committees in the country and even to act as the final court of appeal for researchers who are unhappy about the decisions of the committees to which they originally submitted their protocols. How exactly this latter alleged function of the NHSRC is to be executed is nevertheless unclear. Other questions also prevail about the exact brief of this new structure.

Expert Bodies/Centers

Mention has already been made of Centres for Applied Ethics and Bioethics that have been created at the universities of Cape Town, Stellenbosch, and Wits. At the academic level, these three centers represent the center of gravity in terms of academic work in the field of bioethics in South Africa.

The establishment of the Ethics Institute of South Africa (EthicsSA) in the course of the year 2000 was, in addition, a significant step taken in fostering an ethical business and healthcare culture in South Africa in recent times. The organization was established as the outcome of a comprehensive feasibility study, in the course of 1998–1999, by the Merck Company Foundation (facilitated by the Ethics Resource Center in Washington, DC) and the South African Medical Association (SAMA). The aim was to set up an ethics center, molded along the lines of similar institutions that the former two organizations have set up in other parts of the world. SAMA's involvement had the effect that the center, set up in 2000 as a consequence of the work of a steering committee of which the author of this chapter was a member, initially concentrated on ethical issues in the healthcare sector of South Africa. Willem Landman, earlier professor of philosophy and medical ethics at the University of the Western Cape and East Carolina University in the USA, was appointed as first CEO, a position he held until 2009, when he retired (he continues

as an executive director). Prof. Deon Rossouw, previously from the University of Pretoria, was subsequently appointed as the next CEO.

EthicSA is an independent, Section 21 (nonprofit) company that initiates and supports ethics-related activities. It has a small management team and a board consisting of business people, academics, and professional persons. Its offices are situated in Hatfield, Pretoria. Income is generated through grants, services, and a membership program. The organization has progressed from 100 % dependence on grant income in 2000 to becoming self-sustained at present.

EthicSA's vision is one of an ethical South Africa. Its mission has, from the outset, been ethics advocacy. To this end, it provides thought leadership, does research, offers training, and provides support services. It works in partnerships with the public and private sectors, academia, and the professions. It promotes and advances ethical practices in South Africa (and Africa) in the professions, business, and public policy. To this end, ethical standards are set and resources are provided to meet those standards in the public and private sectors.

In its first 3 years, EthicSA completed four major research projects, all of which attracted wide media attention but, importantly, also led to significant efforts by interested parties to address the practical ethical challenges highlighted in the research reports. Research projects in medical ethics focused on the ethics of the business practices of South African medical doctors, the Chris Hani Baragwanath Hospital in Soweto, and the Universitas Hospital in Bloemfontein. In 2003, the organization published a research report on the state of corporate ethics management and programs in 53 top companies listed on the JSE Securities Exchange.

EthicSA's specific current activities include:

- Encouraging public debate on ethical issues
- Initiating and facilitating ethics research
- Contributing to ethics education and training
- Producing ethics publications
- Facilitating the development and implementation of codes of ethics
- Conducting organizational ethics assessments (audits)
- Setting ethical standards and developing public policy

EthicSA has facilitated a considerably heightened ethics awareness in the country. In terms of its visions and mission, it is a unique organization, and its situatedness as an independent, nongovernmental organization (NGO) outside of the academic departments that deal with ethics creates an opportunity of a unique quality of appeal and sensitization to ethical concerns in the South African populace at large.

Major Bioethics Issues and Discussions

Beginning of Life

Before 1996, South Africa had an extremely conservative dispensation as far as the possibility of abortion was concerned. Abortion was only allowed when the

mother's life was endangered by continued pregnancy, when the pregnancy was the outcome of rape or incest, when the fetus suffered from severe congenital disease, or when continued pregnancy would cause severe mental disease. This dispensation was dramatically changed by the promulgation of a new law, officially called the Choice on Termination of Pregnancy Act (Act 92 of 1996), in the direct aftermath of South Africa's becoming a democracy in 1994. As a result of this act, South Africa nowadays has one of the most liberal abortion dispensations in the world. In terms of the act, abortion on demand is, without conditions, possible for the first 12 weeks of pregnancy. Healthcare workers may refuse to do the procedure on the basis of conscientious objections but are then compelled to refer the patient to a healthcare worker who will perform the procedure. There is no age restriction on the woman that requests an abortion. Children must be counseled and advised to inform their parents but are free not to do so. The father of the fetus (if known) does not have to be informed. When the pregnancy is between 12 and 20 weeks, abortion is still possible on request if certain indications apply, one of which being that abortion is permissible if the birth of the child would disadvantage the pregnant woman financially. This makes abortion up to 20 weeks de facto possible under this law in South Africa.

End of Life

The following quote from Van Niekerk and Benatar summarizes the situation in this regard adequately:

> In South Africa, no form of "active euthanasia" in the sense of active assistance in bringing about death is legal in the clinical situation. Withholding treatment in situations where the treatment is futile and death is inevitable has been defended in South Africa (Benatar et al., 1994b) and is legally permitted. The "new South Africa" has seen a seemingly provocative reinvestigation of this position on assisted death. At the time following the adoption of South Africa's new constitution (1996), the South African Law Commission launched a comprehensive research project on this issue and brought out a report.
>
> While this report and recommendations of the Law Commission were tabled in parliament more than 10 years ago (1998), and its recommendations were widely reported and commented on in the press. . .there has been no further effort by the government of the day to take these recommendations further in terms of legislation.
>
> The earlier referred-to status quo, therefore, still prevails on this issue in South Africa. Whereas it is fair to surmise that bioethical teaching, reflection, and discussion might well have contributed significantly to the formulation of the Law Commission's report. . .the absence of further action and legislation bears testimony to the limited impact of bioethics in South Africa as far as this issue is concerned. (Van Niekerk & Benatar, 2011, pp. 140–141)

Healthcare System: Access to Healthcare

South Africa has a two-tiered healthcare system, namely, a private system and a public system. About 80 % of the population is served by the public system and

20 % by the private system. The situation is, however, considerably reversed when it comes to the utilization of resources. More than 60 % of all resources spent on healthcare in South Africa are spent in the private sector which caters for only 20 % of the population. That means that less than 40 % of resources are spent in the public sector, catering for 80 % of the population. Also less than 15 % of South Africans have medical insurance (in the sense of membership of medical aid funds). The cost of healthcare in the private sector makes such insurance imperative.

The palpable injustice of this dispensation is to a significant extent a remnant of the apartheid system and is therefore widely not regarded as sustainable. The ANC government has, in the past year, announced that it is moving forward with its intention to create a national healthcare system which will, in principle, make effective healthcare (what the package will be is still unclear) accessible for all South Africans. The idea apparently is that everybody will be compelled to contribute to this system according to means and that people who have the resources will still be able to access additional insurance that will transcend the package of coverage that the new system will make available to all.

What remains unclear is exactly how this new system will be financed and when it is foreseen that it will come into operation. Up until now, the idea of such a new national system has not run into serious opposition, even from the ranks of private healthcare providers. That situation might change as more detailed plans for the new system become public in the near future.

Traditional Medicine

South Africa's African social context is such that traditional medicine still plays an important role among many communities in the country, particularly those in rural areas (although urban Africans quite often supplement their adherence to Western healthcare with the occasional visit to and advice from a traditional healer). It does sometimes happen that effective care is thwarted by ill-advised practices or potions recommended by traditional healers. Often, however, their advice and forms of care do not cause clear-cut harm.

A practice that has been explored over the past decade is the possibility of cooperation between traditional healers and Western doctors, particularly as far as HIV/AIDS treatment is concerned. Success has been achieved in training such healers in the basic aspects of HIV diagnosis and utilizing them to channel potentially HIV-positive patients to centers of Western care after a visit to the traditional healer.

Infectious Diseases

For many years, mainly during the second half of the 1990s and the first half of this century's first decade, bioethical discussions in South Africa were dominated by the HIV/AIDS pandemic. The history of this syndrome's first appearance in the early

1980s, its initial association with men who have sex with men and drug abusers, the eventual realization that it spreads even more rapidly through unprotected heterosexual intercourse, and its eventual devastating occurrence and preponderance in sub-Saharan Africa where 10 % of the world's population carries 70 % of the world's burden of HIV/AIDS disease, is well documented. Amidst these alarming findings, it also became clear that South Africa was the country with the highest number (in absolute terms) of HIV infections; at one stage, this figure was 5.1 million, which amounted to 21 % of the adult population of the country. Until fairly recently, the indication also was that as many as 80,000 children were infected annually and that there were 200,000 infected children under the age of 15 in South Africa.

The ethical problems associated with the HIV pandemic seemed endless. Should infection warrant notification of the state? Should there be mandatory testing, particularly given the problems of effective surveillance? Should infecting another person without revelation of one's status be criminalized? Is it warranted to discriminate against infected people, particularly in the workplace? What are the human rights of HIV-positive individuals? How is the stigma associated with the disease to be overcome? Is it morally justifiable to make condoms available to children? Is it morally warranted to do research on children with HIV/AIDS? Is it morally in order to experiment with cheaper drug regimens against placebo in Africa, given that, for a long time, the minimum standard of care was nothing at all? Is it morally in order to violate intellectual property concerns in order to produce cheaper HIV/AIDS drugs in the developing world? The list goes on and on.

What, however, complicated the South African debate very considerably during the indicated time was the attitude of policymakers at the highest level of government. The impression was often created and several times reinforced that pivotal people in government, such as the then Minister of Health, did not accept that AIDS was caused by a retrovirus, that established medical science about the development and treatment of the condition was suspect, and that it should be replaced by treatments designed by people who were generally regarded as quacks by the healthcare establishment. There was, in particular, extreme reluctance to make antiretroviral treatment for the condition available at state health facilities, even when it became clear that some large pharmaceutical companies, who were often suspected of exploiting the pandemic for the sake of profit, were willing to provide the drugs free of charge or at greatly reduced prices. This caused an uproar, and the government was taken on in the streets and in the highest court of South Africa by an activist group called the Treatment Action Campaign under the spirited leadership of Zachie Ahmat. The conflict between the healthcare profession and the government came to another head when Dr. Thys von Mollendorff, superintendent (i.e., chief medical officer and administrator) of a prominent hospital in Nelspruit in the province of Mpumalanga, agreed to make his facilities available for the provision of antiretroviral treatments for rape victims. He was, as a result, fired by the then Minister of Health of Mpumalanga in 2001 for contravening official government policy on the provision of antiretroviral treatments. The incident is

indicative of the enormous obstacles that hindered the effective management of the pandemic for a considerable period in South Africa's recent history.

Governmental resistance to the medically justified treatment of HIV/AIDS has luckily abated in the past few years. There does not seem to be any more governmental denial of the problem, and the provision of proper treatment has now become part of official government policy. South Africa's widespread poverty and the difficulty of people living with HIV/AIDS in the rural areas to reach proper healthcare facilities nevertheless remain enormous challenges for the effective combating of the pandemic. What also remains a serious shortcoming in South Africa's approach to this crisis is the absence of an imaginative prevention campaign along the lines of successful initiatives as were seen in countries like Uganda, Sierra Leone, and Thailand.

Van Niekerk and Benatar write in this regard:

> Education about safe sex and about the use of condoms are important aspects of the thrust against HIV/AIDS, but these are not remotely sufficient to overcome deeply entrenched suspicion of such advice that interferes with procreation and that goes against centuries of socially-accepted and psychologically-driven sexual practices in other cultures. Failure to recognise the pervasive social, economic, behavioural and political aspects of HIV/AIDS – both in terms of its origins and its control – is self-defeating. The complexity of the scientific endeavour required to understand the pathobiology of the disease and to develop appropriate treatment is more than matched by the complexity of understanding and dealing with the social underpinnings of HIV/AIDS and other plagues (Van Niekerk, 2002), locally and globally (Benatar, 2002b).
>
> The example of anti-smoking campaigns illustrates the difficulty in achieving behavioural change even for acquired habits with only mild addictive effects. The greater challenge of achieving change in relation to such basic drives and needs as sexual relations should not be underestimated – and especially when interacting with people whose social and sexual mores differ and who may be suspicious of the underlying motives of "educators" (Van Niekerk, 2002). The programme of action against HIV/AIDS in South Africa includes culturally sensitive education, information and behavior change strategies and vaccine development, but the impact of these will take many years to become manifest. A comprehensive programme will also need amplification by definitive and convincing political and cultural action to dispel the regrettable denial that surrounds HIV/AIDS, and by significant social and economic progress. (Van Niekerk & Benatar, 2011, pp. 143–144)

Future Challenges

As is well known, healthcare as such is not necessarily the major contributor to a healthy population. Clean water, balanced and healthy nutrition, and clean sanitary facilities are much more important. The provision of these in a developing country such as South Africa is a major challenge that also needs to reflect far more in the bioethics research of the future. As far as healthcare itself is concerned, the effective treatment of serious infectious disease such as HIV/AIDS and tuberculosis, as well as achieving such treatment within a context wherein the majority of people have better access to sustainable healthcare services, remains the major challenge in South Africa.

In as far as healthcare will in the future increasingly be provided on the basis of genetic information and will thus be much more population based, the challenge in Africa is to assess the extent to which such new treatments can be relevant for specifically African needs.

Summary and Conclusion

Bioethics is not nearly as big a subject in South Africa as it is in the USA or Britain. However, since the 1980s, there has been a sustained growth of interest in as well as the practice of bioethics in South Africa. A serious breach in basic bioethical practice (i.e., the death of Steve Biko) played a major part in unleashing the (eventually successful) forces of liberation and democratization in the history of this country. The impact that HIV/AIDS has had and continues to have on South African society creates a host of bioethical issues that need to be consistently addressed. South Africa is a favorite spot for biomedical research, and this has also posed the challenge of training people effectively for service on research ethics committees that have to review this research, protect vulnerable populations, and insist on channeling benefits of such research back to local communities. In this sense, bioethics plays a major role in development of the biomedical sciences and thus in the fascinating unfolding story of late-arrived democracy in South Africa.

Miguel Angel Sanchez-Gonzalez and Lydia Feito Grande

Bioethics Development

When and How has Bioethics Started?

A Precursor: Pedro Laín Entralgo

The work of Pedro Laín Entralgo (1908–2001) was an important precedent for many of the themes that bioethics has subsequently covered.

Laín Entralgo created an influential School of History of Medicine and Medical Humanities, as Chair of History of Medicine at the Complutense University of Madrid. Influenced by the thought of José Ortega y Gasset (1883–1955) and Xavier

DOI 10.1007/978-94-007-2512-6_51,

Zubiri (1898–1983), he developed a philosophical anthropology that successfully incorporates the disciplines of Biology, Physiology, and Neurology.

Laín wanted to help solve the problems of the medicine of his time by developing a system of medicine both scientific and personal, which would be part of his theory of the relationship of doctor and patient. One of his best-known works happens to be *The Doctor-Patient Relationship*: *History and Theory* written in 1964. Five years later, he published a synthesis of his ideas in *Doctor and Patient* (Laín, 1969), which is perhaps his most known work and has been translated into other languages. In this work, Laín asserts that "medical friendship" is the affective link in an ideal medical relationship. Medical friendship is a mode of unilateral relationship of aid that puts the physician in direct contact with the other person. The patient participates in this relationship with trust and confidence, while the doctor brings benevolence and beneficence. This medical friendship is essential to making diagnoses and personalizing treatments.

Lain Entralgo still had time to join in debates promoted by the new discipline of bioethics. He participated in the conference on "*Changing values in medicine*" which took place at Cornell University, Ithaca, New York, in 1979. At this conference, he presented a paper entitled: "*What does the Word Good Mean in Good Patient*?" Interestingly, his ideas were hailed as the highest exponent of the old paternalistic tradition; but he was also criticized for not openly acknowledging the autonomy and rights of patients. (Childress, 1979).

Despite such criticism, the humanistic ideas of Pedro Laín and the school he created, as currently represented eminently by Prof. Diego Gracia, have been a powerful stimulus for many current developments in bioethics.

A Triple Source for the Spanish Bioethics with International Links

There were three different and independent origins for the Spanish bioethics with direct international links.

The first was Francesc Abel S.J. who was a friend and disciple of André Hellegers. Abel attended the Kennedy Institute in 1972, where he stayed more than 3 years. He returned to Barcelona with the idea of establishing an institute of bioethics based on the model of the Kennedy Institute. Since 1975, he conducted a seminar on bioethics attached to the faculty of theology in Barcelona. This initial workshop was established in 1984 as a private foundation with the name of *Institut Borja de Bioètica*, within the accommodations offered by the Society of Jesus. Beginning in 2000, this program was integrated into the Ramon Llull University and directed by the jurist Núria Terribas. In addition, Francesc Abel organized the first Committee on medical ethics, within Hospital Sant Joan de Déu in Barcelona. This program was started in 1976 and still operates today.

The second milestone that reflects the movement of international bioethics in Spain is represented by Javier Gafo, S.J. Gafo majored in bioethics in the Gregorian University of Rome with his doctoral thesis in moral theology on "Abortion and the Beginning of Human Life," published in 1979. Appointed Professor and Chair of Bioethics at the Faculty of Theology at the Pontifical University of Comillas, he

began to convene annual seminars on various subjects in 1986. These seminars have continued and gathered almost all Spanish professionals interested in these issues. Gafo has been an important source of editorial and educational activities. After the death of Gafo, his Professorship was directed successively by Jorge Ferrer, S. J., Julio Martínez, S. J., Juan Masiá, S. J., and Javier de la Torre.

The third important scholar with contacts in American and international bioethics was Diego Gracia Guillén. As a disciple of Laín Entralgo and Xavier Zubiri, and after doing postdoctoral studies in Germany, he conducted his first research in the fields of history, philosophy, and medical anthropology. His direct contact with American bioethics began in 1986, through the bioethicist James Drane, who was a visiting scholar in his department (Drane, 2009). Thus, they both began to teach the first course in bioethics that was offered at the Complutense University. In 1987, accompanied by the same Drane, Gracia visited the main centers of Bioethics and Medical Humanities that existed in United States and met their most important leaders. Upon his return, Diego Gracia began to implement a teaching and research program as chair in the Complutense University. Through his teaching, Gracia has gathered a large number of professionals and exercised considerable influence both within and outside of Spain. During all this time, the work of Diego Gracia has been assisted by Miguel Angel Sánchez González, as a Professor in Gracia's department. This Miguel Sanchez, physician and philosopher, had been a fellow at the Center for Clinical Medical Ethics of the University of Chicago in 1988.

Who Have Been the Major Actors/Forces?

Pioneers in the 1970s and 1980s

The first two decades of bioethics in Spain were dominated by the personal initiatives of the three ground breaking individuals mentioned above. This section provides more detail on each.

Francesc Abel i Fabre S. J. (1933–2011) was a physician who specialized in obstetrics and gynecology. With a degree in theology and sociology (with specialization in demography and population), he was also a priest and member of the Society of Jesus.

He was the cofounder of the *International Study Group on Bioethics* (1980–1994); the *Societat Catalana Bioètica* (1990); and the *European Association of Centers of Medical Ethics* – EACME – (1985). He was also a member of the Committee of Bioethics of Catalonia.

The Borja Institute of bioethics founded by Abel in 1975 was the first Bioethics center in Europe. Gifted with an excellent specialized library, this Institute has been an important focus and promoter of bioethical dialogue in Spain, organizing courses, conferences, round tables, publications, and research projects. Since 1996, this center has also offered a MA degree in bioethics.

Javier Gafo Fernández S. J. (1936–2001) was licensed in biology, philosophy, and theology. He was also priest and member of the Society of Jesus.

He was a member of the Theological Commission of the Episcopal Commission of the Doctrine of the Faith of the Spanish Episcopal Conference, and an expert of the Commission of the Congress for the "Study of fertilization in vitro and artificial insemination" (1985). He was part of the National Commission on assisted human reproduction (1997), the Committee of experts in bioethics and cloning (1998), and the Committee for the study of the status of human embryo (2000).

Above all, the editorial activity carried out and promoted by Javier Gafo as chair is perhaps the most voluminous in bioethics in Spain. In 1997, this activity culminated in the creation of a M.A. degree in bioethics.

Diego Gracia Guillén (1941–present) is a physician, specialized in psychiatry. He also has a degree in philosophy. As professor of the history of medicine at the Complutense University of Madrid, he also directs the Institute of Bioethics of the Foundation of the health sciences.

In 1988, Gracia launched at the Complutense University the first M.A. of bioethics in the Spanish language, which up to now has graduated nearly 300 professionals. Between 1996 and 2003, Gracia also headed a M.A. degree in Latin America which conducted concentrated classes during the summer months. He was invited to do this by the authorities of the regional program on bioethics for Latin America and the Caribbean under the sponsorship of the *Pan American Health Organization*.

It can be said that Diego Gracia is the main person who introduced a secular view of bioethics in Spain, while remaining anchored in the European cultural tradition and incorporating the most recent international developments in the field of bioethics (Gracia, 2009). Indeed, the contribution of Diego Gracia has been not only to import an American form of bioethics, but also to enrich and reformulate it from Spanish and European intellectual tradition that he knows well, as director of the Institute of Philosophy "Xavier Zubiri."

One of his early theoretical contributions was the contemplation of the principles of bioethics as a result of the convergence of three traditions: an ancient tradition within the medical profession and two other legal and political traditions that had been kept outside of medicine. He also devoted his efforts in finding a foundation for a bioethics that, rather than limiting itself to the resolution of conflicts, can also advance as an ethic of responsibility. In his search for these foundations, he studied methods of decision making and suggested a method based on deliberation (Gracia, 2003).

New Important Authors in the 1990s

Gradually other actors from different fields entered the field of bioethics.

The contribution of the jurist Carlos Romeo Casabona and his team in the Chair of Law and Human Genome of the University of Deusto is remarkable in the field of law. Maria Casado and her group at the *Observatory Bioètica i Dret* of the University of Barcelona and Javier Sánchez Caro and his group in Bioethics and Law in the government of the Autonomy of Madrid, are also making significant contributions.

The field of moral philosophy began to react to bioethical issues from the publication by Adela Cortina in 1993: "*Applied ethics and radical democracy*" which advocates for a deliberative model. This was a challenge for the academic

philosophy that was joined, among others by Victoria Camps, Margarita Boladeras, Javier Sádaba, Teresa López de la Vieja, and José María García Gómez-Heras.

In the field of theology, theologians ready to intervene in the democratic and pluralistic bioethical debate, advancing their point of view among other approaches, should be distinguished from scholars entrenched in dogma and papal Magisterium, who seek to impose their thesis. In addition to the already mentioned representatives of the Society of Jesus, Javier Elizari and Marciano Vidal have excelled among the theologians open to the public debate. Advocates of a militant bioethics in favor of traditional religious positions, on the other hand, tend to have some relationship with conservative church groups and be integrated into the Spanish Association of Bioethics and Medical Ethics (AEBI). The reputable group led by Gonzalo Herranz at the University of Navarra also has a relationship with these latest positions.

The physician and former socialist deputy Marcelo Palacios, author and draftsman of legislation and propositions of law which have been important for bioethics deserves special mention. In 1997, he founded the International Society of Bioethics (SIBI).

It is also important to cite the work of professionals trained by Diego Gracia and his team; including physicians as Azucena Couceiro, Javier Júdez, and Benjamín Herreros who have produced good research and teaching, and Pablo Simon, professor and coordinator of courses of bioethics in the Andalusian School of public health (Granada). Among bioethicists also trained by Gracias's team, there are psychologists, as Javier Barbero, specializing in spiritual accompaniment, and philosophers as Lydia Feito who since 2008 has been incorporated into the Group of the Complutense University, where she directs a research seminar in bioethics.

What Resources Have Been Developed?

Bioethics associations at the national and regional levels have been created. Among them: the *Asociación de Bioética Fundamental y Clínica* (ABFyC) which represents a pluralistic and nonreligious bioethics, in the wake of Diego Gracia's teaching; the *Asociación Española de Bioética y Etica Médica* (AEBI), more devoted to a catholic bioethics; and the *Sociedad Internacional de Bioética* (*SIBI*), of international scope, founded in 1996 at the proposal of Marcelo Palacios.

Some bioethics journals are being published. Among them: *Cuadernos de* Bioética which is the official journal of the Asociación Española de Bioética y Etica Médica (AEBI); *Labor Hospitalaria*, edited from 1948 by the Hospitaller Order of Saint John of God; *Bioética & Debat*, published by the Instituto Borja de Bioética; and more recently *Debatica*, which is the journal of the Sociedad Andaluza de Bioética.

A good number of bioethics books have been published in Spain during the last decades. The outstanding *Fundamentos de Bioética* (*Foundations of Bioethics*), written by Diego Gracia in 1989, opened the road and were followed by many others (Gracia 2004, 2012). Francesc Abel wrote a history of bioethics in 2001. The Chair of Bioethics in Comillas has published more than 60 books on numerous

topics. The Institute of bioethics in the Health sciences Foundation, together with the College of Medicine, has elaborated several guides on ethics for clinical practice. Romeo Casabona has directed the edition of an *Encyclopaedia of Bio-law and Bioethics*: (2011). More recently, Miguel Sánchez González has written a manual for health care students (2012).

What Have Been the Steps/Measures Taken?

After the death of Franco in 1975, the army and the Church began to lose their traditional sociopolitical influence. This was the start of a process of acceptance of pluralism and search of a minimal civil ethics.

In the political and legislative arenas, the 1978 Constitution introduced a liberal democracy protective of human rights. Since then, liberal and utilitarian moral approaches have been gaining ground. The international movement of bioethics, by being in concert with those trends, could enter Spain and find fertile ground at an opportune moment. In fact, much of the legislation enacted during the past three decades originated from liberal channels similar to those of English-speaking countries. Nevertheless, one can find exceptions to this trend, for example, in the discussions about the beginning and the end of life, dominated by the most conservative sectors of Spanish society.

In 1984, the so-called Palacios Committee was created by the government for study of the problems associated with the new techniques of assisted reproduction.

In 1992, the Ministry of Health created an Advisory Committee to assess and report to the Minister on matters scientific, ethical, professional, and social research and health care.

The biomedical Research Act 14/2007 established the *Comité de Bioética de España* (*Bioethics Committee of Spain*), as an independent body with consultative status on matters relating to the ethical and social implications of biomedicine and health sciences.

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

There has been a struggle between different sectors and University departments on teaching bioethics.

At most Spanish universities, with the exception of the Complutense University, departments of History of Medicine have not shown much interest in bioethics. On the contrary, they have tried to neutralize it as a threatening competitor of the social sciences that they were teaching.

Legal medicine departments have more systematically tended to assume the role of teaching bioethics within universities, although confusing it at times with health law or with the more traditional medical deontology.

Finally, individual initiatives have also proliferated, endorsed by teachers motivated by their own convictions or their ecclesial linkages.

In this context, it is not uncommon to find teaching programs in bioethics without orientation in international bioethics, that sometimes focus on legal reductionisms or are noticeably inspired by faith-based beliefs.

Nevertheless, it can be said that bioethics has been established, albeit in unequal fashion in all training programs of the health professions, especially among doctors and nurses at undergraduate level. At the level of postgraduate training, the offering of bioethics programs is large and growing.

Today in Spain many postgraduate programs are offered. The oldest one is the Master on Bioethics at the Complutense University of Madrid (UCM). The Comillas Pontifical University and the Borja Institute of bioethics have also been offering a master degree on bioethics for a number of years.

Bioethics Committees

At the present moment, there are clinical and research committees in virtually all public hospitals. At the national level, there is the *Comité de Bioética de España* (*Bioethics Committee of Spain*), which was already mentioned above.

Expert Bodies/Centers

As for groups or institutions who are working on issues of bioethics, there are too many to list here. Only some of them can be mentioned: the Borja Institute of Bioethics, the Chair of bioethics of the faculty of theology in the Comillas Pontifical University, the Chair of law and human genome of the University of Deusto, the Department of Biomedical Humanities at the University of Navarra, the Observatory of Bioethics and law directed by Prof. María Casado in El Parc Cientific of Barcelona.

Some institutes and schools are offering regular bioethics courses. It is worth noting the *training course for trainers* offered by the Institute of Bioethics in the Health sciences; and the courses of the Andalusian School of Health.

Relevant Legislation

The last democratic *Constitution* of 1978 established the current legal framework. After the Spain's entry into the European Community in 1986, the EC's directives should be transferred to the legal system.

In Spain, a Royal Decree of 1978 introduced the *first legislation on clinical trials*, which stated the need to establish Research Ethics Committees in hospitals. In 1990, the Act on Medications (*Ley del medicamento*) was adapted to the directives of the European Community.

The *Act of extraction and transplant of organs*. (*Ley de extracción y trasplante de órganos*) was enacted in 1979. This act established a system of presumed consent for the removal of organs after brain death, unless the deceased had expressed their opposition. In practice, however, authorization for the removal of organs continued to come from the family. Subsequently, Spain has come to be the country with the highest rate of donations. Nonetheless, this result seems to depend mostly on the system of detection and collection of organs which implemented the Spanish National Transplant Organization (ONT).

In 1985, the Socialist Government enacted a *Law of decriminalization of abortion* (*Ley orgánica de despenalización del aborto*) in three cases: serious risk to physical or mental health of the woman, rape, and malformations in the fetus. This Act was in force until 2010, when a new *Organic Law of sexual and reproductive health and voluntary interruption of pregnancy* (*salud sexual y reproductiva y de la interrupción voluntaria del embarazo*) was promulgated. This law transformed the previous law of cases into a law of time limits, where the termination of pregnancy is free until the 14th week of gestation. In 2012, the new conservative People's Party government announced his intention to return to the model of the 1985 Act.

The *General Law* of *health* (*Ley General de Sanidad*) in 1986 introduced among other things, the first Bill of Patient's Rights, based on the recognition of patients' autonomy and the need of informed consent.

In 1988, Spain was one of the first countries to enact a law on *assisted reproduction* (*Ley de Reproducción asistida*). That law was expanded in 2006 with the *techniques of assisted human reproduction Act* (*Ley sobre técnicas de reproducción humana asistida*). These laws recognize the right of any woman over the age of 18 to avail of these techniques regardless of their marital status or sexual orientation.

Also enacted in 1988 was a *law on organ donation and use of embryos and human fetuses or their cells*, *tissues or organs* (*Ley de donación y utilización de embriones y fetos humanos o de sus células*, *tejidos u órganos*). This act authorizes the procurement and use of biological structures from dead embryos for the purposes of diagnosis, therapy, or research. At the same time, this act prohibits any modification of healthy human genetic material; the use of embryos or their cells for the manufacture of cosmetic products; the extraction of cells for purposes other than prenatal diagnosis; and experimentation on live embryos, except in the case of nonviable embryos.

The Act of 1994, which established the legal regime of *the contained use*, *voluntary release and marketing of genetically modified organisms* (*utilización confinada*, *liberación voluntaria y comercialización de organismos modificados genéticamente*), in order to prevent risks to human health and the environment, incorporated the substantive rules of the European Community directives into the Spanish law. These standards have been now put into another law in 2003 that bears the same title.

The protection of experimental animals began with a Royal Decree in 1988 on the *protection of animals used for experimental and other scientific purposes*

(*protección de los animales utilizados para experimentación y otros fines científicos*). This decree introduced a system of centralized control following the British model. In 2007, the currently still existing *law for the care of animals, in their exploitation, transport, experimentation and sacrifice* (*Ley para el cuidado de los animales, en su explotación, transporte, experimentación y sacrificio*) was adopted.

Of special importance was the *Convention for the protection of human rights and the dignity of the human being with regard to the application of biology and medicine* (called *Oviedo Convention*) signed in 1997 and ratified by Spain in 1999.

To complete the picture, the most recent laws must be highlighted: the *Organic law of 1999 on Personal data protection* (*Ley Orgánica sobre Protección de Datos de Character Personal*). The *Basic Law of 2002, regulatory of the autonomy of the patient and of rights and obligations in the field of information and clinical documentation* (*Ley básica reguladora de la autonomía del paciente y de derechos y obligaciones en materia de información y documentación clínica*). The *Act of 2003, on cohesion and quality of the national health system*. (*Ley de cohesión y calidad del Sistema Nacional de Salud*.) And *the Act of 2007, for research in biomedicine* (*Ley de Investigación Biomédica*).

Major Bioethics Issues and Discussions

Some discussions (Sánchez-González, 1997) have been related to the cultural and political peculiarities of Spanish society, among them:

1. *Rationalism* versus *empiricism*: *the need of foundations and the search for a model of European Bioethics*

Since the beginning of the Modern Age, rationalistic and idealistic philosophical systems have dominated in Continental Europe. These systems have had a totalizing character, one which is thoroughly systematic and deductive. Meanwhile, empiricism, emotivism, and pragmatism have dominated in English-speaking countries. These differences lead to certain differences in ways of thinking.

First, there are differences in the area of law. Continental Europe emphasizes the importance of the statute. In English-speaking countries, on the contrary, jurisprudence is given much more space. In Europe, there is a tendency toward universal codification which presupposes that all particular situations can be predicted, and a legal deductivism according to which problematic cases must be judged according to their degree of fit with preestablished substantive norms. In all of this, to the influence of systematic rationalism one must add the presence of *iusnaturalism*. This legal doctrine recognizes the preexistence of a Natural Law as the source of law and morality. This natural law can be known rationally and integrated into a legal code in deontological and axiomatic form. The resulting legal framework privileges the idea that all conflicts can and must be previously regulated with certain substantive legal contents which leave little space to individual judgment. This way of thinking is less concerned with who is to decide than with what is to be decided.

All of the foregoing translates into the priority in Spain of the criteria of best interest in decision making and in the practical nonexistence of substituted judgment.

Among the consequences of this latter mentality is support for the concept of medically indicated treatment and for any other formula which permits doctors to discover the best interests of patients. In the United States, on the contrary, certain defenders of patient's rights, such as R. Veatch, have rejected the concept of medically indicated treatment as one which is irremediably charged with value judgments (Veatch, 1991).

Additionally, in the area of moral philosophy, continental European thought tends to consider insufficient an ethics which is merely casuistic and procedural. Instead, it attempts to establish norms which have some universal and substantive content.

Hence, the continental criticism of Anglo-Saxon bioethics for its proceduralism and casuistry as well as the attempts to find a more solid foundation. To fill these perceived gaps, the Spanish bioethicists have participated in the search for a European or Latin model of bioethics (Rendtorff & Kemp, 2000).

2. *Importance of virtue versus rights*, (Gracia, 1993), *giving way to peculiarities in the way of understanding informed consent and the doctor-patient relationship*

Philosophical ethics began in the Greek Antiquity as a reflection on the virtues which human beings can cultivate. The first ethical systems were primarily efforts to discover what type of person one should be. These systems relegated the study of the actions a person should undertake to the second level, because it was understood that a person with a good character would know the right thing to do in each case. The end of ethics was *eudaimonia*, that is to say, human excellence, which brings about the happiness of the moral agent.

During the Renaissance one finds the beginnings of a new moral tradition based on the concepts of rights and duty in Central Europe. The importance of these concepts culminated in the works of the eighteenth century Enlightenment, and became predominant in the Protestant countries of Central and Northern Europe as well as in the British Islands.

Despite these changes in others parts of Europe, the ancient concepts of vice and virtue have persisted with relatively more force in the Mediterranean understanding of morality. The persistence of these concepts can be seen in the importance that is given to character qualities in these countries: honor, fame, nobility, courage, sincerity, trustworthiness, generosity, and friendship, among others. The Mediterranean citizen expects much from his family and friends. It is understood that true friends and family have virtues which predispose them to help and favor each other. And this same citizen tends to place a similar confidence in the virtues of his physician. He requires, before all else, that his physician be trustworthy, compassionate, and capable of friendship (Laín, 1964). And he considers only secondarily the information which he receives from his doctor. The Mediterranean thinks that, if he can trust his doctor, such information is not pivotal. If he cannot trust his physician, such information is useless. He also thinks that little can be accomplished by demanding his legal rights. In fact, here

there are relatively few cases instituted by patients against their doctors, and the practice of medicine here is much less defensive. When there are complaints, they are usually related to a bad doctor-patient relationship. A patient, who has been well served from a personal point of view, will hardly ever denounce his doctor.

In Mediterranean societies, the doctor and the family have a greater role. Their authority seems less arbitrary, because they are supposed to incorporate a whole set of shared communitarian beliefs and values. Physicians understand that they should play a role of protecting and counseling the sick. In this model,, the ethics of the physician is to assume the right attitude as well as the obligations imposed on him by the profession. At the same time, the corresponding virtue for the sick person is to obey the doctor who possessed the necessary virtues.

To sideline a physician in the decision-making process and/or to reduce him to a mere transmitter of information could erode his professional virtue and his human motivation. In addition, to marginalize the family would damage the habitual dynamic of social relations within the community. Thus, the doctor and the family are two factors in the decision making which should not be ignored.

3. *Stoicism versus utilitarianism*: *and the corresponding tendency to assimilate and reduce the ethics to law*

Of all ancient ethical doctrines concerning virtue, Stoicism has left the biggest mark on the Mediterranean countries, and this impression has been the biggest in Spain and the Spanish speaking countries.

Happiness for the stoic is found in the serenity of the spirit independent of material goods and the adversities of fortune. It is a happiness that is reached by limiting one's necessities and dominating one's passions.

Philosophic stoicism has resurged periodically in Europe. It permeated Roman law and Christian moral theology. It resurged with force in the fifteenth century and was intermingled and confused, with Christian asceticism. Above all, it became important in Spain where it inspired great works of literature and mysticism. Spanish stoicism introduced the themes of meditations on death and the vanity of worldly enterprises. This stoicism accompanied the height of the Spanish empire and it is the philosophy which seems most to have found its place in the Spanish soul (Zambrano, 1987, 1994). Its influence can be detected in four cultural attitudes which, for the moment, continue to be widely shared by Hispanic people. First, there is a peculiar disdain for consumer goods, an attitude which considers frugality as the most important virtue. This attitude is contrary to the modern consumerist mentality. Next, stoicism proposed a certain way of understanding happiness, according to which happiness is to be found in inner states of spirit and in relationships with others, rather than in the enjoyment of material commodities. Thirdly, stoicism contributed to the development of a peculiarly anti utilitarian approach to problems which at times can even lead a Hispanic person to disregard practical solutions. In Spain today it is still frequent to think that utilitarianism and pragmatism are directly opposed to ethics. Fourthly, stoicism is accompanied by a particular distrust of the individual ego and a suspicion of the private. For the wise stoic, always attempting to ascertain the universal nature of things, there was

nothing private. The individual self, differentiated from others, was precisely the enemy to be defeated. Perhaps, this last attitude has led Spaniards to give less importance to privacy and to be more concerned with egalitarianism.

There are, however, two aspects to which stoicism could perhaps make a contribution. First, stoic meditation on the dignity of life and death permit one to better accept limitations upon therapeutic efforts in extreme cases. Secondly, the ascetic value accorded to the renunciation of the individual self and its desires makes it easier to accept a culturally shared definition of therapeutic futility.

The tendency to equate ethics with a natural law which obliges all may also be related to the Stoic legacy. And that natural law should be reproduced in statutory laws or mandatory codes of conduct. This explains the prevalence of deontological codes throughout the South of Europe, where health care professionals are more constrained by the professional rules than by the rights of patients. At the same time, the patient has a duty to improve his health and follow the instructions of the physician. This model of ethics in southern Europe, contrasts with the liberal model of Western Europe (UK and the Netherlands) which is based on rights, and with the model of social welfare which is more characteristic of the Nordic countries (Dickenson, 1999).

4. *Political statism versus Citizen Initiatives*: *The difficult liberalization of Spanish political life*

The Greco-Roman political tradition was centralist and based on the state. It tended to concede little importance to spontaneous social dynamics and citizen initiatives. In Continental Europe, it can be said that the common good has been more important that individual liberty. And the European emphasis has been placed more on the social than on the individual.

This tradition is even greater in Hispanic countries. Spain through the political work of the Catholic royalty was the inventor of the modern absolutist State at the end of the middle Ages. It has had a great tradition of political absolutism throughout the modern era and into the contemporary one. No wonder that within this tradition there was a major political centralism, as well as religious dogmatism and a certain moral dictatorship over the individual. Nor is it surprising that, overall, there was less of a tradition of democracy and citizen's liberties. Hispanic countries have had a strong sense of independence against foreigners but a weak sense of individual rights. Thus, the Spanish, perhaps, place too much faith in state politics and political leaders.

In Spain patient's rights have been imposed and advanced almost exclusively by the State. They have not entered by way of common law jurisprudence, nor have they been the result of progress of public opinion or citizens' demands upon the state. Instead, patients' rights have been the results of a legislative act by the state which has implanted them through statutory laws and codes. In Spain, patients' rights were first legally established by the 1986 General Health Law (Ley General de Sanidad). Only since then has a process of implementation been initiated.

This outlook can lead to a weakened respect for individual differences and choices. Of course, this is no excuse for the failure to recognize the right of individual autonomy. On the contrary, this should serve to put more emphasis upon the need to actively promote individual rights and options. The existence of customs contrary to citizen participation should serve to remind one that it is necessary to encourage greater social debate.

On the other hand, it might be said that there is a greater tendency to accept socially established criteria which are publicly recognized as reasonable. There is perhaps a greater disposition toward the acceptance of professional leadership in the establishment of standards. Institutions should not ignore this possibility for shaping public opinion, although, they will certainly have to exercise this leadership by encouraging greater social participation among citizens and fostering open social debate.

5. *Greater sensitivity to justice than to autonomy*: *Prominence of the conflicts between justice and efficiency*, *and debates about health systems*

Philosophical views concerning justice are undoubtedly much older than the very concept of individual autonomy. For Aristotle, as one example, justice was the sum of all the virtues:

> "*We call just that what produces or preserves happiness for the political community. . . This kind of Justice is not a part of virtue*, *but rather the whole virtue*." (Nichomaquean Ethics, 1129b and 1130a).

Throughout almost all of the modern era the liberal political tradition has had relatively little strength in Spain. Since the second half of the nineteenth century it has been counterbalanced by a greater force of workers' social movements.

At the present moment European governments take charge of what in other countries belongs to the realm of private enterprise. Healthcare systems are mostly financed or directly run by the state. In these systems of collectivized assistance, problems of justice go to foreground. When all health services are free, users aspire to obtain the maximum service possible. It can be said that in Spain the most frequent requests are not made to forgo treatments but rather to secure their application.

Taking into account what has been said up to this point, it is no wonder that in Spain the interest in justice is stronger that the interest in individual autonomy. There seems to be a strong belief that no isolated act has purely individual consequences and that any decision in a public health system could affect the whole of the system.

It is to be expected that the growing problem of health costs will make it ever more necessary to take issues of justice into consideration; and these considerations of justice will require the establishment of treatment standards, as well as minimum and maximum levels of assistance,

6. *Persistence of traditional positions*: *discussions about the beginning and the end of life*

The importance that the Roman Catholic Church has had in the history of Spain still can be detected in the willingness of some sectors to enforce positions emanating from the ecclesiastical Magisterium. This explains the prolonged debate in Spain

about the ethical aspects of the beginning of life, such as contraception, assisted reproduction and, especially, the termination of pregnancy.

Debates over the end of life have also proliferated, particularly over treatments which may shorten life, such as withdrawal of treatments, euthanasia, assisted suicide and, more recently terminal sedation.

Future Challenges

1. *Redesigning the thematic agenda*

The bioethical topics discussed in Spain should not be a mere echo of those achieved in other areas. The initial impetus of bioethics in North America was the extension of the civil rights movement. Spanish bioethicists need to be faithful to their own sensibilities and peculiar ethical traditions and know how to respond to the most pressing problems.

Bioethics research and education must not fail to cultivate two essential thematic areas. First they have to examine healthcare justice, reflecting not only the national situation, but echoing also the needs of the global justice affecting developing countries, and especially Latin America. Secondly, bioethics must achieve the global and ecological perspective that Potter advised since its inception. Environmental and sustainable development issues are essential to preserving the quality and sustainability of one's life.

2. *Practicing a pluralistic bioethics in the middle of the two temptations*: *Legalism and confessionalism*

Bioethics in Spain will have to learn to sail between the Scylla of legal reductionism to which lawyers and forensic pathologists subscribe and the Charybdis of theological reductionism by those who try to use bioethics as a way to enforce their own faith-based and more or less conservative ideals.

3. *Finding a space for interdisciplinary bioethics within institutes of humanities*

As yet university departments of history of medicine, social sciences and medical anthropology have not been very favorable toward the cultivation of bioethics, not only for reasons of curricular competition, but because those departments, as it has been pointed out by Diego Gracia (2009), usually consider themselves as scientific and as such they are used to working with empirical facts but not with values.

Institutes of Medical Humanities need to be created independent, and yet with good links to the departments of social sciences, law, and theology.

4. *Developing educational strategies on all educational levels*, *and mechanisms of implementation of bioethics*

It would be necessary to develop models of training in bioethics more unified and coherent on all educational levels.

Knowledge of bioethics should be disseminated to all citizens, to respond to the practical vocation of bioethics, developing procedures for modification and improvement of medical practices.

The increasing importance of bioethics at various educational levels and the active work of a good number of specialists foretell a good future for bioethics in Spain.

Bioethics Development

When and How Has Bioethics Started?

Historical Background

According to the definition given by UNESCO (2005), the modern discipline of bioethics deals with the "ethical issues raised by medicine and the life and social sciences as applied to human beings and their relationship with the biosphere, including issues relating to the availability and accessibility of scientific and

technological developments and their applications" (UNESCO, 2005, General Provisions, Article 1 – Use of Terms, Item 18, p. 3).

However, historical sources reveal that the ethical concerns, policies, and practices which existed in Sri Lanka in ancient times are remarkably consistent with the modern concept of bioethics. The moral and ethical dimensions of issues such as life and death, medicine and the healing arts, and man's relationship with other living beings and the environment were closely influenced by the predominant cultural and religious beliefs existing at the time. From the third century BCE until the advent of Western colonizers in the sixteenth century CE, the predominant influence on the cultural and religious ethos in Sri Lanka was Buddhism.

Buddhism was founded in India in the sixth century BCE by Siddhartha Gautama, who was known as the Buddha after attaining enlightenment. Buddhism was introduced to Sri Lanka (circa 250 BCE) during the reign of King Devānampiya Tissa, by missionaries led by Thera Mahinda, sent by the Mauryan Emperor Aśoka in North India, who had embraced Buddhism after experiencing the horrors of war. Sri Lanka was ruled by its own kings from the sixth century BCE until 1815, when the British annexed the Kandyan kingdom. This long reign of kings is described in Sri Lankan Pali chronicles, such as the *Mahāvamsa* (fifth to sixth century AD) and the *Culavamsa*, which together with the lithic inscriptions left by the ancient kings, and the archaeological remains of ancient hospitals, provide a record of Buddhist influences on health, medicine, man's relations with nature, and the duties of kings towards their subjects in these areas. The epigraphical edicts of Emperor Aśoka in India (third century BCE) refer to hospitals in India as well as in Tambapanni, i.e., Sri Lanka (Fernando, 2005). The morality preached by Aśoka was imbued with the Buddhist values of compassion, moderation, tolerance, and respect for all life (Dhammika, 1993). Aśoka was considered as a perfect example of the Buddhist ideal of a Universal Monarch (Seneviratna, 1994), and kings throughout the ancient Buddhist world were encouraged to emulate his style of government as the ideal.

Buddhist views on ethics in medicine, as stated in the *Vinaya Pitaka*, show a remarkable similarity to the Hippocratic code of ethics. In Buddhism, provision of hospitals, medicine, and food for the sick were considered to be highly virtuous deeds, accruing much merit to the doer. This was the force that drove the kings to construct hospitals in ancient Sri Lanka (Uragoda, 1987). "It is to Gautama and his followers that we owe, apparently, the hospital idea" (BMJ 1928 Editorial, p. 541). George Parker, in his 1927 Thomas Vicary Lecture, says "Thus from before 500 BC downwards Buddhist hospitals were perpetually being built," and "In Ceylon and Burma they seem to have been ubiquitous" (Parker, 1928, pp. 41, 39). In ancient Sri Lankan society, the practice of *karunā* (compassion) and the resulting *ahimsā* (non-malfeasance) were predominant in guiding the meritorious actions of both king and commoner in the areas relevant to "bioethics."

Karuna and *ahimsa* were reflected in Buddhist society's treatment of animals and the environment as well. It is recorded in the ancient chronicles (*Mahāvamsa*, Chapter XIV) that there was a systematic philosophy of conservation dating back to the time of Thera Mahinda's visit circa 250 BCE, when he first preached to the King of Sri Lanka. "*O great King! The birds of the air and the beasts on the earth*

have an equal right to live and move about in any part of this land as thou. The land belongs to the people and all living beings; thou art only the guardian of it" (Weeramantry, 2000, p. 18). This is one of the earliest illustrations of the principle of trusteeship. Buddhists should not destroy any living thing, nor cause others to do so. This precept of abstaining from killing was followed by many kings whose edicts laying down rules for the protection of animals have been inscribed on stone (Uragoda, 1994). Sri Lankan society for the most part did not eat meat until the introduction of Western influences from the sixteenth century onwards.

Respect for nature and the environment is reflected in the treatment and uses of water and other forms of life in ancient Sri Lankan culture. At the World Future Council held in Hamburg in May 2007, Judge C. G. Weeramantry, former Vice President of the International Court of Justice, described the Buddhist perspectives on the interrelationships between all living beings and the environment. Quoting from the Buddhist scriptures, the Pali Canon or the *Tripitaka*, he demonstrated how Buddhist teachings and Buddhist kings have been in the forefront of pioneering laws on environmental protection since ancient times. The numerous moral principles described in the scriptures included protection of trees and other organic life, protection of the environment, goodwill towards all forms of life, rejection of anthropocentrism in favor of ecocentrism, the unity of the human family, the interdependence of all entities and events, and the emphasis on coexistence with other species and groups, rather than their conquest (Weeramantry, 2007).

Judge Weeramantry also advanced another theory that modern international law has much to gain from the wisdom of the past, when he cited the ancient hydraulic civilization of Sri Lanka as an excellent example of the concept of sustainable development. This civilization recognized the need for developing agriculture and, according to the ancient chronicles, built stupendous irrigation schemes using superior technology for the "benefit of the country" (Weeramantry, 2000, p. 17) and "out of compassion for all living creatures" (Weeramantry, 2000, p. 17), while ensuring the protection of the environment at the same time. Felling of forests was prohibited, animals were protected in sanctuaries, and royal edicts decreed that not even a drop of rainwater should be allowed to flow into the ocean without being made useful to man (Weeramantry, 2000).

With the advent of the Portuguese in 1505 and the Dutch in 1656, who successively occupied the Maritime Provinces, and finally of the British in 1796, who ruled the entire country from 1815 to 1948, Sri Lankan society changed from being predominantly Sinhala-Buddhist (with Hindu roots) to a multireligious, multicultural society. With the introduction of Christianity and Western medicine, the scientific community was introduced to a medical ethics having a Christian (or "Western") morality as its model (Fernando, 2005). Hunting animals for sport was introduced by Western colonizers from the sixteenth century onwards and was very popular with the British in the nineteenth century (Uragoda, 1994).

As pointed out by many writers, there are some fundamental differences between the Western model of ethics and the Buddhist and Hindu (indigenous) ethics (Arsecularatne, 1998). Professor Hyakudai Sakamoto (1999) has drawn attention to the contrast between the Asian ethos of "a holistic harmony" and the

"dualistic individualism" of the West (Sakamoto, 1999, p. 194). In Western ethics, the importance of the individual (individual autonomy) is considered fundamental in decision making, while Buddhism emphasizes an individual's duties over his rights. This is exemplified by the *Dasa Raja Dhamma*, or the ten duties of a king, where Buddhism specifies certain basic virtues for rulers. In addition to the virtues such as generosity, morality, and nonviolence, an ideal king (or government) was expected to protect not only the people but quadrupeds and birds and also protect trees and other organic life, as part of his duties.

During the 500 years of colonization by Western powers, the predominantly Sinhala-Buddhist society in Sri Lanka had gradually become a multireligious, multicultural society. With the achievement of independence in 1948, the regular election of democratic governments has made it possible to introduce some of the more admirable bioethical concepts and practices which existed during the times of the ancient kings of Sri Lanka. Since independence, every Sri Lankan citizen has been entitled to free education in State schools and universities and free health services in government hospitals. Hunting of animals is prohibited; protection of fauna and flora is encouraged by legislation, and many wild life sanctuaries and protected nature reserves have been established. There are many lessons in bioethics to be learned from Sri Lanka's ancient history.

Modern Era

Professional ethics: The Sri Lanka Medical Council (SLMC) is a statutory body established for the purpose of protecting health-care seekers by ensuring the maintenance of academic and professional standards, discipline, and ethical practice by health professionals who are registered with it. The Ceylon Medical Council (CMC) was established by the Medical Council Ordinance No. 24 of 1924 and replaced by the Sri Lanka Medical Council by the Medical (Amendment) Act No. 40 of 1998 when the title was substituted for "Ceylon Medical Council." As presently constituted, the Council has representatives from medical faculties of the state universities as well as from professionals in the state and private sector (Sri Lanka Medical Council, www.srilankamedicalcouncil.org). An Ethics Committee was formed in 2001 to consider ethical issues.

The SLMC, being the regulatory body for registered medical and dental practitioners in Sri Lanka, is responsible for maintaining professional and ethical standards. Guidance on professional ethics is circulated to all registered practitioners at regular intervals. The SLMC guidelines on ethical conduct, produced by their Ethics Committee in 2003, were updated in 2009 (Sri Lanka Medical Council, 2009). Advice on serious professional misconduct, advertising, and writing of medical certificates are issued separately. All newly qualified medical practitioners are required to take a modern version of the Hippocratic Oath prior to full registration with the SLMA. In 2005 the SLMC produced a "Provisional Code of Practice for Assisted Reproductive Technologies."

Several other Professional Colleges and Associations (e.g., Sri Lanka Medical Association, Sri Lanka Association for the Advancement of Science) also have ethics committees to deal with ethical issues.

Teaching of Medical Ethics: There are eight Faculties of Medicine in Sri Lanka. The departments of forensic medicine in all the Faculties of Medicine have always included the teaching of professional ethics in their undergraduate syllabus (Babapulle, 1992). Medical ethics as a separate subject was introduced into the curricula of most Sri Lankan medical schools in the 1980s, and some faculties have well-developed courses. The Faculty of Medicine in Colombo, established in 1870, is the oldest medical school in Sri Lanka. A formal course on medical ethics was introduced in 1994, and, with the new medical curriculum introduced in 1996, teaching of ethics was incorporated into the Behavioural Sciences Stream spanning the entire 5 years of the medical course (Jayakody & Kasturiaratchi, 1999).

S. N. Arseculeratne, Emeritus Professor in the Faculty of Medicine, University of Peradeniya, has for many years highlighted the need to take cultural relativity into account when teaching medical ethics to Asian undergraduates and has advocated the use of innovative approaches to teaching ethics (Arseculeratne & Babapulle, 1996). He has described the relationship between culture, ethics, and medical education and suggested how ethics could be made more relevant to medical students in Sri Lanka by incorporating an "indigenous ethics" into medical education (Arseculeratne, Simpson, Premasiri, & Kumarasiri, 2008).

In the Faculty of Medicine, University of Ruhuna, ethics was introduced to new entrant students during the History of Medicine lectures from the very inception in 1981. A short formal course on medical ethics, comprising lectures, case presentations, and discussions, was introduced in 1995, at the beginning of the 3rd year, just before the students commenced their clinical work in the hospital. In addition, clinical ethics teaching was introduced in the wards during the final year of the 5-year medical course when the students did their hospital clerkships with the professors in the four main disciplines – Medicine, Surgery, Pediatrics, and Obstetrics and Gynecology. In order to increase the relevance of medical ethics for our students, some innovations were introduced in 2005 in the Faculty of Medicine, University of Ruhuna. One method was to include Asian medical ethics drawn from the indigenous systems of medicine which have existed for many years in India and Sri Lanka. The other innovation was the introduction of Medical Humanities in October 2005 (Fernando, 2008).

Postgraduate teaching of medical ethics is a more recent development. The Postgraduate Institute of Medicine (PGIM) is the only institute that is responsible for the specialist training of medical doctors in Sri Lanka. It is a national institute attached to the University of Colombo and is internationally recognized with "equivalence" of recognition by the Royal Colleges of the United Kingdom. The PGIM works in close collaboration with the Ministry of Health, the Faculties of Medicine in the state universities, and the Professional Colleges. It has a Board of Management which comes under the Senate of the University of Colombo and functions through several Boards of Study for the different disciplines.

Formal ethics teaching for doctors following postgraduate degree courses in the different fields of medicine is currently gaining popularity. Ethics teaching was first introduced as part of Research Methodology Courses conducted by the PGIM for postgraduate trainees in some of the disciplines that included a research component

in their degree course, e.g., pathology, microbiology, and community medicine. Research ethics thus became an integral part of such courses. Most of the degree courses conducted by the PGIM taught topics on medical ethics at various points in their syllabus (e.g., informed consent, end of life issues), but not as a separate module. The number of courses that include a formal ethics component is still very small. The MD in Medical Administration course introduced a 15-h module on ethics in 2010. It is anticipated that more postgraduate degree courses at the PGIM will incorporate ethics into their formal curricula.

Research ethics: Institutional Ethics Review Committees (ERCs), dealing with the review and approval of research protocols, have been established in all the Medical Faculties of Sri Lanka, commencing in the late 1970s in the older Medical Faculties of Colombo and Peradeniya. The newer faculties in Galle, Jaffna, Kelaniya, and Sri Jayawardenepura established ERCs in the 1980s. Ethics Review Committees were also established in other organizations such as the Sri Lanka Medical Association (in 1999), the Medical Research Institute (MRI), the National Institute of Health Sciences (NIHS), and a few of the larger hospitals (Jayakody & Kasturiaratchi, 1999; Dissanayake, Lanerolle, & Mendis, 2006). Each ERC conducts training programs and workshops on research ethics for their members and for researchers.

The ERC of the Faculty of Medicine, Colombo, established in the late 1970s under the deanship of Professor S. R. Kottegoda, is the oldest Ethics Review Committee in Sri Lanka. It was surveyed and evaluated by the Forum for ERCs in Asia and the Western Pacific (FERCAP) in 2009 and became the first ERC in Sri Lanka to be recognized by the Strategic Initiative for Developing Capacity in Ethical Review (SIDCER) – a worldwide network of independently established regional fora for ethics review committees, health researchers, and invited partner organizations supported by the TDR program of the World Health Organization. The ERC of the Faculty of Medical Sciences at the University of Sri Jayawardenepura also gained SIDCER recognition in 2012.

The Ethics Review Committee of the Faculty of Medicine, University of Colombo, has been very active during the past few years and has conducted several national workshops and training programs on research ethics for doctors and researchers from all over Sri Lanka. It also organized the "Ethical and Regulatory Aspects of Clinical Research Course" conducted by the Bioethics Department of the National Institutes of Health (NIH), Maryland, USA, via live video conferencing, for the first time in 2008.

The Forum for Ethics Review Committees in Sri Lanka (FERCSL) is a forum of ERCs in Sri Lanka, convened under the Sri Lanka Medical Association. Originally formed in 2004, the forum became more firmly established, with its own constitution, in 2007 Sumathipala et al. (2010). It has the objective of fostering an improved understanding and implementation of ethics review of biomedical research in Sri Lanka. FERCSL strives to achieve its goal through the following activities:

1. Improving communication among member ERCs
2. Organizing meetings and symposia

3. Stipulating Guidelines and Standard Operating Procedures for member ERCs
4. Facilitating training and education opportunities for members of ERCs
5. Coordinating communication and responses on the subject of ethics review of biomedical research with the WHO, UNAIDS, CIOMS, UNESCO, and other international organizations involved in fostering ethics review

The Colombo Faculty ERC, together with FERCSL, produced Guidelines for Ethics Review Committees (Forum for Ethics Review Committees in Sri Lanka (FERCSL), 2007) and Guidelines for Ethics Review of Animal Research (Forum for Ethics Review Committees in Sri Lanka (FERCSL), Ethics Review Committee, Faculty of Medicine, University of Colombo, 2009). FERCSL members regularly conduct workshops on research ethics for its member ERCs and for researchers with the aim of improving their knowledge and performance.

The Senior Scientists Forum of the National Science and Technology Commission prepared a very useful document titled "A Guidebook on Research Ethics" in 1995 with a view to assisting all those involved in scientific research to maintain a high standard of professionalism. The document describes the responsibilities, commitments, and obligations of individual scientists as well as laboratory ethics.

The Institute for Research & Development (IRD), an independent nongovernmental organization promoting multidisciplinary research, has conducted courses on research ethics and bioethics, in 2003, 2007, and 2009/10, as part of their program on awareness raising and capacity building in research. The IRD organized a consensus generation meeting on disaster research and ethics from a developing world perspective in 2007, and a working group (Regional WGDRE*)* funded by a Wellcome Trust grant produced a draft guideline for disaster research and ethics: Statement on Ethical Issues in Disaster-Related Research – a Developing World Perspective, 2007 (Sumathipala et al., 2010).

Bioethics: Professional ethics, medical ethics, and research ethics, as described in the previous sections, are fields familiar to most medical students and doctors in Sri Lanka and have a recent history going back several years. The modern discipline of Bioethics, on the other hand, which evolved from medical ethics in response to advances in biomedicine and technology, has a broader definition, describing an interdisciplinary field including the life sciences, the environment, health, and health care. Bioethics is a relatively new field in Sri Lanka, and began to attract attention at the beginning of the new millennium. The evolution of bioethics from medical ethics and the challenges faced in the new century were highlighted in a presidential address at the Sri Lanka Medical Association in 2001(Fernando, 2001).

A National Bioethics Committee (NBC) was established at the National Science Foundation (NSF), Sri Lanka, in August 2003, at the request of the Sri Lanka National Commission for UNESCO. The National Science Foundation, coming under the (then) Ministry of Science and Technology, was identified as a suitable focal point for bioethics in Sri Lanka by the Sri Lanka National Commission for UNESCO. The establishment of the Committee thus complied with Article 19 of the UNESCO Universal Declaration on Bioethics and Human Rights, which states that "independent, multidisciplinary and pluralist ethics committees should be established, promoted and supported at the appropriate level."

The main aims of the newly formed National Bioethics Committee (2003) were:

- To publicize (and help implement) UNESCO and other international declarations on bioethics, and liaise with the UNESCO International Bioethics Committee
- To formulate guidelines for emerging issues in bioethics
- To network with Institutional Bioethics Committees in Sri Lanka
- To promote concerns for human dignity and human rights in research
- To consider ethical issues related to all living organisms in the field of biology

Under this last broad category, the Committee identified the need to inculcate ethical attitudes, by teaching and training at an appropriate level, to be of real importance. In keeping with these aims, the activities of the National Bioethics Committee during the first four years of its existence were concentrated on two broad areas: Bioethics Education and Bioethics Regulation (Fernando & Fernando, 2009). Thus, unlike most national bioethics committees in other countries, our committee became involved in teaching bioethics from the start.

At the inception, the NBC was chaired by the then Chairman of the National Science Foundation, who is a research scientist. According to the UNESCO Guide, recruitment of members could be based on one or more of the four criteria – expertise, representativeness, experience, and integrity. In recruiting members to serve on the committee, the National Science Foundation was restricted by the fact that there are no professional bioethicists in Sri Lanka. (In the West they are usually philosophers and/or theologians.) Therefore its members were recruited mainly from a representative viewpoint and for their experience in the field of medical ethics. There were members representing the Ministries of Health and Justice and the national medical and scientific associations, among others. Special efforts were made to include people with a legal background in view of the activities planned. Subsequently, members were handpicked for their interest and experience.

At the beginning, progress of the NBC was rather slow, mainly due to governance issues at institutional and national levels. In November 2004, the membership was reconstituted and during the next few years many activities were carried out through a number of subcommittees. The number of meetings during this period averaged 10 meetings per year.

In March 2008 the NBC was replaced by the National Committee on Ethics in Science and Technology (NCEST), widening the scope of the committee. The need for a committee with wider terms of reference was highlighted by the NBC itself and became a reality after a long period of gestation. The new committee, at the beginning, had a Bioethics Subcommittee to continue the work already begun by the earlier NBC. Among the Terms of Reference for the National Committee on Ethics in Science and Technology (NCEST) are the following:

1. Recommend programs or activities for communication of ethics in science and technology issues to relevant stakeholders as appropriate.
2. Facilitate activity to enhance understanding and debate on ethics related to science and technology among researchers, students, and the general public.

3. Advise the NSF on priority issues to be communicated to policy makers.
4. Identify ethical issues related to
   - All aspects of research and development and develop a code of ethics for research grantees of the NSF
   - Technology development and propose necessary measures to address same.
5. Guide and support the NSF to work as the focal point for UNESCO Bioethics and ethics of science and technology programs.
6. Advise the NSF to respond in a timely manner to national and international ethical issues related to science and technology.
7. Coordinate, collaborate, and cooperate with other institutions and agencies on national, regional, and international activities related to ethics in science and technology.

Who Have Been the Major Actors/Forces?

The National Science Foundation (NSF), which came under the Ministry of Science and Technology, took the initiative to establish the National Bioethics Committee (NBC) in 2003, and, later, the National Committee for Ethics in Science and Technology (NCEST) in 2008. The Sri Lanka National Commission for UNESCO was responsible for identifying the NSF as the institution where the NBC could be located.

Prior to the introduction of bioethics as a distinct discipline, and the establishment of a National Bioethics Committee, the faculties of medicine in Sri Lanka played the leading role in the field of medical ethics, both in the teaching of medical ethics to medical undergraduates and in establishing research ethics committees in Sri Lanka. However, these activities did not extend beyond the medical profession. Even after ethics review committees had been established in the medical faculties in the early 1980s, there was a significant lack of awareness among hospital doctors on the need for ethical review of research (Kottegoda, 1988). As far back as 1991, the predecessor of the National Science Foundation, called the Natural Resources, Energy and Science Authority (NARESA), appointed a committee to develop ethical guidelines for research in the different scientific disciplines, including biomedical research on humans, animal experimentation, and social science research. The guidelines produced in 1992 failed to gain publicity among researchers and did not develop into National Guidelines.

Long-established professional associations such as the Sri Lanka Medical Association (SLMA), the Sri Lanka Medical Council (SLMC), and the Sri Lanka Association for the Advancement of Science (SLAAS) have played an important role in providing ethical guidance for doctors and scientists through their ethics committees. The work of the SLMC in maintaining the professional and ethical standards of registered practitioners has been described earlier.

The Sri Lanka Medical Association (SLMA) established in 1887 as a branch of the British Medical Association is the oldest medical association in Asia and

Australasia and has always given high priority to ethics. In 1995, its Ethics Committee produced a Patients' Charter, called the Declaration on Health, and also developed Ethical Criteria for the Promotion of Medicinal Drugs and Devices in Sri Lanka in 1996. This has been revised subsequently. The Ethics Committee of the Sri Lanka Medical Association (SLMA) during the past decade has encouraged the establishment of Ethics Committees in the other professional colleges and also facilitated joint meetings and seminars on ethics. The SLMA has also consistently promoted the teaching of ethics by regularly including it in their Continuing Medical Education (CME) programs. More recently, the SLMA initiated discussions among relevant institutes to explore the possibility of introducing Clinical Ethics Committees (Hospital Ethics Committees) in some of the bigger hospitals.

The Sri Lanka Medical Association, the University of Colombo and the National Science Foundation, Sri Lanka, successfully co-organized and hosted the 12th FERCAP International Conference and General Assembly, "Development, Ethnicity, Culture and Ethical Health Research" from 18 to 21 November 2012, in Colombo, Sri Lanka.

Sri Lanka Association for the Advancement of Science (SLAAS) is the premier organization of scientists in Sri Lanka. The Ethics Committee of SLAAS is a statutory committee which has the power to take action against its members who violate the code of ethics. The National Health Research Council (NHRC) and the Drug Regulatory Authority (DRA) of the Ministry of Health have also encouraged and extended their support towards activities in the field of research ethics and medical ethics. The Postgraduate Institute of Medicine (PGIM) has regularly conducted research methodology courses for their postgraduate students, and research ethics is always included in these programs.

What Have Been the Major Concerns Over Time?

The major concerns have been the lack of national laws, regulations, and national guidelines for research ethics and for the practice of the newer technologies in medicine and science, such as assisted reproductive technologies and newer genetic technologies. Where applicable, the general laws have been used as a point of comparison. For example, the Transplantation of Human Tissues Act, 1987, regulates the donation of human organs for specified purposes. The application of this Act can be extended to research relating to the human gene, although the human gene is not specifically mentioned in this Act.

There is an urgent need to regulate assisted reproductive and genetic technologies in Sri Lanka. Regulation of the transfer of genetic material and data also needs attention. Conduct of clinical trials of drugs is increasing steadily in Sri Lanka with the advent of Contract Research Organizations (CROs) and requires regulation in order to ensure ethical compliance as well as scientific quality.

The members of Ethics Review Committees need to be trained more comprehensively in ethical review, and the ERCs supported with more resources to enable

the ERCs to reach the standard required to gain SIDCER recognition. The inability to monitor research projects after giving ethical approval remains a serious problem among all the ERCs. A central research ethics committee having a broad mandate and power to deal with policy and problematic ethical issues at a national level is also desirable.

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

UNESCO Grant to NSF

In 2007, the National Bioethics Committee was awarded a grant under the UNESCO Participation Program to develop bioethics in Sri Lanka. This grant was used to conduct several teacher-training workshops on bioethics education for science teachers in universities and schools. Part of the grant was utilized to obtain several publications on bioethics, some of which were distributed to the university libraries in Sri Lanka while most of the publications were kept in the NSF library.

Forum for Ethics Review Committees in Sri Lanka (FERCSL)

FERCSL is composed of members of ERCs in Sri Lanka. Many members of the faculties of medicine and the SLMA have undergone training in research ethics, both locally and internationally. They provide a pool of expertise for training of researchers and other ERC members in Sri Lanka. A few also act as resource persons in the training and survey programs of FERCAP (Forum for ERCs in Asia and the Western Pacific) conducted in other Asian countries. FERCSL together with the ERC of the Colombo Faculty of Medicine produced Ethics Review Committee Guidelines (FERCSL, 2007) and guidelines for ethics review of research proposals involving animals in Sri Lanka (FERCSL, 2009). Some of the ERCs in Sri Lanka have developed Standard Operating Procedures for their Ethics Review Committees.

Individual Institutes

In addition to the two organizations mentioned above, other institutes and centers, such as the faculties of medicine, SLAAS, the PGIM, the professional colleges, and the Institute for Research & Development (IRD), have developed their own resources.

What Have Been the Steps/Measures Taken (Policies, Legislation, Infrastructures, Teaching Programs, Committees, etc.)?

Bioethics Regulation

Human Reproduction and Genetics Act (HURGA)

The practice of assisted reproduction was fast developing in Sri Lanka in the early part of the present decade and proving to be popular with childless couples. Around

2004 the Sri Lanka Medical Council (SLMC) identified an urgent need for regulation of assisted reproductive technologies (ART) in Sri Lanka. As a first step, the SLMC published "A Provisional Code of Practice for Assisted Reproductive Technologies" (SLMC, 2005). This was based on the Code of Practice relating to the 1990 Human Fertilisation and Embryology Act of the UK and a report of the National Science and Technology Commission of Sri Lanka (NASTEC): New Genetics and Assisted Reproductive Technologies in Sri Lanka: A draft National Policy on Biomedical Ethics (Jayasekera et al., 2003).

In the year 2006, the NBC undertook the task of drafting legislation that would underpin the SLMC Code of Practice for ART. A decision was taken at the outset to widen the scope of the Act such that it would cover genetic technologies as well. Using the 1990 UK Human Fertilisation and Embryology Act as a model, a joint committee composed of members from the NBC, members of the Sri Lanka Medical Council who had been involved in producing the Code of Practice, and experts from the legal and ART fields drafted the Human Reproduction and Genetics Act (HURGA), the principal aim of which is to establish a Human Reproduction and Genetics Authority in Sri Lanka. This Authority will oversee and regulate all forms of Assisted Reproductive Technologies and the introduction and practice of Genetic Technologies, both in the research and clinical spheres. It is a comprehensive Act that deals with the responsibilities of practitioners, the procedures that are permitted, and also provides for the inspection and approval of the clinics and laboratories where both ART and genetic technologies are practiced. The draft is now ready for wide public consultation, where it would be circulated among medical and scientific professionals, interest groups, and the general public to seek their views (Fernando & Fernando, 2009).

One of the expert committee members who was involved in drafting HURGA has recently reiterated the urgent need for enacting regulation of ART in Sri Lanka (Seneviratne, 2011).

National Policy on Human Genetic Material and Data for Sri Lanka

In October 2003 the General Conference of UNESCO adopted the International Declaration on Human Genetic Data. Article 1 defines the aims and scope of this declaration. The aims include ensuring the "respect of human dignity and protection of human rights and fundamental freedoms" in the collection and use of biological samples containing genetic data and goes on to state, inter alia, "to set out the principles which should guide States in the formulation of their legislation and their policies on these issues (and) form the basis for guidelines of good practice in these areas for the institutions and individuals concerned."

This declaration came to the attention of the Sri Lanka Medical Association in 2003 during the period when drafts were circulated for comment, at a time when the SLMA ethics review committee was aware of the importance of this subject. In February 2004 the NBC produced a draft set of guidelines based on this declaration titled "Guidelines – Biological Samples and Human Genetic Data: Collection, Processing, Use and Storage." This was done to bring into sharper focus the issues dealt with in the Declaration and to facilitate exploring

how Sri Lanka should respond and what needed to be done to meet its obligations as required by the Declaration. The draft was sent for scrutiny and comment by members of the Ethics Review Committees and the Solicitor General's Department – that is, the office of the Government's chief legal officer. The latter consultation was necessary as many of the recommendations in the guidelines depended on what was prescribed by Sri Lanka's laws. It was revealed that very few laws existed in Sri Lanka that dealt with the issues covered by the Declaration, and the draft guidelines. It was therefore seen to be necessary to consider new legal enactments to adequately deal with the issues involved.

The NBC thereupon commissioned a law academic to review regulatory legislation in relation to human genetics – both in the fields of clinical application and research – in selected countries that had relevance to Sri Lanka. The legislation existing in five countries – India, Japan, Thailand, the United States of America (USA), and the United Kingdom (UK) – was studied (Watson, 2007). The selection of countries was based, partly, on the availability of their legislation on the World Wide Web. Having identified the lacunae in the Sri Lanka laws and the subject areas that have to be addressed, the NBC (and later the NCEST) at the National Science Foundation was ready for a series of meetings with wide representation to decide on policy in relation to these subjects, before recommending them to the Government for adoption and thereafter for the introduction of new legislation.

At a discussion held in September 2010 between members of the National Health Research Council of the Ministry of Health, the Bioethics Subcommittee of the National Committee on Ethics in Science and Technology (NCEST), and the Sri Lanka Medical Association, consensus was reached as to the urgent need for national regulations in the field of human genetic material and data. Accordingly, a drafting committee comprising members from all three institutions developed a draft National Policy on Human Genetic Material and Data for Sri Lanka as a preliminary step, which is now ready for finalization after stakeholder meetings held in 2011 and 2012.

Bioethics Education

The National Bioethics Committee (NBC) established in 2003 decided to concentrate on activities promoting bioethics education as one of its priorities, in keeping with *Article 23* of the UNESCO Universal Declaration, which states "To achieve a better understanding of the ethical implications of scientific and technological developments, in particular for young people, States should foster bioethics education and training at all levels and encourage dissemination of information about bioethics."

The NBC felt that teaching of medical ethics is adequately covered by the medical faculties and decided to concentrate on the science-based faculties in our universities (i.e., Faculties of Natural and Applied Sciences, Agriculture, and Veterinary Medicine). During the early period, between 2005 and 2008, the NBC conducted several introductory teacher-training workshops for university teachers and secondary school teachers from all over the island, with funding from the

Ministry of Science and Technology. Despite the uncertainties of travel in Sri Lanka at this time due to the prevailing war with the terrorists, there was enthusiastic participation from university academics from all parts of the country, including the North and the East (Fernando & Fernando, 2009).

In 2007, the National Bioethics Committee of the NSF received a grant from UNESCO, to further develop the bioethics teaching program in Sri Lanka. Several comprehensive teacher-training programs were conducted in 2008. In addition to several one-day workshops, a 2-day residential workshop was conducted for university science teachers with the help of a resource person from the University of Durham in the United Kingdom.

In addition to several Train-the-Trainer workshops on bioethics education conducted for university science teachers, other workshops were conducted on *Introduction of bioethics in secondary schools* and *Humane Ethics in the Care, Use and Study of Animals* for secondary school teachers, *Current issues in bioethics & biomedical research* for Medical and Dental faculty researchers, and the *Establishment of Research Ethics Committees in Science Faculties* as well as *Developing guidelines for research on animals* for teachers from the science-based faculties.

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

Teaching Medical Ethics

Medical ethics teaching at undergraduate level is fairly well established in most of the medical faculties. However, the duration and content of the courses are not uniform among the faculties. At postgraduate level, ethics teaching is less formally organized although a few courses have introduced separate modules on ethics. Research ethics is fairly well covered at both undergraduate and postgraduate levels, and is frequently dealt with in workshops and continuing medical education programs.

Teaching Bioethics

Teaching bioethics at university level (other than in the medical faculties) is less well organized. A few science faculties have introduced the subject at undergraduate level.

The National Bioethics Committee (2004–2008) initiated teacher-training activities to promote the introduction of bioethics in the science-based disciplines in universities. This initiative is being continued by the National Committee on Ethics in Science and Technology at the National Science Foundation.

Bioethics was also introduced in government secondary schools through the National Institute of Education.

Bioethics Committees

The need to reflect and act on the ethical, legal, and social dimensions of modern advances in science and biotechnology resulted in the establishment of many kinds of bioethics committees around the world. These committees can be described as falling into four categories, according to their goals, and the level at which they function, national, regional, and local, as described in the UNESCO booklet *Establishing Bioethics Committees – Guide No. 1*. In practice, however, some of these committees could function at more than one level, e.g., Research Ethics Committees, and they could also have a combination of goals:

1. Policy-Making and/or Advisory Committees (PMAs) – at national level
2. Health-Professional Association Committees (HPA) – at national and regional levels
3. Health Care/Hospital Ethics Committees (HECs) – at local and institutional levels
4. Research Ethics Committees (RECs) - at many levels

The following types of bioethics committees are present in Sri Lanka.

Policy-Making and/or Advisory Committees (PMAs)

The need for a National Committee was fulfilled in 2003 with the establishment of the National Bioethics Committee at the National Science Foundation, which came under the Ministry of Science and Technology. This committee was replaced by the National Committee on Ethics in Science and Technology in 2008. The Ministry is now called the Ministry of Technology and Research.

Health-Professional Association Committees (HPA)

Some of the older Health Professional Associations such as the Sri Lanka Medical Association and the Sri Lanka Medical Council have had Ethics Committees for many years, while others are in the process of establishing such committees.

Research Ethics Committees (RECs) or Ethics Review Committees (ERCs)

In Sri Lanka, Research Ethics Committees, dealing with the review and approval of research protocols, have functioned for the past 25 years or so in all the Medical Faculties of the universities. Research Committees have also been established in other organizations, such as the Sri Lanka Medical Association and the Medial Research Institute (MRI), and in some of the larger hospitals, for this purpose.

Health Care/Hospital Ethics Committees (HECs)

In Sri Lanka, no Hospital Ethics Committees have been established in any of the government hospitals, although one functioned for a few years in a private hospital. In 2011, the Sri Lanka Medical Association took the initiative to introduce the concept of Hospital Ethics Committees in Sri Lanka, but as yet, no Hospital Ethics Committees have been established.

Expert Bodies/Centers

There are no associations or societies devoted specifically to bioethics. As yet, there are no Departments of Bioethics in any of the universities in Sri Lanka. The National Committee on Ethics in Science and Technology (NCEST) at the National Science Foundation (formerly the National Bioethics Committee) is the only body involved in the wider discipline of bioethics at a national level. Teaching of medical ethics and research ethics, however, is undertaken by several centers in Sri Lanka, including all the Faculties of Medicine, the Postgraduate Institute of Medicine, the professional medical organizations including the Sri Lanka Medical Association, and the Institute for Research & Development (IRD).

Relevant Legislation

There is no legislation on bioethics at present.

Public Debate Activities

There is no regular forum for the public debate of major ethical issues. Whenever any policies or potential regulations are drafted by professional organizations or academic bodies, stakeholder meetings are convened to obtain public opinion and publicity will be given in the media.

The draft acts prepared by the National Committee on Ethics of in Science and Technology will be discussed at stakeholder meetings including members of the public before being finalized.

Others

The Ethics Committee of the Sri Lanka Association for the Advancement of Science (SLAAS) initiated an annual meeting/oration, on a topic related to ethics, in memory of the late Professor S.R. Kottegoda, who was a Past President of the Association and who encouraged the development of research ethics and research ethics committees at many scientific institutions. These annual meetings/orations have continued without a break since 1997, and provide a suitable forum for the dissemination of ethical issues relevant to Sri Lanka (Arsecularatne, 1998).

Major Bioethics Issues and Discussions

Beginning of Life

There are no specific laws concerning the beginning of life except for the law prohibiting abortions. In Sri Lanka, an abortion is only permitted if the pregnancy

threatens the life of the mother. There is also not much public canvassing to change the existing law either. Respect for human life is considered to be paramount among all the religions in Sri Lanka although paradoxically, a large number of illegal abortions are carried out under different names.

End of Life

End of life ethical issues are not issues that generate a lot of controversy in Sri Lanka. Unlike in the West, where patient autonomy is paramount, in Sri Lanka, as in most other Asian countries, while informed consent is routinely obtained for most procedures, the wishes of the family are also given a lot of consideration by doctors with regard to end of life ethical issues, such as life-sustaining interventions and withholding/withdrawal of life support. Living wills and advance directives are not common. Euthanasia is illegal.

Health and Disease

There are no major ethical issues in this area. Sri Lanka is proud of the free health service provided to all its citizens who wish to avail themselves of this service. Private health care is also available to those who can afford it. Ethical issues may arise in the allocation of scarce resources in an equitable manner in the state hospitals. Some of the very expensive drugs such as cytotoxic drugs may not be available for free in the state sector hospitals. On the other hand, many drugs issued free to patients are not utilized properly simply because they are given free.

Health-Care System, Access to Health Care

Sri Lanka has a history of successful health action at relatively low levels of per capita expenditure since independence and is often praised by the World Health Organization for its achievements in the public health domain. Sri Lanka has the best health indices in South Asia, on par with some of the richer countries in the region. Citizens of Sri Lanka have high literacy rates and enjoy the benefits of universal access to free health care and free education up to university level. These achievements are mainly due to the socialist policies of successive governments democratically elected since gaining independence from Britain in 1948.

Many of the older infectious diseases have been eradicated, and the public is generally satisfied with the quality of and access to health care provided by the State. Private health care and hospitals are also available to those who can afford it.

In 1996, the Ethics Committee of the Sri Lanka Medical Association produced a Patients' Charter, called the *Declaration on Health*, which spells out some of the rights (and obligations) of the people. The aim was to produce greater understanding of health-related issues by the people, leading to further improvement of

the health of the people as well as closer cooperation among all categories of health professionals, the State, and society in general.

Traditional Medicine

Approximately 50 % of the population of Sri Lanka utilizes traditional/indigenous medicine, which system is recognized as an essential partner in the health-care services of the country. Practitioners of traditional medicine have been encouraged to conduct research on indigenous medicines together with Western qualified doctors, and this has resulted in a more scientific research outcome as well as recognition of the products by drug regulatory authorities. Practitioners of traditional medicine are also included as members of research ethics committees that review research protocols. This has led to better cooperation and understanding between the practitioners of the two systems of medicine in the country.

One of the problems in this area is the illegal export and smuggling of valuable herbal preparations out of the country. This not only deprives the country of an important source of income, but local researchers are also deprived of the opportunity of developing new medicinal drugs and the benefits resulting from the intellectual property rights that should accrue to them.

Genetics

Lack of effective regulations for the exportation of human genetic material is known to be a serious problem in the country. The Transplantation of Human Tissues Act No 48 of 1987 states in its preamble that the Act provides for the donation of human bodies and tissues for therapeutic, scientific, educational, and research purposes and the removal, use, and preservation of such tissues. Although there is no specific mention of genetic material, theoretically, genetic materials that are parts of tissues are covered by this act, and their use for any of the preceding purposes is covered by the provisions as well.

In view of the tremendous technological advances in the field of genetics and the various ethical concerns resulting from the accelerated growth in genetic research and services, it was agreed that specific national policies and regulations in the field of human genetic data are desirable. It was decided to draft a National Policy on Human Genetic Material and Data as a preliminary step prior to the formulation of legislation. This draft policy was discussed at stakeholder meetings held in 2011 and 2012 and is now ready for finalization.

Reproductive Medicine

The practice of assisted reproduction is well established in Sri Lanka. There is little public debate about ART in Sri Lanka, the issue being generally kept very private. There is also not much publicity given to this field in the media, possibly due to

cultural factors. Currently there is no legislation on ART, the practitioners of ART being guided by self-imposed ethical guidelines. As a first step, the SLMC published "A Provisional Code of Practice for Assisted Reproductive Technologies" (SLMC 2005). An Act to provide regulations for assisted reproductive medicine and genetics has been drafted (Human Reproduction and Genetics Act (HURGA)).

Medical Research

Research protocols involving humans and animals have to be submitted to an independent recognized Ethics Review Committee for approval before commencement of the research. While research ethics is taught to medical undergraduates and postgraduates at some point in their career, and the need to obtain ethical approval is emphasized, the only way to ensure that this is done is to insist on evidence of approval when presenting or publishing the research findings. Most academic bodies and journals have begun to do this.

All clinical trials in humans conducted in Sri Lanka are required to be registered in a Clinical Trials Registry. The Clinical Trials Registry of the Sri Lanka Medical Association is recognized as a Primary Registry by the World Health Organization. All clinical trials on new drugs conducted in Sri Lanka are also required to be registered with the Drug Regulatory Authority of the Ministry of Health, where a special Sub Committee on Clinical Trials (SCOCT) has been established to approve such clinical trials.

There has been a gradual increase in the number of clinical trials being conducted in Sri Lanka, often as multicenter global trials with foreign/pharmaceutical industry funding. The introduction of Contract Research Organizations (CRO) into the country is also anticipated. It has therefore become necessary to ensure that such trials are conducted according to international standards of Good Clinical Practice (GCP). Since the existing regulatory framework for clinical trials do not meet these standards, a Clinical Trials Act has been drafted by the Ministry of Health to provide regulations for the conduct of clinical trials of drugs and other interventions, conforming to international standards as well as existing Sri Lankan law. An increase in foreign/industry funded research also indicates a need for properly functioning ERCs in the country. There is an obligation on the part of the sponsors/government to ensure the proper functioning of the ERCs by providing the necessary funds and resources.

"Guidelines on Stem Cell Research and Therapy" have been developed by the Ethics Review Committee of a private hospital where such research is being planned. This area need to be discussed and debated in ethics fora.

Public Health

Sri Lanka has a very good system of public health and is often praised by the World Health Organization for its achievements in eradicating many diseases such as polio, leprosy, and malaria.

Infectious Diseases

Sri Lanka has done very well in controlling and even eradicating some infectious diseases. The country has been praised for its excellent immunization program for children. There are no ethical issues in this area.

Transplantation Medicine and Organ Donation

The first renal transplantation operation was carried out in 1985, using a kidney from a living related donor. Since then, over 1,000 successful renal transplantations have been carried out in Sri Lanka. Antirejection drugs are provided free of charge at National Hospital of Sri Lanka, Colombo, and at the two specialized transplantation centers in Colombo and Kandy. Renal transplantation using a kidney from a brain-dead donor was done for the first time in 1995. In Sri Lanka the most common and accepted type of donors are living relations of the patient. Non-related altruistic donors are also becoming common. The ethical issue here is to prevent an altruistic donor from becoming a commercial one. The Human Tissue Transplantation Act of Sri Lanka in Section 17 outlaws the sale of organs (Sheriffdeen, 2011).

Sri Lanka has recently expanded its organ transplant services by adding liver transplantations to the already existing kidney transplant program. The existing "Transplantation of Human Tissues Act" is inadequate to deal with all the new developments, and a new Act or a revision of the existing one is desirable.

Emerging Technologies (Nanotechnology, Information Technology, etc.)

Nanotechnology (NT)

The National Science Foundation, Sri Lanka, is participating in a joint project with India and Pakistan to develop a regulatory framework for nanotechnology-related activities in the respective countries. This project is funded by the IDRC. One of the five components of the project is "Ethics of Nanotechnology." Under this component, a code of ethics for nanotechnology-related activities in Sri Lanka and ethical guidance for researchers in nanotechnology have been developed.

Intensive Care

The PGIM had introduced a Diploma in Critical Care Medicine. The course work for this degree includes an ethics module which deals with end of life and emergency medicine ethics.

Palliative Care

Except at the main cancer hospital, facilities for the terminally ill are not commonly available. Such patients are usually looked after at home with great difficulty. This is partly due to religious and cultural reasons. Hospices and similar institutions should be established and attention paid to the development of palliative care.

Care for the Elderly

Geriatrics is also not a well-developed specialty in Sri Lanka. However, the population of Sri Lanka is rapidly aging, due to increasing life expectancy and improved health care. This is an area that needs attention.

Chronic Diseases

No specific ethical issues.

Psychiatric Care

The mental health-care facilities in Sri Lanka are gradually increasing although there is a dearth of qualified psychiatrists to cope with the patient load.

Pediatric Care

No specific ethical issues.

Emergency Care

Free treatment at all state hospitals is available to all citizens and noncitizens as well.

General Practice

No specific ethical issues.

Health Promotion and Education

The Ministry of Health has a department dealing with this area and programs have been introduced in schools as well. No specific ethical issues.

Scientific and Professional Integrity, Conflict of Interest, and Corruption

These issues are dealt with in several guidelines and codes of conduct applicable to the professionals and scientists. The Sri Lanka Medical Council provides "Guidelines on Ethical Conduct for Medical and Dental Practitioners" registered with the SLMC. A Professional Code of Ethics for Scientists was developed by the National Committee on Ethics in Science and Technology (NCEST) in 2010. The Organization of Professional Associations of Sri Lanka also produced a code of ethics titled "General Principles and Guidelines of Ethical Conduct for Professionals" in 1995. SLAAS has a very comprehensive set of ethical guidelines for research.

Relations with Industry and Donors/Sponsors

Industry sponsorship plays a major role in the academic activities of the professional medical associations. Ensuring ethical practices during sponsorship is the responsibility of the association and its ethics committee. In 1996, the Sri Lanka Medical Association produced a booklet "Ethical Criteria for the Promotion of Medicinal Drugs and Devices in Sri Lanka." This was based on the WHO document "Ethical Criteria for Medicinal Drug promotion." These criteria have been accepted by the medical, dental, and veterinary professions, as well as the pharmaceutical manufacturers and traders in Sri Lanka.

Future Challenges

In the Field of Bioethics Infrastructures (Need for Legislation, Ethics Committees, Ethics Education, etc.)?

Legislation

The Clinical Trials Act that has been drafted should be finalized and enacted. Ethical guidelines for biomedical research on humans should be developed, ideally by the Ministry of Health, so that all researchers in Sri Lanka could follow standard guidelines. This would also make it easier for ERCs to review and approve research protocols in a uniform manner.

Ethics Committees

While there are several Ethics Review Committees (ERCs) evaluating and approving research proposals, they do not have statutory powers nor the resources or infrastructure to monitor the research or take action against unethical research on humans. A central Research Ethics Committee could be established to deal with these important functions, as well as to decide on policy issues. The existing Ethics Review Committees (ERCs) need financial and other support from the Ministry of Health in order to increase their efficiency in reviewing, approving, and monitoring

research protocols in human biomedical research. Another urgent need is to initiate the establishment of Hospital Ethics Committees. The initiative for this should come from the Ministry of Health.

Ethics Education

Currently, most of the activities are concentrated in the teaching of medical ethics and research ethics to medical undergraduates and postgraduates. Doctors and academics trained in ethics are available to conduct courses and workshops with financial support provided mainly by the World Health Organization. Currently there are no degree programs or ongoing courses in bioethics in Sri Lanka. Short courses in bioethics are conducted infrequently by some institutes such as the National Science Foundation. The medical faculties concentrate on teaching medical ethics and research ethics. The establishment of University Departments of Bioethics is desirable. A UNESCO Chair in Bioethics established in a recognized state university with experience in teaching medical ethics would be a stimulus for the further development of bioethics in Sri Lanka.

In the Field of New and Emerging Issues?

The National Bioethics Committee (subsequently the National Committee on Ethics in Science and Technology) of the National Science Foundation has drafted the Human Reproduction and Genetics Act (HURGA) and the National Policy on Human Genetic Material and Data for Sri Lanka. It is hoped that these two drafts could be finalized and implemented as legislation in the near future.

The National Science Foundation has also taken the initiative to develop a National Policy on Nanotechnology for Sri Lanka. It is now in the process of finalizing a regulatory framework for nanotechnology-related activities. This includes ethical guidelines for research in nanotechnology and a code of ethics for application of nanotechnology in Sri Lanka.

Recently, Sri Lanka expanded its organ transplant services by adding liver transplantations to the already existing kidney transplant program. There is also an increasing demand for the transfer of human biological material and data from Sri Lanka to other countries, ostensibly for research purposes, giving rise to several ethical issues. The existing "Transplantation of Human Tissues Act, No 48 of 1987" is inadequate to deal with all the new developments and a new Act or a revision of the existing one is desirable.

Any Other Problems and Opportunities for the Further Development of Bioethics in the Country?

Lack of funds to conduct courses and training workshops is a major constraint for the development of bioethics in Sri Lanka. To develop bioethics as a discipline, the

governmental institutes and bodies currently involved in bioethics activities in Sri Lanka would need to attract financial support from funding agencies such as UNESCO, the Wellcome Trust, the Nuffield Council on Bioethics, and similar international bodies. There should be more commitment and enthusiasm from the educational institutes in Sri Lanka for the teaching of bioethics.

The small group of experts and academics currently working in the field of bioethics should create more awareness among other academics and professionals, as well as the general public about the need for discussion and debate on bioethical issues. They should also impress upon the government the necessity of enacting necessary laws and regulations to support the development of bioethics in Sri Lanka.

Summary and Conclusion

The need for teaching medical ethics to undergraduates is accepted by all the medical schools in the country. However, the content and methods vary from faculty to faculty and need to be improved. Teaching of medical ethics at postgraduate level has already started and will eventually be formalized.

The bioethics teacher-training program started in 2005 by the National Bioethics Committee needs to be continued with the ultimate aim of introducing bioethics into the curricula of all science-based faculties in the universities and also in secondary schools. In this regard, it would be useful to promote the establishment of at least one university department of bioethics.

Researchers in the field of medicine, at both undergraduate and postgraduate level, are familiar with the principles of research ethics and obtain approval from ERCs before commencing their research. This awareness should be extended to other areas of research. Ethics Review Committees reviewing biomedical research in humans function adequately at present but need to be strengthened by providing them with more support to enable all ERCs to attain the high standard necessary to gain recognition by FERCAP/SIDCER. National guidelines for ethical research should be developed, in order to achieve standardized procedures of giving ethical approval for research.

Bioethics activities in Sri Lanka could also benefit by drawing inspiration from its ancient history and the influence of Buddhism on many areas and issues of bioethical relevance. The words of Judge C.G. Weeramantry, spoken at the World Future Council held in Hamburg in May 2007, would be a fitting conclusion.

"In the result Buddhism offers us a range of powerful concepts for the protection of the long-term future through such principles as interdependence, universalism, moderation, trusteeship, environmental protection, environmental education, sustainable development and a consciousness of the rights of future generations. Buddhism's infinite treasury of wisdom cannot any longer be neglected without damage to the human future" (Weeramantry, 2007).

Introduction

This chapter describes the development and the current status of bioethics in Switzerland with special emphasis on the historical evolution and the social and cultural contexts that have shaped the debate in the country. Medical ethics

developed in the late 1970s and was progressively institutionalized in the following decades through the establishment of ethical committees, guidelines for health care professionals, academic training in medical schools, and ethical consultation in Swiss hospitals.

Over the past three decades, discussions within academia, policy making, and the public arena have resulted in the adoption of regulations on several bioethical issues. As elsewhere in Western Europe, major issues of discussion include abortion and the status of prenatal life, assisted suicide, end-of-life care, organ transplantation, reproductive technologies, ethical issues of genetic technologies, and protection of human subjects of research. Nevertheless, these issues have a considerable bearing on Swiss public debate because of the system of semi-direct democracy, in which citizens can be called upon to vote on legislative proposals or on challenges to parliamentary bills. Decentralized governance, cultural and confessional differences, as well as the value placed on individual choices have largely influenced discussions, laws, and practices regarding many bioethical issues outlined in this chapter.

Bioethics Development

When and How Has Bioethics Started?

Certain aspects of ethical issues in medical care were part of graduate courses of moral theology and forensic medicine before the existence of bioethics as a distinct field. From the 1970s, medical ethics began to be considered as a specific field grounded in philosophical ethics and dealing with normative questions in medical practice and research.

In 1979, the Swiss Academy of Medical Sciences (SAMS) (http://www.samw.ch/en/News/News.html), founded by medical schools and health care professions, set up a SAMS Central Ethical Committee (http://www.samw.ch/en/Ethics/CEC.html) in charge of establishing guidelines on controversial issues in medical practice. Over time, some of these guidelines have acquired binding authority, either through endorsement by the Swiss Medical Association (http://www.fmh.ch/index.html) as part of the professional code of physicians or by being referred to by laws or by case law. In the following decades, academia progressively took an interest in ethics, in general and medical ethics in particular. Progressively, Swiss universities established chairs in ethics within philosophy departments and medical schools.

Who Have Been the Major Actors/Forces?

Switzerland is a multicultural federal republic with a system of semi-direct democracy where governance is strongly decentralized. This is also reflected in bioethics. The major actors in the field are as follows:

– The Swiss Academy of Medical Sciences (SAMS), based in Basel

- The Zurich University Centre for Ethics (ZUCE) (http://www.ethik.uzh.ch/index_en.html).
- The Institute for Biomedical Ethics (IEB) (http://www.unige.ch/medecine/ib/accueil.html) at the University of Geneva.
- More recently, the University of Basel's Institute for Biomedical Ethics (IBMB) (http://ibmb.unibas.ch/) and the University of Lausanne's ETHOS – Interdisciplinary Ethics Platform (http://www.unil.ch/ethos/page60109_en.html).

In December 1998, the Swiss National Advisory Commission on Biomedical Ethics (NEK-CNE) (http://www.bag.admin.ch/nek-cne/04236/index.html?lang=en) was set up as an independent, extra-parliamentary deliberative body, with the mission to promote public debate and advise policymakers on ethical issues in the field of biomedical research and practice. The Federal Ethics Committee on Non-Human Biotechnology (ECNH) (http://www.ekah.ch/en/index.html) was established the same year as an independent expert committee to advise authorities on ethical issues of nonhuman biotechnology and gene technology. Ethics commissions providing advice for clinical practice are increasingly present in Swiss hospitals.

The Confederation also established the Centre for Technology Assessment TA-SWISS (http://www.ta-swiss.ch/en/) with a view to investigate the social impact of new technologies and advise the Parliament and the Federal Council on controversial technologies. Research in the field of biomedical ethics is mainly sustained by the Swiss National Science Foundation (SNSF) (http://www.snf.ch/E/Pages/default.aspx) through various forms of financial support to academic institutions and individual researchers and through national programs on specific topics. Among nonacademic institutions, the Brocher Foundation (http://www.brocher.ch/pages/default.asp?lang=en) supports research on ethical, social, and legal issues of biomedical technologies.

The Swiss Society for Biomedical Ethics (SGBE/SSEB) (http://www.bioethica-forum.ch/content/e_SGBESSEB.php) – a multidisciplinary, multilingual, and non-confessional association of scholars and practitioners joining various ethical perspectives and a pluralistic approach to bioethical issues – promotes research and training in bioethics (see section "What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?" below).

What Have Been the Major Concerns Over Time?

During the 1990s, the Swiss debate was characterized by lively public discussions on ethical dilemmas related to genetics, reproductive technologies, and end-of-life care. Beside these major topics, the bioethical debate within academia, policy making, and the public arena has focused on organ transplantation, the protection of human subjects of research, experimentation on animals, abortion, and the ethical status of human prenatal life, the prevention of infectious diseases, and patient rights.

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

Numerous publications in the field are produced at the local level in the various linguistic regions of the country. In addition, several resources in bioethics have been developed at the national level. The Swiss Academy of Medical Sciences (SAMS) and the Swiss Medical Association promoted the publication of a textbook of biomedical ethics discussions and regulations in the country (Bondolfi and Müller, 1999).

Since the early 1990s, the universities of Zurich and Geneva initiated formal bioethics courses for medical students. Until 2006, the Swiss Society for Biomedical Ethics (SGBE/SSBE) has organized a summer school for health care professionals and researchers who did not have the opportunity to have training in bioethics during their education. Every 2 years since 2005 and annually since 2009, the SGBE/SSBE organizes workshops where research projects are presented and discussed.

Two main book series on bioethical research in Switzerland are published in German and French by Schwabe editions in Basel within the collection *Ethik und Recht* and by Georg editions in Geneva within the reader's collection *Controverses en éthique*. The SGBE/SSBE publishes the journal *Bioethica Forum* (http://www.bioethica-forum.ch/e_index.php), as well as a collection of thematic essays in French and German entitled *Folia Bioethica*.

What Have Been the Steps/Measures Taken?

Over the past three decades, Switzerland has adopted regulations on several bioethical issues, such as reproductive technologies (http://www.admin.ch/ch/d/sr/c810_11.html), genetically modified organisms (http://www.admin.ch/ch/d/sr/c814_91.html), research on human embryonic stem cells derived from spare embryos (http://www.admin.ch/ch/d/sr/810_31/index.html), human genetic testing (http://www.admin.ch/ch/d/sr/810_12/index.html) including prenatal testing and newborn screening, and organ transplantation (http://www.bag.admin.ch/transplantation/00694/01739/index.html?lang=de). A new law on biomedical research on human subjects will soon become effective (http://www.bag.admin.ch/themen/medizin/00701/00702/07558/index.html?lang=de), and a far-reaching revision of the civil code will make advance directives recognized on a federal level in 2013 (http://www.ejpd.admin.ch/content/ejpd/de/home/themen/gesellschaft/ref_gesetzgebung/ref_vormundschaft.html).

Whereas the cantons hold legal prerogative in the field of health care policy, on most of the issues listed above, the Confederation enlarged the scope of its power, otherwise limited to infectious disease control. Giving the Swiss Parliament the authority to enact laws on additional topics requires a change in the Constitution, which in turn requires that citizens be called upon to vote. In the last 30 years, this happened regularly on many issues regarding medical practice and research.

It should be noted that abortion and assisted suicide are regulated by the Swiss criminal code and that no specific legislation on these practices has been

introduced. In particular, Articles 118–120 of the code authorize abortion on demand in the first trimester and on medical indication thereafter, and Articles 115 and 114 legally condone assisted suicide for altruistic reasons and outlaw "murder on demand by the victim" or voluntary active euthanasia.

The Swiss law on epidemics dates back to 1974 and has never been amended over time. During the AIDS pandemic, no specific standards were introduced, although information campaigns were strongly supported by public authorities to prevent the spreading of the disease in the country.

Besides the regulatory activity of the Confederation, the Swiss Academy of Medical Sciences (SAMS) regularly provides recommendations and guidance for health care professionals on various topics relevant to medical practice and research as outlined above.

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

The teaching of bioethics is currently present in all the faculties of human and veterinary medicine, in some faculties of sciences, and in many bachelor- and master-level training programs for health professionals. The Swiss Academy of Medical Sciences (SAMS) is compiling a complete list of teaching institutions and programs. The federal law defining training for the medical profession requires academic programs to include courses on the ethical aspects of the professional activity, with a view to develop students' personal skills and social competences. Although education in bioethics is compulsory for medical students, training programs can be defined by universities with a high degree of autonomy.

Bioethics Committees

Research involving animals or human participants needs to obtain clearance from an ethics committee, as is the case in all countries recognizing international ethical principles of biomedical research. A new federal law on biomedical research on human subjects will come into force by 2014. Until then, the ethical review of research protocols and the establishment of ethics committee fall under the jurisdiction of cantons. At present, cantons where universities have faculties of medicine have set up cantonal ethics committees, organized in various subcommittees covering different research fields. Where no faculty of medicine exists, an inter-cantonal ethics committee is established, with the exception of Ticino where the cantonal committee was created because of intense research activities in the canton and because of its geographic isolation.

In addition to ethics committees for the review of research protocols, clinical ethics committees are present in almost half of all Swiss hospitals to provide ethical consultation to health care professionals (Hurst et al., 2008). The functioning of each clinical ethics committee is regulated by its statute.

Expert Bodies/Centers

At the national level, two ethics committees exist in Switzerland to promote public debate and advise policymakers on ethical issues: the Federal Ethics Committee on Non-Human Biotechnology (ECNH) examines ethical issues of biotechnological interventions on plants and animals, whereas the Swiss National Advisory Commission on Biomedical Ethics (NEK-CNE) considers ethical and health policy issues in the field of biomedicine.

Relevant Legislation

The relevant Swiss legislation in the field of bioethics is detailed in section "What Have Been the Steps/Measures Taken".

Public Debate Activities

In Switzerland, public discussion of bioethical issues is largely determined by the political agenda set by the Parliament. However, the system of semi-direct democracy, in which parliamentary bills can be called into question, new laws can be proposed, and constitutional amendments can be passed by popular vote, have a considerable bearing on public debate activities in the country. Bioethical issues that are currently under discussion in the public debate include the following:

- The use and reimbursement of reproductive technologies, especially preimplantation diagnosis.
- Various issues in environmental ethics, especially the regulation and use of genetically modified organisms.
- The relevance of further regulating the legal practice of suicide assistance, and/or of legalizing voluntary euthanasia.
- The application of patient rights within the health care system.
- The costs of the Swiss health care system and the ethical and health policy issues relating to access to health care.
- Ethical issues of direct-to-consumer genetic testing.

Major Bioethics Issues and Discussions

Beginning of Life

Within academic discourse, dilemmas surrounding the ethical standing of human prenatal life and reproductive technologies are discussed largely in the same terms in Switzerland as elsewhere in Western Europe, and controversies run along similar lines. Nevertheless, these issues have been particularly visible in Swiss public life on account of the system of semi-direct democracy, in which citizens are regularly

called upon to vote on legislative proposals or on challenges to bills adopted by Parliament. In the last two decades, this occurred a number of times for topics relevant to this section. In 2002, Parliament adopted a far-reaching reform of criminal law as regards abortion, basing the protection of embryos and fetuses on a "gradualist" view of their moral status – the view according to which the appropriate protections grow, as it were, along with it. This made Swiss criminal law much more liberal than the (nominally) conservative status quo. Conservatives and certain religious circles gathered the requisite number of signatures to put the issue before the people, but their challenge to a liberal abortion law was resoundingly defeated (72.2 % votes were in favor of the new law; a competing proposal to prohibit abortion in most situations was defeated by 81.7 % of votes).

The ethics and politics of reproductive technologies as well as related issues such as research using human embryonic stem cells show a far more complex picture. Broadly speaking, Swiss legislation on reproductive technologies rests on the paradigm of application within a nuclear family, recognizes an individual's right to know her biological ascendency, and has strictly banned the production of embryos for any purpose other than implantation. At the same time, however, research is highly valued, and this extends to human embryonic stem cells. In the early 1990s, a fairly restrictive constitutional amendment was adopted (Article 119 of the Constitution) with strong popular support at the time. Among other restrictions, oocyte donation, embryo donation, and preimplantation genetic diagnosis (PGD) were outlawed, as were the production of more than three embryos in vitro per cycle of fertility treatment; keeping frozen spare embryos for an ulterior treatment cycle was also forbidden. In the early years of this century, a bill softening these prohibitions in order to make human embryonic stem cell research possible was put to the popular ballot and accepted (66.4 % "yes" votes). Among other elements, this new law establishes a requirement for parental consent for the use of surplus embryos in human embryonic stem cell research (Porz, Bürkli, Barazzetti, Scully and Rehmann-Sutter, 2008). The climate of public opinion on these issues seems to have changed. The prohibition of PGD is currently challenged, and a correspondingly revised legislation is being discussed.

End of Life

The Swiss debate on end-of-life care can be traced back to the 1960s. Discussions were nourished by philosophers, theologians, and health care professionals, confronting new dilemmas of end-of-life care raised by medical progress. There are many publications on the topic in Switzerland, although this literature is relatively fragmented due to its multilingual character. Early discussion on end-of-life care centered on a medical decision to limit life support of a dying person. Eventually, this decision was not enacted, but it brought about an energetic debate on withdrawing medical care at the end of life. In the wake of this discussion, the Swiss Academy of Medical Sciences (SAMS) drew ethical recommendations that allow doctors to withhold futile treatments to dying patients. Issued in 1976, the SAMS guidelines have been regularly reviewed as the debate on end-of-life care in

the country continued to evolve (revisions were published in 1981, 1988, 1995, and 2004). The analysis of the successive versions of the document shows a growing consensus on the moral wrongness of futile medical care.

Besides issues of end-of-life care, the practice of assisted suicide has been extensively discussed in the country (Pfister and Biller-Andorno, 2010). Assisted suicide is legally condoned by Article 115 of the Swiss criminal law if the motive is altruistic, and it can be performed by nonphysicians (Hurst and Mauron, 2003). The viewpoint of the SAMS on assisted suicide has changed over time. While the 1995 revision of the SAMS guidelines (Available at http://www.samw.ch/de/Ethik/Richtlinien/Archiv.html) stated that assisted suicide is "not a part of medical activity," the last version of the document (Swiss Academy of Medical Sciences, 2004a) acknowledges that a conscientious decision by a doctor to assist suicide should be respected. During the last few years, the political discussion has focused on whether to regulate both assisted suicide and voluntary euthanasia by law. In June 2011, the Parliament decided to maintain the status quo.

Discussions about palliative care and advanced directives were less controversial and have rapidly reached a general consensus. Palliative care is promoted and sustained by the Confederation and the cantons. Advanced directives, which already exist in several cantons, are recognized on a federal level by a revision of the Swiss civil code, as of 2013.

Health and Disease

In Switzerland, coverage by medical insurance is based on the presence of disease and the indication for medical treatment, making the definition of what constitutes disease, or not, a key element. Excluded areas include long-term care, viewed as required by old age rather than disease, but also contraception and fertility treatments, both of which are considered lifestyle choices rather than health issues. More recently, coverage for vision correction in childhood has been excluded from coverage: based on statistical frequency, it was argued that it was normal and thus not a health condition.

Health Care System, Access to Health Care

The Swiss health care system is a universal coverage system based on an individual mandate for the purchase of state-regulated but privately managed health insurance, with subsidies toward this purchase for lower income groups (Gagnebin and Sprumont, 2009). Voluntary additional insurance can be purchased by individuals who so choose; it covers greater comfort and choice of provider in hospitals, as well as certain interventions not covered by basic health insurance such as travel insurance or some forms of alternative medicine. Despite universal coverage and a very well-funded health system with dense regional access, barriers to access exist. The most visible one is a high rate of

out-of-pocket payments, which have been shown to lead some persons to forgo needed care (Wolff, Gaspoz and Guessous, 2011). Moreover, as outlined above (see section "Health and Disease"), coverage under basic insurance is predicated on interventions targeting disease, making the definition of what constitutes disease, or not, a key element. Dental care is also excluded from health care coverage. Rather than being based on a link between dental care and personal behavior in the prevention of dental disease, however, this exclusion is based on early requests by dentists to be excluded from what they viewed as obligations linked to their interventions' inclusion under the basic health insurance mandate.

Coverage for alternative medicine has been the object of a long-standing debate in Switzerland, where some forms of alternative therapy have originated and where several have been in use for a long time. Coverage of medical interventions is legally predicated on the intervention being "effective, appropriate, and efficient." Thus, one part of the discussion regarding alternative medicine has centered on its effectiveness. Despite a negative recommendation by the official commission on health coverage, however, the exclusion of these forms of alternative medicine proved so unpopular that they were covered despite not being proven effective.

Moreover, discussions regarding the possibility of excluding marginally beneficial interventions have taken place (Zimmermann-Acklin, 2005). These have been politically difficult and hence sporadic.

Traditional Medicine

As outlined above (see section "Health Care System, Access to Health Care"), coverage for alternative medicine has been the object of a long-standing debate in Switzerland, where some forms of alternative therapy have originated and where several have been in use for a long time. Several forms of alternative medicine – phytotherapy, homeopathy, Chinese traditional medicine, neural therapy, and anthroposophic medicine – are practiced by physicians with officially recognized courses of training. Coverage of medical interventions, however, is legally predicated on the intervention being "effective, appropriate, and efficient." Thus, one part of the discussion regarding alternative medicine has centered on its effectiveness. Despite a negative recommendation by the official commission on health coverage, however, the exclusion of these forms of alternative medicine proved so unpopular that they were covered despite not being proven effective.

Another part of the discussion has centered on the place of alternative medicine in medical training. Since 2009, Switzerland is required by its Constitution to "take alternative medicines into account". Although it is not entirely clear what this might mean for medical schools, it is broadly accepted that making students critically aware of alternative medicines and their claims will be the main application of this law in universities.

Genetics

Discussions about human genetics in Switzerland cover a wide range of topics, as it is the case elsewhere: from presymptomatic and susceptibility testing to DNA fingerprinting for criminal investigations; from disclosure and confidentiality of test results to gene therapy. A *Federal Act on Human Genetic Testing* (http://www.admin.ch/ch/e/rs/c810_12.html) was enacted in 2004 to regulate human genetic testing in the country.

Ethical and science policy issues that have been extensively discussed in the Swiss context have centered on the use of genetically modified (GM) crops in agriculture and on the commercialization of GM food, ensuing from the lack of specific regulations and transparent authorization procedures. For nearly 15 years, from the first field experiments in the early 1990s to the moratorium for GM crops that was passed in 2005, the debate spread out across the country in the form of a controversy about safety and environmental risks. The controversy was triggered by the action taken by ecologist groups who proposed an initiative for a restrictive regulation of various aspects of GM food, including patenting and commercialization. In response, molecular biologists organized protest marches in defense of new genetic technologies, also supported by pharmaceutical companies. Farmers concerned about the coexistence of traditional and genetically modified crops also called for a careful consideration of environmental and economic impacts of GM crops onto the small-size Swiss agriculture. The spreading controversy forced public authorities to accelerate the process of planning regulations. A directive on the labelling of food containing GM organisms was enforced in 1996, and the Federal Ethics Committee on Non-Human Biotechnology (ECNH) was set up in 1998 to examine ethical issues of developments in gene and biotechnology with a view to assess their impacts on humans and the environment. The ECNH should work in cooperation with the Swiss Expert Committee for Biosafety (SECB) (http://www.efbs.admin.ch/en/index.html) to review experimental protocols of GM crops field experiments and to inform the Federal Office for Environment (FOEN) (http://www.bafu.admin.ch/index.html?lang=en) in charge of giving the final clearance. The initiative proposed by ecologists was eventually voted in 1998 and rejected by a majority of the electorate (66 %). This result did not close the controversy in the country, which turned to be focused on field experiments. Notwithstanding the approval of the SECB and the favorable evaluation from several scientists, between 1999 and 2001, the FOEN repeatedly denied authorization of field experiments on the basis of the precautionary principle. The decision of the FOEN was contested by scientists who considered field experiments essential to their research work, which was conducted under a national research strategy on biotechnology financed by the Swiss National Science Foundation (SNSF). This crisis in national science policy was the consequence of various ethical and social issues of GM food that were still under discussion in the public debate. Indeed, in the course of the controversy, the evaluation and management of risks has evolved from a model where decision making is restricted to a qualified group of experts and policy makers,

to a model of public negotiation of risks (Audétat, November and Kaufmann, 2005). Although the agenda for discussion was initially focused on potential risks of GM food, the widening controversy contributed to democratize and enrich the public debate, which eventually included economic, environmental, and health-related issues of genetically modified crops (Kaufmann et al., 2004).

In 2005, a referendum was held to decide whether or not to prohibit the use of GM plants for a period of 5 years. The majority of the voters accepted the five-year moratorium, which was later extended to November 2013. The ostensible purpose of the moratorium was to provide time for evaluation of potential benefits and risks of GM plants, as well as their social acceptability. To this end, a national research program was implemented by the SNSF (NRP 59) (http://www.nrp59.ch/e_index.cfm). Since the empirical part of this research necessitates field testing of GM plants, and since such tests raise fierce opposition by legal and illegal means, it is doubtful whether this research program will provide enough results to inform public policy on this matter.

Reproductive Medicine

Discussions regarding reproductive medicine in Switzerland have centered on what should be allowed on the one hand and what should be covered by health insurance on the other. Broadly speaking and as outlined above (see section "Beginning of Life"), Swiss legislation on reproductive technologies rests on the paradigm of application within a nuclear family and recognizes an individual's right to know her biological ascendency.

As regards abortion, the Swiss Parliament adopted a reform of criminal law in 2002, basing the protection of embryos and fetuses on a "gradualist" view of their moral status – the view according to which the appropriate protections grow, as it were, along with it. As outlined in section "Health and Disease," contraception and fertility treatments are generally excluded from health coverage, as both are considered lifestyle choices rather than health issues.

Medical Research

International principles and guidelines are applied to research with human subjects in Switzerland. Swiss law makes explicit reference to the ICH guidelines for Good Clinical Practice, and Swiss Academy of Medical Sciences (SAMS) recommendations (http://www.samw.ch/de/Ethik/Richtlinien/Archiv.html) refer to the declaration of Helsinki. Specific issues have nevertheless been raised in the Swiss context, in particular, since the first project for a federal law on research with human subjects was put to public consultation in 2006. Three issues have been the object of particular debate.

First, the scope of protections for human subjects of research outside of biomedical sciences is controversial. On the one hand, it is difficult to see how the area of

research where human subjects incur risks should make a difference to the protection they are given. On the other hand, ethical codes and oversight bodies are often younger, fewer, or even nonexistent in fields other than biomedical science. When it came to defining the required protections' scope of application, the authors of the law project rejected application based on the discipline or professional group of the investigators as too difficult to define exhaustively and too likely to include research involving no risk to human participants. They also rejected application based on the degree of risk, based on the lack of bodies competent to review such research outside the scope of biomedicine. They defined the scope of protection, which includes ethics committee review, based on two criteria (Duetz and Gruberski, 2009):

1. Research on human disease and the development and functioning of the human body, where the term "disease" is understood broadly and includes psychological health impairments.
2. A risk threshold based on the possibility of harm to human dignity and personal integrity: This is defined by the exclusion of research on in vitro embryos, anonymous biological material, and anonymously obtained or completely anonymized health-related data.

Second, federalism has led to decentralized review of multicenter studies even within Switzerland, and coordination of ethics review by different ethics committees has proved difficult. Recently, the working group of Ethics Review Committees has implemented a rotating centralized review to facilitate multicenter review.

Third, the interface between research with animals and research with human subjects is a particular point of tension in Switzerland. Research with animals is particularly strictly regulated in Switzerland, based on a constitutional clause protecting the integrity of living organisms – or the "dignity of creatures" in the German version. The "dignity" of animals is explicitly different from human dignity: it means that animal interests must be considered in the balance of risks and benefits but can nevertheless be subordinated to greater human interests (ECNH, 2008). In practice, application predictably remains difficult. In 2008, a decision to stop two experiments on monkeys was upheld by the Swiss Supreme Court based on the uncertainty and distance of the expected clinical applications in view of the burden imposed on nonhuman primates. As such decisions illustrate, the appropriate thresholds to apply in balancing human and animal interests remain controversial.

Public Health

Ethical issues in public health tend to cluster around three main issues: tensions between public health efforts and individual self-determination, questions regarding legitimacy and appropriate decision makers, and difficulties in distinguishing public interventions for the prevention of disease on the one hand and the moralization of health on the other. In Switzerland, a strong focus on individual self-determination, combined with the cantonal organization of many aspects of the health care system, has tended to make concerted public

health efforts more difficult. Antismoking campaigns, for example, have tended to focus on individual efforts rather than on limits to the availability of tobacco. It is only when it became clear that smoking was harmful to others that bans on smoking in public spaces were implemented. Information campaigns for organ transplantation have also been criticized for focusing on neutrality and avoiding any appearance of promoting organ donation. This focus on individual self-determination extends to the prevention of infectious diseases, with very few mandatory vaccinations and some resurgence, for example, of measles as one consequence. During the beginning of the AIDS pandemic, public health interventions struck many as signalizing a shift away from the moralization of sexuality as advertisement for condoms were used in public spaces to promote effective protection. More recently, however, health itself has tended to risk becoming moralized as part of prevention campaigns aimed, for example, at the prevention of smoking or obesity.

Infectious Diseases

As outlined above (see section "What Have Been the Steps/Measures Taken"), the Swiss law on epidemics dates back to 1974 and has never been amended since. At the beginning of the AIDS pandemic and during concerns regarding avian flu outbreaks, no specific standards were introduced, although information campaigns were strongly supported by public authorities to prevent the spreading of the disease in the country. As outlined under Public health, however, a strong focus on individual self-determination, combined with the cantonal organization of many aspects of the health care system, has tended to make concerted public health efforts in prevention more difficult. This focus on individual self-determination extends to the prevention of infectious diseases, with very few mandatory vaccinations and some resurgence, for example, of measles as one consequence.

Transplantation Medicine and Organ Donation

In 2004, the Confederation adopted a federal law on organ transplantation. Before that date, this practice was regulated by the directives of the Swiss Academy of Medical Sciences (SAMS) (Available at http://www.samw.ch/en/Ethics/Guidelines/Archive.html) and by 15 different cantonal laws. Notwithstanding the new federal regulation and the information campaigns for the promotion of organ donation, the practice is limited by the significant shortage of organs available for transplantation. There are important differences in the attitude of Swiss citizens with regard to transplantation. The paucity of cadaveric donations in the country has contributed to increase the number of transplants from living donors, a practice strictly regulated by the new federal law. According to the current legislation, explicit consent to organ donation should be given by persons before death or should be witnessed by family members after death.

The Confederation mandated the SAMS to draw recommendations for clinicians on both the definition of brain death and the procedures to assess it. The SAMS regularly updates these directives (Updated versions are available at http://www.samw.ch/en/Ethics/Guidelines/Currently-valid-guidelines.html).

More recently, the Swiss Parliament has discussed the adoption of an implicit consent to organ donation. The Swiss National Advisory Commission on Biomedical Ethics raised several concerns on the ethical implications of this measure for medical practice.

New legal provisions have been introduced on allocation of organs available for transplantation, with a view to establish stringent eligibility criteria for patients on the basis of urgency and efficacy. At present, the practice of xenotransplantation, which was extensively discussed as an alternative to organ transplantation, has been progressively abandoned and eventually prohibited by law due to the high risks of transmission of zoogenic pathogens.

Emerging Technologies

Discussion of new emerging technologies in Switzerland is mainly, although not exclusively, focused on nanotechnology. Similarly to what happened in the case of the GMO controversy, the agenda for discussion is dominated by concerns about risks and safety of nanoparticles. This approach is manifested in the national research program founded by the Swiss National Science Foundation (SNSF) to investigate impacts of biomedical and environmental use of nanomaterials (NRP 64) (http://www.nfp64.ch/E/Pages/home.aspx), as well as in the initiatives launched by the Federal Office of Public Health (FOPH) (http://www.bag.admin.ch/index.html?lang=en), such as the platform for public dialogue NANO and the *Precautionary Matrix for Synthetic Nanomaterials*, a method to assess potential risks of the production of nanomaterials.

Very recently, some arenas of discussions have been developed, such as the following: the publifocus organized by the Centre for Technology Assessment TA-SWISS (http://www.ta-swiss.ch/en/projects/nanotechnologies/); the newsletter published by the Innovation Society, an independent consulting company based at the Technology Center of the Federal Institute of Materials Science and Technology in St. Gallen (http://www.innovationsgesellschaft.ch/index.php?page=93); and *Nanopublic* (http://www.unil.ch/nanopublic/page32013.html), the nanotechnologies and society interdisciplinary platform aiming at fostering dialogue between the Swiss nanotechnology stakeholders.

Intensive Care

Discussion of ethical issues in intensive care has focused on questions raised at the end of life and on admission criteria in triage situations. It is generally accepted in Switzerland that competent patients have a right to refuse medical interventions, including life-sustaining measures. Consequently, withholding and withdrawing

therapy is an accepted part of medical practice. It is further accepted that futility, the absence of hope that an intervention will bring sufficient benefit to the patient to warrant the burden to that patient, can justifiably ground a decision to withhold or withdraw medical interventions. One consequence is that, among patients who die in Swiss intensive care units, a significant number does so following a decision to limit life-sustaining measures. Such decisions are usually based on consensus within interdisciplinary teams, on agreement with competent patients, and in the case of incompetent patients on discussions with family members regarding what the patient would have wanted. A revision of the Swiss Civil Code, giving greater representation power to family members of incapacitated patients, should result in a shift toward greater participation of families in such decisions in the near future.

Issues arising in the allocation of intensive care beds have been minimized by nationwide coordination among intensive care units. As indications for intensive care grow, however, such issues have been increasingly debated at the local level.

The Swiss Academy of Medical Sciences (SAMS) published guidelines on ethical issues in intensive care in 1999 (SAMS, 1999). Separate guidelines for the treatment of severely premature newborns have been regularly updated by the Swiss Society for Neonatology.

Palliative Care

As outlined in section "End of Life", discussions about palliative care and advanced directives have rapidly reached a general consensus. Palliative care is promoted and sustained by the Confederation and the cantons. Advanced directives, which already exist in several cantons, are recognized on a federal level by a revision of the Swiss civil code, as of 2013.

Care for the Elderly

Although discussions on care for the elderly are similar in Switzerland and other countries, four issues can be noted. First, the medical specialty of geriatrics or gerontology is rather new in clinical medicine, and in Switzerland, it has faced difficulties in identifying its specificities in clinical settings. As clinical approaches in gerontology tend to be rather different from those in other areas of medicine treating elderly patients, this has meant that ethical issues in the care of the elderly have varied with the clinical setting. Second, discussions of ethical issues in old age have tended to focus on practical clinical issues (Monod, Chiolero, Büla and Benaroyo, 2011), such as adapting medical interventions *to* old age, how to define the proper aims of medicine *in* old age, attempting to avoid both critiques of "agism," or doing too little, and concerns that medicine is doing too much. Third, antiaging medicine has been a focus of research, and this has led to considerable discussions regarding ethical issues raised by medical enhancements. Fourth, as in many other western countries, issues are raised by the coverage of elder care.

As resource constraints meet rising needs, concerns have also been voiced that the elderly could become a population particularly vulnerable to unjustified rationing. In Switzerland, coverage by medical insurance is based on the presence of disease and the indication for medical treatment. Dependence for the activities of daily living is not considered a disease, and thus it is not covered by insurance. Any such costs are paid out of pocket by individuals, with state help available for those who become indigent as a result. Although this still affects a minority of the population aged >85, its unpredictability has led to calls to extend insurance to cover long-term care. Tensions arising between the costs which this would involve and the requirements for solidarity in facing old age are an ongoing debate.

Ethical guidelines for the care of dependent elderly patients were published by the Swiss Academy of Medical Sciences (SAMS) in 2004 (SAMS, 2004b). They focus on issues including appropriate care, continuity of care, interdisciplinary collaboration and collaboration with family members, advance directives, informed consent, decisions for incapacitated patients, adaptation of prevention, acute care, rehabilitation and palliative care to old age, and end-of-life issues.

Chronic Diseases

Issues related, among others, to access to health care and indications for palliative care do arise in the context of chronic diseases, they are not different from those outlined in the sections "Health and Disease, Health Care System, Access to Health Care, Traditional Medicine" above.

Psychiatric Care

All the main issues raised in other areas of medicine are also raised in psychiatric care. A further focus has centered in Switzerland on whether suicide assistance should be allowed in the case of competent patients suffering from psychiatric diseases. In 2006, a Swiss Supreme Court ruling established that suicide assistance could be allowed in the case of competent psychiatric patients on the strict condition that their wish to die be well-considered, durable, and free of any outside influence based on an expert psychiatric evaluation. Controversies on this topic, however, are still ongoing.

Pediatric Care

Various issues outlined in the above sections are also relevant to pediatric care (Kind, 2009). In the Swiss context, it should be noted that the threshold which allows a patient to make her own decisions regarding health care is not adulthood but decision-making capacity regarding the choice at stake. "Mature minors" who are patients in Switzerland can thus consent to – or refuse – medical interventions, including life-saving interventions. Specific laws require additional parental

consent in cases where greater protection is necessary – such as consent for participation in research – and in some cases, minors are excluded from particularly risky altruistic medical interventions entirely – such as live donation of solid organs. Such cases, however, are exceptions. Competent minors' consent is also required to divulge any confidential information to their parents or other guardians.

Emergency Care

Aside from a brief attempt in 2007 to exclude illegal immigrants from emergency care, which was swiftly rejected by the Swiss Supreme Court, the Swiss National Advisory Commission on Biomedical Ethics (NEK-CNE), and Swiss health care providers in their practice, no specific ethical issues have been raised in Switzerland regarding emergency care.

General Practice

All the main issues raised in other areas of medicine are also raised in general practice. More recently, policy issues regarding general practice, such as the usefulness of a gatekeeper role within the health care system or the importance of increasing the attraction of general practice for young physicians, have been increasingly debated within the health policy discussion. Moreover, Switzerland is a destination country in the global medical brain drain, which clearly raises ethical issues far beyond those which have been addressed to date.

Health Promotion and Education

See section "Public Health" above.

Scientific and Professional Integrity, Conflict of Interest, Corruption

Issues of scientific fraud and other breaches of scientific integrity have regularly surfaced in Swiss academic life, as is the case elsewhere. Beginning in the 1980s, there was increased controversy and dissatisfaction about the informal manner with which these cases were traditionally handled by academia. In particular, the lack of clear procedural rules meant that investigations of alleged scientific misconduct by academic authorities were easy targets for legal challenge. This led universities and the Swiss Academies of Arts and Sciences (http://www.swiss-academies.ch/en/index/Portrait.html) to adopt more detailed, formal regulations. The Swiss Academy of Medical Sciences (SAMS) released a set of regulations on scientific integrity in 2002 (SAMS, 2002). This document defined the nature and scope of scientific misconduct in biomedical research and perhaps even more importantly, established a detailed procedure to investigate

accusations of scientific misconduct. The document was in line with similar guidelines on this topic issued by various national and international bodies (e.g., European Science Foundation – US Office of Research Integrity: *Research Integrity: global responsibility to foster common standards* (http://www.esf.org/index.php?id=4479). These guidelines were influential in getting universities to develop their own framework for issues of scientific integrity, by adapting the rules that had evolved in the context of medical faculties and biomedical research institutes to a broader range of scientific and scholarly fields.

In 2007, the Swiss Academies of Arts and Sciences issued a memorandum in which they define basic principles and offer to help research institutions in setting up specific rules and procedures. This was followed by setting up a permanent commission on scientific integrity, which issued a much more detailed document in 2008 delineating ethical principles and procedural rules (Swiss Academies of Arts and Sciences, 2008). The principles tend to go beyond the "FFP core" (fabrication or falsification of research results, plagiarism) familiar to Anglo-American researchers and include attitudinal goals concerning, for instance, the role model provided by senior researchers, the importance of quality vs. quantity of research output, and the responsible use of the constitutionally guaranteed freedom to do research. The procedural rules involve a four-pronged organization of integrity protection. This includes an ombudsperson who deals with initial complaints and may arbitrate minor cases and an integrity protection commissioner who selects a suitable fact-finding panel to conduct the inquiry and, in case solid evidence of misconduct is found, passes the results to a decision-making panel to whom authority to decide the case has been delegated by the dean, university president, or director of the research institution. This somewhat complex system was felt to be needed in order to guarantee due process and the presumption of innocence as well as protecting whistleblowers and safeguarding relevant evidence.

Relations with Industry and Donors/Sponsors

The relationship between the pharmaceutical industry on the one hand and academic biomedical research and medical practitioners on the other has special significance in Switzerland. Some of the largest pharmaceutical companies in the world have originated in this country, where they still maintain their headquarters and a significant proportion of research and manufacturing facilities (for how long is unclear). This means that the pharmaceutical industry enjoys a great deal of political influence, for instance in negotiating drug prices with Swiss health authorities. It also entails a strong presence of industry in postgraduate medical education and academic medicine. As regards medical research, this close connection between academia and industry is not always, or necessarily, problematic. In fact, during the "golden age" (roughly from the 1950s to the 1980s), when biomedical advances quickly resulted in the availability of whole classes of important new drugs, this relationship was quite constructive and useful. In recent decades, however, important global changes have affected

both sides of this divide. As a result, it has become more and more apparent that the primary interests of universities, industry, and public health are often at odds with each other. The old "cozy" relationship came increasingly under fire, and it was again the Swiss Academy of Medical Sciences (SAMS) which took the lead in setting up regulations to deal with these issues. Its guidelines on this subject were initially greeted with skepticism and controversy but are now firmly established (SAMS, 2005). These include not only general principles but also specific and practical rules, especially as regards industry-initiated or industry-supported grand rounds and postgraduate training sessions.

One industrial sector that poses a unique challenge to scientific integrity and public health is the tobacco industry. Several world companies involved in cigarette manufacturing have established their headquarters in Switzerland, where they happen to be beyond the reach of American and European law. They enjoy a position of enviable privilege and influence, with dismal consequences as regards scientific integrity (University of Geneva, 2004; Diethelm et al., 2005) and health policy, as evidenced by the fact that Switzerland is one of the few countries that has not ratified the WHO tobacco convention.

Other: Addiction

Since 1994, Switzerland has had a rather unique policy on illegal addictive drugs, based on a fourfold objective: prevention, therapy, risk reduction, and repression. Risk reduction entails the setting up of "injection rooms," where persons addicted to opioids can inject themselves in safe conditions and, more controversially, the provision of heroin under medical supervision to prescreened, highly dependent drug users (foundation Sucht Info Schweiz: http://www.suchtschweiz.ch/de/themen/). From its onset, this program was considered experimental and involved continuous evaluation of its efficacy in improving the health and social integration of long-term drug users. This attracted a great deal of attention and often skepticism on the domestic and international scene. In a sense, this reaction is understandable since the pragmatic and evidence-based Swiss approach is inherently alien to the "moral crusade" which often energizes the "war on drugs" on a global scale. This risk reduction policy was confirmed by a majority of Swiss voters in a referendum held in 2008. Recently, the Swiss experiment has been viewed more sympathetically from abroad, as the failure of a purely prohibitionist stance is increasingly and more openly discussed internationally.

Future Challenges

The ongoing debate on eligibility criteria for patients to be listed for organ transplantation and the paucity of organs available in the country show that cultural forces and individual preferences have important impacts on the implementation of health care policies and need to be carefully examined. This debate shows that the authority

of the state to deal with health policy issues through nudge campaigns aiming to affect individual choices should be reconsidered. However, it also raises the question of whether the state can endorse some ethical perspective or should be neutral on bioethical issues. Further discussion is needed to develop a richer understanding of the societal implications of individual choices and of the role of the state in this field.

Although the Swiss health care system guarantees a universal coverage based on individual health insurance, the increasing rate of out-of-pocket payments has raised ethical concerns regarding barriers to access to needed care. The concept of personal responsibility that fuels the ethos of health care coverage needs to be reconsidered to prevent the state-regulated but privately managed health insurance system from producing health care inequalities in the country.

A significant proportion of academic biomedical research in Switzerland is funded by pharmaceutical companies, and even modest changes in the pharmaceutical industry may have important consequences on medical research and practice. Therefore, future challenges also include the discussion of ethical issues in the governance of biomedical research in the country.

Since Switzerland has developed an outstanding environment for technological innovation and industrial development in the life sciences, it is likely that issues related to science policy, both on the national level and internationally, will become more urgent in the near future.

Summary Conclusions

The Swiss debate over controversial bioethical issues in the country is characterized by the coexistence of academic expertise on the one hand and of public participation in the discussion of possible solutions on the other. Occasionally, public engagement has influenced the roadmap for regulation, as was the case for genetically modified plants.

Over the last decade, scholars in the field of bioethics have progressively abandoned the role of exclusive experts in the field and have turned into participants into a wider debate involving multiple competences and varied public actors. Most importantly, however, direct democracy, decentralized governance, and the value placed on individual choices have largely influenced debates, laws, and practices regarding many bioethical issues.

Ghiath Alahmad

Introduction

Even though all societies share many ethical values and agree on many ethical principles, each of them has a unique point of view due to their differing political, economic, and social structures and different historical events and circumstances. Syria, as a Middle Eastern country, has a rich history.

While discussions about ethical issues in Syria are on the rise, there are still very few studies on the subject. In this chapter, different situations regarding bioethics in Syria will be explored, by first studying the social and economic conditions under

which they arise. The major bioethics issues and discussions in Syria will be addressed. The related activities of different governmental institutes are explored such as the Ministries of Health and Higher Education and nongovernmental offices that also have an interest in bioethical issues.

Background: Syrian Society and Culture

As a start, an overview of Syrian culture and society is given, including the political and economic circumstances that may affect the development of bioethics. Then, the growth of bioethics in Syria is generally explored. Three different hot topics are investigated as examples of the Syrian method of deliberating about bioethics.

All people in the Middle East are strongly connected to history. Historical events and peoples' heritage form a vital part of the daily life of the community. While all nations share many characteristics and history, two categories of Arabic societies can be recognized. The first kind of society became a center of culture, civilization, and the sciences shortly after the establishment of an Islamic state 1,400 years ago. This society lasted until the First World War, when these countries started to fall, one after the other, under European colonization; they fell under the direct influence of the quick technical and civil developments of Europe. These countries include Syria, Iraq, Egypt, and others. The second kind of society does not have the same rich scientific history and suffers from the direct delegation of foreigner workers. These countries, most of which are Gulf countries, continued to use Islamic judicial systems.

The regimes differ between the two groups; while the systems were a hereditary monarchy for the second group, the countries of the first group fell under dictatorial regimes, which came after the military coups that have occurred since the middle of the past century. Since the beginning of 2011, the countries of the first group have witnessed a movement of revolt through what is called the Arabic Spring, which led to a change of government for many of these countries and the establishment of democratic regimes in Tunisia, Egypt, Libya, and Yemen, most probably followed by Syria in the near future.

From an economic point of view, Syria did not directly benefit economically, politically, or culturally from the great oil discoveries in the neighboring Gulf region during the middle of the twentieth century. Instead, Syria started to lose its importance due to the dictatorial political system and its economic needs. The cultural center in the Middle East started to move from its old centers in Damascus and Cairo to new centers in Riyadh, Kuwait, and Dubai. This change became obvious during the last two decades of the previous century and the beginning of the twenty-first century and was a result of the huge economic jumps in the Gulf region and the crisis and economic needs in other countries like Syria.

Syrian society has a mixed and rich structure. Different Islamic sects can be found, including various Christian denominations, Jews and many other diverse and special ideological disciplines (Abduh, 2003; Alzarkah, 1995). Sunni Islam, however, remains the major religion in Syria (Alzarkah, 1995), encompassing nearly 72 % of the population. Regardless of this mixed structure in Syrian society, the

social and cultural habits and thoughts are similar across all the Syrians groups. It is remarkable that the social ethics and morals of many Syrians have undergone extensive changes due to historical and social responses.

Bioethics in Syria

Even with a common history and similar religious, social, and ethical links, there are many differences between the Middle Eastern countries, and these differences are related to each country's societal structure and economic development. Syria is a country with a rich history and an extensive civilization that was formed by the mixing of many ethnic groups, people, and religions. Unfortunately, the economic growth of Syria is not very good, and there have not been any great oil discoveries like in the Gulf area.

Syrians, like many other Middle Eastern citizens, are religious people. The majority are Sunni Muslims, with other Islamic groups contributing to the minority. Christians make up 8–10 % of Syrians (المركز اللبناني للدراسات الاستراتيجية The Lebanese Center for Strategic Studies, 1985; Central Intelligence Agency [CIA], 2011). These groups are used to living together, as they have for hundreds of years, and practicing their beliefs freely (Alsebaee, 1999).

The model of Syrian society and historical developments affect Syrian judicial law, including laws that are related to medical practice issues. Many resources were used when creating Syrian judicial law in 1949 (decree 84 in May 18, 1949), including Islamic jurisprudence, French law, and Egyptian law (Alzarkah, 1995).

Foundations of Bioethics in Syria

Bioethics, as a field of science, is still very new in Syria; the National Bioethics Committee was only established in 2003 through an initiative of UNESCO. The committee consists of seven members from many specialties (medicine, law, religion, and the sciences) (Saleh, 2007). Another committee was proposed by the Syrian Ministry of Health (MOH) in the same year. In 2005, Damascus University established an ethics committee. In the same year, a presidential decree was issued for the initiation of the Higher Commission for Scientific Research. This decree sets the principles and rules that guarantee that research be conducted ethically (Higher Commission for Scientific Research, 2006). In 2008, a special research committee was established according to this decree. This ethical research committee is independent from the National Bioethics Committee. However, all of these committees are still new and have not yet been activated. No research ethics code, national guidelines, or Good Clinical Practice (GCP) exist in Syria at this moment. The Helsinki Declaration and the International Organizations of Medical Sciences (CIOMS) guidelines are the resources that have been chosen by the research

committee of the MOH to be the references for the ethical standard for conducting clinical research. Some local ethical committees have judicial ground. These committees are consulted to resolve the different cases and ethical problems of different types of organizations and associations.

Five years ago, bioethics was included in the undergraduate curriculum of Damascus University, and the subject is being studied from ethical, legal, and religious perspectives (Saleh, 2007). Because Syria is part of the Arabic and Islamic region, it helps to make informal decisions for some Islamic and Arabic institutes like the Islamic Organization for Medical Sciences, the Islamic Jurisprudence Assembly, and the Arab League Educational, Cultural, and Scientific Organization. *Many* fatwas have been issued by these organizations.

Other deliberations on bioethics are made through conferences and discussions held by government institutes such as the Ministry of Health, the Ministry of Higher Education and the Syrian Medical Association. The first symposium was focused on the medical, legal, and religious aspects of effeminacy surgery and sex change and was organized by the Medical Association in Syria in Damascus on 2002 (Saleh, 2007). In May 2005, a bioethics in the Arabic World Symposium was held in Damascus; about 24 scientific papers were discussed. The Syrian American Medical Association has also made very good efforts to promote bioethics discussions. American doctors of Syrian descent are trying, through an annual convention, to educate the Syrian medical community about the advances in the bioethics field (Alshammas & Affof, 2006). Similarly, a workshop about organ transplantation was conducted by the Syrian Medical Association on 2003, with the participation of people from different specialties including Muslims and Christian researchers, lawyers, and medical doctors. The Syrians and the French doctors held their first meeting on bioethics 2003, which included important topics such as a symposium on organ transplantation and a seminar on the moral repercussions of research into stem cells (Saleh, 2007). Furthermore, there have been many books written by religious scholars about medical issues from Islamic and Christian points of view. These books are very popular and are widely accepted, as most people trust religious scholars. The books of Prof. Mohammad Said Al-Buty, one of the most famous scholars of the Islamic world, are a good example, like his book titled: "مسألة تحديد النسل وقاية وعلاجاً The issue of birth control in prevention and treatment" (Albouti, 1988).

Major Bioethics Issues and Discussion

Many bioethical issues receive public interest and debate in Syria; however, the most frequent bioethical talks and discussions concern two issues: reproductive technologies and organ donation. The recent developments in bioethics could be understood by elaborating on these two issues using reproductive technologies as an example of an attempt to harmonize Islamic jurisprudence and law and organ transplantation as an example of the need for regulation and the effects of economic crises. Besides these two issues, reproductive technologies and organ donation,

another issue starts to take a significant position in the public concerns that is the honor killing. In fact, honor killing is a controversial issue, and it is an example of the conflict between religion and social customs.

Honor Killing

Honor killing is a crime in which a victim is killed by one or more of their close relatives because they were caught having sex outside the family system. The claim, then, is that this killing was to "maintain the honor" of the family.

While the main reason for honor killing is usually for having sex outside of marriage, there are also other less frequent reasons, such as marrying a man from another religion or another sect. In many cases, there is no sex at all; the woman is just seen alone with a man. The sensitivity of these reasons varies across different regions of the world.

Some writers consider honor killing a kind of "communion" of a human provided by the family members to the surrounding community to achieve the desired behavior of women in accordance with the values and customs of that society (Syrian Women Observatory [SWO], 2009). It carries a clear message from the killer and his family: "We are clean, we have taken out the reason for your refusal of us, please accept us again, we are similar and like each other." This reasoning explains the overt ritual of the murder when it is performed in a public place in rare cases. Other families' women show their happiness for this familial purification.

Therefore, calling the act an honor killing is used to distinguish it from other kinds of crimes by connecting it to the reason for killing: the preservation of honor.

Honor crimes are committed in many parts of the world but mostly in Islamic countries, especially Afghanistan, Pakistan, Iran, Jordan, and Syria, due to the popular belief that Islam supports this murder because of the legal protection provided in some of these countries for the killers if they prove that their motive was "honor."

Usually, honor killing does not take this name except in countries that have some kind of legal protection that lightens or exempts the killer from punishment, as is the case in countries such as Syria and Jordan. In Syria, there are two legal articles that give honor killers a lighter punishment of "not less than 2 years imprisonment for murder": Article 584 and Article 192 of the Syrian Penal Code. However, some scholars argue that there is no legal protection for those who commit honor killings because there are many conditions that must be met for the excuses to be valid, such as the element of surprise and the intention of killing. Consequently, anyone who kills or injures any female, sister, wife, or girl, because she is secretly married, married to a man of a different religion, ran away with her lover, committed adultery with another man (who is married or not), or practiced prostitution is not excused from or receives a lighter punishment (Misk, 2010).

Usually, honor killings are linked to the religion of Islam, but the experience of several organizations that work against these crimes, including the Syrian Women Observatory, has shown that people who commit these crimes follow different religions. Scholars of different religions, including Islam, stress that their religion

rejects these types of crimes, asserting that the right of retribution is an exclusive right of the government and that no individual has the right to exact revenge. Muslim jurists say that nothing can be called an honor killing. One Muslim scholar, Dr. Tawfeeq Ramadan Al-Buty, says: it is a crime (killing), resulted from another crime (adultery). It deserves lightening the punishment. But he has not the right to kill (Alnasher, 2010).

There have been efforts in other countries against honor killing. In Syria, a campaign entitled the National Campaign against honor killings was launched by a private group called Women of Syria in September 2005 and continues to this day. This campaign aims to repeal the two articles, Article 548 and Article 192, of the Syrian Penal Code that allow for the reduction of the punishment to at least 2 years. Recently, some people in Syria have tried to bring this issue up for public debate (see: Syrian Women Observatory (http://nesasy.org). Others oppose such debate and consider the issue to be exaggerated (Misk, 2010). The statistics released by the Syrian Interior Ministry state that in 2010, there were 249 cases of honor killing in Syria. This equates to 1 crime per 100,000 people (the Syrian population is 21 million) (Alawsat, 2011).

The Syrian government recognizes these crimes and held a national conference in October 2008 entitled the National Meeting on honor crimes, which concluded with important recommendations aimed at opposing these crimes of honor in Syria.

Other countries also contribute to the fight against these crimes. Jordan, Turkey, Pakistan, and Tunisia have canceled any legal excuse for honor killing.

Honor killing is a controversial issue: it is and remains a crime. We do not see any legislator, jurist, or writer who considers it to be anything else. Activists are concentrating on trying to change the laws that lessen the punishment for honor killing rather than on simply educating people. The idea is that anyone who would commit an honor killing would do so regardless of the punishment. Studies show that 80 % of honor killings are performed in rural areas where there is less education (Alawsat, 2011). Increasing public awareness about human rights, justice, respect, and humanity can help make this change.

Family Planning/Reproductive Technology

There are many labels used for the policy that aims to reduce the population growth in Syria. The common label among people is the term birth control, followed by the less popular term, birth planning. Those who contribute to the implementation of this policy prefer to use the term family planning, as it is more general, more comprehensive, and not limited to only birth control but also includes the concept of reproductive health in general. However, the most important reason to adopt the label of family planning is to hide behind it to avoid arousing religious people who reject the idea of birth control altogether. There are many questions about the feasibility of this policy, which is still in the beginning stages in Syria.

Some say that interest in this matter goes back to the 1970s, following the release of the census results in 1970, in which the rate of population growth was 3.6 %,

which resulted in the formation of government committees. In 1974, the Syrian Family Planning Association was established, but this did not prevent the granting of a family medal to all families with more than 12 children until late 1986 (Albuni, 2008). Moreover, the government continued granting incentives to mothers to have more children.

The situation remained unchanged in terms of the number of children in families until 2002, when a decree was released that explicitly indicated the number of children for which the mother will be granted maternity leave and that referred to the Syrian Commission for Family Affairs that was developed in the same year. Family planning policies are no longer restricted to the government alone but are also influenced by the Family Planning Association and the Syrian Commission for Family Affairs; the Ministry of Health and the Women's Union also play a role. There is a consensus among the members of all of these parties to call the issue family planning and not birth control. They find family planning and birth control two different issues, even if they have the same results.

The Family Planning Association claims that it is working in accordance with the religious and social values of Syria. There are 19 clinics that follow the guidelines of the association in all provinces; the clinics implement the policy of the association and distribute various family planning methods such as birth control pills, IUDs, and condoms. There is also a mobile clinic that tours the 20 villages in the countryside of Damascus and provides services. The Family Planning Association intervenes in the interests of young girls and gives advice to raise awareness among them.

The primary health care unit of the Ministry of Health has several programs under the name of reproductive health including family planning, care for the pregnant, the early detection of cervical cancer, and emergency obstetric care. It does not advocate birth control or a reduction of the population, but it instructs parents to leave an interval of 3 years between children, for example, so that they are able to secure a decent life for each child. The Ministry of Health centers across the country distribute family planning methods. This year, these methods are being distributed free of charge to citizens, in cooperation with the United Nations Fund.

There are some difficulties regarding family planning in Syria because of the different social, religious, and cultural backgrounds.

Religion and Family Planning

There is no doubt that the Islamic religion rejects the idea of birth control, much like the Christian religion does, as is stated in the first chapter of Genesis: "and God blessed them and said unto them, Be fruitful and multiply, and fill the earth and subdue it." This is further reflected in the principles of Pope Pius II, which state that a clean marriage is a marriage that produces children without interruption or regulation.

There is a great deal of talk about the opposition to birth control in Islam, but another school of thought states that there is a call for family planning in Islam, citing three Quranic verses that call for birth planning and show that breastfeeding should be conducted for two full years. There are also a few prophetical traditions that confirm that the companions of Prophet Mohammed were ejaculating outside

of the woman (isolation العزل is the expression used in the prophetic tradition). They said: we ejaculate outside, while the Quran was delivered, and the Prophet did not prevent isolation. Institutions that are interested in birth control in Syria attempt to mobilize the position of religious jurists for their purpose because of the importance of the jurists in influencing people's opinions. However, the dominating opinion among the jurists, which is what is taught to the public, is that reproductive technologies cannot be used for birth control unless under the guise of family planning, such as leaving 3 years between every birth, or in cases of risk to the mother. Permanent methods to prevent pregnancy, like tubal ligation, are not allowed.

Numbers

Reports issued by the Syrian Commission for Family Affairs, a commission that records data on the Syrian population, show that the rate of population growth has declined and it is currently at 2.45 %, after a period of significant growth that was not met with a similar growth in economic performance. In a study on the attitudes and beliefs of women toward family planning issues, the current rate of use for methods of family planning in Syria is 73 %. This percentage exceeds the 60 % percent that was hoped to be achieved by the year 2015. The study was conducted with 10,000 married women at the age of reproduction from rural and urban areas.

Some researchers question the 73 % statistic and believe that the figure was drawn from the results using multi-indicators and that the true percentage is 58.3 %. The UNDP report of the United Nations regarding poverty in Syria reported that the number of women who engage in family planning in Syria is less than 46 % and that 25 % of women do not use any method of family planning.

A study by the Syrian Commission itself showed that 43 % of women want to have more children and the average number of desired children is 4.89. However, 17.5 % of women who have recently had a baby say that they are not willing to get pregnant again very soon, and 9.2 % of pregnant women are not pleased that they are currently pregnant.

Laws

All of the involved agencies, the Syrian Family Planning Association, the Syrian Commission for Family Affairs, and the Women's Union work under the risk of punishment by law through a number of articles. Articles 523 and 530 prevent the advertising, sale of goods, acquisition of goods, or facilities for the use of family planning methods. Furthermore, Law No. 23 of 1998 associates the use of family planning methods with an exposure to sanctions. In 2002, 22 women were convicted of the offense of preventing pregnancy. Article 523 and Article 208 state that methods leading to the prevention of pregnancy or an offer to use them for prostitution to prevent pregnancy will be punished by imprisonment for 1 month to 1 year and a fine of 100 Syrian pounds.

In article 524, anyone who sells, offers for sale, or acquires for the purpose of selling any material intended to prevent pregnancy shall be punished with the same punishment.

Thus, theoretically, the application of these laws could lead to the punishment of the Ministry of Health, which oversees the distribution of family planning methods, as well as the Syrian Women's Union, but these laws are so rarely enforced that many family planning workers have not even heard of the laws. Some believe that these legal articles do not actually constitute an obstacle as they are never enforced, but people still fight for their repeal. However, the government has not responded to such appeals, and these laws are still intact today.

The rate of population growth in Syria is one of the highest in the world but has declined from 3.30 % in 1993 to 2.45 % in 2004. There is no proof that this reduction is the success of the policies enacted to decrease the population growth; the pressure from the current economic conditions may be stifling to Syrian citizens, preventing them from having a greater number of children and forcing them to resort to using birth control.

Even though the sale of contraceptives is not legally allowed, many local officials and authorized organizations are doing just that; there are about 15 centers that are working without any legal frame. However, people in Syria are mostly following the jurisprudential rules that were released by the Islamic institutes and scholars regarding the use of all new reproductive technologies that state that they allow them for family planning but not for reducing the number of births. They argue that the population density in Syria is just 112 people per km^2, which is considerably less than the density in the UK, Germany, France, and many other countries (United Nation, 2009). They contend that concentrating on improving the economy can solve the problem of the increasing population.

Organ Transplantation

The subject of organ transplantation and donation is a highly sensitive issue because of the economic and social aspects and the concerns about health and humanity.

There is an active global trade in this area that lures some weak people to deviate from the nobility and honor of medicine to the extortion and brokerage of these organs for large sums of money. There is a growing black market for organ trafficking and a stock exchange to rival the prices of oil and gold. While most families are still reeling from the high costs of the transplant and from the difficulties involved in finding a suitable donor, they now also have to contend with the dangers posed by the impact of this rush.

There is a trend in many developing countries, including Syria, to regulate organ transplantation and to give it legitimacy and legality. Kidneys are the most common used organ on transplantation.

Kidney transplantation began at two centers in Syria in December 1985. The first was at Al-Mowasat, a university hospital in Damascus, where 501 kidney transplants were conducted from living donors to relatives through 2003. The second center was at the Tashrin military hospital in Damascus, where about 216 cases of kidney transplantation have been performed. In 2001, the Ministry of Health

Table 86.1 Kidney transplantation in Syria

	Kidney transplantations in Syria		
Year	Inside	Outside	Total
1998	53	130	183
2003	225	12	237
2007	335	1–2	336–337
2008	252	70	322

established a center for kidney transplantation in the Kidney Hospital which is located also in Damascus. Overall, 214 kidney transplants from living donors, to both relatives and nonrelatives, have been performed there through 2003. Only 10–15 % of all kidney transplants occur in the private sector.

The overall number of patients who have had a kidney transplant in Syria and were still alive at the end of 2003 is 1,320, 70 % of which were males and 30 % were females. This number includes 28 patients who had a second kidney transplant. There are about 100 transplants performed outside Syria every year in India, Iraq, and Egypt; transplants that are performed in these areas may be complicated by blackmail, brokerage, and the wasting of money, on top of other surgical and internal complications including the transfer of malaria or AIDS.

The rate of kidney transplants in the Syrian population by the end of 2002 was 11 transplants per one million people. Considering that the incidence of chronic renal failure in Syria is about 65–70 patients per one million people each year, it can be concluded that the rate of transplantation is still below the normal limit, which is not acceptable, and that the reason that this number is so low is that the kidneys had to be taken solely from living donors who were relatives of the patients between 1985 and mid-2002. In 1998, 130 kidney transplants were conducted outside Syria (like Egypt and India) and 53 were conducted inside. In 2003, there were only 12 transplants performed outside and 225 inside Syria, and in 2007, there 2–3 cases outside and 335 cases inside Syria. The effects of new laws that were developed can be easily recognized by comparing the 1998 statistics with the 2003 and 2007 statistics and show the effects of new laws that were developed, especially those that allowed for the taking of kidneys from nonrelated live donors. In 2008, the prime minister issues a new decree that limited kidney transplantation to governmental hospitals only and increased the number of governmental centers for transplantation from three to eight. The effect of this decree was that the number of transplantations decreased to 252 inside and increased to about 70 outside Syria (Akroosh, 2010) (see Table 86.1).

After kidney transplantations, cornea transplantations are considered to be the most common type of transplantation in Syria; the last statistics published in official journals in 2008 state that there were 1,200 cornea transplants, and there were about 1,500 cases by 2010. All of these corneas were donated by the international tissue bank TBI or the ORBIS organization.

Other kinds of organ transplantations, including liver, pancreas, and heart, are still not very common in Syria. There is a plan to establish a center for organ donation, but such a plan is still in the beginning stages (Alasaad, 2010).

Organ transplantation, transfer, and donation in Syria are governed under Law No. 31 of 1972 and the amended law No. 43 of 1986. This law and its amendment were issued to encourage people to donate their organs to save the lives of other people who are in need, but it seems this purpose has not been achieved. On the one hand, the practical application of these laws resulted in a lack of donations received during that period. On the other hand, a global organ trade began, creating a significant risk for patients who were in need of a transplant and did not have enough money, to the extent that some of them died for lack of the organ they needed. These factors led to a push to intervene and amend the provisions governing organ transplantation, to encourage donors, and to facilitate procedures in a way that matched the accelerated scientific progress in this area, especially as it became possible to store organs in special banks until it they are needed. A new law on transplantation and donation, No. 30, was promulgated on 11/20/2003. On 11/7/2004, a new regulatory decision, No. 73/T, was made that contained instructions governing organ transplantation. It regulates the mechanism and conditions of the transplantation to ensure the safety, health and dignity of both the donor and the recipient and to keep this good noble work as a humanitarian exchange. This new law will help in controlling the hidden black market in two ways. Firstly, it states to punish anyone who violates the provisions of the new law on organ transplantations with imprisonment from 6 months to 2 years with a fine of 5,000–10,000 Syrian pounds. Secondly, organ trafficking was not punishable earlier; this new law fills this gap, making organ trafficking punishable by imprisonment with hard labor (between 3 years and 15 years) with a fine of 50,000–100,000 Syrian pounds.

Organ transplantation is a serious problem in Syria due to the gap between the need for organs and available organs. Sixty-five to seventy patients per one million people need kidneys each year, while only 11–12 kidneys are available per one million people each year. The black market can manifest itself in many ways, including fliers full of compassion and propitiation that are pasted on walls, on the streets, and near hospitals or even through hidden agreements that are mediated by a surgeon. These situations may result in harmful outcomes when the transplantation is performed by an unqualified doctor, in unsuitable circumstances or in unprepared hospitals. It is estimated that one kidney from a live donor costs 15,000 American dollars (Gusen & Alsubeh, 2006).

The laws issued in 2003 and 2004 were a great step toward regulating transplantation and controlled, to some degree, some of these unethical practices, but they were unable to prevent organ trafficking completely. Many changes are still needed to further control the issue, such as allowing for transplantations from dead people with new regulations and a new definition of brain death. Organs taken from dead people can help solve these problems and increase the number of available organs.

It is notable that this black market exists despite the many fatwas from Islamic institutes and scholars that have forbidden organ selling. There is some doubt whether these fatwas are known to the public, so it is a good idea to make these Islamic opinions that allow for organ transplantations and that prevent organ selling known to the public. These opinions include those of individuals, like those that

have been written by many Muslim scholars, and the institutional fatwas, especially the fatwas of the International Islamic Fiqh Academy and the Fiqh Council (Muslim World League), to help create a good and suitable environment and culture for organ donation. In the future, policies may exist that state that everyone is a donor unless he or she refuses, which will open a new discussion in this debate.

Future Challenges

Without a doubt, Syrians have gone through many painful events since February of 2011. The killing of thousands of Syrians, including doctors and other health care providers when Syrians began their movement for freedom and democracy as a part of the "Arabic Spring," will deeply affect the future life of a variety of Syrian groups. This is expected to initiate radical change in the structure of Syrian society following over 40 years of dictatorial ruling.

The current unrest has disrupted the normal daily life of people scientifically, economically, and socially, which will deeply affect biomedical issues in the coming years. Typical bioethical dialogues regarding issues such as organ transplantation and medical research do not capture the interest of Syrians at this stage of unrest. Other issues take precedence, including how to survive, excruciation of arrested people, how to obtain proper treatment, and offering protection to doctors as wounded civilians and the doctors treating them have become a target of the regime. This has led to a new phenomenon of having primary and hidden clinics for providing emergency procedures for civil victims (Daniel, 2012). This is necessary because a doctor treating the wounded is considered the same as the holder of a bomb by the Syrian regime (Agence France-Presse [A. F. P], 2012).

The future of Syria is ambiguous. However, an optimistic look might argue that this transient period of unrest will lead to a democratic government, similar to that seen in other countries of the "Arabic Spring." In this case, many Syrian immigrants who spent decades of their life in different regions around the world would likely return home, bringing their diverse backgrounds, cultures, and experiences, to mix with the people that remained inside Syria. All of this, in addition to the economic investments expected by the Syrians and others, would likely lead to cultural, economic, and social richness and build suitable ground for dialogue and debates regarding vital bioethical issues. On the other hand, a dual effects and cooperation might develop regarding such bioethical issues among Syria and the surrounding countries in the region, through some activities arranged by some parties, like the Regional Office for the Eastern Mediterranean of World Health Organization WHO and the Maryland University which organizes yearly workshops in research ethics in different countries in the Middle East through the "Middle East Research Ethics Training Initiative (MERETI)."

The issues of organ transplantation and family planning are expected to remain the main biomedical issues in Syria in the future. Additionally, increased interest is

expected for issues such as in vitro fertilization, premarriage testing, medical research, and storing of genetic materials. Autonomy and justice are expected to have an increased value for both the public and bioethicists in case the current unrest leads to democracy.

Conclusion

The social, economic, and historical circumstances of Syria have led to the development of a special vision about some vital issues. Although the Syrian view matches the international view regarding many issues, Syrians take interest in some issues that are not considered very important in other countries.

Although there have been notable efforts by some government and nongovernment parties regarding bioethical issues, a clear failure is recognized, especially in the field of medical research, as there were no national guidelines regulating clinical research. Organ donation, even with the very important laws from 2003 to 2004, still requires greater regulatory efforts to prevent the sale of organs on the black market. The new national center for organ donation that is planned will play an important role in this regard. Debates on reproductive technologies and honor killing highlight the importance of raising public awareness about human rights and human dignity.

Confronting the future challenges of these issues will require a large number of qualified Syrian researchers in the field of bioethics who understand the nature of Syrian society, its economic circumstances, and its social structure. Cooperation between these bioethicists, jurists, politicians, economists, and socialists is vital if Syria wants to match the huge international developments that are occurring in the field of bioethics.

Berna Arda and M. Volkan Kavas

Introduction

When and How Has Bioethics Started?

The very first academic bioethics discussions were devoted to issues regarding the beginning of life. The 2827 numbered law, promulgated in Turkey in the year 1983

B. Arda (✉) • M.V. Kavas
Department of History of Medicine and Ethics, School of Medicine, Ankara University, Sihhiye, Ankara, Turkey
e-mail: arda@medicine.ankara.edu.tr; volkankavas@yahoo.com

H.A.M.J. ten Have, B. Gordijn (eds.), *Handbook of Global Bioethics*,
DOI 10.1007/978-94-007-2512-6_56,

about population planning, stipulates the right to medical abortus with the consent of the parents until the tenth week of pregnancy (Law on Population Planning 1983). The spouse's consent for a married woman is also required in the case of an abortion. The consent of the spouse should also be obtained for both male and female sterilizations (the bylaw related with abortion 1983). In the mentioned regulations, "mother's health" was put as the core element by the legislator. Feminist ethics today emphasizes "maternal rights" implying that during determination periods in medical abortion and usage of prenatal diagnostics methods, the main determinant should be the woman. "Mother's sovereignty" and "fetus' benefit" seem to be the main conflicting issues regarding abortion. However, while treating this topic, "benefit of the society" emerges as another important parameter to be taken into consideration, even though it is rarely addressed. As time progresses, a woman's sovereignty on her body and sexuality becomes much more important than the benefit of society due to feminist influences. Today, maternal rights are always thought of along with the concept of "inside uterus property rights." Therefore, it is crucial that the medical team communicates with all family members, starting with the candidate's mother; the couple should be well informed about the situation since their consent shall be determinative and required for further actions.

Other early bioethical discussions in Turkey focused on research ethics (Oğuz and Arda 1991). In 1988, the usage of a plant abstract (Nerium Oleander, NO) by a physician for cancer therapy as an application of folk medicine instead of standard scientific treatment methods has triggered a public discussion. The efficiency of NO extract in cancer patients, the place of such "alternative" methods, and the harmful side effects of these sorts of tools were the main discussion points. On one hand the rights of the subjects and on the other hand the limits of social responsibility of scientific activity have been discussed. As a result of these efforts, the very first ethics committees concerned with the biomedical trials were established in Turkey in the early 1990s.

Usage of prenatal diagnostic methods for sex determination, professional attitude of the physician on the human rights topics, medical ethics issues to do with vulnerable groups, publication ethics, patient rights, and physician rights are the main topics that have been discussed since 1990s.

Who Have Been the Major Actors/Forces?

Turkey belongs to the upper-middle income class among the income classes defined by the World Bank. With respect to scientific expenditure, Turkey is one of the two Muslim countries that are comparable with other countries. Another point to emphasize is that while the member countries of Islam Conference Organization (ICO) have maintained or even regressed in scientific output for the last 20 years, Turkey, which had only 500 scientific publications in 1988, has increased that number to more than 16,000 today. Despite a lack of rich petroleum resources, Turkey has been the most successful member of the ICO, which has been attributed to the 1923 revolution during which a secular state was

established. Another important point is the presence of female academicians at a rate of 30 % in Turkish universities (Butler, 2006; Giles, 2006).

Considering the infrastructure in the country, the research process has been the most important factor in the field of ethics. Especially after the 1980s, a lot of biomedical research has been started in Turkey. Since the period of 2000–2008, 1–3 % of all trials in Europe were conducted in Turkey. Most of them (92 %, $n = 416$) were interventional and the rest (8 %, $n = 34$) were observational. Fifty-five percent of these trials were Phase 3 drug trials (Gülen 2010). The research potential and infrastructures of the country, full membership candidacy to the European Union, and legislative necessities are main factors underlying these results.

What Have Been the Major Concerns Over Time?

Informed consent has become one of the most significant topics in daily medical practice and biomedical research; it covers two main domains: medical treatment and medical research. The first regards the acceptance of the medical interventions by the patient who will undergo them after being informed about the content, risks, and benefits of the diagnostic, the treatment methods, and their alternatives. The latter is about guaranteeing that a participant, whether they are ill or healthy, is fully informed about interventions applied to their body for research purposes. Due to some specific features of the cultural base in the country, such as paternalism, and problems arising from the transformation of the healthcare system mostly according to market needs (such as the fact that doctors have less time to spare for each patient, work harder, and have less professional independence), obtaining informed consent is becoming more difficult for healthcare professionals. Since the emergence of bioethics debates, important progress has been made in terms of informed consent. The necessity of informed consent in both daily therapeutic practices and research processes of medicine has gained indisputable acceptance. Reasons for this result vary; however, the fact that this issue has been emphasized in medical education over the years and took place in medical legislation early enough may be considered the most effective factor. Currently, comprehensive, written, and signed consent forms are used before invasive interventions, surgical operations, and research projects. Many medical specialty associations have prepared informed consent forms taking special interventions and practices of their fields into consideration. Yet it should not be ignored that this dimension of the patient-physician relationship is a continuous process, which must be verbal as well, and should not be diminished merely to the scope of written forms.

What Resources Have Been Developed?

Most of the medical schools with a medical ethics department have books related to undergraduate medical ethics education. These books usually contain the main ethical issues and are updated periodically (Arda, Oğuz, & Şahinoğlu Pelin,

1999; Sarı et al., 2007). There have been a lot of translated books and guides from English to Turkish for scholars and general readers (Carmi, 2003; Harris, 1998; United Nations Educational, Scientific and Cultural Organization [UNESCO], 2008a, b, 2010; Veatch, 2010).

The Turkish Bioethics Association (TBA) was established in Ankara in 1994 as the very first society in the field. Due to its authority of representation, all ethics scholars were recognized by the state in 1999, when it was authorized to use name of the country. The main objectives of TBA are to contribute to the development and education of bioethics and to improve its connections with healthcare disciplines. TBA organizes biannual symposia on bioethics and since 2001 has also organized the national congress of medical ethics, as well as courses on medical ethics and conferences on special issues. TBA has published a number of books and reports, mostly the proceedings of symposia and congress (see www.tbd.org.tr).

The Society for Medical Ethics and Medical Law was established in Istanbul as the second professional society in 2004. It has organized periodical national and international conferences, expert meetings, and seminars and has published most of the proceedings of these academic events. The aims of this society are to promote scientific research, support education of medical ethics and law, and provide international scientific relations in the field of the medical ethics and law (see www.teth.org.tr).

The Ethics Committee of the Turkish Medical Association (ECTMA) is another body working on bioethical themes. The ECTMA was founded in Ankara in February 1994. The composition of the ECTMA is multidisciplinary. The members are academicians from different fields, such as Medicine, Nursing, Philosophy, Medical Sociology, and Law. The meeting frequency is twice a month. These meetings are closed to the public, but press announcements have been made. The committee strives for consensus and has produced reports during its activity period. The opinions of ECTMA are prepared in a way to cover a lot of different topics, such as organ and tissue transplantation, sex determination, electroconvulsive therapy usage, and hunger striking (Arda 1996; www.ttb.org.tr). There have also been a few published studies related to this nongovernmental ethical body (Akşit & Arda, 2003; Anonymous, 2008, 2009a; Arda et al., 2004).

There are two important periodicals: Turkiye Klinikleri Medical Ethics and Law and History Journal (started in 1993 with the name of Medical Ethics, and after 2000 the name changed to Medical Ethics, Law, and History) (see http://tipetigi.turkiyeklinikleri.com). The other journal is the Turkish Annual on the Studies of Medical Ethics and Law.

What Have Been the Steps/Measures Taken

Turkey has been a democratic, secular, unitary, constitutional republic since 1923. The Republic of Turkey is a parliamentary representative democracy. The constitution governs the legal framework of the country. The constitution was changed in the years of 1924, 1961, and 1982.

Health was among the priorities set by the founders of the Republic of Turkey. This is why one of the first laws issued by the Turkish Grand National Assembly, founded on April 23, 1920, during the years of the Turkish War of Independence, was the law to establish the Ministry of Health. With this law, health services were accepted as a public service conducted by a ministry of the state (Arda, 2012).

There are a lot of international conventions ratified by Grand National Assembly of Turkey, such as UN Conventions on the Elimination of all Forms of Discrimination against Women and the Rights of the Child and Convention for the Protection of Human Rights and Dignity of the Human Being with regard to the Application of Biology and Medicine: Convention on Human Rights and Biomedicine of the Council of Europe. According to the article 90 of Turkish constitution:

> Ratification of the treaties concluded with other countries and international organizations on behalf of the Republic of Turkey shall be subject to adoption by the Turkish Grand National Assembly of a law approving the ratification. . . .. International agreements duly put into effect shall have the force of law and no appeal to the Constitutional Court can be made with regard to these agreements on the grounds that they are in contradiction to the Constitution. In conflicts between international treaties concerning basic rights and freedoms and national laws, priority will be given to the international treaties. (Anonymous, 1982)

This Convention for Human Rights and Biomedicine is an integral part of the Turkish legal system. The Oviedo Convention was ratified according to article 90 of the constitution by the Grand National Assembly on December 3, 2003, and the law on the "Convention for the Protection of the Rights and Dignity of the Human Being with regard to the Application of Biology and Medicine: Law on the Approval of the Ratification of the Convention on Human Rights and Biomedicine No. 5013" was put into effect with the publication in the official paper No. 25311 on December 9, 2003 (Anonymous, 2003, Katoğlu, 2005, Uygur & Sancar, 2005).

The Additional Protocol to the Convention on Human Rights and Biomedicine, concerning biomedical research, has also been ratified and published in official gazette in 2011 (Anonymous, 2011a).

The presence of the medical ethics and deontology classes in undergraduate medical education as compulsory courses seems to have some advantages. After the 1990s, classical medical education has been modernized in terms of its content and methods. In 2002, with the emergence of the National Core Curriculum (NCC) project, the aim and learning objectives of undergraduate medical education have been determined on the national level. To determine the objectives of undergraduate medical education for Turkey, clinical and basic science, knowledge, skills, and attitudes relevant to bioethical topics, such as physician-patient relationship, patient privacy, and patient autonomy, have been defined and classified. A total of 1,610 cognitive, 428 psychomotor skills, and 247 attitudes have been named. Thus, the core curriculum defined is not just a set of diseases, conditions, and symptoms. The major outcome of this work initiated an atmosphere of collaboration and understanding between different medical schools in Turkey. This process has led to the development of a National Core Curriculum which contains ethical issues and targets as well (Kemahlı et al., 2004).

Ethics committees (ECs) are important entities because they regulate the steps taken for biomedical trials, most of which are authorized by the Ministry of Health. According to the regulation, ECs must be comprised of between 7 and 15 members. At least one of these members must be a non-healthcare professional and one must be a jurist. The majority of the members must consist of healthcare professionals holding a doctorate or medical residency degree. The EC must meet in order to perform a scientific and ethical assessment of the trial protocol, the design and suitability of the trial, the inclusion and exclusion criteria, the suitability of investigators, the adequacy of the trial sites, the methods and documents used to inform the subjects, and the consent obtained from trial subjects, as well as any other aspects pertinent to the trial. In doing this, the EC must try to ensure that the subjects' rights, safety, and well-being are protected. The EC ensures that the study is conducted and monitored according to the regulations. According to the Implementing Regulation on Clinical Research, different sorts of ethics committees have been defined. There are ECs for Drug Clinical Trials, ECs for Bioavailability/Bioequivalence Trials, ECs for Non-drug Clinical Trials, and ECs for Clinical Trials (Anonymous, 2011b).

As different sorts of ECs, hospital ethics committees, university ethics committees, or ad hoc ethics committees have also been organized mostly in order to conserve and defend patient rights in different contexts. The EC on sexual determination in Ankara University School of Medicine is one of the successful examples working in a multidisciplinary way for long years (Öcal et al. 2010). These committees also play an important role in resolving ethical conflicts, analyzing the bioethical cases, and proposing action choices to relevant parties.

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

In Turkey, within the medical school tradition, duties and responsibilities of the physician have always been a part of the curriculum since the first quarter of the nineteenth century. Currently, it is a *sine qua non* for undergraduate medical education, too. In 1961, "medical deontology" and "history of medicine" were accepted together as one specialty branch in medicine in Turkey (with the statement of October 13, 1962 and number: 5/1789; Official Gazette No. 10942, Code of the Medical Profession). This situation lasted until 2002, the year the MoH changed the concerning regulation. After 1981, when the legal changes related to the university system of the country took effect, the main characteristics constituted the final transition from the concept of "deontology" to "medical ethics." Drastic changes have occurred in lecture contents. Today, any student receiving his/her training at any medical school in Turkey has to take a "medical ethics" course and pass (Arda, Oğuz, & Şahinoğlu, 2009). Medical ethics

education is an indispensable part of undergraduate medical education according to the National Core Curriculum (Kemahlı et al., 2004).

It is possible to find the details of all the courses related with ethics in the database study GEOBS (Global Ethics Observatory) on Database3 (see www.unesco.org). Totally, 35 ethics teaching programs, undergraduate and postgraduate level, have been documented from Turkey: 29 are about medical ethics, 4 about bioethics, 1 about environmental ethics, and 1 about science ethics. Thus, medical ethics teaching has a central role in the field of bioethics (Arda, 2011).

The undergraduate curriculum of the other health sciences, such as dentistry, pharmacy, veterinary medicine, and nursing, also contains similar courses to the ones mentioned above. There have been a few courses related to ethics in some other fields, such as law, engineering, biology, and environment, on the postgraduate level (master or doctorate programs) of some universities (see www.unesco.org).

Bioethics Committees

Despite some deficits, for example, the absence of a national bioethics committee, legislative instruments concerning research as well as ECs are available in Turkey (Arda & Aydın, 1995). The very first ECs were founded in the early 1990s according to the rules of the Regulation on Medical Research in 1993.

There has also been a bioethics specialty committee under the UNESCO National Commission of Turkey (see www.unesco.org.tr). This committee was founded in 2000 for the purpose of following international developments in the area of bioethics and adapting to them under the duties of the National Commission. The main aims are to increase the public and individual awareness, to remind professionals of their responsibilities regarding the protection of human dignity in research and practice of biomedical sciences, to create an environment for discussion with diverse participation, and to improve bioethics education in Turkey at every level through consultation meetings and workshops. The committee organized meetings such as rotating conferences in bioethics, ethics experts meetings, and workshops. The committee has also finalized the Turkish translation of the three declarations published by the International Bioethics Committee of UNESCO.

Expert Bodies/Centers

Medical ethics departments of the schools of medicine, UNESCO Philosophy and Human Rights Chair in Maltepe University, non governmental organizations in the field, like Turkish Bioethics Association (TBA) and Society for Medical Ethics and Medical Law, are expert bodies mostly originated from academic area.

Relevant Legislation

In the Turkish juristical system, there are many legislative regulations which can be associated directly or indirectly with bioethical themes. The concerning major legal instruments are as follows:

- Civil Law, Law No. 4721
- Turkish Penal Code, Law No. 5237
- Law on Turkish Medical Association, Law No. 6023
- Law No. 2238 on the Procurement, Preservation, Grafting, and Transplantation of Organs and Tissue
- Law on Population Planning, No. 2827
- Law on the "Convention for the Protection of the Rights and Dignity of the Human Being with regard to the Application of Biology and Medicine: Law on the Approval of the Ratification of the Convention on Human Rights and Biomedicine No. 5013"
- Medical Deontology Regulation
- Implementing Regulation on Patient Rights
- Implementing Regulation on Clinical Research

Public Debate Activities

The congresses of medical ethics, medical law, and bioethics serve as a discussion platform in academia. Bioethics issues are also occasionally debated in popular publications regarding medicine or news portals, daily newspapers, and on national radio and television channels. The contribution of civil associations such as some active medical chambers and HAYAD (society for patient and patients' relatives' rights) to this process is worth mentioning (see www.hayad.org.tr). At the end of the 2000s, physician's ethical responsibility in hunger strike cases (Arda, 2002, Oğuz & Miles, 2005) and the social responsibility of scientists – against the backdrop of the Dilovası case (Tuncer and Özen, see www.ttb.org) – have been important issues in recent debates.

Major Bioethics Issues and Discussions at the Moment

Beginning of Life

From the perspective of feminist bioethics, the 1983 Law on Population Planning is considered an important women rights acquisition. Elective abortion can be held only with the woman's consent. Thus, a secondary consent of the partner is not necessary. There are two main sides regarding the issue of abortion: those who defend the embryo's right to live by claiming with traditional and religious approaches that life is holy and it begins from the first moment of fertilization and those who assert that a woman is the only subject who can decide freely about

her body and her life. The social and economical status of women in Turkey should be taken into consideration while handling this subject.

End of Life

One critical problem seems to be that there is a general ignorance among professionals, academics, and the public about end-of-life issues. This topic is one of the least debated aspects of clinical ethics in Turkey. Moreover, there is no comprehensive data portraying the situation to undergraduate students in medical school, but it is thought that education programs about systematic end-of-life issues are very little or mostly none. Studies focusing on the attitudes of medical professionals toward the dying patient are increasing in number, even though the pace of such initiatives is far from satisfactory.

Euthanasia is forbidden in Turkey by law which often leads to contradictory clinical situations. Physicians might feel forced to continue treatment which is known to be futile and only helps extend the dying period of the patient which might be full of suffering for him/her and his/her relatives. Although not legal, what is usually preferred in such cases is to withdraw the treatment and discharge the patient, if the person can receive adequate palliative care at home.

Health and Disease

"Socialized healthcare services" have been abandoned gradually since the 1980s, and the healthcare system has been left to the dynamics of a free-market economy. This process is almost completed, suggesting that healthcare services are treated as goods to be sold to citizens who ask for them by private companies but not provided by the state with the people who need them. One of the most prominent examples of this process is the total elimination of health centers by January 2010 all over the country. These health centers would usually be financed by the government from the state budget and provided both preventative and therapeutic services together on a population-based regional scale. The medical team working in a health center was supposed to be responsible for monitoring the health status of all individuals from birth to death living in the territory of the concerning center and taking necessary measures to improve it. Preventing diseases was acknowledged as the top priority. Although it seems to be a big responsibility at the moment, healthcare workers were motivated to work that way in the context of that time, most likely because the socioeconomical substructure was suitable for collective work, unlike today's context promoting individualism.

Since the early 1980s, all governments attempted to polish therapeutic services while devaluing preventative ones by applying several policies which prepared today's conditions. Limiting the budget of health centers, terminating national vaccine production, and unjust allocation of healthcare professionals throughout the country are some examples. Through the 1980s and the 1990s, the approach of

"treating diseases after they occur" was intensely advocated by politicians and stakeholders, either explicitly or implicitly, and thus, almost all investments in healthcare made both by the state and private sectors were based on this understanding.

In line with this trend, the commercialized healthcare system, whose final aim was to turn health services to complete subject to free-market economy, has been established step-by-step for the last 30 years. When a person is ill, he/she would have to undergo the appropriate treatment for his/her illness. Obviously, this is more profitable but not cheaper than preventing the person from diseases. With this plan, incomes were privatized and costs were publicized. The enormous increase in recent years in the number of medical examinations, applications to emergency services, and sales of medications and medical technologies in Turkey can be explained when this trend is taken into consideration.

An ideological turn was also achieved parallel to this process. The "health" concept has gone through a dramatic change. While on one hand, "health" was promoted as a "demand" of individuals rather than a "basic need" of people living in interaction in a community, on the other hand it was isolated from its social determinants and diminished to individuals' own responsibility by all the governments since the 1980s. Unquestionably, AKP (Party for Justice and Development), which has been in power for the last 10 years in Turkey, was the most eager and powerful of all governments striving for this end. Thus, "health" has happened to be redefined without a holistic look. A natural consequence of this trend was the growth of medications and the medical technologies market.

Healthcare System, Access to Healthcare

The transformation of the healthcare system in Turkey from a state-funded and organized structure toward a fully market-oriented one can be considered the most crucial bioethics issue. This issue has covered a large part of the bioethics agenda in Turkey for almost a decade, not only because of its critical consequences on financing, provision, quality of and access to healthcare services in short term, and on the community's health parameters in long term but also because of the irreversible changes in values accompanying this process. Professional bodies such as Turkish Medical Association, unions such as Union of Health and Social Service Workers, some political parties and journalists, and writers and scholars from various disciplines have produced a great deal of literature on this issue and have mostly taken a negative stance toward it.

The transformation of healthcare has had two main components: not only has the previous system been gradually destroyed and replaced with the new one, but also new definitions for key concepts, such as "the state's social responsibility" and "right to healthcare," were suggested and a great deal of money and effort has been spent to make this conceptual transformation widely accepted. The first can be determined as the "structural change," which includes the emergence of new models for providing healthcare services, establishing institutions for financing and

regulating the "health market," and marketization of state hospitals and making relevant legislation. The latter is aimed at changing the thinking of people, an ideological turn, which served to create expectations compatible with market economy on behalf of the community and newly attributed identity for healthcare professionals as well as patients and individuals who are in need of healthcare services.

The transformation of the healthcare system, which has been implemented dramatically and drastically in the last 10 years, is about to be completed by the beginning of 2013 in terms of legislation. However, it seems that relevant structural change will take more time. Eventually, the organization of healthcare management will be decentralized, health institutions belonging to the state will be either completely privatized or made subject to free health market dynamics, the Ministry of Health's (MoH) responsibilities of financing and managing, and serving free, equal, and quality healthcare to every citizen will be reduced to a mere health market-regulating function. The state's social security institutions' coverage will also be narrowed gradually, giant health corporations and chains will continue to be supported by state resources, and medical education will be commercialized. Hence, while an increasing number of healthcare professionals will be losing their job security, their income security, and professional independence, individuals will have to pay either directly or through other mechanisms such as contribution margins or private heath insurances for every healthcare service they need to get. It is not hard to foresee that, on a very general scale, "health" will turn into a commodity, to be bought and sold, and "patients" will be customers buying services necessary for the quality of his/her own life.

When overlooking the historical epoch of social services in Turkey since the foundation of the modern republic in 1923, it is seen that free and equal access to healthcare has always been problematic. If one accepts providing every citizen with equal and quality healthcare services as a supreme ethical ideal, then starting from the foundation of Turkish Republic, which is said to be the point in history when the Turkish modernization broke through, this ideal has never been achieved. It is not surprising, as it is argued by many authors, that it is only possible if the political authority aims to provide these services for free as well. Although during the period of "socialized healthcare services" lasting from the early 1960s to the mid-1980s, Turkish citizens experienced practices in the health sector closest ever to the ideal mentioned above, being a capitalist state, Turkey has never had a free and universalized healthcare system.

Nevertheless, parallel to the "globalization" process and application of neoliberal policies, Turkey began to lose whatever practices, institutions, and understandings were inherited from the period of "socialized healthcare services." Accordingly, the "right to free, equal, and quality healthcare" was replaced by the promotion of "healthcare as a commodity." With the marketization of the healthcare system, it has been widely claimed that the idea that the state can provide with every citizen free, equal, and quality healthcare services, both therapeutic and preventative, was neither possible nor necessary. Once it was widely accepted that healthcare could not be free and cannot be equally provided anymore, then it was not that difficult as it

was 30 years ago to convince people that it can be treated as a commodity whose quality was variable according to where it is sold and for what price.

The commercialized healthcare system does not improve but limits access to equal and quality healthcare services. Before the neoliberal policies, healthcare services used to be brought to people's living spaces, for example, to their homes, working sites, and schools, through several mechanisms, such as working site doctors, first-step preventative services, health-scanning programs, and periodical region-based vaccinations. Today, these policies have mostly been abandoned. People are supposed to find their way to a health institution when they are sick or when they are in need of healthcare. In addition to that, a decree law was recently passed, including regulations for a completely market-determined healthcare system (see www.resmigazete.gov.tr, Anonymous, 2011c). According to this law, people will have to pay an extra payroll tax in order to have the right to benefit from "basic health assurance package" provided by the state. The content of this package is unknown yet. Moreover, they will start paying a "share" for every box of medication they receive and per examination session when they see a family physician. Hospitals will not serve for free either, but there will be diversity in prices, since health institutions will be classified and graded according to the level of accreditation they have. It is not hard to anticipate that stakeholders will invest more money where they expect more profit. Thus, it is anticipated that while health corporations will concentrate in some regions, some other parts of the country will have to be content with worse quality low-grade healthcare institutions.

Traditional Medicine

The most recent decree law (663 No.) regulating the provision of healthcare services recognizes practices called "traditional, supplementary, or alternative medicine" as a part of modern medicine and, thus, claims that such practices can be done in hospitals with the permission of the MoH. Traditional medicine and relevant practices have always been considered a research area within the history of medicine discipline. However, for quite a long time, ethicists have claimed that integrating such practices into the current healthcare provision system without any scientific inquiry on their reliability and validity is inconsistent with the scientific fundamentals of modern medicine. Apparently, this issue necessitates a bioethical evaluation with broad participation of scholars from the field, medical professionals, historians, and such.

Reproductive Medicine

Sperm and egg donation is prohibited by law in Turkey. However, allowing non-married women to utilize these methods has been an issue of hot debate. Besides the fact that the number of eggs to be transferred is strictly stated in Healthcare Practice Notification (SUT) and Medical Help Practice Notification (BUT), being

married is an absolute necessity to be eligible for such methods on the legal context. For that reason single women or irregular couples, such as homosexual or lesbian, have no right to use such artificial reproductive technologies. Limitations of the transfer number have been based on the scarcity of economic resources, and only the first transfers have been afforded by national health system. This limitation has been discussed by clinicians and found unrealistic.

Medical Research

Ethical aspects of medical research have occupied a considerable place on the public agenda recently. Especially, directions about funding and conducting research ethics committees have been changed frequently, and uncertainty prevailed until very recently. During the last 2 years, the MoH has put several regulations into rule. Configuration, rules of working procedures, and scope of research ethics committees happened to be the topics of disagreement between authorities. For example, TMA litigated one such regulation, since it used to limit the autonomy of TMA to elect its own representative who would have taken part in central RECs. When observed closely, this process has given the general impression that MoH does not want to leave the final decision especially about drug and medical technologies researches to local RECs. According to the most recent legislation, dated August 19, 2011, if an REC is not approved by MoH inspectors, then it cannot examine medical research about medications and medical technologies. The applicants whose research is approved ethically and scientifically by an approved committee must be directed to the MoH, so that they can get a second approval there to be able to start conducting their research.

Public Health

The period of 1960–1985 is worth mentioning, during which "socialized healthcare services" were implemented and generalized throughout the country to some degree (though not fully). There was a common understanding that providing every citizen with just, equal, and free healthcare was the duty of the state in that era. Despite their numerous defects and flaws they embodied, "socialized healthcare services" policies affected public health figures positively. However, problems such as regional inequality in access to health remained the same.

Starting from the beginning of the 1980s, the marketization operation in healthcare continues parallel to marketization of all social sectors. Under neoliberal policies apart from a small portion of the population, people are said to be deprived of adequate housing possibilities, balanced nutrition, systematic basic health education, sports facilities, cultural activities, and, last but not least, preventative healthcare services. In a world under the dominion neoliberal policies, which are actually shaped according to the wills of world capitalists, people are forced to migrate to bigger cities for work; since they have lost their job insurances, they have

to change their jobs frequently if not completely unemployed; and natural environment has been destroyed in rural areas in order to create new domains to be exploited, and urban spaces have been drastically transformed for profit under the name of "urban renewal."

In relation to public health, two processes work together against the best interest of majority of people: (1) The transformation of living and working conditions of the community for profit – this brings about a total destruction of social and natural measures to improve the secondary determinants of health. For example, in many factories, workers have to work without necessary measures and substructure, which would otherwise protect them from the possible harms of the job they are doing. They also work without insurance, for long hours up to 10–14 h a day, for very little money, under stress and humiliation. They can barely earn their living. The unemployment rate is quite high as well (around 19 %). Similarly, people are to leave their hometowns and migrate to the ghettos of big cities for work, where they are deprived of healthy living conditions. It is becoming more frequent that working class peoples' houses are taken from them by the state under a policy called "urban renewal." Only those who can afford the high prices can move to their new flats, which are said to be healthier. However, this claim is proved to be very suspicious with the reports of Union of Chambers of Turkish Engineers and Architects. (2) The destruction of preventative health services.

National public health figures might be suggestive about the consequences of these policies. However, these figures should be examined in terms of short-term and long-term consequences. It is widely accepted that displays, such as death at birth rate and mother death rate, cannot be observed in short term. The early data shows that the number of people seen by a doctor has increased since 2002. Similarly, there seems to be a decrease in death at birth rate. However, the reliability of these findings is controversial. It is difficult to obtain such comprehensive results of healthcare policies in a short time, namely, in several years. At least a decade is needed to obtain the first reliable data about public health displays. The effects of HTP on the general health status of people can only be anticipated to worsen but is not known yet.

Infectious Diseases

With the decentralization and opening up the health sector to free-market economy, it is claimed by public health scholars that it will be either very difficult or impossible to control infectious diseases. As a matter of fact, epidemics of previously eradicated, limited, or controlled contagious diseases were seen again in the last decade. These epidemics seemed confined to certain regions, for example, malaria was determined in southeast and cholera in some small cities. However, as with the case of tuberculosis, some diseases appeared again in big cities, like Ankara or Istanbul, especially in suburban areas.

The stigmatization of people with AIDS also continues to be a problem. Apart from a limited number of campaigns calling out particular groups, such as medical students

and healthcare professionals, to promote awareness about the syndrome, very few or no constant programs have been implemented aimed at the general public.

Transplantation Medicine and Organ Donation

Organ donation has always been a problematic issue. First, the number of donors is generally very limited and far from meeting the need of waiting lists. Second, it is observed that the religious beliefs have a retentive effect on many people about donating their organs. Third, the way the national media treats this issue might have some undesirable consequences, and thus, should be analyzed morally. News about transplantation medicine and organ donation is usually given with news of criminal deaths or death of young people. The main discourse in such news is benevolence, which is often served too dramatically, and far from being prudent, lacking scientific and systematic information on organ donation programs. Thus, the way the issue of organ donation is treated in the media is far from educating people on a conscious level, rather it is committed only by means of personal conscience. Fourth, the government tends to use this issue to propagandize how successful they are in their health policies. Recently, composite tissue transplantations, such as face and/or extremity transplantations, have been made very frequently in some big university hospitals. The MoH spared quite a big budget for these operations, since these interventions are totally free of charge but very expensive. Some cases were lost due to the risk of the composite tissue transplantations. The controversial aspect of this latest policy is that while the government seems to be proud of itself for its so-called worldwide successes in organ transplantation, it does not implement campaigns or education programs, to promote organ donations or support non-composite organ transplantation operations, while thousands of people are queued on the waiting lists. Fifth, Turkey is said to be on the conjunction point of organ trafficking routes; however, this issue has never been brought to the public agenda or discussed in front of public conscience by policymakers. Sixth, the government plans to establish organ transplantation centers which would serve on an international level. These centers are said to be established on health-free regions, where corporations would invest on healthcare sector completely unaffiliated with national legislation. This attempt seems to have undesirable consequences, since it might lead to the emergence of an organ market on international level and birth of an organ transplantation tourism industry.

Emerging Technologies

Today, medicine cannot be thought of apart from the high-technology products. Emerging technologies bring about both new possibilities and risks. Therefore, having a leading power on the development of new technologies becomes critical in order to control the risks/benefit ratio in favor for the second. However, Turkey

cannot produce its own biomedical technology consistent with its national necessities. Similarly, since Turkey has no national science policy, it has no national technological investment program either. Such initiatives are under the control of international corporations. This results in being subject to technological advancements rather than having a say in steering them.

Technological products are continually served to the healthcare market. Being a conscious consumer, as individuals or institutions, becomes critical in order to evaluate which products meet the current primary needs and which do not. With the marketization of healthcare, needs and other motivations such as maximizing the profits often contradict. Developing a critical approach to this issue seems to be an important task for bioethicists.

Lastly, the emergence of genetically modified organisms (GMOs) and their entrance into the food market should be analyzed carefully. There are also serious concerns about the possible negative biological effects of GMOs on national agriculture and animal breeding. GMO technology, which is said to be more efficient than the previous production techniques, is under control of international power groups, such as monopolies investing the GMO technologies, market, and industry. The fact that the GMO industry imposes itself over Turkey's national agriculture sector is another aspect of this issue, which is subject to hot debates.

Intensive Care

Unfortunately, this issue is one of the topics hardly debated. However, subjects such as "medical futility," "advance directives," "consent for organ donation," and "proper supervision of intensive care units" are in need to be examined and discussed in depth. "Which cases are to be accepted as futile, and what is to be done with them?" or "how to get the advanced directives for the patients under intensive care conditions?" are questions awaiting to be answered. Bioethicists in Turkey must work with neurologists, oncologists, surgeons, nurses, anesthesiologists, rehabilitation specialists and technicians, and administrators, in taking the very first steps in order to discuss and improve intensive care implementations.

Palliative Care

There seems to be no consensus among concerning parties on how palliative care should be conducted and improved. In addition, this issue is not a hot topic of bioethics discussions. Research focused on the needs and concerns of terminally ill patients, and their relatives are very few in number. Although the MoH currently covers medical expenses of terminally ill patients in state or university hospitals, there is no comprehensive scanning study about programming, standardization, and priorities of palliative care in the country. Bioethicists might play an important role in filling this gap, fostering efforts to organize palliative education programs in collaboration with clinicians, such as oncologists, surgeons, and rehabilitation practitioners.

Care for Elderly

There has been an increase in the aging population over recent decades. This fact necessitates taking measures. The most prominent issues seem to be (1) lack of social support mechanisms, (2) stigmatization, and (3) providing the elderly with medical care.

The limited official social support systems that had existed before have now been gradually abandoned and taken over by the private sector. The quality of state intuitions, where elderly people are cared for free, has been gradually corrupted, while the number of "quality" private companies providing elderly care services has increased. This becomes problematic because many people will not have access to these services. Luckily, it is a common tradition to take care of the elderly within the family. However, research on the quality of life and social support of elderly people is very limited.

Stigmatization does not seem to be a common problem in Turkey, as elderly patients are treated as patients from other age groups in hospitals. Nevertheless, some specific aspects of the professional relationship with the elderly are in need of attention. The participation of elderly people in daily social life is quite limited, due to a lack of necessary measures such as appropriate conditions for transportation, facilities where they can be productive and active, convenient areas for socialization, clean environment, as well as support mechanisms enabling them live more independently.

Medical care for the elderly is expected to be the subject of greater problems in the near future with the recent regulations transforming the healthcare system completely to a free-market economy. Elderly people usually have complicated medical problems and, thus, need intense, multidimensional, and time-consuming medical care, which can be expensive. Since care will not be covered by the state anymore, it is not unreasonable to anticipate that only a small portion of elderly people will be able to benefit from such medical care in a fully marketized system.

Chronic Diseases

Cardiovascular diseases, endocrinological diseases, and diseases related to physical medicine are the most common chronic diseases in Turkey. The quality of care for chronically ill patients and the timely access to chronic care need to be examined ethically.

General Practice

Informed consent has become one of the most significant topics in daily medical practice. Since obtaining informed consent has become one of the routine activities in medicine, it is necessary to add this subject to the medical curriculum.

The "family physicians" system, an important branch of Health Transformation Program (HTP), basically meant the marketization of first-step healthcare services. The first practices started in 2004 in some cities as a pilot study. In January 2010, the system was broadened to the whole country. With the system, the "health centers" structure and "healthcare teams" that were supposed to protect and improve the health condition of the population for which they are responsible were abandoned. Instead, it was claimed that first-step services were to be conducted by "family physicians," who are motivated for their own profit as they work under pay for performance. The "family physician" is considered responsible for both preventative and therapeutic services, as well as other expenses, such as the wage of employees, the rental costs and maintenance of the "family health centers" where they serve healthcare. The main character of the system is to attach individuals, not families, to physicians. Physicians have to compete with each other in order to catch up with the minimal number of patients registered, otherwise, their wages decrease. Public health scholars and experts from TMA anticipate that this system will have severe consequences. Primary healthcare services might not be conducted properly which would create severe problems by means of preventing diseases and improving living conditions of people. Besides, they claim that it would be harder to maintain the basic intrinsic values of the physician-patient relationship, such as trust, benevolence, and fidelity, because the physician would become a "seller," and the patient would become a "buyer."

Health Promotion and Education

The main determining factor, marketization of healthcare services, has also affected health promotion and education negatively. This aspect can be examined under two main branches: (1) promotion of "better health" toward general public and (2) medical education.

Parallel to the trends turning health to a commodity and destroying preventative healthcare services, a more systematic and comprehensive health promotion toward the general public, which used to be conducted by the state to some extent, has been gradually abandoned. Instead, health promotion campaigns and television programs or medical advertisements filled this gap. The promotion campaigns have usually been supported or organized directly by private hospitals, drug companies, and/or medical technology corporations. As people started to be seen as potential customers, these organizations began to function mostly as advertizing facilities. Medical advertisements have been used frequently through mass media with the same goal. As known, promotion campaigns are not systematic and are usually done for a group of people (not the whole community) for a limited period of time. Information provided by campaigns and in TV programs or advertisements are criticized by professionals because they are not thought to be based on scientific data.

The reorganization of medical education according to free-market conditions is an important component of this process. The commercialization process in the healthcare sector suggests that medical education will be left gradually to monopolies and will be privatized or marketized by public-private partnership policies in the near future. This can also be inferenced from the enormous increase in the number of private medical schools all over the country. State medical schools have been in financial difficulty, as their budget previously supplied from the Treasury was reduced. Therefore, they had to behave like a company, in order to sustain physical continuity and educational quality. Moreover, in the last 10 years, a lot of private medical schools were established. The Council of Higher Education has implemented policies toward limiting the administrative autonomy of medical schools in terms of the curriculum, the number of undergraduate students, and the student fees. Also, it is observed that the content of education is to be determined according to the working circumstances after school, namely, for the purpose of creating the type of physician who can adjust to the market conditions. While perspectives associating the medical profession with values, such as equality, public benefit, and social justice, are being abandoned, the education process is changing with the purpose of creating more submissive, competitive, individualistic, timid, and less quizzical healthcare professionals.

Relations with Industry and Donors/Sponsors

It is a well-known fact that many scientific activities in the medical arena were held with the sponsorship of the drug and medical technologies industry. Drug companies have supported many scientific gatherings, medical congresses, symposiums, etc., and financed research in several medical subdisciplines. Moreover, representatives of these companies have had continuous contact with clinical physicians through various methods. Many argue that there is enough evidence to substantiate that the industry has a remarkable effect on the conduct and even the results of many research studies (Gottlieb, 1999; Hensley & Abboud, 2004; Ibia et al., 2010; Lexchin, Bero, Djulbegovic, & Clark, 2003; Melander, Ahlqvist-Rastad, Meijer, & Beermann, 2003; Wahlbeck & Adams, 1999). Some authors even claim that if there is any relationship with the industry, it is intrinsically unethical (Civaner, 2006). Nevertheless, it is promising that recently this issue has been studied and discussed more often than before when representatives of scientific authorities, such as medical specialty societies, and the majority of researches considered it mostly normal and inevitable. “Conflict of interest” is another problem. Although both the TMA and the MoH have declarations about principles regarding the just conduct of relationships of physicians and researchers within the medical industry, this issue is not supervised strictly in Turkey. Relations with drug companies have been perceived as legitimate within the medical society, even though this issue has been criticized by several bioethics scholars and discussed to some degree in a few studies examining the moral

aspects of physician-drug company relationships. Initially, researchers should be asked to declare that they have no conflict of interest while conducting medical research and presenting their results. Necessarily, bioethics scholars should also focus on this issue more intensely.

Future Challenges

In the Field of Bioethics Infrastructures

The standardization of ethics education on the undergraduate and postgraduate level as well as the establishment of an autonomous and interdisciplinary national bioethical committee seems to be the major challenges for the near future. Relating to the undergraduate ethics education in Turkey, although it is mandatory in approximately 75 medical schools, standardization is necessary in terms of curriculum, teaching methods, and competence of scholars. This effort will make it possible to reach the aims expressed in the National Core Curriculum as well. The foundation of a national advisory bioethics committee, which would work independently and autonomously on this issue in order to create a discussion platform in the light of national priorities and needs, would help solve relevant problems on both cultural and social bases.

In the Field of New and Emerging Issues

In Turkey for the last 20 years, new sci-tech tools have been invading the daily life. For that reason, creating awareness in public opinion on commercialization of life and preventing acts of populism seem important. Despite paternalistic trends in the cultural context, there has been important progress in obtaining informed consent. However, protecting patient privacy has always been a problematic aspect of this process due to the bureaucratic procedures in health reimbursement systems.

The protection of vulnerable groups, such as minors, mentally handicapped, immigrants, and refugees, is another important issue regarding the right to access to healthcare for all of society.

Other Problems and Opportunities for the Further Development of Bioethics

Ethics as a basic field for humankind necessitates a free discussion environment and open inquiry. Most of the time, a suitable normative base is maintained after a prolific and fruitful discussion. All relevant parties of the society should find the opportunity

to express their own opinion through such a discussion process. During the preparation of new legislation, common and widespread debate processes have not been realized; it seems to be an important point in the way of democratization which is related to the expression of bioethics in daily life (Arda, 2009).

Summary Conclusion

Bioethical debates seem to follow two main interrelated paths: (1) the increasing necessity to answer questions arising from structural changes in healthcare in accordance with the marketization process of social services and, thus, to redefine current concerns about what the future is going to be like and (2) bioethicists' growing interest toward medical law and vice versa. This distinction also reflects the two dimensions of marketization in healthcare: a vivid confusion about conflicting values and efforts to constitute legislative regulations necessary for a new paradigm. While bioethicists have been reluctant to define and examine the former, they are often called for providing moral ground for new legislations with regard to the latter.

The marketization process, which started by the beginning of 1980s and gained speed during the last 10 years, is about to be completed by the first half of 2013. In terms of the healthcare system, a structural transformation necessitated a coherent ideological framework. In short, healthcare services have been commercialized, health institutions have been privatized substantially, and healthcare professionals have been forced to leave their previous rights, such as employment assurance, income assurance, and professional independence, and accept working under circumstances of a new health market economy.

How justifiable it is to replace previous values with new ones, which have been promoted as intrinsic to inevitable trends of the "new world order," is a question currently underlying many discussions of the field of bioethics. Parallel to this comprehensive paradigmatic transition from the understandings and institutions of social state to those of a complete free-market economy state, moral conflicts on the macro-level have happened to cover a great portion of the bioethics agenda. They have been widely challenged by professional bodies, unions, practitioners, and also scholars from other disciplines, such as law, sociology, and public health. Limitation of free access to healthcare, growing inequalities between different social classes and regions by means of basic parameters about health, implementation of pay for performance and flexible working models in the healthcare sector, decentralization of the healthcare system, emergence of public-private partnership, giant hospital-chain enterprises, etc., are some examples to the components and results of HTP. Parallel to this comprehensive paradigmatic transition from the understandings and institutions of social state to those of a complete free-market economy state, moral conflicts on a macro-level have happened to cover a great portion of the bioethics agenda.

Svitlana Pustovit and Liudmyla Paliei

Introduction

Bioethics in Ukraine as in many post-Soviet countries has been developing in the context of preceding millennial experience. From the 1970s to 1980s, Soviet scientists got involved in research of the ethical dimensions of science, techniques, medicine and biology, the relationships between values, science, and society. Along with foreign scientists, they came to underline the hazards of modern science and technologies as well as the need for development of philosophical fundamentals

DOI 10.1007/978-94-007-2512-6_57,

and ethics of science and technology. Ethics of science was discussed within the frame of biophilosophy proposed by Soviet philosopher I.T. Frolov (Frolov & Yudin, 1986; Pustovit, 2009).

Until the early 1990s, the term "bioethics" had been used only as a scientific term; the content of bioethical principles had been interpreted in the light of social values and collectivistic ethics. Personality, individual autonomy, and dignity as well as freedom of choice had remained subordinate to social priorities (Frolov & Yudin, 1986). Therefore, the society had lacked constructive criticism of the traditional paternalism of medical ethics and the ethics of Hippocrates. Any "nonacademic" approach (including religion) to the problems of ethics and the values of science had been rejected.

However, the ideas of cosmism (harmony of society, nature, and the cosmos) were developed in the Soviet Union. A concept of the evolution of humankind suggested by Academician V. Vernadsky gained popularity. According to these views, the planet is at the beginning of a new evolutionary stage of its development – the noosphere or sphere of reason, where scientific thought plays a crucial role (Vernadsky, 1991). Therefore, the concept of global bioethics as comprehensive ethics and philosophy, proposed by the American scientist V.R. Potter, found a fertile ground for development in the post-Soviet countries including Ukraine.

In 1991, Ukraine became an independent state. Implementation of a neoliberal model of social development in Ukraine in the early 1990s led to significant losses in social guarantees and a decline in civil rights. The systems responsible for securing national interests in the area of economics, education, health care, ecology, and property management turned out not to be effective enough to provide social protection of the population. The income gap polarized the society into the extreme rich and the extreme poor. The health care and ecology standards decreased owing to reduction in budget support. Infringements of basic constitutional provisions concerning social orientation of the state, its major responsibility, namely, securing fundamental rights and freedoms of the citizens, caused emerging national security challenges and threats.

It was apparent that the present system of health care and environment protection needed to be changed in the light of new democratic values and priorities, protection of man's fundamental rights and freedoms.

More than 10-year experience with bioethics in Ukraine led to the implementation of global bioethics ideas and principles into education, medical legislation, health-care practice, clinical trials, and environment protection.

Bioethics Development

When and How Did Bioethics Start?

Until 1991, Ukraine had been part of the USSR; therefore, originally its scientists had investigated philosophical problems of biology, medicine, and ecology in relation to Soviet philosophy and the Marxist paradigm. After the breakup of the

USSR and the appearance of new independent states, society faced difficult tasks of development of new legal frameworks and ethical principles in the field of medicine, health care, environment protection, and social politics.

In the last 10 years, bioethics, after having been a section of philosophy of science in the past, has turned into a fast-developing area of public discussion, interdisciplinary studies, social practice, and education. The social movement committed to ideas of bioethics propagation and implementation of its principles into practice has been developing.

Since November 1995, when Ukraine became a permanent member of the Council of Europe (CE), Ukrainian representatives have been working actively at the Steering Committee on Bioethics at the CE. In the framework of this activity, Ukraine participated in the development of all international bioethics documents including the Convention of Human Rights and Biomedicine (Oviedo, 1997).

On 25–29 September 2000, the First Ukrainian-British Bioethics Symposium, organized and sponsored by Kyiv Research Centre REAL, the Ukrainian Association on Bioethics (UAB), the Shupyk Kyiv Medical Academy of Post-graduate Education, University College and Guys Hospital of London University, Whitefield Institute, and Green College of Oxford University, was held in Kyiv.

Who Have the Major Actors/Forces Been?

In 1998, the National Committee on Bioethics at the National Academy of Sciences of Ukraine (NASU) was established on UNESCO's recommendation. Later it was transformed into the Commission for Bioethics at the Cabinet of Ministers of Ukraine, then into the Commission on Bioethics Issues at the NASU. Now it is a central body for coordination of bioethical activity in Ukraine. Its activity contributed to establishing contacts between Ukrainian scientists, Ukrainian government, nongovernmental organizations (NGOs) and UNESCO, WHO, Council of Europe, European Parliament and European Union, NGO in CIS and other countries. The Commission takes an active part in different bioethics activities: bioethics symposia and congresses organizing, implementation of bioethics principles into legislation and social practice, public bioethics discussions, education in bioethics, etc. Now it is a central coordinative and organizing center on bioethics in Ukraine. Its responsibilities include the following: bioethics education; drafting recommendations for bioethical expertise, development of proposals concerning legislation in the field of bioethics; support of Ukraine in international cooperation regarding bioethics; coordination and monitoring of departmental bioethics commissions' and committees' activities; and informing the public about current concerns in bioethics. The Commission is an organizer of regular International Congresses on Bioethics (2002–2013) in Kyiv.

In 2000, the Ukrainian Association on Bioethics (UAB) became the first officially registered all-Ukrainian nongovernmental organization committed to propagation of bioethics ideas, which consolidated under the aegis of philosophers, biologists, health professionals, scientists, and public representatives. Organization

of the First Ukrainian-British Bioethics Symposium in 2000 and translation, publication, and free dissemination of the book "Bioethics: bridge to the future" by the founder of bioethics V. R. Potter by UAB in 2002 became important steps in the development of bioethics in Ukraine. The first monograph on bioethics in Ukraine "Bioethics: beginnings and foundations. Philosophical and methodological analysis" (Authors: S.V. Vekovshynina, and V.L. Kulinichenko) – was published by UAB in 2002. The first Ukrainian Standard Operation Procedures for Ethics expertise of biomedical research was developed and published by UAB in cooperation with the National Scientific Centre for Medical and Biotechnical Research of the NASU. UAB is an organizer of regular International Symposia on Bioethics (2000–2012) in Kyiv.

Various public organizations, such as the Psychiatric Association of Ukraine, the National Scientific Centre for Medical and Biotechnical Research of the NASU, the Information Centre for Bioethics, Kyiv Ecological and Cultural Centre, Kharkiv Humane Society, the Bazylevych Institute of Bioethics, the Ukrainian Medical and Legal Association, Institute of Medical Law, Pharmaceutical Law and Bioethics at the Academy of Advocacy of Ukraine, the All-Ukrainian Council for Patients' Rights and Safety, the All-Ukrainian Physicians' Society, have become the major actors of bioethics developments. With their efforts, a number of foreign books, journals, and other materials have been translated into Ukrainian and Russian; course books and teaching manuals on bioethics have been written and published to be used in Ukrainian universities and institutes; many seminars and symposia on bioethics have been held; and bioethics training programs have been elaborated.

What Have the Major Concerns Been Over Time?

A range of topical issues pertaining to bioethics in Ukraine have arisen over time: (1) the clarification of theoretical and methodological fundamentals of bioethics important for bioethics as a special branch of science; (2) the acquisition of status of an academic discipline taught at higher educational institutions; (3) the implementation of bioethical principles and requirements into Ukrainian legislation and social practice; (4) building relations with European international organizations (UN and UNESCO, WHO, etc.) in the area of bioethics; and (5) the standardization of ethics expertise and accreditation of ethics committees.

What Resources Have Been Developed (e.g., Books, Programs, Media, Networks, Societies)?

Over the last 12 years, about 20 large symposia and congresses as well as a great number of smaller seminars and workshops on bioethics, medical law, and ethics committees (Kyiv, Khakiv, Lviv) have been held in Ukraine. Lots of articles, brochures, and books on medical ethics and law issues, bioethics, and ethical

expertise have been published. Several fundamental studies in theoretical and practical issues of bioethics, which resulted in defense of candidate and doctoral theses in philosophy of science and ethics, have been conducted.

It is necessary to mention the great role of WHO, United Nations and UNESCO, other international organizations, and funds in the development of bioethics in Ukraine, constant collaboration of Ukrainian NGOs with Russian, Belarusian, and Moldavian bioethicists and other countries of the Commonwealth of Independent States (CIS).

Ukraine takes an active part in the development of bioethics at the international level represented by its experts; it participates in work of the European Council, United Nations and UNESCO, WHO, and other organizations. In particular, Ukraine participated in discussion and adoption of the United Nation International Convention against the Reproductive Cloning of Human Beings (International Convention against the Reproductive Cloning of Human Beings, 2005) and UNESCO's Universal Declaration on Bioethics and Human Rights (Second Session of the Inter-governmental Meeting of Experts aimed at Finalizing a Draft Declaration on Universal Norms on Bioethics, 2005). In 2010, the Ukrainian Unit of the UNESCO Chair in Bioethics (based in Haifa, Israel) on the basis of the Academy of Advocacy of Ukraine was established.

In 2001, an important bioethical resource – the Forum for Ethics Committees in the CIS (FECCIS) – was established in the CIS region within the framework of the WHO project "The Strategic Initiative for Developing Capacity in Ethical Review" (SIDCER). During the period of its existence (2001–2007), Ukraine was involved into FECCIS activities: development of regulatory and methodical basis of research ethics and ethical expertise, development and implementation of educational programs for members of ethical committees, creation of information space and extensive dialogue of different parties involved in the ethical review of biomedical research, and process of harmonization of regional and international ethical standards in biomedical research (Kubar, Yudin, Nikitina, & Vladimirova, 2007).

What Steps/Measures Have Been Taken (Policies, Legislation, Infrastructures, Teaching Programs, Committees, etc.)?

Transformation of Ukrainian legislation toward meeting international requirements to conducting biomedical investigations, obtaining informed consent to medical intervention from patients, ethical work, has been initiated in the second half of the 1990s.

The first step in bioethics development was establishment of the Ethics Committee at the state Pharmacological Centre of the Ministry of Health (1995), transformed into the Central Commission on Ethics Issues (exist from 1996 till 2012), and local ethics committees at higher educational institutions, research institutes and medical and prophylactic establishments in order to provide ethics expertise in clinical trials and other biomedical research.

The Commission on Bioethics headed by the vise-president of the National Medical Academy of Science of Ukraine (NMASU) Yurii Kundiev (at the Ukrainian Cabinet of Ministers; 2001–2005) transformed into the Commission on Bioethics Issues at the Presidium of the NASU (exist from 2005 till now); the Commission was created for coordination of all bioethics actors in Ukraine. Many other public organizations and centers promoting bioethics have been created in Ukraine during 2000–2012.

Of huge importance is the Law "On Pharmaceutical Products" in line with requirements of the Directive 2001/20/EC of the European Parliament, the Council of Europe, ICH-GCP, and the Declaration of Helsinki; the law was approved by the Ministry of Health of Ukraine in 2006. The law specifies regulation of development, manufacturing, operation, exploitation, control over security of pharmaceutical products, and determines the rights and obligations of persons, responsible for their putting into operation or exploitation in Ukraine.

In 2004, an elective course in bioethics for students of the 5th year at medical universities was approved by the Ministry of Health. The course consists of lectures (10 h), practical seminars (17 h), and students' individual work (54 h). Today, bioethics is approved as a compulsory course only in medical specialties (dentistry, pharmacy).

Current Bioethics Infrastructure

Teaching of Bioethics at University and Other Levels

Since 2000, some bioethics courses and training modules have begun to appear in the undergraduate and postgraduate university programs for medical professionals, biologists, social workers, and veterinaries.

Today, bioethics in Ukraine is mostly taught as a part of philosophy training program or as a fragment of routine courses for medical students, biologists, or veterinarians.

The Philosophy Department of the Shupyk National Medical Academy for Postgraduate education (Kyiv) was one of the first in Ukraine to introduce the course "Bioethics as modern medical ethics" (12 h) for postgraduate students in 2000. Today, it has a great experience in bioethics teaching for medical postgraduates. A considerable experience in teaching bioethics and organizing of methodical seminars for students has been accumulated at the Bohomolets National Medical University and at Ukrainian Medical College (Kyiv).

In the western region of Ukraine, bioethics is taught in the context of fundamental principles of Christian morals. The Galytsky Lviv Medical University offers an elective course in bioethics for the third year students. The Valeology Department at the Karazin Kharkiv National University has become a methodological and theoretical center for teaching bioethics in Eastern Ukraine. It offers a special course "Bioethics as the ethics of health" (90 h). Bioethics is also taught at institutes of higher education in Dnipropetrovsk, Zaporozhzhia, Luhansk, Odesa, Poltava, and Sumy.

Development of bioethics courses in Ukraine is still complicated by the fact that many professors during the Soviet period taught Marxist philosophy and had no opportunity to study special foreign literature and discuss bioethics problems with foreign colleagues freely.

In Ukraine as in other European countries, there is a tendency to teach bioethics not as global bioethics but as applied biomedical ethics. The reason is that the majority of bioethics teachers for medical students are physicians with a pure humanitarian background which influences the general tendency of bioethics education and academic discussion of main bioethics problems.

Bioethics Committees

In the beginning of the 1990s, bioethics committees began to be established.

The Ethics Committee at the State Pharmacological Centre of the Ministry of Health (then - Central Commission on Ethics Issues at Ministry of Health of Ukraine) was the first central body aimed to systematize ethical expertise of all biomedical research in Ukraine in 1995.

Over the past 10 years, the Central Commission on Ethics Issues at the Ministry of Health of Ukraine has reviewed over 2,000 drug trials, more than 500 of them being multicenter ones. In 2010, local ethics committees and commissions monitored biomedical investigations at 412 health-care facilities and medical establishments within Ukraine. The number of large-scale clinical trials amounted to 384 and 30,000 individuals (11,000 in 2005) participated in them (Kornatskii, Talaieva, & Silantieva, 2011).

However, there are still a lot of unresolved issues: (1) institutionalization of ethics committees, (2) securing their independence, (3) establishing hierarchy and relations between ethics committees at different levels, and (4) training and certifying of members of ethics committees. The creation of an association of ethics committees is essential for the coordination of their work, the protection of those involved in investigations as well as the professional development of the researchers.

Unfortunately, it should be noted that the degree of formalization and bureaucracy of ethical expertise in Ukraine is rather high. This defect can be avoided only by comparing “ideals” (projects that are declared) with “reality” (the practice of biomedical research). The fact is that the existing “paradigm" of ethical expertise has a “preventive and idealistic” character: It aims to prevent adverse and side effects of studies and minimize potential risks to subjects not during research but at a design stage. That is why the idea of the real “monitoring” of studies is rather slow to move and put into practice. Thus, the principle of prevention is simultaneously both the main advantage and weakness of the ethical expertise paradigm.

Lack of financial resources and weak material base of ethics committees are related to the functions and status of local ECs as independent and not-private organizations. Institutions are usually not interested in the development and financial support of the ECs functioning in their premises. The problem is that the list of

financial activities authorized for institutions includes only scientific expertise; ethical expertise is not included in this list.

A great resonance got a question of a division of powers and responsibilities between the Central Ethics Commission of the Ministry of Health and local committees. In 2007, the Ministry of Health of Ukraine developed "Typical Regulation on the Ethics Committee," which has several provisions that conflict with each other. Thus, it said that all "ethics committees are equal in their powers to approve the clinical trial," but during a multicenter clinical trial, the applicant must apply for approval of clinical trials exclusively to the Central Ethics Commission of the Ministry of Health. In practice, this provision actually deprives local ECs of the right to "approve" and monitor not only multicenter, but single-center clinical studies at the institutions where they work.

In 2010, the draft Law of Ukraine "On pharmaceutical products" was posted on the official Web site of the Ministry of Health for public hearings; in 2012, new rules restoring the authority of local ethical committees in ethical expertise of clinical and other biomedical research were approved.

As the first country in CIS, Ukraine introduced the "Ethical code of Scientists"; it was approved by the National Academy of Science of Ukraine in 2009.

Expert Bodies/Centers

The Ministry of Health, the Ministry of Environment Safety, National and Medical Academies of Sciences of Ukraine, philosophical and medical chairs at universities, many NGOs, and ethics committees are involved in the process of implementation of bioethics principles into biomedical research, medical practice and environment protection.

The Commission on Bioethics (2012) at Ministry of Health of Ukraine, the Commission on Bioethics issues at the Presidium of the National Academy of Sciences of Ukraine, and numerous local committees have been playing a great role as expert bodies.

The Commission on Bioethics issues at the Presidium of NASU prepared recommendations on the ratification of the Convention on Human Rights and Biomedicine for the Ukrainian Parliament. In cooperation with the Ministry of Justice, much work has been done on comparing Ukrainian legislation with the main statements of every article of the Convention. Ukrainian bioethicists are also UNESCO bioethics experts.

Relevant Legislation

The Constitution of Ukraine is the main law proclaiming the priority of the individual, his/her life and health, dignity, honor, personal inviolability and safety, protection of human rights and freedoms (art. 3). The Constitution states the principle

of freedom and equality with regard to human rights and dignity (art. 21); nonadmission of discrimination (art. 24); the inalienable right to life (art. 27); and everyone's right to have their dignity respected (art. 28). The Constitution declares that everyone has the right to health protection, medical care, and medical insurance (art. 49), and that everyone has the right to an environment that is safe for life and health is guaranteed by the right of free access to information about the environment situation, the quality of food, and consumer goods (art. 50). Thus, the Constitution secures the fundamental human rights to life and health.

Another important document is the Basic Legislation on Health Care in Ukraine. This law was adopted in 1992. It has continuously been revised and amended. It sets general health-care principles. There are some other important laws concerning bioethics issues: On Pharmaceutical Products, On Prevention of AIDS and Social Protection of Population, On Providing Psychiatric Care, On Prohibition of Reproductive Human Cloning, On Transplantation of Organs and Other Anatomic Human Materials, On Rules of Conducting Clinical Trials of Pharmaceutical Products and Reviewing Materials of Clinical Trials.

In 2004, the representative of Ukraine, professor Z.A. Shkiriak-Nyzhnyk, was elected to the Board of the Steering Committee on Bioethics of Council of Europe as a Committee Reporter on the activity of Ethics Committees at medical research institutions. In the framework of the Steering Committee on Bioethics of the Council of Europe, Ukraine participates in the development of guidelines for the protection of fetus and embryo, and in the design of a protocol related to genetic testing (Kundiev, Chaschin, Chaschin, Pustovit, & Vitte, 2007, p. 320).

Public Debate Activities

The end of the twentieth century was marked by the collapse of totalitarian regimes, renewal of private ownership, and drastic changes in the professional and practical ethos in post-Soviet countries, all of which promoted extensive discussion of bioethics problems in the society, first of all in the field of medicine and health care. Issues of corruption in medicine and ethical principles of health-care delivery, doctors' errors, informed consent, problems of organ donation, and others got prominent coverage in leading newspapers and journals.

A number of TV programs and sites on the Internet are devoted to problems of high-quality medical aid. Of great public resonance was a fatal case in Cramatorsk (Donetsk oblast). A schoolboy died after vaccination against measles and rubella due to untimely medical aid (The schoolboy died from toxic shock, 2008). The criminal case of activity of "black" (illegal) transplant business was also widely discussed. The group of four Ukrainian surgeons, who worked at one of the well-known Kyiv's clinics, used their official positions to take part in a criminal group that recruited and transported citizens of Ukraine abroad for illegal transplantation of kidneys (2007–2011) (Crime of transplantologists, 2012).

Public discussion concerning rights of dying people as well as ethical principles of biomedical studies with involvement of people is virtually absent. Problems of widespread corruption at medical establishments as well as overpricing medical products and medicines are hushed up.

Other

Use of laboratory animals in scientific research is regulated by the Law of Ukraine № 3447-IY of 21.02.2006 "Against the Cruel Treatment of Animals" and "General Ethical Principles of Experiments on Animals" adopted by the First Ukrainian National Congress on bioethics in 2001. According to these regulations, laboratory animals are to be provided with humane care and healthful conditions during their stay and use in research.

Major Bioethical Issues and Discussions

Beginning of Life

Legalization of abortion is an important embodiment of the bioethical principle of respect for autonomy and women's choice. Abortion is available on request during the first 12 weeks of gestation. Thereafter, induced abortion is available within 13–22 weeks from conception, on judicial, genetic, vital, broad medical, and social grounds, as well as for personal reasons with the special authorization of a commission of local physicians.

Since 2006, according to the Ministry of Health Order N508 Statement on Abortion Procedures and Obligatory Requirements Regarding Statistics Recording (2006) and Resolution N144 of Cabinet of Ministry Realization of Civil Code Chapter N281 (2006), the social grounds and personal reasons discontinued to be indications for abortion performance in the second trimester. According to the law, only assault or incest, life-threatening conditions, or fetal impairment can be indications for legal abortion.

From January 2007 Ukraine follows WHO standards – a baby born after 22 weeks of gestation with weight $\geq$ 500 g is considered not as a foetus but as a new-born. However, the practice when medical staff strongly advise to have an abortion in any health disorders in pregnant woman or the fetus, in Ukraine, as in other post-Soviet countries, can be acknowledged to be rather common (Hrevtsova, 2011).

The current birth rate in Ukraine can be assessed as low (10.8 births/1,000 population as of 2010). Total fertility rate amounted to 1.45 children born/woman in 2008–2009 (Bogatyreva, 2011). As specified in the annual report of the Ukrainian Institute for Strategic Studies, the Ministry of Health, the birth rate compensates only about half of the death rate (Annual report about health condition, sanitary and epidemiological situation in Ukraine, 2008). It is associated

with transition to a modern European model of childbearing: increased mean age of mother at childbirth, postponement of the initiation of childbearing, decreased number of children, decreased birth rate at younger fertile age, concerns about medical complications and infertility at a later age, and other social and economic circumstances.

Iodine deficiency disorders (IDDs) are recognized as a national health problem in Ukraine. According to some studies, about 38 million Ukrainians suffer from iodine deficiency to varying degrees. Of the 417,000 children born each year, 341,000 have congenital iodine deficiency (Iodine deficiency in Ukraine becomes threatening, 2008). Unluckily, various business interests related to promotion of iodine-containing preparations in the pharmaceutical market in the county are the only reasons why health-care specialists have not yet supported adoption of the law on universal salt iodization.

End of Life

Average life expectancy is one of the lowest in Europe (67.9): Maximum male life span equal 64.2 years was registered in 1992–1992; in women, it was 74.9 in 2008–2009 (Bogatyreva, 2011, p. 123–124).

The problem is that Ukrainians do not get high-quality medical care at the final stage of their life. Palliative and hospice care have not been developed in Ukraine. This worsens the suffering of dying people and is indicative of a lack of a humane attitude toward them on the part of the state and society.

As for the terminal stage, according to Ukrainian legislation, it is a physician's responsibility to give medical aid to any patient for improving his or her condition. At present, euthanasia is forbidden and being treated as premeditated murder. As provided in Clause 115 (intentional homicide) of the Criminal Code of Ukraine, it carries punishment of up to 7–15 years imprisonment. Current legislation is not promoting the liberalization of this issue.

Health and Disease

According to the WHO prognosis, Ukraine's population could fall from 45,778 million (2010) to 30 million (by 2030), if medical care in the country remained as low standard as it is at present. In many ways, today's dramatic situation in health care and environment protection can be explained by the loss of moral values and priorities of the society that existed during the Soviet period as well as political and economic instabilities.

Outstanding physicians who lived and worked in Ukraine during the twentieth century (M. Maksimovich-Ambodic, D. Samolovich, M. Pirogov, N. Strazhesko, A. Bohomolets, M. Amosov, and others) not only followed high ethical standards and rules in their medical practice but also developed and extended them (Kundiev et al., 2007). They used new methods of diagnostics, treatment, and prevention only

after having studied those in research on animals and often in "auto-experiments." They developed the best tradition of Zemstvo medicine (a special form of medical and sanitary care of the rural population in 1864–1917) and were against an abnormal system of private medical practice that made physicians to live on money they received from their patients. They tried to develop a new system of public health care based on democratic principles, equity, creative approach, and with the emphasis on preventive medicine.

In the Soviet period, medical ethics used the best of what had been accumulated by preceding generations. All medical graduates took the Oath of the Soviet Physicians based on Hippocrates Oath and collectivistic ethics. However, in practice, the totalitarian state often used physicians, their knowledge, and power for non-humanistic and moreover repressive aims, for example, psychiatrists for punishment of dissenters.

Health-Care System, Access to Health Care

One of the cardinal bioethics principles is respect for autonomy and informed consent. According to Ukrainian Law "Basic Legislation on Health Care," a physician is obliged to explain the patient the state of their health, the goal of suggested research and treatment measures, and a prognosis for a possible disease evolution including potential risk for person's health and life. The patient's consent should be sought before applying methods for diagnostics, treatment, and prevention of a disease (art. 43.1).

In spite of the fact that the right to free medical care provided by state and municipal medical establishments is guaranteed by the Constitution (art. 49), in the majority of cases, people have to pay the full cost of medicines and services out of their own pockets. Due to chronically underfunded health care, legislation of Ukraine in terms of free medical care is violated almost in all regions of the country as patients are illegally charged for medical services. Considerable contingents of people with low social and economic status have problems with access to health care. Untimely delivery of medical care, territorial remoteness of medical establishments, waiting in long queues to see the doctor, high cost of medicines, and corruption are among the main causes.

Unfortunately, systematic recording and analysis of cases of medical harm is not done in Ukraine. Huge public and personal financial resources have been spent to relieve the consequences of medical harm and for social payments to the disabled (Legal nuances of medical errors, 2012). According to the State Court Administration, in 2009, only 10 persons were convicted for improper performance of their health-care professional duties, including those resulting in death or other grave consequences (Legal nuances of medical errors, 2012).

Presently (2011–2014), a pilot project on reforming medicine is being implemented in Kyiv, Vinnytsa, Dnipropetrovsk, and Donetsk oblasts (regional authority areas). According to the new conception of medical service the following are envisioned: (1) medical care will be provided at three levels: primary,

secondary, and tertiary health care; (2) the main care will be delivered by family doctors who must supersede internists and specialized doctors; (3) first aid will be reformed; and (4) budget funding for free care delivery will be preserved, and medical care insurance, hospital funds, and other ways of cash security will be implemented (Health care reform in Ukraine will start in 2014, 2012).

Traditional Medicine

In the Soviet tradition, traditional medicine is considered to be the official scientific medicine. All other areas of medicine (folk, homeopathic, Oriental) are referred to as nontraditional or alternative medicine. There are several governmental and nongovernmental institutions of alternative medicine which train the relevant specialists.

A new discipline, valeology, which has flourished in recent years, appears to be interesting as an area of alternative medicine (Kulinichenko, 2001). Valeology is the science of how to keep healthy. It includes knowledge and skills to be healthy, which can be scientifically proven but have not officially been recognized yet. Several valeologic centers have been created, for example, in Kyiv, Kharkiv, and Sevastopol. Valeology as a discipline is officially taught for teachers at the Karazin Kharkiv State University.

Genetics

According to the Law on Prohibition of Reproductive Human Cloning (2004), it is unlawful to perform human cloning as well as to import or export cloned human embryos. Ukraine has acceded to the European Agreement on the Exchange of Therapeutic Substances of Human Origin (1958), the International UN Declaration on the Human Genome and Human Rights (1997), and the Additional Protocol to the Convention on Human Rights and Biomedicine Concerning Prohibition of People Cloning (1998), that provide the general principles of manipulation of genetic material, which would not conflict with human dignity.

The Law on State Biosafety System of Creation, Trials, Transportation, and Use of GMOs was adopted in 2007. However, this law has several deficiencies. The main gap of the law is that it does not involve establishing an institution responsible for providing safety of creation, trials, registration, transport, use, and utilization of GMOs. As a result, it can lead to the situation of fragmented responsibility and holes in biosafety systems. In addition, this law does not provide any registration procedure for GMOs either. No GMO threshold for food products is set; no labeling requirements are outlined (although mandatory labeling of GM food is provided by the Consumer Law). Finally, protected natural areas and zones of genetic safety for GMOs are not mentioned either (New Biosafety Law in Ukraine: Effort to Regulate or to Legalize GMOs, 2007).

Reproductive Medicine

Surrogacy programs including commercial surrogacy and surrogacy in combination with egg/sperm donation are legal. Ukrainian surrogacy laws are the most favorable in the world and fully support the individual's reproductive rights.

Surrogacy is officially regulated by Clause 123 of the Family Code of Ukraine and Order 24 of the Health Ministry (Reg. 04.02.97). Ukrainians can choose between gestational surrogacy, egg/sperm donation, special embryo adoption programs, and their combinations. No specific permission from any regulatory body is required. The prospective surrogate should be 20–40 years old. She must be mentally and somatically healthy and have at least one healthy child of her own. Surrogates must not have any relation to commissioning parents. A written informed consent of all parties (prospective parents and surrogate) participating in the surrogacy program is mandatory. The marital status of the surrogate is irrelevant. Ukrainian legislation allows prospective parents to carry on a surrogacy program and their names will be on the birth certificate of the child born as a result of the surrogacy program from the very beginning. The child is considered to be legally "belonging" to the prospective parents from the very moment of conception. The surrogate cannot keep the child after the birth. Even if a donation program took place and there is no biological relation between the child and intended parents, the prospective parents' names will be on birth certificate. Embryo research is allowed; gamete and embryo donation is permitted on a commercial level.

Medical Research

According to the Basic Legislation on Health Care (art. 44), the Law on Pharmaceutical Products and other legislative documents, new methods of prophylaxis, diagnosis, treatment, rehabilitation, and medicines, which have not been approved for use yet or are under trial, can be applied merely for the benefit of healing a person and only after obtaining their informed written consent. For 14–18-year-old patients, it is necessary to obtain their personal informed written consent as well as their parents' or other representatives' informed written consent (Lukianova & Shkiriak-Nyzhnyk, 2003).

However, in fact, doctors-researchers frequently make the following mistakes: (1) do not receive the informed consent from the patient leaving the latter uninformed about the fact that they are involved in a study; (2) obtain consent from patients not in writing but only orally, thereby violating the requirements regarding the scope and content of informing; and (3) design a consent form incorrectly, thus misleading participants. Unfortunately, clinical studies in many cases turn out not to provide any direct benefit to patients' health or be of little scientific value.

In many countries, the lion's share of medical research falls on clinical trials. Today, the list of problems in this area includes the following: (1) the accreditation

and licensing of clinical facilities for conducting clinical trials (CT), (2) the validity of placebo-controlled studies, and (3) state regulation of insurance of clinical trial subjects (Kornatskii et al., 2011; Zhupanets, Moroz, Bezuglaia, & Grintsov, 2011). Over the past 5 years, the number of studies on the bioequivalence of drugs as well as phase I clinical trials increased greatly. The first circumstance is of particular importance for Ukraine because the domestic market contains 86–92 % of generics. Conducting phase I clinical trials is complicated by the limited number of specialized clinics and the poor facilities as according to existing legal norms healthy volunteers can be hospitalized only in specially equipped hospitals.

Public Health

Ukraine currently faces a number of major public health issues. Besides a demographic crisis due to the high death rate and low birth rate, a high mortality rate among working-age males from preventable causes such as alcohol poisoning is a factor contributing to depopulation (http://www.worldbank.org/html/prddr/trans/julaug99/pgs3-4.htm). The high unemployment rate especially in rural areas might be considered among the main reasons. The nation also suffers a high mortality rate from environmental pollution, poor diets, widespread smoking, and deteriorating medical care (Starostenko,1998). Of current concern are consequences of the Chornobyl disaster which affected agricultural areas of 18,000 square miles, and estimates say that 40 % of the country's forested areas were also contaminated. As of January 1, 2010, 2,354,471 residents were registered by labor and social protection services as affected by the disaster. Analysis of the health condition of the affected cohort is indicative of an increase in the incidence of thyroid and breast cancers by 5.6 and 1.5 times, respectively (Bogatyreva, 2011, pp. 244–245). Insufficient provision of the affected population with non-polluted food has contributed to increased internal irradiation of the population. To mitigate the negative impact, the government subsidizes programs aimed at improvement of the affected population's health.

In addition to the UN Framework Convention on Climate Change, Ukraine signed and ratified the Kyoto Protocol (1997) which outlines the procedures and principles for sharing of the country's commitments to reduce greenhouse emissions. The country received over three billion hryvnias (375,000,000,000 dollars) for the sold quotas to reduce emissions of carbon dioxide into the atmosphere specified by the Protocol. In general, emissions of pollutants into the atmosphere from stationary sources are gradually reducing; on the contrary, emissions from vehicles are increasing.

Ukraine is one of the first countries in Europe to sign and ratify the Aarhus Convention (1998–1999). However, involvement of the public in decision making regarding the environmental situation is still difficult because of the lack of influential civilian institutions and corruption. Urban green zones and nearby forest areas are being destroyed to be built up with new blocks of flats and offices

in violation of the sanitary and other legislative norms; private and state enterprises often ignore safety rules; and advertising and sale of alcoholic beverages and cigarettes is widespread.

In recent years, there has been some decrease in rates of occupational traumatism, morbidity, accidents, and fires.

Infectious Diseases

Over 4.5 million Ukrainians, mostly children, are vaccinated for a wide variety of diseases each year. The Law on the Protection of the Population Against Infectious Diseases (2000) determines the legal basis for activities of bodies of executive power, bodies of local self-government, enterprises, institutions, and organizations, directed at prevention of human infectious diseases. Unfortunately, a widespread scare about vaccine side effects has led to a sharp drop in immunizations that could result in disease outbreaks spreading beyond the former Soviet republics.

In Ukraine, babies are to be vaccinated against tuberculosis (TB) at birth within the first 3–7 days and then revaccinated twice when 7 and 14 years old. In spite of this, Ukraine is among the countries with a high TB morbidity rate. The major challenges in TB morbidity are as follows: (1) increasing number of cases of multidrug-resistance TB, (2) lack of conditions for treatment of TB patients at temporary detention facilities, (3) TB coinfection in 50 % of HIV infected, and (4) underfunding of relevant state program for TB (Bogatyreva, 2011, p. 174).

Ukraine has one of the fastest growing HIV/AIDS epidemics in the world. Experts estimated at the beginning of 2010 that 360,000 people (0.78 % of the adult population) of Ukraine were HIV positive (Bogatyreva, 2011). As a result of large-scale antiretroviral therapy introduction in 2007, a decrease in the number of registered patients and mortality rates as well as a stabilization of these parameters in 2008–2010 were recorded, for the first time since 1994. However, access to antiretroviral therapy does not meet the patients' needs yet.

The epidemiological situation regarding hepatitis B and C is deteriorating because of the high risk of nosocomial and community-acquired infection in public and private dentistry surgeries, beauty and hairdressers' salons, due to inadequate quality of disinfection and sterilization in medical institutions in collecting and processing blood and its components.

Transplantation Medicine and Organ Donation

The first renal transplant in the world was performed by Prof. Yurii Voronoi in Ukraine (Kharkiv) in 1933. Today, however, Ukraine lags behind the USA and other developed countries in terms of the number of transplants. Ukraine has a mere 1.5 transplants per million (compared to 20–40 donors per one million residents in other developed countries) (Poliachenko, 2007).

The Law on Transplantation of Organs and Other Anatomic Human Materials (1999) established a presumption of the dead person's disagreement on taking their organs, and thus put an end to the practice of unauthorized organ harvesting that had existed back in the USSR. Each capable adult person during their life may give their consent or refusal to become a donor of anatomical material after death. In the absence of such a notarized declaration, anatomical materials from a deceased person may still be harvested with the spouse's, relatives', or legal representatives' consent.

Lack of effective legal mechanisms of donation promotion led to curtailment of transplantology and reduction in the number of legal transplantations. The existence of "black" market organ donation in Ukraine means that some poor people may sell their organs and some unmoral physicians are ready to make money on human health (Crime of the transplantologists, 2012).

Out of the scope of regulation of the law are such important medical interventions such as transplantation of gonads, reproductive cells and alive embryos, donation of blood and blood products, bioimplantates made from anatomical structures, and tissues harvested from cadavers for the further use in the reconstruction of bone or other tissue defects in the patient.

Emerging Technologies (Nanotechnology, Information Technology etc.)

In Ukraine, research institutes of the NASU and NAMSU, universities conduct research on nanotechnologies, nanobiology, nanomedicine, nanopharmacology, nanopharmacy.

Important studies on carbon nanostructures were held in the Shevchenko Kyiv State University in 1985, 6 years earlier than in Japan. A possibility of existence of tubular carbon (carbon nanotubes) was speculated. Manufacturing nanotubes by electrolysis in molten salts, which is considered to be the latest technique in the West, was developed by academician Yu. Delymarsky and coworkers in Kyiv as early as in 1964. These studies were ahead of time and remained non-demanded (http://nano.com.ua/content/blogcategory/23/40/).

The Paton Electric Welding Institute and the Bohomoletz National Medical University have developed methods for synthesis of nanomaterials of metals (silver, copper, iron) and organic compounds (carbon). The Chuiko Institute of Surface Chemistry of the NASU has been conducting research on nanodispersed silica suspension properties for the past 10 years.

In connection with development and introduction of nanoproducts in the Ukrainian society, the concept of ethics corresponding to the complexity of arisen ethical challenges generated by nanotechnologies has been discussed. Of current concern is the appropriate ethical education of scientists and engineers involved in nanotechnology. Ethical challenges associated with nanotechnology were widely discussed during the IV National Congress on Bioethics in 2010.

Intensive Care

In accordance with the Law on Transplantation of Organs and Other Anatomic Human Materials, a human is considered to be dead from the moment of brain death. The moment of death of a potential donor is established by consultation of physicians of the corresponding health establishment or research institution. These physicians cannot participate in harvesting the donor's anatomical materials, in their transplantation or manufacturing bioimplants.

IC ethical problems are as follows: (1) impossibility to perform high-quality intensive care at home or in an ambulance, (2) depersonalization of patients in hospitals, (3) failure of life-support equipment as a result of depreciation and lack of operating skills in medical staff and patients themselves, (4) iatrogenic harm of invasive methods of intensive therapy, and (5) limited doctors' personal responsibility for the patient due to the administrative governing in the state sector of health care (Zilber, 2009). IC units still lack beds as well as equipment of appropriate quality.

Palliative Care

In Ukraine, the first hospice facilities were established in 1997–1999 in Lviv, Ivano-Frankivsk, and Kharkiv. Today, there are ten in-patient hospice and palliative care departments at oncology and multidisciplinary hospitals in different regions. In some cities, there are several charitable palliative care structures at church and various public organizations. Unfortunately, the majority of them do not receive sufficient funding and are kept only by the enthusiasm of medical staff, volunteers, and support of local authorities.

In July 2008, the Institute for Palliative and Hospice Medicine under the Ministry of Health was created. The Institute is aimed at coordination of the development of the governmental palliative care program, improvement of relevant legislation, staff training, and development of relevant protocols and guidelines. Thanks to these activities, the number of palliative care facilities is increasing. In 2002, there were 400 in-patient beds in 12 palliative care facilities; in 2007, 550 beds in 18 facilities; and in 2008, 600 beds in 19 facilities (Gubs'kii, 2012).

But the number of palliative care facilities, their material and technical level, the legal basis for the accreditation and functioning, funding and delivering of health services, especially in terms of narcotic (opioid) analgesics use, in general, do not meet international standards, including the WHO protocols. The problem of availability of modern opioid analgesics, including tablet forms of morphine for palliative patients, remains unresolved in Ukraine, which causes sharp resentment not only on the part of patients and their families, but among doctors, general public, and domestic and international human rights organizations as well.

Christian churches have been established at many hospitals, with clergymen carrying out pastoral care for the dying.

Care of Elderly

The age structure of the Ukrainian population is indicative of a regressive type of generations' revival. According to the UN scale, the population is considered to be old when the percentage of people aged over 65 is more than 7 %. As a whole, in Ukraine, it has reached 15.9 % and among the rural population 19.8 %. Therefore, its population is estimated as very, very old. Along with high aging rate of people, Ukraine is distinguished by very high aging rate of the female population.

There is also an increasing population of the elderly supported by a decreasing number of taxpayers. Immigration and population decrease have increased this trend, which would doubtless be accelerated if Ukraine joined the EU. Secondly, some relatively inexpensive medical and social interventions could markedly decrease the numbers dying prematurely but leave them to consume more expensive health care.

Until recently, there have been frequent cases and relevant facts of nonpublic directives from administrations of medical institutions not to provide surgical and intensive care to people over 70–80, which is indicative of widely spread event of stigmatization and discrimination against elderly patients. Rural areas are particularly affected by the lack of necessary medical and social services. The lonely elderly in care homes, entirely dependent on the state, are in severe conditions.

The problems of obesity, which impact hugely on the health of the elderly, and of diabetes, which is increasingly prevalent and brings major problems especially to the elderly, need urgent attention and a multi-sectoral approach from government, health, schools, and the food industry itself.

Chronic Diseases

The health and demographic crisis is determined by constant decreasing and aging population over the past 10 years as well as an unprecedented high level of mortality, particularly from such chronic diseases as cardiovascular and cerebrovascular pathologies, malignancies, respiratory diseases, diabetes, and increase in number of people suffering from neurodegenerative diseases of the brain.

For a variety of economic and moral reasons, ideals of a healthy lifestyle, which were influential in the Soviet Union, gave way to the ideals of consumerism, the freedom of private business, and corruption. Moreover, due to the relatively high cost of diagnosing and lack of regular medical checkup, many chronic diseases are detected when being in advanced stages.

Chronic disease prevalence is high – nearly half of the adult population (i.e., those between 18 and 65 years of age) suffers from one or more chronic diseases or conditions. Angina, which is detected in 7.3 % of cases, is the most common disease. Elevated cholesterol (3.8 %) takes the second position, diabetes mellitus (3.6 %) and osteoporosis (2.4 %) the third and the fourth position, respectively. The prevalence of cancer among Ukrainians is 0.8 %. Most Ukrainians simply do not live up to the age group which represents the average age for cancer rise (data of the World Bank).

Smoking poses important medical and social problems. It's a grave danger to public health, which contributes to a range of chronic non-communicable diseases: cardiovascular, malignancies, chronic obstructive pulmonary diseases, etc. At least 45 % of men and 30 % of women, and over 70 % of students and older pupils smoke regularly. The fight against smoking is not systematic. Of the latest important laws, the Law on Measures to Prevent and Reduce the Consumption of Tobacco Products and Their Harmful Influence on the Population's Health (2005) is the primary law governing smoke-free places, packaging, and labeling.

Currently, in Ukraine, there are a number of programs to combat the development of chronic diseases: the Program on Prevention and Treatment of Hypertension in Ukraine aimed at early detection of risk of cardiovascular system; the program on "Diabetes Mellitus" providing patients with insulin therapy and oral antidiabetic drugs; National Tuberculosis Program, National Program on HIV-AIDS.

Psychiatric Care

Ukraine has inherited a psychiatric system overshadowed by particularly disturbing legacies from the Soviet Union, where psychiatric diagnoses and confinement were used as forms of political repression. However, in post-communist Ukraine, the state security systems have been reformed and there is no evidence of political abuse of psychiatry.

Compared with the other countries, Ukraine had the highest prevalence of mood disorders (9.1 %) and the second highest prevalence of substance misuse disorders (6.4 %). In 2004, only a small proportion (4.9 %) of those with any mental disorder had received any treatment during the preceding 12 months, including 19.7 % of those who had a serious mental disorder (Yur'yev, 2004).

Mental health care remains essentially state funded and hospital based. However, Ukraine is accessing the European Committee for the Prevention of Torture and Inhumane and Degrading Treatment or Punishment (CPT), which enables monitoring all facilities where prisoners or patients are in custody or detained. The Ukrainian Psychiatric Association proposed the new Law on Psychiatric Assistance (2000). The Law is broadly in line with similar legislation elsewhere in Europe, but there are significant difficulties in translating its principles into everyday psychiatric practice.

The ICD-10 classification of mental disorders (WHO, 1992) has officially replaced Snezhnevsky's nosography, although it has not yet been universally adopted. The transition from centralized control to a social health insurance system, adopting principles of managed care, is under scrutiny. Ukrainian psychiatrists are developing new models of delivering services and devising new strategies for mental health care.

Pediatric Care

Given the demographic prospects of Ukraine marked by negative trends, the state of child welfare and maternity is of particular concern. According to the data of the

Ministry of Health, among children who died under 1, almost one third passed away in central district and maternity hospitals due to the lack of necessary equipment and qualified professionals. Children under 3 and disabled children are not provided with free medicines at all (Bogatyriova, 2011, p. 55). The decision of the state to solve the problem of child care by single payment at birth, which was nearly 9 % of the average salary rate (in the first year of the child), has led to some increase in the number of children being born in recent years, but the rise in birth rate is being depreciated by exorbitant prices for baby food and necessities.

In the USSR, one of the best systems of children's vaccination and safety against epidemics in the world was created, but in connection with Ukrainian society liberalization and giving patients the right to withdraw from the medical intervention in recent years, parents began to refuse to vaccinate children.

Infectious diseases remain one of the five leading causes of infant mortality under 1 year. In addition, every ninth child, and in total more than a million children less than 14 years old suffered from an infectious disease (from 2004 to 2008). Death and serious complications have also been reported. However, only 32 % of parents believe that vaccination is necessary and safe. But other parents due to the fear of complications refuse to vaccinate their children, putting them at risk of infectious diseases such as diphtheria, measles, mumps, tetanus, and hepatitis B.

Emergency Care

Emergency care is supposed to be free for everyone including those without state health insurance. However, once the patient's condition is stabilized, the doctors will probably ask for a fee for their services due to the low salary that the state provides. Emergency departments are open nonstop all year. Every year, one in three residents of Ukraine seeks emergency care. Unfortunately, the latter has many unsolved problems. Late delivery and poor quality are among the main challenges. Three most common types of violations of patients' rights deserve a special mention: (1) the patient's opinion and consent regarding the extent and quality of intervention is not taken into account; (2) the aid is limited to the simplest measures that cannot restore health, leading to irreversible consequences: chronic diseases or disability; and (3) if the physician does not receive a immediate effect, the routine and standardized practice is replaced by hyper-therapy without obtaining approval of patients or their relatives.

Of course, in critical conditions, the patient does not always have the practical possibility to choose doctors, medical facilities, strategy, volume of medical intervention, specific methods of diagnosis or treatment, which leads to the violation of their rights.

General Practice

Since the Soviet time, Ukraine has had the system of training internists and pediatricians, who were specialists in their fields.

In accordance with the new project of reform initiated by the Ministry of Health in 2000, health care is planned to be clearly divided into primary health care, which will be delivered by *family doctors*, as well as secondary (specialized) and tertiary (highly specialized) health care. The legal framework for family medicine has been developed and the Scientific and Methodological Center for Family Medicine of the Ministry of Health has been established. According to the plans, internists and pediatricians in outpatient care would be replaced by family doctors by 2020. Family doctors are able to provide qualified, including emergency, medical care to the vast majority of patients. However, the institution of family medicine is still in the making and cannot solve all health-care challenges.

Health Promotion and Education

Due to the low-income rates and high cost of diagnostic and therapeutic procedures, Ukrainians often turn to the representatives of alternative medicine and use folk methods of treatment and self-treatment. In pharmacies, the majority of products are represented by generic medicines and copies of drugs with unknown efficiency, which often poses a hazard to patient's health, and causes financial loss; 88.2 % of adverse reactions to drugs in Ukraine are known to be caused by generic drugs. Besides, unfortunately, the system of establishing original generic drugs equivalence is only being created.

Active governmental and nongovernmental programs aimed at health promotion are as follows: Reproductive Health of the Nation for 2006–2015, National Program Against Tuberculosis for 2007–2011, Ukraine against AIDS, All-Ukrainian Youth Project (since 2010), Tuberculosis and HIV/AIDS Control in Ukraine Progect, etc.

Through these programs, patients with cancer, tuberculosis, AIDS, and diabetes can get free medicine, medical care, medical devices (e.g., metal stents). However, the low level of patients' awareness, limited funding, and patients' distant location from health-care centers may limit access to these services.

There is no unified program for the development of mass physical education and sport. Also, the number of sports facilities for children is limited. In addition, there is practically no promotion of a healthy lifestyle.

Scientific and Professional Integrity, Conflict of Interest, Corruption

In Ukraine, during the last 20 years of independence, five physicians' codes of ethics have been developed and adopted. In 2009, the All-Ukrainian Congress of Physicians Societies adopted the Ukrainian Physician's Ethical Code, which included the basic principles of bioethics: respect for autonomy and dignity, do no harm, beneficence, privacy, and confidentiality.

There are a lot of medical organizations uniting physicians of various medical specialties: the Dental Association of Ukraine, the Ukrainian Association of

Ophthalmologists, the Association of Cardiologists of Ukraine, etc. Generally, these organizations are poorly integrated and cannot significantly influence policy in health care, largely due to strong tradition of command-and-governance institute of health. Traditionally, only the Ministry of Health and its establishments can provide physicians the right to pursue professional activities, conduct their certification, grant licenses, and determine the scope and list of medical disciplines at universities. In 2008, the draft of the Law on Physicians' Self-government, which proposed to entrust many regulation functions of physicians' professional activities to the All-Ukrainian Physicians Society, the national organization of independent professional government that could have united all the doctors of Ukraine, was submitted to the Supreme Council of Ukraine. However, this law was not adopted.

The most frequent violation of medical ethics is related to the infringement of the Constitutional provision to deliver free medical services in public institutions. It involves several reasons: (1) depreciation of basic funds resulting from inadequate funding from the state, (2) low salary for doctors, (3) lack of health insurance, (4) imbalance of public and private sectors, (5) total corruption in the society, (6) lack of citizenship, and (7) a violation of bioethical principles by doctors. Lack of personal doctors' liability for committed medical errors is another ethical problem. The responsibility for errors of doctors working in the public health-care system is allocated to the administration of medical institutions.

Many people note the conflict between two strategies of patients' management arising in medical practitioners: the strategy of advisability and benefit for the patient who expects that long-term preservation of natural functions and capabilities of the body is possible and the strategy of the latest expensive technology and business benefits. Due to the lack of information, the patient is often prevented from making the right choice between therapeutic, surgical treatment strategies and the strategy of alternative medicine.

Relation with Industry and Donors/Sponsors

At this stage of bioethics development, the relation between bioethics and the industry is still weak. Financial support for the development of bioethics by the State is largely aimed at administrative and legal work to improve the health-care system activity at the Ministry of Health level.

Projects for development of medical and environmental bioethics are funded by private foundations, such as the Soros Foundation "Vidrodzhennia," MATRA (the Netherlands), McArthur Foundation, USAID (USA), etc., as well as by the international organizations, such as the International Bank for Reconstruction and Development, European Commission, WMA, and UNESCO. A number of initiatives for congresses and workshops, centers and programs on bioethics are organizationally and financially supported by certain research institutes and universities, for example, by the Shupyk National Medical Academy of Post-graduate Education, the Institute of Occupational Medicine, the NAMSU, and NASU.

Future Challenges

In the Field of Bioethics Infrastructures (Need for Legislation, Ethics Committees, Ethics Education, etc.)

The imperfect legislation, frequent discrepancy between resolutions, lack of continuity in lawmaking, and poor efficiency of the institute of the human and citizen rights should be attributed to disadvantages of the legal regulation of bioethics. Unfortunately, the model bills on bioethics (e.g., On the Legal Foundations of Bioethics and the Guarantee of its Security), which were developed by the CIS Interparliamentary Assembly and have passed the public consultation phase, have not been adopted as the laws of Ukraine.

Opportunities for education in the field of bioethics and good clinical practice on the international level for specialists from Ukraine are still limited. In the majority of cases, the training is limited to congresses, symposia, seminars, conducted in Ukraine, but the participation of leading specialists from other countries is often limited by financial capacity of the inviting party. Ukraine does not have a state system of bioethics and GCP education for medical pre- and postgraduates yet.

The main directions of a future international cooperation in the field of bioethics are the extension and intensification of contacts with the CE Commission for Ethics in Science and Commission for Ethics at the European Parliament, UNESCO, and WHO.

In the Field of New and Emerging Issues

In recent years, topical issues of consumer rights, various social services, starting with housing and public utility services and shops, and ending with hairdresser's or beautician's services, have been discussed in the Ukrainian society. Bioethical problems of human ecology, food quality, and occupational hygiene are also considered to be urgent. Of great concern are misappropriation of public finances and property by high-ranking officials, problems of injustice, inequality in distribution of social benefits, which affect disadvantaged and vulnerable social groups, especially children, pensioners, and people with disabilities. Along with the Physician's Ethical Code, Ukrainian society has been discussing ethical principles of valeologists, teachers, social workers, and politicians.

Any Other Problems and Opportunities for the Further Development of Bioethics in the Country

Among the positive aspects and original achievements of bioethics as a theory and practice, science and academic discipline in Ukraine, one should note the following: (1) the desire to consider bioethics as global ethics that combines medical and

environmental ethics; (2) the formation of multiple bonds of bioethics with valeology, sanology, social work, practice of ethical expertise, pedagogy, Christian ethics; and (3) the desire to write "the discipline" in the cultural and historical context and relate the achievements of Western bioethics to the tradition of soviet biophilosophy.

Guidelines for the ethical expertise of the studies carried out in natural and biosphere reserves, national nature, and landscape parks were developed in 2003 (Nikolskii et al., 2003). However, the practice of routine ethical expertise of scientific studies on objects of nature and wildlife in reserves and national parks has not become widespread, or supported in the community yet.

Ukraine needs radical transformation of the health-care system, an improvement of the way it operates, structural adjustment, and an improvement of patient care.

In bioethics education, there is an urgent need to teach bioethics not only as applied biomedical ethics but as a special form of worldview, a really interdisciplinary science, and practice uniting different fields of natural sciences and humanities.

Summary Conclusion

To conclude, the process of reception and assimilation of bioethical principles and values in Ukraine cannot be called simple. The difficulties are connected with the following: (1) the transitional nature of the Ukrainian economy, (2) a spiritual crisis caused by the assertion of private property as a social value, (3) the legacy of the administrative and command system of governance in medicine and collectivist ethics, (4) traditional medical paternalism and doctors' abuse of power over human lives, and (5) technocracy – the predominance of diagnosis over therapy and an attitude toward the patient as an object of medical intervention.

At the current stage, Ukraine, like the majority of post-Soviet countries, is in the process of civil society formation. Under these circumstances, the role of bioethics, as a social institution, science and discipline that promotes formation of genuinely democratic relationships based on respect for human rights and freedoms as well as other living creatures and nature objects, is important. Problems of bioethics are becoming markedly interdisciplinary in nature. Therefore, all new social institutions, governmental agencies, and community organizations are being involved in the solution of these problems.

In the systems of Ukrainian health care and higher education, ecology, and conservation of natural resources, bioethics can and must become the main alternative to phenomena such as moral nihilism, consumerism, biologization, technocracy, and anthropocentrism. At the same time, there must be creative rethinking of its forms and methods based on the current political, economic, and social situation in Ukraine. The future of bioethics will be certainly determined by the nature, quality, and pace of democratic reforms in all spheres of Ukrainian society.

Gerard Magill

Introduction

Bioethics in the United States has developed into a highly sophisticated enterprise, including both secular and religious perspectives, since World War II. The pace of its development continues robustly as the established and the emerging aspects of bioethics increasingly involve diverse global populations with vast environmental implications. The continued breakthroughs in medicine and biotechnology contribute significantly to the continuing challenges that the field encounters from scientific, cultural, and ecological perspectives. With the impressive number of academic and professional institutions that engage the field in a scholarly and critical manner

and the striking growth in degree granting Universities for the field of bioethics, there is a fast flowing stream of newly trained experts to provide strenuous leadership for the future.

Bioethics Development

The development of bioethics in the United States as a distinct discipline reflects the extraordinary growth in biotechnology, medical science, and health care. The historical roots of US bioethics can be traced to crisis moments after World War II that helped not only to initiate academic centers and professional associations but also to instigate government intervention on pivotal issues that shaped the new field.

Moments of Crisis

Albert R. Johnson has provided perhaps the most comprehensive account of the history of medical ethics and the birth of bioethics in the United States (Jonsen, 1998, 2000) from which this essay has developed several points. The 1803 code of medical ethics written by the English physician Thomas Percival (1740–1804) provided a basis for the 1847 *Code of Ethics* for the *American Medical Association*, a new organization at that time. The code has undergone several revisions since then including receiving a new name, the *Principles of Medical Ethics*, in 1903 and 1912. The fast pace of breakthroughs in science and medicine after World War II, such as tuberculosis treatment, synthetic penicillin (first discovered in 1928), polio vaccines, antihypertensive drugs, discovery of DNA, early cancer chemotherapy, effective oral contraceptives, heart transplantation, definition of brain death, etc., created a fascinating new landscape for ethical discourse in medicine. Also, moments of crisis challenged the new discipline of bioethics to mature quickly. In particular, there were two crises that absorbed the public: the Willowbrook experiment ending in 1958 and the Tuskegee experiments ending in 1972.

At Willowbrook State Hospital for retarded persons in New York, an experiment began in 1956 to study the natural history of hepatitis. The experiment infected retarded children with hepatitis, recognizing that insofar as most children would contract the disease eventually during their stay at the hospital, the intentional infection would provide subsequent immunity. The purpose was to study the disease in order to create a vaccine, and the outcome was successful insofar as an effective vaccine was created to prevent viral hepatitis type B. Nonetheless, parents of the children and the public were outraged that helpless children had been intentionally infected in the experiment and that consent had not been obtained.

In 1972, the media broke another shocking story about human experimentation in Tuskegee, Alabama. The U.S. Public Health Service had continued an experiment for 40 years, starting in 1932, with 600 African American poor and uneducated patients, 400 of whom had been diagnosed with syphilis, the other 200 without syphilis constituting the control arm of the study. But those with

syphilis were not informed about the diagnosis, not told that they were part of a research study, and not advised that penicillin treatment was available. The purpose of the study was to understand what damage the disease causes the body, discoverable only after the infected patients died. After the public became aware of the study (already known in professional circles), a panel including the bioethicist Jay Katz was appointed to investigate the study. In 1972, the panel deemed the study to be unethical from the beginning, and the study ended immediately with 74 patients still living. The media story had astounded the public and forced the government to develop better regulations for federal funding of research with human subjects, leading to the National Commission discussed below.

Just recently, another long-term study shocked the public when revealed by the media. In the fall of 2010, the media reported that the U.S. Public Health Service supported research on sexually transmitted diseases in Guatemala from 1946 to 1948. The US President's Bioethics Commission undertook a thorough fact-finding investigation reviewing approximately 125,000 pages of documents and approximately 550 secondary sources collected from public and private archives around the country, plus a fact-finding trip to Guatemala to meet with Guatemala's own internal investigation committee. The research study intentionally exposed and infected vulnerable populations to sexually transmitted diseases without the subjects' consent. The President's Commission report was titled, "*Ethically Impossible: STD Research in Guatemala from 1946 to 1948*" (September, 2011). The Commission Chair Amy Gutman reported that the Guatemala experiments involved unconscionable basic violations of ethics, even as judged against the researchers' own recognition of the requirements of the medical ethics of the day (bioethics.gov).

Early Centers and Associations

The nascent field of bioethics led to the establishment of centers to foster discussions across disciplines. For example, in 1969, the *Hastings Center* on the river Hudson in upstate New York was established as an Institute of Society, Ethics, and the Life Sciences under the leadership of the philosopher Dan Callahan. The center specializes in the contributions of interdisciplinary working groups. In June 1971, the first issue of the *Hastings Center Report* appeared. The center and its journal continue to shape and lead the discipline today, four decades later.

Also, in July 1971, André E. Hellegers, born in the Netherlands and teaching at Georgetown University's School of Medicine, provided the leadership (until his death in 1979) for the new *Kennedy Institute of Ethics* at Georgetown University in the nation's capital city, Washington, D.C. Its original title was the *Joseph and Rose Kennedy Center for the Study of Human Reproduction and Bioethics*. The *Kennedy Institute* was founded to be an academic research and teaching center to address moral perspectives related to prominent policy issues, publishing quarterly the prestigious *Kennedy Institute of Ethics Journal* (since 1990). LeRoy Walters was appointed as director of the Center for Bioethics within the *Kennedy Institute*.

He and his faculty colleague Warren Reich developed much needed resources for bioethics. They initiated a research library with funding from the National Library of Medicine that would become a leading resource over subsequent decades, publishing the landmark *Bibliography of Bioethics* (Walters, 1975), and eventually being known as the *Reference Center for Bioethics Literature*. A few years later, Warren Reich edited a four-volume collection, *The Encyclopedia of Bioethics*, with subsequent updating, to provide a comprehensive scholarly resource (Reich, 1978). The *Kennedy Institute* nurtured an early generation of scholars as faculty chairs or Kennedy professors who would lead the field of bioethics over subsequent decades. Many of these scholars became leaders in the field, including Tom Beauchamp, John Connery, James F. Childress, H. Tristram Engelhardt, Jr., William May, Richard McCormick, and Gene A. Outka. Also, it was at this time that Robert Veatch moved from the *Hastings Center* to the *Kennedy Institute*, succeeding Edmund D. Pellegrino as director of the institute in 1989. One of the best-recognized accomplishments was the first systematic analysis in the fast-growing field, *Principles of Biomedical Ethics*, now in its 6th edition (2009), coauthored by Tom L. Beauchamp and James F. Childress (Beauchamp and Childress, 1979, 2009).

Around the same time as these centers were formed, in 1969, a new professional association was established for the discipline, the *Society for Health and Human Values* (SHHV). The society hosted its first annual meeting in October 1971. The society sought to foster medical humanities (including art, history, philosophy, and literature) in medical education, especially focusing upon understanding health, disease, and healing, thereby going beyond ethical issues in health care to include broader issues of human values. Other associations and organizations followed as the discipline of bioethics developed. In 1986, the *Society for Bioethics Consultation* (SBC) was initiated with the mission to study and support ethics consultation services in health care. In the fall of 1994, the *American Association of Bioethics* (AAB) was established to foster dialogue among scholars in the discipline, to enhance their clinical activities, to encourage teaching, to promote research, and to create a new stream of bioethicists.

Then, in January 1998, the *Society for Health and Human Values* (SHHV) combined with the *Society for Bioethics Consultation* (SBC) and the *American Association of Bioethics* (AAB) to form an integrated organization called the *American Society for Bioethics and Humanities* (ASBH). The consolidation was organized by representatives of the different associations and was voted on by mail ballot of the full memberships with overwhelming approval. The ASBH holds an annual conference in different cities within the United States. In addition to this large national organization, there is a smaller and more focused annual conference that involves a significant participation of bioethicists from the United States called the *International Conference on Clinical Ethics and Consultation* (ICCEC). The ICCEC initially hosted biannual conferences in 2003, 2005, and 2007. In 2008, the conference focused on emerging ethics committees as a preconference participant in the World Congress of the *International Association of Bioethics*. Thereafter, the conference has met annually in different cities across the world.

Government Interventions

The development of the new discipline of bioethics also was influenced by government oversight reflecting sensitivity to both the *Nuremberg Code* in 1947 and the World Medical Association's *Declaration of Helsinki* in 1962, *Ethical Principles for Medical Research Involving Human Subjects*. In particular, two government commissions, the National Commission and the President's Commission, had unusually significant influence on the nascent field. In addition to these government commissions, between 1978 and 1980, there was an important but short-lived *National Ethics Advisory Board* that was established at that time in the US Department of Health, Education, and Welfare. This board's focus was upon research on children and the human fetus. In 1980, the board was discontinued in part because of a controversial fetal research protocol that it had been developing. A closer look at the accomplishments of the two government commissions helps to enlighten the context for the emerging discipline of US bioethics.

The *National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research* was established in1974. In the wake of discussions over the Tuskegee scandal and debates over fetal research, President Nixon signed the National Research Act in 1974 to establish ethical parameters to sanction behavior in federally funded research. The work of the National Commission led to a clearer understanding of the meaning of research on human subjects and the importance of consent, including its 1977 report on *Research Involving Children* that had arisen from the Willowbrook crisis in 1958. The Commission recognized proxy consent by parents for nontherapeutic research upon children with a crucial caveat that there was only minimal risk to the child. The commission culminated with a report arising from a retreat in 1976 at Belmont House, the *Belmont Report: Ethical Principles and Guidelines for the Protection of Human Subjects of Research*. The report, initially approved in 1978 and published a year later (Belmont Report, 1979), promotes three ethical principles as foundational for medical research, respect for persons, beneficence, and justice. After completing the report the National Commission ended in 1978.

Another government body for ethics oversight was the *President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research*. Building on the prominence of the National Commission, the President's Commission adopted a broader purview dealing with a range of bioethical issues. The commission brought even further prestige to the nascent discipline of bioethics insofar as its members required presidential appointments. This first President's Commission published several crucial reports that helped to delineate the terrain of bioethics, including, *Defining Death: Medical, Legal and Ethical Issues in the Determination of Death* (1981), *Splicing Life: The Social and Ethical Issues of Genetic Engineering with Human Beings* (1982), *Screening and Counseling for Genetic Conditions: The Ethical, Social, and Legal Implications of Genetic Screening, Counseling, and Education Programs* (1983), and *Deciding to Forego Life-Sustaining Treatment* (1983). Since the original President's Commission in

1980, there has been many others with a variety of progressive or conservative bioethicists being appointed, reflecting the politics of presidents. Reports by the *National Bioethics Advisory Commission* (NBAC), now called the *Presidential Commission for the Study of Bioethical Issues*, are available through the US Department of Health and Human Services (HHS). Also, a remarkably useful index to reports from NBAC has been prepared under the directorship of Eric M. Meslin (bioethics.gov).

A further crucial contribution from the branch of government, this time from the United States Supreme Court (410 U.S. 113), was the legalization of abortion until viability around 7 months in its 1973 *Roe v Wade* decision. The decision was based upon a woman's right to privacy implied in the due process clause of the Fourteenth Amendment. Since then, the nation has been split more or less equally on the abortion debate into so-called pro-life and pro-choice camps, and the bioethics debate on the issue continues unabated, not least from the substantive body of scholarly literature on feminist bioethics which extends across the entire discipline (e.g., Mahowald, 2006).

Bioethics as a Discipline

Over these decades, the new discipline adopted a word to identify its interdisciplinary field – the word "bioethics" was used to combine biology and ethics. The creation of the name for this new field can be attributed not only to André Hellegers at the *Kennedy Institute* but also to Van Rensselaer Potter who was a research oncologist at the University of Wisconsin who published work profiling the word bioethics (Potter, 1971). Albert Jonsen suggests that the definition of bioethics by Warren Reich in *The Encyclopedia of Bioethics* (Reich, 1978) appears to have settled the purpose of bioethics as the study of the ethical dimensions of medicine and the biological sciences (Jonsen, 1998).

Whether bioethics is technically a discipline continues to be disputed insofar as there is ambivalence about its methodological approaches (to provide and use a normative framework) and its theoretical approaches (to ascertain which normative framework is adequate for the moral life). Rather than settle on any given ethical theory or method, bioethics has tended to focus more on principles to solve problems and guide actions (Beauchamp and Childress, 1979), in contrast to theories representing different ways of systemically organizing principles and rules. There have been efforts to create a foundational theory or a persuasive method for the disciple, but none have elicited consensus. Examples include the following: locating medical ethics within the philosophical tradition of contract theory (Veatch, 1981), presenting bioethics as dealing with controversy resolution via agreed procedures that uphold autonomy and beneficence as content poor yet nonetheless also as foundational principles providing boundaries for dispute resolution (Engelhardt, 1986), promoting beneficence around which medical ethics should develop (Pellegrino and Thomasma, 1981), adopting casuistry and the focus on decision-making in clinical ethics (Jonsen, Siegler and Winslade, 2006),

and relating applied ethics to a systematic account of common morality as a public system to guide decisions and actions while allowing some irresolvable moral disagreement without conceding to relativism (Gert, Culver and Clouser, 2006).

There appears to be a general agreement that a variety of methods are needed for bioethics, including methods adopted in fields like law, philosophy, theology, history, literature, and sociology as well as quantitative and qualitative research methods, including ethnographical and experimental methods (Sugarman and Sulmasy, 2010). In part due to the lack of an agreed approach to bioethics and because of the significant contribution that varied approaches make to theoretical and applied issues in the field, it is no surprise that anthologies in bioethics continue to be popular (e.g., Steinbock, Arras and London, 2003). As a result, it appears that bioethics in the United States can be construed at least as a discipline in a secondary manner insofar as it relies upon other clearly defined disciplines like theology, philosophy, law, medicine, and the social sciences to engage practical issues as a matter of applied ethics. In this secondary manner, bioethics will likely develop the type of disciplinary standards for excellence and assessment that other disciplines have developed over their longer histories. Perhaps one of the greatest ironies of US bioethics is that it has not yet reached consensus on an acceptable code of ethics, though the ASBH has been trying to accomplish this difficult task for several years.

Current Bioethics Infrastructure

In the United States, a sophisticated bioethics infrastructure has emerged that engages religious and secular discourse, relating patient rights in clinical ethics with systemic issues in organizational ethics.

Religious Bioethics

In addition to the centers and professional associations mentioned above, many large nonprofit and religiously affiliated health systems have professional ethicists at senior positions in the organization as director or vice president of ethics. These professional bioethicists typically focus on matters related to clinical ethics or organizational ethics within their health system, collaborating with colleagues in the field. Religiously affiliated health care constitutes a significant portion of US health care. By far, the largest of these is Catholic health care. Because of the extensive outreach of Catholic health care across the nation, providing approximately one sixth of the nation's health care, there is a professional association to support its needs including bioethics, the *Catholic Health Association* (founded in 1915) serving approximately 600 hospitals and 1,400 care facilities (long-term care, etc.). Also, in religious bioethics, there are prominent journals that adopt a religious perspective, such as *Christian Bioethics* and *The National Catholic Bioethics Quarterly*.

Secular Bioethics: Degree Programs and Journals

An abundance of academic hubs for bioethics are now well established across the nation. Many of these academic centers offer degree programs to train an ongoing stream of bioethicists. In addition to Ph.D. programs that offer traditional doctoral degrees, for example, in philosophy, there is a variety of doctoral degree programs that are dedicated specifically to the field of bioethics as a distinctive discipline. For example, there are research doctorate degrees (Ph.D.) as well as professional doctorate degrees focusing upon normative ethics. Also, there are doctorate degree programs (Ph.D.) that provide extensive training in empirical research. Moreover, there are many master's degree programs in different universities across the United States. A list of academic centers and degree programs in bioethics can be found on the website of the American Society for Bioethics and Humanities (asbh.org/meetings/resources/academics.html).

In addition to these academic hubs for bioethics, there is an abundance of scholarly publications, books and journals, on bioethics in the United States. Examples of books in the field are discussed below in relation to major topics. The major journals on bioethics in the United States include: *The American Journal of Bioethics*, *The Journal of Medicine and Philosophy*, *Theoretical Medicine and Bioethics*, and *HEC Forum* (Healthcare Ethics Committee Forum: An Interprofessional Journal on Healthcare Institutions' Ethical and Legal Issues). Also, there are journals that focus especially on the relation between bioethics and law, such as *The Journal of Law, Medicine, & Ethics* and the *American Journal of Law & Medicine*. From the perspective of public debate, public policy, and legislation in the United States, major developments are identified in the next section that discusses specific bioethical issues.

Rights of Individuals

The autonomy of the patient, with concomitant rights such as regarding consent, has become a central reference point in US health care and is crucial for issues related to clinical ethics and organizational ethics. In the scholarly literature, there continues to be significant debate about different meanings of personal autonomy and processes of consent (Miller and Wertheimer, 2010) reflecting the indispensable rights of patients. One of the clearest practical approaches to the rights of individuals, especially from the perspective of upholding patient autonomy and requiring informed consent, is the *Comprehensive Accreditation Manual* of the *Joint Commission* that reviews and accredits health care facilities on a voluntary basis every 3 years (laboratories, every 2 years) in the United States. The independent, not-for-profit organization was founded in 1951 and is the nation's oldest and largest standards setting and accrediting body in health care. Currently, the *Joint Commission* evaluates and accredits more than 19,000 health care organizations and programs in the United States (jointcommission.org). In the organization's *Comprehensive Accreditation Manual* (Joint Commission, 2011), section

RI delineates the "Rights and Responsibilities of the Individual," as dealing with these issues: identification of fundamental, overarching patient rights; the right to effective communication; the right to participate in care decisions; the right to informed consent; the right to know the care providers; the right to participate in end-of-life decisions; and services provided by organizations to respect patient rights.

Clinical, Organizational, and Professional Ethics in Health Care

Because of the significance of patient rights in US health care, with the robust focus upon patient autonomy and informed consent, it is understandable that the dominant interest in bioethics tends to focus upon clinical issues. However, clinical ethics relates in an integrative manner with organizational ethics and professional ethics in health care.

In addition to general discussions across a range of relevant issues about organizational ethics in health care, there are pivotal issues that need close scrutiny in bioethics: the pervasive compromise of trust, the neuralgic question of legitimate complicity and accountability, and the egregious problem of conflicts of interest such as occurred in the death of the first gene-therapy trial patient, Jesse Gelsinger in 1999. A foundational aspect of organizational ethics deals with the issue of compromised trust that has occurred because of market forces in medicine detracting from or compromising patient care. Issues related to this trust crisis, such as research ethics, disputes over decision-making, or medical errors are discussed below. To help organizations better manage the dilemmas they encounter when market or business forces press against patient needs, bioethics needs to investigate more thoroughly how to navigate the awkward issue of legitimate complicity, whereby individual accountability and collective or corporate interests can be squared in a manner that holds health care accountable. Moreover, conflicts of interest can be egregious in health care, and a clear sense of how to manage or resolve them is needed to maintain confidence in the general system (Rodwin, 2011). Although many of these organizational issues overlap with discussions about professional ethics, the latter requires a much more constructive approach that fosters the development of virtue and character among clinicians as they integrate their clinical and organizational responsibilities (Pellegrino and Thomasma, 1993).

Major Bioethics Issues and Discussions

In addition to the general development of bioethics as a discipline, in which a variety of topics were very influential as discussed above, there are several major issues in bioethics that have reached a level of stability, being well developed though continuing scrutiny is required, as follows.

Research Ethics and Institutional Review Boards (IRBs)

Given the outrage over the scandals at Willowbrook and Tuskegee and in light of the government commissions that followed in their wake, US bioethics was highly attuned early in its formation to the controversial issues around research and experimentation on human subjects. The *National Commission* vigorously embraced the policy of the *National Institutes of Health* to have institutional review boards (IRBs) that would review and oversee research protocols implementing federal regulations. The President's Commission also was involved in the early development of IRBs with its 1981 report, *Protecting Human Subjects*, and its 1983 report, *Implementing Human Research Regulations*. Also, in 1974, a new federal office (under the leadership of the renowned bioethicist John C. Fletcher from 1975) was created at the *National Institutes of Health* to provide compliance oversight of research institutions engaging in human research subjects, the *Office for Protection from Research Risks* (OPRR). The US Department of Health and Human Services (HHS) now houses OPRR as the *Office for Human Research Protections* (OHRP) to protect the rights, welfare, and well-being of subjects involved in research conducted or supported by the HHS. Also, OHRP provides clarification and guidance, develops educational programs and materials, maintains regulatory oversight, and provides advice on ethical and regulatory issues in biomedical and social-behavioral research (hhs.gov/ohrp). Moreover, the *Joint Commission* that accredits health care facilities in the United States has a specific standard (in section RI on patient rights) to protect patients who are also enrolled as research subjects. Standard RI.01.03.05 reads, "The hospital protects the patient and respects his or her rights during research, investigation, and clinical trials" (Joint Commission, 2011).

A highly influential organization was established in 1974, continuing today, to support and educate IRBs – *Public Responsibility in Medicine and Research* (PRIM&R). The organization, based in Boston, offers training and professional development for animal care and use as well as human research subjects, such as in Human Research Protection Programs (HRPPs). Also the organization is involved strenuously in policy advocacy and provides a resource center with many reports (white papers, etc.) and networking opportunities for members, such as at its many conferences, including its annual *Advancing Ethical Research* (AER) Conference and its annual *Institutional Animal Care Use Committee* (IACUC) Conference. Over the decades since it was established, the organization has become a leading body to support and train IRB members, such as via its certification programs, including the *Certified Institutional Review Board* (IRB) Professional and the *Certified Professional Institutional Animal Care and Use Committee* (IACUC) Administrator (primr.org). Although this organization and its programs emphasize compliance, bioethics weaves through everything so that ethical practices arise from advanced knowledge of relevant regulations.

Another very helpful resource for the continuing discourse in bioethics about research ethics and IRBs is the Hastings Center's professional publication (six times annually), *IRB Ethics & Human Research*. Moreover, there were several influential reports just before and after the start of the new millennium from the

President's *National Bioethics Advisory Commission* (NBAC), such as *Research Involving Patients with Mental Disorders That May Affect Decisionmaking Capacity* (1998), *Ethical and Policy Issues in Research Involving Human Subjects* (2001), and *Ethical and Policy Issues in International Research: Clinical Trials in Developing Countries* (2001).

Also, there is an abundance of excellent scholarly studies on IRBs and research ethics, covering many topics such as the following: the history of and relevant codes and regulations governing research involving human subjects, such as the *Common Rule* (explained further below), regulations from the Department of Health and Human Services (HHS) and requirements from the US Food and Drug Administration (FDA); the social value and sound design of scientific research, including equipoise, randomization, and placebo-controlled trials; fair selection of research subjects, including special or vulnerable populations (ethnic or minority groups, children, prisoners, subjects with impaired decision-making capacity); appropriate ratio or balance between risks and benefits; independent oversight and review; informed consent, waivers of consent, and respect for human participants; and behavior of the research investigators to maintain ethical standards in the research, such as relating to conflict of interest, falsification of data, and accurate authorship (Emanuel et al., 2008).

The *Common Rule* mentioned above is the federal policy for the protection of human subjects, published in 1991 and codified in separate regulations by 15 federal departments and agencies. The HHS regulations, *45 CFR part 46*, include four subparts: subpart A, also known as the federal policy or the *Common Rule*; subpart B, additional protections for pregnant women, human fetuses, and neonates; subpart C, additional protections for prisoners; and subpart D, additional protections for children (hhs.gov/ohrp/humansubjects/commonrule).

There is continuing public interest in the bioethical debate over developed countries like the United States undertaking research in developing nations, including being responsive to the *Council for International Organizations of Medical Sciences* (CIOMS) and being respectful of regulations from other governing bodies globally, such as the Council of Europe's regulations governing human rights and clinical research ethics. In addition to the topics mentioned above regarding research ethics and IRBs, other issues need to be discussed from the international perspective of research involving human subject, including collaborative partnerships between researchers and host nations, especially striving for justice and avoiding exploitation; fair and proper selection of participating communities that host the research; and making the drugs that are developed from the research affordable for the populations who participated and other developing populations (Macklin, 2004). This discourse on international research ethics, especially when US government funding is involved, recently led the *Presidential Commission for the Study of Bioethical Issues* under the Commission Chair Amy Gutman to assemble an *international research panel*. The panel represents ten countries as a commission subcommittee to conduct an independent review of the effectiveness of US rules and international standards for protecting human subjects in the US government–supported scientific studies.

Institutional Ethics Committees

The institutional review board is typically distinct from the institutional ethics committee, the former dealing with compliance over research with human subjects, the latter focusing upon issues related to patient care, such as deciding to withdraw treatment in end-of-life care. A brief account of the development and work of ethics committees reveals an extensive aspect of the work of bioethicists in clinical ethics. In 1976, the New Jersey court that adjudicated the Quinlan case (discussed below) supported a role for developing ethics committees to resolve the sort of disputes over end-of-life care rather than bringing them to courts for resolution. However, progress was slow, and in 1983, the report by the President's Commission, *Deciding to Forego Life-Sustaining Treatment* gave further support to the concept of developing ethics committees to address end-of-life decision-making. The report included as an appendix (item F), a statute that had been prepared by the *American Society for Law and Medicine* for the design of hospital ethics committees. Dramatic progress was made over subsequent decades, and now ethics committees are widespread across US health care, including hospitals, long-term care facilities, etc.

Over several decades, the role of an ethics committee has developed around several tasks: to educate the committee and colleagues in health care about relevant bioethics issues related to patient care; to review policy in the organization to enhance patient care consistent with relevant regulations; to engage in ethics consultation in situations where significant dispute arises about treatment decisions for patients; and to undertake research on all of the above to foster quality improvement of patient care across the organization. Different organizations focus upon these tasks in varying ways.

A fairly dominant model has emerged based on the work undertaken by the *National Center for Ethics in Health Care* (NCEHC), founded in 1991, at the Veterans Health Administration in the Department of Veteran Affairs. The NCEHC, under the leadership of Ellen Fox, chief ethics in health care officer, developed in 1999 a program called IntegratedEthics (one word). The program has three integrated functions: the ethics consultation function provides assistance to patients, families, and staff; the preventive ethics function develops policies and fosters a quality improvement system; the ethical leadership function creates a culture that inspires employees to act in an ethical manner (ethics.va.gov/integrated ethics).

Because a great deal of the time of ethics committees deals with ethics consultation, an explanation of what is involved sheds light on the work of the bioethicist in the clinical ethics environment of a hospital, or long-term care facility, etc. The role of the ethics consultant is typically to act as a facilitator (individually or working in a team) at times of dispute between patient, clinicians, and family over treatment decisions. Hence, sophisticated mediation skills are usually crucial for successful ethics consultations (Dubler and Liebman, 2004). The goals are to bring the relevant stakeholders together, to ascertain the facts, to clarify the problem, to consider appropriate options, and ideally, to build consensus, if feasible, around a decision, such as to withdraw end-of-life treatment like a ventilator or medically assisted feeding.

The *American Society for Bioethics and Humanities* (ASBH) published a set of core competencies to assist in the process of ethics consultation. In 1998, the first edition was published, *Core Competencies for Health Care Ethics Consultation*, with a revised and updated second edition published in 2011 (American Society for Bioethics and Humanities, 2011). The monograph has four main sections: the nature and goals of ethics consultation; the core competencies for health care ethics consultation (HCEC) that describes the necessary skills and knowledge for ethics consultation; evaluating health care ethics consultation services; the ethical dimension of HCEC as an emerging professional practice. The ASBH also has an education guide that was designed around the 1st edition of its core competencies but also remains relevant for the revised edition (American Society for Bioethics and Humanities, 2009). Related to but distinct from the ASBH *Core Competencies*, the field continues to await the development by ASBH of a code of ethics for bioethicists in general and ethics consultants in particular. Moreover, there remains significant discordance among ASBH members about the best way to train ethics consultants, a process that currently requires urgent attention. Finally, just as there are excellent studies on research ethics and IRBs as discussed above, there are excellent studies that are widely adopted by ethics committees, especially regarding ethics consultation and decision-making in clinical ethics (Jonsen, Siegler and Winslade, 2006; Aulisio, Arnold and Youngner, 2003).

End-of-Life Decision-Making

A large proportion of the work of ethics committees deals with end-of-life decision-making. The ethical dilemma over withholding or withdrawing end-of-life treatment from patients has revolved around two issues: the treatment being futile and/or the patient or surrogate deciding to forego or discontinue available treatment. In this debate, the underlying bioethical factors have been resolved, even if specific decisions continue to elicit dispute and controversy for a given patient, family, or care provider.

In the United States, the legal and ethical debate over withdrawing treatment in end-of-life care became national in 1975 when Karen Ann Quinlan was brought by ambulance to the emergency department of Newton Memorial Hospital in New Jersey. Being comatose from a barbiturate overdose, she was placed on a ventilator to breath and provided a nasogastric tube for medically assisted feeding, with her condition deteriorating over subsequent months, involving transfer to other facilities. She was diagnosed to be in a persistent vegetative state (PVS), though such a diagnosis is difficult to provide with accuracy until after death, with effectively no possibility of recovery. Her parents asked the physicians to remove the ventilator to let her die. The physician and hospital declined out of fear of criminal charges that might result, so the parents petitioned the court to end the treatment. The New Jersey Supreme Court eventually adjudicated the case, overruling a lower court decision. In 1976, the court concluded that under the right to privacy in the US constitution, the patient, if lucid, could decide to withdraw treatment; the Court added that the parents of the patient, given her legal incompetency, were

appropriate surrogates to exercise that right for the patient, adopting a substituted judgment standard that has become widely adopted in such cases. Moreover, the court ruled that the state had no compelling interest in forcing the patient to continue in the circumstances she found herself with no prospect of recovery. Interestingly, after the ventilator was withdrawn, the patient began to breath spontaneously, was transferred to a nursing home, and lived another 10 years via artificial feeding as a PVS patient, dying in 1985 at the age of 31. An important part of the court's ruling was to encourage ethics committees to be developed in hospitals as an appropriate body to resolve such cases. This case led to the *California Natural Death Act* in 1976 that provided the nation's first living-will statute whereby patients could document their wishes about end-of-life care.

Several other major cases followed the Quinlan case. Each ruling created further precedent, cumulatively clarifying the legal and ethical landscape for end-of-life decisions in the United States. The courts recognized the substituted judgment standard whereby surrogates can decide for an incompetent patient and the best interest standard whereby a decision is made based on the patient's best interests. The case of Nancy Cruzan in 1990 was especially significant insofar as the Missouri Supreme Court ruled against the request of the patient's parents to withdraw a feeding tube from their PVS daughter. The US Supreme Court backed the Missouri Supreme Court, arguing for a requirement of clear and convincing evidence that the patient would have wanted treatment withdrawn. Subsequently a Missouri Circuit Court accepted new testimony that Nancy had previously provided clear and convincing evidence, artificial feeding was withdrawn, and the patient died 12 days later. Another crucial legal precedent had been established. As a result, end-of-life care decisions are now legally and ethically acceptable across the United States via living wills, advanced directives, and health care power of attorney designation. On this matter over multiple cases and court ruling, the law is effectively settled (Menikoff, 2001).

However, permitting these end-of-life decisions about withholding or withdrawing treatment is different from assisted suicide measures. In two decisions in 1997, courts rejected a right in the US constitution for assisted suicide. In the case of *Washington v. Glucksberg*, the US Supreme Court ruled that the Due Process Clause in the Fourteenth Amendment of the US Constitution (prohibiting the government from interfering with an individual's rights and liberties) does not include the right to assisted suicide. Also, in the case of *Vacco v. Quill*, the US Supreme Court ruled that the Equal Protection Clause in the Fourteenth Amendment of the US Constitution (prohibiting States from denying an individual equal protection under the law when faced with comparable circumstances) did not permit assisted suicide being understood as substantially similar to withdrawing end-of-life care. However, these rulings did not prevent individual States from passing legislation to permit assisted suicide, and several States in the United States have since passed such legislation.

In the face of an increasing demand to legalize assisted suicide, there is a robust movement among many bioethicists to resist the legislative trend by supporting the role of hospice care and palliative care to provide appropriate relief from pain at the

end of life. In particular, there is widespread agreement about the legitimacy of using palliative or terminal sedation to induce a coma for patients whose pain is so intractable that no other effective relief is available. Typically, such patients die within a few days of the coma being induced. The palliative care movement has become increasing significantly in the United States (Emanuel and Librach, 2011).

Future Challenges

In addition to the above topics that are well developed and fairly stable in US bioethics, there are several other large arenas that need to be much better engaged and therefore present significant challenges for US bioethics: patient safety, organ and tissue procurement, and genetics and biotechnology.

Patient Safety

The debate over patient safety emerged as a substantive concern after a shocking report on avoidable medical error at the turn of the millennium (Institute of Medicine, 2000). The astoundingly high number of patients being killed as a result of avoidable medical error gripped the nation – and there is no current data that the original estimates of up to 100,000 deaths per annum in the IOM report have diminished noticeably. However, since the IOM study, improvements have been made to report medical errors and near misses called sentinel events in a concerted effort to enhance patient safety, as evidence by the inclusion of a category on "National Patient Safety Goals" in the Joint Commission's *Accreditation Manual* (section, NPSG) that assesses health care facilities (Joint Commission, 2011). Nonetheless, it remains extraordinarily difficult to obtain reliable, comprehensive statistics on medical error and sentinel events because there is no centralized mandatory database. A gargantuan task for bioethics is to help create an independent organization, perhaps located in the *National Institutes of Health*, to accurately track and radically diminish the outrageous numbers of patients whose health and lives are being compromised by the current fragmented system of reporting.

Organ and Tissue Procurement

There has been remarkable progress in the procurement and transplantation of tissue and organs over recent decades, and future progress appears immensely promising, bringing many accompanying dilemmas for bioethics. The definition of brain death (by an Ad Hoc Committee at Harvard University's Medical School in 1968) opened the doors to more extensive procurement – the patient could be declared to be dead, while tissue and organs remained viable for transplantation.

Recently, there has been a return to cardiopulmonary criteria for death to facilitate donation after cardiac death (DCD) from non-heart-beating cadavers (NHBCs) via controlled death (whereby life support is removed in a controlled environment) and uncontrolled death (whereby catheters are inserted to preserve organs of patients who arrive dead). There is general agreement that death is a process, but if it is required to wait until the end of the process, viable procurement would not be feasible. Hence, the crucial step for DCD interventions is to recognize that the patient is legally dead even though technically artificial resuscitation could but will not occur. The so-called Pittsburgh Protocol that was developed at the University of Pittsburgh's Medical Center specifies that death occurs at a specific period of time after life support is removed, with procurement occurring immediately thereafter. The *National Network for Organ Sharing* (UNOS) adopts all of these criteria for defining death. An extensive debate has developed and will continue over the definition of death and transplantation ethics (Veatch, 2000). A fundamental problem is the dramatic shortfall of procurement in the face of massively increasing demand, requiring both policy and technology solutions. From the policy perspective, the debate revolves around opt-in (such as on a driving license) or opt-out approaches (where the assumption is that citizens are donors unless they indicate otherwise). From the technology perspective, significant breakthroughs are being researched to develop ways for organ and tissue growth in laboratories.

Human Genetics, Biotechnology, and Population Health

The health and safety not only of individuals but also of large populations and even the species and planet environment are now an important part of bioethics discourse in the wake of sequencing the human genome, creating human embryonic stem cells, and the manipulation of pluripotent stem cells. The pace of progress in science and medicine, from molecular science and synthetic biology to regenerative medicine and tissue engineering, is astounding, and bioethics must keep apace with transcultural and global attentiveness. Several NBAC reports have been issued by the President's Commission to guide the bioethics debate in the public arena, including: *Human Research Involving Human Biological Materials: Ethical Issues and Policy Guidance* (1999); *Ethical Issues in Human Stem Cell Research* (1999); *Cloning Human Beings* (1997); and another ongoing study, *New Directions: The Ethics of Synthetic Biology* (2010). However, bioethics continues to struggle with keeping apace with scientific progress, not least in the foundational debate about transhumanism and posthumanity (Buchanan, 2011). Furthermore, new technologies bring new world-wide threats, and bioethics now has to engage with disaster related issues of global health. Such threats can be terror or crime related as well as caused by virulent pandemics (Annas, 2010). Now that the global population has passed seven billion, especially in an environment where climate change can cause flooding across vast coastal areas, a basic problem for global bioethics will be justice related especially regarding the provision of clean water, nourishing food, and basic housing for enormous populations.

Summary Conclusions

The development of bioethics in the United States has spawned a comprehensive discipline that combines clinical, organizational, professional, and global ethics. Its sophisticated infrastructure fosters robust interdisciplinary discourse with multiple academic degree programs and professional resources to maintain a continuing stream of future experts. There are plenty of issues that require their expertise.
